Abstract

Background: Despite the steady rise in electronic cigarette (e-cigarette) uptake among young adults, increasingly more young people want to quit. Given the popularity of smartphones among young adults, mobile-based e-cigarette cessation interventions hold significant promise. Smartphone apps are particularly promising due to their varied and complex capabilities to engage end users. However, evidence around young adults' preferences and expectations from an e-cigarette cessation smartphone app remains unexplored.

Objective: The purpose of this study was to take an initial step toward understanding young adults' preferences and perceptions on app-based e-cigarette cessation interventions.

Methods: Using a qualitative descriptive approach, we interviewed 12 young adults who used e-cigarettes and wanted to quit. We inductively derived themes using the framework analysis approach and NVivo 12 qualitative data analysis software.

Results: All participants agreed that a smartphone app for supporting cessation was desirable. In addition, we found 4 key themes related to their preferences for app components: (1) flexible personalization (being able to enter and modify goals); (2) e-cigarette behavior tracking (progress and benefits of quitting); (3) safely managed social support (moderated and anonymous); and (4) positively framed notifications (encouraging and motivational messages). Some gender-based differences indicate that women were more likely to use e-cigarettes to cope with stress, preferred more aesthetic tailoring in the app, and were less likely to quit cold turkey compared with men.

Conclusions: The findings provide direction for the development and testing of app-based e-cigarette cessation interventions for young adults.

Introduction

Electronic cigarettes, or e-cigarettes, deliver nicotine via inhaled vapor [1], which is why e-cigarette use is often called "vaping." The use of e-cigarettes has risen exponentially in North America, especially among young adults. According to the Canadian Tobacco and Nicotine Survey conducted between December 2020 and January 2021 [2], 15% of those aged 20-24 reported e-cigarette use in the past month and 48% reported having tried e-cigarettes once at some point. Similarly, in the United States, there has been a surge of nicotine-based e-cigarette uptake among young adults, with 20% of Americans aged 18-29 using e-cigarette products [3]. Uptake of e-cigarettes among young adults is occurring among both smokers and nonsmokers, with curiosity (27%) and smoking cessation (20%) the primary reasons for uptake among 20-24 year olds, and smoking

cessation (41%) and avoidance of cigarettes (17%) the primary reasons for uptake among those 25 and older in Canada [4].

Regardless of the reason for e-cigarette uptake, an increasing number of young people have indicated a desire to quit. Between 2018 and 2019, Canadian young adults who used e-cigarettes indicated that they were planning to quit in the next 6 months [5]. According to a recent study by Sanchez et al [6], 44% of Canadian young adults between 18 and 29 years of age had tried to quit, 33% were thinking about quitting, and 15% made plans to quit e-cigarettes. In the United States, 62.4% of current adult e-cigarette users, with the majority consisting of young adults (ages 18-34 years), planned to quit e-cigarettes for good, and 25% reported a past-year quit attempt [7]. Moreover, a similar study conducted by Berg et al [8] found that 20.8% of young adult e-cigarette users reported their willingness to quit e-cigarettes in the next 6 months and 32.3% reported past-year quit attempts.

Providing interventions to help support reduction and cessation of nicotine dependence associated with e-cigarettes is a promising way to help young adults in their cessation journey. e-Cigarette cessation support is in a nascent stage of development and to date, includes in-person counseling, group-based counseling, and quit lines [9]. Given the popularity of smartphones among young adults [10], a few mobile-based interventions are now on the market. One of them includes an SMS text messaging intervention to promote e-cigarette cessation among young adults [11], for which preliminary evidence in relation to user engagement and effectiveness is promising [11,12].

Smartphone apps provide promising ways to engage young adults in behavior change interventions, including the opportunity to incorporate gamification [13-15]. Not surprisingly, smartphone apps for e-cigarette cessation have received widespread support among young adults [8,16]. However, evidence around young adults' preferences and expectations from an e-cigarette cessation app remains unexplored. Therefore, in this study, we took an initial step toward understanding young adults' preferences and perceptions on app-based e-cigarette cessation interventions.

Methods

Design

We used a qualitative descriptive study approach. Qualitative description is appropriate because it aims to help researchers explore and understand end user perspectives or experiences on a topic where little is known [17,18]. This aligns with the goal of this study, which is to provide a rich description of young adults' perspectives and preferences for an app-based e-cigarette cessation support.

Ethics Approval

Ethics approval for this study was obtained from the University of British Columbia (Okanagan campus) Behavioral Research Ethics Board (BREB #: H21-00272).

Participants

We purposively recruited 12 young adults' aged 20-29 (mean age 25.5 [SD 2.66] years) who were current e-cigarette users and wanted to quit or reduce the use of e-cigarettes. The recruitment procedure included a single online advertisement that was distributed across 3 platforms (Kijiji [19], Castanet [20], and university web postings) with the caption "If you vape and want to quit, we want to hear from you!" All participants were recruited within 2 weeks of releasing the online recruitment advertisements. All participants provided informed consent prior to data collection.

Data Collection

Data collection included semistructured interviews conducted online using Zoom (Zoom Video Communications, Inc.). At the start of the interview, participants were asked to answer a short questionnaire to gather demographic (eg, age, gender) and e-cigarette information (eg, e-cigarette usage history, quit attempts, app use). For each interview, the same interview guide was followed. During the interviews, participants reported on their perceptions and preferences for receiving app-based support for reducing and quitting e-cigarettes, with interview prompts centered on common behavior change app features (eg, personalization, behavior tracking, social support, and notifications). The interviews were audio recorded and lasted approximately 45 minutes each. Each participant received a CAD $40 (US $32) e-gift card for their participation. The interview questions are presented in Multimedia Appendix 1.

Data Analysis

We adopted the framework analysis approach [21] to inductively develop themes within the qualitative data. The framework approach is a flexible and systematic approach that is ideal for developing themes from semistructured interviews [22]. This approach is hallmarked by a series of clear stages so that a coherent audit trail is provided during thematic development [22]. This process of thematic development allowed us to compare and contrast findings, particularly to assess gender influences.

The interviews were first transcribed verbatim and uploaded in the qualitative data analysis software program NVivo version 12 (QSR International) [23]. We disaggregated the data by gender to identify notable differences in e-cigarette patterns as well as needs and preferences related to e-cigarette cessation. After a detailed reading of the transcripts in their entirety to become familiar with the data, 2 researchers (ZH and LS) iteratively developed a coding framework using data from the interviews with young women and young men. All authors then reviewed and approved the framework. One author (ZH) then coded major themes and subsequent subthemes in relation to the analytical framework in NVivo, which were revised or added to as new data were collected.

Results

Sample Characteristics

We interviewed 12 e-cigarette users who were interested in quitting. The mean age of participants was 25.5 (ranging from

19 to 29) years, 50% (6/12) were male, 50% (6/12) were Caucasian, and most (9/12, 75%) completed postsecondary education (diploma or degree), and worked either part-time or full-time (7/12, 58%; Table 1). Most participants vaped more than once/day (9/12, 75%), having been using e-cigarettes for 6 months to a year (7/12, 58%), and primarily used devices with refillable cartridges (9/12, 75%). Men mostly reported e-cigarette uptake to replace smoking, while women also reported e-cigarette uptake to manage stress, or due to peer influence. Most participants reported wanting to quit for the last 6 months (7/12, 58%), and have made more than 3 quit attempts (8/12, 67%). Health and money were the primary reasons for quitting. While more men preferred to quit cold turkey compared with women, an equal number also preferred gradual reduction. None of the participants had used an app to help them quit e-cigarettes.

[a]e-cigarette: electronic cigarette.

In addition to the closed questions, we asked 3 open-ended questions. First, we asked if they could tell us what they did on a day that they left to do something and forgot to bring their vape. Both women and men said that they did 1 of 3 main things: smoked a cigarette, went back to get their e-cigarette, or bought a new vape device altogether. Second, we asked about what their friends and family did to support their quit efforts. Both women and men said that they received encouragement from family and friends, but women were more likely to report unhelpful support from family and friends, including telling them not to vape, and telling them that e-cigarettes are bad for them. Finally, we asked from whom they sought advice for quitting. While friends were the primary go to for both women and men, more men went to their family than women, and more women were likely to keep it to themselves compared with men.

Desirability of an e-Cigarette Cessation App

All young adults unanimously agreed that reaching them through a smartphone app for supporting e-cigarette cessation aligned with their preferences for behavior change interventions. It aligned with their interest and proficiency in navigating new technologies:

> *I actually find the idea really quite smart. I think it's would definitely help like younger people who are on their phones a lot like I have a smartwatch, so I am already used to kind of depending on technology. So, I think that it would be really beneficial to the people who are like techno natives.* [P12, male, 21]

Preferences for App Features and Content

Overview

Analysis of the data resulted in 4 categories related to app preferences: (1) flexible personalization (2) e-cigarette behavior tracking, (3) safely managed social support, and (4) positively framed notifications.

Flexible Personalization

Participants indicated that personalization was very important so that they felt supported in their individual quit journey. Key to this personalization was flexibility in terms of how they engaged with the app. At the outset, participants thought that having the option to sign-up through their email or various social media accounts (eg, Facebook) was the best way to begin use of the app:

> *Some people are sticklers for logging in with their other social media accounts. So, the ability to log in through any platform is definitely, it has to be there....why close the door on somebody ready to start?* [P1, male, 27]

Once they were signed up, participants reported that it was important for them to tailor the app according to their needs. As such, they wanted the app to have an option wherein they can input their e-cigarette behavior including amount consumed per day, level of addiction, situations of temptations, reasons for quitting, and personal goals:

> *I think it's important for a person who wants to quit e-cigarettes to give them the best chance maybe the software has to determine what level of addiction they have. So, you know, inputting the user's typical day and amount they smoke and then you know, calculating a reduction rate and maybe you know the ability to calculate when this person has the most usage maybe, you know asking questions like do you smoke at work? Do you work a stressful job? When do you smoke most?* [P1, male, 27]

Furthermore, to make the app more personalized and stand out from the rest of general intervention apps, they wanted the ability to set and modify their personalized goals.

> *I can personalize my stats, and my goals will motivate me to keep using the app.* [P5, male, 26]

Women were particularly insistent that the personalized content was matched with a personal look and feel. When they were talking about the design of the app, female participants suggested adding options to change the appearance of the app, such as changing the background color or adding pictures.

> *I love color. So, to be able to customize background colors and appearance of your dashboard, that would probably be really cool.....[I] would be more willing to, you know, log in every day and actually give it a shot.* [P6, female, 20]

They also mentioned the desire to have the current day/time portrayed, and a personalized greeting to be displayed when users log in the app.

> *When user logs in, it can say, like, good morning and then your name….to make it more personalized and to make it feel like the app is talking to you.* [P10, female, 24]

e-Cigarette Behavior Tracking

Another feature that the participants wanted in the app was to track their e-cigarette behavior, particularly their progress in staying away from using an e-cigarette and the direct benefits they could expect from this reduction in e-cigarette use. They

wanted information about associated improvements in health and money saved listed as the top 2 items that they would like to be tracked, which directly reflected their top reasons for quitting. Additionally, participants wanted apps to have options to track withdrawal symptoms, progress to desired goals, and situations where they vape the most. The majority of participants wanted a graphical representation (pictures, charts, graphs, etc.) of the data monitored by the tracking feature to make it easier to understand:

> *Like [show] a picture of lungs, and then as the app goes on, and based on your own personal progress, like [show] the change in lungs, that's kind of cool.* [P4, female, 26]

Safely Managed Social Support

To make the app engaging, participants expressed a desire to see a social support or a community feature incorporated in the app. The participants indicated this feature would allow users to view and share their e-cigarette cessation journey, including any difficulties they are facing, as well as progress, making the process of quitting "less lonely." One participant explained:

> *Like [part of the] recovery process is to have some camaraderie with other people that are going through the same thing whether it be drugs or alcohol or smoking. I definitely think that sense of community is really super important.* [P11, female, 29]

A few participants wanted a buddy option added with the community feature to enable others to provide encouragement, increase accountability, and to help them stay motivated. The use of tags was also suggested by participants, such as withdrawal symptoms, tips on setting goals, testimonies/advice from successful quitters, and inspirational messages/positive reinforcement. With these tags, users would have tools to navigate the community and find the support they needed.

Underpinning the desire for social support through an app, participants were adamant that the delivery platform is managed safely. Some suggested that a moderator in the community feature would be needed to prevent users from posting abusive and inappropriate content. Similarly, an age limit added to this feature was suggested to help make the community feature safe from predators.

> *[It] should have a moderator or an admin type so that it does not go out of hands and everyone stays civil.* [P8, female, 27]

Finally, participants showed their interest in sharing posts anonymously to ensure the privacy of app users:

> *A lot of people don't want to talk about why they're quitting. So having it be a bit more anonymous or being able to post anonymously.* [P12, male, 21]
>
> *[I would be] more comfortable using it if there was an anonymous posting feature, or like, it didn't include your name and your profile picture. And you could just choose the option to post anonymously.* [P6, female, 20]

Positively Framed Notifications

Participants suggested that an effective app needs to provide positively framed notifications that consist of motivational messages, encouraging reminders related to personal goals to strengthen and sustain motivation, and notifications that focus more on the benefits of quitting e-cigarettes rather than providing information on harmful effects of e-cigarettes.

> *Notification messages like, congratulations or like, keep going, you're doing great, that type of thing to encourage people. People respond well to acknowledgement, and like instant gratification, positive reinforcement.* [P4, female, 29]

Participants also wanted notifications to give insight into their progress, such as through an end of the day or weekly report:

> *You've gone 24 hours this week without an e-cigarette you know, you've cumulatively given up e-cigarettes for 48 hours, like those kind of milestones. So, I definitely think like those kind of milestone notifications might be helpful.* [P11, female, 29]

Additionally, participants expressed their interest in receiving updates and notifications on e-cigarette research and cessation from reliable sources.

Discussion

Principal Findings

In this study, we examined young adults' perceptions and preferences around receiving e-cigarette cessation support via smartphone technology. The findings reveal that young adults not only want support via smartphone apps, but also that they want this support to be as tailored and as flexible as possible to meet their personal needs. Prior research on app-based health interventions indicates that users prefer customizable features that meet their personalized needs [24-26]. Unfortunately, however, a recent evaluation of health-promoting apps revealed that most apps incorporate a static, one-size-fits-all approach when it comes to personalization [26]. This is likely contributing to the ongoing finding that most app-based interventions have a minimal effect compared with usual care [26], including cessation apps [27]. Enhancing personalization of these interventions would arguably enhance the effect of these interventions. In relation to e-cigarettes, capturing granular information from an end user would ensure that the app learns about the characteristics of the vape user, and uses this information to tailor the type and intensity of intervention and target different aspects of the quitting process on an individual level. Future research on harnessing end user data for improved personalization and the impact it has on outcomes is needed.

We also found that the participants welcomed receiving positive, nonjudgmental notifications and messages versus receiving messages around the negative impacts of e-cigarette during their quit attempt through an app. This finding is in line with previous research findings indicating that young adults who are ready to quit prefer positively framed messaging to support smoking cessation [28,29]. In addition, positive message framing has been found to be more persuasive in prompting smoking cessation compared with negative message framing [30].

However, one must be cautious when considering these findings in light of evidence that message framing should be considered in the context of the cessation trajectory [31], nicotine-dependence levels [32], and user characteristics, such as gender [33]. For example, Cornacchione and Smith [31] found that smokers were more receptive to positive message framing if they were moving from contemplation to preparation to quit. In this regard, positive message framing may be most effective and helpful when a user first signs up and during the early stages of quitting, with negative messaging an effective approach later on once their confidence and motivation are higher (eg, present what they would lose if they started e-cigarettes again). Future research on the preferences of young adults moving through the process of e-cigarette cessation is needed to determine the most effective messaging at different time points for different end users.

Tracking one's behavioral patterns was perceived as a critical component in an e-cigarette cessation app. To track user's behaviors and outcomes more precisely, designers should consider designing smart cases for e-cigarette products that could collect e-cigarette intake and related data and send them to the smartphone app for advanced analysis [34,35]. This could complement the mobile app–based e-cigarette cessation intervention. The VapeTracker, which tracks the number of puffs and puff duration by attaching it to an e-cigarette device, is an example of an external device that vapers perceived positively [35]. Exploring user preferences around how an external device could be engaged to support their e-cigarette cessation needs further study.

This study also indicated a difference in the preference of young men and women in the design of the app, with female participants wanting more tailoring in terms of the appearance of the app (such as background color, font size/color, greetings from the app when logged in) compared with male participants. In addition, according to the demographic questionnaire data, female participants often used e-cigarettes to cope with stress, which holds implications for incorporating stress management strategies (eg, meditation, exercise) into the app. We also observed that male participants preferred quitting cold turkey, whereas women preferred a more gradual approach toward quitting. This is similar to findings from research related to preferences for a smoking cessation app, where young men reported a preference for cold turkey and young women preferred a gradual approach to quitting [36]. It has been suggested that these preferences may tie into heteronormative narratives (eg, men can quit when they want; women are more open to receiving help), and that masculinities (eg, autonomy and ability) and femininities (eg, caring and emotionally attuned) carry potential in being leveraged to support behavior change [36]. These noted differences in preferences suggest that attention to health equity and gender influences is necessary when developing such interventions.

Comparison With Other Work

When examining other app-based interventions, only 3 were found in the iTunes and Apple stores (Quit e-Cigarettes, Escape the Vape, and Quit E-cigarette Addiction) that specifically targeted e-cigarettes (versus smoking or smoking and e-cigarette). None of these apps have been evaluated in the scientific literature to determine the level of personalization, social support, tracking features, and type of messaging. The text-messaging intervention (This is Quitting) [37] to help young people quit e-cigarettes has been evaluated. This program offers young people a minimum of 4 weeks of messages tailored to age and a resettable quit date, which are focused on skills and confidence building [37]. Results from a randomized control trial revealed that this program achieved 30-day point prevalence abstinence of 24.1% at 7 months compared with the control (18.6%) [12], adding support to our findings in relation to the value of personalization and positive-message framing. Our findings also suggest that there is an appeal among users for gamification and behavioral self-monitoring when it comes to e-cigarette interventions. Therefore, future researchers should consider how incorporating such features into a potential app might increase the acceptability of this type of cessation intervention, and explore the longevity of app-based e-cigarette cessation.

Researchers have indicated that there is an urgent need for research to inform vaping cessation programs for young adults and enhance an evidence base [38]. While the findings of our study fill some important content-related gaps, more research is needed to understand how a cessation app might account for the context of young adult vaping, including varying patterns of use, co-use with other products (eg, tobacco and cannabis), various perspectives and experiences with quitting, and various motives for both vaping and cessation [38]. Future research, therefore, not only needs to test features described in this study, but also needs to pay attention to the complexity of young adult vaping in order to successfully advance science in this area.

Limitations and Strengths

A limitation of this study is that it was conducted with 12 participants, and there may be additional views that are not represented in this sample. Further, given our recruitment procedures (online and through a university), we acknowledge that our findings are limited to a sample that has internet access and is likely pursuing a postsecondary education. We are, however, confident that the study provides important insights that can be used as a foundation for guiding the development of novel apps to support e-cigarette cessation. In addition, our findings do not account for new regulatory policies that may impact the way people vape and their needs for support (eg, policies around nicotine concentration, where you can vape, taxation on e-cigarettes). Therefore, our study does not account for the influence of a wide variety of e-cigarette policies and its impact on e-cigarette use. As such, an app would need to be attuned to those policies. Strengths of this study include equal representation of young women and men, providing a more equitable look at what end users would want from a cessation app. Another strength of the study is the use of inductive qualitative methods to identify key themes in relation to app features. This lends to a strong evidence base from which to move forward with recommendations.

Conclusion

In this qualitative study, we took an initial step to explore the preferences and perceptions of young adults on mobile

app–based e-cigarette cessation interventions. Participants provided suggestions on the content and design of the mobile app–based intervention for e-cigarette cessation. These suggestions provide direction for the development and testing of technology-based e-cigarette cessation interventions for young adults.

Abstract

Background: People with low health literacy experience more challenges in understanding instructions given by their health providers, following prescriptions, and understanding their health care system sufficiently to obtain the maximum benefits. People with insufficient health literacy have high risk of making medical mistakes, more chances of experiencing adverse drug effects, and inferior control of chronic diseases.

Objective: This study aims to design, develop, and evaluate a mobile health app, MediReader, to help individuals better understand complex medical materials and improve their health literacy.

Methods: MediReader is designed and implemented through several steps, which are as follows: measure and understand an individual's health literacy level; identify medical terminologies that the individual may not understand based on their health literacy; annotate and interpret the identified medical terminologies tailored to the individual's reading skill levels, with meanings defined in the appropriate external knowledge sources; evaluate MediReader using task-based user study and satisfaction surveys.

Results: On the basis of the comparison with a control group, user study results demonstrate that MediReader can improve users' understanding of medical documents. This improvement is particularly significant for users with low health literacy levels. The satisfaction survey showed that users are satisfied with the tool in general.

Conclusions: MediReader provides an easy-to-use interface for users to read and understand medical documents. It can effectively identify medical terms that a user may not understand, and then, annotate and interpret them with appropriate meanings using languages that the user can understand. Experimental results demonstrate the feasibility of using this tool to improve an individual's understanding of medical materials.

Introduction

Background

Effective communication in health care has an enormous impact on the health and safety of patients. Limited health literacy is one of the major obstacles to good health care results including health status, health outcomes, health care use, and health costs for patients [1]. Health literacy is "the degree to which individuals have the capacity to obtain, process, and understand basic health information and services needed to make appropriate health decisions" [2]. In today's health care systems, patients are expected to read long lists of complex health care documents, such as detailed home care guidelines, medication information, consent forms, discharge instructions, insurance summaries, and health educational materials. Misunderstanding of such information can lead to negative results. Unfortunately, many of these materials are difficult to understand. New medical achievements have introduced new jargon, descriptions, and medical terminologies, making it even more difficult to comprehend, even for individuals with sufficient literacy. Studies have shown that people with insufficient health literacy know less about their illness, lack proper health

self-management knowledge, and have few precautionary measures for their health [3].

However, according to the US Department of Health and Human Services, only 12% of adults in the United States have proficient health literacy, whereas more than one-third of adults have low health literacy levels, which make it difficult for them to deal with common health tasks such as following directions for how to use prescription medications [4]. Low health literacy is a serious problem, especially in underrepresented racial or ethnic groups and older adults [4]. For example, the proportion of adults with basic or below basic health literacy ranges from 28% among White adults to 65% among Hispanic adults [5]. Adults aged ≥65 years are more likely to have below basic or basic health literacy skills than those aged <65 years. The proportion of adults at these lower levels of literacy was greatest for those aged >75 years [4]. Centers for Disease Control has been engaged in the plain language effort to encourage communication effectively in culturally appropriate ways. Although using plain language is a promising idea, many organizations do not use it as often as they should [6].

Objectives

Given the aforementioned gap between the current health information and people's poor understanding of this information to make life-altering decisions, many policies and strategies have been proposed by policy makers, administrators, educators, and health care professionals to simplify medical information and improve health literacy. Besides these efforts, there is an increasing need to provide tools to facilitate people to understand medical information. This may enhance the patient-physician relationship and improve health care outcomes by reducing the incidence of morbidity, mortality, and misuse of health care [7]. For this purpose, in this paper, we propose a mobile health (mHealth) app to help users understand complex medical documents and improve their health literacy. On the basis of a user's health literacy level, the tool will translate into or interpret a complex medical document in languages that the user is familiar with and at appropriate reading levels. Evaluation surveys are provided to users to evaluate the effectiveness of this tool and the users' satisfaction. This tool will help to make health information accurate, accessible, and actionable.

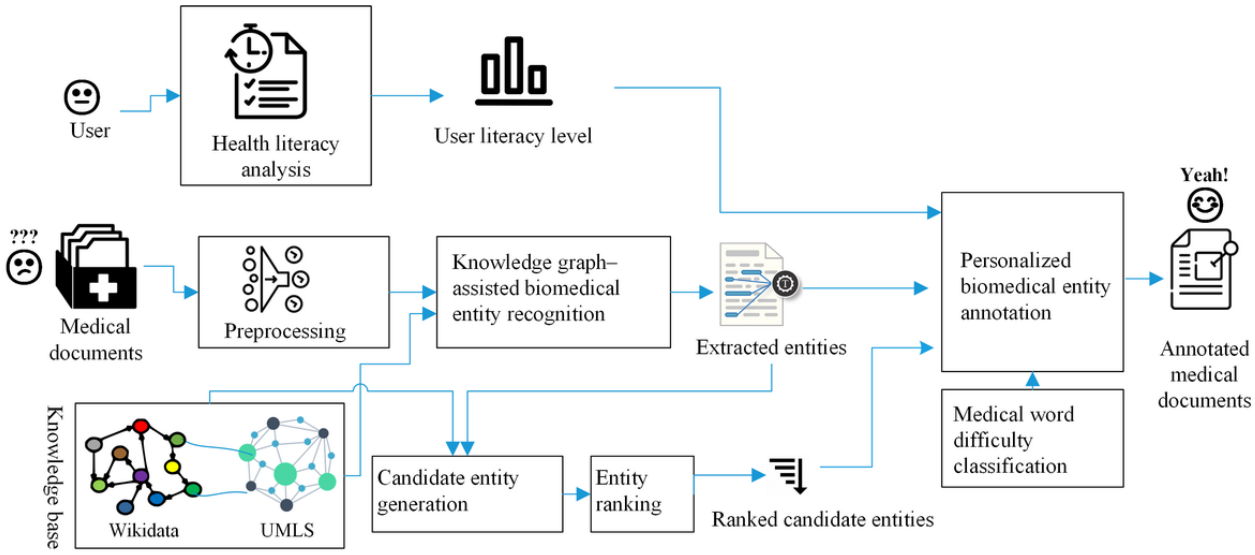
This study was approved by the institutional review board of North Dakota State University (IRB0003857).

System Overview

The goal of the system is to design a mobile app to remove people's barriers to understanding difficult medical documents by annotating or interpreting medical terminologies with plain texts, which they can understand easily. The app, MediReader, is built based on comprehensive knowledge sources and artificial intelligence–based processing mechanisms. It annotates a medical document with external knowledge according to each user's health literacy level. Figure 1 illustrates the architecture of the proposed system. First, MediReader identifies a user's health literacy level. Then, it annotates the documents such that it is tailored to the user's skill level. Medical terms will be identified with the help of external medical dictionaries. Then, based on the user's health literacy level, *complex* medical entities will be linked to and explained by entities in the external knowledge base or data set. The complexity of a term is relative to the specific user; therefore, users with different health literacy levels may obtain different annotation results. We present the details of the system components in the following subsections.

Figure 1. The architecture of the system. UMLS: Unified Medical Language System.



Knowledge Base Construction

We created a comprehensive medical knowledge base by integrating multiple publicly available knowledge sources, including Unified Medical Language System (UMLS) [8] and Wikidata [9]. Specifically, we used UMLS's three knowledge resources: Metathesaurus, semantic network, and specialist lexicon and lexical tools. Vocabularies gathered in the UMLS Metathesaurus include the National Center for Biotechnology Information taxonomy [10], gene ontology [11], Medical Subject

Headings [12], Online Mendelian Inheritance in Man [13], Digital Anatomist Symbolic Knowledge Base [14], Systematized Nomenclature of Medicine–Clinical Terms [15], International Classification of Diseases and Health-Related Problems–10th edition [16], Medical Dictionary for Regulatory Activities [17], and others. Wikidata is a multidisciplinary ontological database that encompasses many medicine-related entries such as human genes, human proteins, diseases, drugs, drug classes, therapies, human arteries, human muscles, human nerves, medical specialties, surgical procedures, human veins, pains, human bones, human enzymes, syndromes, human joints, and human ligaments.

User Health Literacy Measurement

The objective of our health literacy measurement was to identify the degree to which individuals can understand health information and services. We studied many health literacy screening and measurement approaches, including the National Assessment of Adult Literacy [4], Rapid Estimate of Adult Literacy in Medicine [18], Test of Functional Health Literacy in Adults [19], Newest Vital Sign [20], Wide Range Achievement Test [21], ComprehENotes [22], and so on. We adopted the recently proposed approach, ComprehENotes, as our literacy screening approach, as its questions are sufficiently general to be applicable to a wide variety of individuals while still being grounded in specific medical concepts. Most of the questions have low difficulty estimates, which makes the test appropriate for screening for low health literacy. We chose questions from the question set of ComprehENotes that is created from real patients' electronic health records (EHRs) [22]. Experts including physicians and medical researchers identified important concepts from the EHR of six common diseases (heart failure, diabetes, cancer, hypertension, chronic obstructive pulmonary disease, and liver failure). Medical experts believe that these concepts are important for patients to understand the EHR materials. The test questions were designed to assess the comprehension of these concepts.

We chose a subset of ComprehENotes' questions to perform user evaluation, as a test with fewer questions can be administered more quickly than the full test. The subset of the questions should be sufficiently informative to identify different health literacy levels. We used the item response theory (IRT) [23] to choose a good subset of questions. IRT models the relationship between latent traits (unobservable characteristics or attributes) and their manifestations (ie, observed outcomes, responses, or performance) [24]. IRT has been widely used to analyze individuals' responses (graded as right or wrong) to a set of questions. IRT predicts the performance of a test by jointly modeling individual ability and item characteristics. Using IRT, we repeatedly removed questions that cannot distinguish between individuals with high ability levels and individuals with low ability levels. Then, we identified n (n<55) questions from the original 55 questions with the largest discrimination capability and highest average information for inclusion in the short form of the test to make it as informative as possible.

ComprehENotes uses the IRT model that is widely used in education to calibrate and evaluate items in tests, questionnaires, and other instruments and to score participants on their abilities, attitudes, or other latent traits. Specifically, we applied the 3-parameter logistic model, in which the item characteristic curves are assumed to follow a logistic function with a nonzero lower asymptote:

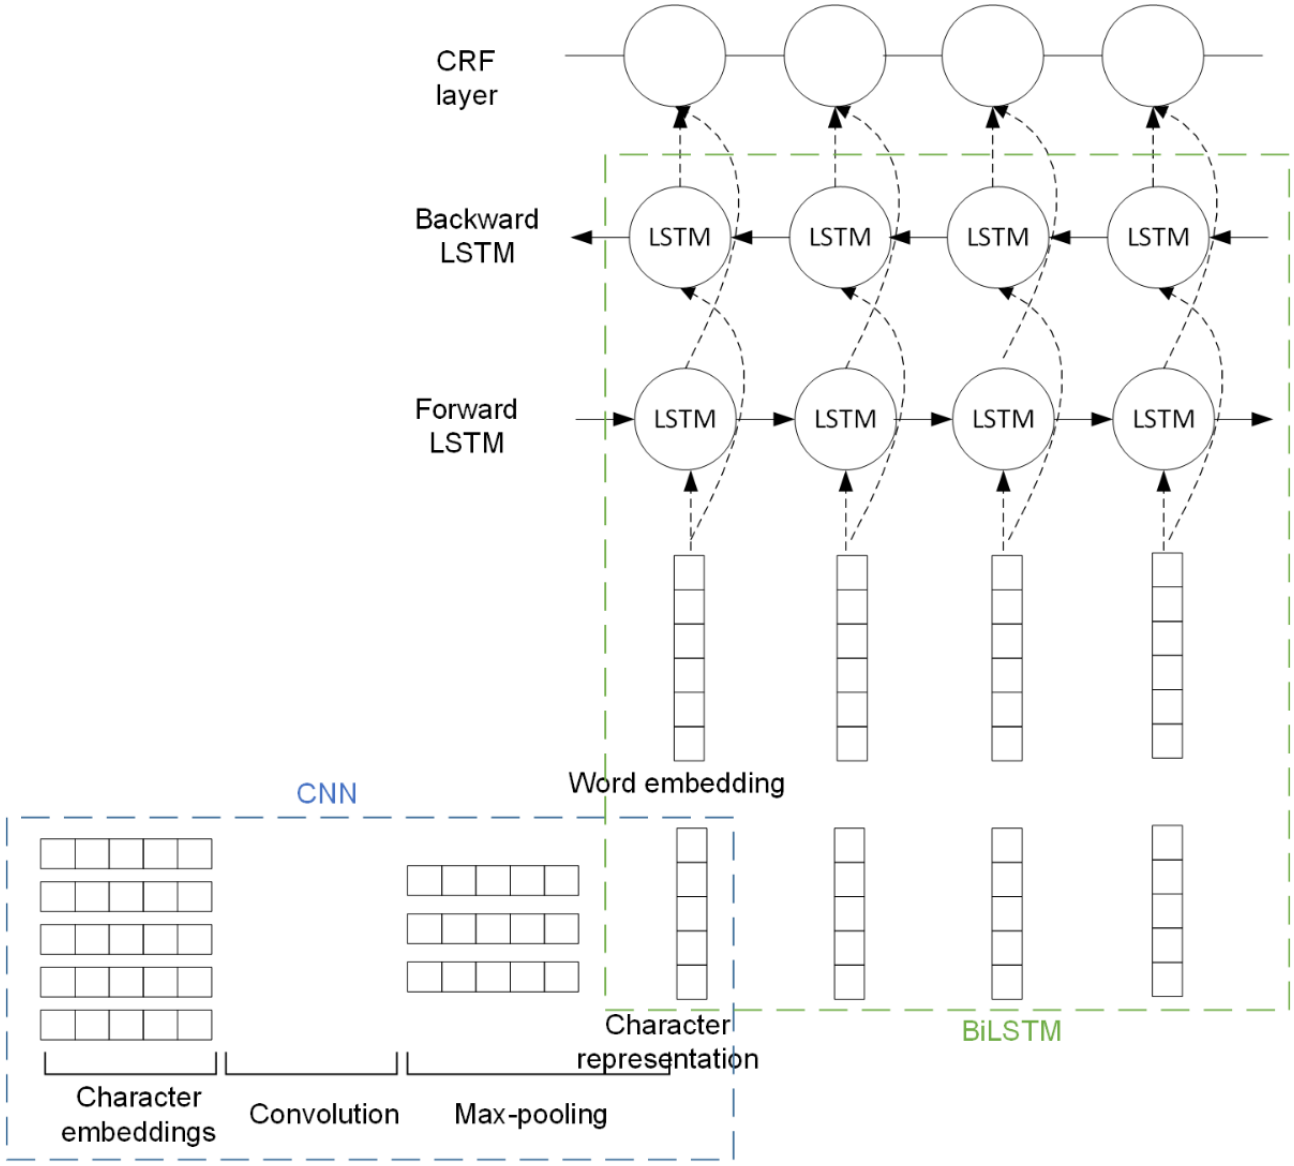
In the above equation, Pij is the probability that person j answers item i correctly, and θj is the ability level of individual j. In our project, θ represents the ability of an individual in the task of medical document comprehension. As individuals are assumed to be sampled from a population, their ability levels are assumed to have a random effect with a standard normal distribution. Therefore, a score of 0 is considered as average (ie, in the 50th percentile), scores >0 are considered as above average, and scores <0 are considered as below average.

Medical Entity Identification

In this task, medical entities in a document, such as diseases, medical problems, drug names, tests, and examinations, will be identified. Existing research on biomedical named entity recognition can be classified into three types: rule-based [25], dictionary-based [26], and machine learning–based approaches [27]. Machine learning–based approaches are more accurate and stable than rule-based and dictionary-based approaches, as machine learning–based approaches have the potential to manage features with high dimensions and find new terms and variants based on the learning trends.

MediReader uses the so-called *BiLSTM-CNN-CRF* deep learning neural tagging network based on works of Lample et al [27] and Ma et al [28]. This network combines bidirectional long short-term memory (BiLSTM) [29], convolutional neural networks (CNNs) [30], and conditional random field (CRF) [31] to enable effective entity recognition. The overall architecture of the proposed neural network is shown in Figure 2.

Figure 2. Bidirectional long short-term memory (BiLSTM), convolutional neural networks (CNNs), and conditional random field (CRF) neural network architecture.



Word embedding [32] is used to transform words into low-dimensional vectors, so that the semantics of words and relationships between them can be captured. In our model, we use publicly available pretrained word embeddings from large medical corpora to accurately represent the meaning of each entity in the medical and health care domain. The word embeddings we used included global vectors embeddings [33] and a new embedding we generated using concepts that we extracted from the MedMentions data set [34]. In addition to word embedding, character-level embedding was used to represent input tokens. A CNN was used to encode the character-level information of a word.

For each word, the character-level representation was computed by the CNN with character embeddings as inputs. Then, the combined character-level and word-level encoding were fed into a BiLSTM to model the context information of each word. LSTMs [29] are variants of recurrent neural network [35], designed to cope with the gradient vanishing problems of recurrent neural network. A total of 2 LSTMs were used so that each sequence can be presented forward and backward to 2 separate hidden states to capture both the past and future information, respectively. Then, the 2 hidden states were concatenated to generate the final output. Finally, the output vectors of BiLSTM were fed into a CRF layer to jointly decode the best labels for the whole sentence.

Medical Entity Linking

After the medical entities (referred to as *mentions* in this section) were identified from a document, they were mapped into appropriate entities defined in the knowledge base that has rich information describing the mentions and their relationships with other entities. Then, the entities defined in the knowledge base can be used to explain the mentions in the document. Owing to of text ambiguity, the same mention can often refer to many different entities depending on the context, as many entity names tend to be polysemous. This task was executed in two steps, namely, candidate generation and candidate ranking.

To link mentions to the right entities defined in a knowledge base, the system needs to generate a manageable candidate list containing possible entities that the mention may refer to. In

our system, the knowledge base entries were retrieved from a subset of the UMLS concepts data set and extended using Wikidata [9]. Wikidata is a multidisciplinary ontological database that encompasses many medicine-related entries, such as human genes, human proteins, diseases, drugs, drug classes, therapies, and so on. All these items are connected to create an extensive biomedical taxonomy using taxonomic Wikidata properties [36]. Wikidata was used as a secondary database, relying mainly on other resources to match its content. Wikidata connects with UMLS through its concept unique identifier. We used the taxonomic properties of Wikidata, such as the instance of (P31), subclass of (P279), part of (P361), and has part (P527), to extend an entity.

Entities (concepts and aliases) in the knowledge base were encoded using term frequency-inverse document frequency scores of character n-grams (n=3 in our implementation) that appears more than a certain number of times in the knowledge base. Then, the k-nearest neighbor search was applied to generate candidate entities for linking a given mention.

Entity linking may encounter the problem of entity ambiguity; that is, 1 mention may be mapped to several candidate entries in the knowledge base. For example, the word *cold* has multiple meanings even in the medical domain including *common cold*, *cold sensation*, and *chronic obstructive airway disease (cold)* [37]. In the candidate ranking phase, we disambiguated the candidate entities using the word sense disambiguation system proposed by Stevenson et al [38]. This system leverages the context in the text and combines various types of information including linguistic features and knowledge sources specific to the biomedical domain. The domain-independent linguistic features include local collocations and salient bigrams and unigrams. For knowledge sources, UMLS concept unique identifier and Medical Subject Headings were considered. Vector space model [39] was used as the learning model.

Personalized Annotation

After mentions in the document and entities in the knowledge sources were linked, annotation was performed. Annotating all medicine-related mentions is unnecessary as readers may know many of them. By contrast, a full annotation may cause discomfort to readers. Therefore, the system needs to determine which mentions should be annotated. MediReader proposes a personalized annotation scheme that annotates a mention based on an individual reader's health literacy level, as discussed in the previous section. For readers with very low literacy levels, more mentions should be annotated, and the annotation should be easy to understand. For readers with high literacy levels, only complex medical terms should be annotated.

Medical term's difficulty and readability assessment was approached as a classification problem. We used a feature set with many features commonly used for standard natural language processing, such as grammatical metrics, semantic metrics, and new composite metrics. We also added new features to the biomedical domain to make the classification specialized in this field. The feature set included the following items:

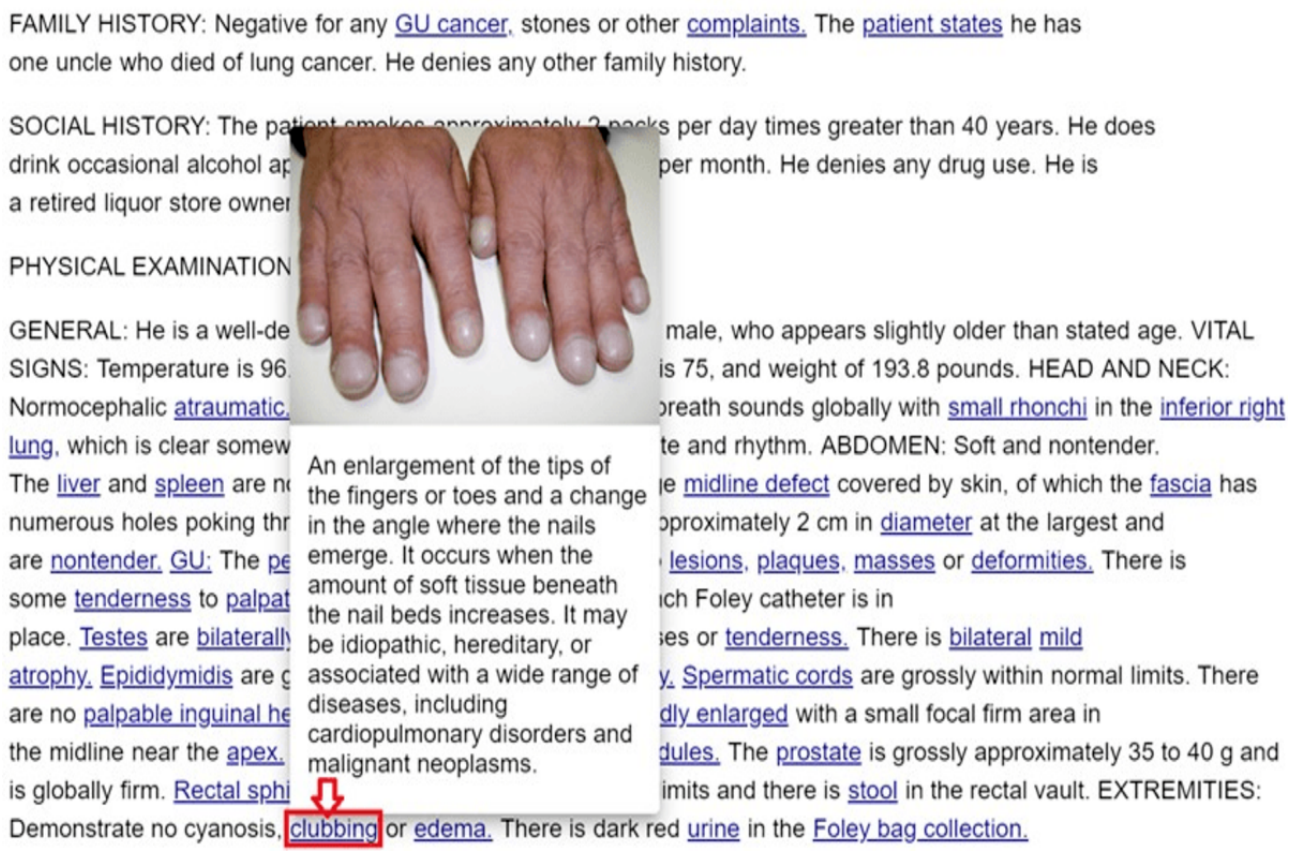
1. Syntactic categories; for example, nouns, adjectives, proper names, verbs, and abbreviations
2. Number of characters and syllables in the word
3. Prefixes and suffixes of the word
4. Number and percentage of consonants, vowels, and other characters (ie, hyphen, apostrophe, and commas)
5. Presence of words in WordNet
6. Word frequency in Google
7. Word frequency in UMLS
8. Word semantic categories in UMLS
9. Pretrained word embeddings using MedMentions

To build our data set, we extracted medical concepts from the website of Medical Transcription Samples [40], which contains a vast collection of transcribed medical transcription sample reports of many specialties. We used the data set to train a prediction model that again used the BiLSTM-CNN model. We extracted 1000 terms from the website. We used 6 graduate students (n=1, 17% native English speaker and n=5, 83% nonnative speakers) to identify whether they can understand the meaning of each of the 1000 words. If a word received 6 positive answers, it was labeled as easy. If it received 5 or 4 positive answers, it was labeled as medium. If it received <4 positive answers, it was labeled as difficult. These labeled terms were used to train the classification system.

On the basis of a reader's health literacy level, medical mentions were annotated. For readers with high health literacy levels, only difficult words were annotated. For readers with low health literacy levels, medium and difficult words were annotated. We did not annotate easy words such as *fever*, *wound*, *operation*, and so on. In addition, medical stop words were removed before the entity linking process.

Each entity was annotated with its definition in the knowledge source. In addition, they were linked by taxonomic relations, such as *instance of*, *subclass of*, and *part of* and major nontaxonomic associative relations (eg, *drug used for treatment* and *risk factor*) to allow a reader to better understand the various aspects about the concept. Figure 3 shows a screenshot of an annotated document for readers with low health literacy levels.

Figure 3. Screenshot of an annotated document.



Results

Test Setup

We implemented the MediReader prototype system as a mobile app. We conducted a set of evaluation tests with representative users to assess the technical viability and effectiveness of this app. To conduct the test, we developed a test plan, recruited participants, and then, analyzed and reported our findings. In our study, we used 2 types of quality metrics that combine to form the big construct we call *usability*. One type of metric was objective criteria, and the other type was subjective criteria.

For the *objective* quality measurement, we invited participants to use MediReader and created a set of tasks for them to complete. Then, we recorded the time they spent on the tasks, their success rates, and errors. For comparison, a control group was also used to perform the same tasks but without the help of MediReader. In our test, we used the same participants to act as both the experimental and control groups. Specifically, the task was to ask users to read 2 sets of medical documents; each set contains 3 physicians' notes on three different diseases, namely, endometrial adenocarcinoma, bladder cancer, and breast calcifications. We tried to choose common and familiar diseases that involve unfamiliar vocabularies. Cancer is a familiar disease. However, many cancer-related documents are difficult to understand. Therefore, we chose two types of cancer: endometrial adenocarcinoma (uterine cancer) and bladder cancer. Breast calcifications are common among women; thus, we chose it as the third disease. One set of documents was annotated using MediReader, and the other set was original medical documents without any annotation. Each set of documents contained 12 questions related to the notes to identify whether the participants can understand the notes. All questions were multiple-choice with 3 answers, and only 1 of them was correct. These notes focused on different diseases and treatments and were randomly selected from real-world web-based physician notes [40]. For a particular participant, one set of documents was randomly selected and annotated using our app, and the other set of documents was shown to the participants without any annotation. In this way, we created a control group that read the same physician notes as the experimental group and answered the same set of questions, but without the help of MediReader. Before the task, health literacy tests were conducted to assess the participants' health literacy skills (high and low only).

We also performed a *subjective* evaluation of the system through a user satisfaction survey. We surveyed participants with 6 satisfactory questions after they used our MediReader prototype system. All the questions were measured using a 4-point Likert scale that ranged from strongly disagree (rating=1) to strongly agree (rating=4).

Before conducting the test, we conducted a pilot study to verify our programming, database, and scoring. We expected that some participants may not read the assigned documents and questions and may choose random answers. To eliminate such responses, we included qualifying questions in different sections. In each multiple-choice section, we added 1 question that could easily be answered correctly if the participant read it. Participants who did not answer these questions correctly were eliminated from the data set.

Test Outcome

Owing to the difficulty in recruiting participants, we had to include as many participants as possible. Therefore, we only required the participants who were aged ≥18 years and knew English. A total of 52 individuals participated in our test. Among the 52 individuals, 13 (25%) individuals did not complete the test and 11 (21%) individuals were disqualified based on our qualifying questions. The remaining 54% (28/52) of the participants completed the test successfully. Table 1 shows the basic demographic information about the participants.

Table 1. Demographic information of the participants (N=28).

Variable	Value, n (%)
Sex	
Men	13 (46)
Women	15 (54)
Age (years)	
40-50	4 (14)
30-39	7 (25)
20-29	17 (61)
Education	
Undergraduate	19 (68)
Postgraduate	9 (32)
Health literacy level	
Low	10 (36)
High	18 (64)

We compared the average scores between the experimental and control groups for all the questions. We noticed that the experimental group significantly exceeded the control group, as they scored 76% compared with 36% for the control group, which means that participants who were provided with medical documents annotated using our tool had a higher score than those who were given documents without annotation.

In terms of the time spent for the reading test, we found that the experimental group spent more time than the control group (29 minutes and 24 minutes, respectively). From the participants' comments, we learned that they spent time in reading more information about the annotated terms and other information related to the term. We believe that this explains why the experimental group spent more time in the test.

Table 2 demonstrates that the contents of the medical documents affect the participants' reading and impact our tool's performance. For example, regarding the first type of document, that is, the document about endometrial adenocarcinoma (disease 1 in Table 2), the control group obtained a score of approximately 60% when they read unannotated documents. However, the score moderately increased to approximately 70% for experimental groups when they read the same document annotated using our tool. For the third type of document, that is, the document about breast calcifications (disease 3 in Table 2), there was great increase (from 27% to 87%) in the scores for the experimental group compared with the control group.

Table 2. Comparison of the average scores of the experimental and control groups on different medical domains or diseases.

Disease and group	Score, mean (SD)
Disease 1	
Experimental	70 (0.35)
Control	60 (0.32)
Disease 2	
Experimental	74 (0.39)
Control	26 (0.29)
Disease 3	
Experimental	87 (0.19)
Control	27 (0.16)

Our tool has a different impact on participants with different health literacy levels. The average score increased from 36% to 88% for participants with high health literacy levels. For participants with low health literacy, the score greatly increased from 17% to 85%.

Table 3 shows the detailed scoring of the experimental and control groups with different health literacy levels for different medical subjects. The scores increased for the participants in the experimental group, who read annotated medical reports regardless of their level of health literacy. For documents on endometrial adenocarcinoma (disease 1), the score for the participants with low literacy in the experimental group showed a moderate increase of approximately 20%; the increase was lower (10%) for participants with high health literacy. The experimental group showed great increase in the average score for the questions related to bladder cancer (disease 2) and breast calcifications (disease 3) for participants with both high and low health literacy levels. The score for participants with low health literacy increased considerably from 12.5% in the control group to approximately 61% in the experimental group for documents related to bladder cancer (disease 2). The score for participants with high health literacy increased from approximately 43% in the control group to approximately 86% in the experimental group for the same type of documents. Similarly, for questions about breast calcifications (disease 3), the average score increased from 36% to 88% for participants with high literacy and from 17% to 85% for participants with low literacy.

We applied the Wilcoxon rank-sum test [41] to determine the differences between the experimental and control groups. *P* value <.05 was considered as significant. Regarding endometrial adenocarcinoma (disease 1) document, the difference between the experimental group and control group was not significant (*P*=.54 for participants with high literacy and *P*=.20 for participants with low literacy). On the other hand, there was significant difference in the score for the participants who solved questions on disease 3 (breast calcifications; *P*=.002 for participants with high literacy and *P*=.002 for participants with low literacy). For participants who dealt with the document about bladder cancer (disease 2), there was significant annotation effect only on users with high health literacy (*P*=.02); for participants with low health literacy, the difference was not significant (*P*=.06).

Table 3 summarizes the detailed scoring of the experimental and control groups and shows the *P* values.

To identify participants' overall satisfaction, they were asked to provide their satisfaction feedback regarding the use of the mobile app. The participant satisfaction analysis showed that, in general, the participants were satisfied with the mobile app. As shown in Table 4, most participants agreed (18/28, 64% strongly agreed, and 6/28, 21% agreed) that the app helped them understand the medical documents better. Only 14% (4/28) of the participants disagreed (1/28, 4% strongly disagreed, and 3/28, 10% disagreed). Similarly, as shown in Table 4, most participants agreed that the app was easy to use and that they would recommend it. Regarding whether appropriate medical terms were annotated, 43% (12/28) of the participants strongly agreed, and 46% (13/28) of the participants agreed that the app annotated medical terms, as shown in Table 4.

Table 3. Comparison of the average score and *P* values of the experimental and control groups with different health literacy levels on different medical domains or diseases.

Disease, health literacy level, and group	Score, mean (SD)	*P* value
Disease 1		
High		.54
Experimental	71 (0.30)	
Control	62 (0.23)	
Low		.20
Experimental	67 (0.42)	
Control	46 (0.25)	
Disease 2		
High		.02
Experimental	86 (0.26)	
Control	43 (0.25)	
Low		.06
Experimental	61 (0.49)	
Control	12.5 (0.25)	
Disease 3		
High		.002
Experimental	88 (0.16)	
Control	36 (0.15)	
Low		.002
Experimental	85 (0.23)	
Control	17 (0.11)	

Table 4. Overall feedback regarding the use of the mobile app (N=28).

Survey question	Strongly agreed, n (%)	Agreed, n (%)	Disagreed, n (%)	Strongly disagreed, n (%)
The application helped me understand medical documents better	18 (64)	6 (21)	3 (10)	1 (4)
The application was easy to use	18 (64)	4 (14)	4 (14)	1 (4)
I will recommend the application to others	18 (64)	6 (21)	3 (11)	1 (4)
The application annotated appropriate medical terms	12 (43)	13 (46)	2 (7)	1 (4)

Discussion

Principal Findings

People need to understand medical information to have the best chance of a good health outcome. However, understanding medical information is more difficult than what most people realize, as it requires a certain degree of health literacy. To assist people in understanding medical documents, we designed, developed, and evaluated a mobile app, MediReader. MediReader uses external knowledge sources to annotate medical documents according to each user's health literacy level. Algorithms based on machine learning and natural language processing have been proposed and implemented to recognize medical entities, identify the complexity of medical terms, and link medical terms to external knowledge that can explain the terms. MediReader was evaluated through task-based user studies with a control group and users' satisfaction survey.

On the basis of the comparison with a control group, the test results demonstrate that MediReader can improve users' understanding of medical documents. This improvement is particularly significant for users with low health literacy levels. The satisfaction survey shows that users are satisfied with the tool in general. The result also shows that some medical information is more difficult to understand than others, even with the help of MediReader. In summary, our study demonstrated that it is feasible and effective to implement an mHealth tool to help people better understand medical documents.

MediReader simplified medical documents for the general public and improved their understanding, whereas most existing annotation tools, such as MetaMap [42] and Clinical Text Analysis and Knowledge Extraction System [43], were designed for medical professionals such as physicians, medical students, and biomedical researchers. It is not clear how these tools will benefit the general users. MediReader adapts its interface based on users' health literacy, whereas most existing tools (eg, National Center for Biomedical Ontology Annotator [44] and BioMedical Concept Annotation System [45]) do not distinguish between users. MediReader uses an effective machine learning mechanism to locate medical terms and subsequently link and explain medical terms that are most appropriate for the given context. Many existing systems (such as National Center for Biomedical Ontology Annotator [44] and ConceptMapper [46]) have adopted the dictionary-based matching that lacks disambiguation ability; they only list all meanings of the annotated entity.

Limitations and Future Work

This study had some limitations. The qualitative evaluation was performed with limited participants and most of them were college students. The results that will be obtained if it is conducted on underrepresented racial or ethnic groups and older adults remains questionable. More comprehensive user studies will be performed on a large population to evaluate the usability, satisfaction rate of users, and health and quality of life-improvement outcomes.

Some medical information is still difficult to understand even after our tool's annotation. Through our test, we found that some medical terms are annotated with annotations and definitions that are difficult to understand, especially when the annotations are retrieved from professional medical resources such as the UMLS vocabularies. We will work on exploiting more information sources (eg, Google Knowledge Graph) to enrich and simplify the annotation.

When a new document is loaded, there is a delay in providing the annotations to the users. We will continue to optimize our algorithms in natural language processing and machine learning to reduce the execution time. In addition, we plan to encode frequently used knowledge and store it in the storage memory of the device to further reduce the delay.

Conclusions

Limited health literacy may restrict an individual's participation in health contexts and activities. To help people improve their health literacy and understand medical documents better, in this study, we proposed and evaluated an mHealth app, MediReader. The app annotates medical documents with information that people can understand. Our experiments demonstrated that this tool can help users better comprehend the contents of medical documents. It is especially useful for people with low health literacy levels. From our test, we found that low health literacy does not necessarily correspond to general low literacy; individuals who may be extremely literate in their areas of expertise (eg, graduate students) may also have a problem in understanding medical terminology. Further research is needed to overcome the limitations of this study.

Abstract

Background: Lower extremity complications of diabetes represent major health care complications both in terms of cost and impact to quality of life for patients with diabetic peripheral neuropathy. Temperature monitoring has been shown in previous studies to provide a useful signal of inflammation that may indicate the early presence of a foot injury.

Objective: In this study, we evaluated the temperature data for patients that presented with a diabetic foot injury while using a sock-based remote temperature monitoring device.

Methods: The study abstracted data from patients who were enrolled in a remote temperature monitoring program (2020-2021) using a smart sock (Siren Care). In the study cohort, a total of 5 participants with a diabetes-related lower extremity injury during the study period were identified. In the second comparison cohort, a total of 26 patients met the criteria for monitoring by the same methods but did not present with a diabetes-related podiatric lower extremity injury during the same period. The 15-day temperature differential between 6 defined locations on each foot was the primary outcome measure among subjects who presented with a diagnosed foot injury. Paired *t* tests were used to compare the differences between the two groups.

Results: A significant difference in temperature differential (temperature measured in °F) was observed in the group that presented with a podiatric injury over the course of evaluation versus the comparator group that did not present with a podiatric injury. The average difference from all 6 measured points was 1.4 °F between the injury group (mean 3.6, SD 3.0) and the comparator group (mean 2.2, SD 2.5, t=–71.4, df=39; P<.001).

Conclusions: The results of this study suggest temperature monitoring in a sock form factor could be used to predict a developing foot injury. The continuous temperature monitoring system employed has implications for further algorithm development to enable early detection. The study was limited by a nonrandomized, observational design with limited injuries present in the study period. We look forward to further studies that will refine the predictive potential and confirm or refute the current promising data.

Introduction

Diabetic foot ulcers (DFUs) represent a major challenge for the health care system as both a major contributor of health care cost and the greatest single contributor to lower limb amputation [1]. DFUs are estimated to cost public and private payers in the United States US $9-13 billion in addition to the costs associated with diabetes itself [2].

To curtail the devastating ramifications of DFUs, greater efforts have been made toward prevention. One method of early detection that has been studied is the use of temperature monitoring, which has been shown to be a surrogate marker. The elevation of temperature is from inflammation that may be potentially due to and a precursor to tissue injury. The predictive potential of temperature monitoring to detect ulceration was first proposed in 1994 by measuring mean plantar foot temperature by Benbow et al [3]. The potential for foot temperature monitoring was further advanced by Armstrong et al [4], who demonstrated the potential of measuring 6 sites on each foot, with a temperature differential of >4 °F signaling an inflammatory response significant enough to either warrant a change in behavior or seek medical attention. The authors concluded high temperature gradients between feet may predict the onset of neuropathic ulceration, and self-monitoring may reduce the risk of ulceration. Their results showed patients using temperature monitoring were one-third less likely to develop an ulcer compared with the standard therapy group. Armstrong's study and others have led to the inclusion of temperature monitoring in the guidelines for management of the diabetic foot [5].

The introduction of new technologies for the remote temperature monitoring of patients with diabetes and neuropathy at risk of ulcer formation suggests more patients may be able to use temperature monitoring in their daily lives. One such technology, Siren Socks (Siren Care), is a smart sock worn by patients; it has a regular connection to the cloud for the capture and sharing of temperature data with health care professionals. Siren Socks are available for patients under the supervision of a physician. Reyzelman et al [6] first evaluated Siren Socks in a 35-patient study and found the temperatures measured by the stand-alone sensors were within 0.36 °F of the reference standard. Patients reported the socks were comfortable and easy to use, ranking them at a median score of 9 and 10 on a 10-point scale for comfort and ease of use, respectively.

In this study, we review the actual temperature recordings and real-world monitoring data from patients using remote temperature monitoring. The purpose of this study is to investigate any significant difference of foot temperature prior to the presentation of a foot injury as confirmed by a medical diagnosis.

Methods

Study Design

Patients were retrospectively reviewed in the Siren Care data registry between December 1, 2020, and April 15, 2021. Inclusion criteria consisted of patients who had greater than 50 days of wear of the Siren Socks temperature monitoring device during the study period. To be eligible to use Siren Socks, patients needed to have a diagnosis of peripheral neuropathy. The study cohort included patients in the database who had a diagnosed lower extremity injury that presented itself during the study period. The 15-day period prior to the diagnosis of an injury was reviewed, and a total of 900 minutes of temperature monitoring were analyzed during the period. For the control cohort, patients meeting the same criteria of wear (ie, diagnosed with peripheral neuropathy) without reported foot injuries in the study period were selected. For the control cohort, the temperature monitoring data for a randomly selected 900 minutes over a randomly selected 15 days were chosen for comparison.

The temperature data were reviewed retrospectively for a 15-day period before the presentation of an injury to a medical professional. For comparison, a similar 15-day period of temperature monitoring was reviewed for other patients who wore the Siren Socks but did not present with an injury in the study period.

Description of Temperature Monitoring Workflow

Patients in both cohorts were prescribed remote patient monitoring socks by their podiatrist. The patients in both cohorts were under the care of a podiatrist who directed a licensed practical nurse (LPN) to regularly monitor these patients based on temperature monitoring data, and to escalate any identified issues to their attention for possible clinical follow-up and intervention. Each patient had continuous measurements of temperature taken at 6 points on each foot (hallux, heel, arch, metatarsal 1, metatarsal 3, and metatarsal 5). The temperature is measured automatically throughout the day. The socks turn on when worn and turn off automatically when no longer worn. No charging is required, and data transmission does not require a smartphone. A hub is plugged into the wall for data transmission, and monitoring data is also stored on the socks to allow for monitoring when away from home.

Data are collected at each point in the foot, and the temperature differential between each right and left point is computed each minute. Finally, the daily average temperature differential is computed for each area on the foot and each patient. Figure 1 and Figure 2 are examples of the data capture for study patients.

Figure 1. The temperature difference of a patient who developed a foot ulcer. The green plot reveals the baseline measurements, the red plot shows the 15 days before the ulcer was diagnosed, and the grey plot shows the active ulcer period.

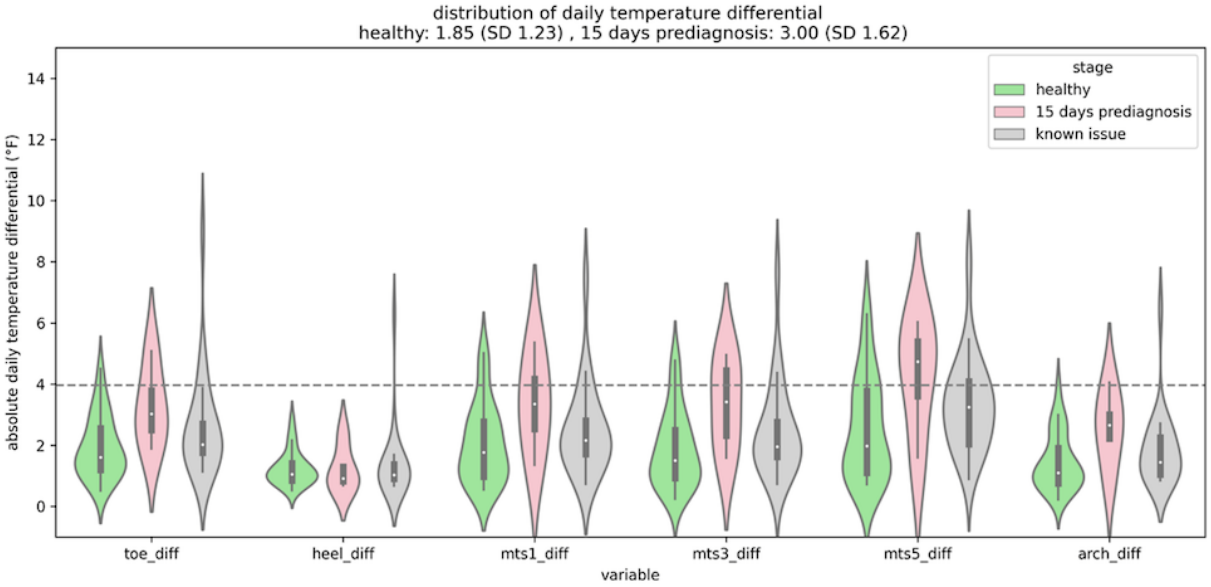

Figure 2. The temperature differentials measured over the study period for a patient who developed an ulcer at the right fifth metatarsal (mts) location. The green plot represents the baseline period, the red plot is the period 15 days prior to the ulcer presenting, and the grey plot is the period after the issue was diagnosed by a medical professional. Changes in temperature trends are noticeable even before the 15-day period, suggesting earlier detection of foot ulcers might be possible.

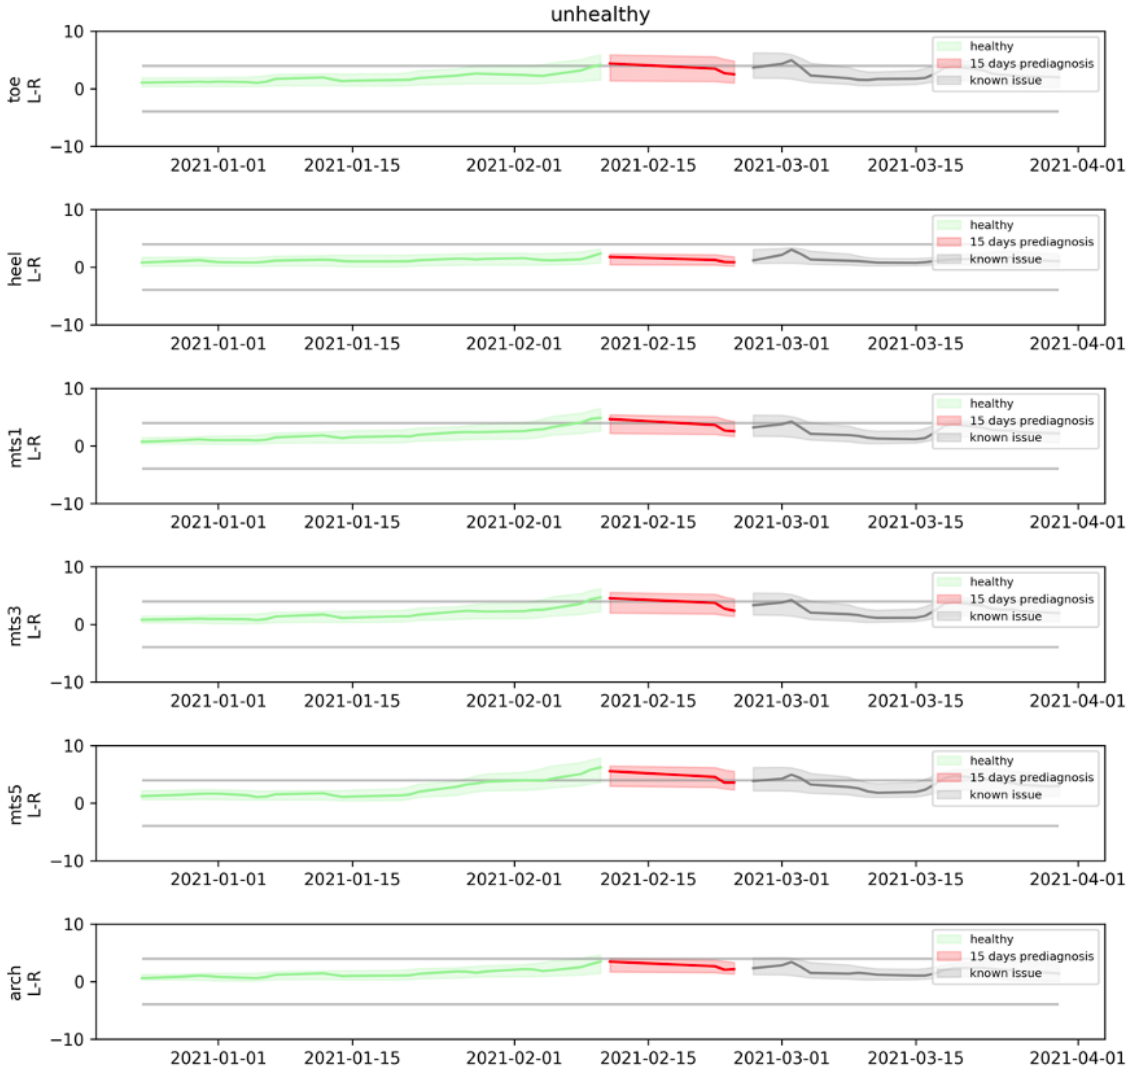


Description of Follow-up Routine

The data from the remote patient monitoring device were reviewed by LPNs under the supervision of a podiatrist. Any temperature differentials greater than 4 °F sent an alert to the LPN that required follow-up via a phone call to the patient. In each case, the sustained level of temperature rise with the possible presentation of an injury caused the patient to be referred to the clinic for evaluation. In the case of the control cohort, the temperature was monitored using the same method used for the study cohort, and the same alert criteria for temperature differential and follow-up routine were used.

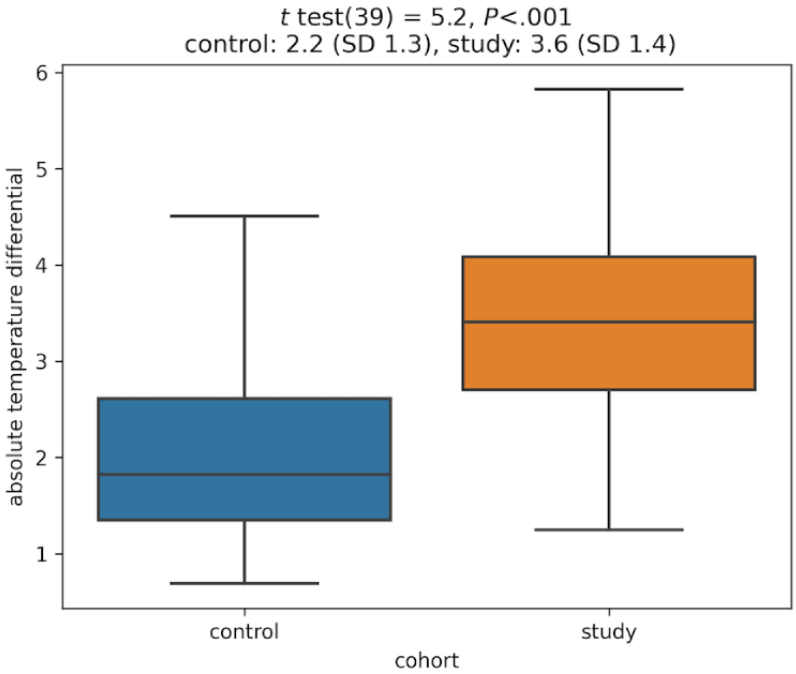
Description of Outcome Measures

The primary outcome measure is the difference in temperature between two points on the feet of a patient.

Statistical Analysis

A Welch *t* test was applied to determine that the mean temperature deviation in the study cohort was significantly higher than the control cohort (Figure 3) ($P<.001$). The analysis was performed using SciPy v1.6.3 programmed in Python (Python Software Foundation).

Figure 3. Comparison of the average temperature differential between two cohorts.



Ethics Approval

This study was approved by the WCG IRB (study number 12843666). If an individual wished to participate in the study, they were informed about the study objectives, and they could consent through a mobile app or over the phone after having started using the socks.

Results

A review of the relevant patient demographics is presented in Table 1. None of these differences are considered clinically relevant in terms of temperature data observations. During the observation period, a total of 5 patients presented with lower extremity injury with a temperature differential of 4 °F compared to the contralateral foot. The profile of each injury is listed in Table 2.

Table 1. Patient demographics.

Criteria	Study cohort (N=5)	Control cohort (N=26)
Average age (years)	66.0	70.4
Sex, n		
Female	1	9
Male	4	17
Additional diagnosis, n (%)		
Diabetes	3 (60)	24 (92)
Peripheral artery disease	2 (40)	5 (19)

Table 2. Study cohort.

Injury type	Age (years)	Patient history	Clinical notes
Charcot arthropathy	68	Neuropathy, type 1 diabetes	5-6 days of hotspots. Patient saw provider in clinic for diagnosis of early onset Charcot. Treatment: stay off of foot, use CAM[a] walker, x-rays of right foot.
Ulcer	75	Type 2 diabetes	New diagnosis added: traumatic blister of right hallux—right blister (nonthermal), right lesser toe(s), initial encounter. Crest pads added to shoes.
Osteomyelitis	61	Peripheral artery disease	Persistent hotspots at all 6 foot locations, patient hospitalized for infection symptoms. Osteomyelitis diagnosed with subsequent angioplasty and stent placement.
Fifth metatarsal head ulcer	48	Type 2 diabetes, history of ulcers	Right fifth metatarsal diagnosis changed to ulcer during provider visit. Ulcer was debrided. Go to his cast boot. Continue Siren Socks. Antibiotic ointment to the wound.
Blood clot	76	Peripheral artery disease	Patient began alerting with temperature differential in entire right foot. Patient reported thigh, knee, calf, and foot are swollen. Provider discussed and advised to go to emergency room where deep vein thrombosis was diagnosed and treated.

[a]CAM: controlled ankle movement.

A mean significant temperature increase of 3.59 °F (SD 1.42) was observed in the study cohort in the 15 days preceding an injury confirmed by physical medical examination. The control cohort had a mean temperature differential of 2.20 °F (SD 1.31) during a 15-day comparative period. The difference in means between the two cohorts was 1.4 °F (95% CI 0.859-1.20). Of note, the *P* value between the two cohorts was <.001, demonstrating statistical significance between the two cohorts as to the level of temperature differential.

Discussion

Principal Findings

The prevalence of DFUs and the extent of the clinical complications suggest new methods must be explored. Though temperature monitoring on an episodic basis has been previously described in the literature, this study appears to be the first to use a continuous temperature monitoring device in a real-world environment. The goal of this evaluation was to determine how temperature data would be different, particularly as an early warning indicator, for those patients presenting with a diagnosed foot injury. Previous studies have demonstrated the inflammatory response to injury does lead to a measurable increase in temperature [7,8].

The results of this study suggest that an inflammatory signal is seen with temperature monitoring when there is an injury. Of note, the presence of the temperature difference in the 15-day period prior to the patient presenting and the injury being assessed by a clinician is of particular interest in terms of potential impact on clinical practice. If at-risk patients routinely used a remote temperature monitoring device, it might be possible to identify risks and intervene sooner than standard practice currently allows. In addition to observing the absolute temperature differential, the creation of a continuous temperature monitoring device offers new possibilities to establish a baseline level of variation for a particular patient. The potential exists for significant temperature data to be used to create algorithms to better predict the early formation of podiatric injuries.

Study Limitations

The study has several limitations. There was a small number of injuries, which limited the study population. As the overall number of patients using a remote patient monitoring solution grows, there will likely be a much larger number of cases where a foot injury diagnosis is made. The study was limited to observations made in a 135-day period. The 15-day period was chosen for evaluation, but data certainly suggested temperature differentials of longer periods are of interest. Further study is needed with greater numbers of patients to establish the optimal early detection period.

Comparison With Prior Work

Several studies have been published that evaluate the role of temperature monitoring in the detection or possible prevention of DFUs. Of note, this study appears to be the first to evaluate a continuous temperature monitoring device in patients who did and did not experience a podiatric injury, with both groups providing continuous temperature monitoring data. In an evaluation of an episodic temperature monitoring device, the threshold of 4 °F was used to predict 97% of observed ulcers in a study of patients at risk of recurrent DFUs, but the false-positive rate was 57% [9]. Raising the temperature differential threshold reduced sensitivity but also reduced the false-positive rate. Another study looked at the validity of a specific 4 °F threshold for ulceration detection and postulated daily variations could influence outcomes [10]. The authors suggested future research should identify ways to use continuous monitoring sensors to further define individual thresholds.

Conclusion

The results of this study suggest temperature monitoring using a sock form factor may be a predictor of a developing foot injury. The study cohort had a mean foot temperature differential that was significantly different from that of the control cohort. The ability to review continuous temperature data in a 15-day period prior to a recognized problem showed that temperature differences beyond expected baseline variation were observed. The predictive value of these temperature data suggests patients and providers may become aware and engage earlier to address an issue before it progresses to a more serious level.

The value of temperature monitoring has been demonstrated in controlled studies in the past, but limited real-world data exist of its use in clinical practice. This study showed a statistically significant difference in the continuous temperature monitoring differential of patients who presented with a podiatric injury in the 15-day period prior to seeing a health care professional. Further study is warranted in larger patient groups over a longer follow-up period to better understand the predictive power of temperature monitoring for earlier detection of foot injury in patients with neuropathy and diabetes.

Conflicts of Interest

HJS, RM, KM, and MN are employees and shareholders of Siren Care, Inc. AMR and DGA are advisors to Siren Care, Inc. CDS is a prescriber of Siren socks. GT declares no conflict of interest.

Abstract

Background: The Integrated Clinical and Environmental Exposures Service (ICEES) serves as an open-source, disease-agnostic, regulatory-compliant framework and approach for openly exposing and exploring clinical data that have been integrated at the patient level with a variety of environmental exposures data. ICEES is equipped with tools to support basic statistical exploration of the integrated data in a completely open manner.

Objective: This study aims to further develop and apply ICEES as a novel tool for openly exposing and exploring integrated clinical and environmental data. We focus on an asthma use case.

Methods: We queried the ICEES open application programming interface (OpenAPI) using a functionality that supports chi-square tests between feature variables and a primary outcome measure, with a Bonferroni correction for multiple comparisons (α=.001). We focused on 2 primary outcomes that are indicative of asthma exacerbations: annual emergency department (ED) or inpatient visits for respiratory issues; and annual prescriptions for prednisone.

Results: Of the 157,410 patients within the asthma cohort, 26,332 (16.73%) had 1 or more annual ED or inpatient visits for respiratory issues, and 17,056 (10.84%) had 1 or more annual prescriptions for prednisone. We found that close proximity to a major roadway or highway, exposure to high levels of particulate matter ≤2.5 μm ($PM_{2.5}$) or ozone, female sex, Caucasian race, low residential density, lack of health insurance, and low household income were significantly associated with asthma exacerbations (P<.001). Asthma exacerbations did not vary by rural versus urban residence. Moreover, the results were largely consistent across outcome measures.

Conclusions: Our results demonstrate that the open-source ICEES can be used to replicate and extend published findings on factors that influence asthma exacerbations. As a disease-agnostic, open-source approach for integrating, exposing, and exploring patient-level clinical and environmental exposures data, we believe that ICEES will have broad adoption by other institutions and application in environmental health and other biomedical fields.

KEYWORDS

open patient data; electronic health records; airborne pollutant exposures; socioeconomic exposures; medication exposures; asthma exacerbation

Introduction

Several large-scale initiatives are advancing efforts to reduce barriers surrounding access to patient data maintained in electronic health record (EHR) systems. Relevant initiatives include Columbia Open Health Data [1] and Medical Information Mart for Intensive Care [2]. The common goal is to promote open access to and sharing of patient data for research purposes, while respecting and preserving patient privacy and institutional assurances.

As part of the Biomedical Data Translator program (Translator) [3,4], supported by the National Center for Advancing Translational Sciences, we have developed a disease-agnostic, regulatory-compliant framework and approach for openly exposing and exploring patient data: the Integrated Clinical and Environmental Exposures Service (ICEES) [5]. ICEES was designed to overcome the regulatory, cultural, and technical challenges that hinder efforts to openly share and explore patient data [6,7]. ICEES is unique from similar efforts toward open patient data in that the service provides access to clinical data that have been integrated at the patient level with environmental exposures data derived from a variety of public sources. Thus, ICEES allows for patient-level research in environmental health and related fields.

Herein, we describe the further development and application of ICEES to data on a large cohort of patients with a diagnosis of asthma or a related condition. We examine the impact of select airborne pollutant exposures, demographic factors, and socioeconomic exposures on asthma exacerbations, which we define using 2 primary outcome measures: annual emergency department (ED) or inpatient visits for respiratory issues and annual prescriptions for prednisone. We present our findings and compare results for the 2 outcome measures.

Methods

Study Approval

All study procedures were approved by the Institutional Review Board at the University of North Carolina at Chapel Hill (protocol #16-2978). Informed consent was not required as the study involved existing biomedical data only and patient contact was not involved.

Asthma Cohort

ICEES was designed as a disease-agnostic, regulatory-compliant, open platform. For the work described here, we focused on 157,410 patients with asthma or a related pulmonary condition at UNC Health (all available sites). The specific criteria used to select patients for inclusion in the ICEES asthma cohort were adapted from [8] and included a combination of diagnoses, medications, and laboratory measures. (Details can be found in [5].) Briefly, we captured data on (1) patients with a diagnostic code for "asthma" and prescribed or administered medications that are typically used to treat asthma; (2) patients with a diagnostic code for a respiratory condition other than asthma and prescribed or administered medications that are typically used to treat asthma; (3) patients with a diagnostic code for a pulmonary condition other than asthma but prescribed tests or procedures that are typically used to manage asthma; and (4) patients with a diagnostic code for a respiratory condition other than asthma but with frequent ED visits in which albuterol nebulizer treatments were administered.

ICEES Integrated Feature Tables

"ICEES integrated feature tables" are key to the open design of ICEES. These tables were created using a complex custom software pipeline within a secure environment and under a protocol (#16-2978) approved by the Institutional Review Board at the University of North Carolina at Chapel Hill. For data extraction, Clinical Asset Mapping Program for Health Level 7 Fast Healthcare Interoperability Resource (CAMP FHIR) converted patient data from the PCORnet common data model to FHIR files [9]. FHIR Patient data Integration Tool (FHIR PIT) then ingested the FHIR files and integrated the patient data with multiple sources of environmental exposures data, using patient geocodes as reported in the EHR and dates [10]. The exposures data were derived from public sources and included airborne pollutant exposures data from the United States (US) Environmental Protection Agency Fused Air Quality Surface Using Downscaling repository; major roadway or highway exposures data (a proxy for airborne pollutant exposures) from the US Department of Transportation; and socioeconomic exposures data from the US Census Bureau American Community Survey. (Additional information on the sources of environmental exposures data can be found in [11].) After the data were integrated, the resultant ICEES integrated feature tables were stripped of identifiers per the Safe Harbor method outlined in the Health Insurance Portability and Accountability Act (HIPAA) before being exposed with an open application programming interface (OpenAPI).

ICEES integrated feature tables were created with respect to 1-year "study" periods, that is, calendar years, to provide a reference point for date-based calculations such as age and estimated exposure. Rows contained binned or recoded data on individual patients, with column headers representing data fields for each of the integrated feature variables. Of note, our institution classifies exposure estimates as "secondary protected health information" because the estimates are derived using primary protected health information (PHI; namely, geocodes and dates) to account for the fact that exposure estimates vary across space and time. We addressed this concern by binning all exposure estimates.

The binning strategy that was applied to each feature variable was based on a combination of expert opinion, published literature, and mathematical approaches. Age on day 1 of the 1-year study period was binned using our prior approach [5,12,13]: <5, 5-17, 18-44, 45-64, and 65-89 years (89 years being the oldest permissible age per HIPAA). Sex was treated

as male or female as coded in the EHR. Multiple race categories were available in ICEES; we focused on Caucasian and African American, as each of the other categories encompassed ≤1% of the total patients. Rural versus urban residence was examined using the US Census Bureau classifications based on American Community Survey–estimated residential density: rural area (<2500 persons per Census block group); urban cluster (between 2500 and 50,000 persons per Census block group); and urbanized area (>50,000 persons per Census block group). Estimated probability of no health insurance and estimated median household income were binned using the pandas.qcut function, which bins according to frequencies: [0, 0.637], [0.0637, 0.1121], [0.1121, 0.1644], [0.1644, 0.5548] estimated probability of no health insurance; [7,470, 36,635], [36,635, 46,750], [46,750, 59,566], [59,566, 78,355], [78,355, 250,001] estimated median household income (US $). Proximity to a major roadway or highway was binned based on published work [14]: 0-49, 50-99, 100-149, 150-199, 200-249, ≥250 m). Average daily particulate matter ≤2.5 μm ($PM_{2.5}$) and maximum daily ozone exposure were averaged over the 1-year study period and binned using the pandas.cut function, which bins patients according to the distribution of value estimates: [3.27, 6.30], (6.30, 7.81], (7.81, 10.83] μg/m^3 $PM_{2.5}$; [27.80, 39.00], (39.00, 42.73], (42.73, 46.45] ppb ozone. Importantly, bins were determined in our prior work to be sufficiently granular for statistical analysis [5].

ICEES OpenAPI

We accessed the ICEES OpenAPI through the ICEES Swagger OpenAPI interface and by command-line requests. An ICEES user interface was also available. ICEES was designed to support several functionalities for exploring and displaying the data, including chi-square tests, with counts of patients, chi-square statistics, and probabilities returned to users. In this study, we applied an ICEES functionality that allows users to run multiple chi-square comparisons based on available features and a primary outcome measure, with options to include a correction metric for multiple comparisons or collapse contiguous bins. In all cases, missing data were excluded from analysis. We queried the ICEES OpenAPI for data on all patients included in the asthma cohort and focused on outcomes in year 2016, which was the most recent year available with complete exposures data. We ran separate queries for each of the following primary outcome measures: (1) 1 or more annual ED or inpatient visits for respiratory issues; and (2) 1 or more annual prescriptions for prednisone. Specifically, we asked the following natural language question: “Among all patients within the ICEES asthma cohort, what airborne pollutant exposures, demographic features, and socioeconomic exposures differ significantly between patients with 0 versus 1 or more annual ED or inpatient visits for respiratory issues in year 2016?” The corresponding command-line API request was:

curl -X POST “https://icees.renci.org:16340/patient/2016/cohort/COHORT%3A12/associations_to_all_features” -H “accept: text/tabular” -H “Content-Type: application/json” -d “{\”feature\“:{\”TotalEDInpatientVisits\“:{\”operator\“:\”=\“, \”value\“:0}},\”maximum_p_value\“:1}”

A similar query was used to examine the primary outcome of 1 or more annual prescriptions for prednisone.

Statistical Analysis

The exploratory 1 × N feature association functionality available via the ICEES OpenAPI automatically invoked a chi-square test of the association between available features and our user-defined primary outcome measure, significance level, and multiple-comparison correction. We considered the primary outcomes of 1 or more annual ED or inpatient visits for respiratory issues and 1 or more annual prescriptions for prednisone. We focused our analysis on select feature variables that were considered a priori to have a potential impact on asthma exacerbations and were available for patients within the asthma cohort: demographic factors (age, sex, and race); socioeconomic exposures (residential density, health insurance access, and median household income); and airborne pollutant exposures (proximity to major roadway or highway, and exposure to $PM_{2.5}$ and ozone). We set the significance level at α=.05, which was adjusted by Bonferroni correction to α=.001. A power calculation was not conducted, as this was an observational, exploratory study focused on existing biomedical data.

Results

We successfully queried the ICEES OpenAPI for outcomes data on year 2016. Of the 157,410 patients who met the criteria used to define the asthma cohort, 26,332 patients (16.73%) had 1 or more annual ED or inpatient visits for respiratory issues, and 17,056 patients (10.84%) had 1 or more annual prescriptions for prednisone. Table 1 provides additional details on the cohort, including demographic and clinical profile and environmental exposures.

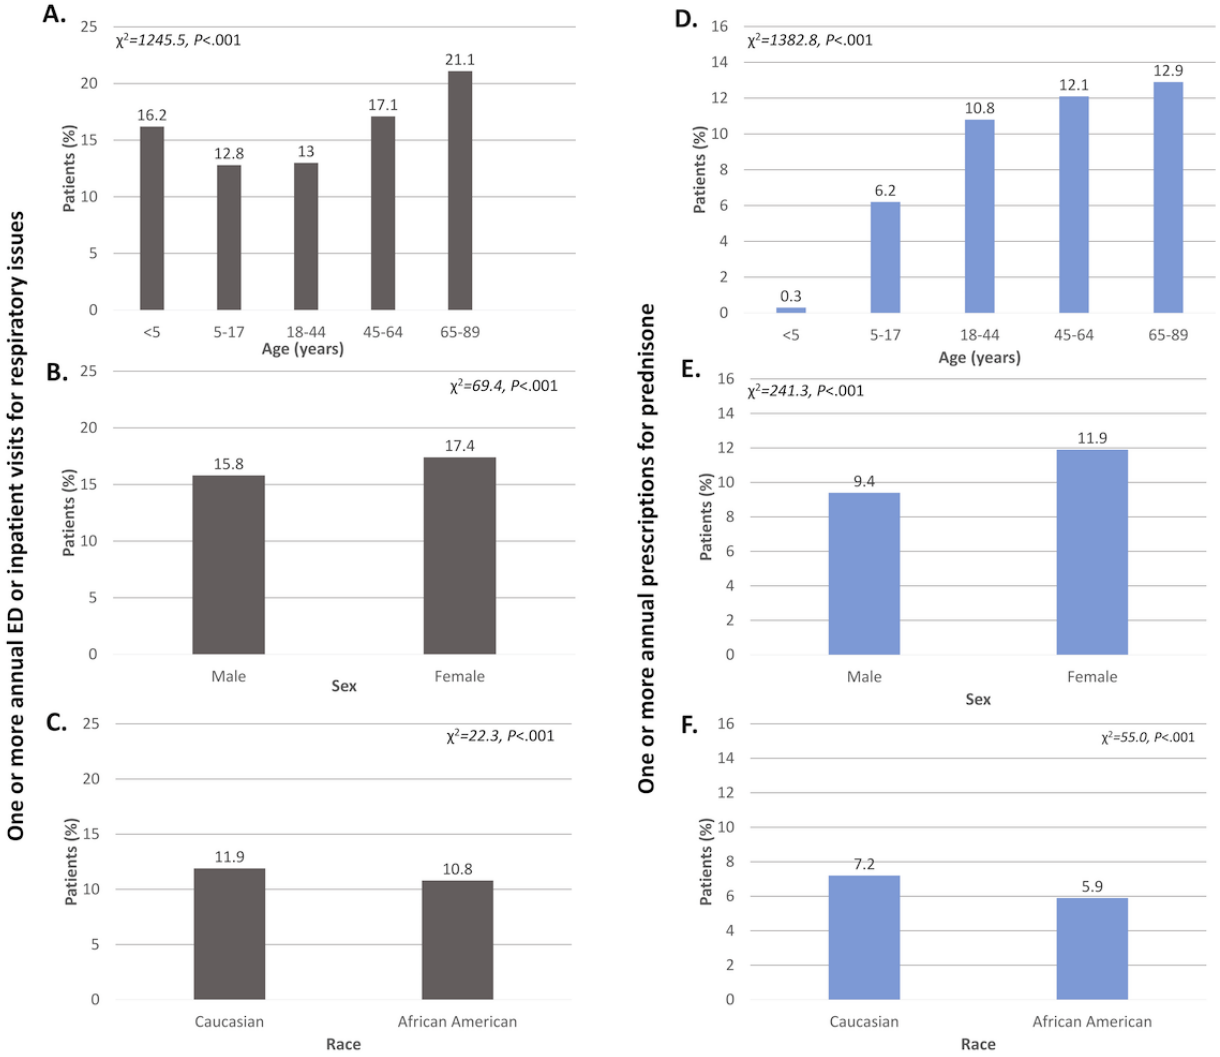
[a]Missing data reflect gaps in the electronic health record data, particularly missing geocodes that prevented the determination of exposure estimates.
[b]Averaged over the 1-year study period.

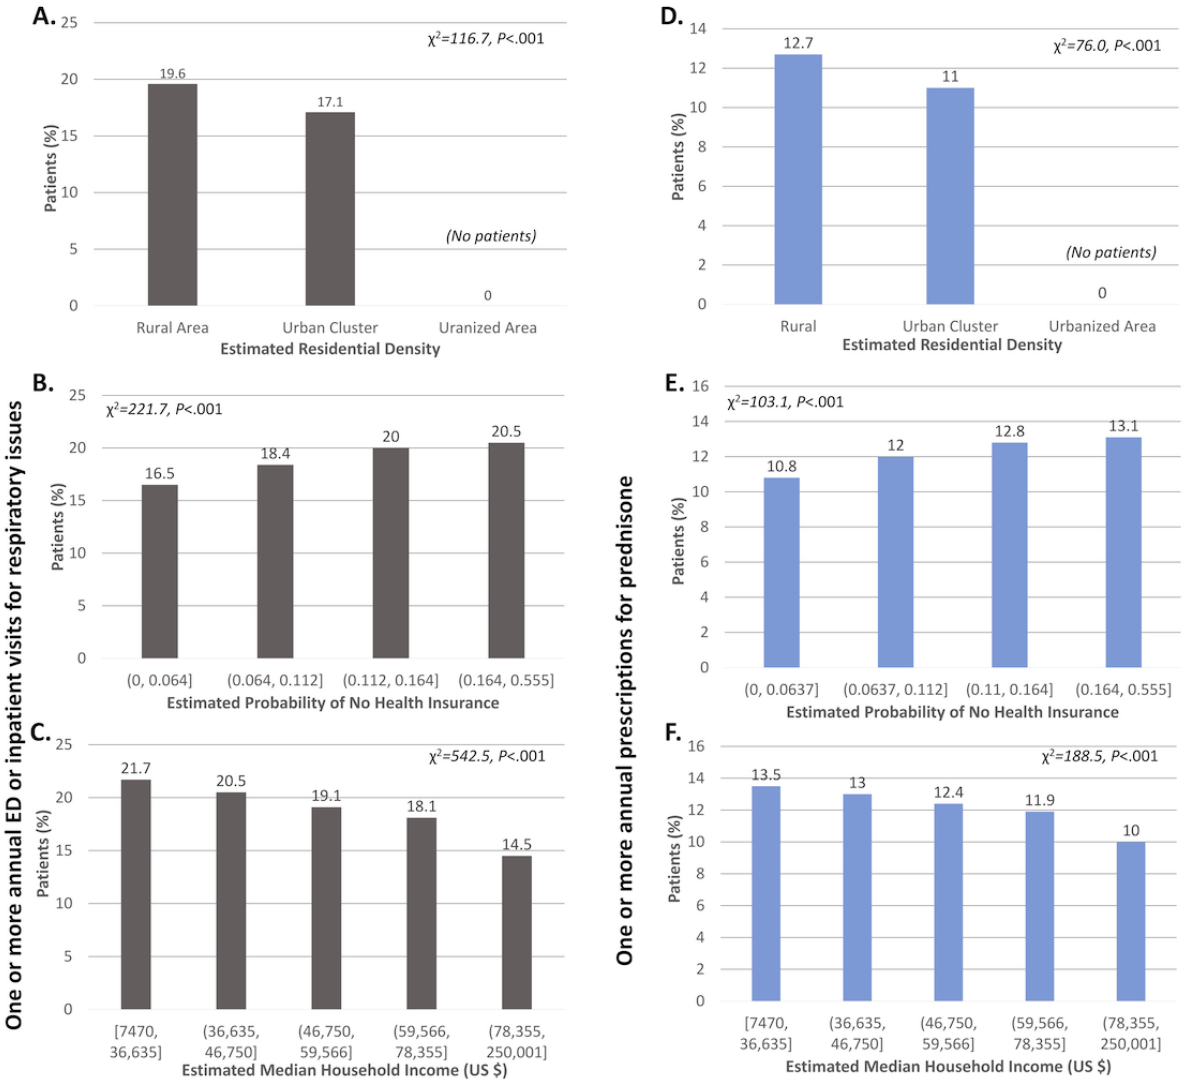
We then examined associations between select feature variables and annual ED or inpatient visits for respiratory issues, focusing initially on demographic factors (Figure 1A-C). We found that the percentage of patients with asthma exacerbations was higher among females than males (17.41% [15,587/89,531] vs 15.83% [10,743/67,875]; χ^2=69.4; *P*<.001) and among Caucasians than African Americans (11.86% [9304/78,418] vs 10.83% [3137/28,977]; χ^2=22.3; *P*<.001). A U-shaped relationship was found between age and the percentage of patients with 1 or more ED or inpatient visits for respiratory issues (<5 years, 16.21% [914/5638]; 5-17 years, 12.83% [2576/20,071]; 18-44 years, 13.01% [4655/35,777]; 45-64 years, 17.13% [8822/51,495]; 65-89 years, 21.08% [9365/44,429]; χ^2=1245.5; *P*<.001). (Degrees of freedom are not returned by ICEES and thus are not reported here.)

Figure 1. Associations between age (A,D), sex (B,E), race (C,F) and asthma exacerbations, defined as one or more annual emergency department (ED) or inpatient visits for respiratory issues (A-C) or one or more annual prescriptions for prednisone (D-F) (N = 157,410).



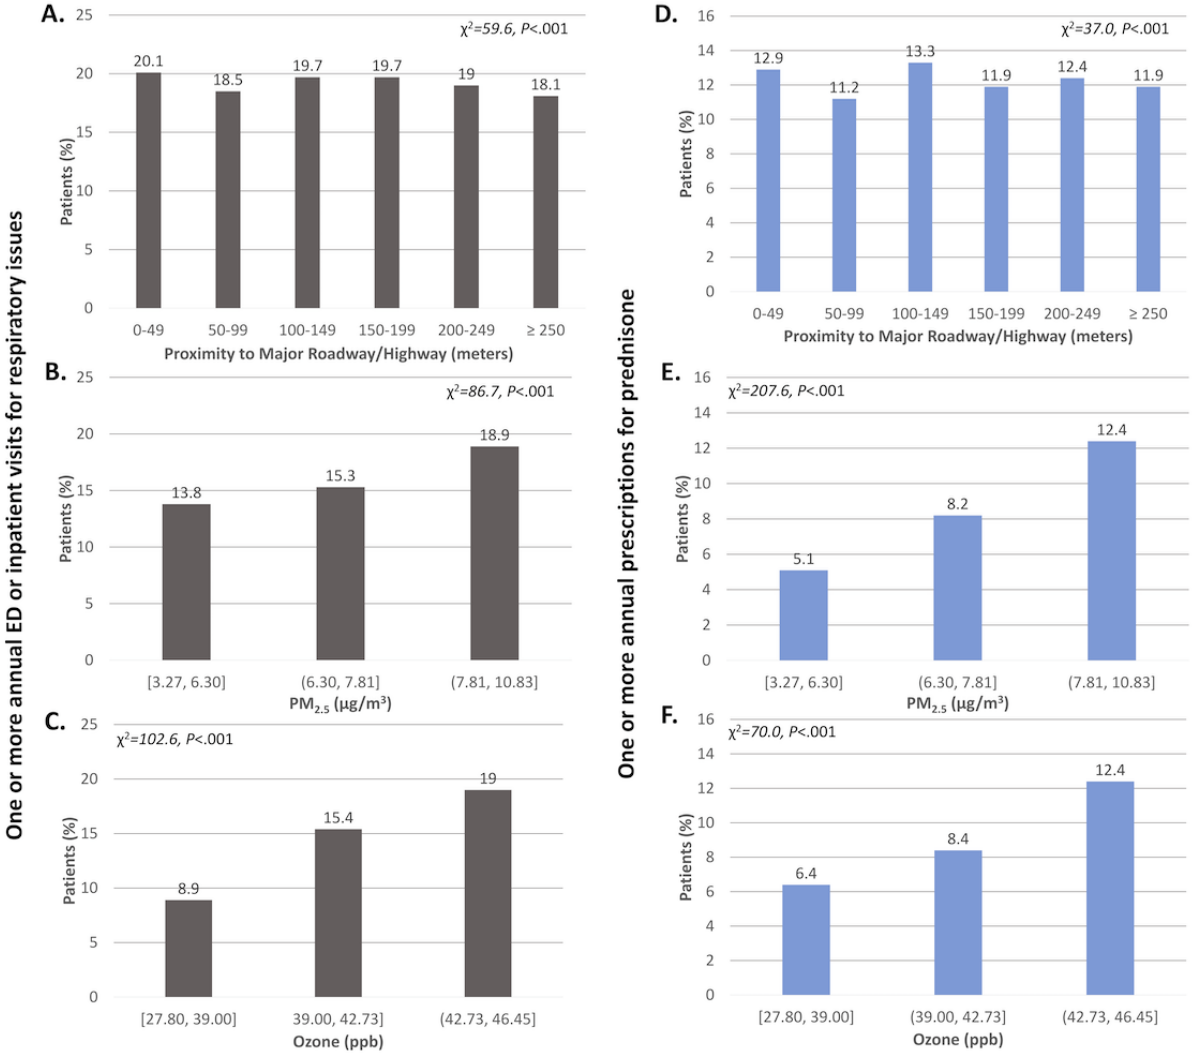
We also examined associations between socioeconomic exposures and annual ED or inpatient visits for respiratory issues (Figure 2A-C). We found that the percentage of patients with 1 or more annual ED or inpatient visits for respiratory issues was higher among patients residing in low-density rural areas than among those residing in higher-density urban clusters (19.59% [18,739/95,632] vs 17.12% [7155/41,798]; χ^2=116.7; *P*<.001). No patients were identified as residing in urbanized areas, as estimated by the American Community Survey and classified by the US Census Bureau. Asthma exacerbations increased with increasing probability of no health insurance (bin 1, 16.47% [5681/34,500]; bin 2, 18.43% [6325/34,313]; bin 3, 20.03% [6878/34,340]; bin 4, 20.47% [7000/34,201]; χ^2=221.7; *P*<.001) and decreased with increasing median household income (bin 1, 21.68% [5847/26,967]; bin 2, 20.51% [5553/27,081]; bin 3, 19.10% [5127/26,843]; bin 4, 18.07% [4872/26,968]; bin 5, 14.46% [3898/26,955]; χ^2=542.5; *P*<.001). (Bin values are provided in Table 1.)

Figure 2. Associations between residential density (A,D), probability of no health insurance (B,E), and median household income (C,F) and asthma exacerbations, defined as one or more annual emergency department (ED) or inpatient visits for respiratory issues (A-C) or one or more annual prescriptions for prednisone (D-F) (N = 157,410).



We then examined associations between airborne pollutant exposures and annual ED or inpatient visits for respiratory issues (Figure 3A-C). Asthma exacerbations decreased with increasing household distance from a major roadway or highway (0-49 m, 20.11% [3516/17,485]; 50-99 m, 18.45% [1800/9754]; 100-149 m, 19.73% [2021/10,244]; 150-199 m, 19.69% [1850/9398]; 200-249 m, 18.96% [1607/8477]; ≥250 m, 18.06% [15,529/85,989]; χ^2=59.6; *P*<.001) and increased with exposure to increasing levels of $PM_{2.5}$ (bin 1, 13.82% [300/2170]; bin 2, 15.33% [1017/6636]; bin 3, 18.89% [24,975/132,206]; χ^2=86.7; *P*<.001) and ozone (bin 1, 8.90% [21/236]; bin 2, 15.38% [1749/11,372]; bin 3, 18.95% [24,522/129,404]; χ^2=102.6; *P*<.001).

Figure 3. Associations between proximity to a major roadway or highway (A,D), exposure to particulate matter ≤ 2.5-μm (PM2.5) (B,E), exposure to ozone (C,F) and asthma exacerbations, defined as one or more annual emergency department (ED) or inpatient visits for respiratory issues (A-C) or one or more annual prescriptions for prednisone (D-F). (N = 157,410).



Results for the primary outcome of annual prescriptions for prednisone (Figures 1D-F, 2D-F, and 3D-F) were similar to those for annual ED or inpatient visits for respiratory issues, with 1 exception. Specifically, a linear relationship was found between age and prednisone prescriptions, with the percentage of patients with 1 or more annual prednisone prescription increasing with age (<5 years, 0.27% [15/5638]; 5-17 years, 6.1% [1235/20,071]; 18-44 years, 10.79% [3861/35,777]; 45-64 years, 12.08% [6222/51,495]; 65-89 years, 12.88% [5723/44,429]; χ^2=1382.8; *P*<.001).

Discussion

Principal Findings

We describe the further development and application of ICEES+ to explore select feature variables associated with asthma exacerbations in a large cohort of patients with asthma or a related condition. We focused on select demographic factors, socioeconomic exposures, and airborne pollutant exposures. We compared results for 2 outcome measures that are indicative of asthma exacerbations: annual ED or inpatient visits for respiratory issues and annual prescriptions for prednisone. We found that female sex, Caucasian race, rural residential density, high probability of no health insurance, low estimated median household income, close residential proximity to a major roadway or highway, and exposure to relatively high levels of $PM_{2.5}$ or ozone were significantly associated with asthma exacerbations. Moreover, the results were largely consistent across outcome measures, even though rates of annual ED/inpatient visits for respiratory issues were higher than those for annual prednisone prescriptions.

Limitations

Our study has several limitations that should be considered when interpreting the results. Specifically, as an open service that exposes EHR data, ICEES must abide by stringent regulatory and institutional regulations that limit the granularity of data that can be exposed and the statistical capabilities that are supported. For instance, ICEES exposes binned or recoded data, not raw data. In addition, our institution treats exposure estimates as secondary PHI because they are derived from primary PHI (ie, geocodes and dates); as such, we are unable to reveal the estimated values themselves, only the bins, thus

preventing a determination of mean exposures and other statistics based on continuous values. Finally, ICEES currently only supports basic bivariate statistical capabilities. However, we are developing approaches to adapt ICEES to support, in a regulatory-compliant manner, more sophisticated multivariate statistical approaches and machine learning algorithms [15,16].

Comparison With Prior Work

We highlight several scientific findings and discuss unexpected findings. First, we observed an increase in the proportion of asthma exacerbations among females versus males. Asthma and acute exacerbations of asthma are more common in males than females in childhood. However, in adulthood, the effect of sex shifts, with females accounting for the majority of asthma and asthma exacerbations. As the majority of patients in our cohort were adults, this observation is consistent with what has been reported in the literature [17-19]. In addition, the increase in asthma exacerbations among patients with lower median household income and those lacking health insurance reflects established disparities in asthma management, particularly among minorities [20]. However, the increase in the proportion of asthma exacerbations among Caucasians versus African Americans was unexpected and contradicts both our findings [10] and those of other investigators [21]. While the reason for this apparent discrepancy is unclear, several possible explanations exist, including the fact that our institution's racial category of "Caucasian" does not definitively distinguish Hispanic Caucasians from non-Hispanic Caucasians, which may have introduced variability. We are currently exploring approaches that may allow us to clearly distinguish Hispanic and non-Hispanic Caucasians and thus refine our racial and ethnic categorization. Another possible explanation is that our prior study focused on year 2010 [10], whereas this study focused on year 2016, and our institution's demographics and patient catchment area have changed significantly over that period [22].

Second, the relationship between age and asthma exacerbations was U-shaped when based on annual ED or inpatient visits for respiratory issues and linear when based on annual prescriptions for prednisone. We suspect that this difference is due to the heterogeneity of wheezing phenotypes in the younger age range, which can be associated with different long-term prognoses for the development of asthma and variance in the use of oral corticosteroids for disease exacerbation [23-26].

Third, one of the key features of ICEES is that it supports research on the impact of environmental exposures such as airborne pollutants on health and disease. Indeed, we identified that asthma exacerbations increased with increasing exposure to $PM_{2.5}$ and ozone, as we and others have shown [5,27]. We also found an increase in asthma exacerbations among patients residing in close proximity to a major roadway or highway, as others have found when using roadway exposure as a proxy for airborne pollutant exposure [14,28,29], although the effect in this study was modest. While one might have expected an increase in asthma exacerbations among persons living in densely populated areas, we found the opposite to be true, with increased asthma exacerbations among persons residing in low-density regions classified by the US Census Bureau as rural areas versus higher-density regions classified as urban clusters. We suspect that several factors might explain these findings. For instance, UNC Health's patient catchment area draws heavily from rural regions of North Carolina, with multiple clinics and small hospitals located across the state and many patients relying on the state hospital system for health care services. Indeed, not a single patient in the cohort described in this study resided in a region classified by the US Census Bureau as an urbanized area. This may have introduced bias into the results. In addition, we note that many major roadways and highways run through rural parts of our patient catchment area, and so any presumption that close proximity to a major roadway or highway is more common in urban versus rural regions may not be valid. A related point is that rural exposures carry risks that may differ from urban exposures. For instance, we are expanding ICEES to include data on concentrated animal farming operations and landfills so that we can begin to examine exposures that may uniquely impact persons residing in rural regions.

We also highlight key technical aspects of this study and discuss limitations. First, the data reported herein are openly available via the ICEES OpenAPI, without any regulatory restrictions or login credentials. This allowed us to rapidly execute the queries and analyze the results, thereby accelerating the speed of discovery. Because ICEES is designed to be disease agnostic and is not restricted to patients with asthma and related conditions, we can adapt our approach and the service itself to support any number of use cases and explore environmental influences on virtually any disease. Indeed, we have deployed additional ICEES instances that expose data on patients with drug-induced liver injury and patients with coronavirus infection. In addition, we are adapting ICEES to support a use case on primary ciliary dyskinesia and related rare pulmonary disorders.

Second, by using health care system EHR data, a large and clinically relevant patient sample can be identified. In this study, our sample size was approximately 160,000 patients, thus supporting rigorous open statistical analysis. While the statistical tests available via the ICEES+ OpenAPI are currently limited to bivariate analyses, we are developing approaches to support multivariate analyses such as generalized linear models, random forest trees, and causal inference models, with options to control for potential covariates, account for missing data, and examine only those patients who are active in a given year, meaning that they were seen at 1 or more clinics within UNC Health. One significant challenge is the binning approach that is adopted for variables. For instance, automated binning algorithms typically bin data by value or by frequency. The former supports the study of extreme values, but at the expense of evenly distributed bin sizes; the latter supports an even distribution of observations among cells, but at the expense of overlap in patients with equal exposures between bins and bin cutoff points that may not be scientifically meaningful. We are systematically exploring this issue.

Conclusions

Our results demonstrate that the open-source ICEES can be used to replicate and extend published findings on factors that

influence asthma exacerbations. While we are actively researching the limitations of the service and developing ways to improve it, we believe that ICEES will greatly speed and democratize the use of EHR data to support research and discovery. Moreover, to the best of our knowledge, ICEES is the only open source of clinical data that have been integrated at the patient level with multiple sources of public environmental exposures data. While we have described an application use case focused on asthma, ICEES is disease agnostic. We expect the service to advance research in environmental health and related fields and continue to grow as we expand both our user base and the service itself to support new clinical use cases, additional EHR elements (eg, laboratory measures), and new data sources (eg, survey data). Moreover, because ICEES is open source, the model and software code [30,31] can be adopted by other institutions as a novel approach for openly exposing and sharing sensitive data. Indeed, ICEES may have application as an open, privacy-preserving approach to inform decision making by the US Environmental Protection Agency and other federal agencies regarding the patient-level impact of environmental exposures on risk of disease. Finally, we are assessing regulatory-compliant options for applying ICEES as a tool for clinical decision support by identifying patients with asthma (and eventually patients with other chronic diseases) or geographical regions at high risk for poor health outcomes based on their exposures profile and then flagging those patients in their EHR to inform patient care.

Acknowledgments

This work was supported by the National Center for Advancing Translational Sciences within the National Institutes of Health (OT3TR002020, OT2TR003430, UL1TR002489) and the US Environmental Protection Agency (CR 83578501). The sponsors were otherwise not involved in the work. The authors acknowledge the following persons: James Champion for assistance with the patient data; Ann Moss Joyner and Allan Parnell of Cedar Grove Institute for Sustainable Communities for guidance on the ACS data; Patrick Wang and Max Wang of CoVar Applied Technologies for development of the Integrated Clinical and Environmental Exposures Service user interface; and Perry Haaland, Ashok Krishnamurthy, Bo Lan, Priya Sharma, and Meghamala Sinha for helpful discussions and critical comments. We also thank our collaborators within the Biomedical Data Translator Consortium and the Personalized Environment and Genes Study at the National Institute for Environmental Health Sciences.

Authors' Contributions

KF, SCA, and EP conceived the general design of the Integrated Clinical and Environmental Exposures Service (ICEES); KF led the scientific implementation of ICEES; HX led the technical implementation of ICEES; KF and HX developed and implemented the binning strategy and statistical functionalities and also performed quality control testing; KF analyzed the data, prepared the figures and table, and drafted the first version of the manuscript; S Appold contributed the US Census Bureau American Community Survey data; S Arunachalam contributed the US Environmental Protection Agency Fused Air Quality Surface Using Downscaling airborne pollutant data; LS and AV contributed the US Department of Transportation roadway data; EP contributed the UNC Health patient data; LS performed all geocoding; SCA provided project leadership; DBP led the study design and asthma use case, provided scientific rationale, and served as the subject matter expert. All authors reviewed and approved the manuscript for journal submission.

Conflicts of Interest

DBP receives funding from the National Institute of Environmental Health Sciences; the National Institute of Allergy and Infectious Diseases; the National Heart, Lung, and Blood Institute; the US Environmental Protection Agency; and the US Department of Defense. He has been a consultant for GlaxoSmithKline, Teva, and Sanofi. All other authors declare no potential conflicts of interest.

Abstract

Background: Depression and anxiety are growing issues for college students, with both aerobic resistance training and mindfulness yoga exercises known to be effective in reducing symptoms and severity. However, no known research is available comparing these 2 depression and anxiety interventions simultaneously and in a web-based environment.

Objective: This study aims to determine the effects of a web-based aerobic resistance exercise intervention (WeActive) and a web-based yoga mindfulness exercise intervention (WeMindful) on depression and anxiety symptoms in college students.

Methods: The participants were 77 college students who anonymously completed a Qualtrics survey, including the Generalized Anxiety Disorder Scale and the Major Depression Inventory at baseline and after the intervention. Participants were randomly assigned to either the WeActive or WeMindful group and underwent two 30-minute web-based aerobic resistance exercise lessons or yoga mindfulness lessons per week for 8 weeks.

Results: The results of analysis of covariance with repeated measures indicated that although not statistically significant, both groups showed a notable decrease in anxiety with a marginally significant main effect of time (F_1=3.485; P=.07; η^2=0.047) but no significant main effect of group and no significant interaction effect of time with group. The 2 intervention groups experienced a significant decrease in depression with the main effect of time (F=3.892; P=.05; η^2=0.052). There was no significant main effect of group or interaction effect of time with group for depression.

Conclusions: College students in both WeActive and WeMindful groups experienced a significant decrease in depression symptoms and a decrease, although not significant, in anxiety as well. The study suggests that web-based WeActive and WeMindful interventions are effective approaches to managing US college students' depression and anxiety during a pandemic.

Introduction

Background

It has been well-documented that mental health issues are increasing within a college student population [1,2]. This increase in mental health problems, such as anxiety and depression, seems to have been exacerbated by the onset of the COVID-19 pandemic [3-6], making the task of determining effective reduction strategies more pressing. Examining for potential increases in depression and anxiety issues due to the COVID-19 pandemic, global research has found that mental health problems have increased both in prevalence and severity in several countries. In China, 31% and 41.8% of 1396 surveyed college students experienced depression and anxiety, respectively [5]. Corroborating these findings, a separate longitudinal study on 66 Chinese college students found that qualities of mental health, including anxiety, were negatively affected by the pandemic [6]. In Italy, research has found that 27.8% of 400 analyzed college students and employees displayed notable depressive symptoms and 34.3% displayed notable anxiety symptoms [3]. In the United States, 44% of 195 interviewed college students reported an increase in depressive symptoms, whereas 71% of the same sample of students reported an increase in stress and anxiety symptoms [4]. In a meta-analysis examining the percentage increases in self-reported anxiety and depression worldwide, researchers found an increase in anxiety from 19% to 37% and an increase in depression from 21% to 54% after March 1, 2020, the time at which the SARS-CoV-2 virus started to rapidly spread worldwide [7]. Many colleges and mental health researchers have focused on finding ways to prevent or treat this rising rate of anxiety and depression [4,8,9], as these mental health problems are thought to have been aggravated by the onset of the global COVID-19 pandemic. Recently, attention has been given to potential lifestyle-based anxiety and depression prevention and treatment strategies, such as through the use of physical activity and mindfulness exercise interventions.

The 2018 Physical Activity Guidelines for Americans recommends that adults participate in 150 minutes of moderate-intensity aerobic activity per week or 75 minutes of vigorous-intensity aerobic activity per week or a combination of the 2 intensities [10]. Research has shown that engaging in physical activity, even in amounts that are less than those recommended by the aforementioned guidelines, can lessen the severity of mental health disorder symptoms, including anxiety and depression [5,11-15]. Depression, in particular, seems to experience the greatest benefits from increased physical activity time, including through group exercises and sports play [16] and through outdoor activities [17]. Anxiety has also been shown to decrease with participation in either individual or group sport–based exercises, with a higher frequency of physical activity correlated with lower levels of both anxiety and depression [13].

Web-based physical activity interventions have also been shown to be associated with reductions in depression and anxiety symptoms in a collegiate population [18]. Recent research on physical activity and mental health has found that more than half of all college students have not participated in an adequate amount of physical activity during the COVID-19 pandemic [5]. Researchers have discovered that individuals who have participated in high-volume and high-frequency structured exercise during the pandemic showed a decrease in depression and anxiety compared with inactive individuals [19]. At the time of study completion, the COVID-19 pandemic had not yet ended, and the lasting effects of this lack of activity in most college students were not yet known. However, as physical activity has been established to have a clear negative correlation with anxiety and depression symptoms, it can be reasonably predicted that inactive students may have more severe long-term mental health effects in the near future.

College students' mental health has also been found to improve with the practice of mindfulness activities, which are designed to allow participants to practice self-awareness of sensation and feeling [12,20-22]. In particular, mindfulness practices of meditation [21-23] and awareness and breathing exercises [21] have been shown to be correlated with improvements in college students' anxiety and depression issues. Yoga exercises, which combine aspects of mindfulness practices and physical activity, have also been shown to be effective in reducing depression, anxiety, and overall stress [21,23]. In addition, research has found a connection between mindfulness exercise practice and other positive psychological constructs, such as psychological flexibility [24] and nonreactivity [25], which, in turn, further decreases mental distress. Similarly, practicing mindfulness has been shown to mediate negative psychological factors, such as intolerance of uncertainty [26], and reduce anxiety symptoms that occur in connection to these negative factors.

In a web-based setting, the use of mindfulness-based interventions to reduce anxiety and depression symptoms in college students has demonstrated similar results to those of in-person interventions [27,28]. An experimental trial with 72 participants on mobile game–based meditation found a significant decrease in depression scores in the intervention group [28]. An 8-week web-based mindfulness study by Ahmad et al [27] with 113 student participants compared a full-time mindfulness virtual community (MVC) group, a part-time MVC group, a cognitive behavioral therapy group, and a waitlist control group. The study by Ahmad et al [27] found statistically significant reductions in depression scores in the full- and part-time MVC groups as well as statistically significant reductions in anxiety scores for the part-time MVC group [27]. However, not all studies on mindfulness-promotion interventions have produced significant positive changes in anxiety and depression. For example, a study examined the changes in perceived stress, anxiety, and depression in students over the course of a semester and found no statistically significant differences among the control group, mindfulness and yoga group, and stress management class group [29]. Similarly, a study examining college students' anxiety and depression after using a mindfulness smartphone app for 5 weeks did not find significant changes from the baseline test to the postintervention test [30]. Despite the few studies that have not shown a correlation between mental health problems and mindfulness practices, most studies examining this topic have found a positive connection [12,20-28].

Overall, there is clear and repeated evidence showing that practicing mindfulness activities or physical activities can positively affect mental health problems. One study compared the influence of mindfulness exercises with that of physical activity on stress, anxiety, and depression in the adult population and found significant reductions in the severity of mental health symptoms across both interventions [31]. Another study examined the impact of physical education activities and mindfulness activities on reducing the severity of anxiety and depression in 125 university students [32]. The results indicated significant reductions in these variables in the mindfulness group, with nonsignificant but observable reductions in the physical activity group, suggesting that mindfulness practices may be more effective in combating anxiety and depression symptoms [32]. In contrast, a recent systematic review comparing the mental health effects of mindfulness-based interventions with exercise interventions in collegiate populations found that the effect size on depression and anxiety was greater with exercise interventions than with mindfulness interventions [12]. To date, few studies have examined the influence of the web-based application of these 2 intervention strategies. Furthermore, there are no intervention studies that have directly compared mindfulness exercises with physical activity using a web-based format during the pandemic. In addition, with contradictory information on intervention effects on reducing mental health problems, there is a critical need to explore the effects of web-based or Zoom-based physical activity and mindfulness exercise in counteracting mental illness symptoms. In addition, the impact of the COVID-19 pandemic on the average mental health status of college students may have complicated the ways in which mindfulness and physical activity interventions interact with anxiety and depression symptoms, furthering the need to understand the utility of these interventions. To the best of our knowledge, there is a lack of research on the effects of web-based aerobic and resistance exercises or yoga with mindfulness on college student depression and anxiety in a midpandemic environment.

Purpose and Hypothesis

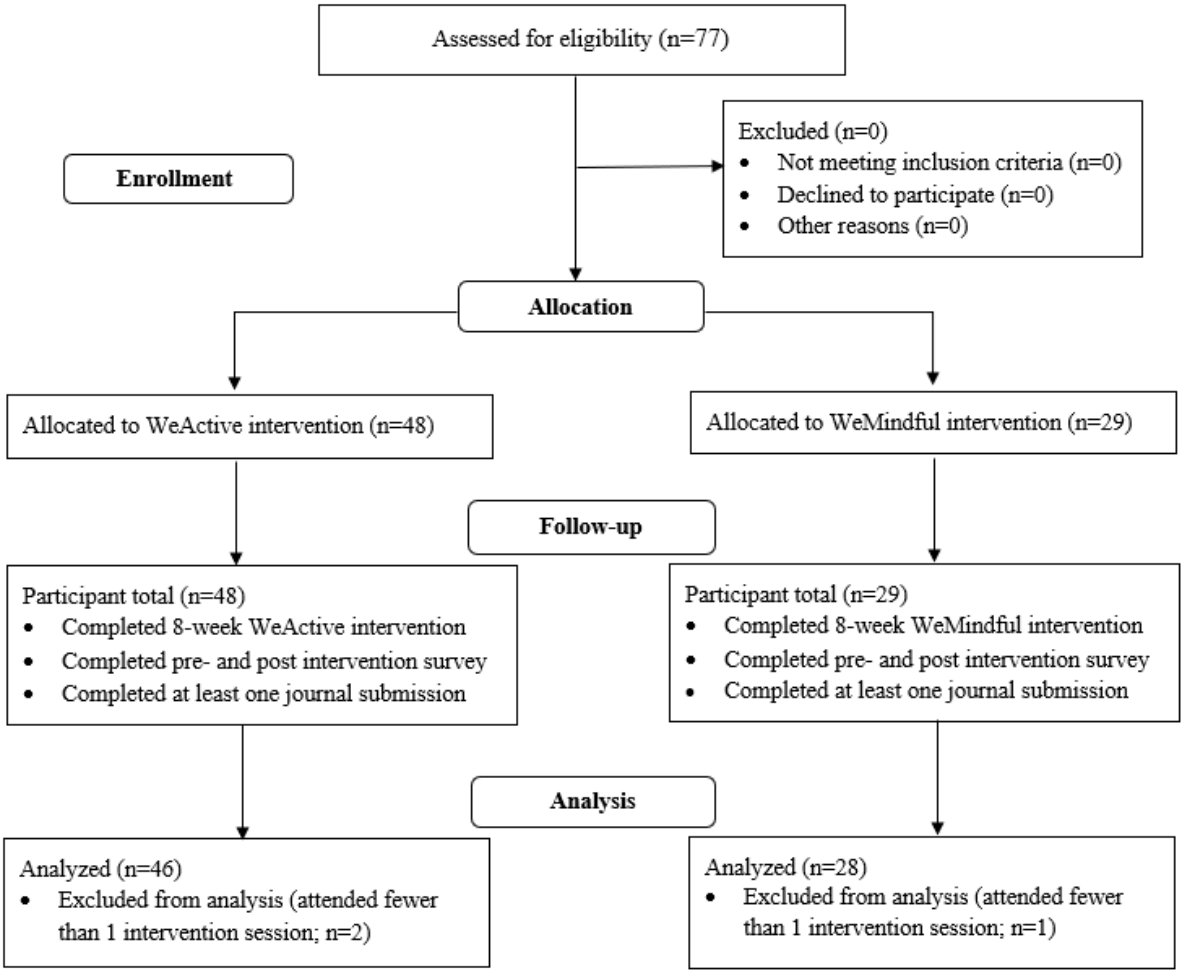
Therefore, this study aims to compare the effects of a web-based aerobic resistance exercise intervention (WeActive) and a web-based yoga mindfulness intervention (WeMindful) on depression and anxiety in college students during the winter semester of 2021. It was hypothesized that both intervention groups would produce improvements in depression and anxiety but that the fitness intervention would show slightly higher positive improvements in both measures. As fitness and mindful exercise interventions have been shown to assist with depression and anxiety improvement, the significance of this study is in determining the effectiveness of web-based fitness exercise and mindfulness exercise interventions on improving student mental health in the midst of a pandemic.

Methods

Participants and Study Design

We recruited college students from a large public university in the Midwestern region of the United States to participate in a randomized quasi-experimental study during the spring semester of 2021. We used several recruiting strategies, including the targeted email response system, the university's canvas learning management platform, undergraduate and graduate bulletins, and university social media pages. The eligibility criteria included being at least 18 years of age, having current status as a student at the university, and having consistent access to the internet and to the web-based conferencing app Zoom (Zoom Video Communications). Participant enrollment information is available in Figure 1.

Figure 1. CONSORT (Consolidated Standards of Reporting Trials) recruitment and study design diagram.



As seen in Figure 1, after the pre-evaluation, 77 participants attended the 8-week intervention components and completed the postintervention test. We calculated the study sample size with an effect size, Cohen *d*=0.80, on college students' anxiety [33], 2-tailed with an α level of .05 and a power of 0.80 using G*Power 3.1.9.7 software. The results showed that the total required sample size of the study was 52, with 26 students in each intervention group. On the basis of our previous study's adherence rate of >90% and an estimated program dropout rate of 10%, we needed to recruit a targeted sample size of 57 college students. Our sample size of 77 participants exceeded the required sample size of 57.

Intervention Conditions

Overview

Both intervention groups were asked to attend two 30-minute group exercise classes via Zoom twice per week. Participants opted to attend 1 synchronized Zoom exercise lesson and 1 asynchronized lesson or 2 asynchronized lessons that were Zoom-recorded and uploaded to the University Canvas study-related website. The asynchronous recording contained the same lesson content from the synchronous live session, meaning content was repeated for the second session each week. In addition, all participants were asked to attend synchronous, researcher-led peer coaching sessions that took place once every 2 weeks for 30 minutes.

The intervention lasted for 8 weeks over the course of the winter 2021 semester. Before the intervention started, participants were given 1 week to complete a preintervention Qualtrics survey that included anxiety and depression measures. Immediately after the intervention period, the participants were again given 1 week to complete a postintervention Qualtrics survey that included the same anxiety and depression measures used in the preintervention survey.

WeActive Intervention

The objectives of the WeActive intervention were to help the participants engage in at least 150 minutes of moderate to vigorous physical activity per week and improve their abilities to achieve the recommended amount of weekly moderate to vigorous physical activity minutes throughout the intervention. The participants were instructed to attend two 30-minute exercise classes via Zoom per week for 8 weeks. The class duration was set to 30 minutes to maximize participant retention while still allowing participants to achieve an amount of exercise that has been shown to be beneficial [17]. The lessons were taught by a student instructor who had previously taken the University of Michigan classes *Methods of Instruction for Exercises* and *Fundamentals of Strength and Conditioning*. In

addition, the WeActive student instructor was a certified strength and conditioning specialist and a graduate student with ≥5 years of experience in personal training. Each exercise lesson used a structured format, consisting of 5 minutes of warm-up (eg, marching in place and dynamic stretching), 20 minutes of both aerobic and resistance exercises (eg, squats and pushups and high knees and jumps), and 5 minutes of cooldown with static stretching exercises (eg, hamstring and quadriceps static stretching when lower body exercises were used in the session). For the first 4 weeks of the intervention, the lesson focused on introducing participants to low to moderate impact resistance and cardio exercises. As lessons continued, exercise difficulty progressed (eg, from a 2-leg bodyweight squat to a moving lunge). The last 4 weeks of the intervention included high-intensity exercise with a greater cardiovascular focus.

WeMindful Intervention

The WeMindful group was instructed to participate in two 30-minute web-based yoga mindfulness classes per week for 8 weeks. The use of yoga, which incorporates movement with breathing and self-awareness, as a primary mindfulness exercise has been supported by previous research [21,23]. The lessons were taught by a student instructor who had previously taken the University of Michigan classes *Methods of Instruction for Exercises* and *Fundamentals of Strength and Conditioning*. In addition, the WeMindful student instructor was a junior undergraduate student studying movement science with 3 years of experience teaching yoga and dance classes. Class content consisted of a 5- to 7-minute–long movement and breathing-based warm-up (eg, focusing on space and deep breathing), followed by 15 to 20 minutes of learning and practicing sequences of basic yoga poses (eg, cat-cow and triangle pose) and ending with a 3 to 5 minutes of mindfulness relaxation (eg, reading meditation scripts). Yoga poses used in the classes often included accommodations for more difficult positions if participants needed to decrease difficulty. The lessons progressed by adding 1-3 new yoga poses per week for the first 3 weeks of lessons, followed by the fourth week that consisted of an overview of all poses learned up to that point. The fifth through eighth weeks followed a similar format, with weeks 5, 6, and 7 consisting of new poses that were reviewed during week 8.

Intervention Implementation Strategies

To facilitate the participants to attend the WeActive or WeMindful exercise lessons and to provide ongoing emotional, informational, and appraisal support for them, we offered all participants in both groups with four 30-minute peer coaching sessions conducted via Zoom, with 1 session every 2 weeks. Each peer coaching session included experience and feedback sharing from participants, barrier or challenge reflections, and participant suggestions for class content. The focus of the first peer coaching session was on orienting and introducing participants to the session formatting, which included goal-setting prompts, self-regulation prompts, self-monitoring reflection, and time for social support. The second, third, and fourth peer coaching sessions delved deeper into obtaining participant feedback on any challenges or preferences they had during the main intervention group components, along with continued goal-setting, self-regulation, and self-monitoring exercises. The peer coaching sessions were led by 1 doctoral student and 1 other undergraduate student of the research team. In addition to peer coaching sessions, all participants were instructed to complete weekly journals that asked participants to provide their weekly attendance for both synchronous and asynchronous classes. In addition, participants received encouraging messages on the web from the research team every Thursday, with content including praise and motivational phrasing.

Intervention Outcome Measures

Anxiety Measure

This study used the 7-item Generalized Anxiety Disorder (GAD-7) scale by Spitzer et al [34] for participants to self-rate their anxiety symptoms. The GAD-7 questionnaire measures anxiety symptoms occurring within the past 2 weeks on a 4-point scale, ranging from 0 (not at all) to 3 (nearly every day). The 7 items were added together to provide a total anxiety score. The scores for the questionnaire ranged from 0 to 21. A score between 5 and 9 indicated mild anxiety, a score between 10 and 14 indicated moderate anxiety, and a score above 15 indicated severe anxiety [34]. In this study, the Cronbach α coefficients of the GAD-7 scale at baseline test and after the test were .794 and .795, respectively, indicating acceptable internal consistency.

Depressive Symptoms Measures

This study used the 10-item Major Depression Inventory (MDI) developed and validated by Bech et al [35] for participants to self-rate their depression symptoms. The MDI questionnaire measures depression symptoms occurring within the past 2 weeks on a 6-point rating scale ranging from 0 (no time) to 5 (all the time). Items 8 and 10 consist of 2-part questions (a and b), where the highest score between the 2 subquestions is used as the item score. The scores for this questionnaire ranged from 0 to 50. A score <20 indicates no or doubtful depression, a score between 21 and 25 indicates mild depression, a score between 26 and 30 indicates moderate depression, and a score >30 indicates severe depression [35]. In this study, the baseline test of the MDI had a Cronbach α of .770, whereas the posttest evaluation of the MDI had a Cronbach α of .773, indicating both having an acceptable internal consistency level.

Data Analysis

Of the 77 participants who completed the preintervention and postintervention surveys, 3 were excluded from the final data analysis because of poor participation. The final data set included 46 participants from the WeActive intervention and 28 participants from the WeMindful intervention, for a total of 74 participants.

The preintervention and postintervention data were analyzed using SPSS 26 software (IBM Corporation), with statistical significance set at $P<.05$ for the tests. Of the 77 students who completed both the preintervention and postintervention surveys, 74 were included in the final analysis (46 from WeActive and 28 from WeMindful). Overall, three participants (2 from WeActive and 1 from WeMindful) were excluded from the final

analysis because of a lack of adequate participation. The mean scores of the GAD-7 and MDI tests were compiled and used for dependent variable analysis. Descriptive statistics of each intervention at baseline were calculated, and 2-tailed independent *t* tests were used to determine any significant differences in the dependent variables of each intervention group. A mixed-design analysis of variance repeated measure was used to examine the effect of either intervention group on depression and anxiety measures. Depression and anxiety scores were the main dependent variables in this study, with univariate tests separately for each variable. In this study, the between-factor was the analysis of the WeActive intervention group against the WeMindful intervention group. The within-subject factor was the comparison of the preintervention test against the postintervention test. In the analysis of covariance (ANCOVA) tests, if sphericity was violated, the Greenhouse-Geisser correction was applied. The results showed no significant differences in the preintervention mean scores for X3month_exercise, X3month_yoga, MDI score, GAD-7 score, education, race, and age, with the only significant difference between groups coming from the X3month_therapist variable (F_1=15.083; P=.01). Therefore, ANCOVA was used to determine the intervention effects on anxiety and depression while controlling for covariates. The between-subject factor for analysis was the intervention group, comparing the WeActive group with the WeMindful group, and the within-subject factor was time, comparing the baseline test scores with the posttest scores.

Ethics Statement

This study was reviewed and approved by the University Institutional Review Board-Health Sciences and Behavioral Sciences (IRB-HSBS) (HUM00189120). We conducted this study in accordance with the principles of the Declaration of Helsinki. All participants in the study have provided written informed consent to participate in the study.

Results

Overview

The results showed significant decreases in depression symptoms in both intervention groups as a main effect of time. Anxiety symptoms decreased marginally in both groups. There were no significant effects of group or of time and group in affecting anxiety or depression symptoms.

Baseline Characteristics

The final WeActive group consisted of 48 participants, with a mean age of 23.02 (SD 4.83) years. The final WeMindful group consisted of 29 participants, with a mean age of 24.31 (SD 7.48) years. Both groups had similar educational and racial distributions. A summary of the descriptive statistics is presented in Table 1**.**

Table 2 displays the baseline score difference between the 2 intervention groups.

[a]X3month_exercise=number of exercise sessions in the previous 3 months.

[b]X3month_yoga=number of yoga sessions in the previous 3 months.

[c]X3month_therapist=number of therapist visits in the previous 3 months.

[d]*P*<.01.

[e]PreGADtotal=baseline total Generalized Anxiety Disorder.

[f]PreMDItotal=baseline total Major Depression Inventory.

As seen in Table 2, the mean scores of depression in both groups were similar, with the WeActive mean scores of 16.89 falling slightly lower than that of WeMindful at 17.75. Both scores are in the nondepressed classification range through the MDI, which is classified as a score under 20. According to the MDI criteria, both groups' scores indicated *no or doubtful* levels of depression at baseline. Both groups presented similar scores in the anxiety measure, with WeActive at 7.15 and WeMindful at 7.79. These scores placed both groups within the *mild* anxiety range (score between 5 and 9) through the GAD-7. The mean scores of an overall health rating, 3-month history of exercise, and 3-month history of yoga were similar across both groups. Only the measure of the past 3-month therapist visits differed to a notable extent, with WeMindful averaging a higher score at 0.48 compared with the 0.2 therapist visit average for WeActive.

The independent sample *t* tests revealed no significant baseline differences in the outcome variables and demographic variables between the 2 groups (age: *P*=.41; race: *P*=.29; education: *P*=.77; physical activity: *P*=.36; anxiety: *P*=.32; depression: *P*=.60). With regard to the past 3-month therapist visit measure, the WeMindful group had a significantly higher mean average visit number than the WeActive group (t_1=−2.660; *P*=.01). This baseline difference was controlled for when conducting repeated measures ANCOVA.

Intervention Effects on Anxiety and Depression

Table 3 presents the baseline and posttest scores of anxiety and depression by group, whereas Table 4 displays the ANCOVA repeated measure results for anxiety and depression.

Table 3. Baseline and posttest scores of anxiety and depression.

	Values, mean (SD)
Baseline anxiety	
WeActive	7.152 (5.517)
WeMindful	7.786 (4.475)
Posttest anxiety	
WeActive	6.652 (5.225)
WeMindful	6.429 (4.710)
Baseline depression	
WeActive	16.89 (12.97)
WeMindful	17.75 (10.77)
Posttest depression	
WeActive	13.57 (10.98)
WeMindful	16.89 (12.61)

Table 4. Results of analyses of variance with repeated measures for anxiety and depression.

[a]*P*<.05.

[b]*P*<.01.

For the anxiety measure, while controlling for the past 3-month therapist visit, the results of ANCOVA with repeated measures indicated no significant main effect of time and group and no significant interaction between time and group. However, the main effect of time was close to a significant level (F=3.485; P=.07; η^2=0.047), indicating that the 2 groups had a marginally significant decrease in anxiety over time. The resulting GAD-7 classification for both groups after the intervention was still considered within the *mild* range for anxiety severity. The results also showed that the past 3-month therapist visit was a significant covariate of anxiety (F=8.629; P=.004; η^2=0.108).

With regard to the depression measure, the results of ANCOVA with repeated measures yielded a significant main effect of time (F=3.892; P=.05; η^2=0.052), while controlling for the past 3-month therapist visit. The results indicated that the 2 groups showed a significant reduction in depressive symptoms from baseline to after the intervention. In contrast, the ANCOVA with repeated measures revealed no significant main effect of group and no significant interaction effect of time with group. The resulting MDI classification for both groups after the intervention was still considered within the *no or doubtful* range for depression severity. Similarly, the 3-month therapist visit was a significant covariate for depression (F=7.007; P=.01; η^2=0.090).

Discussion

Principal Findings

This study aims to examine the effects of a web-based aerobic resistance exercise (WeActive) intervention and web-based yoga mindfulness (WeMindful) intervention on college students' anxiety and depression levels. Both the 8-week interventions were hypothesized to have positive effects on anxiety and depression, with greater positive effects predicted in the WeActive group. As expected, the participants in the 2 groups experienced a significant decrease in depression scores over the 8-week period. Although not statistically significant, the participants experienced a decrease in anxiety scores as well. Contrary to our second hypothesis, there were no significant interactions between group and time, indicating that the WeActive group did not experience greater improvements in mental health scores than the WeMindful group over time.

The decrease in depression scores across both intervention groups in our study aligns with results from previous mindfulness interventions [12,20-23] and physical activity interventions [5,11-18]. The connection behind depression reduction and mindfulness exercises is thought to be caused by a variety of factors. With regard to emotional regulation, mindfulness activities interact directly and indirectly with mechanisms such as rumination and suppression, which act as mediators in the development of both depression and anxiety [36]. At the biological level, cortisol levels have been found to be higher in depressed individuals than in nondepressed individuals, with mindfulness activities such as yoga showing positive effects in reducing cortisol and improving depression measures [37]. Similar to the cortisol-related depression reduction mechanism seen with the use of mindfulness interventions, a reduction in depression due to increased physical activity has been linked to biological factors, such as neurogenesis in the hippocampus, acting similarly to antidepressant drugs [38], and through the regulation of stress hormone release through the hypothalamic-pituitary-adrenal axis [39]. With the implementation of both aerobic and resistance training interventions, some psychosocial symptoms of depression, such as negative thinking and self-efficacy, have been found to directly decrease, which in turn reduces depression severity [39]. It is likely that our WeActive and WeMindful interventions acted across a multitude of depression-meditating mechanisms, although the intervention sessions or length of intervention did not measure for biological changes in participants in either intervention group.

It is important to note that the participants in both groups experienced a marginally significant decrease in anxiety, a result that mostly supported our original hypothesis. Previous research that has examined the relationship between anxiety and either mindfulness or aerobic resistance exercise has displayed mixed results. Although most studies reveal a significant positive relationship [12-14,21-23], some studies show no significant interaction between the intervention and anxiety measure [16,20,29]. In a study by Bosso [30], inadequate participant adherence rates likely caused this lack of significance, with the anxiety measure in this study displaying a dose-dependent response to mindfulness activities. In addition, both the Bosso [30] and Conder [29] studies discovered that shortened intervention duration or low frequency likely limited the intervention effectiveness in reducing anxiety symptoms. Johnston et al [16] suggested that the anxiety levels in their study were likely influenced by external variables, such as increasing college demand over the course of a semester [16].

It is possible that our study had an insufficient frequency to produce significant anxiety changes. It is also likely that the onset of the college final examination period toward the end of the study greatly affected the overall anxiety levels of the participants. Although the results of our study do not indicate statistical significance, the mean anxiety scores across both interventions still notably decreased over time, showing the potential benefit of both the WeActive and WeMindful interventions.

Contrary to our expectations, there was no statistical significance in the group and time interactions, meaning neither the WeActive nor WeMindful group showed significant differences in depression or anxiety changes over time. Of the few studies that have compared the mental health effects of mindfulness exercises with aerobic or resistance exercises, only van der Zwan et al [31] showed similar results across both intervention groups, as in our study [31]. In the study by van der Zwan et al [31], both mindfulness exercise and aerobic exercise interventions showed significant reductions in anxiety and depression scores. As no research on this topic has been conducted in a pandemic environment, there are no definitive reasons yet established on why both intervention types displayed similar results. It is possible that the recent and collective changes in lifestyle may have contributed to the statistically equal impact of both the mindfulness exercise and aerobic resistance exercise interventions, suggesting that both interventions are effective in combating pandemic lifestyle–related depression symptoms. It is necessary to note that despite the presence of academic stressors such as final examinations and learning-related issues on the web, the students in both intervention groups showed a significant reduction in depression scores. This finding suggests that both aerobic and resistance training exercises as well as mindful exercises may be beneficial in buffering academic stress–related depression.

Limitations

This study has several limitations. First, although initial participant interest was high, most interested potential participants decided not to proceed with the study. This limitation was likely caused by the completely web-based nature of this study, which prevented opportunities to connect more directly with participants and by the increasingly busy period of the school semester during which this study was conducted. The stressful nature of college classes, where stress often builds as the semester goes on, may have greatly hindered some of the students' participation, as higher levels of stress related to schoolwork could have reduced the free time these participants had to complete the study. Second, the demographics of participants may have interfered with obtaining widely applicable findings, as most participants identified as female. Previous research has shown that females tend to report higher rates and severity of anxiety and depression symptoms than males [1,2]. Third, there may have been a ceiling effect present in the improvements of each group's anxiety and depression scores, as both groups scored in the lowest severity categories of each disorder at baseline evaluation (*no or doubtful* for depression and *mild* for anxiety). These low baseline scores, indicating a low prevalence of anxiety and depression, may have prevented both the WeActive and WeMindful groups from showing larger improvements. A future study that screens more selectively for individuals experiencing higher levels of symptoms may show a greater effect. Finally, as this study was conducted during the midpandemic in a completely web-based environment, it is possible that some participants may have experienced *Zoom fatigue*, a state of exhaustion from overuse of internet web-based conferencing [40]. As school, work, and social settings had shifted to a primarily web-based setting for many students, the use of web-based interventions may have had effects opposite to what had been intended; instead of providing an accessible mindfulness exercise or physical activity option, the intervention setting could have been perceived as a deterrent or a reason for participant dropout. Future research on the topic of web-based mental health interventions would benefit from more gender-equal participant recruitment and distribution, possibly by comparing an in-person intervention setting with a web-based setting. In addition, future studies of mental health interventions in students could use different strategies to motivate and communicate with participants to reduce the participant attrition rate.

Conclusions

Our study showed that the participants in both the WeActive and WeMindful groups experienced significantly decreased depression symptoms over time. This decrease in depression occurred despite the stressors of upcoming final examinations for all participants. Anxiety symptoms decreased but did not reach a statistically significant level. Both web-based aerobic resistance training and web-based yoga mindfulness exercises seem to be effective in buffering mental health distress, especially with depression. Future research should focus on examining the effects of web-based environments against in-person environments for reducing mental health disorder severity or symptoms in college students. In addition, as this study used multiple modalities in both aerobic resistance training and yoga mindfulness exercise interventions, future research could benefit from exploring single modality interventions, such as aerobic exercise compared with resistance training or yoga compared with meditation. This study suggests that both the combination of aerobic resistance training and the combination of yoga mindfulness exercises are associated with a reduction in college student depression scores over an 8-week period. As the findings from our study indicate the potential efficacy of WeActive and WeMindful interventions in improving student mental health measures, this study design could be a useful resource for colleges and mental health treatment providers.

Acknowledgments

The authors would like to thank the students who participated in this study and the entire research team for their hard work during this unpredictable year.

Abstract

Background: The risk of urinary tract infections is increased by the inappropriate placement and unnecessary prolongation of the use of indwelling urinary catheters. Sustained behavior change in infection prevention could be promoted by empowering patients through a smartphone app.

Objective: The aim of this study is to assess the feasibility and efficacy of implementation actions on patients' use of the Participatient app on a clinical ward and to compare 3 survey methods for urinary catheter use.

Methods: Participatient was introduced for all admitted patients at the surgical nursing ward in a university hospital in the Netherlands. Over a period of 3 months, the number of new app users, days of use, and sessions were recorded. In a comparison of urinary catheter use before and after the implementation of the app, 3 methods for point prevalence surveys of catheter use were tested. Surveys were conducted through manual parsing of the text in patients' electronic medical records, parsing a survey of checkbox items, and parsing nursing notes.

Results: In all, 475 patients were admitted to the ward, 42 (8.8%) installed the app, with 1 to 5 new users per week. The actions with the most ensuing app use were the kick-off with the clinical lesson and recruiting of the intake nurse. Between the survey methods, there was considerable variation in catheter use prevalence. Therefore, we used the standard method of manual parsing in further analyses. Catheter use prevalence decreased from 38% (36/96) to 27% (23/86) after app introduction (OR 0.61, 95% CI 0.32-1.14).

Conclusions: The clinical application of Participatient, the infection prevention app for patients, could be feasible when implementation actions are also used. For surveying indwelling urinary catheter use prevalence, manual parsing is the best approach.

Introduction

The risk of urinary tract infections increases with the inappropriate placement and unnecessary prolonged use of indwelling urinary catheters. As a result, catheter-associated urinary tract infections (CAUTIs) are a leading cause of health care–associated infections (HAIs). In Europe, CAUTIs account for 152 (95% CI 145-161) cases of HAIs and 81.2 (95% CI 69.0-94.2) disability-adjusted life years per 100,000 population per year. CAUTIs cause excess morbidity, increased length of hospital stays, and increased use of antibiotics [1,2].

Current infection control programs for CAUTI prevention increase health care worker knowledge and awareness of inappropriate catheter use with varying success. Best practices for preventing CAUTIs in acute care hospitals include providing guidelines, supplies, and documentation; performing CAUTI surveillance; educating and training staff; ensuring the use of appropriate technique for aseptic insertion; and ensuring appropriate management [3,4]. Sustained behavior change in appropriate catheter use is often arduous [5]. However, although challenging to implement and compare, we hypothesize that patient participation in infection prevention could be an effective sustainable strategy [6].

Together with patients, nurses, and physicians, we initially developed the smartphone app Participatient for patients. It contains details on practical matters related to the hospital stay, such as visiting hours, and a catheter check function aiming to promote communication on catheter use [7]. The catheter check helps patients assess the indication for their catheter. If no appropriate indication is found, the app advises the user to ask their nurse or physician for the indication. This way, the app helps create awareness and reduce the unnecessary (long-term) use of catheters, thereby aiming to reduce CAUTIs on the entire ward. Surveys of catheter use will be essential for testing the eHealth intervention Participatient in the future. Therefore, in addition to the standard manual survey, 2 alternative methods for surveying catheters will also be evaluated. If accurate enough compared to the standard method, parsing of checkboxes or nurses' notes parsing methods could be a more efficient alternative to manual text parsing.

This study is embedded in the National eHealth Living Lab (NeLL). Through interdisciplinary collaboration, eHealth studies conducted in partnership with the NeLL will create new and innovative solutions that improve health and wellbeing by using suitable eHealth tools for each specific research question.

In this study, the main objective was to assess the feasibility of implementing the Participatient app and the efficacy of sequential stimulating actions on patients' use of the app. The secondary objective was to compare the accuracy of 3 survey methods for urinary catheter use.

Methods

Study Design and Setting

In this study, a before-and-after design was used; surveys were conducted on indwelling urinary catheter use before (T0) and after (T1) the app was introduced. Usage data were continuously collected from the app after introduction.

Adult patients were eligible for inclusion in the surveys if admitted to the 36-bed nursing ward for general, gastrointestinal, and oncological surgery at the Leiden University Medical Center in the Netherlands. Patients were excluded from the point prevalence surveys (PPS) if they were not present on the ward at the time of the survey or if they were admitted on the day of the survey. Patients in T1 were invited to use the app during their stay.

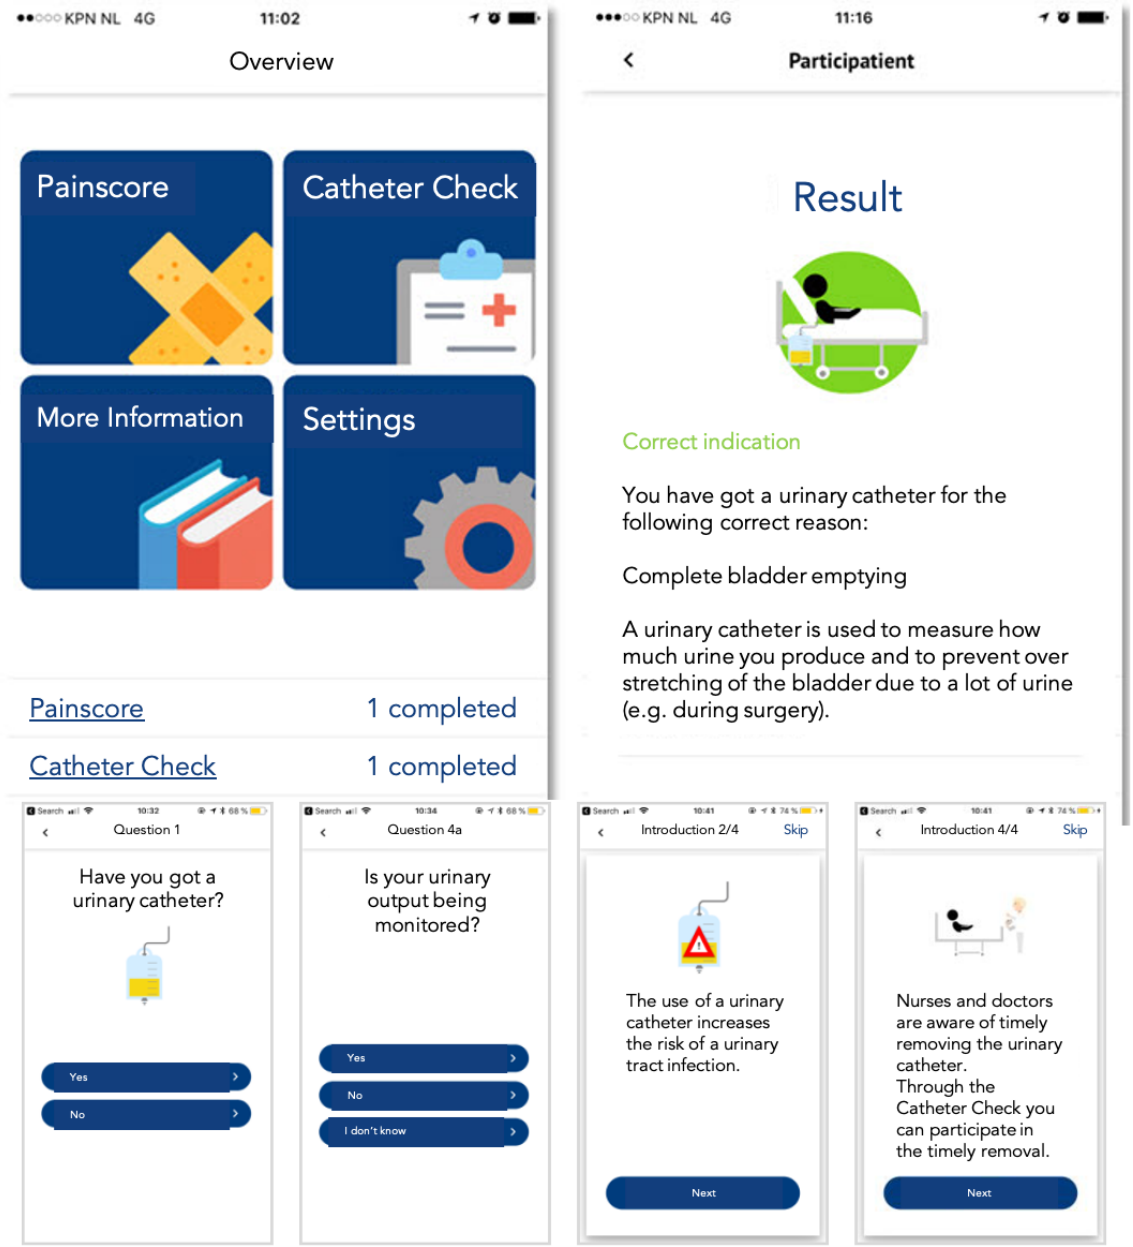
Ethics Approval

This trial was approved by the Medical Ethics Research Committee of the Leiden University Medical Center, with a waiver for individual informed consent (protocol C17.075). Local feasibility was approved by the ward.

Participatient App

The top left panel of Figure 1 shows the Participatient app menu with links to the following pages: painscore (added to help with pain management during admission), catheter check, more information, and settings. The top right panel of Figure 1 shows the result screen for the catheter check function with, depending on the outcome of the questionnaire, an appropriate indication for catheter use (measuring urinary output) with background information. The bottom row of Figure 1 shows screenshots of the questions in the catheter check function with an explanation and a prompt for the patient to discuss their catheter use with their nurse or physician. App development and the final product were previously described in full [7].

Figure 1. The Participatient app with the catheter check function.



Feasibility Testing of the Implementation Actions

In preparation for putting this previously developed app (Figure 1) into practice, the nursing team was given a clinical lesson on urinary tract infections, catheter indications, patient involvement, and the functions of the Participatient app (this implementation action is hereby referred to as the kick-off with the clinical lesson). The nurses were asked to provide input for updating the app and for adjusting it to the ward. Adjustments included the addition of visiting hours, staff, and medical information. After updating the app with these adjustments, nurses merely invited patients to download the app upon admission to the ward. As an implementation action during the course of the study, the intake nurse was recruited and trained to invite patients early in the patients' admission to the ward to further stimulate app use. Additionally, the researchers scheduled reminders of the project for the nurses to promote app use (stimulant reminder given to nurses).

The efficacy of the implementation actions on app use was evaluated by calculating the number of new users, sessions, and days of active use. A new user was registered when the catheter check was used on a unique mobile device. Every instance of opening the app was counted as a session. The days of active use were calculated as the days with one or more sessions per user. Access to the app was restricted to the ward through a 4-digit code.

Feasibility Testing of the 3 Survey Methods

The PPS were conducted using 3 methods and the accuracy of these methods was compared. Data were collected on the prevalence, indication, and duration of urinary catheter use. The PPS were carried out according to national and international guidelines [8,9], as was the scoring of the appropriateness of the catheter indication (Multimedia Appendix 1).

The prevalence and indication of catheter use were manually scored as documented in-text on the date of the survey in the

electronic medical record (EMR). This method was compared with the sensitivity and specificity of surveys of checkboxes (which could be automated) and with parsing nursing notes surveys (Table 1 and Multimedia Appendices 2-4). In the event of missing data on the catheter indication, the reason for catheter use was scored as "not registered" and thus, inappropriate. A total of 2 trained observers (MLB and RGB) independently surveyed catheter use to reduce bias in the measurement of the outcome [10]. We compared the results and discussed discrepancies with a senior observer (KEV).

Data were analyzed using descriptive statistics with the statistical package SPSS (version 26.0; IBM Corp). Between categorical variables, associations were tested with the Pearson chi-squared test, calculating odds ratios with confidence intervals and *P* values. Two-sided *P* values less than .05 were considered significant.

Table 1. A comparison of the 3 survey methods for urinary catheter use before (T0) and after (T1) the implementation of the Participatient app.

Survey methods	Urinary catheter prevalence at T0 (n=96), n (%)	Urinary catheter prevalence at T1 (n=86), n (%)	Odds ratio (95% CI)	*P* value[a]
Manual text parsing	36 (38)	23 (27)	0.61 (0.32-1.14)	.12
Checkbox survey parsing	37 (39)	29 (34)	0.81 (0.44-1.49)	.50
Nurses' notes parsing	28 (29)	18 (21)	0.64 (0.33-1.27)	.20

[a]Two-sided *P* values less than .05 were considered significant.

Results

App Use

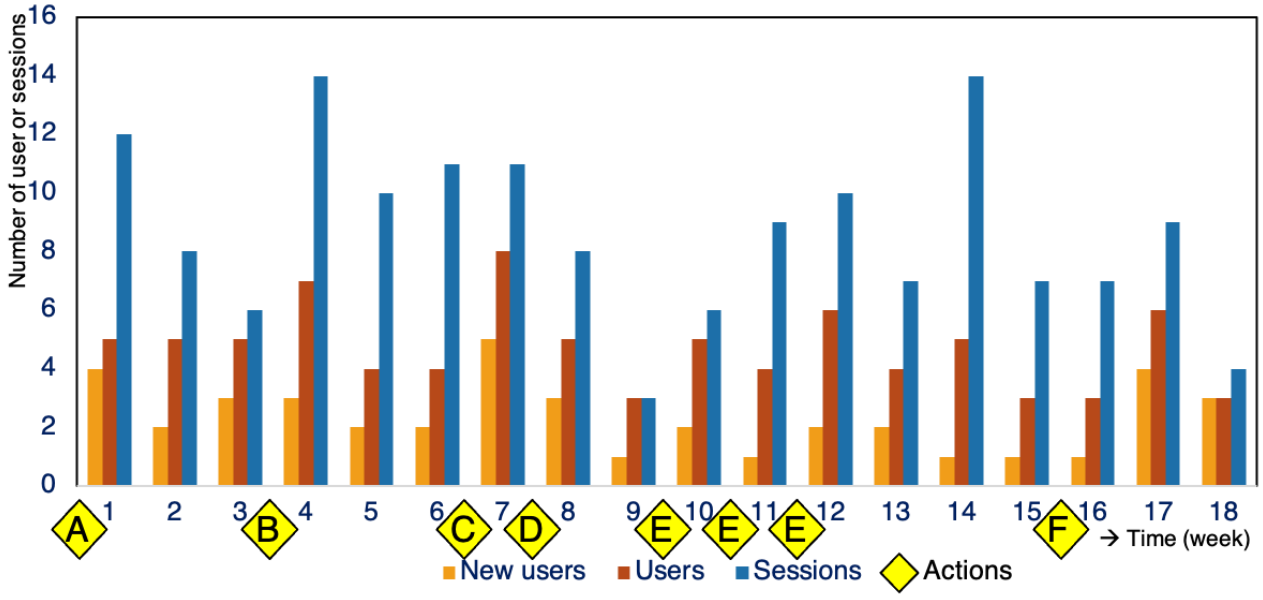
The Participatient app was introduced between October 2017 and January 2018 (T1). Of the 475 patients admitted to the ward, 42 (8.8%) new users installed and used the catheter check function. We registered 85 days of active use and 156 sessions, with an average use of 3.7 sessions per individual user (Multimedia Appendix 5). Since the app is meant to be privacy-friendly, we did not collect demographic data on users.

The highest number of new users was seen following the kick-off with the clinical lesson for nurses and after recruiting the intake nurse to promote app use for the project. The infographic posters and the stimulant reminder given to nurses resulted in the fewest new users among the implementation actions used (Figure 2). The app users reported to be very satisfied with their involvement and the personalized advice they received, rating the app 4.7 out of 5 stars.

The efficacy of the implementation actions for promoting app use was registered as the number of new users, users, and sessions.

A new user was measured as a new installation on a unique mobile device. The number of users referred to the total number of unique users per 24 hours, and a session was counted for every instance of use. Within Figure 2, the following implementation actions are marked at the time point when they began: (A) kick-off with the clinical lesson, (B) infographic posters, (C) recruiting the intake nurse, (D) stimulant reminder given to the nursing team, (E) support rounds with technical assistance performed by the research team, and (F) feedback given to the nursing team on app use and catheter use prevalence. Actions C and D were added to the scheduled actions after interim analyses and feedback from the ward.

Figure 2. Results of implementation actions to increase patients' app use. The efficacy of the implementation actions was registered as the number of new users, users, and sessions.



Catheter Use Surveys

Of the 182 patients included in the PPS, 96 patient records were surveyed in T0 and 86 were surveyed in T1. Baseline characteristics (sex and age) were similar between the groups (Multimedia Appendix 6). The mean age was 63 years, and 41% (75/182) of patients were female.

The prevalence of indwelling urinary catheter use differed considerably between survey methods (Table 1 and Multimedia Appendices 2-4). Compared to the customary method of manual parsing of the text in the EMR, parsing a survey of checkbox items in the EMR had a sensitivity of 96.6% and a specificity of 92.7%. Paring nurses' had a sensitivity of 64.4% and a specificity of 93.5%. Therefore, we decided to continue to use manual parsing in further analyses.

Catheter use prevalence on the ward decreased from 38% (36/96) of patients to 27% (23/86) of patients after app introduction (OR 0.61, 95% CI 0.32-1.14). The average duration of catheterization dropped from 6.9 days to 2.3 days, while the median remained 2 days. We found a 39% (from 56% to 17%) decrease in the number of inappropriate indications for catheter use after the introduction of the app (OR 0.17, 95% CI 0.05-0.60). A total of 56% (20/36) of patients had an inappropriate indication before the introduction of the app, and 17% (4/23) had an inappropriate indication after the introduction of the app. This is shown in Table 2.

Table 2. The number of incorrect indications for catheter use before (T0) and after (T1) the implementation of the Participatient app.

Time point of inappropriate indication	Urinary catheter prevalence at T0 (n=36), n (%)	Urinary catheter prevalence at T1 (n=23), n (%)	Odds ratio (95% CI)	*P* value[a]
At catheter insertion	10 (28)	0 (0)	N/A[b]	.006
At catheter survey	20 (56)	4 (17)	0.17 (0.05-0.60)	.004

[a]Two-sided *P* values less than .05 were considered significant.

[b]Not applicable due to an inappropriate urinary catheter prevalence of 0% at T1.

Discussion

The Participatient app aims to reduce the inappropriate (long-term) use of indwelling urinary catheters through patient involvement. The primary objective of this study, to assess the feasibility of the implementation and efficacy of implementation stimulating actions on the use of the Participatient app, was achieved by registering new users each week. Additionally, we were able to compare the 3 survey methods for catheter use.

A total of 1 in 11 patients admitted to the ward used the app. The highest number of new app users per week was registered following the kick-off with the clinical lesson and after recruiting the ward's intake nurse. The peak in downloads in weeks 17 and 18 could be a delayed result of the feedback given to nurses in week 16. We hypothesize that actively engaging the nurses increases their motivation to promote the app. This is largely consistent with patient involvement in infection prevention, which increases with explicit permission to use the app and participate in their care by staff. As in the other HAI prevention studies, we found that involving nursing staff and keeping them engaged through multifaceted stimulant actions is essential for patient empowerment [4,6,11,12].

Parsing the survey of checkbox items or parsing nursing notes for indwelling urinary catheter use prevalence was inadequate compared to manual text parsing. Manual EMR parsing is laborious; however, this method is most in line with guidelines and previous studies [4,8,9] and is needed for the assessment of the catheter indication. Additionally, the results of the alternative survey methods (parsing checkboxes or nursing notes) are too far removed from the standard method. This could be due to a failure to register the catheter removal date in the proper EMR entry field or updating the daily nursing note too late.

A strength of this study is that it assesses the innovative approach of using eHealth to reduce CAUTIs. Additionally, engaging with physicians, nurses, and patients provides a relevant new perspective. A possible limitation of this study is the manual survey method with the registration of indications for catheter use is limited to parsing of the text in the EMR. Indications not described could have been missed. Additionally, the results could be biased by the introduction of the app to a specific department and/or the small sample size. Registered use of the catheter check function was only 8.8% (42/475), with the target group being elderly hospitalized patients. This was not unexpected as the app should be seen as part of a bundle of interventions to create awareness on the ward as a whole. Encouraging patients to use the app and employing nurse ambassadors who can promote the app could help improve app use. Furthermore, CAUTIs, which are also a relevant outcome, were not scored as this was not the objective due to the short duration of this feasibility study. Remarkably, the prevalence of urinary catheter use was high, with a decreasing trend after the introduction of the app. Additionally, the fraction of inappropriately used catheters decreased significantly.

Jones et al [13] found interventions aimed at the prevention of CAUTIs and *Escherichia coli* bacteremia often did not use behavioral theory or frameworks, and research is required using robust methodologies to evaluate these interventions. The Participatient intervention is designed and built according to the CeHRES (Centre for eHealth and Wellbeing Research) framework, with the involvement of all stakeholders in the development [7]. The before-and-after study design used for this feasibility study could be improved to decisively conclude on the intervention's effectiveness. In mHealth interventions, economic evaluations are limited. In future assessments, this should be included in the analysis [14].

The clinical application of Participatient, the infection prevention app for patients, could be feasible when

implementation actions are combined. Engaging physicians and nurses could help because additional users are observed after the implementation stimulating actions, particularly when actively involving nursing staff. Manual parsing is the preferred method for surveying the effect on urinary catheter use. A larger study spanning various populations could further evaluate the app's effectiveness with the outcomes of catheter use appropriateness and infections.

Acknowledgments

We thank all the patients, physicians, and nurses from the participating ward of the Leiden University Medical Center. We also thank Tobias Bonten for assisting with the statistical analyses. We thank Erin Gail MacDonald for assistance with phrasing and grammar while writing the manuscript. The Leiden University Medical Center Department of Anesthesiology, Department of Medical Microbiology, and eHealth working party all provided funding to develop the app used in this feasibility study.

Authors' Contributions

The conception and design of the study were done by RGB, MLB, NHC, and KEV. RGB and MLB collected the data. The formal analysis of the data was done by RGB. RGB and KEV wrote the original draft of the manuscript. All authors contributed to and approved the final manuscript.

Abstract

Background: Web-based interventions are at an early stage in non–English-speaking low- and middle-income countries, where they remain scarce. Help for Depression (HDep) is one of the few unguided web-based interventions available in Latin America. The results of a use/usability analysis of the original version served as the basis for generating a more user-friendly second version.

Objective: The aim of this study is to explore participants' satisfaction and acceptability for the second version of HDep.

Methods: A retrospective cross-sectional design was used. An email invitation to complete a web-based survey was sent to all people who accessed HDep in 2018. The questionnaire included satisfaction and acceptability scales and open-ended questions. Complete questionnaires were retrieved from 191 participants: 35.1% (67/191) from those who visited only the home page (home page users [HPUs]) and 6.47% (124/1916) from those who registered to use the program (program users [PUs]).

Results: In all groups, users experienced high levels of depressive symptoms (189/191, 98.9%; Center for Epidemiological Studies Scale-Depression >16). Moderate levels of satisfaction (HPUs: mean 21.9, SD 6.7; PUs: mean 21.1, SD 5.8; range: 8-32) and acceptability (HPUs: mean 13.8, SD 3.9; PUs: mean 13.9, SD 3.2; range: 5-20) were found in both groups. Logistic regression analyses showed that among HPUs, women were more satisfied with HDep (odds ratio [OR] 3.4, 95% CI 1.1-10.0), whereas among PUs, older respondents (OR 1.04, 95% CI 1.01-1.08), those with paid work (OR 3.1, 95% CI 2.4-7.6), those who had not been in therapy (OR 2.42, 95% CI 1.09-5.98), and those who had not attempted suicide (OR 3.4, 95% CI 1.1-11.1) showed higher satisfaction. None of the sociodemographic/mental health variables distinguished the acceptability ratings among HPUs. Among PUs, those with paid work (OR 2.5, 95% CI 1.1-5.5), those who had not been in therapy (OR 3.1, 95% CI 1.3-7.3), those without disability (OR 2.9, 95% CI 1.3-6.6), and those who had not attempted suicide (OR 2.6, 95% CI 1.0-6.6) showed higher acceptability.

Conclusions: HDep has good levels of satisfaction and acceptability for approximately half of its users, and the information provided by respondents suggested feasible ways to remedy some of the deficiencies. This qualitative–quantitative study from a low- to middle-income, non–English-speaking country adds to existing knowledge regarding acceptance and satisfaction with web-based interventions for depression in resource-limited countries. This information is important for the creation and adaptation of web-based interventions in low- and middle-income countries, where access to treatment is a major concern, and web-based prevention and treatment programs can help deliver evidence-based alternatives. It is necessary to document the pitfalls, strengths,

and challenges of such interventions in this context. Understanding how users perceive an intervention might suggest modifications to increase adherence.

Introduction

Background

The World Health Organization [1] has ranked depression as the single largest contributor to global disability, accounting for 7.5% of all years lived with disability. More than 80% of this nonfatal disease burden occurs in low- and middle-income countries (LMICs). In Mexico, depressive disorders account for 8.6% of the years lived with disability [1]. Prevention and treatment interventions can reduce the burden associated with depression and other mental health disorders. However, mental disorders remain untreated in many nations; in Latin America, only 5% of people with affective disorders receive adequate treatment [2]. In Mexico, only 6.4% of those diagnosed with major depressive disorder receive minimally adequate treatment [3].

Internet- or web-based interventions represent effective, accessible, and low-cost means to treat and prevent depressive disorders, and they can be broadly disseminated [4,5]. Unguided interventions, based purely on self-help with no human support, can reach large numbers of people at low cost, and there is evidence that even those who experience enough symptoms to screen positive for a major depressive episode use preventive interventions [5]. Meta-analytic studies show that these interventions have benefits but exhibit low adherence rates [6]. The average rate of adherence in unguided interventions is estimated at 26%, compared with 72% in guided interventions [7]. Despite the high attrition rates and lesser effectiveness of unguided programs, these low-cost, low-intensity, web-based interventions are suitable from a public health perspective as early intervention in a stepped-care process [8] and are thus of particular benefit in LMICs [9].

Web-based interventions for common mental health problems, such as depression, have a long history and have evolved rapidly in high-income countries, but they are at an earlier stage of development and are less common in LMICs [10-12]. Web-based interventions to prevent depression are associated with small but positive effects on the symptoms [13]. Help for Depression (HDep; Ayuda para Depresión) [14], in Mexico, was the first such web-based intervention in Latin America [15].

The initial version of HDep (2009-2013) was modeled after a face-to-face psychoeducational intervention in Mexico to prevent depression in women, based on multimodal and cognitive behavioral principles (Table 1) [16]. This initial intervention was modeled after that of Muñoz and Ying [17] in California, designed for the ethnic minority groups, including the Latino population. The content of the program that we developed went through a step-by-step process including focus groups and open-ended questionnaires to verify that language, illustrations, and content were sensitive to the target population [18].

Table 1. Help for Depression content.

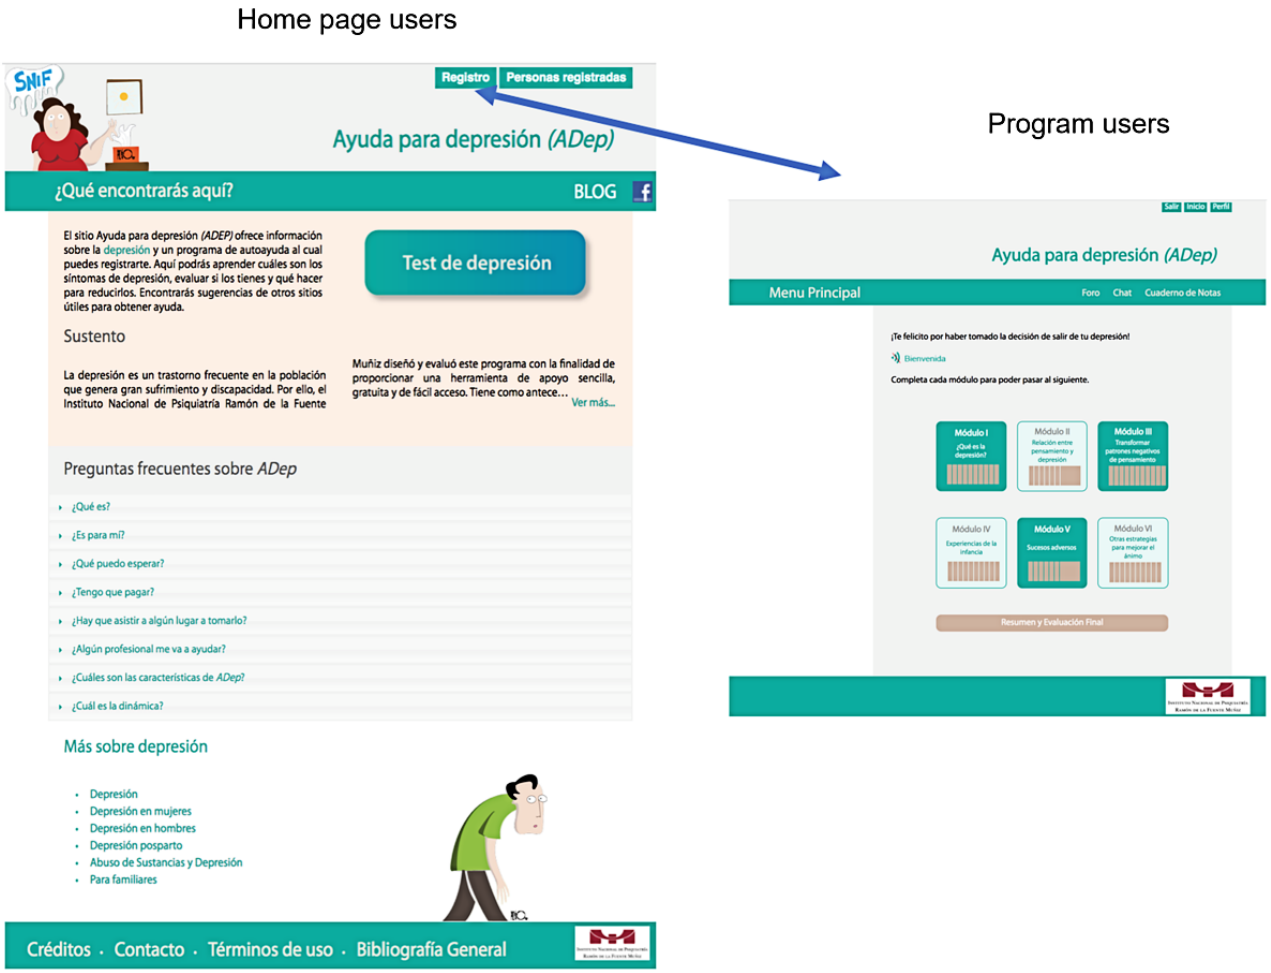
Module	Content
1. What is depression?	• Diagnosis • Symptoms • Risk factors
2. Identify negative thoughts	• Relationship between ways of thinking and depression • Identifying your ways of thinking
3. How to transform negative thoughts	• Changing negative thought patterns • Questioning your negative thoughts • Transforming your negative thoughts
4. Childhood experiences	• Your thought patterns derived from your childhood experiences • Transforming your negative thoughts • Reinforcing your positive thoughts in daily life
5. Adverse events	• Adverse life events • Stressful events in everyday life • Adverse events and negative thoughts • Relaxation exercise
6. Other strategies to improve mood	• Increasing social support • Behavioral activation

A use/usability analysis of the first version of HDep showed that 15.6% of the users were men [15]. Two psychologists with experience working with men reviewed the language and vignettes for cultural sensitivity to male users. The analysis of that version also suggested the need for a shorter and more user-friendly version [15], which was produced by reducing the number of modules. In the new version, users need to provide minimal information (sex, age, and email) to access home page content. The home page includes (1) a self-assessment scale for depressive symptoms (Center for Epidemiological Studies Scale-Depression [CES-D]), with feedback provided via email; (2) extensive information on depression and places to receive help; (3) a description of the aims and content of the intervention; and (4) a link to register to use the program modules. This arrangement allows for two types of users: home page users (HPUs), who are those who prefer to visit only the home page or landing page and program users (PUs), who decide to register for the program modules after exploring the home page (Figure 1). PUs are asked to provide additional information (marital status, education, psychological or psychiatric treatment for depression, suicide attempts, alcohol and drug use, and medication for mental health problems). HPUs and PUs who answer the CES-D and other health measures are given feedback on their responses; those who may be at risk for clinical depression or mental health disorders are advised to find additional psychological or psychiatric help. HDep is freely accessible, with no inclusion criteria for registration; it is thus available not only for people who meet a clinical diagnosis of depression but also to those with other mental health problems, such as substance abuse [15].

The lack of adequate mental health services for most of the population of Mexico and other Latin American countries means that very few people receive even minimally adequate treatment for depression [3]. In this context, internet-based interventions play an important role in the prevention and treatment of depression; however, they are still at an early stage of development in these countries.

Since 2014, the revised version of HDep has had around 2956 visits each month from individuals who answered the depression scale (CES-D) and received feedback based on their scores. At the same time, there is a high rate of attrition, which is consistent with data from a scoping review in Latin America [19]. To improve adherence, it is important to analyze users' experience, perception, and satisfaction with HDep to find ways to encourage people to complete the intervention [5].

Figure 1. Help for depression home page: types of users of the intervention.



Objectives

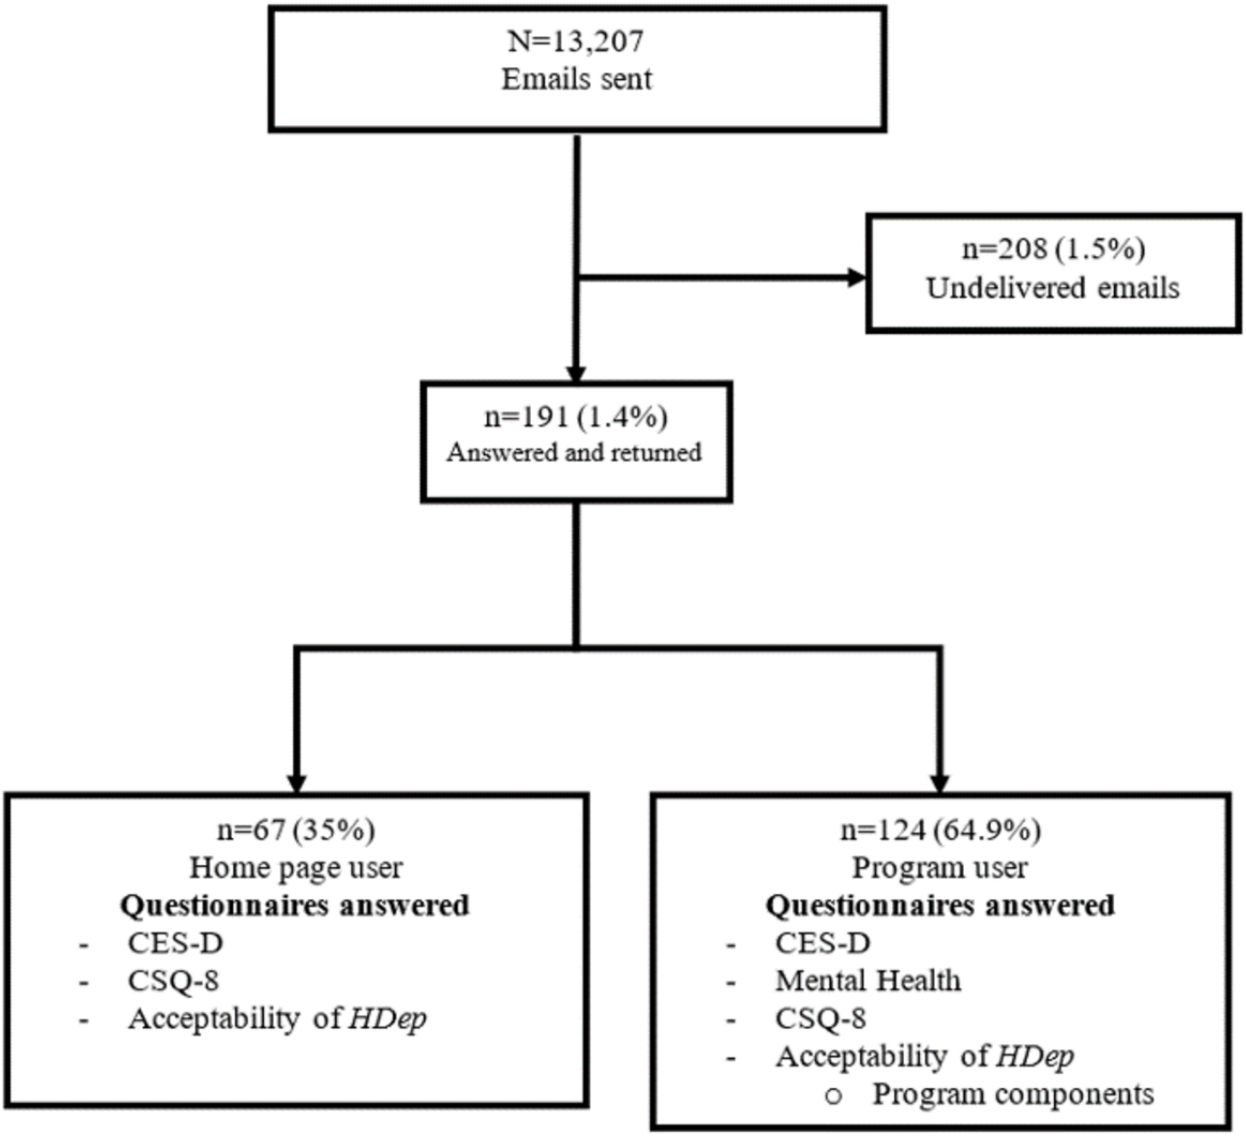
The aim of this study is to assess the acceptability of and satisfaction with the updated version of HDep, considering both types of users separately: HPUs and PUs. This was an exploratory study, with the underlying hypothesis that PUs would show greater acceptance and satisfaction than HPUs, as they were receiving a higher dose of the intervention.

Methods

Study Design and Participants

A retrospective cross-sectional design was used in this study. The population corresponds to people who visited HDep: HPUs and PUs from January to December 2018 (N=13,207) and answered the initial depressive symptoms questionnaire (CES-D), which is accessible on the home page. The sample size was determined according to the procedure of Lemeshow et al [20] for the following parameters: a finite population with a CI of 95% and a margin of error of 10%. This margin of error was chosen because web surveys have response rates approximately 12% points lower than other survey modes [21]. The minimum number of responses required was 96. Of the 13,207 emailed questionnaires, 191 (191/13,207, 1.45%) were answered and returned. A total of 208 (208/13,207, 1.57%) were undelivered (indicated by automatic replies). There is no information on whether the rest reached the target users (Figure 2). The CI for the response rate was 95%, with a margin of error of 7%.

Figure 2. Participant flowchart. CES-D: Center for Epidemiological Studies Scale-Depression; CSQ-8: Client Satisfaction Questionnaire-8; HDep: Help for Depression.



Instruments

Data retrieved from HDep databases: email, sex, age, marital status, occupation, education, depressive symptoms (CES-D), disability during the previous month owing to depressive symptoms, psychological or psychiatric treatment for depression, suicide attempt in the last 6 months, alcohol and drug use, and medication [15].

Depressive Symptoms

Depressive symptoms are assessed with the CES-D [22], which has 20 items with Likert response options (0=rarely or never to 3=most of the time). The cutoff point indicating the presence of depressive symptoms was ≥16. The CES-D has been validated in Mexico [23].

Satisfaction With HDep

Satisfaction with HDep is measured with the short version of the Client Satisfaction Questionnaire-8 (CSQ-8) [24] (Spanish version [25]), which includes 8 questions on a Likert scale of 1 to 4, with higher scores indicating greater satisfaction. A change was made in the wording of the questions to align it with the purpose of the study: *HDep* was used instead of *service*. The CSQ-8 is reliable across a variety of ethnic contexts, including Hispanic groups, and the Spanish version is as reliable as the English version (Cronbach α=.90) [26]. The Cronbach coefficient for the scale in the sample was a Cronbach α of .95.

Acceptability of HDep

As in many studies [27,28], an ad hoc questionnaire was developed to evaluate this construct. It consisted of 17 questions, of which only 15 quantitative questions were analyzed (the other two were open-ended questions that received few responses; thus, they were not included: *Is there something additional that helped you that is not listed here?* and *Are there any additional comments you would like to add?*). The first five questions were related to general acceptability: *Is the home page persuasive? Is the page layout of the modules inviting? Does HDep seem useful for managing depression? Did HDep meet your expectations?* and *Is the website user friendly?* Respondents were asked to answer the questions on a 4-point Likert scale (1=low to 4=high acceptability). The Cronbach coefficient for these 5 questions in the sample was a Cronbach α of .89. In all, 2 questions rated the HDep content and design on a scale of 1 to 10, with a space to provide open-ended elaboration. The final eight questions scored the following elements of HDep on a scale of 1 to 10: module information, sample cases, activities, forums, chats, thought charts, audio, and depressive symptom assessment and feedback. The Cronbach coefficient for the scale in the sample was a Cronbach α of .95. Except for the depressive symptoms assessment and feedback, these questions were analyzed only for users who registered for the program (PUs), as these elements are part of the program modules.

Procedure

The link to the web survey was delivered via email (using the Mail Chimp and Google Forms platforms), including a cover letter explaining the objectives of the study and why users were being contacted. A follow-up email was sent 1 month later to those who had not answered. As a token of appreciation, those who responded to the survey were sent a list of 10 positive thoughts to reinforce HDep activities and improve mood.

The survey was designed to be user friendly; it was configured to prevent users from leaving questions unanswered.

Ethical Considerations

The study was approved by the Ethics Committee of the National Institute of Psychiatry, Mexico (CEI/C/050/2018). The terms of use on the HDep home page explain that some of the data provided by users may be used for scientific reports and publications but that participant confidentiality will be maintained. An informed consent letter was included with the survey, underscoring the guarantee of confidentiality.

Data Analyses

The percentages of sociodemographic characteristics and the means and SDs of the overall satisfaction scale and for individual items were obtained for HPUs and PUs and compared using chi-square and 2-tailed *t* tests. The same procedure was followed to evaluate the elements of acceptability (user friendly, scope, usefulness, motivation to register and carry out the activities, and expectations) of HDep overall and for each component. Logistic regression analyses were conducted to assess the characteristics of users who were satisfied with the HDep program among the HPUs and PUs. For these analyses, the acceptability and satisfaction scales were dichotomized: the cutoff points were defined at the 75th percentile for each scale (for the CSQ-8, it was ≥26 and for the scale of acceptability, ≥16). Finally, a qualitative thematic analysis was conducted on the responses to the 2 open-ended questions regarding design and content.

Results

Demographic and Psychological Characteristics

Of the 13,207 emailed invitations, 191 (1.45%) were completed questionnaires; 67 (67/191, 35.1%) were from HPUs and 124 (124/191, 64.9%) from PUs. Most were women (141/191, 73.8%; HPUs: 42/67, 63%; PUs: 99/124, 79.8%; χ^2_1=6.22; *P*=.01) and aged 20 years (57/191, 29.8%; HPUs: 24/67, 36%; PUs: 33/124, 26.6%) or aged 21-30 years (68/191, 35.6%; HPUs: 24/67, 36%; PUs: 44/124, 35.5%; χ^2_1=6.22; *P*=.01).

Nearly all users (189/191, 98.9%) experienced high levels of depressive symptoms (CES-D>16), with no significant difference between PUs (124/124, 100%) and HPUs (65/67, 97%; χ^2_1=3.74; *P*=.12). Questions on mental health problems were answered only by PUs; 70 (70/124, 56.4%) PUs reported disability associated with depressive symptoms, 20 (20/124, 16.1%) PUs reported psychological or psychiatric treatment for depression, 21 (21/124, 16.9%) PUs reported a previous suicide attempt, 27 (27/124, 21.8%) PUs reported excessive alcohol use, 15 (15/124, 12.1%) PUs reported excessive drug use, and 39 (39/124, 31.5%) PUs had received drug treatment (Table 2).

[b]CES-D: Center for Epidemiological Studies Scale-Depression.

Satisfaction With HDep

The mean satisfaction with HDep was 21.9 (SD 6.7; range 8-32) for HPUs and 21.1 (SD 5.8; range 8-32) for PUs. No significant difference was found in the overall level of satisfaction among types of users (t_{189}=0.845; *P*=.39; Table 3) or on individual items. The highest scores were given to *If a friend needed help, would you recommend HDep?* and *If you were to seek help again, would you come back to HDep*? The item with the lowest score was *To what extent did HDep meet your needs?* (Table 3). No significant differences were found between HPUs and PUs on individual items.

Table 3. Satisfaction with Help for Depression (N=191).

Item	Home page user (n=67), mean (SD)	Program user (n=124), mean (SD)	Values	
			t test (*df*)	*P* value
Scale mean	21.90 (6.74)	21.10 (5.83)	0.84 (189)	.39
1. How would you rate the quality of help you have received?	2.87 (0.88)	2.73 (0.79)	1.04 (189)	.29
2. Did you get the kind of help you wanted?	2.58 (1.00)	2.51 (0.87)	0.53 (189)	.95
3. To what extent has the program helped to solve your problems?	2.21 (0.89)	2.07 (0.77)	1.05 (189)	.27
4. If a friend were in need of similar help, would you recommend our program to them?	3.04 (0.89)	3.00 (0.79)	0.35 (189)	.72
5. How satisfied are you with the amount of help you have received?	2.84 (0.97)	2.64 (0.82)	1.49 (189)	.13
6. Has the help you received helped you to deal better with your problems?	2.60 (0.90)	2.60 (0.79)	0.06 (189)	.95
7. Overall, how satisfied are you with the service you have received?	2.72 (1.05)	2.65 (0.94)	0.47 (189)	.63
8. If you needed to seek help again, would you come back to this program?	3.04 (1.03)	2.90 (0.89)	0.98 (189)	.32

HDep Acceptability

The mean of general acceptability of HDep was 13.84 (SD 3.97; range 5-20) for HPUs and 13.97 (SD 3.29; range 5-20) for PUs, with no significant difference among types of users (t_{189}=0.24; *P*=.80; Table 4). The item with the highest rating was *HDep, a user-friendly program*, and the item with the lowest rating was *HDep, which met my expectations*.

Table 4. Help for Depression (HDep) acceptability (N=191).

Item	Home page users (n=67), mean (SD)	Program users (n=124), mean (SD)	Values	
			t test (*df*)	*P* value
Scale mean	13.84 (3.97)	13.97 (3.29)	0.24 (189)	.80
1. Home page specifies what I can find in HDep and persuades me to register.	2.81 (0.89)	2.92 (0.78)	0.91 (189)	.36
2. Once I am registered, the layout of the module page motivates me to go into each module.	2.72 (0.91)	2.69 (0.77)	0.24 (189)	.80
3. HDep seems like a useful tool to manage depression on my own.	2.70 (0.87)	2.73 (0.88)	0.24 (189)	.80
4. Participating in HDep has met my expectations.	2.72 (0.90)	2.58 (0.85)	1.02 (189)	.30
5. HDep is a user-friendly program.	2.90 (0.97)	3.05 (0.80)	1.23 (189)	.21

Profiles of Users' Satisfaction and Acceptability With HDep

Logistic regression analyses showed that among HPUs, women (odds ratio [OR] 3.44, 95% CI 1.16-10.0) were more satisfied with HDep, whereas among PUs, older participants (OR 1.04, 95% CI 1.01-1.08), those with paid work (OR 3.12, 95% CI 2.40-7.69), those who had not been in therapy (OR 2.42, 95% CI 1.09-5.98), and those who had not attempted suicide (OR 3.44, 95% CI 1.08-11.11) showed higher satisfaction (Table 5). There were no significant differences in acceptability ratings among HPUs by sex, age, or the presence or absence of depressive symptoms. Among PUs, those with paid work (OR 2.50, 95% CI 1.16-5.55), those who had not been in therapy (OR 3.17, 95% CI 1.38-7.30), those without disability associated with depression (OR 2.94, 95% CI 1.35-6.66), and those who had not attempted suicide (OR 2.63, 95% CI 1.03-6.66) gave higher acceptability ratings (Table 6).

Acceptability of Content, Design, and Tools of the Program

Content was assessed similarly for HPUs and PUs (HPUs: mean 7.1, SD 2.9; PUs: mean 7.0, SD 2.5; range 0-10; t_{189}=0.16; *P*=.87). The design was also evaluated positively, with means of 7 and 7.5 (HPUs: mean 7.5, SD 2.6; PUs: mean 7.0, SD 2.5), with no significant difference among types of users (t_{189}=1.33; *P*=.18; Table 7).

HDep individual components, evaluated only by PUs, were scored from 5.19 (SD 3.31) to 6.88 (SD 3.14). Forums (mean 5.62, 3.24) and chats (mean 5.19, SD 3.31) had the lowest acceptability. Depressive symptom assessment and feedback, evaluated by both types of users, had the highest acceptability (PUs: mean 6.88, SD 3.14; HPUs: mean 6.73, SD 3.79), with no significant difference between the 2 user types (Table 7).

Table 7. Users' evaluation of Help for Depression (HDep) content, design, and tools.

Item (rate from 0 to 10 how much each of the following has helped you to manage depression)	Home page users (n=67), mean (SD)	Program users (n=124), mean (SD)	Values

Analysis of Open-ended Questions

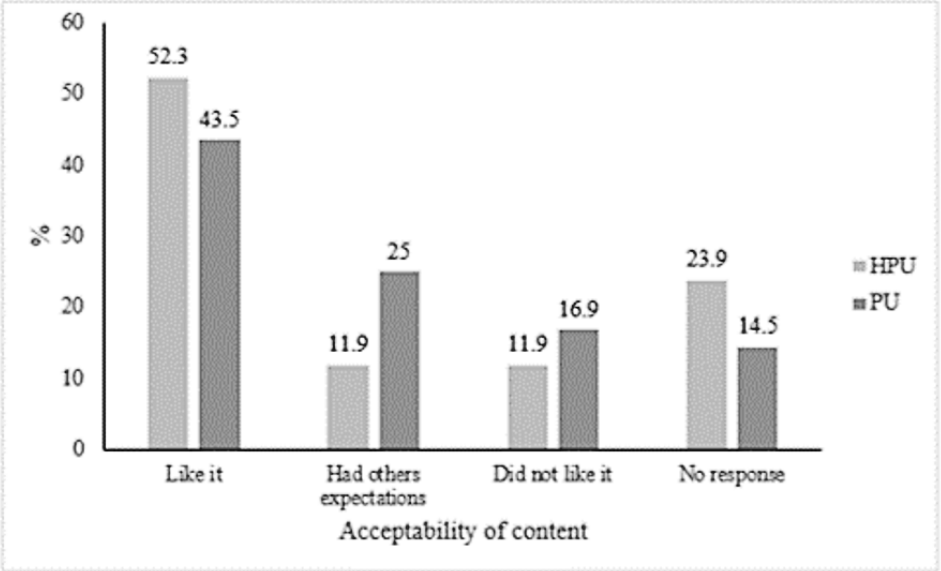
HDep Content

Responses to open-ended questions fell into one of three categories: (1) Liked it, (2) Had other expectations, or (3) Did not like it. The fourth category included those who did not respond (Figure 3). Examples of these explanations are presented in Table 8.

The three categories were as follows:

1. Liked the content—approximately half of the users liked the content: 52% (35/67) of the HPUs and 43.5% (54/124) of the PUs, with no significant difference observed between the 2 groups (Figure 3). HPUs considered the content good, that the help was excellent, and that the use of cases from everyday life encouraged reflection; however, they sometimes considered the web interface cold (Table 8). PUs who liked the content found it systematic, that it gradually made it easier to face life, that the content was meaningful and friendly, and that it allowed them to measure their personal progress. Some respondents who mentioned positive features also pointed out others that required improvement, including a need for additional resources to strengthen individual commitment and motivation.
2. Had other expectations—a significantly greater number of PUs had other expectations (31/124, 25%) than HPUs (8/67, 12%; Figure 3). HPUs reported signing up in search of new information and help and someone to tell them everything was okay, which they did not find. PUs also sought not only interaction with a machine but also contact with a human being, an expert, in forums and chat, with email and mobile phone reminders (Table 8).
3. Did not like the content—respondents who did not like HDep content included 12% (8/67) of HPUs and 16.9% (21/124) of PUs (Figure 3). HPUs thought HDep was neither helpful nor harmful, that they did not need *a pat on the back*, and that *a little rough treatment might not hurt*. PUs said that the content did not motivate them to continue; in the opinion of one, "there was too much content to read which you can't when you are depressed" (Table 8).

Figure 3. Acceptability of help for depression content and design. (A) Liked it (χ^2_1=1.32; *P*=.15); Had other expectations (χ^2_1=4.56; *P*=.02); Did not like it (χ^2_1=0.84; *P*=.24); No response (χ^2_1=2.60; *P*=.08). (B) Liked it (χ^2_1=0.77; *P*=.23); Had other expectations (χ^2_1=0.19; *P*=.47); Did not like it (χ^2_1=3.95; *P*=.03); No response (χ^2_1=9.13; *P*=.001). HPU: home page user; PU: program user.



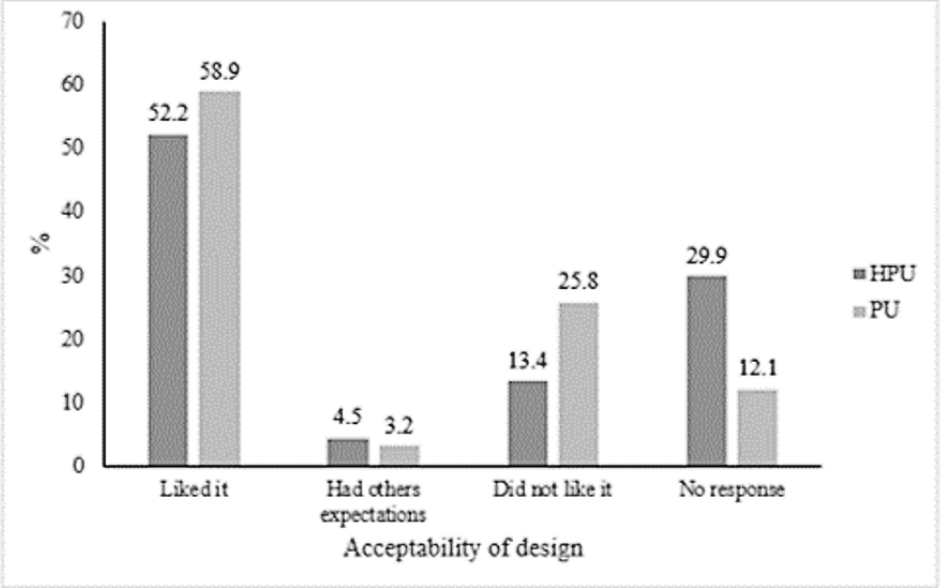


Table 8. Open-ended explanations of score given to acceptability of Help for Depression content.

Category	Home page users	Program users
Liked it	• "In general, its content is good." • "It seems like a very good page, with a lot of satisfactory content." • "The help has been excellent; however, I get the impression that the interface part of the webpage sometimes seems a bit cold." • "It seems to me that something important they get right is that they show phrases and cases from everyday life and that they encourage reflection on personal actions based on those examples."	• "Because it is very systematic, although some strategy is needed to strengthen individual commitment with the help." • "When I opened the page, I doubted it would help me. But as I did the exercises I realized that, although it was very gradual, my way of facing life was getting easier. The problems were getting smaller." • "The content seemed good to me, but not so motivating." • "The content is very meaningful and concrete, the way it is presented is very friendly and allows us to keep measuring our personal results." • "I understand that my level is very high, and there is support, but I think there should be other tools to address the problem, even if the level of depression is as high as mine. It is not a bad option, it is a good one, however, I would recommend increasing or improving the strategy a bit."
Had other expectations	• "I signed up for news and help, but it never got to me." • "They didn't give me any advice, they just gave me a number to search for psychologists in my city. I even said that all I wanted was for someone to tell me that everything was going to be okay."	• "For a topic like this, the human part is necessary, the information is good, but only being able to interact with a machine is cold, at critical times you need to be able to be heard by a person." • "Both in the forum and in the chat, there needs to be an expert moderator, since the participants share personal and often erroneous information." • "I think they need the interaction of email or cell phone reminders to keep the process going."
Did not like it	• "It didn't help me, but it didn't hurt me either." • "What's needed aren't pats on the back, a little severity might not hurt." • "To be honest, it didn't really help me, but thanks anyway."	• "Doesn't motivate to follow the steps." • "Because when someone is depressed you don't have the head to read a lot, in fact that's why I didn't continue with the modules." • "It's a lot of content to read, and due to insomnia, my eyes hurt and reading on the computer didn't help anything." • "Lack of content and motivation."

Design

Open responses regarding the HDep design were also organized into 3 categories, plus one for nonrespondents (Figure 3). Examples of open-ended explanations for the design ratings are presented in Table 9.

The three categories were as follows:

1. Liked the design—more than half of the users liked the design, with no significant difference between HPUs and PUs (HPUs: 35/67, 52%; PUs: 73/124, 58.9%; Figure 3). HPUs found it attractive, user friendly, and colorful; they considered the depression test to be active and they liked how it worked. PUs considered the site neat and well organized, the tools simple, the design motivating, intuitive, and entertaining but perhaps a little too long (Table 9).
2. Had other expectations—fewer participants in each group had other expectations (HPUs: 3/67, 5%; PUs: 4/124, 3.2%). HPUs said they did not receive the expected response or care for their symptoms and had no improvement; PUs believed that the web program, by its nature, reinforced the causes of their depression, not because of problems with its design, but simply because it was a website, meaning that it did not provide contact with a professional, which led to feelings of abandonment (Table 9).
3. Did not like the design—significantly more PUs disliked the design (32/124, 22.8%) than HPUs (9/67, 13%). HPUs noted that HDep was only readable on a computer screen, and it was not encouraging; from their perspective, it should have fewer bright colors and simpler graphics (Table 9).

Table 9. Open-ended responses to acceptability of Help for Depression design.

Category	Home page users	Program users
Liked it	• "It explains things and invites you to interact with the page." • "It's user-friendly." • "It's very colorful, you understand everything" • "The evaluation was active, which made it work nicely." • "The design lets you navigate to find the page, I would recommend it." • "It grabs you."	• "Very nicely organized." • "The tools are simple." • "Good design and motivating." • "It's practical and easy to navigate." • "It's intuitive and entertaining with graphics, maybe a little long." • "Gets your attention at a glance."
Had other expectations	• "I haven't gotten a reply." • "I didn't get attention." • "I haven't gotten better."	• "I believe that the program, by its nature, reinforced the causes of my depression rather than alleviated them. I mean, it's not that it's a bad platform, it's that it's a platform." • "Its lack of online specialists on the page was the constant issue I observed with the others in the chat." • "I felt abandoned."
Did not like it	• "Could be more attractive, I don't know." • "Because if you don't see it on the computer screen, it's a bit difficult to read, select and participate. I recommend that you move to a cell phone version in the future."	• "It's a bit confusing." • "It doesn't grab your eye, it's not encouraging." • "It should have softer colors and simpler graphics, something like headspace or calm." • "Not very motivating."

Discussion

Principal Findings

This study explored the satisfaction and acceptability of the updated version of the internet-based preventive intervention, HDep [14] and found them to be consistent with evaluations in a review of digital interventions in LMICs [29]. Two types of users were observed: HPUs, who visit only the home page, make use of the information available there, respond to the CES-D questions, and obtain feedback on their scores and PUs, who also register for a 6-module intervention. The results showed that HPUs and PUs with similar initial levels of depressive symptoms (CES-D>16; 97% and 100%, respectively) showed moderate levels of satisfaction (HPUs: mean 21.90, SD 6.7, range 8-32; PUs: mean 21.10, SD 5.8, range 8-32) and acceptability (HPUs: mean 13.84, SD 3.97, range 5-20; PUs: mean 13.97, SD 3.29, range 5-20). Among HPUs, women expressed higher satisfaction than men, and among PUs, those who were older, employed, not in therapy before, and reported no previous suicide attempts showed higher acceptability.

Of the survey respondents, 52% (35/67) of HPUs and 43.5% (54/124) of PUs reported liking the HDep content; 12% (8/67) and 25% (31/124), respectively, had other expectations, and 12% (8/67) and 16.9% (21/124), respectively, did not like it. With respect to the design, 52% (35/67) of HPUs and 58.9% (73/124) of PUs reported liking it; 5% (3/67) and 3.2% (4/124), respectively, had other expectations, and 13% (9/67) and 25.8% (32/124), respectively, did not like it. Thus, there was no evidence that PUs were more satisfied or indicated a higher degree of acceptability than HPUs, as was hypothesized, based on the fact that the latter received a smaller portion of the intervention. It may be that there is self-selection of users to the dose of the intervention they need. For some, the home page information and feedback about their symptoms seem to be sufficient, whereas others seem to need the entire intervention.

The satisfaction level was above the scale mean, suggesting that users were more satisfied than dissatisfied, to the degree that they "would recommend it to someone in need" or "would use it again if depressed." Less satisfied participants believed that HDep did not meet their needs. This finding may reflect the high levels of depressive symptoms reported by almost all participants, as well as possible psychopathologies in PUs. Such participants were not the target population of the intervention design, but they were the ones seeking help. Muñoz et al [5] found that this is a common phenomenon, as internet-based interventions intended to be preventive seem to attract individuals who are currently experiencing enough symptoms to screen positive for a major depressive episode; however, only 30% are appropriate for a depression prevention intervention. Other studies have also found a high percentage (up to 90%) of participants in web-based interventions who were highly depressed [30].

Consistent with this notion, higher satisfaction was observed in PUs with less disability owing to depression, no suicidal ideation, and no experience with psychotherapy. According to Rost et al [27], the severity of symptoms and possible comorbidities affect users' perceptions of acceptability and satisfaction. Self-guided interventions have been observed to be more efficacious for users with less psychotherapeutic experience [31].

Findings from the World Mental Health Survey show that in Mexico, 58.3% of people with a diagnosis of major depressive disorder who felt they needed treatment, only 6.4% received treatment that was minimally adequate [3]. This situation may explain why many people with probable mental health disorders seek help in web-based interventions. One-third of HDep users said they had, at some point in the past, sought either

psychological or psychiatric mental health treatment; a similar web-based intervention for depression reported by Christensen et al [32] also found that 64% of participants had previously sought professional help. Our findings show that users with previous experience in therapy were least satisfied and gave HDep lower acceptability ratings. Participants with this experience could be advised early on about what they could realistically expect from HDep.

The general acceptability ratings of HDep were above the mean, suggesting that users considered it acceptable but with room for improvement. Some of the features they valued were its user-friendliness and usefulness in managing their depression, but it did not fully meet their expectations. Regarding the content, more than half of the respondents described it as good, meaningful, and helpful in making them feel better, friendly, systematic, well-paced, and encouraging reflection. More than half of the respondents liked the design, describing it as easy to understand, well organized, attractive, user friendly, colorful, intuitive, and entertaining.

The test for depressive symptoms and feedback regarding results had the highest acceptability ratings, whereas forums and chats had the lowest ratings (Table 6). Some studies have found a high degree of satisfaction with mood-monitoring rating tools in web-based treatment for depression [33]. Questionnaires and psychometric tests sometimes give participants a feeling of personalized treatment [34]. The acceptability of HDep and similar interventions may therefore be improved by increasing the use of these tools.

It is noteworthy that forums received low ratings, although it has previously been observed that forums allow for meaningful social exchange of experiences [15]. One possible explanation may lie in the observation that although a large proportion of participants used forums (60.9%), far fewer posted comments (16.3%) [15]. The lack of participation of a professional in forums and chats is also a possible reason for the low ratings.

Three major areas were found to be lacking in the design and content of HDep. These were described as (1) not being sufficiently persuasive, dynamic, motivating, or appealing; (2) not meeting users' expectations; and (3) being cold, being *just a platform*, and lacking professionals to support, advise, and track people's progress. Other studies have also found that participants in automated programs are concerned about their being too impersonal [35]. Therapeutic persuasiveness, the incorporation of persuasive principles of design, and behavior change have been described as the most robust predictors of adherence [36]. Not meeting users' expectations may be particularly important for depressed users, because as Bernard et al [37] reported, these users become particularly upset when they find unexpected, irrelevant, or inappropriate content. Despite the importance of design in developing successful web-based interventions, Neilsen and Wilson [38] concluded in a literature review that design elements and human–computer interaction remain poorly understood and that "internet-based e-mental health interventions are routinely implemented without sufficiently describing the relevant human–computer interaction design features applied." In this respect, HDep would benefit from incorporating a user-centered design approach to improve the layout of its content [29].

The content deficiency perceived by HDep users was the need for professional help or specialized guidance. This issue has often been reported in the literature on unguided interventions [8,15], and it also turned out to be important for Mexican users in our survey. One of the most attractive aspects of web-based interventions for mental health problems is their reduced cost, including personalized professional help, which would be a significant burden. This is very much the case for HDep, which is supported by a public health institution as a translational research project. Features to compensate for the lack of professional support could include automated dialogue components, such as automated SMS text messages or email messages or gaming features [38].

Conclusions

Overall, HDep showed moderate levels of satisfaction and acceptability and high levels for more than half of its participants, despite a level of depressive symptoms high enough to suggest a major depressive episode. HPUs and PUs rated satisfaction and acceptability similarly, contrary to our hypothesis that the latter, having received a larger portion of the intervention, would be more satisfied. Respondents' ratings on satisfaction and acceptability may be related to their ability to choose how much of the program they want to do: whether they just want an overview from the home page or want to work on the intervention modules. They considered the content culturally sensitive, reflecting their everyday experiences; they found the design to be friendly, with tools that were well organized, simple, and motivating. The main limitations were the lack of contact with a professional, and in some cases, content that did not motivate and was not encouraging. Users who responded to the survey provided abundant suggestions on feasible ways to alleviate some of the deficiencies. Some of these deficiencies coincide with those observed in other web-based interventions for depression [8,27,35,38].

This study has the strength of being based in a real-world setting, not in a confined research environment, so that it reflects more closely what real participants do. However, this feature also makes it more difficult to implement strict methodological control. HDep is the first web-based self-help intervention for depression in Latin America and has been in operation for 11 years. It is a promising and cost-effective tool that can contribute to reducing the treatment gap for depression in Mexico [3]. It has the potential to provide mental health literacy to a large group of users and can be integrated into a preventive stepped-care approach [39]. Being a qualitative–quantitative study from a non–English-speaking LMIC, this study adds to existing research on acceptance and satisfaction with cognitive behavioral therapy–based programs for depression in high-income countries. There appear to be no studies directly comparing users' performance in web-based interventions to assess differences among countries with different income levels. These could include cultural differences: English-speaking users of web-based interventions tend to emphasize the benefits of introspection and self-awareness, which is congruent with *the dominant individualized focus of Euro-American cultural*

orientation compared to a more collectivist and relational Latin American cultural orientation [40].

Although there are many effective internet-based interventions for depression, there are far fewer with open access for general use [41]. Web-based interventions have great potential in Mexico, where it is estimated that 80.6 million people use the internet [42], 58% of whom are interested in health content [43]. The findings of this study are important for the creation and adaptation of web-based interventions in an LMIC, such as Mexico, where access to treatment is a major concern [2] and web-based prevention and treatment programs can help to deliver evidence-based alternatives. HDep is promising, but it is necessary to further document the pitfalls, strengths, and challenges of this type of intervention in this particular context.

Limitations

A major limitation of this study was its response rate of 1.45% (191/13,207). This response implied a CI of 95% and a margin of error of 7%. Low response rates are an important concern that affects the validity of web surveys [44]. In a meta-analytic study, Daikeler et al [21] found that web surveys yielded a response rate that was 12% points lower than other survey modes and concluded that the difference is not the result of a particular study design. They also found evidence that low response rates do not necessarily indicate a large nonresponse error.

Participants who did not respond may have been less satisfied and less positive than those who did [35]. The levels of depressive symptoms and other mental health problems of the people surveyed may explain the low response rate; people with emotional stability are more likely to complete a survey [44]. It is also likely that many of the people contacted were no longer using the intervention, as the survey was sent to those registered in the previous year. There was just 1 reminder email; additional reminders may have increased the response rates [21]. Some of those contacted may have visited HDep just once. It may also be that the incentive (receiving a list of positive thoughts to practice) was not found attractive [44]. There was also no confirmation that users received the survey; email questionnaires are often treated as spam or blocked [21,44].

To estimate other possible sources of bias, the characteristics of the study sample were compared with those of a previous study on HDep [15], which obtained data directly from registered users. No differences >10% were found between the 2 samples in terms of sex, depressive symptoms, disability, suicide attempts, previous psychological or psychiatric treatment, alcohol or drug use, or drug treatment. The proportion of users aged >30 years was >12.5% in the current sample. The proportion of HPUs and PUs in this study was similar to that in a previous study [15]: HPUs made up 35.1% (67/191) of respondents in this study and 38.32% (10,760/28,078) in the previous study; PUs made up 64.9% (124/191) and 61.69% (17,318/28,078), respectively. These figures suggest that the low response rate did not skew the sample with respect to these variables, but there could still be other biases, such as a self-selection bias of eagerness to respond.

Acknowledgments

We wish to thank Lucero Sáenz of the Department of Psychiatry of the Autonomous University of Nuevo León, who participated in the design of the study protocol, while an intern at the National Institute of Psychiatry and Jorge Nuñez, from Insurgentes University, also an intern who participated in emailing and received the completed questionnaires.

Authors' Contributions

MAL and MT conceptualized the study; MAL, MT, and PP worked on the methodology; PP and LN worked on the statistical and qualitative analyses; MAL wrote the original draft; MT reviewed and edited the manuscript. All authors have read and agreed to the published version of the manuscript.

Conflicts of Interest

Abstract

Background: Digital health apps are efficacious treatment options for mild-to-moderate depressive disorders. However, the extent to which psychological guidance increases the efficacy of these apps is controversial.

Objective: We evaluated the efficacy of a web-based intervention, called Selfapy, for unipolar depression. We also investigated differences between psychotherapist-guided and unguided versions.

Methods: Selfapy is a cognitive behavioral therapy–based intervention for depressive disorders. Participants with mild-to-severe depressive disorders were assigned randomly to participate in either guided (weekly 25-minute duration telephone calls) intervention, unguided version, or waiting list (control group) for 12 weeks. We assessed depressive symptoms at the start of the study, midway through the intervention (6 weeks), at the end of the intervention (12 weeks), and at follow-up (6 months). The main outcome was difference in the Beck Depression Inventory score between the start of the study and the end of the intervention. Secondary outcomes were the Quick Inventory of Depressive Symptomatology—Self Report, the Hamilton Rating Depression Scale, and the Beck Anxiety Inventory.

Results: Of 401 participants, 301 participants (75.1%) completed the intervention. Changes in the Beck Depression Inventory from baseline differed significantly between groups at the postintervention ($F_{2,398}$=37.20, P<.001). The reductions in scores for both guided and unguided intervention groups were greater than that for the control group, with large between-group effect sizes (guided vs control: d=1.63, 95% CI 1.37 to 1.93; unguided vs control: d=1.47, 95% CI 1.22 to 1.73) at postintervention. No significant differences were found between guided and unguided intervention groups (P=.18). At follow-up (6 months), treatment effects on the primary outcome were maintained for both intervention groups (guided: $F_{1,194}$=0.62, P>.999; unguided: $F_{1,176}$=0.13, P>.999).

Conclusions: Both guided and unguided versions of the intervention were highly effective in reducing depressive symptoms. Follow-up data suggest that these effects could be maintained. The guided version was not superior to the unguided version.

Introduction

Background

With more than 300 million people affected worldwide, unipolar depression is a common mental disorder [1]. Depressive disorders reduce quality of life for affected persons and are linked to an increased prevalence of suicide and a shortened lifespan [2,3]. However, access to treatment is limited, which represents an obstacle in the care of people with depressive disorders. Health care systems can only rarely give necessary acute help, such as immediate access to a psychotherapist [4]. In Germany, it takes approximately 20 weeks to obtain outpatient psychotherapeutic treatment [5].

In addition to evidenced-based treatments for depressive disorders, such as psychotherapy and pharmacotherapy, web-based interventions are becoming increasingly important in the treatment of depressive disorders. Web-based interventions based on cognitive behavioral therapy are suitable due to their structured and standardized approach, their focus on psychoeducation, and the homework tasks assigned in-between treatment sessions [6]. Various forms of web-based interventions exist, which differ in terms of the level of guidance that they provide to the participant. The guided forms of web-based interventions can involve support from a psychotherapist via email, chat, or telephone. Unguided forms of web-based interventions usually do not include personal contact.

The use of web-based interventions in the treatment of depressive disorders has been deemed efficacious in several controlled studies [7-9] and meta-analyses [10-12]. In one meta-analysis [10], self-guided web-based cognitive behavioral therapy was found to be more effective than the control treatment in reducing depressive symptoms severity (β=−0.21; Hedges g=0.27) and treatment response (β=0.53; odds ratio 1.95, 95% CI 1.52 to 2.50). In a recent systematic review and individual patient data network meta-analysis of 39 randomized control trials, Karyotaki et al [12] made the distinction between guided and unguided web-based cognitive behavioral therapy. Both guided (PHQ-9 score: mean difference −1.7, 95% CI −2.3 to −1.1) and unguided (PHQ-9 score: mean difference −0.9, 95% CI −1.5 to −0.3) were more efficacious in reducing depressive symptoms than treatment as usual, and both guided (PHQ-9 score: mean difference −3.3, 95% CI −3.9 to −2.6) and unguided (PHQ-9 score: mean difference −2.5, 95% CI −3.2 to −1.8) were more efficacious in reducing depressive symptoms than waitlist control [12]; guided web-based cognitive behavioral therapy was also more effective than unguided web-based cognitive behavioral therapy postintervention (PHQ-9 score: mean difference −0.8; 95% CI −1.4 to −0.2), however, not at follow-up at 6 or 12 months. Baseline severity of depressive symptoms was a modifying factor, with better effects for guided web-based cognitive behavioral therapy for patients with baseline PHQ-9 scores greater than 9 [12]. However, Karyotaki et al [12] used varying definition of guidance between the studies and only 6 trials included in the meta-analysis directly compared guided to unguided web-based cognitive behavioral therapy within a single trial.

Objectives

We aimed to evaluate the efficacy of guided and unguided versions of a web-based intervention, called Selfapy, to investigate the effect of psychological guidance in web-based interventions. In a randomized controlled trial, participants were allocated to 3 treatment groups: guided, unguided, and control.

Hypotheses

We hypothesized that participants in the 3-month Selfapy program would experience a greater reduction in depressive symptoms than the control group, and we hypothesized that participants in the guided version would experience a greater reduction in depressive symptoms than participants in the unguided version.

Secondary Hypotheses

We hypothesized that a greater reduction in depressive symptoms and anxiety symptoms would be present in both intervention groups after the 3-month Selfapy program than that in the control group.

Methods

Recruitment

Participants with depressive symptoms were recruited via the Selfapy website, advertisements in social media and numerous information brochures from health insurance companies. The recruitment took place throughout all of Germany. The central recruiting tool was a study website through which interested individuals could register their participation. This preregistered trial was conducted according to the study protocol [13].

Ethical Standards

The study was approved by the ethics committee of the medical faculty of the *Charité* University Medicine Berlin (EA/047/19). All procedures contributing to this work comply with the ethical standards of the relevant national and institutional committees on human experimentation and with the Helsinki Declaration of 1975, as revised in 2008 [14].

Inclusion and Exclusion Criteria

Potential participants were screened by telephone. Eligibility for participation in our study was assessed by conducting a diagnostic interview using the Mini International Neuropsychiatric Interview (MINI [15]), the Hamilton Rating Depression Scale (HRSD-24) [16] (score ≥8), and by collecting personal data. All MINI and HRSD-24 interviews were conducted by trained interviewers (psychologists and medical students, trained at the *Charité* Department of Psychiatry and Psychotherapy). The inclusion criteria were (1) age 18 to 65 years; (2) sufficient German-language skills to use and understand the web-based intervention (determined by interviewers); (3) reliable internet access; (4) a Beck Depression Inventory (BDI-II) [17] score ≥13; (5) willingness to provide electronic data; and (6) diagnosis of a major depressive disorder or dysthymia based on the MINI, in accordance with the International Statistical Classification of Diseases tenth revision (ICD-10: F32, F33, F34).

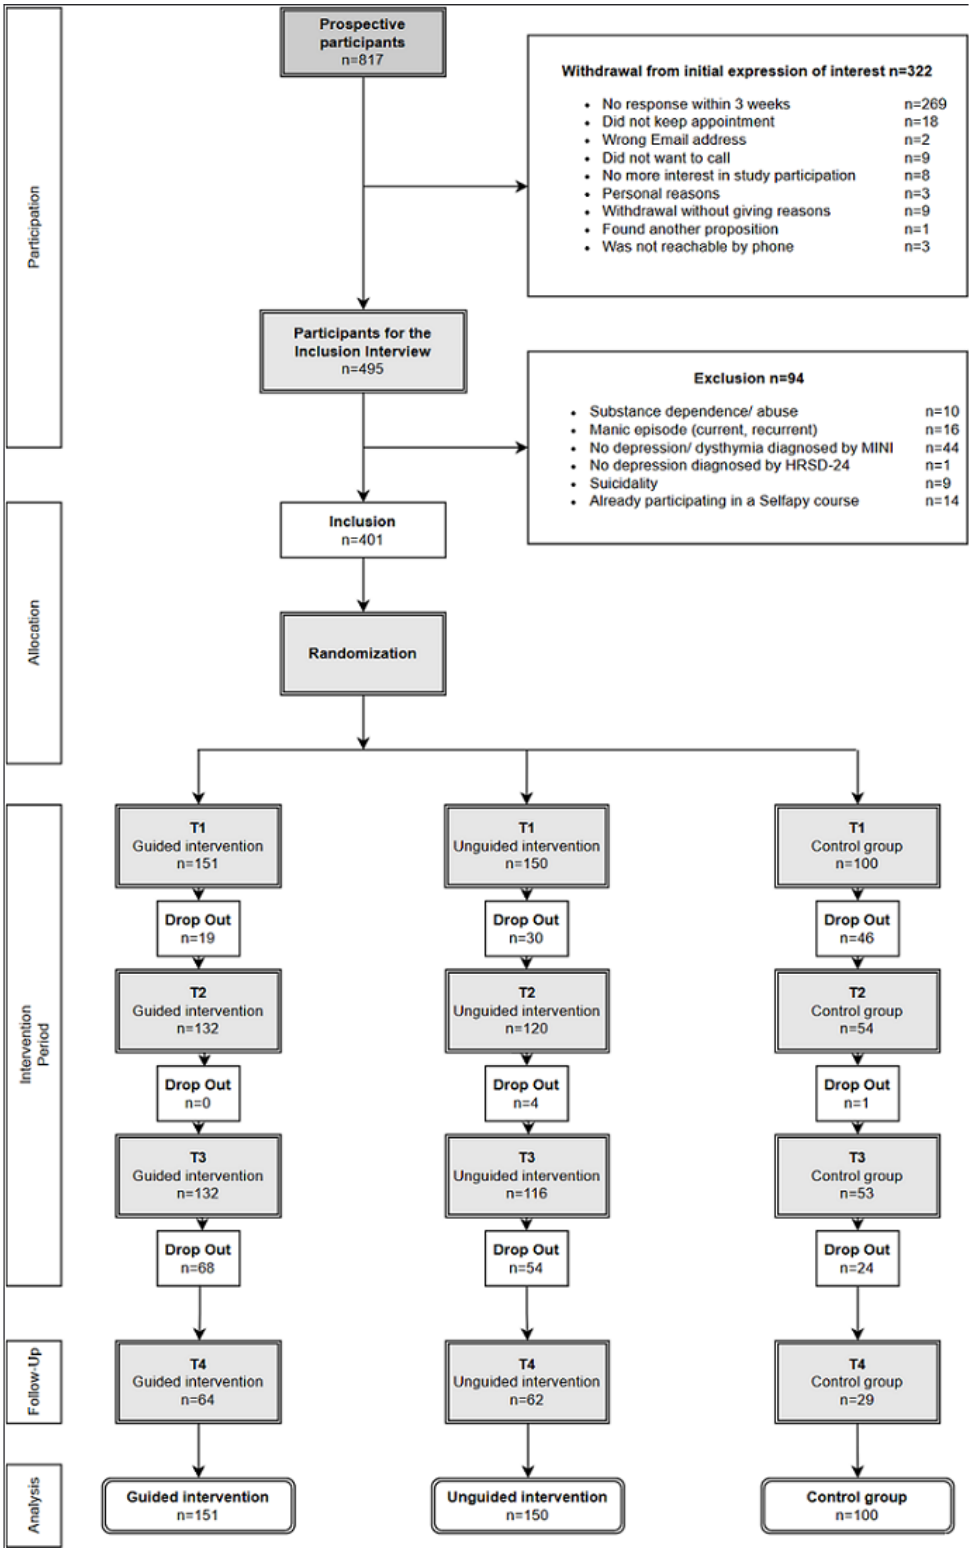
Exclusion criteria were (1) diagnoses of a bipolar disorder or schizophrenia; (2) acute psychotic symptoms; (3) current substance dependence (within the past 6 months) or withdrawal syndrome (ICD-10: F1x2, F1x3); (4) acute suicidality (assessed using HRSD-24; individuals were excluded if they had a score ≥3 on suicidality items). Individuals who were excluded from the study due to illness severity were advised to seek professional help. Additional details have been previously published [13].

Randomization and Blinding

Participants meeting eligibility criteria were randomly allocated to 3 groups (Figure 1). Participants were allocated in a 3:3:2 ratio (guided group: n=151, unguided group: n=150, control group: n=100). Block randomization was performed by an independent researcher using a random number assignment plan with a computer-controlled random number generator (Randlist, version 1.2).

Participants either received immediate access to the guided version of the program, immediate access to the unguided version of the program, or delayed access (24 weeks) to their choice of the guided or unguided program (ie, control group). Participants were informed via email about the result of the allocation process. Individuals in the intervention groups received an email with a link and their unique access code to register and start the intervention immediately. Individuals in the control group also received an email with a link to the assessment material. Therefore, participants enrolled themselves in the study. Diagnostic interviewers were blind to the assigned group of individuals.

Figure 1. Participant flowchart.



Intervention

The web-based intervention aimed to treat depressive symptoms in individuals with mild-to-moderate depressive disorders, with instructions on evidence-based methods and exercises in the areas of cognitive behavioral therapy, systemic therapy, and mindfulness training. The intervention consisted of 6 core modules and 6 additional optional in-depth modules representing different psychotherapeutic approaches (Multimedia Appendix 1), each of which could be completed in 10 to 60 minutes, depending on the user's reading speed, interest, motivation, and individual path through the program. The modules could be accessed repeatedly during the intervention period. The course was designed to engage the user in active exercises, provide helpful and interesting content, and encourage self-reflection. In addition, the intervention included short questionnaires to assess current mood, which allowed the mood trajectory to be visualized over the course of therapy. Furthermore, individual

goals could be set and reviewed. The program provided the user with printable summaries and worksheets for each exercise. Optionally, the user could receive reminder emails to use the course and reiterate program content.

Participants in both intervention groups used the same web-based course for 12 weeks, and access to course content was also available after the 12-week intervention period until follow-up. Telephone or chat support was only offered during the treatment period. Participants in the intervention and control groups were not influenced or advised to change their existing treatment patterns and were free to seek pharmacological or psychological treatments to meet the reality of care.

Guided Group

In the guided version of Selfapy, the participants received personal guidance by a psychotherapist-in-training (17 behavior therapists and depth psychologists in training, registered at German institutes) for the entire duration of the program. The topics discussed were in line with the course content (Multimedia Appendix 1). The therapists were able to set their own focal points within the weekly topic and the associated exercises. At the start of the program, the psychotherapist-in-training and the participant got to know each other, and psychotherapist-in-training and the participant had weekly telephone calls (25 to 30 minutes duration) throughout the intervention period. The telephone calls focused on discussing and reflecting on the exercises of each module. Each module addressed issues such as resources, behavioral activation, self-esteem, and automatic thoughts. All therapists who guided the participants received a 1-hour training session that included: general information on the study; risks and their mitigation; a discussion of the contingency plan; information on handling and documenting dropouts; and information on the standardization of telephone calls. The focus of the guided version was to support web-based intervention use.

Unguided Group

In the unguided version of Selfapy, the intervention was independently followed. There was no option to have contact with a psychotherapist-in-training via telephone. However, a chat functionality allowed the participants to ask questions regarding the correct use of the course. Active asynchronous communication occurred only in the event of patient safety concerns. For an increase in acute symptoms or suicidality, a specific protocol [13], for all study groups, was followed to secure the safety of each participant.

Control Group

During the 24-week waiting period, the control group received weekly standardized mindfulness exercises via email, with content comparable to that of a self-help mindfulness guide. A waitlist design with mood-stabilizing activities was chosen for the control group to control for changes related to treatment expectancy and to better mitigate loss of motivation compared with an untreated or passive waitlist control group [18]. These exercises were only available for the control group so that there was no content-related overlap between the intervention groups and the control group. The control group was also free to access other pharmacological and psychological treatments. After the 24-week period, participants from the control group were given access to the web-based intervention and allowed to choose which type of program (guided or unguided) they wished to participate in.

Measurements

Depressive symptoms were evaluated using the BDI-II (primary outcome), Quick Inventory of Depressive Symptomatology—Self Report (QIDS-SR-16) [19] and the observer-rated HRSD-24. The Beck Anxiety Inventory (BAI) [20] was used to measure changes in the self-assessment of anxiety symptoms (secondary outcome parameters). The primary and secondary outcome parameters were measured at the start of the intervention (T1), 6 weeks after the start of the intervention (T2), at the end of the intervention (12 weeks after the start of the intervention, T3), 24 weeks after the beginning of the intervention (follow-up, T4). All web-based questionnaires were completed independently by the participants.

Statistical Analyses

Consistent with CONSORT (Consolidated Standards of Reporting Trials recommendations) [21], we conducted (1) intention-to-treat (which comprised observed and imputed data from all randomized participants, regardless of whether they used the intervention or activated their access vouchers to enter the program), and (2) per protocol (which comprised data from participants who completed pretreatment and postintervention assessments) analyses (Multimedia Appendix 2).

The primary endpoint was the decrease in depressive symptoms in the BDI-II between study entrance (T1) and the end of the intervention (T3). One-way analysis of variance (within-factor group) was performed to analyze differences in the decrease of depressive symptoms between the intervention groups.

Repeated measures analysis of variance was used to evaluate secondary endpoints and effects of group (guided vs unguided vs control) and time interaction. If significant effects were found, pairwise comparisons were carried out by applying Bonferroni correction ($P<.016$) for multiple testing. Results of the posthoc comparisons are presented as the mean with 95% CI and SD.

The Kolmogorov–Smirnov test was used to test for a normal distribution. Values for the mean and SD of each variable were calculated in addition to the Kolmogorov–Smirnov Z-value, and the asymptomatic significance (for both intervention groups) was specified. $P<.05$ indicated that the data did not have a normal distribution.

Independent 2-tailed t tests and chi-square tests were used to estimate the differences between groups in terms of demographics and sample characteristics at baseline. Values for the mean, 95% CI, and SD were calculated. Interim analyses were not undertaken. Due to the high dropout rate from T3 to T4, repeated measures analysis of variance was performed for the follow-up-analysis, including only those who completed.

Moderator analysis was used to analyze the influence of various sociodemographic variables on the primary outcome. Regression analysis was directed at explaining the changes in the BDI-II (the difference between T3 and T1 was used as a criterion). The

predictors used were the BDI-II at baseline as well as potential moderators, assigned group, and sociodemographic variables (sex, age, relationship status, and number of children). All variables except age were dichotomous and coded as 0 or 1. The moderator variables were generated by multiplying the *z*-standardized BDI-II score at baseline with the dichotomous sociodemographic variables, the assigned group, and the *z*-standardized age. All dichotomous variables, assigned group, and *z*-standardized age were included as regressors. Subsequently, we used hierarchical linear regression, which had all predictors in the first block via the enter method and all moderators in the second block via the stepwise method.

Furthermore, response rates (decrease of BDI-II score from baseline of 50%), remission rates (postintervention BDI-II score ≤10 [22]), and the minimal clinical important difference (decrease of 17.5% of the BDI-II score from baseline [23]) for the primary outcome at postintervention were calculated and reported.

For the intention-to-treat analysis, missing values in the data were replaced using multiple imputation by chained equations (with m=5 imputations). The pooled data (the mean of all 5 imputations) were calculated using the data imputed by linear regression. Subsequently, scale values were determined from the imputed and existing values. After data imputation, imputed and observed results were compared. The pooled imputed values proved to be more conservative, therefore, the results of imputed data set were used to evaluate the outcome of the web-based intervention.

Results

General

Out of 401 participants, the number of dropouts at postintervention (T3, end of the intervention) was 100 (24.9%) for the BDI-II and the QIDS-SR-16, 128 (31.9%) for the HRSD-24, and 103 (25.7%) for the BAI, respectively.

Characteristics

Upon study entrance, 353 out of 401 randomized participants (88.0%) fulfilled the diagnostic criteria for a current major depressive episode (MINI interview), and 53 (13.2%) for dysthymia (Multimedia Appendix 3). Data at baseline indicated an average mild-to-severe level of depression in all participants (BDI-II: mean 30.5, SD 9.5, range 13-56). A one-way analysis of variance with the factor group revealed no differences at baseline ($F_{2,398}$=0.23, P=.80). The mean age of participants was 37.1 years (SD 11.0).

For factor relationships, fewer participants (33/151, 22.0%) reported themselves to be married or living with a partner in the unguided group than in the control group (52/100, 52.0%; χ^2_1=8.25, P=.01), whereas no difference was shown between the guided and control groups (χ^2_1=1.56, P=.21) or between the guided and unguided groups (χ^2_1=2.97, P=.08). More participants were employed in the guided group (82/151, 54.3%) and the unguided group (86/150, 57.3%) compared to those in the control group (57/100, 57.0%; guided vs control: χ^2_1=9.12, P=.01; unguided vs control: χ^2_1=18.98, P<.001), while there was no difference between the guided and unguided groups (χ^2_1=1.76, P=.18). More participants in the control group (25/100, 25.0%) were trainees than those in the guided group (12/151, 7.9%; χ^2_1=5.68, P=.01) or unguided group (6/150, 4.0%; χ^2_1=12.62, P<.001), while there was no difference between the guided and unguided groups (χ^2_1=1.27, P=.26). Lastly, more participants in the control group (14/100, 14.0%) than in the unguided group (3/150, 2.0%; χ^2_1=6.55, P=.05) reported other occupations.

Analyses of the other sociodemographic variables did not reveal a significant difference between groups (sex: P=.81, number of children: P=.93).

Being on waitlist (χ^2_2=6.76, P=.03), use of antidepressant medication both currently (χ^2_2=7.31, P=.03) and in the year before the intervention (χ^2_2=10.25, P=.006) differed at baseline, with more participants in the guided group having taken antidepressants than the unguided group in the year before the intervention (χ^2_1=9.36, P=.002) and currently (χ^2_1=6.56, P=.01). There were no differences compared to the control group in the year before the intervention (guided vs control: χ^2_1=0.66, P=.42; unguided vs control: χ^2_1=3.2, P=.07) and currently (guided vs control: χ^2_1=0.47, P=.49; unguided vs control: χ^2_1=2.11, P=.15). The groups did not differ with respect to current psychotherapy at baseline (χ^2_2=1.50, P=.47).

Not reported	47 (31.3)	51 (34.0)	2 (2.0)	100 (24.9)

Usage Data

A total of 301 participants received the intervention after baseline assessment. A mean of 9.4 (SD 2.3) modules were completed by each participant during the intervention period, and 254 participants (84.4%) completed the main course (Multimedia Appendix 3).

Primary Outcome

Descriptive statistics for the for each assessment point are shown in Table 2 for completer and intention-to-treat samples. Kolmogorov-Smirnov tests did not reveal any violation of the normal distribution for BDI-II scores. One-way analysis of variance revealed a significant interaction (factor group) in the intention-to-treat sample ($F_{2,398}$=37.20, P<.001). Posthoc pairwise comparisons with Bonferroni correction at postintervention (T3) revealed a significant higher reduction in depressive symptoms (BDI-II) in the guided group vs the control group (P<.001) and the unguided group vs the control group (P<.001). There was no significant difference (P=.18) between guided and unguided groups (Multimedia Appendix 4).

Within-group effect sizes for BDI-II (Table 3) were large both for the guided (d=1.44, 95% CI 1.21 to 1.68) and unguided (d=1.38, 95% CI 1.15 to 1.65) groups, whereas the control group showed no effect (d=0.07, 95% CI −0.21 to 0.37). Postintervention between-group effect sizes between the guided and control groups (d=1.63, 95% CI 1.37 to 1.93) and between the unguided and control groups (d=1.47, 95% CI 1.22 to 1.73) were large, whereas effect sizes between the guided and unguided groups were negligible (d=0.20, 95% CI −0.04 to 0.45).

[a]T1 represents the start of the study.

[b]T2 represents the midpoint of the intervention (6 weeks after the start of the study)

[c]T3 represents the end of the intervention (12 weeks after the start of the study).

[d]No data.

[e]Not available because the Hamilton Rating Depression Scale was not used at the midpoint assessment.

Response and Remission Rate

Response, defined as the percentage of participants that had a reduction of depressive symptoms by 50% or more at postintervention (T3), was reached by 34.9% of all participants (n=140/401). In the guided group, the response rate was 48.3% (73/151), 43.3% (65/150) in the unguided group, and 2.0% (2/100) in the control group. Remission, defined as a postintervention BDI-II score of 12 or less, occurred in 25.4% of all participants (102/401) of the intention-to-treat sample. In the guided group, 39.7% of participants (60/151) reached remission, with 28.0% (42/150) in the unguided group. No participants in the control group reached remission.

Minimal Clinical Important Difference

Overall, 63.1% (253/401) of participants in the intention-to-treat sample had depressive symptom reductions greater than the minimal clinical important difference, with 74.2% (n=112/151) for the guided group, 70.7% (106/150) for the unguided group, and 35.0% (35/100) for the control group. In comparison, both the guided group (χ^2_1=36.44, *P*<.001) and the unguided group (χ^2_1=29.61, *P*<.001) had significantly more occurrences of symptom improvement than the control group, whereas no difference was found between the intervention groups (χ^2_1=0.30, *P*=.58).

Moderator Analysis

The regression analysis was conducted using the intention-to-treat sample. The number of data sets that could be used for the calculation was reduced to 279, due to missing values in the sociodemographic variables. The regression appeared to be unproblematic (Durbin-Watson-statistic 1.762 and collinearities <2.0). As the nonstandardized residuals had a mean of 0, homoscedasticity of the regression was indicated. The Kolmogorov-Smirnov-test was asymptotically significant (*P*=.03). The skewed distribution lay within the 5% confidence interval; the kurtosis lay slightly above. Based on the histogram, the normal distribution of residuals is accepted. In the first block of the hierarchical multiple linear regression analysis, a significant model was found (explained variance r^2=0.592; $F_{6,272}$=65.9, *P*<.001). Notably, age influenced the treatment outcome significantly—the older the participants, the greater the improvement in the BDI-II score (*b*=0.103; β=0.087, *t*=2.25, *P*=.02). In addition, a higher BDI-II score at T1 was associated with greater reduction in BDI-II score at T3 (*b*=−0.98, β=−0.632, *t*=−15.93, *P*<.001). In addition, being assigned to the control group was associated with a lower reduction in the BDI-II score at T3 (*b*=11.6, β=0.34, *t*=8.52, *P*<.001). The other variables (relationship status: *P*=.96; sex: *P*=.29; number of children: *P*=.90) did not significantly predict the outcome variables. In the second block of the hierarchical regression

analysis, the moderators that are the interaction terms of the variables from the first block at baseline were included using the stepwise method. None was found to be significant, therefore no moderation effect was indicated by the analysis.

Secondary Outcomes

Descriptive statistics of secondary outcomes are displayed in Table 2, and Table 3 shows within- and between-group effect sizes for all secondary outcome measures for the intention-to-treat sample. No violation of the normal distribution was identified for any of the secondary outcomes.

Repeated measures analysis of variance revealed a significant main effect for the factor time—QIDS-SR-16 ($F_{3,1194}$=200.08, P<.001, η^2=0.25), HRSD-24 ($F_{2,796}$=152.26, P<.001, η^2=0.19), and BAI ($F_{2,796}$=62.2 P<.001, η^2=0.09). Additionally, we found a significant interaction (factors group × time) for all secondary measurements in the intention-to-treat sample—QIDS-SR-16 ($F_{6,1194}$=33.2, P<.001, η^2=0.10), HRSD-24 ($F_{4,796}$=23.3, P<.001, η^2=.07), and BAI ($F_{4,796}$=30.4, P<.001, η^2=0.09) (Figure 2).

Bonferroni-adjusted posthoc analyses of the QIDS-SR-16 (Figure 3) revealed a greater reduction of depressive symptoms for both the guided group (P<.001) and the unguided group (P<.001) compared to the control group. However, no difference between the guided and unguided groups was found (P=.50).

Figure 2. Change in depressive symptoms. BDI-II: Beck Depression Inventory-II.

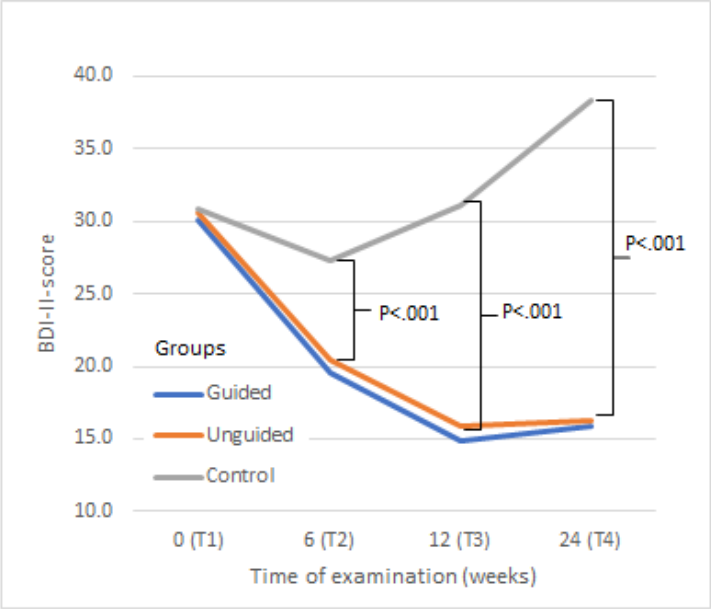

Figure 3. Change in depressive symptoms. QIDS-SR-16: Quick Inventory of Depressive Symptomatology—Self Report.

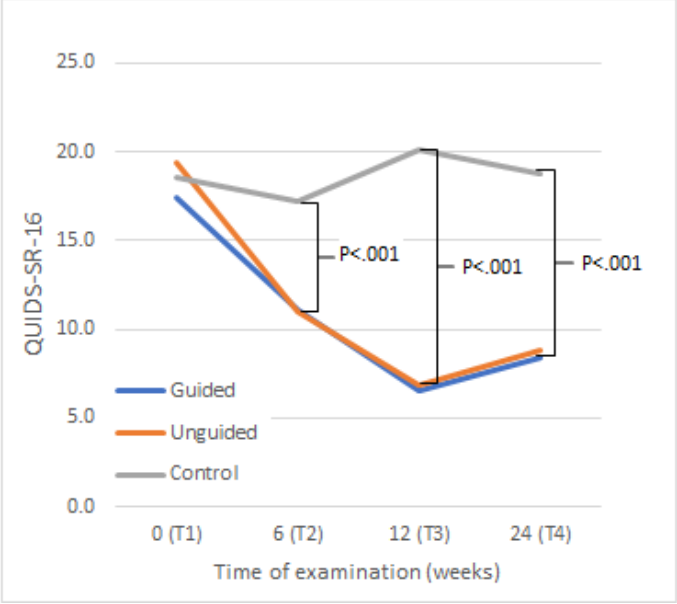

Similarly, posthoc analyses of the HRSD-24 (Figure 4) revealed a greater reduction of observer-rated depressive symptoms both for the guided group (P<.001) and the unguided group (P<.001) compared to the control group. A greater reduction in symptoms was found for the guided group compared to the unguided group (P=.001).

Finally, posthoc analyses of changes in BAI scores (Figure 5) revealed significantly greater reductions in anxiety symptoms in the guided (P<.001) and unguided groups (P<.001) compared to that of the control group. There was no significant difference between the guided group and unguided group (P=.08).

Figure 4. Change in depressive symptoms. HRSD-24: Hamilton Rating Depression Scale.

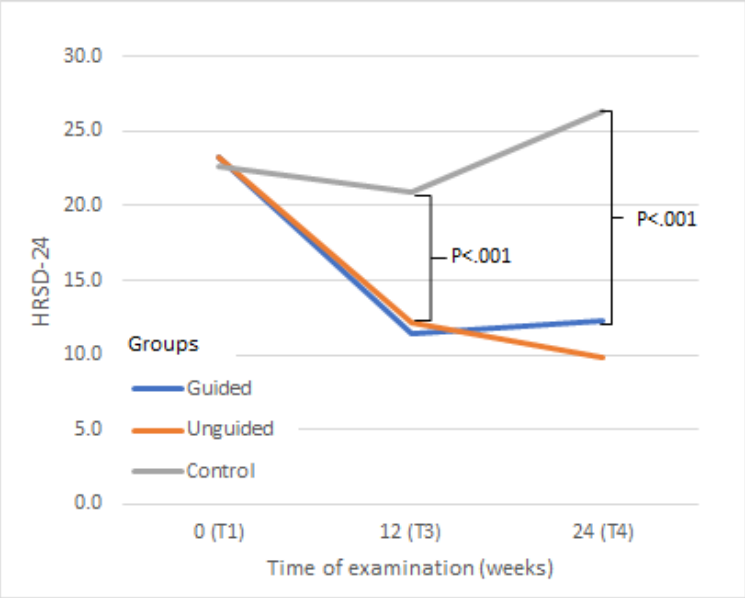

Figure 5. Change in anxiety symptoms. BAI: Beck Anxiety Inventory.

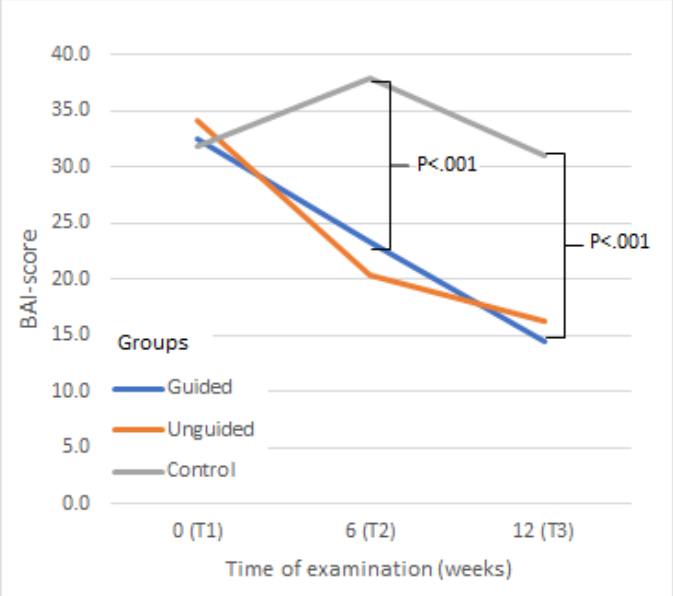

Three-Month Follow-up

For the follow-up assessment 24 weeks after the start of the intervention (T4), repeated measures analysis of variances were carried out using per protocol data for the BDI-II, the QIDS-SR-16, and the HRSD-24. Data were available at follow-up for 155 (38.7%) for the BDI-II, 156 (38.9%) for the QIDS-SR-16, and 30 (7.5%) for the HRSD-24 out of all 401 participants (Table 4).

Repeated measures analysis of variance revealed a significant interaction (factors group × time) for the BDI-II ($F_{2,152}$=3.7, P=.03, η^2=0.02). Pairwise posthoc comparisons with Bonferroni-correction at follow-up (T4) showed a significant difference between the guided group (P<.001) and the unguided group (P<.001) compared to the control group, but not between guided and unguided (P>.999) demonstrating a symptom deterioration in the control group and maintenance of the treatment effects in both intervention groups. Compared to baseline (T1), the BDI-II scores at follow-up (T4) remained significantly lower for both the guided group (d=1.58) and the unguided group (d=1.88). Moreover, the remission rate at T4 in the BDI-II was 29.2% for the guided group and 21.3% for the unguided group. Repeated-measures analysis of variance did not reveal a significant interaction effect (group × time) for the QIDS-SR-16 ($F_{2,153}$=3.32, P=.39, η^2=0.02) or the HRSD-24 ($F_{2,19}$=0.27, P=.77, η^2=0.15).

Table 4. Change from T3 to follow-up (T4) with completer data for depression outcomes.

Outcome and group	T3[a]		T4[b]		Test statistics (T3-T4)			Within group
	n	Mean (SD)	n	Mean (SD)	*F* test (*df1*,*df2*)	*P* value	η^2	T1−T4, Cohen *d* (95% CI)
Beck Depression Inventory-II								
Guided	132	14.87 (8.77)	64	15.92 (8.79)	0.62 (1,194)	>.999	.00	1.58 (1.29, 1.95)

Guided	123	11.46 (6.81)	17	12.24 (7.02)	0.19 (1,138)	>.999	.00	1.65 (0.94, 2.63)
Unguided	70	12.19 (6.57)	6	9.83 (5.19)	0.73 (1,74)	>.999	.01	2.22 (1.81, 3.03)
Control	80	20.91 (8.78)	7	26.29 (4.15)	2.55 (1,85)	.342	.03	−0.65 (−1.35, −0.09)

[a]T3 represents the end of the intervention (12 weeks after the start of the study).

[b]T4 represents the follow-up point (24 weeks after the start of the study).

Discussion

Principal Results

We investigated the efficacy of a guided and unguided web-based intervention for the treatment of depressive disorders and found a significant improvement of depressive symptoms in the BDI-II (primary outcome) and the HRSD-24 for both intervention groups compared with those in the control group in the intention-to-treat sample, with large pre- and postintervention difference effect sizes observed for each intervention (BDI-II: guided group, *d*=1.44; unguided group, *d*=1.38; HRSD-24: guided group, *d*=1.76; unguided group, *d*=1.34). Similarly, self-reported measures for depression and anxiety symptoms revealed a significant pre- and postintervention difference intervention decrease in scores for both intervention groups (QIDS-SR-16: guided group, *d*=1.94 and unguided group, *d*=2.32; BAI: guided group, *d*=1.35 and unguided group, *d*=1.21) compared with those in the control group (QIDS-SR-16: *d*=0.13; BAI: *d*=−0.27).

In a similarly structured web-based intervention for depressive disorders, Meyer et al [24] investigated an unguided web-based cognitive behavioral therapy intervention for depressive disorders and found the web-based intervention to be highly efficacious (compared with waitlist control, pre- and postintervention differences using PHQ-9: *d*=1.32), which is comparable to our within-group effect sizes for the BDI-II.

In another trial with guided web-based intervention, Beiwinkel et al [25] investigated the efficacy of a 12-week web-based program for depression, with therapeutic support upon request (ie, psychologists gave feedback via telephone or email) compared with a waitlist control (which included unguided internet-based psychoeducation only) and reported pre-and postintervention BDI-II scores showed a significant reduction in depressive symptoms with large within-group effect size for the intervention group with guidance (*d*=1.42; control group: *d*=0.65).

In our randomized controlled trial, the treatment effects of both intervention groups were slightly higher than those in previous studies [24,25]. In [25], the intervention duration was also 12 weeks, but therapeutic support was offered only upon request. This approach might have stopped patients from seeking contact, and therefore, may have hampered the overall effect. Moreover, our interventions provided the option to contact a psychologist in both intervention groups (guided group: telephone calls; unguided group: standardized chat option) which, arguably, led to a better outcome. Other than differences in study design, the characteristics of the participants may also be a reason for the high effect sizes. Compared with other web-based cognitive behavioral therapy studies [24,26,27], the percentage of women in our randomized controlled trial (333/401, 83%) was higher (74.4% [24]). In general, women tend to seek web-based interventions more frequently than men [26,27]. Moreover, considerably more participants completed higher education, ie, university (28.4%) and vocational school (10.2%). A high education level is a predictor of high adherence to treatment [28] and a positive outcome of treatment [29] because participants are better able to transfer the content of a particular treatment to their life [30]. In individual patient data network meta-analysis, Furukawa et al [31] found a higher baseline severity of depressive symptoms associated with a better response to web-based interventions and being unemployed with a poorer outcome. Sex did not influence the response. We also found that baseline severity, treatment, and age (higher age with better outcome) were significant moderators of treatment outcome.

The efficacy of the web-based intervention over waitlist control is larger but consistent with previous literature on similar interventions for both guided (between-group effect size *d*=0.55

[24]) and unguided (between-group effect size d=0.57 [25]) web-based cognitive behavioral therapy. The response rate in our control group was relatively low compared to that in other web-based intervention trials (within-group effect size in BDI-II: d=0.07)—Meyer et al [24] found an average within-group effect size (d=0.71) in the primary outcome (PHQ-9) for the control group. Klein et al [32] reported for their control condition (care as usual alone) small effects in the pre- and postintervention comparison (PHQ-9: d=0.39). In contrast, Berger et al [33], also did not find significant changes between pre- and postintervention symptoms in their waiting list control group (BDI-II: d=0.14). Our results were similar. The low effects in our control group could be explained by many different reasons. Active waiting list condition, as in our control group, might have nocebo effects compared to no treatment condition [34]. Additionally, specific interventions in the waiting list condition may also have negative effects in internet interventions. For example, Furukawa et al [31] reported that relaxation training was even harmful compared to other components in web-based cognitive behavioral therapy.

The effects of could be maintained at 3-month follow-up. BDI-II scores remained significantly lower for the guided group (d=1.59) and unguided group (d=1.91) compared with baseline scores. Our findings are similar to those from previous research, which found web-based interventions have positive long-term effects [10].

We also investigated on the effects of guidance in web-based interventions. We found in both groups with different guidance as equally and highly effective to reduce depressive symptoms. Completely unsupported web-based interventions have been suggested to be less efficacious [8,12], associated with higher attrition rates [35], and to carry greater risks than supported interventions [34]. However, findings are to some extent heterogeneous: Berger et al [33] compared an unguided internet-based self-help program with the same intervention supported by a therapist and waitlist control group. Our comparison of guided and unguided did show differences, which, however, were not significant between the unguided group and guided group (mean groups difference at postintervention: d=0.24 in favor of guided self-help). In a recent investigation, Zagorscak et al [36] compared web-based cognitive behavioral therapy alone with therapy and semistandardized email feedback from psychologists. Again, between-group effects were nonsignificant across outcomes.

Regarding our study, the dose of psychological contact might not vary sufficiently to elicit substantial differences between the groups. Instead, both groups had contact with a therapist, although the unguided group could only reach out for non–content-related questions. Both groups also had a high main course completion rate, especially compared to nonguided web-based interventions in other studies [31]. Karyotaki et al [10] revealed that treatment adherence to web-based cognitive behavioral therapy (session completion rate) influenced the outcome. In contrast to the meta-analysis findings [12], we also did not find severity of depression to be a predictor for better outcome in the guided group.

Strength and Limitations

Our study has several strengths. We included self- and observer ratings and included a follow-up assessment. Furthermore, we compared different forms of guidance. We also considered multiple aspects in our evaluation, such as completion rate and sociodemographic factors. However, there are also some limitations. First, using wide inclusion criteria, we acquired a heterogeneous study sample [37]. Second, the option to receive additional treatment impeded the attribution of treatment effects solely on the web-based intervention. Additional treatment (12 people were in therapy and 70 were receiving psychiatric treatment in both intervention groups) could have contributed to the effects and possibly caused a reduction in internal validity. Third, although conversations between psychotherapists and participants were standardized in the guided group, we had no insights into the actual conversations and whether the structure of the predetermined content was followed. Last, our sample size might have been too small to detect differences between the guided and unguided groups.

Conclusions

The web-based intervention offers a highly efficacious and clinically relevant intervention for people with depressive disorders. Contrary to our hypothesis, the efficacy of the guided g and unguided intervention did differ. Our findings demonstrate the value and applicability of the Selfapy web-based intervention as a clinically significant treatment option for depressive disorders.

Authors' Contributions

RK, LKV, AS, and SK contributed to the design of the study and coordinated recruitment and data collection. All authors drafted, read, and approved the manuscript.

Conflicts of Interest

The study was funded by a commercial organization: Selfapy GmbH. RK worked for Selfapy as a student (November 2016 to September 2017). SK, LKV, and AS have no relationship with Selfapy GmbH.

Abstract

Background: The COVID-19 pandemic has profoundly transformed substance use disorder (SUD) treatment in the United States, with many web-based treatment services being used for this purpose. However, little is known about the long-term treatment effectiveness of SUD interventions delivered through digital technologies compared with in-person treatment, and even less is known about how patients, clinicians, and clinical characteristics may predict treatment outcomes.

Objective: This study aims to analyze baseline differences in patient demographics and clinical characteristics across traditional and telehealth settings in a sample of participants (N=3642) who received intensive outpatient program (IOP) substance use treatment from January 2020 to March 2021.

Methods: The *virtual IOP (VIOP) study* is a prospective longitudinal cohort design that follows adult (aged ≥18 years) patients who were discharged from IOP care for alcohol and substance use–related treatment at a large national SUD treatment provider between January 2020 and March 2021. Data were collected at baseline and up to 1 year after discharge from both in-person and VIOP services through phone- and web-based surveys to assess recent substance use and general functioning across several domains.

Results: Initial baseline descriptive data were collected on patient demographics and clinical inventories. No differences in IOP setting were detected by race (χ^2_2=0.1; *P*=.96), ethnicity (χ^2_2=0.8; *P*=.66), employment status (χ^2_2=2.5; *P*=.29), education level (χ^2_4=7.9; *P*=.10), or whether participants presented with multiple SUDs (χ^2_8=11.4; *P*=.18). Significant differences emerged for biological sex (χ^2_2=8.5; *P*=.05), age (χ^2_6=26.8; *P*<.001), marital status (χ^2_4=20.5; *P*<.001), length of stay ($F_{2,3639}$=148.67; *P*<.001), and discharge against staff advice (χ^2_2=10.6; *P*<.01). More differences emerged by developmental stage, with emerging adults more likely to be women (χ^2_3=40.5; *P*<.001), non-White (χ^2_3=15.8; *P*<.001), have multiple SUDs (χ^2_3=453.6; *P*<.001), have longer lengths of stay ($F_{3,3638}$=13.51; *P*<.001), and more likely to be discharged against staff advice (χ^2_3=13.3; *P*<.01).

Conclusions: The findings aim to deepen our understanding of SUD treatment efficacy across traditional and telehealth settings and its associated correlates and predictors of patient-centered outcomes. The results of this study will inform the effective development of data-driven benchmarks and protocols for routine outcome data practices in treatment settings.

KEYWORDS

telehealth; substance use treatment; patient outcomes

Introduction

Background

In 2019, an estimated 20.4 million individuals aged ≥12 years met the criteria for a substance use disorder (SUD) in the United States. Substance misuse and use remain the leading causes of disability, years of life lost, and death [1,2]. Drug-related overdoses in the United States were responsible for >100,000 deaths in a 12-month period from April 2020 to April 2021 [3-5]. Research supports the idea that the COVID-19 pandemic has further exacerbated the substance use and drug overdose crisis in the United States. Provisional public health data illustrate that drug-related overdose deaths increased by 28.3% from 2019 to 2020 and subsequently by 28.5% from 2020 to 2021 [5]. A study found that 13.3% of US adults reported starting or increasing substance use to cope with pandemic-related stressors and emotions [6]. However, in any given year, <15% of individuals who need specialized substance use–related treatment receive it, illuminating the significant unmet need for substance use–related treatment services in the United States [3].

Novel applications of treatment are necessary to enhance access to care and reduce health care disparities. Before the pandemic, telehealth platforms were already growing in popularity among mental health providers and demonstrated similar treatment outcomes as in-person care [7]. The use of telehealth for the treatment of SUD has historically been lower than its use for general mental health conditions, often focused on individual digital recovery tools and applications [8-10]. A number of barriers exist that largely prevent widespread use including regulations, reimbursement issues, and usability of platforms [11]. The COVID-19 pandemic has created a catalyst for the rapid expansion of SUD services through telehealth platforms. Emergency federal and state policies removed geographic and site-of-service restrictions while increasing the number of telehealth services covered by insurers. Many states also expanded take-home services for methadone, allowed buprenorphine prescriptions without face-to-face requirements, and dropped prior authorization requirements for opioid use disorder medications.

Despite a nationwide increase in telehealth services within licensed substance use treatment facilities, little is known about the long-term effectiveness of substance use interventions delivered through digital technologies [12,13]. Preliminary evidence supports high user engagement across a variety of digital platforms but does not provide a strong evidence base for recovery-related outcomes [10]. Since the onset of the COVID-19 pandemic, the literature has highlighted the need for specific research considerations related to the delivery of telehealth for SUDs, including whether treatment outcomes are comparable between in-person and telehealth delivery methods [14]. Although scholars have contributed to this gap in knowledge, these studies of SUD telehealth have been primarily limited to samples and settings, including a large reliance on single clinics or populations with limited geographic scope that precludes comparisons across national variations. Furthermore, much has been focused on individual treatment formats, whereas even less data exist for telehealth group-based intensive SUD treatment services [15].

Objectives and Hypotheses

The primary aim of this study is to examine treatment-related outcomes and patient predictors of treatment effectiveness across traditional in-person and telehealth settings in an outpatient addiction treatment setting. This study also aims to better understand the correlates of treatment efficacy in telehealth group formats as well as how outcomes of data collection practices may differentially impact response rates in web-based programming. Finally, this study aims to identify clinician-level characteristics that contribute to the successful engagement of patients and whether these characteristics are also associated with enhanced patient outcomes. The findings of the study provide actionable evidence to sustain internet-based SUD services and offer data to guide an effective response to the SUD public health crisis. The authors hypothesized that patient outcomes and treatment effectiveness across in-person and web-based settings would be comparable while providing equitable patient access across rural and urban geographic locations.

Methods

Ethics Approval

This study was evaluated by Emory University's Institutional Review Board (Emory IRB ID: STUDY00001822) and was determined to have met human research exemption under 45 Code of Federal Regulations 46.104(d; 4), as all study data were collected in the context of Hazelden Betty Ford Foundation's (HBFF) standard routine outcome monitoring (ROM) practices. Similar to other health care organizations, HBFF's putative ROM practices include regular, methodical collection of diagnostics, patient progress, and overall treatment effectiveness data beginning at intake and ending 12 months after treatment discharge. The intent of ROM data is to provide direct care providers with consistent, reliable assessments of individual patient progress and treatment experience to reduce instances of treatment deterioration and failure and thereby bolster patient outcomes [16-18]. Similarly, these data inform patient-centered clinical operations and organizational quality improvement procedures to ensure that ethical quality health care is delivered [19,20].

Study Design and Procedures

The virtual intensive outpatient program (VIOP) study is a naturalistic, prospective longitudinal cohort design that followed patients discharged from IOP care for alcohol and substance use–related treatment at the largest nonprofit treatment provider for SUDs in the United States between January 2020 and March 2021. The HBFF provides SUD treatment for thousands of patients each year through its 17 locations nationwide. In 2019,

HBFF began piloting a single VIOP group to better understand the core functionality and acceptability of using a new web-based platform, with an incremental expansion of VIOP planned to begin in 2020. However, the onset of the COVID-19 pandemic greatly accelerated the internet-based rollout, necessitating immediate changes to in-person programming in March 2020. As a result, the HBFF quickly pivoted most IOP services to a web-based format while continuing to collect routine patient outcome data. Within a 2-week period beginning at the end of March, 74 IOP groups transitioned from in-person to web-based programming, representing 541 unique patients.

VIOP was developed to be as close a corollary to in-person IOP as possible while simultaneously expanding access to care to those who may not otherwise have lived close enough to a physical HBFF location to regularly attend the sessions. This included video-based, real-time group interactions and individual sessions, leveraging the use of technology that could accommodate low-bandwidth internet connections, thus ensuring the quality and stability of video feeds during sessions. In-person systems for patient accountability have also been adapted for internet-based care, including crisis or emergency response protocols, privacy monitoring, and random drug and alcohol testing using in-home testing kits or blood alcohol content devices with video support. Remote testing through laboratories in patient communities was also used when needed through a partnership with a remote testing company.

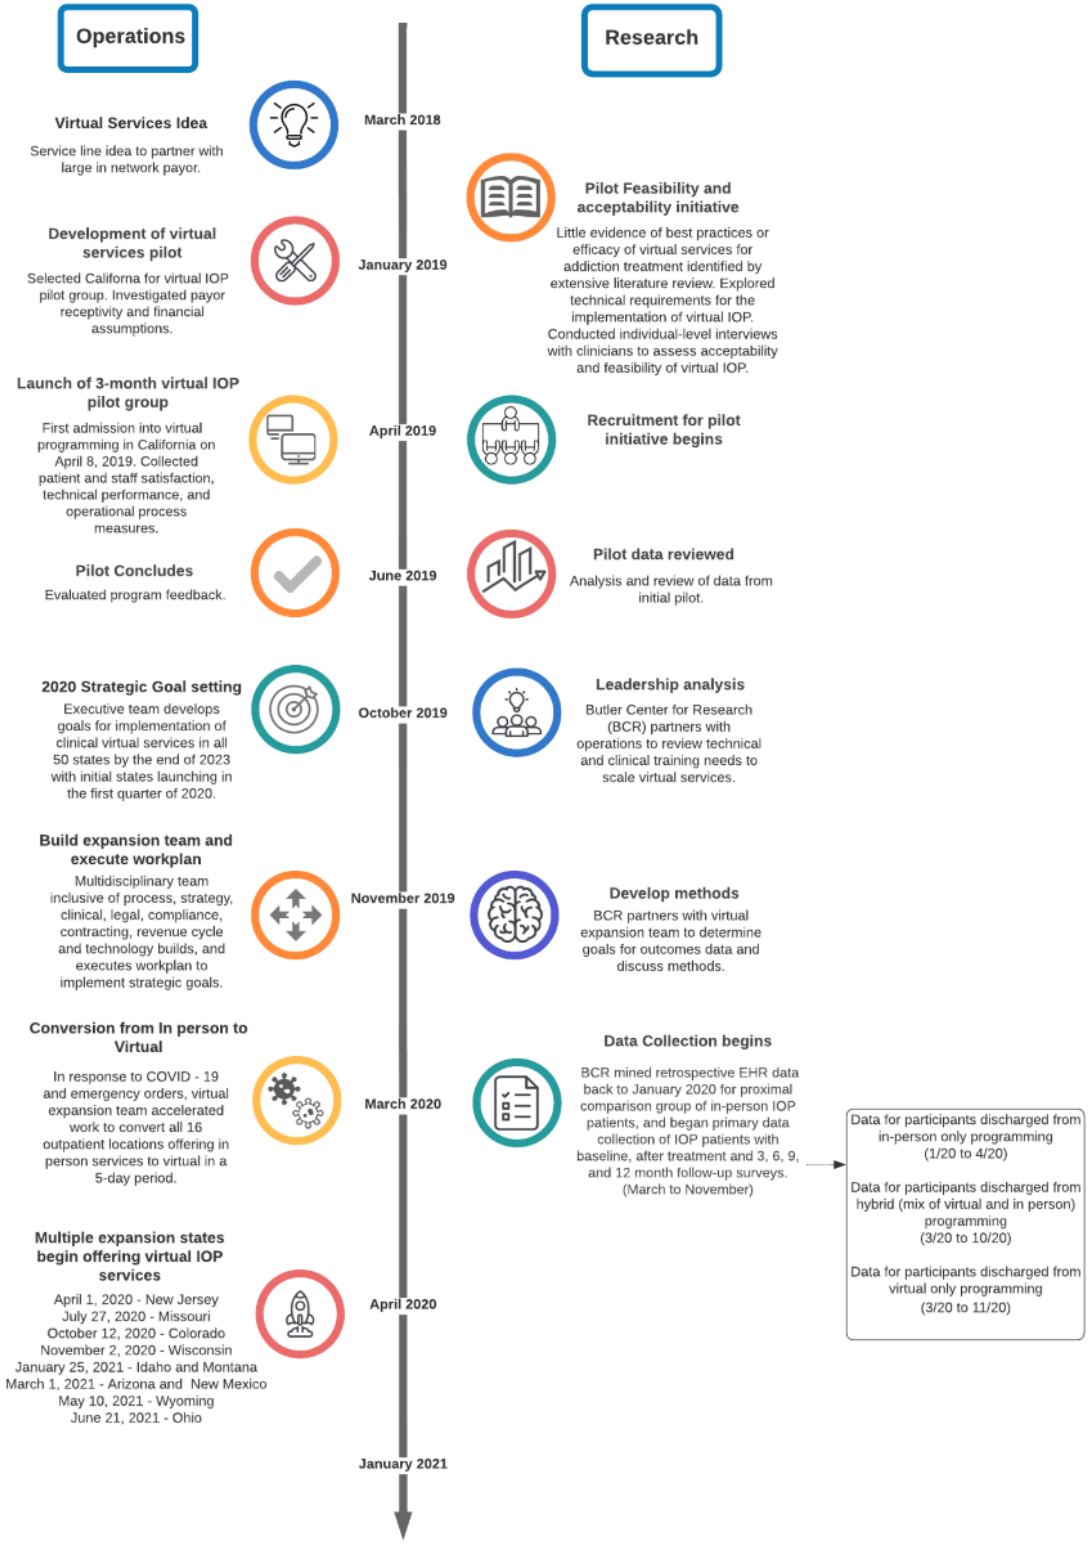
Individuals participating in VIOP who were identified as potentially benefiting from medication for SUD were either partnered with an HBFF provider for evaluation and follow-up or were recommended to obtain a local community provider educated in addiction treatment. Web-based clinical staff were trained to collaborate on treatment recommendations and to provide monitoring to ensure safe use and medication compliance. This monitoring was multifactorial and included increased toxicology, prescription drug monitoring reviews, and multidisciplinary case reviews.

An overview of the operations and study procedures is presented in Figure 1. All patients who were discharged from the IOP between January 1, 2020, and March 17, 2021, were considered eligible and contacted to participate. Although the transition to VIOP occurred at the end of March 2020, study data collection did not begin until May 2020. To capture a comparison group of those who attended IOP in person, all patients who were discharged from any in-person IOP on or after January 1, 2020, were opted to receive the IOP-specific outcome surveys. Owing to the timing of the mass opt-in and the shorter windows of the initial surveys (ie, 30 days from treatment admission for the baseline survey and 30-60 days following discharge for the 1-month survey), most of the in-person and hybrid cohorts were not eligible to complete the baseline or 1-month postdischarge survey.

Data were collected at six periods: baseline (within 30 days of admission) and 1, 3, 6, 9, and 12 months after discharge from IOP, through phone- and web-based surveys. Demographic data and IOP episode-level information, including length of stay, discharge status, and the number of sessions attended, were acquired from *Compass*, HBFF's electronic health record database management system. The baseline and postdischarge follow-up surveys asked patients to assess their recent substance use and general functioning across several domains, including previous treatment, craving level, peer-support group attendance, use of anticraving medications, substance use, quality of life, economic stressors, exposure to violence, psychological well-being, self-efficacy, gratitude, parental substance use, and parenting stressors.

Baseline and postdischarge follow-up surveys were administered by the HBFF's team of data collection specialists (DCSs). Each DCS team member was systematically and rigorously trained to follow the same set of procedures to ensure data integrity and security in adherence to patient confidentiality standards as per Health Insurance Portability and Accountability Act and 42 CFR Part 2 governance. As part of the ROM procedures, coordination of survey administration and completion includes a brief check-in between DCS and patients' primary clinical staff to alert patients of survey availability.

Figure 1. Timeline of development and implementation of web-based services. The left side of the figure depicts the conceptualization and delivery of internet-based services. The right side represents the underlying research and data collection across the protocol timeline. EHR: electronic health record; IOP: intensive outpatient program.



Study Population

Patients were considered eligible to participate if they were discharged from the IOP at HBFF between January 2020 and March 2021 and were aged ≥18 years at the time of treatment admission. No additional exclusion criteria were applied.

The final sample included 3642 patients who fell into three comparison groups: (1) those who received in-person only programming (957/3642, 26.28%), (2) those who received hybrid in-person and internet-based programming (541/3642, 14.85%), and (3) those who received internet-only programming (2144/3642, 58.87%).

Measures

Overview

Demographics were captured at the time of admission within HBFF's electronic health records.

The following measures were used to collect data across the 6 periods (Table 1).

Table 1. Study measures and time points.

Study measures	Time points					
	Before discharge	After discharge				
	Baseline	1 month	3 months	6 months	9 months	12 months

Revised Conflict Tactics Scale	✓	✓	✓	✓	✓	✓
Drug and alcohol use	✓	✓	✓	✓	✓	✓

Depression Symptoms

Patients were administered the 10-item Patient Health Questionnaire-9 (PHQ-9) to self-report any occurrence of the 9 depression-related symptoms representative of Diagnostic and Statistical Manual of Mental Disorders Volume 5 (DSM-5) Major Depressive Disorder [21]. Each patient was asked to evaluate and rate the frequency of each symptom statement using one of four ordinal categories: 0 (*not at all*) to 3 (*nearly every day*). Possible scores ranged from 0 to 27, with higher scores indicating a greater frequency and severity of the DSM-5 Major Depressive Disorder symptoms. The PHQ-9 had high internal reliability (Cronbach α=.89) [21].

Anxiety Symptoms

To measure symptoms indicative of co-occurring generalized anxiety disorder (GAD), patients were administered the 8-item General Anxiety Disorder-7 (GAD-7) screener [22]. Patients were asked to reflect on and estimate the occurrence of symptoms indicative of GAD in the past 2 weeks on a 4-point scale, ranging from 1 to 4. Sample questions included, "Over the last two weeks, how often have you been bothered by the following problems? Feeling nervous, anxious, or on the edge." The response categories included 4 Likert-type ranges of occurrence: 1 (*not at all*), 2 (*several days*), 3 (*more than half the days*), and 4 (*nearly every day).* Patient self-reports were scored and totaled; item scoring replaced the 1-4 scale with designated scores of 0, 1, 2, and 3. Scores range from 0 to 21, with higher scores indicating an increased occurrence and severity of general anxiety symptoms that impede daily functioning. Internal consistency calculations indicated high internal reliability (Cronbach α=.82) [22].

Confidence and Commitment to Staying Sober

The ratings of patient-perceived level of motivation and dedication to achieving initial and maintaining ongoing sobriety for substance use were measured using the 5-item Commitment to Sobriety Scale (CSS-5) [23]. Each statement was rated on a 6-point Likert scale, ranging from 1 (*strongly disagree*) to 6 (*strongly agree*). Example items included, "Staying sober is the most important thing in my life" and "I will do whatever it takes to recover from my addiction." The CSS-5 displayed high internal reliability at posttreatment follow-up (Cronbach α=.89) [23].

After the completion of the CSS-5, patients were asked to reflect and rate their level of confidence in their commitment to abstinence for the next 30 days using a 10-point scale, ranging from 1 (*not at all confident*) to 10 (*very confident*).

Desire and Intent to Use

The 6-item short form Desire for Alcohol Questionnaire was used to assess patient-reported desire (ie, cravings), intent to use, and the role of negative reinforcement on their primary substance of choice [24]. The word *alcohol* in the questionnaire was replaced with *drugs* to expand the measurements'

applicability to a wide range of substances. Patients rated their level of agreement with each statement on a 7-point Likert scale, ranging from 1 (*strongly disagree*) to 7 (*strongly agree*). Statements are comprised two subscales: (1) desire and intention to use (ie, "I want to use drugs so much I can taste it" and "My desire to use drugs now seems overwhelming") and (2) negative reinforcement (ie, "I would feel as if all the bad things in my life had disappeared if I used drugs now" and "I would feel less worried about my daily problems if I used drugs now"). For each subscale, responses were summed and divided by 3, resulting in a score between 1 and 7, with 7 indicating higher levels of desire and intent to use [24]. Subscale internal reliability calculations illustrated high consistency for both subscales: desire and intention to use (Cronbach α=.94) and negative reinforcement (Cronbach α=.89) [24].

Web-Based Therapy Platform Evaluations

The 10-item System Usability Scale was used to measure patient-perceived evaluations of the usability of the software platform for the VIOP platform [25]. To better fit the applied context, the word *system* was changed to *VIOP platform*, and the word *cumbersome* was replaced with *awkward*. These minor adaptations had no adverse impact on the internal consistency of the scale (Cronbach α=.89). Patients were asked to assess and rate their level of agreement with a list of statements describing the usability of the VIOP platform using a 5-point Likert scale, ranging from 1 (*strongly disagree*) to 5 (*strongly agree)*. Example questions included, "I thought the virtual IOP platform was easy to *use*" and "I felt very confident using the virtual IOP platform."

Psychological Well-being

The self-reported Flourishing Scale is a measure of *psychological well-being* comprising 8 statement items indicative of predictors of social–psychological prosperity (ie, flourishing), such as social support, self-acceptance and capability, and leading a purposeful life [26]. As an example, item 5 reads, "I am competent and capable in the activities that are important to me." Patients were instructed to rate their level of concurrence with each item using a 7-point Likert rating scale. Responses were scored from 1 (*strongly disagree*) to 7 (*strongly agree*) and added together to provide a composite score, with higher scores indicating high social–psychological prosperity. Calculations of the scale's Cronbach α showed a high internal consistency (Cronbach α=.92).

Financial Well-being

Patient-perceived financial well-being, the belief that one is financially secure (ie, can meet current financial commitments) and has financial freedom (ie, the ability to make financial choices that go over and beyond purely basic needs), was assessed using the Consumer Financial Protection Bureau (CFPB) Financial Well-being Scale [27]. Applying a 5-point Likert scale, patients rated their level of agreement with 5 statements describing diverse financial situations. We adapted and recoded the response categories for items 1 through 3 from 5 (*completely)* to 1 (*not at all*) to 4 (*strongly disagree*) to 0 (*strongly agree*) for internal scale validity and reliability. Example item statements included, "Because of my money situation, I feel like I will never have the things I want in life" and "I have money left over at the end of the month." The alpha calculations indicated high internal consistency (Cronbach α=0.88). Higher scores indicated greater perceived financial well-being.

Attitudes of Gratitude

Patients' self-reported propensity toward attitudes of gratitude in day-to-day experiences was assessed using the Gratitude Questionnaire—6-item form [28]. Questionnaire Likert-type responses allowed patients to choose their level of agreement from 1 (*strongly disagree*) to 6 (*strongly agree*) for statements such as, "I have so much in life to be thankful for" and "As I get older I find myself more able to appreciate the people, events, and situations that have been part of my life history." Higher scores indicated a higher propensity to perceive gratitude in daily experiences. The Cronbach α for this measurement was high (Cronbach α=.84), indicating high internal consistency [28].

Quality of Life

Quality of life was measured using the 4-item self-reported Centers for Disease Control Healthy Days Survey [29,30]. An additional question assessing overall quality of life was also added: "How would you rate your overall quality of life?" Patients were asked to rate their overall quality of life and quality of general health using a 5-point Likert scale, ranging from 1 (*poor*) to 5 (*excellent*), and indicate the number of days out of the previous 30 days that they experienced either one or both: poor mental or physical health. A higher number of unhealthy days indicated a lower quality of life.

Self-efficacy of Sustained Sobriety

Self-reported measurements of patients' confidence in their ability to stay sober comprised an adapted form of the *Brief Situational Confidence Questionnaire* to create a sobriety self-efficacy scale [31]. Sample questions included, "I would be able to resist using alcohol or drugs right now if I were physically uncomfortable [eg, feeling sick, headache, and in pain]" and "I would be able to resist using alcohol or drugs right now if someone I cared about offered it to me [eg, a good friend at a gathering or a spouse at home]" [31].

The 7-point Likert response categories were reworded from 1 (*not confident at all*) to 7 (*totally confident*) to 1 (*strongly disagree*) to 7 *(strongly agree*) to maintain consistency across the different scales. Initial interitem correlations and α values indicated that in comparison with the other questions, the original Brief Situational Confidence Questionnaire question 5, "I could probably go back to social drinking or other moderate drug use if I wanted to," did not adequately add to the measure of sobriety self-efficacy. After discussing the inventory with the DCSs, it was determined that multiple patients were unable or unwilling to answer item 5 when prompted. This question was likely uniquely difficult for this population, given the abstinence-based focus of HBFF's programming and the consistent message during treatment that no amount of substance use is safe. This item was removed shortly after data collection began in 2020. After the removal of item 5, the adapted scale

of sobriety self-efficacy showed high internal consistency (Cronbach α=.89).

Peer Group Support Engagement

Self-reports of engaging in peer group support were measured by 1 item adapted from the Alcoholic Anonymous Involvement Scale, which asked respondents, "About how often have you been attending 12-step/peer support/mutual aid group meetings since you were discharged?" [32]. Adaptations were made to include peer support groups other than alcoholics anonymous. Participants answered using a 6-point ordinal scale: *daily, ≥4 times per week, 1-3 times per week, 2-4 times per month, once a month or less,* or *never.*

Parenting Stressors

The 20-item Parenting Daily Hassles Scale was used to measure the frequency and intensity (or impact) of common daily parenting or caregiver stressors [33,34]. Respondents were also asked to rate the frequency of occurrence of experienced hassles on a 4-point Likert scale, ranging from 1 (*rarely*) to 4 (*constantly*). In addition, *parents* was changed to *caretakers* for inclusion of nontraditional caregivers. Sample questions included, "For the past 6 months, how often have you found yourself continually cleaning up messes of toys or food" and "The kids are constantly underfoot, interfering with other chores." The internal consistency was excellent (Cronbach α=.91).

Finally, 2 questions were added to capture participants who had to manage homeschooling because of the pandemic: (1) "Since January 2020, have you had to manage homeschooling for children under 18 due to the pandemic?" which participants answered *yes* or *no* and "During any of the following months, did you have to manage homeschooling for children?" where participants selected all months in which they homeschooled.

History of Parental (Family of Origin) Alcohol or Drug Use

We used the 6-item modified Children of Alcoholics Screening Test to assess exposure to parental alcoholism [35]. Participants were able to opt out of this question if it did not apply. Questions were modified to include exposure to parental drug use, such as *drinking or drug problem* or *drunk or high*. In addition, the gendered language in item 3 was changed from *he or she* to *they* for gender inclusion. Respondents were asked *yes* or *no* questions related to past experiences with their parents and alcohol or drugs. Questions included, "Have you ever thought that one of your parents had a drinking or drug problem?" and "Have you ever heard your parents fight when one of them was drunk or high?" The internal consistency of this scale was a Cronbach α of .90.

Lifetime Exposure to Family and Intimate Partner Violence

The 3-item survey adapted from the study by Easton et al [36] based on the Revised Conflict Tactics Scale was used to measure the lifetime prevalence of family and intimate partner violence [37]. Participants answered *yes* or *no* to questions related to their lifetime exposure to childhood physical and sexual violence in addition to a history of perpetrating or experiencing intimate partner violence. For the purposes of this study, we modified 2 questions to parse out those with exposure to physical and sexual violence. For example, item 3 ("As a child, were you ever physically or sexually hurt by a parent, family member, friend of the family, or some other adult? [eg, slapped, pushed, punched, beat up, or sexually abused]" was changed to, "As a child, were you every sexually hurt by a parent, family member, friend of the family, or some other adult? [eg, sexually abused]" and "As a child, were you ever physically hurt by a parent, family member, friend of the family, or some other adult? [eg, slapped, pushed, punched, or beat up]." Other questions included, "In your lifetime, have you been in a fight with a spouse or partner in which you were physically hurt? [eg, slapped, pushed, punched, beat up, or sexually assaulted]." The internal consistency of the scale was a Cronbach α of .53. In addition, we added 1 question to measure the respondent-perceived impact of violence exposure on a 10-point Likert scale (ie, 1=*not at all* to 10=*enormous daily impact*).

Drug and Alcohol Use

To measure self-reported substance use duration and severity during the study period, we used the modified Form-90 Quick Drinking Assessment (Form-90-AQ) [38]. The Form-90-AQ was developed as a brief assessment tool to determine an individual's alcohol use during a discrete period leading up to the present day [38]. Questions were modified to improve clarity when given over the phone (eg, including each participant's specific period as well as the number of days in the period in every question, rather than only in the initial prompt). Sample questions included, "Have you used any alcohol since discharge or your last survey on [last survey or discharge date], a period of [number of days between today and last survey or discharge]?" and "On those days when you did drink, how much did you have to drink on average?" Next, the question included in the Form-90-AQ about binge drinking was updated to reflect the National Institute on Alcohol Abuse and Alcoholism's (NIAAA's) most recent recommendation for the definition of the concept, from 6 to 5 drinks (eg, "Of those days on which you drank, on how many days did you have five or more drinks?"). In addition, a question about blacking out from alcohol use was added (eg, "On those days on which you drank, on how many days did you drink so much that you *blacked out* or couldn't remember?") [39]. Finally, some questions were adapted to ask about other substance use (eg, "Have you used any drugs or alcohol since your last survey on [last survey date]" and "Have you used any drugs, not including tobacco/nicotine, since your last survey on [last survey date], a period of [number of days between today and last survey]?"

Statistical Analyses

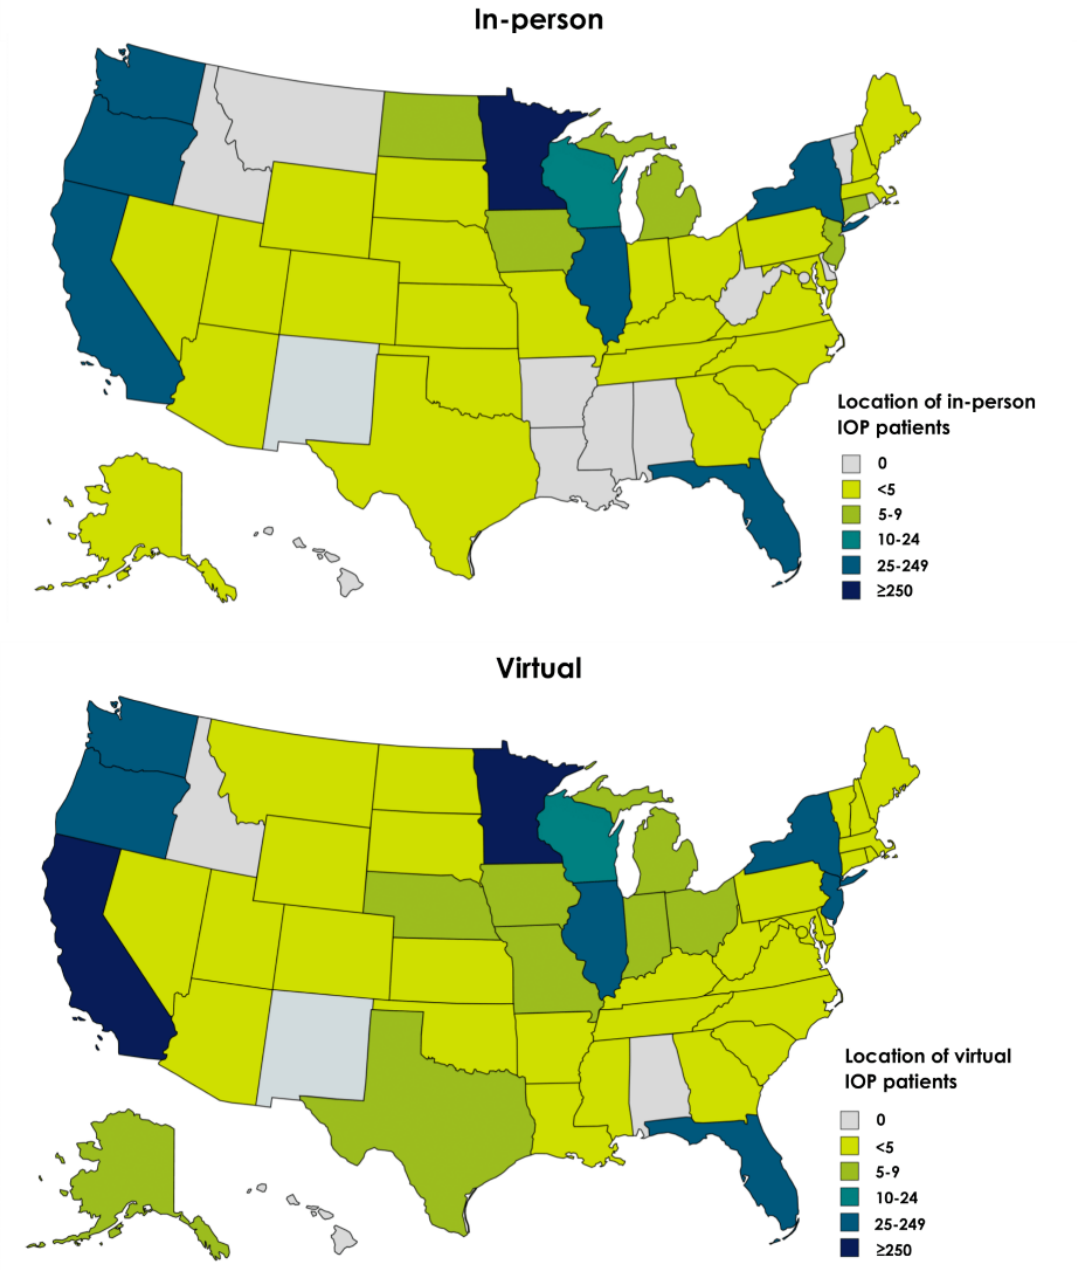
Analyses were conducted using SPSS statistics (*version* 28; IBM Corp) [40]. Chi-square tests of independence and 1-way ANOVA were performed to examine the relationships between the group format and baseline participant characteristics.

Results

Sample Characteristics

The sample characteristics are reported by IOP setting in Multimedia Appendix 1. Most patients were White (3296/3642, 90.49%) and men (2258/3642, 62%), with a mean age of 39.1 (SD 13.5) years. Approximately 37.97% (1383/3642) of the patients were diagnosed with 2 or more active substance use diagnoses, and the vast majority (3519/3642, 96.62%) accessed treatment through insurance. The national spread of patients by home state is shown displayed in Figure 2. Patients from a greater number of states attended VIOP (37 states: in-person and 46 states+Washington DC: internet-based), suggesting increased accessibility to care. Data were also considered according to the developmental stages presented in Multimedia Appendix 2, ranging from emerging adulthood to late adulthood to better understand how an individual's age may impact participation and engagement in different modalities of IOP.

Figure 2. Geographic distribution of participants by home state. IOP: intensive outpatient program.



Bivariate Group Comparisons: IOP Setting

At the beginning of the transition to web-based services in early 2020, a small proportion of patients were discharged before treatment completion when they elected not to switch to VIOP or when they stopped attending the sessions shortly after the change in treatment modality occurred. Patients who were discharged within 14 days of a group switching to internet-based were significantly more likely than those in the hybrid or web-based-only groups to be men (χ^2_2=8.7; P<.05), to be younger (χ^2_4=24.7; P<.001), and to have obtained a lower level of education (χ^2_4=12.7; P<.05). There were no significant differences between these groups in the proportions of White,

Hispanic, or Latinx individuals; employed full time or part time; or diagnosed with one or more SUDs.

Key features included differences in biological sex distribution, where participants in the hybrid group were significantly more likely to be men, whereas those in the internet-based group were more likely to be women. Significant differences were observed in age distributions. A greater number of individuals aged 18-25 years participated in the hybrid, and a greater number of individuals aged 45-64 years participated in the internet-based-only IOP. Regarding marital status, those in the hybrid group were significantly more likely to be single, whereas those in the web-based-only programming were more likely to be divorced, separated, or widowed. Individuals in hybrid programming had significantly longer lengths of stay and were significantly less likely to be discharged against staff or medical advice than individuals in both in-person and internet-only IOP. No significant differences were detected between formats by race, ethnicity, employment status, education level, or whether the participants presented with multiple SUDs. Similarly, no differences emerged in the type of SUD except for cocaine use disorder, where a significantly higher proportion of participants in the in-person group and a lower proportion in the internet-only group were diagnosed with a cocaine use disorder.

Developmental Stages

More differences emerged when examining the relationship between developmental stage and baseline participant characteristics, primarily driven by the emerging adults (those aged 18-25 years at treatment entry) in the sample (full results in Multimedia Appendix 2). Emerging adults were significantly more likely to participate in hybrid programming and less likely to participate in the web-based-only IOP. In terms of biological sex distribution, emerging and early adults were significantly more likely to be men, whereas middle-aged adults were more likely to be women. Owing to the preponderance of White participants in the sample, the race variable was collapsed to compare White with non-White participants (with full self-reported identification reported in Multimedia Appendix 1). Emerging adults were significantly more likely to be non-White, whereas middle-aged adults were significantly more likely to be White. Differences also emerged related to programming, with those aged 18-25 years engaging in treatment for a significantly longer period than older participants while also being more likely to be discharged against staff or medical advice. Emerging adults were less likely to be diagnosed with an alcohol use disorder and more likely to be diagnosed with all other SUDs, except for inhalant and other psychoactive disorders. Finally, emerging adults were significantly more likely to be diagnosed with multiple SUDs.

Regarding baseline clinical and functional measurements (Table 2), no differences emerged between the formats. Missing values reflect a delay in our ability to collect baseline and 1-month data from the in-person and hybrid groups.

Table 2. Baseline measurements of participants in intensive outpatient program.

Average baseline measurement scores	In-person only (n=957), mean (SD)	Hybrid (n=541), mean (SD)	Internet only (n=2144), mean (SD)	Overall (N=3642); missing, n (%)	Overall, *F* test (*df*)	*P* value

Discussion

Principal Findings

The VIOP study represents an important advancement in expanding our understanding of the role of telehealth in alcohol and substance use addiction treatment, providing richer insight into whether comparable care can be delivered through the internet.

At treatment entry, adults were similar across most demographic and substance use variables for all formats of IOP. Similarly, average scores on clinical inventories (eg, PHQ-9 and GAD-7) at baseline did not differ significantly by delivery setting, illustrating similar levels of psychiatric symptoms and physical cravings, regardless of the IOP delivery setting and timing of treatment in relation to the pandemic. This supports the literature on the use of web-based methods for the treatment of mental health symptoms and also shows that this treatment modality is viable for substance use populations as well. One notable difference emerged: individuals who participated in hybrid programming stayed in treatment significantly longer and were discharged against staff advice at a lower rate than those in traditional (in-person) or internet-based-only programming. Future publications will assess whether hybrid settings improved patient outcomes over and beyond those who received care in 1 setting only or whether it was a reflection of the extra support needed during a time of significant disruption in individuals' lives associated with the onset of the COVID-19 pandemic.

More differences emerged when comparing participants across developmental stages. Emerging adults (aged 18-25 years) in IOP showed consistent differences across a variety of demographic variables than those in early adulthood, mid-adulthood, and late adulthood and were more likely than patients at other developmental stages to present with multiple co-occurring SUDs, have longer episodes of care, and discharge early despite recommendations by program staff to continue treatment. These results suggest that patients in emerging adulthood have unique needs over and beyond those in older adult stages.

Strengths and Limitations

There are strengths and limitations to the use of ROM data. As these explorations are not bound by a clinical trial, there are inherent measurement errors that may affect the data, such as instances of inaccurate manual data entry, missed measurement scores, or diversity of standard measurements used in initial diagnostic assessments across clinical service departments and disciplines (ie, solely alcohol and substance use treatment vs co-occurring treatment). As a result, mental health diagnoses outside of substance and alcohol use disorders were not consistently documented and had to be excluded from the analyses. As data collection began in May 2020, much of our baseline data were pulled retrospectively through electronic health records, and in-person and hybrid patients missed some baseline measurements and what would have been their 1-month follow-up. Although not ideal, the remaining baseline measurements and 3-month follow-up can be compared, and any notable differences will inform future research. Furthermore, findings will be limited by the predominance of White, non-Hispanic men in our sample and therefore should not be generalized to patient populations' representative of minority and marginalized persons. Owing to the lack of randomization, our results do not allow for causal associations. However, these findings will provide an ecologically valid examination of web-based care in an existing health care system that is relevant and informative to other health care systems providing alcohol and substance use addiction treatment. Indeed, clinically efficacious explorations are inherently advantageous, and ecologic examinations may offer richer insight and practical implications in the real-world day-to-day lived experience of patients undergoing alcohol and substance use treatment.

Conclusions

Future findings hope to inform the effective development of data-driven benchmarks and protocols for routine outcome data practice. Investigations may also leverage these data to identify the patients for whom and circumstances under which telehealth is most efficacious, as these services are integrated into the standard of care for addiction treatment and recovery.

Abstract

Background: The Onduo virtual care program for people with type 2 diabetes (T2D) includes a mobile app, remote lifestyle coaching, connected devices, and telemedicine consultations with endocrinologists for medication management and prescription of real-time continuous glucose monitoring (RT-CGM) devices. In a previously described 4-month prospective study of this program, adults with T2D and baseline glycated hemoglobin (HbA_{1c}) ≥8.0% to ≤12.0% experienced a mean HbA_{1c} decrease of 1.6% with no significant increase in hypoglycemia.

Objective: The objective of this analysis was to evaluate medication optimization and management in the 4-month prospective T2D study.

Methods: Study participants received at least 1 telemedicine consultation with an Onduo endocrinologist for diabetes medication management and used RT-CGM intermittently to guide therapy and dosing. Medication changes were analyzed.

Results: Of 55 participants, 48 (87%) had a medication change consisting of a dose change, addition, or discontinuation. Of these, 15 (31%) participants had a net increase in number of diabetes medication classes from baseline. Mean time to first medication change for these participants was 36 days. The percentage of participants taking a glucagon-like peptide-1 receptor agonist increased from 25% (12/48) to 56% (n=27), while the percentages of participants taking a sulfonylurea or dipeptidyl peptidase 4 inhibitor decreased from 56% (n=27) to 33% (n=16) and 17% (n=8) to 6% (n=3), respectively. Prescriptions of other antidiabetic medication classes including insulin did not change significantly.

Conclusions: The Onduo virtual care program can play an important role in providing timely access to guideline-based diabetes management medications and technologies for people with T2D.

Introduction

Background

The Centers for Disease Control and Prevention (CDC) estimates that approximately 35 million people have type 2 diabetes (T2D), which is approximately 11% of the US population [1]. The incidence and prevalence of T2D continue to climb and outcomes are not improving despite increases in the number of effective drugs and advances in management technology. A growing body of evidence suggests that telehealth programs for T2D including smartphone apps, connected devices, and remote lifestyle coaching may help to address this public health crisis [2]. Participation in these programs has been associated with improvement in glycated hemoglobin (HbA_{1c}) and other related comorbidities [3-14]. Recently, telehealth programs have begun to incorporate medical management and the use of advanced remote monitoring technology; however, data on methodologies and outcomes are limited [13,15].

The Onduo virtual care program for adults with T2D provides access to video consultations with endocrinologists for medication management and prescription of real-time continuous glucose monitoring (RT-CGM) devices, which are used to facilitate optimization of medication regimens and lifestyle coaching and participant self-management. A recent prospective trial of the Onduo program reported a reduction in laboratory-measured HbA_{1c} of 1.6% (SD 1.0; P<.001) from 8.9% (SD 1.0) to 7.3% (SD 0.9), and a significant improvement in continuous glucose monitoring (CGM)–derived glycemic metrics at 4 months in 55 adults with suboptimally controlled T2D [13]. Here we report the detailed medication management that occurred during the study.

Study Objective

The objective of this analysis was to evaluate remote medication management by Onduo endocrinologists during telemedicine visits in conjunction with RT-CGM use among participants who completed the recent 4-month prospective trial [13].

Methods

Participants

Detailed study methods have been previously reported [13]. In brief, participants were ≥18 years of age, had a confirmed diagnosis of T2D, had HbA_{1c} level ≥8.0% and ≤12.0%, were willing to use a blood glucose monitor and CGM device, and owned a smartphone. Major exclusion criteria included malignant cancer, dialysis or end-stage renal disease or dialysis, liver or pancreatic failure, cystic fibrosis, chronic heart failure, or use of an insulin pump.

Protocol

Baseline and final assessments were conducted in person at the 2 study sites and included physical measures, blood draws, and questionnaires. The intervention was conducted remotely through the Onduo virtual care program.

Virtual Care Program Participation

The Onduo virtual care program for adults with T2D combines connected devices, remote lifestyle coaching, and clinical support with a mobile app has been previously described [11,12,14]. In this study, participants were asked to engage at least once per week with their health coach or care team and to participate in a telemedicine consultation with an Onduo endocrinologist. All participants were mailed a RT-CGM device (Dexcom G6, Dexcom) for intermittent use as indicated in the American Diabetes Association (ADA) Standards of Medical Care in Diabetes for adults with T2D [16]. Participants were asked to wear six 10-day sensors, with an initial period of 20 days (2 sensors); the remaining 4 sensors were worn on a 10-day "on" and 11-day "off" cycle. CGM glucose data were used by the care team for education and lifestyle coaching on the impact of diet and exercise and by the Onduo endocrinologists for medication management and to evaluate the efficacy of medication changes on glycemic control. Optimization of medication regimens was done remotely by endocrinologists and incorporated medical history, laboratory test results, and patient preferences, and was done in accordance with the ADA Standards, which is analogous to an in-person clinical practice [16]. The ADA Standards indicate that glucagon-like peptide-1 (GLP-1) receptor agonists are recommended as the first injectable medication, preferable to insulin. GLP-1 receptor agonists are also preferred over dipeptidyl peptidase 4 (DPP-4) inhibitors and sulfonylureas due to greater potency and positive cardiovascular outcomes. In addition, GLP-1 receptor agonists have superior side effect profiles compared to sulfonylureas, which carry risks of severe hypoglycemia and weight gain [17].

Statistical Analysis

Change from baseline at 4 months for clinical characteristics and the number of diabetes medication classes prescribed to participants were evaluated by Wilcoxon signed-rank tests. The change in number of participants prescribed specific diabetes medication classes was evaluated by McNemar exact tests. Statistical significance was defined as P<.05. All analyses were performed in Python 3.6.7 (Python Software Foundation).

Ethics

The study protocol and informed consent forms were approved by the Western Institutional Review Board (20182873) and registered with ClinicalTrials.gov (NCT03865381).

Results

Participants

Of 55 participants, 48 (87%) had a medication change. Baseline and follow-up demographic and clinical characteristics of the cohort with a medication change are presented in Table 1. At baseline, 8% (4/48), 44% (n=21), and 48% (n=23) of participants

were prescribed 1, 2, and ≥3 classes of diabetes medications, respectively.

Table 1. Participant baseline and follow-up characteristics (N=48).

Parameter	Baseline	Follow-up	*P* value
Gender			N/A[a]
Male, n (%)	26 (54)	26 (54)	
Female, n (%)	22 (46)	22 (46)	
Age (years), mean (SD)	56.9 (11.1)	56.9 (11.1)	N/A
Weight (pounds), mean (SD)[b]	217.74 (60.5)	208.7 (54.4)	<.001
BMI, mean (SD)[b]	33.5 (7.0)	32.2 (6.3)	<.001
Baseline HbA_{1c}[c] (%), mean (SD)	8.9 (1.0)	7.3 (1.0)	<.001
Number of diabetes medication classes, n (%)			.03
0	0 (0)	0 (0)	
1	4 (8.3)	3 (6.2)	
2	21 (43.8)	14 (29.2)	
≥3	23 (47.9)	31 (64.6)	
Systolic blood pressure (mm Hg), mean (SD)[b]	133.6 (16.2)	128.4 (17.1)	.02
Diastolic blood pressure (mm Hg), mean (SD)[b]	81.5 (10.7)	80.5 (10.9)	.46
Total cholesterol (mg/dL), mean (SD)	169.9 (42.6)	151.8 (42.1)	<.001
HDL[d] cholesterol (mg/dL), mean (SD)	40.2 (9.6)	39.0 (11.0)	.35
LDL[e] cholesterol (mg/dL), mean (SD)	101.8 (36.1)	94.4 (32.3)	.01
Non-HDL cholesterol (mg/dL), mean (SD)	129.8 (42.6)	112.7 (38.7)	<.001
Total cholesterol/HDL ratio, mean (SD)	4.5 (1.4)	4.0 (1.3)	.006
Triglycerides (mg/dL), mean (SD)	242.7 (205.1)	197.0 (172.0)	.007

[a]N/A: not applicable.

[b]As one subject did not complete the 4-month assessment at the study site, but submitted results from an external laboratory, n=47.

[c]HbA_{1c}: glycated hemoglobin.

[d]HDL: high-density lipoprotein.

[e]LDL: low-density lipoprotein.

Medication Management

The baseline and final medications at 4 months are presented in Table 1 and Table 2. Time to first medication change was 36.4 (SD 17.6) days. The most notable changes were a decrease in use of DPP-4 inhibitors, a decrease in sulfonylurea use, and an increase in GLP-1 receptor agonist use from baseline to 4 months. Medication changes including additions, discontinuations, and dose changes are presented in Table 2. Overall, 31.3% (15/48) of participants had an increase in the number of classes of diabetes medications prescribed from baseline and 10.4% (n=5) of participants had a decrease in number of classes of diabetes medications from baseline. In addition, 31.3% (n=15) of participants had a dose titration of an existing medication or a new medication.

Table 2. Participant baseline and follow-up medications by drug class (N=48).

Diabetes medication classes	Participants, n (%)			
	Baseline	Baseline medication stopped	Medication addition during study	Follow-up
Alpha glucosidase inhibitor	1 (2.1)	0 (0)	0 (0)	1 (2.1)
Biguanide	40 (83.3)	0 (0)	3 (6.3)	43 (89.6)
DPP-4[a] inhibitor	8 (16.7)	7 (14.6)	2 (4.2)	3 (6.2)
GLP-1[b] receptor agonist	12 (25)	1 (2.1)	16 (33.3)	27 (56.2)
Insulin	18 (37.5)	0 (0)	2 (4.2)	20 (41.7)
SGLT2[c] inhibitor	18 (37.5)	2 (4.2)	3 (6.3)	19 (39.6)
Sulfonylurea	27 (56.2)	13 (27.1)	2 (4.2)	16 (33.3)
Thiazolidinedione	1 (2.1)	0 (0)	0 (0)	1 (2.1)
Other diabetes medications	0 (0)	0 (0)	4 (8.3)	4 (8.3)

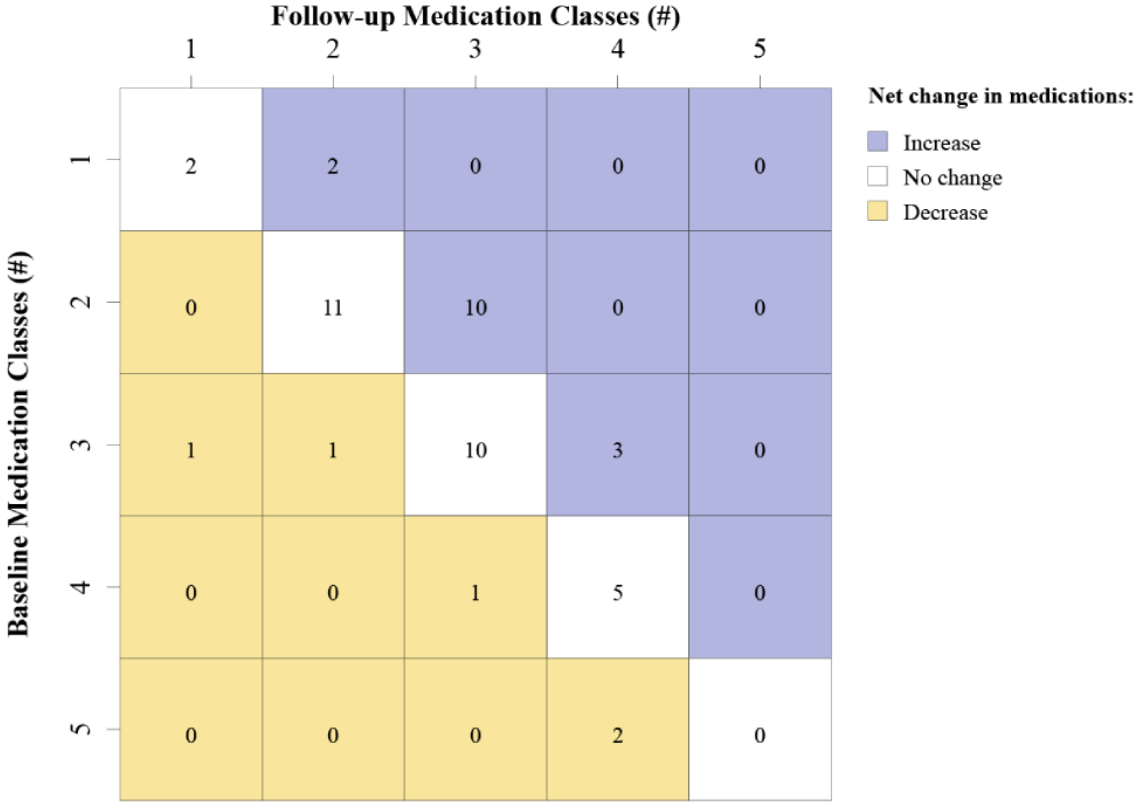
[a]DPP-4: dipeptidyl peptidase-4.

[b]GLP-1: glucagon-like peptidase-1.

[c]SGLT2: sodium/glucose cotransporter 2.

At a more granular level, the pattern of medication changes consisting of additions and discontinuations varied according to the baseline number of medication classes prescribed (Figure 1). The value in each cell represents the number of participants with a net increase, net decrease, or no change in number of medication classes prescribed from baseline to follow-up. Addition of a class was most frequently observed (n=10) for individuals on 2 classes at baseline. No additional classes were prescribed for individuals on 4 or 5 medications at baseline. Discontinuations were observed for individuals on 3, 4, or 5 medications at baseline and in one instance an individual on 3 classes at baseline had a final regimen of only 1 class at the end of the study.

Figure 1. Number of participants and net change in number of medication classes prescribed from baseline to follow-up. The value in each cell represents the number of participants with a net increase, net decrease, or no change in number of medication classes prescribed from baseline to follow-up.



Change in HbA_{1c}

HbA_{1c} for the present cohort (n=48) decreased by 1.6% (SD 1.0; P<.001) at 4 months, which was similar to change in HbA_{1c} reported for the full study cohort (n=55).

Use of RT-CGM for Medication Management Case Study

Figure 2 demonstrates the use of intermittent RT-CGM to accomplish medication management in a female study participant aged 66 years, baseline HbA_{1c} 12.0% and weight 174 pounds, taking 3 antidiabetes medications (glipizide, insulin glargine, and sitagliptin) upon entering the study. A total of 4 medications changes were made over the course of the 4-month study. Baseline sensor wear (two 10-day sensors) revealed mean glucose values ranging from 200-250 mg/dL and time in range (TIR) 70-180 mg/dL of <50%, with a few readings <70 mg/dL. Based on this glucose profile and the use of insulin, the Onduo endocrinologist made the following changes on day 27: the sulfonylurea (glipizide) was discontinued due to concurrent insulin use and the DPP-4 inhibitor (sitagliptin) was discontinued and exchanged for a GLP-1 receptor agonist (liraglutide) to address hyperglycemia. The dose of the GLP-1 receptor agonist was increased on day 47 due to glycemic excursions >200 mg/dL. Basal insulin was decreased on day 67. Further decreases in insulin were observed at day 108 in response to a small increase in CGM readings <70 mg/dL to minimize the risk of hypoglycemia. A comparison of the first CGM wear period to the last demonstrates less glycemic variability and reductions in postprandial glycemic excursions (Figure 3). The participant had a follow-up HbA_{1c} of 6.3% and lost 25 pounds during the 4-month study period.

Figure 2. Medication changes over 4 months for one sample participant (use of real-time continuous glucose monitoring for medication management). A total of 4 medications changes were made: day 27, sulfonylurea was discontinued due to concurrent insulin use, and the DPP-4 inhibitor was discontinued and exchanged for a GLP-1 receptor agonist to address hyperglycemia; day 47, GLP-1 receptor agonist dose was increased due to glycemic excursions >200 mg/dL; day 67, basal insulin was decreased; day 108, insulin was further decreased due to small increases in percent time <70 mg/dL. DPP-4: dipeptidyl peptidase 4; GLP-1: glucagon-like peptide-1.

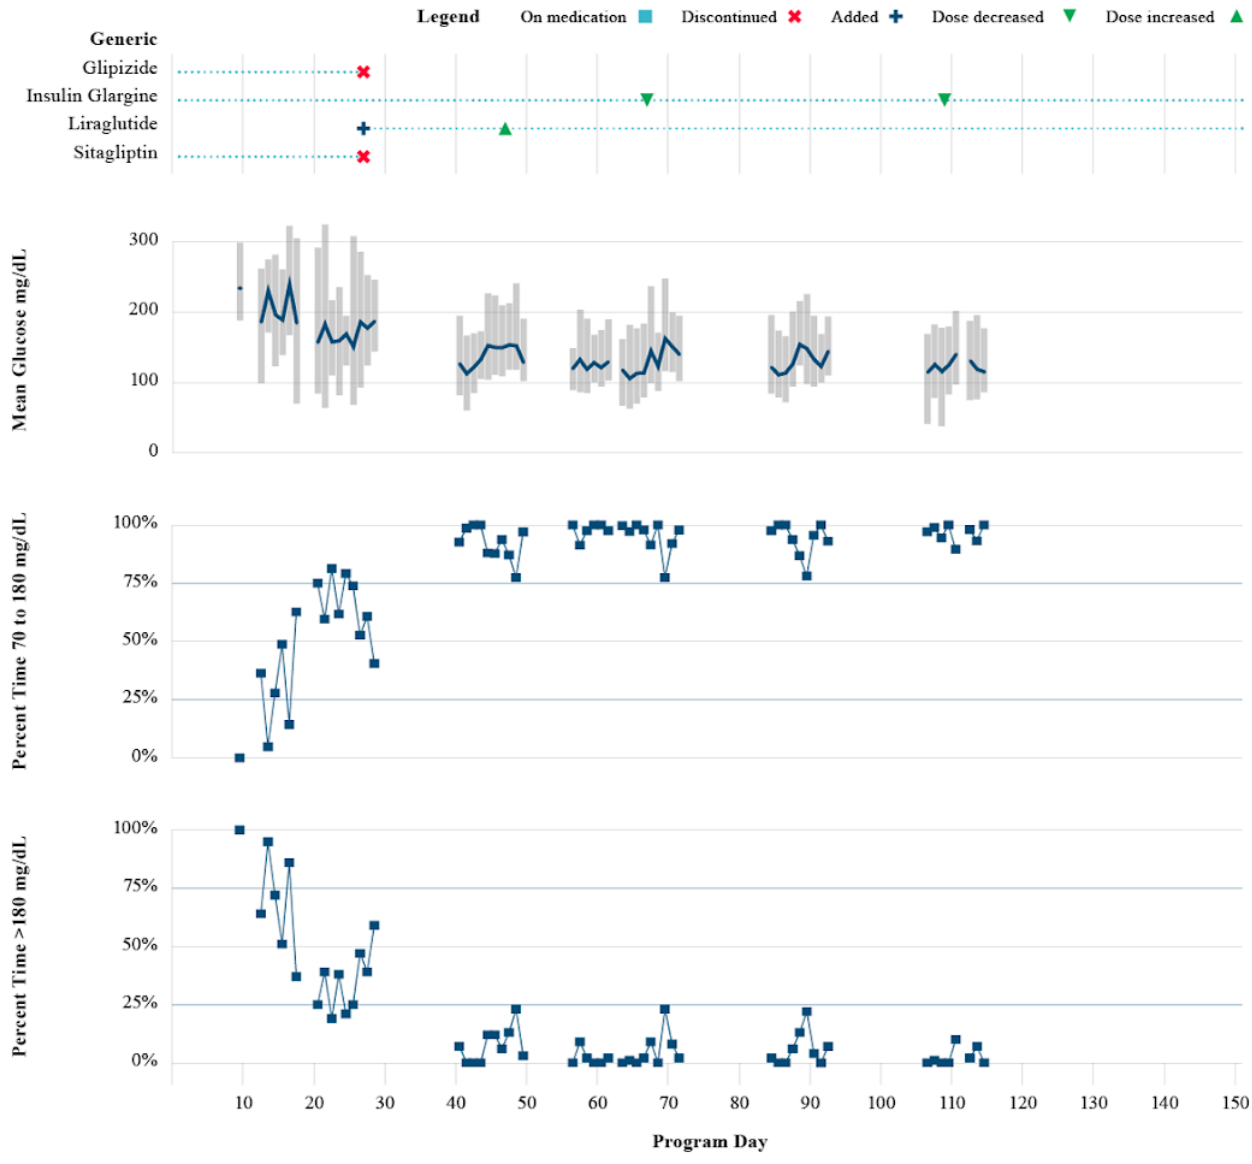


Figure 3. Median glycemic response over 24 hours for one sample participant. Comparison of the glycemic response for the (A) first 10-day real-time continuous glucose monitoring sensor wear period to the (B) last 10-day sensor wear period demonstrates less glycemic variability and reductions in postprandial glycemic excursions. Baseline HbA_{1c} improved from 12.0% to 6.3% at 4 months; baseline weight decreased 25 pounds at 4 months.

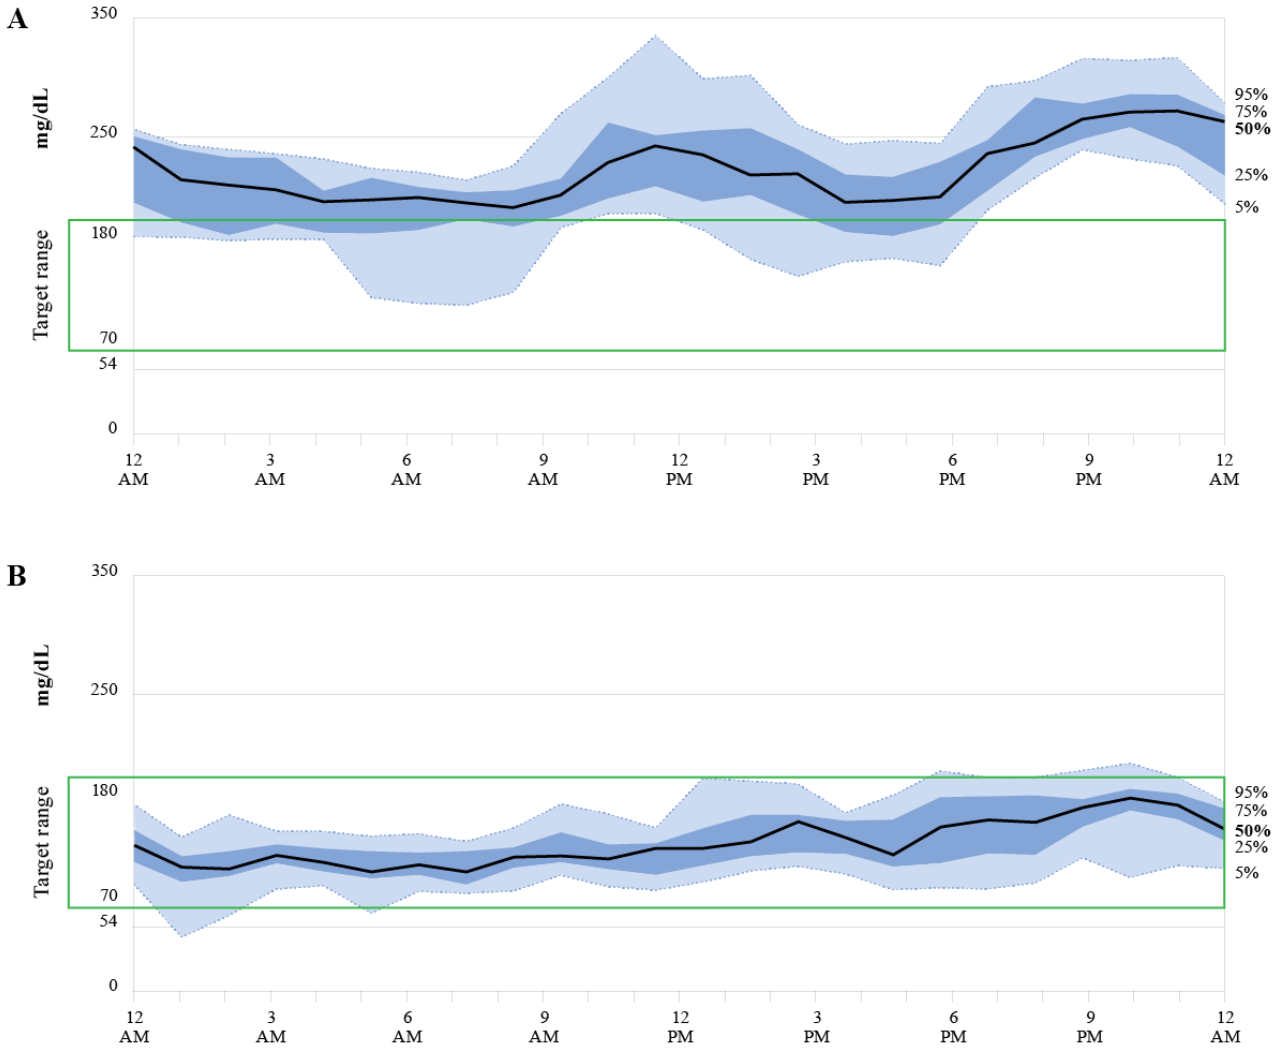

Discussion

Principal Findings

This prospective study of adults with suboptimally controlled T2D participating in the Onduo virtual care program resulted in improved glycemic control, which was achieved through a unique model of telemedicine consultations with specialists for medication management combined with remote health coaching and access to mid-level providers, all facilitated by intermittent use of RT-CGM. The major patterns of medication changes were discontinuation of sulfonylureas in approximately half of participants and a 2-fold increase in the number of participants prescribed GLP-1 receptor agonists over the course of the 4-month study.

Clinical inertia is a key barrier to optimal diabetes management, prolonging poor glycemic control and, as a result, increasing the likelihood of diabetes complications [18]. The rapid therapeutic feedback loop enabled by the Onduo care model through timely sharing of glycemic data and patient-provider communication is likely a key factor in reducing time to therapeutic intensification/change. In clinical practice, the delay in therapeutic intensification is prolonged, and tends to occur at a higher rate among patients already taking ≥2 oral antidiabetic drugs [19], which was the case for 92% (44/48) of participants at baseline. A recent study reported that approximately 50% of patients with an HbA_{1c} level between 8.0% and 8.9% on 2 oral antidiabetic drugs had no therapy intensification for 6 months following the identification of poor glycemic control [20].

Optimizing medication regimens in line with evidence-based guidelines, as was done in this study, is essential to improving glycemic control. Although GLP-1 receptor agonists are recommended based on efficacy, better side effect profiles, and demonstrated cardiovascular benefit, some reports indicate that these are prescribed in <6% of people with T2D, even those with established cardiovascular disease [20,21]. In contrast, by the end of this study, 56% (26/48) of participants were prescribed a GLP-1 receptor agonist and only 2 participants had therapeutic intensification with insulin. Thus, the data from the present analysis, when taken in context of the clinically significant improvements in HbA_{1c} and TIR we previously reported [13], support early medication intensification and optimization in people taking multiple oral antidiabetic drugs

who are particularly susceptible to clinical inertia [4]. The resulting improvement in glycemic control we observed, if sustained, may lower incidence of diabetes complications.

In addition to the Onduo program, there are several telehealth programs for T2D that have reported improvement in HbA_{1c} levels [3-10]. Although some of these programs are beginning to incorporate CGM use and telemedicine visits, to our knowledge there is only one recent study of a digital health program for people with T2D reporting medication management with CGM use [15]. However, the results of that study are not directly comparable to the present study due to substantial differences in study objectives and designs. This report by Shamanna et al [15] focused on deprescribing medications in participants provided a 90-day intensive nutrition intervention program in a retrospective design that analyzed only the 72% (64/89) of participants who were at least 60% adherent to the program.

The present study by contrast included the full range of medication management including class substitutions, dose titration, and additions, as well as deprescribing, in a prospective trial with an intent to treat analysis. Baseline glycemic control as measured by CGM was also better and met the clinical target [22] in participants in the Shamanna study (87% TIR versus 65% in this study). Both programs studied support the utility of CGM to improve short-term glycemic control, although longer duration studies are needed to evaluate acceptability, durability, and long-term clinical benefit for people with T2D.

Limitations of our study include the small sample size, the short duration, and lack of a randomized control arm, which limit the generalizability of our results. The intervention was intensive, which may not be reproducible or feasible for real-world telemedicine program participation. Although we were able to track and report recommended medication changes precisely in relation to real-time glycemia, we were not able to verify that prescriptions were filled from claims data due to the duration of the study. Thus, it is possible that participants did not make all the reported medication changes. In addition, we are not able to distinguish the clinical effects of individual components of the program (ie, lifestyle coaching, CGM use, and medication changes) from the program's overall clinical efficacy.

Conclusion

Although all aspects of the Onduo virtual care program may have contributed to improvement in glycemic control, telemedicine visits with endocrinologists and use of RT-CGM may have helped to overcome clinical inertia. Although further study is needed, optimization of medication regimens in line with current guidelines may be associated with long-term health benefits.

Acknowledgments

The authors thank the study participants and Onduo clinical team, Care Leads, Certified Diabetes Care and Education Specialists, and John Schmucker and Anne Vermeulen for their leadership. We thank the staff at the participating research centers, including Ashley Wilferd, and the staff of the Allegheny Singer Research Institute of the Allegheny Health Network, and Elizabeth Mesghina and the staff of Sutter Health, Palo Alto Medical Foundation Research Institute. Abstract

Background: Chronic pain is the leading cause of disability, affecting between 20% and 50% of the global population. The key recommended treatment is physical activity, which can be measured in daily life using a pedometer. However, poor adherence to pedometer use can result in incorrect measurements. Furthermore, only a few studies have investigated a possible curvilinear association between physical activity and chronic pain.

Objective: In this study, we developed the Pain-Note smartphone app to collect real-world data on step count, using the smartphone's built-in pedometer. The aims of our research are (1) to evaluate the association between daily step count and pain level among patients with chronic pain and (2) determine if the association between daily step count and pain level was curvilinear.

Methods: We conducted a cross-sectional study based on step count data collected with the app and on the results of questionnaires, which measured the duration and intensity of pain, the widespread pain index, the symptom severity score, and the insomnia severity scale, including 7 questions for symptoms of depression. We analyzed the association between step count and pain level as a nonlinear relationship using a restricted cubic spline model. A prespecified subgroup analysis was also conducted based on fibromyalgia criteria.

Results: Between June 1, 2018, and June 11, 2020, a total of 6138 records were identified, of which 1273 were analyzed. The mean age of the participants was 38.7 years, 81.9% (1043/1273) were female, and chronic pain was present for more than 5 years in 43.2% (550/1273) of participants. Participants in the third and fourth quartiles for step count (more than 3045 and 5668 steps a day, respectively) showed a significant positive association between higher step count and lower numerical pain rating scale (mean difference –0.43, 95% CI –0.78 to –0.08, *P*=.02; –0.45; 95% CI –0.8 to –0.1, *P*=.01, respectively) than those in the first quartile (less than or equal to 1199 steps a day). The restricted cubic spline model for the association between step count and pain scale displayed a steep decline followed by a moderate decrease as the step count increased; the inflection point was 5000 steps. However, this association was not observed among participants who met the fibromyalgia criteria (491/1273), who showed a steep positive increase below 2000 steps. Data were collected between June 1, 2018, and June 11, 2020, and were analyzed on November 18, 2021.

Conclusions: Step count measured with the Pain-Note app showed a nonlinear association with pain level. Although participants with and without fibromyalgia showed a negative correlation between step count and pain level, participants who meet the criteria for fibromyalgia may present a different relationship between walking and pain perception compared to those in the general chronic pain population.

KEYWORDS

smartphone; iPhone; cross-sectional study; chronic pain; fibromyalgia; step count

Introduction

Chronic pain is a global health problem that affects from 20% to 50% of the general population, depending on the level of severity and how it is reported. It is also a leading cause of disability [1-5]. Low back and neck pain, osteoarthritis, and fibromyalgia are the major chronic musculoskeletal disorders associated with chronic pain. Chronic pain limits physical function and reduces the long-term quality of life. Health care costs associated with chronic pain range from US $261 to $300 billion per year in the United States, with total costs, direct and indirect, over $600 billion [6]. A previous randomized controlled trial suggested the use of nonpharmacological interventions, such as walking, to reduce pain and improve physical function [7]. In particular, increasing the level of daily activity in fibromyalgia has led to lower perceptions of functional deficits and pain level [8]. Since the mechanisms of pain perception are different in fibromyalgia and other types of chronic pain, the effectiveness of physical activity also differs with the type of chronic pain [9,10].

The US Centers for Disease Control and Prevention/American College of Sports Medicine guidelines recommend a minimum of 30 minutes per day of brisk walking for most adults [11], while the Ministry of Health, Labour and Welfare of Japan guidelines for health promotion advise Japanese adults to perform 60 minutes of moderate to vigorous physical activity per day [12] to achieve beneficial effects. In addition to exercise, previous research suggests that daily step count can be used to measure daily activity [13,14]. Pedometers are commonly used to measure total walking activity. However, use of pedometers is limited due to poor patient adherence; therefore, unless their use is effectively encouraged, the results can be an underestimate [15]. To study real-life daily activity with higher adherence, we used the pedometer function that is built into the iPhone smartphone platform (Apple Inc). To utilize the built-in pedometer function, we designed an app we named Pain-Note, which was based on the Research Kit function built into the iPhone.

One previous study analyzed data based on the assumption that the relationship between physical activity and pain is linear [16]. Some studies have found that the relationship between health care outcomes and physical activity is nonlinear when a restricted cubic spline model is used. [17-19] Therefore, we hypothesized that the association between step count and numerical pain rating scale would not be linear, as in previous studies that utilized a pedometer to measure physical activity. By using a built-in smartphone pedometer that allowed high adherence, we obtained data that reflected real-world circumstances. Further, an analysis based on a nonlinear model allowed us to assess the relationship between daily step count and pain.

This study aims to (1) evaluate the association between daily step count and pain level in patients with chronic pain, with consideration to the subtypes of chronic pain, using a pedometer developed on a smartphone platform; and to (2) determine if the association between daily step count and pain level was curvilinear.

Methods

Data Source and Participants

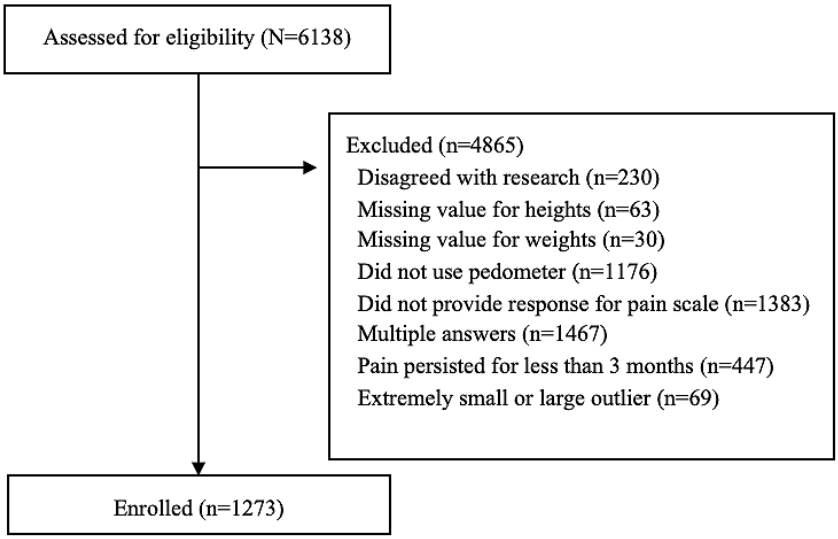
We conducted a cross-sectional study based on data collected with the Pain-Note app developed by Medical Logue Inc. (Tokyo, Japan). The company was under a consignment contract with the Faculty of Medicine of the Department of Psychiatry of our university.

The Pain-Note app was developed for subjects with chronic pain to help monitor their daily pain levels. It has been available in the Apple Store in Japan for free since June 1, 2018. This study included subjects who downloaded and used Pain-Note in Japan between June 1, 2018, and June 11, 2020, and completed the entire questionnaire. There was no financial compensation for participating in the study. Incomplete or duplicate answers were excluded.

Data Collection

Pain-Note collected baseline characteristics, including demographic information, medical history, and lifestyle information. Disease-specific questionnaires were used to obtain data on the duration of pain, the widespread pain index (WPI) and symptom severity (SS) score for fibromyalgia, and the insomnia severity scale (ISS) for sleeping disorders. The questionnaire also included 7 questions on symptoms of depression. Participants also reported daily subjective symptoms, including baseline pain, which was recorded using a 10-point visual analog scale. After providing written consent, the study participants provided the following information in the following order in the Pain-Note app: baseline demographic characteristics, medical history (including cancer status and cardiac, respiratory, brain, liver, renal, hematological, and collagen disease), subjective pain symptoms, WPI, SS score, ISS, and symptoms of depression (Figure 1).

Figure 1. Flow chart of the study sample selection.



Daily Step Count and Distance

We used the Research Kit function built into the iPhone to collect data on daily step count. The daily step count was automatically recorded in the participants' smartphones for 24 hours a day, 365 days of the year, regardless of whether the Pain-Note app was running or not. We categorized participants into quartiles based on step count distribution on the day the participants answered the questionnaires. Previous research has categorized step count into quartiles to estimate its association with other baseline variables [20]. Participants in the 2.5th and 97.5th percentiles for step count were excluded as outliers.

Chronic Pain Symptoms

Chronic pain data were collected using the WPI and SS score. WPI is a measure of pain or tenderness occurring within the 7 days before the test in 19 different body areas, from the jaws to the legs. The participants were also asked to rate their degree of physical pain on a scale of 0 to 19. The SS score measures the severity of symptoms on a scale of 0 to 12 by scoring fatigue, cognitive impairment, and unrefreshing sleep. Since the mechanisms of pain perception are different in fibromyalgia and other types of chronic pain, the effectiveness of physical activity also differs across types of chronic pain [9,10]. We determined the presence of fibromyalgia using the answers to the following questions in the questionnaire, based on the current fibromyalgia diagnosis guidelines: the duration of pain, WPI, and SS score [21]. The questions used to detect fibromyalgia symptoms included questions based on the validated Japanese version of the American College of Rheumatology 2010 criteria [22]. Based on answers from this section of the questionnaire, we classified patients into two groups: (1) those who fulfilled the criteria for fibromyalgia and (2) those who did not.

Symptoms of Depression

Symptoms of depression were evaluated using 9 questions (Multimedia Appendix 1) that were based on depression research conducted in Japan and were consistent with other depression scales [23]. The association between depression and chronic pain is well established [24], as is the relationship between depression and low levels of physical activity [25].

Symptoms of Sleep Disorder

Symptoms of sleep disorder were measured using the ISS, which assesses the severity of insomnia using 7 questions. The total score can range from 0 to 28 and indicates the severity of symptoms as follows: insomnia (0-7), subthreshold insomnia (8-14), and moderate and severe insomnia (15-28) [26]. The association between regular physical exercise and a lower incidence of sleep disturbance has been previously demonstrated [27]. In addition, sleep disturbance is common in chronic pain syndromes [28,29], especially fibromyalgia [29].

Statistical Analyses

We compared patients' baseline characteristics in all step count quartiles. Continuous variables are presented as the mean (SD) or median (IQR) based on their distribution. Categorical variables are presented as percentages. We conducted a 1-way ANOVA test for continuous variables and the chi-square test for categorical variables. We conducted multivariable regression analyses to identify and quantify the association between step count in each quartile and the pain scale; based on previous research, we adjusted for potential confounders, including age, sex, BMI, medical history (including cancer status and cardiac, respiratory, brain, liver, renal, hematological, and collagen disease), WPI, SS score, ISS, and depression questionnaire answers [23].

A previous study [16] suggested that there cannot be a linear relationship between physical activity, including step count, and clinical outcomes, such as pain level, in fibromyalgia. In response, we performed a restricted cubic spline analysis, which is able to investigate nonlinear relationships between 2 continuous variables. We followed the rationale reported by Marrie et al [30] and placed the knots, which are breakpoints representing inflections in the distribution of the data, at the 5th, 35th, 65th, and 95th percentiles, to make the model flexible enough for our assumed nonlinear association. We evaluated

nonlinearity using the likelihood-ratio test by comparing the model fit when cubic spline terms were used and when only linear terms were used [31]. To test the association between fibromyalgia and the number of steps, we also constructed linear regression models that included fibromyalgia symptoms as the independent variable and step count as the dependent variable. We then adjusted for potential confounders, including age, sex, pain level, ISS, and symptoms of depression.

Sensitivity Analysis

We conducted a sensitivity analysis to confirm the robustness of the main results. We used the daily distance moved, which was measured using the built-in smartphone GPS (rather than the step count) to confirm the relationship between distance moved and pain scale score. All comparison tests were 2-sided and set statistical significance as $P<.05$. We did not adjust the significance level for multiple comparisons due to the exploratory nature of our study. All statistical analyses were performed using Stata (version 16.1; Stata Corp).

Ethics Approval

This study was conducted after obtaining approval from the independent ethics committee of our university hospital. Written informed consent was obtained electronically from all participants before they answered the questionnaires. Ethical approval was obtained from the Research Ethical Committee of Juntendo University Nerima Hospital on March 3, 2020 (2019032). Data were collected between June 1, 2018, and June 11, 2020, and analyzed on November 18, 2021.

Results

A total of 6138 records were identified in our database. A total of 4865 records were excluded for the following reasons: consent was not provided for the research (n=230), height data were missing (n=63), weight data were missing (n=30), the pedometer function was disabled (n=1176), pain scale data were lacking (n=1383), data were duplicated (n=1467), pain history was less than 3 month (n=447), or the record was an extremely small or large outlier (n=69). A total of 1273 participants were included in the study (Figure 1). The mean age was 38.7 years (SD 13.4), and the number of women was 1043 of 1273 (81.9%). The participants mostly lived in large cities in Japan, such as Tokyo, Nagoya, Osaka, and Sapporo (Figure 2).

Figure 2. Geographic distribution of participants.

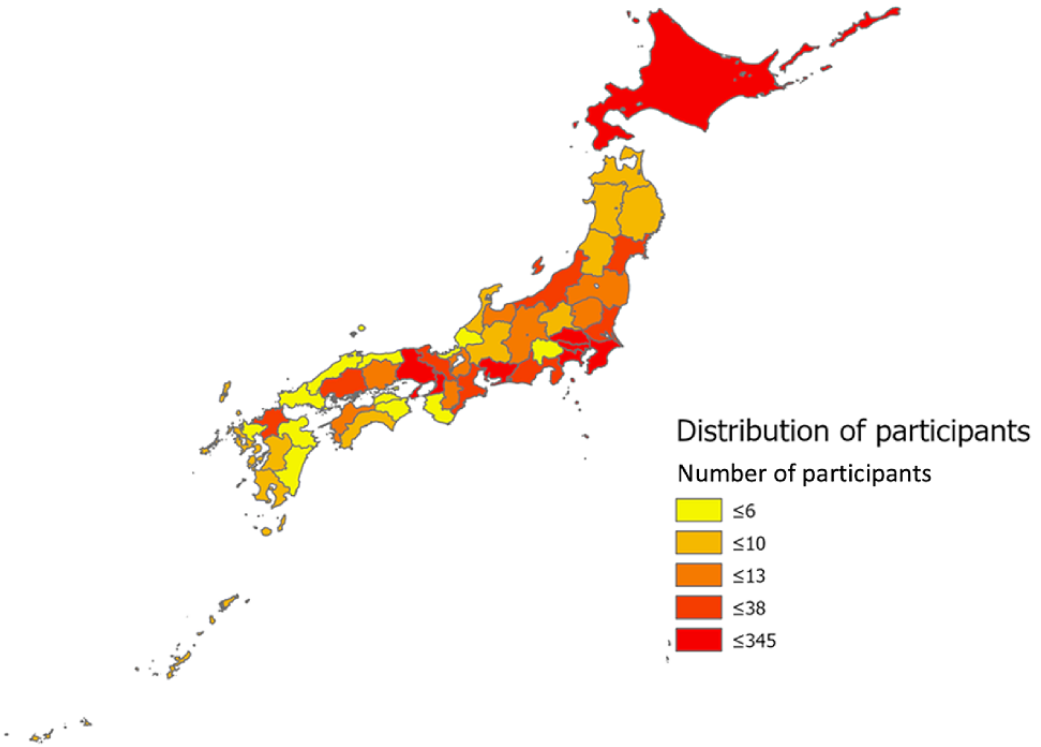


Table 1 shows the baseline characteristics of the participants. Participants in the first quartile had 24 to 1199 steps, the second quartile, 1205 to 3036 steps, the third quartile, 3045 to 5664 steps, and the fourth quartile, 5668 to 14,473 steps. Participants in the first quartile had the highest mean age at 40.22 years (SD 13.75) and the highest BMI at 23.8 (SD 5.6), while those in the third quartile had the lowest mean age at 36.97 years (SD 13.53) and those in the fourth quartile had the lowest BMI at 22.8 (SD 4.4). Among comorbidities, the largest proportion of participants had respiratory disease (210/1273, 16.5%). Among the 210 participants with respiratory disease, participants in the first quartile were the most numerous, followed by patients in the third, fourth, and second quartiles (66/210, 21%; 57/210, 18%; 44/210, 14%; and 43/210, 14%, respectively).

Table 1. Patient characteristics.

Characteristics	Total	First quartile (24-1199 steps)	Second quartile (1205-3036 steps)	Third quartile (3045-5664 steps)	Fourth quartile (5668-14,473 steps)	*P* value[a]
Age (years), mean (SD)	38.72 (13.47)	40.22 (13.75)	39.53 (12.77)	36.97 (13.53)	38.14 (13.65)	.01
Female sex, n (%)	1043 (81.9)	281 (88.1)	265 (83.3)	260 (81.8)	237 (74.5)	<.001
BMI, (kg/m^2), mean (SD)	23.2 (4.9)	23.8 (5.6)	23.3 (5)	22.9 (4.7)	22.8 (4.4)	.04

Cancer, n (%)	42 (3.3)	11 (3.4)	10 (3.1)	10 (3.1)	11 (3.5)	.99
Collagen disease, n (%)	91 (7.1)	21 (6.6)	25 (7.9)	23 (7.2)	22 (6.9)	.93

[a]*P* was calculated with ANOVA for age and BMI and the chi-square test for all other variables.

Data on pain level, depression, and sleeping disorders are shown in Table 2. More than 40% (550/1273) of the participants had chronic pain for at least 5 years. The second quartile had the fewest participants with chronic pain lasting more than 5 years (122/318, 38%). The second quartile had the largest number of participants with clinical insomnia (62/318, 20%). Participants in the first quartile had the most symptoms of depression, while those in the fourth quartile had the least.

Table 2. Step count and findings on pain, sleeping disorders, and responses to depression questionnaire.

	Total group	First quartile for step count	Second quartile for step count	Third quartile for step count	Fourth quartile for step count	*P* value[a]
Step count, median (IQR)	3036.0 (1199.0-5664.0)	324.0 (95.0-636.0)	1995.5 (1557.0-2454.0)	4281.5 (3623.0-4927.0)	7998.5 (6602.0-10,050.0)

Do you feel depressed?	269 (22.5)	57 (18.5)	60 (20.6)	71 (24.1)	81 (26.8)	.07

[a]All *P* values were calculated with the chi-square test.

[b]Data for depression represent "yes" answers on the questionnaire.

A restricted cubic splines model was used to assess the association between step count and pain scale; it revealed an obvious nonlinear association in the overall sample (Figure 3). When compared to the results of the linear regression, the results of the likelihood test were nearly, but not quite, statistically significant, which suggests that a model including patients with and without fibromyalgia would accommodate a nonlinear relationship with a better fit than a linear model for the association between step count and pain scale (P=.06). The results of the multivariable linear regression model for pain scale (divided in quartiles) are shown in Table 3. Participants in the third and fourth quartiles, who had a higher step count, were significantly less likely to report pain (mean difference –0.43, 95% CI –0.78 to –0.08, P=.02; mean difference –0.45, 95% CI –0.8 to –0.1, P=.013, respectively). Stratifying the sample into 2 groups based on the fibromyalgia criteria revealed no significant association between step count and pain scale score in any of the 4 quartiles in the fibromyalgia group.

However, the restricted cubic spline curve in the fibromyalgia group showed a mild increase in pain level as step count increased, until an inflection point around 2000 daily steps, followed by a decrease between 2000 and 5000 steps, suggesting the importance of visualization with the restricted cubic spline curve. The nonfibromyalgia group showed a steep negative association between step count and pain until around 3000 daily steps, followed by a nearly unchanging, steady line above that (Figure 4, Figure 5). Among participants with chronic pain but without fibromyalgia, the second, third, and fourth step count quartiles demonstrated a significant linear association between step count and reduced pain (mean difference –0.61, –0.59, and –0.78, P=.01, .02, and .002, respectively) (Table 3).

Figure 3. Association between step count and pain scale using restricted cubic splines. Four knots restricted the cubic spline curve. The curve showed an inflection point around 5000 steps.

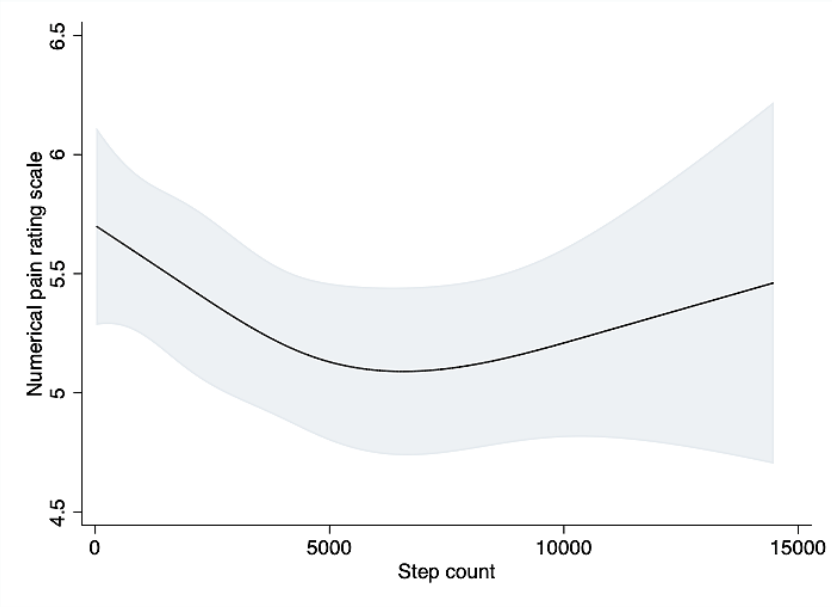

Table 3. Association between step count by quartile and pain scale in a multivariable regression model.[a]

Type of pain	Mean difference (95% CI)	*P* value
Overall chronic pain		
1st quartile (24-1199 steps)	Reference	
2nd quartile (1205-3036 steps)	–0.19 (–0.54 to 0.16)	.29
3rd quartile (3045-5664 steps)	–0.43 (–0.78 to –0.08)	.02
4th quartile (5668-14,473 steps)	–0.45 (–0.8 to –0.1)	.01
Participants fulfilling fibromyalgia criteria		
1st quartile (25-657 steps)	Reference	
2nd quartile (662-2187 steps)	0.26 (–0.23 to 0.74)	.30
3rd quartile (2188-4578 steps)	0.29 (–0.2 to 0.78)	.25
4th quartile (4600-14,264 steps)	0.17 (–0.33 to 0.66)	.51
Participants not fulfilling fibromyalgia criteria		
1st quartile (24-1396 steps)	Reference	
2nd quartile (1397-3537 steps)	–0.61 (–1.09 to –0.12)	.01
3rd quartile (3538-6198 steps)	–0.59 (–1.08 to –0.1)	.02
4th quartile (6199-14,473 steps)	–0.78 (–1.27 to –0.29)	.002

[a]All models were adjusted for age, sex, and comorbidities that included cardiological, respiratory, stroke, liver, renal, and hematological disease, cancer, symptom severity scale, insomnia scale, and the results of the depression questionnaire.

Figure 4. Association between distance and pain scale using restricted cubic splines in fibromyalgia patients. Four knots restricted the cubic spline curve. The curve showed an initial peak in numerical pain rating scale around 2000 steps and started to increase after 5000 steps.

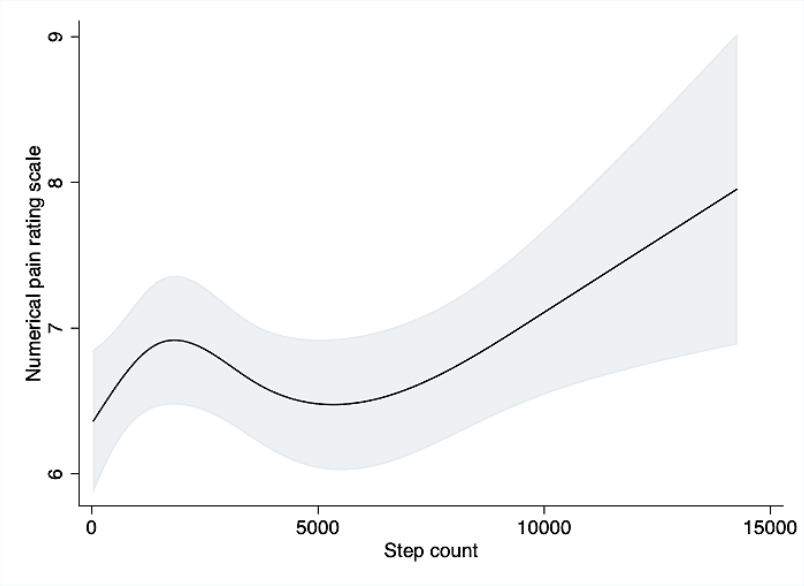

Figure 5. Association between distance and pain scale using restricted cubic splines in nonfibromyalgia patients. Four knots restricted the cubic spline curve. Step count and numerical pain rating scale were negatively correlated before 3000 steps, then showed no association past 3000 steps.

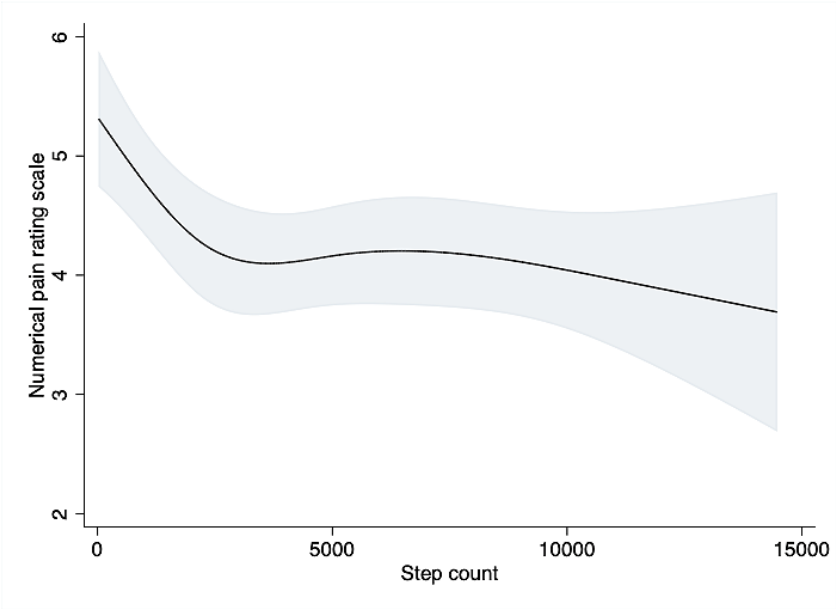

As the spline curves suggested a curvilinear association, the likelihood test for both restricted cubic spline curve models (ie, patients with fibromyalgia and those without) showed that the fit was statistically significantly superior to that of a linear regression model (P=.03 and P=.007, respectively) when the data were stratified for the presence of fibromyalgia, while in the overall model, the difference was not significant (P=.06). This suggests that the relationship between step count and pain scale should be considered separately in patients with and without fibromyalgia. In our sensitivity analysis, the association between distance and pain scale was similar to our main analysis.

The results of the univariate linear regression model revealed a statistically significant association between the presence of fibromyalgia and step count (mean difference –1.13, 95% CI –1.69 to –0.58, P<.001). In the multivariable models adjusting for age, sex, pain level, and the ISS score, the association remained significant (P=.01). However, when we added depression symptoms to the model, this association became nonsignificant (P=.1), suggesting that depression acts as a major confounder in the association between step count and the presence of fibromyalgia.

Discussion

In this study, we compared pain level with step count data collected with a smartphone app (Pain-Note). This is the first known study to examine the relationship between step count, measured objectively with a smartphone pedometer, and pain

scale in patients with chronic pain. We recruited diverse participants across Japan and obtained real-world data. Using smartphones to obtain step count data enables the data to be easily translated to the general population. Our study shows that a high daily step count is associated with a lower pain scale score except in participants who meet the criteria for fibromyalgia.

One concern of our study is the accuracy of step counts obtained with smartphones. This could be affected both by adherence to use of the smartphone app and by the accuracy of the built-in pedometer itself. A past validation study of adherence to smartphone pedometer use compared step counts derived from a smartphone pedometer and an accelerometer in a free-living test and found that there was an approximately 20% bias between the smartphone and the accelerometer [32]. Therefore, our step count results may be biased by a deviation of, at most, 20% from the true step count. The accuracy of smartphone pedometer step counts has also been investigated, such as in a previous study that showed that a pedometer app was more accurate when data from the built-in pedometer was compared to data from the built-in GPS function [33]. In our study, we used the distance moved (as measured with GPS) in the sensitivity analysis and decided to use only the built-in pedometer in the final analysis. The results obtained with GPS and the pedometer were similar, highlighting the robustness of our procedure. A previous study also reported that adherence to pedometer use was a limitation [15]. Although one-third of our participants disabled the pedometer function during this study, we believe that once they had enabled the pedometer, few of them repeatedly turned the pedometer function on or off during the day. We attribute our relatively low disagreement rate (230 out of 6138) to this. A plausible explanation for why some participants disabled the pedometer function was that they wanted to reduce battery consumption caused by the app working in the background of the smartphone. Therefore, we consider that our study results reflect real-life step counts and that data from the pedometer were complete.

The total daily step count of a typical elderly person in the United States ranges from 2000 to 9000 steps [34]. In a prospective study conducted in Yokohama, Japan, the average daily step counts throughout the year for participants between 40 and 69 years old was 9304 for male participants and 7246 for female participants [35]. In our study, the mean daily step count of the participants was approximately 3000 steps, which is less than half of the previously reported mean daily step count for women in Japan. This discrepancy could be due to the fact that most of the participants in our study had chronic pain; since the Pain-Note app was intended for this population, their step count was lower than that of the general population.

In our study, patients with symptoms of both insomnia and depression had lower walking counts. This result is consistent with previous studies, which have demonstrated that patients with a sleeping disorder or depression participated in fewer daily activities than individuals without these conditions. [36-38] Therefore, a lower daily step count might indicate insomnia or depression; identifying lower step counts might be useful for screening patients with these conditions.

We found, using restricted cubic splines, that there was a noticeable association between higher step count and a lower pain level. Furthermore, the slope of the association was steeper in participants with a smaller step count. Previous studies that have investigated the effect of walking or exercise therapy on pain reduction have assumed a linear association. In fact, the favorable association between increased step count and lower pain level is seen only among patients with chronic pain who do not have fibromyalgia. Participants with fibromyalgia show a different association between step count and pain level. Gracely et al showed that fibromyalgia alters the threshold of pain perception and makes patients more afraid to move [39]. This fear of moving could affect pain level, regardless of step count, but could also help explain the particular increase in pain level we observed in patients with fibromyalgia who had a daily step count below 2000. A meta-analysis of randomized studies with exercise as an intervention found that patients with fibromyalgia reported initial pain when they started to exercise at the beginning of the trials [40]. A previous study also revealed that daily exercise, including walking, reduced pain in fibromyalgia patients [40]. However, there was no association between step count and pain level in patients with fibromyalgia in our study. This may be because the participants who were classified as fulfilling the criteria for fibromyalgia in our study had not been diagnosed and did not have access to proper treatment by health care providers. Furthermore, these patients may not have been informed of the importance of exercise. Previous research suggests that a multidisciplinary approach combining physical exercise and education is important for pain reduction [41-43]. The results from our linear regression analyses, with step count as the outcome and the presence of fibromyalgia as the independent variable, also highlighted why the association between step count and pain level was different in our population. The fact that symptoms of depression are a major confounding variable in the association between fibromyalgia and step count suggests that, as expected, several variables can influence activity level in individuals with this complex syndrome.

This study has several limitations that should be noted. First, our results cannot determine causal associations because the study used a cross-sectional design. Second, there may have been selection biases for age, socioeconomic status, and user characteristics because of the requirement that participant be able to use iOS and the iPhone; in addition, our app is currently available only in the Japanese App Store and in the Japanese language. We also excluded more than 70% of participants who downloaded the app. This large proportion of excluded patients can be explained by the free distribution of our app. We believe that this free distribution means that the accessibility of our app was relatively high, but it also means that a large number of subjects were excluded from the analysis, mainly due to lack of complete data. On the other hand, to improve adherence, we could have distributed the app through a subscription or one-time purchase, but this might have led to additional selection bias, as only participants who could purchase the app would then have been included in the study. Third, our study suffers from self-reporting bias, because the data were collected using self-administered questionnaires. In addition, our analyses related to the presence of fibromyalgia were based on the

American College of Rheumatology 2010 criteria, which has been validated in the Japanese language, but has not been validated for use in the form of a smartphone app. Therefore, we must interpret our results as as being obtained from subjects who fulfilled the criteria for fibromyalgia, rather than subjects who had a clinical diagnosis. Finally, step count does not precisely reflect daily physical activity if participants turn off the pedometer function or if they perform activities that do not involve walking, such as swimming or mind-body practices. Considering that previous research has found a 20% bias in smartphone-based step trackers, the step count recorded by our app might have been an underestimate by as much as 20%.

Future research might include a longitudinal study to further explore the causal relationship between step count and pain. Analyzing predictors of the development or improvement of chronic pain would allow the planning of notification strategies or interventions in high-risk populations to reduce the burden of chronic pain.

In conclusion, our study revealed a significant association between high step count and low pain level among participants who did not meet criteria for fibromyalgia. In data that were stratified for patients with and without fibromyalgia, the likelihood test of a spline model did not show statistical significance; this could be the result of a lack of power, since the association was nonlinear in the overall sample. The characteristic shape of the association between patients with fibromyalgia and those without fibromyalgia might reflect different mechanisms of physical movement and pain perception. To find the causal association between step count and pain level, future studies should be designed to obtain longitudinal data and include participants from other countries who speak different languages; this would broaden the generalizability of our findings to a more diverse population. The extensive health care data that can be obtained with our Pain-Note app may ultimately help raise awareness regarding the importance of daily activity for preventing chronic pain.

Abstract

Background: News of the impact of COVID-19 around the world delivered a brief opportunity for Australian health services to plan new ways of delivering care to large numbers of people while maintaining staff safety through greater physical separation. The rapid pivot to telemedicine and virtual care provided immediate and longer term benefits; however, such rapid-cycle development also created risks.

Objective: The aim of this study was to understand the sociotechnical aspects of the rapid-cycle development of seven different COVID-19 virtual care tools, and to identify enablers, barriers, and risks at three health services in Victoria, Australia.

Methods: A qualitative, embedded, multiple case study design was adopted. Researchers from three health services collaborated with university researchers who were independent from those health services to gather and analyze structured interview data from key people involved in either clinical or technical aspects of designing and deploying seven different virtual care tools.

Results: The overall objectives of each health service reflected the international requirements for managing large numbers of patients safely but remotely and for protecting staff. However, the governance, digital maturity, and specific use cases at each institution shaped the methodology and specific outcomes required. Dependence on key individuals and their domain knowledge within an existing governance framework generally enabled rapid deployment, but sometimes posed barriers. Existing relationships with technical service developers enabled strong solutions, which in some cases were highly scalable. Conventional project methodologies such as steering committees, scope, budget control, tight functional specification, consumer engagement and codesign, universal accessibility, and postimplementation evaluation were ignored almost universally in this environment.

Conclusions: These three health services took a variety of approaches to the rapid-cycle development of virtual care tools to meet their urgent needs for triaging and remote monitoring during the first year of the COVID-19 pandemic. Their experiences provided insights into many social and technical barriers and enablers to the development of virtual care tools. If these are addressed proactively, they will improve clinical governance and technical management of future virtual care. Some changes can be made within individual health services, while others entail health system policy reforms. Enhancing the environment for virtual care tool design and implementation now will yield returns not only during future health emergencies but also in many more routine care settings.

KEYWORDS

COVID-19; health system innovation; rapid development and deployment methods; remote patient monitoring; software development

Introduction

The COVID-19 pandemic overwhelmed health resources in many countries. To handle unprecedented health risks and patient loads, health systems rapidly changed their models of care. In a matter of weeks, acute care health services around the world developed web and mobile applications to triage confirmed or likely COVID-19–infected patients (including their own health workers) to the most appropriate location, including outpatient testing clinics, hospital admission, in-home quarantine, or a dedicated isolation facility. Digital tools also enabled the hospitals to maintain clinical oversight of each remote patient through daily or more frequent contact (voice, text message, email, or other online service) and through the use of patient self-assessment tools to monitor symptoms (eg, temperature, heart rate, oxygen saturation, and respiratory rate). The term "virtual care tools"—including remote monitoring and tools (eg, [1])—describes this range of digital health interventions that track, monitor, assess, and manage decisions about care by health care workers and their patients when they are not colocated [2].

Health services had to make major decisions rapidly about their priorities for innovating with this range of virtual care tools. Some aimed at initial screening or triage of the general public or hospital staff, such as self-screening questionnaires (eg, [3-8]) and even chatbots [5]. Some aimed at follow-up of COVID-19–positive low-risk patients discharged from hospital, such as by providing them with pulse oximeters, thermometers, or similar digital devices; these innovations are described in an increasing number of articles (eg, [3,9-19]). Many virtual care solutions included web platforms with functionality for patients to report daily physiological data and symptoms of concern; if these data fell outside predetermined levels, suggesting deterioration, an automated message alerted the clinical team (eg, [10,11,15]). Other so-called "virtual ward" initiatives (reviewed by [18]) used technologies ranging from telephone calls to patient monitoring apps to capture the details of symptoms and personal data.

Some virtual care initiatives leveraged technologies already implemented in a health service, such as using or adapting existing electronic medical record (EMR) functionality to develop integrated tools for screening, triage, generating treatment order sets, remote monitoring of patients at home, and using health data effectively (eg, [5,6,10,12,14]). The implication is that patients were already enrolled in a health service EMR or could be enrolled readily in the EMR as necessary. Similarly, existing telehealth and video health applications were the foundation of some COVID-19 screening initiatives [20]. Other virtual care initiatives required novel technical solutions. Apps were developed for self-triage [4], for symptom grading [9], for reporting daily signs or to initiate a teleconsultation if a patient were concerned [11,14,17], or for use within the hospital emergency department [8]. Patient registries were established to identify, track, and monitor at-risk patients [12,20]. Purpose-built dashboards and analytics tools were used in some sites [6,9,10,20,21]. Survey software was also used for screening questionnaires [22] and for symptom tracking [17]. Continuous virtual monitoring infrastructure was adapted to monitor COVID-19 inpatients in negative pressure rooms and emergency department screening tents [20].

Design, development, and deployment of virtual care tools, which otherwise might take years to progress through research trial phases and clinical approval of software as a medical device (eg, [23]), were fast-tracked or short-circuited by the health care crisis. Few health services had time and even fewer had digital health expertise to attend to standards of technical development [24] or standards of clinical evidence [25]. Reviews published in late 2020 [18,26,27] summarized studies of the rapid deployment of digital technologies to cope with the COVID-19 pandemic in the early months of 2020, largely in the United States and Europe, most with fewer than 1000 participants. A case example in the University of Washington health care system [21] illustrates clinical informatics experts' involvement in supporting the clinical management of COVID-19 patients, and highlights the rapid governance and change control mechanisms that enabled this rapid shift. Commenting on the difficulty of data exchange within and between countries, O'Reilly-Shah and colleagues [28] proposed rapid development and implementation of data standards to overcome fundamental barriers to a data-driven response to the risks posed by pandemics. Likewise, Lenert and McSwain [29] argued for wider informatics innovations to enable electronic health record data from health systems to flow into collaborative public health data repositories.

Many sociotechnical aspects of developing and implementing virtual care tools in these circumstances—decisions about hardware and software, clinical content, human computer interaction, people, workflow and communication, policies and procedures, laws and regulations, and system-level monitoring [30]—have not yet been described in detail. Therefore, in this study, we examined, from a sociotechnical perspective, rapid virtual care tool innovations in three health services, and consolidated the lessons they learned in the first year. In particular, we addressed the following two questions: (1) which virtual care approaches were chosen and how were they designed? (ie, hardware and software, clinical content, human computer interaction, clinical workflow and communication), and (2) how was innovation influenced by factors internal and external to the organization? (ie, policies and procedures, laws and regulations).

The pandemic affected Victoria, Australia, from the time it was first declared by the World Health Organization (WHO) in early 2020. Health services began preparation for the transition to virtual care when the virus' impact on China, Europe, and the United States became evident through clinical communications, social media, and traditional media. Victoria's COVID-19 case numbers fluctuated over the course of the pandemic and regional

variation in numbers due to intermittent lockdowns was also apparent. This variation had minimal impact on the need to prepare proactively for worst-case scenarios, even though the utilization of the applications did vary greatly based on actual regional case numbers and infection waves.

The aim of this study was to provide insight into organizational readiness for future virtual models of care or service delivery through close examination of the evolution of virtual care tools during COVID-19 at three health services in Victoria, Australia. Understanding barriers and enablers that can be addressed in policy can inform the streamlining of current practices, and can ensure that digital health responses to future health crises and future routine care are managed and governed optimally.

Methods

Setting

This research was performed under the auspices of the Centre for Digital Transformation of Health at the University of Melbourne to address the need to facilitate cross-institutional learning during the pandemic [31]. The study took place at three health services in the State of Victoria, Australia. Austin Health (site A) and Melbourne Health (site C) are major metropolitan hospitals providing acute care and community services, and Bendigo Health (site B) is a major rural health alliance with 17 partner services.

Ethics Approval

The Royal Melbourne Hospital (part of site C) is the designated state-wide provider for quarantinable diseases. Melbourne Health Human Research Ethics Committee approved this study (HREC/67522/MH-2020; October 16, 2020); this ethics approval was recognized by the other organizations involved, and governance authorization was obtained for each participating site.

Design

This research used a qualitative, embedded, multiple case study design whose value has been demonstrated in previous health services research (eg, [32-34]). Researchers from the three health services collaborated with university researchers who were independent from those health services to initiate the project (project-managed by researcher URK), and gather and analyze data from people who had been involved in either clinical or technical aspects of designing and deploying the virtual care tools that were the focus of study: Austin Health community self-assessment platform [35], Austin Health COVID-19 symptom monitoring system, Austin Health COVID-19 symptoms management tool, Bendigo Health teamplay myCare Companion “Pandemic” [36,37], Royal Melbourne Hospital Home Monitoring [22,38], Royal Melbourne Hospital Screening Clinic tool, and Royal Melbourne Hospital COVIDCare. Table 1 describes the virtual care tools’ functions and features.

Table 1. Virtual care tools' functions and features.

Health service	Tool type	Short description	Hardware and software requirements	Location of potential or current patient
A	Screening app (members of the public)	App that issues the patient or visitor with a QR code after they identify themselves and respond to COVID screening questions	Internal: internet connectivity, accessed through smartphones or web portal	In hospital
A	Screening app (staff)	Web page form in which staff identify themselves and their workplace and answer COVID screening questions	Internal: internet connectivity, accessed through smartphones or web portal	In hospital
A	Home monitoring	Patient routing self-assessment and triage app	Internal: Microsoft Azure cloud data storage; external: audio recording of breathlessness, pulse oximeters. Internet connectivity: smartphone	Out of hospital
B	Home monitoring (digital)	Patient routing self-assessment and triage	Internal: Amazon Web Services using Australian cloud data storage; external: pulse oximeters, digital thermometers. Bluetooth capability and internet connectivity on smartphone or tablet computer	Out of hospital
B	Home monitoring (with manual option)	Patient monitoring at home using manual and electronic Excel forms for self-assessment	Internal: Amazon Web Services using Australian cloud data storage; Microsoft Excel; external: internet connectivity. Computer or tablet (to read and input into Excel) or print capability to manually enter form	In hospital and out of hospital
C	Screening app (members of the public)	App that issues the patient or visitor with a QR code after they identify themselves and respond to COVID screening questions	Internal: Local data servers; external: internet connectivity. Smartphone with basic functionality: web browser–enabled and/or text message receiving–enabled	In hospital and out of hospital
C	Home monitoring	Patient monitoring at home for self-assessment	Internal: Local data servers; external: pulse oximeters, tablet computers with internet connectivity, or smartphone with internet connectivity/text message receiving–enabled	Out of hospital

Interview Protocol

A semistructured interview protocol was developed based on the WHO digital health monitoring and evaluation guidelines phases 1 and 2 (prototyping and piloting), which focus on feasibility, usability, and efficacy [39] (see Multimedia Appendix 1). The questions sought individuals' descriptions and observations of the process of developing and deploying the virtual care tools at each health service, including what clinical and technical features were prioritized and how the tools functioned in early stages of actual use.

Three site-based researchers who had lead roles in tool development at their site (GH, MD, MB) were interviewed themselves, and also nominated additional people to be invited for an interview by a university researcher (TW). Subjects for the interview were identified on the basis of their key roles in information technology (IT) and informatics or their clinical pivot to virtual care in the case of emergency medicine, respiratory medicine, or infectious diseases staff members. Participation was voluntary; all who were nominated agreed to participate given the strategic nature of the work (N=13, Table 2). In health services that developed more than one tool, interviews with staff who had been involved in development of each tool were conducted separately and data about each tool were collected separately. The interviews were conducted between December 2020 and March 2021 via video conference and were audio-recorded. They occurred after the tools had been deployed and significant numbers of cases had been processed. The interviewees therefore spoke with that experience in mind.

Table 2. Interview participants

Health service	Position
A	Clinical lead for virtual care tools/infectious diseases physician
A	Contracted external programmer
A	Director of information technology services
A	Chief Medical Information Officer (site-based PI[a] in this study)
B	Director of Nursing
B	Executive Director of Information Services
B	Nurse Unit Manager (Admissions)
B	Registered Nurse (Psychiatry/Admissions)
B	Clinical lead, Integrated Care Services (site-based PI in this study)
C	Emergency physician/clinical lead (site-based PI in this study)
C	Assistant Manager, Nursing (Emergency)
C	Contracted external programmer
C	Emergency research director/senior physician

[a]PI: principal investigator.

Analysis

Analysis of the interviews followed the 7-step process of the framework method, which provided a structured and systematic approach to analyze data, while also providing the necessary rigor required in qualitative research [40]. First, the interviews were transcribed with the aid of an online voice-to-text transcription service, and interviewees reviewed the transcripts for accuracy. Second, the interviewing researcher (TW) worked with two experienced qualitative researchers from the university (AB, CG); the three familiarized themselves with the transcripts, and TW annotated them with contextual notes that he had made during interviewing. Subsequently, the three researchers began the process of coding, independently analyzing and coding the first three interview transcripts using NVIVO software. They used WHO digital health monitoring and evaluation guidelines to characterize the tools deductively; they also performed inductive coding to characterize the interviewees' comments thematically and to ensure that no themes were missed. The inductive approach used the open coding method, followed by constant comparison to refine the themes. The three researchers met regularly to discuss the codes, which underwent several iterations until they reached agreement on a working analytical framework. This framework was then used by AB and CG to code the rest of the transcripts. They aggregated comments at the level of each health service to reduce individual participants' public identifiability. Thereafter, they sought corrections and clarifications on matters of fact from the principal researcher at each health service. All codes with relevant illustrative quotes were exported to a spreadsheet in the form of a framework matrix to summarize the data. The commissioning and coordinating university researchers (WC, KG) then applied Sittig and Singh's [30] sociotechnical lens to review and organize the data into themes and subthemes for reporting. The three site-based researchers (GH, MB, MD) worked iteratively with the university researchers to reach consensus among all authors on the interpretation of the data and the implications for the Discussion section of the paper.

Results

Which Virtual Care Approaches Were Chosen and How Were They Designed?

Three priority aims for developing virtual care tools were described: reducing exposure (of staff and patients noninfected with COVID-19) by reducing admissions (including emergency department attendances), efficiency, and patient experience. See Textbox 1 for representative quotes for each aim.

The content of virtual care tools built by all three health services incorporated state government triage and management criteria [41]. Department changes and updates to their official case definitions were progressively incorporated into the screening and triage tools of the respective health services. Tools included risk stratification questionnaires relating to the general wellness of the patient ("How do you feel?") and screening information related to travel and general symptoms (eg, headache, fever, diarrhea, cough, sore throat, and shortness of breath). Specific physiological aspects of heart rate, blood pressure, oxygen, and temperature were included in home monitoring for self-assessment, but patient data were collected in more than one way, using both digital and manual means and depending on the home context.

Textbox 1. Representative quotes reflecting the three priority aims for developing virtual care tools.

- **Reducing exposure by reducing admissions**

"What we needed to do in the first instance was to make our staff as safe as possible to reduce the potential spread of the virus…The design [was] around two things: keeping patients away from the hospital - because we didn't want to be overwhelmed, and we needed to keep the staff safe so that we had a workforce that was able to do the work... [also] Being able to give people up-to-date information and to have a screening tool, that could triage patients, to stop them from coming to the hospital, to go to centers that were closer to their home. So that we could just bring the sicker ones and the ones that needed our care." [site A]

"The context was that we were asked to start a virtual home team which was looking after COVID-positive patients who were in the community...The key users that we targeted were COVID-positive patients who didn't require hospitalization. The whole idea of this home monitoring is to prevent frequent presentations. That precludes the need for a lot of people to actually come into hospital." [site B]

- **Efficiency**

"There's been a huge efficiency bonus—we could never have triaged that number of people, if they'd all physically come up and lined up in the car park, it would have been impossible. And the amount of data that's been assessed would also have required hundreds, tons and tons of staff if we'd had to do it on fax or paper or any other technology. So it's been very efficient for the hospital because the number of staff that have had to be deployed actually to managing this triage and a follow-up process has remained, I think, at three or four which we could never, ever have possibly done if it had been a more manual process." [site A]

"Our senior emergency clinicians stepped back, asking, 'What's going to happen when we get a planeload of potentially exposed travelers from overseas who are going to land in Melbourne and arrive at the emergency department all at once for screening? They're probably all well. They're all potentially infectious. How are we going to manage this?' It became obvious to us that we would need to do something different fairly quickly." [site C]

- **Patient experience**

"Patients are able to isolate within their own home yet feel like somebody's watching them and monitoring them. There is a physical benefit because they can be in an immediate intervention if something is noticed to be wrong." [site B]

"We want people to arrive in hospital just at the point in their illness when we can make a difference, and to leave when we can no longer make a difference." [site C]

Virtual care tools' functions are described in Table 1. All three health services provided home monitoring kits with digital devices such as pulse oximeters and thermometers and recording devices for breathlessness. Patients were provided with options for reporting their data; for example, they could manually record their oxygen levels measured using pulse oximeter devices and send the data via text message, or they could report to the triage team by phone call; tablets for connecting to web-based virtual care tools were provided to patients who had the capacity to use them. A variety of patient interfaces were described:

> *…can be configured to send the text to a carer, not just the patient. We do have knowledge of whether it's a carer-based or a patient-based response.* [site A]

> *…if someone had difficulty utilizing the system, then we'd find someone else to add the numbers into the system, or they would phone us with the numbers and we'd enter their data on the system.* [site B]

> *If you're coming to a screening clinic…you could have six QR codes, with six languages and if you speak Italian, you just click the Italian one and the form will be sent to you in Italian and the information will go back in whatever format we want it to go to…in the screening clinic [we] have a couple of tablets or iPads, that can be handed out to people while they're in the queue, to fill in the information* [site C]

Data management solutions varied from sophisticated cloud applications to Excel spreadsheets. Each health service developed local clinical workflows for reporting data, and in most cases for triaging respondents on clinical needs. Extraction of reportable information to the State Department of Health was enabled but had variable manual dependencies. No common clinical terminology (eg, SNOMED CT [Systematized Nomenclature of Medicine-Clinical Terms]) was adopted; however, Department of Health requirements mandated reasonably consistent word forms. How these were represented in underlying data structures was not consistent across sites. Data integration and systems interoperability were considered but were also foregone for the sake of expediency.

> *Generally speaking [the solutions] are quite separate and sole-purpose. Where relevant, data has been shared and there's interoperability. Integrates with the contact tracing solution so we can monitor potentially exposed or at-risk staff for symptom. No integration with the [state government] contact tracing system.* [site A]

> *We know that integration is a key thing for us from a user point of view.* [site B]

> *It doesn't integrate directly into the EMR.* [site C]

Data privacy and security measures were implemented through local processes at each site. A participant from health service A noted:

> *Health is a very legislated and regulated environment. There were standard operating procedures under which this was all done…For example, we didn't collect date of birth, just the age; not full addresses,*

> *just postcodes. So these principles were built into the apps*
>
> *…a role-based approach to ensure that only certain people are allowed to see certain data; encrypted link sent to the patient or their carer*

Platform choice was directed by ascertaining that data were stored in Australia on secure facilities, governed and secured by their own staff. Tools provided on browser interfaces relied on secure socket layer encryption. Health service C noted "Hopefully the robustness of the REDCap [Research Electronic Data Capture] platform is providing a layer of security." Strategies such as segmentation of data sets were used to keep screening records for health services staff separate from reports for patients and visitors at the sites; health service B commented on the potential for staff to become patients themselves: "Because of staff privacy issues and confidentiality, [information] was segmented." All used two- or three-factor authentication steps for patients to access portals or for staff accessing dashboards from their own devices. IT staff also reported using penetration tests and running vulnerability assessments on their systems.

How Was Innovation Influenced by Internal and External Factors?

All three health services had to create new project teams and use a rapid cycle design ("agile") philosophy [42], necessitated by the clinical requirements and human resource management prescribed by public health officials and local infection control experts. Projects were built on existing staff capability, assisted by contract programmers or developers, led by senior IT and clinical staff who were familiar with privacy and security requirements and who had the authority to proceed. The agile project team had responsibility for each of the rapid-cycle applications. This was a shared experience at each site. There were daily design, build, test, and adapt meetings to ensure the fastest possible deployment. Once a stable base system was established, additional functionality was added in a similar rapid-cycle format. Traditional considerations such as final functionality specification, design, tender, contract, and project governance largely were suspended. In applications where internal clinical staff were the end users, there was significant informal engagement in the design and build phases, including testing functionality and wording. This was not the case where the end users were consumers. User acceptance testing was incorporated into the rapid-cycle development framework. Postimplementation evaluation was mainly informal and based on functional user acceptance and utilization numbers. In addition, some of the virtual tools were adopted by other Victorian health services for use in the pandemic or were modified for use in other clinical settings.

The solutions deployed at each site were dependent, in part, on existing infrastructure, agile teams, applications, and relationships. Victoria differs from other states in Australia in having a decentralized system where each health service operates under its own board, following objectives and outcomes set by the State Department of Health. Each health service in this study uses a different EMR (site A, Cerner Millennium; site B, Intersystems; site C, Epic). These are at various stages of implementation, but fall within intermediate to high bands of digital health maturity, that is, levels 3-6 of the Healthcare Information and Management Systems Society's Electronic Medical Record Adoption Model. At each site, access to informatics and IT staff to rapidly build and deploy COVID-19 applications was not straightforward; they were generally fully engaged in other projects or intensive adaptations to prepare for COVID-19 in business-as-usual operations. However, internal development was essential due to the short timeframe for decision-making, without specific direction from state health authorities or market-ready software. Where local staff could not be redeployed, additional contract staff with relevant computing expertise were engaged through existing relationships with external consulting companies for this purpose, and all external service providers contributed substantial goodwill to these projects.

Site A had standing multiyear master services agreements in place that enabled application development within enterprise software solutions. Health service A is also moving toward procurement panels similar to larger-scale state procurement panels to reduce the effort and time to project commencements. In this case, there was a continuity of mutual understanding and trust that the intent of organizational policies and procedures would be observed during the rapid-cycle deployment. Health service A had been building knowledge and capability of artificial intelligence, machine learning, and natural language processing in their Microsoft Azure tenant together with external developers familiar with that platform. This platform allows flexibility in application selection and is highly scalable. As this relationship already existed, it was used to rapidly build and scale the applications. Together with the product developers, they agreed on a base application and rapidly designed electronic forms for a symptom reporting web-based application hosted on the health service's Microsoft Azure cloud.

Similarly, site B leveraged an existing relationship with the commercial product developers of their patient monitoring platform. Prior to the pandemic, health service B was in discussion with Siemens about a chronic disease management home monitoring tool and app. Senior management approval was granted to proceed to pilot on this basis. The clinical team responsible for chronic disease home monitoring became the group that took on the monitoring of COVID-19 patients.

Site C used an existing online research data system (REDCap) to rapidly build their capability. The clinical requirement at health service C was determined by local clinicians to manage expected high numbers of attendances at the emergency department. Development was driven by emergency clinicians and the tools were programmed in the service's established REDCap electronic data capture system [43]. REDCap was already approved for clinical research use; its three virtual care tools (patient screening, staff screening, and home monitoring) were granted a waiver of ethical clearance, as a quality improvement program. This system was highly dependent on two clinicians not normally involved with IT or EMR development to maintain service and alter software in a rapidly evolving data content environment.

Three enabling factors were noted to accelerate development of the tools in all three health services: having access to external IT developer expertise, close collaboration between internal clinical and technical staff and external developers, and strong support from senior management. Comments from site C summed up the organizational obstacles to be overcome, "the hospital bureaucracy committees, red tape permission, all of that," and the enabling characteristics, "it helps to have someone in the organization with the ability to question what is the outcome that's needed, and you need a small group able to work intensively on a solution that matches this."

Being enabled by working within an integrated health information environment was also expressed, but as an unmet need:

> *Victoria needs […] to have a single EPR [electronic patient record] or EMR so that these things would all link uniformly into the same platform…*
>
> *You need adequate architecture linked to systems and the workforce.*
>
> *Companies want to deal with you […] and they don't have a vision about an integrated, a fully integrated connected care model.* [site B]

Enabling funding was deemed secondary to rapid and effective deployment at the metropolitan health services, as those sites faced substantially increasing COVID-19 case numbers. The regional and rural health service (site B), with a lighter case load, voiced a greater sense of the financial resource limitations:

> *You can have whatever you want, provided you're prepared to pay for it.*
>
> *A major intervention like this requires a considerable amount of development. If you're buying something off the rack, so to speak, to tailor it to the needs of your particular area takes time and effort and work, which again, equates to money at some point, but it's resourcing and availability of resourcing.*

Social barriers to design and implementation of the virtual care tools emerged at all three sites. The prime concern was the digital divide affecting some groups of health service users:

> *There were concerns about accessibility for the non-English language speakers and the elderly, or the "digitally challenged," if you like.* [site A]
>
> *We initially looked at connected oximeters and trying to capture that data automatically. What we found was that that seemed to be a barrier of entry because the patient would then have to figure out how to connect at home and go through that process.* [site A]
>
> *We're contacting people and finding out they didn't have computers or didn't understand computers.* [site B]
>
> *The cohort that we had with these chronic complex issues were elderly patients. So there were very few patients who were computer literate and very few patients who even had phones and computers.* [site B]
>
> *You've got to look at the user interface to see whether it's practical and whether it provides a product that they can utilize fairly intuitively.* [site B]
>
> *A little bit more challenging for the uptake by the consumers because 12 months ago, a lot of us didn't know what a QR code was. But we built in some education around that…installed some big posters on the wall on how to access a QR code.* [site C]

To sum up, key results reported here can be mapped against the eight dimensions of a sociotechnical framework summarized in Textbox 2. Multimedia Appendix 2 presents additional interview quotes that illustrate these sociotechnical themes.

Textbox 2. Dimensions of the sociotechnological framework.

- **Hardware and software**

The sites worked around rather than through their electronic medical record systems; their solutions to store and process patient data varied from local servers to cloud services. Solutions assumed that the majority of people had ready access to internet-connected phones or tablets.

- **Clinical content**

Clinical content was structured in the most expedient way and prioritized to the essential elements for two decision support scenarios: triaging emergency attendance at a hospital and monitoring home-based care remotely.

- **Human-computer interaction**

An array of novel reporting and analysis interfaces was assembled for staff, with little concern for their overall user experience under the circumstances. Unfamiliar information interfaces such as QR codes, oximeters, and teleconsultations became normalized for health service consumers.

- **People**

Small teams of digital health champions undertook extraordinary development efforts. Given infection rates, both health service consumers and health care workers were likely to be patient "end users" of the solutions.

- **Clinical workflow and communication**

Initiatives at these three sites went beyond the scope of routine care and practice. They contributed efficiently and effectively to preserving health workforce capacity and preventing health service overload.

- **Internal policies and procedures**

Routine business processes for planning and implementing digital innovations did not run at the speed required by the health crisis. Innovation arose in organizational cultures where there was a foundation of trust in key staff and industry partners.

- **External policies and procedures**

In the absence of shared, centralized management of hospital information systems, the sites in this study mobilized informal communities of practice. This approach to sustain and extend the use of virtual care solutions beyond the health crisis will depend on shifts in digital health regulation and resourcing.

- **System monitoring**

The sites in this study have committed to formative evaluation of the development and piloting stages of their virtual care solutions in the form of research reported in the present paper. The World Health Organization staged evaluation model referenced here carries the expectation of further monitoring of solution performance and outcomes over a longer term of implementation.

Discussion

In summary, all three cases showed priorities, issues, and outcomes similar to those in the COVID-19 virtual care literature around the world: rapid development and iteration, staff and community safety through distancing and virtual care, scalability and efficiency, uncertainty, and constraints of business-as-usual models. The ability to rapidly leverage existing infrastructure and relationships proved critical in each case, even though the technical responses varied considerably. None of the sites used their EMRs as the primary digital tool, largely due to the administrative difficulty of enrolling so many new patients formally into the EMR. The tools that were developed enabled consumers to self-register and hence reduced the administrative burden, which is known to be significant in other jurisdictions where an EMR was used (A Ritchie, Chief Medical Information Officer, Sydney Local Health District, Royal Prince Alfred Virtual, personal communication, May 13, 2021).

Governance maturity was just as important as technical maturity; organizational dependence on trusted employees to drive these projects in a responsible and defensible manner was critical to timely, successful application deployment. Maturity implies that the organizations had developed sufficient internal processes and policies, so that responsible staff could rapidly deploy within those principles without necessarily following the operational and committee procedures, which would have taken too long. Informal sign-offs were more often the case, even though one health service found that there was a tension between formal and informal processes. Projects at all three sites had a high level of risk because of their critical dependencies on a few key actors. These were pressing factors in the pandemic setting, but these might not be as relevant in postcrisis or in less threatening situations.

Difficult choices needed to be made regarding time to deployment versus equity of access. All respondents noted that there were certain consumer groups who could not access these applications due to limitations in language, technical access, or skills. These issues were identified internationally, such as by Houlding et al [1], where barriers to the use of remote monitoring technologies included equity-related barriers (such as affordability of technology for users, poor internet connectivity, poor health and digital literacy), the need for good practice guidelines for use in clinical care, and the need for additional resources to develop and support new technologies.

In our study, some access issues were mitigated by use of patient proxies and one health service enabled some multilingual content. Consumer consultation and codesign were noticeably absent as were formal evaluation and benefits realization. To overcome these issues systematically as virtual care tools become part of business as usual, health services will need to establish consumer engagement structures proactively and embed them in usual practice so that these ways of working with consumers are trusted and effective. Another victim of development and deployment speed was the failure to use recognized coding systems and terminologies in the apps design. There was congruence of clinical concepts, clinical triage criteria, and state government reporting requirements, which drove content in these apps; however, the underlying data structures are inconsistent and would require mapping to consolidate the data. This is another area where embedding capability into usual practice, specifically stronger informatics skills within health services' IT teams, would provide benefits.

Health services have widely recognized the success of these rapid IT implementations and now have more confidence in enabling and sustaining virtual health care applications [3]. Although it is a limitation that consumer views have not yet been assessed in our study sites, we note that strong consumer satisfaction is reported in the literature (eg, [3,15]). Further developments would be streamlined by formalizing the enabling and success factors identified in this study and building in mitigations for the deficiencies (eg, consumer panels and multilanguage capabilities embedded in consumer-facing digital health applications). Formal partnerships and collaborations between health services and IT companies may offer a significant long-term benefit for in-house design and deployment and should have a legitimate place alongside the competitive project tendering mechanism. This is especially the case where enterprise platforms are used for related deployments.

The authors of this study brought our diverse experiences and perspectives as practitioners, technologists, administrators, and researchers to bear to reflect on the data that we highlighted in our Results section and on additional thematic data garnered in this study (as summarized in Multimedia Appendix 2). Our collective lessons learned about barriers, enablers, and suggestions for future work are captured in the recommendations we propose in Table 3 and Table 4.

Table 3. Recommendations for improvement in policy and practice, based on barriers experienced in rapid virtual care tools development (after Houlding et al [1]).

Barriers	Normal practice	Rapid cycle	Suggestions for future
Poor internet connectivity	Solution delivery platform designed for optimal functionality for the target population; multichannel delivery with "low tech" where possible	Solution delivery can take into consideration the availability, access, speed, and other requirements of applications depending on the project context. The latter can encompass pilot applications across any of 3G, 4G, 5G, and WiFi	Create a registry of available technology platforms for areas where optimal solutions are unavailable; these could be related to geography, topology, rurality, service outages, or cost of access
Low health literacy	Design with language optimized for target populations	Considerations often overlooked or unavailable in the project context due to emphasis on rapid prototyping without participation of a spectrum of service users	Create design templates for developers to utilize in specific low literacy populations
Low digital literacy	Design with "low tech" optimized for target populations	Considerations often overlooked or unavailable in the project context due to emphasis on rapid prototyping without participation of a spectrum of service users	Consider development of support models for users (eg, training, adoption support)
Need for quality, best-practice guidelines for use of remote monitoring technologies in clinical care	Project design and funding aimed to support optimal solutions	Utilize technology already available and approved; design interface around available devices	Development and maintenance of tool sets and guidelines for remote and home monitoring use
Lack of resources to develop and support new technologies	Project design and funding aimed to support optimal solutions, which may include new technologies where feasible	Rapid design of applications leveraging existing technologies, devices, and/or platforms. Innovation is often in the reuse of technologies to extend and/or enhance functionality	Structured simulation and validation frameworks for rapid-cycle development, testing, clinical trial, and deployment. Consider total cost of ownership (eg, unmeasured development costs, hosting costs). Manage human resources cost (eg, informal time of subject matter expert clinicians, technical developers' time)
Equity-related unaffordability of technology for users	Scoping outcomes and target clientele; mitigations for identified consumers; alternate funding models or subsidies; design for least-cost technology; stratified interventions	Equity considerations frequently not addressed; 80/20 rules due to rapid prototyping process for majority service users; mitigations for descoped users may be considered in a subsequent evaluation phase	Identify and resolve long-standing equity and access issues so that standing solutions are available to be incorporated at short notice; build in multilanguage capability; develop policies and mitigations for equity access as part of business as usual; apps delivered if possible over multiple channels, including low-cost SMS and phone

Table 4. Recommendations for improvements in policy and practice, based on enablers experienced in rapid virtual care tools developments (after Houlding et al [1]).

Enablers	Normal practice	Rapid cycle	Suggestions for future
Governance: policies reflect required outcomes and describe allowable emergency and rapid-cycle processes and permissions framework	Review internal policies and ensure they reflect both business-as-usual and emergency situations to enable appropriate rapid responses	Existing policies describe acceptable process and outcomes in the absence of conformance with standing committee and approvals framework in defined circumstances	Identify "special needs and emergency" situations; review business-as-usual practice to reduce unnecessary delays
Master services contracts: reducing procurement delays with trusted providers	Individual projects defined, budgeted, and tendered; project management framework defined	Existing relationships leveraged to create short-term team with focused but flexible and evolving outcomes as external environment evolves	Establish panels of approved partners and consultants to enable rapid design and deployment, especially using existing enterprise solutions
Standing consumer working groups for rapid cycle codesign	Consumer groups engaged on project basis, often ad hoc	Consumer groups might be largely ignored in the rapid prototyping process and in participatory practices over the course of the rapid cycle	Establish panels of educated consumers who can contribute knowledgeably across all projects and be available at short notice; actively engage a spectrum of users and consumer organizations; cocreate a participation framework with a cross-section of consumers/service users throughout the life of the service, including options for training (eg, digital and health literacy)
Upskilling and enabling clinicians and subject matter experts to lead projects targeted at their specific issues (eg, predicting issues and rapid problem enunciation)	Clinician-led projects battle for priority and resourcing against "top-down" projects	Clinician-led and developed applications target local requirements using defined, secure, integrated platform applications; informal international clinical networks and peer review rapid publications flag concerns prior to official body pronouncements: lead the local curve	Training and enabling clinicians in supported platform applications (eg, Dynamics, Forms, REDCap[a]), reduces lead time and impact on core IT[b]/EMR[c] applications teams. Clinical networks promote data conformance and spread of successful applications
Collaboration (clinical and technical) networks facilitate shared understanding and requirements for development, together with resource sharing	Organizational, cross-organizational, and professional and clinical networks advise on priority applications and consulted ad hoc regarding application selection and deployment issues	Existing networks should be convened as priority to coordinate and share resources to expedite planning development and implementation. Parochial variation should be reduced or eliminated	Convene, support, and sustain these networks as business as usual so they deliver benefits and are functional when required in emergency scenarios

[a]REDCap: Research Electronic Data Capture.

[b]IT: information technology.

[c]EMR: electronic medical record.

This study provides an in-depth qualitative assessment of the sociotechnical environment in three large Australian health services during the rapid deployment of staff- and consumer-facing COVID-19 applications. Its strength is in capturing the diversity of technology platforms and development models and sharing the reflections of key personnel across these three sites. Although the number of interviewees perhaps seems limited, in fact, all key decisions were made by those few people, in consultation with other key clinical groups. Where possible, clinical staff who both provided expert advice on form and content of the applications and who became key testers and users of the applications were interviewed. In terms of a full sociotechnical evaluation, the paper has limitations due to the focus on operational efficiency at a time-critical period in history. The availability of multiple cases located within the same state of Australia (Victoria) provided an opportunity to describe and analyze varied experiences of virtual care innovation within a national health care system.

During the initial period of the pandemic, state health policy makers were occupied in managing whole-of-system preparedness, state and national reporting systems and contact tracing systems, vaccination preparation, and quarantine. In Victoria's decentralized public health system, each health service is responsible for implementing state policy in its own way, and this will be partly determined by prior decision making around EMR/paperless administration system selection, implementation stage, and other elements related to digital maturity. In a similar manner, hospital executives, who are often overwhelmed by preparations and hospital ward reconfigurations, staff protection and visitor policies, logistics, and supply chain challenges, provided support but not direction for those clinicians and EMR/IT experts charged with response and virtual care preparation. The state government provided a significant funding stream for COVID-19–related activities, including virtual care preparation. Expenditure allocation was authorized by department heads in consultation with finance department officials.

This context makes our results less comparable with other states in Australia where digital health strategy and implementation are more centralized. A limitation of our study is that we were constrained from including cases from additional major health services in Victoria, in part due to onerous, site-by-site research

ethics and governance processes. Further work needs to be done on evaluation. In particular, we could not meaningfully interpret usage data to give a clear picture of immediate uptake of these applications, and we are not yet able to provide a full sociotechnical analysis of longer-term, scaled-up experiences or outcomes. Such evaluation research is the focus of another study.

Despite these factors, our findings are consistent with other reported projects of similar nature in the international literature. The presence of mature EMR and supporting IT infrastructure and governance models enables rapid development and deployment of digital health applications in support of new models of care. Preexisting contractor relationships at two study sites enhanced the capacity of those services to deploy rapidly. All of the relationships reported here underwent standard probity assessments when initially contracted (eg, fairness, avoidance of favoritism, hidden inducements); however, within these contracted relationships there was scope to modify and evolve service requirements within reason. The preexisting personal and technical engagement enabled the rapid-cycle design and development of the COVID-19 virtual care tools. Conventional governance models are essential for establishing normative behaviors, checks, and balances; however, emergency, rapid-cycle developments can be performed safely using the principles established by this governance without rigid adherence to committee structures and procedures. User acceptance of virtual digital applications described in the international literature is high, and the intent to support large cohorts of at-risk people and manage emergency service utilization has been demonstrated. Direct consumer involvement and codesign were not features of our study cohort, nor were these aspects comprehensively described in the literature about other COVID-19 applications. Applications supporting clinicians were more likely to have undergone some degree of codesign, with short-cycle deploy review and revision, simply because clinician users were in proximity to app developers.

In conclusion, we agree with Boyle and Henderson [44]: “As we move from a pandemic to an endemic state, delivery of care must also change to ensure this—and similar diseases—can be managed safely, alongside regular emergency care, within our departments and wider healthcare systems.” The findings of our study confirm that the pandemic has affected us in similar ways to the rest of the world and that our responses have been similar. Lessons learned elsewhere have relevance for Australia; it is clear that rapid deployment of triaging and remote monitoring technologies has occurred successfully in numerous countries and contexts. These findings support clinical recommendations, to governments and other funders, that structures and systems for developing virtual care tools should be strengthened in organizational and funding models. This will not only engender resilience in health emergencies but also has the potential to transform chronic disease management and routine clinical care to be more accessible and less costly and to reduce pressure on fixed health service infrastructure.

Acknowledgments

The University of Melbourne’s Centre for Digital Transformation of Health provided funding for this research. Ursula Soulsby from the university’s Business Services unit provided invaluable support with human research ethics applications and governance agreements. A number of companies assisted in the development of these health services’ COVID-19 applications and subsidized much of this activity; apart from those named in the paper, we gratefully acknowledge the contributions of Arden Street Labs and Dan Trembath.

Abstract

Background: The use of the internet for research is essential in the practice of evidence-based medicine. The online search habits of medical practitioners in clinical settings, particularly from direct observation, have received little attention.

Objective: The goal of the research is to explore online searching for information as an evidence-based practice among medical practitioners.

Methods: A cross-sectional study was conducted to evaluate the clinical teams' use of evidence-based practice when making clinical decisions for their patients' care. Data were collected through online searches from 2015 to 2018. Participants were medical practitioners and medical students in a Malaysian public teaching hospital's neonatal intensive care unit who performed online searches to find answers to clinical questions that arose during ward rounds.

Results: In search sessions conducted by the participants, 311 queries were observed from 2015 to 2018. Most participants (34/47, 72%) were house officers and medical students. Most of the searches were conducted by house officers (51/99, 52%) and medical students (32/99, 32%). Most searches (70/99, 71%) were directed rather than self-initiated, and 90% (89/99) were completed individually rather than collaboratively. Participants entered an average of 4 terms in each query; three-quarters of the queries yielded relevant evidence, with two-thirds yielding more than one relevant source of evidence.

Conclusions: Our findings suggest that junior doctors and medical students need more training in evidence-based medicine skills such as clinical question formulation and online search techniques for performing independent online searches effectively. However, because the findings were based on intermittent opportunistic observations in a specific clinical setting, they may not be generalizable.

evidence-based practice; online information searching; information retrieval; information seeking; clinical setting

Introduction

Online Searching Practice for Evidence-Based Medicine

Internet use for information searching has increased significantly since the early 21st century. There has been a significant increase in medical information searching because of the availability of health information online [1-3]. While searching for health information online allows laypeople to learn more about their health, medical experts search for information to make informed clinical decisions for their patients [4,5]. Evidence-based medicine (EBM) refers to the process of seeking medical information to make informed clinical decisions. The definition of EBM is "the conscientious, explicit, and judicious use of current best available clinical evidence, with the integration of clinical expertise, to make clinical decisions for the care of patients" [6]. Because the human brain has limited capacity, EBM allows medical practitioners to make decisions based on validated and reliable evidence. This will improve the overall health care quality by ensuring consistency of care provided to patients through informed clinical decisions [7,8].

Many medical practitioners have reported difficulties encountered while performing an EBM search. Among them are a lack of resources, a lack of search skills and experience, a lack of role models practicing EBM, and a lack of time to practice EBM [9-12]. These are the challenges that online EBM practitioners in resource-limited countries face [9,10,12-15]. One reason for this is the unavailability of adequate resources. As a result, it is critical to comprehend how information is sought during EBM practice in resource-limited country hospitals. Such research is limited and still in its early stages [9]. According to a review of literature from resource-limited countries in this context, interviews and questionnaires are used to investigate the challenges faced by online EBM practitioners [13,16-20]. These research studies may not provide data on real challenges encountered during a live information retrieval process. Examining real and live challenges can provide insight into actual searching behavior in situations where challenges with query expression and results review may arise during the information-seeking process. Thus, there is a need to investigate medical practitioners' true searching behavior during live clinical rounds so that recommendations can be made based on the findings from actual searching challenges that arise during EBM practice.

This study focuses on online EBM practice in a resource-limited country, specifically Malaysia, which meets the World Bank's definition [21]. Early research studies on EBM practices in Malaysia revealed that many medical practitioners are aware of EBM and have used the Cochrane database, and 6.7% of those polled have used MEDLINE to conduct a literature search [13]. According to these findings, the overall uptake of performing online EBM is lower. Malaysia, as a Southeast Asia—Optimizing Reproductive and Child Health in Developing Countries (SEA-ORCHID) project participant, took part in a large intervention project that took place throughout the region [22]. The SEA-ORCHID project sought to investigate how evidence-based teaching and practices are carried out in the departments of obstetrics and gynecology. Despite such an intervention, a recent study found that challenges remain around the knowledge and skills required for conducting searches for relevant information during EBM practice [12,23].

Related Works

According to research, the practice of EBM requires medical practitioners to integrate 3 important aspects during clinical decision making: (1) the medical practitioner's clinical expertise, (2) the best available evidence from multiple resources, and (3) patient values and preferences [8]. The second criterion is closely related to online information-seeking behavior and EBM. It is not the same as searching for information, in general, to be able to use the best available evidence from multiple sources. This is because the practice of EBM is governed by a specific set of procedures. As a result, only EBM-trained medical practitioners and allied health experts are known to be able to practice EBM [24]. Improper EBM practice, especially when searching for evidence, may result in the retrieval of incorrect or inappropriate information, posing threats and risks to patients' lives. Medical practitioners must search multiple resources for validated and reliable evidence to support their medical decisions [24]. When making clinical decisions, medical practitioners were initially encouraged to rely on facts derived from books and printed materials as their primary sources of offline health information [25]. In recent years, however, medical information has been deployed and searched through online resources via information and communication technology (ICT) [26-30]. This indicates a shift in the EBM practice from offline to online. By providing access to online medical information, ICT facilitated the practice of online EBM [31-34].

Furthermore, the emergence of the internet and the World Wide Web sparked the development of online medical search domains and medical databases. Medical search domains and databases are designed with built-in customized search features to assist the searcher in finding relevant medical information in the shortest amount of time. Examples of such online medical search domains are PubMed, UpToDate, and the British Medical Journal. Information seeking is also an important part of the learning process, which includes searching, obtaining, and using information for evidence [35]. According to the findings of research studies, medical practitioners who use specialized medical information retrieval systems find them useful. They specifically reduced the amount of time needed to search for information and made it easier to incorporate searching into their medical workflow processes [4,26,36-38]. Nonetheless, it is critical to ensure that evidence is searched appropriately using ICT to retrieve only validated and reliable medical information during EBM practice [4,38].

Information Searching Process Model

No evidence that explicitly defines the online searching process within the practice of EBM as the practice of EBM moved from offline searching to online searching. As a result, no search models exist to describe online EBM searching. However, EBM guidelines were developed to help medical practitioners practice EBM [24,39-41]. Sackett's 5-step guide, depicted in Figure 1, is the most used guideline, and consists of 5 parts: inquire, access, appraise, apply, and evaluate [6].

As EBM practice has shifted to online, the information searching process (ISP) model (Figure 2) is the closest model that adapts to the online EBM searching process and describes the holistic experience of a typical searcher when searching for information [42]. It is the most appropriate model to explain the ISP within the context of EBM practice because it is a groundbreaking theory that models the holistic approach of a typical searcher. The ISP model is divided into 6 stages: initiation, selection, exploration, formulation, collection, and presentation [42]. All stages in the ISP model are adaptable and can be mapped to the EBM searching process.

When looking at the stages of the ISP model, there are 3 that are related to the online searching process: exploration, formulation, and collection. These stages describe the process of searching for information on the internet, including the formulation and reformulation of queries as well as the collection of desired information. They are analogous to the second step of the EBM guidelines, namely the access phase when practicing online EBM. In the EBM guidelines, the access phase denotes the process of searching for medical information (ie, accessing online resources to obtain information for clinical queries). As a result, the ISP model and EBM guidelines can be better classified as (1) querying behavior and (2) result viewing behavior. A thorough investigation of these behaviors was conducted in this study to provide a better understanding of online information-searching behavior during EBM practice. Another technique for searching for information, described by Bates [43], is insufficient because it involves interaction between the documents to be searched and the systems or browsers used, like the berry-picking process. The search for information will alter the overall search process, requiring users to investigate new information. This will provide the user with new directions to follow, which will change the search terms and queries.

Figure 1. The 5-step guide to practice evidence-based medicine (adapted from Sackett [6]).

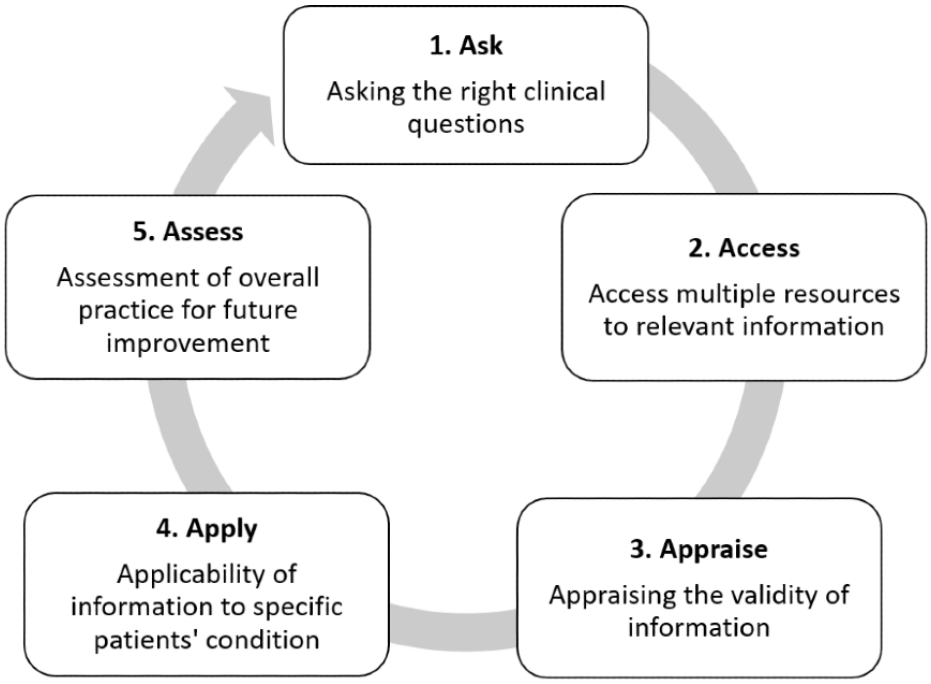

Figure 2. Information searching process model (adapted from Kuhlthau [42]).

Model of the Information Search Process

	Initiation	Selection	Exploration	Formulation	Collection	Presentation	Assessment
Feelings (Affective)	Uncertainty	Optimism	Confusion frustration doubt	Clarity	Sense of direction/ confidence	Satisfaction or disappointment	Sense of accomplishment
Thoughts (Cognitive)	Vague →			Focused →		Increased interest	Increased self-awareness
Actions (Physical)	Seeking relevant information			Seeking pertinent information			
	Exploring →				Documenting		

Previous Studies on Querying Behavior and Result Viewing Behavior

A few previous studies reported on querying behavior during the EBM practice [44-47]. These research studies were conducted on a single search domain and were based on self-perception of the search process. These studies did not include equally important aspects of querying behavior, such as the number of queries issued and query reformulation. According to the findings of research studies examining results viewing behavior during the practice of EBM, challenges are also encountered in this stage of the information seeking process [5,44,48,49]. Therefore, this study aims to explore and describe the online information-seeking behavior of EBM practitioners at the point of care where information-seeking activities were documented. Findings from this study can be used to design initiatives to improve the online searching process during the EBM practice.

Methods

A cross-sectional study was conducted from 2015 to 2018 at the University of Malaya Medical Center, a tertiary teaching hospital in Malaysia.

Setting

This study was conducted in the neonatal intensive care unit (NICU). The unit admitted 30 newborn infants per month on average, all of whom required critical care and constant monitoring. A clinical team of consultants, specialists, medical officers, science officers, nurses, and medical students will conduct clinical rounds at the NICU twice a day, every day (morning and evening). Two portable laptops were placed on a mobile trolley inside the NICU for use during clinical rounds. A few stationary desktop computers were also provided to aid in the search for clinical information. When a clinical question arose, members of the clinical team searched for answers using laptops or desktop computers preloaded with electronic databases such as the Cochrane Library and PubMed. The clinical team was told to search these electronic databases whenever they needed to for clinical queries.

Ethics Approval

This study was approved by the Monash University Human Research Ethics Committee (project ID 4690). Further, the data collection methods for this research study were approved by the medical ethics committee of the University of Malaya Medical Council (MEC ID No. 201311-0506).

Participants

A total of 47 participants were recruited from clinical teams that made clinical decisions for their patients' care by constantly referring to the best empirical evidence. They were routinely involved in online search activities that took place during the study period between December 2015 and December 2018. A research assistant was present during these online activities.

Data Collection

A standardized questionnaire containing information on the demographic characteristics of the participants was used to collect data. The questionnaire also included a structured observation involving the length of the search, time of the search, and method of search (either advanced or simple search) for 2 electronic databases. Before analysis, all data were deidentified. The process was documented through video recordings of the computer screen made with the Morae Manager (TechSmith Corp) key-logging recorder, and search terms were transcribed to a spreadsheet. Whenever a query was entered into the search field (eg, infan* or newborn or neonat* or premature or preterm or very low birth weight or low birth weight or VLBW or LBW) of the web browser or the search field of the search engine, the queries were observed and recorded using the Morae recordings. For both databases, a search strategy was developed. The keywords were identified before the search based on the clinical queries of participants/problems, interventions, comparisons, and outcomes (PICO). Using advanced search and Medical Subject Headings (MeSH) terms, similar terminology for each PICO will be identified. The literature search identified the information in all languages. The information collated included the number of queries, keywords used, length of the query (determined by calculating the number of terms/words used in a single query), use of Boolean operators (such as AND, OR) in queries, proportion of queries with typing and other errors, and the proportion of repeat queries to answer the same clinical question. For postsearch interviews, voice recordings were made and transcribed verbatim using NVivo (version 10, QSR International) software.

Data Analysis

The data were analyzed for descriptive statistics using SPPS (version 22, IBM Corp) software for participant characteristics and online search, including querying pattern, resulting viewing pattern, and search duration. We presented the data collected from postsearch interviews narratively.

Results

Participant Characteristics

The characteristics of the participants are shown in Table 1. The participants included medical students, house officers, medical officers, and specialists.

Table 1. Demographic details of participants.

Variable	MS[a] (n=15)	HO[b] (n=19)	MO[c] (n=8)	Specialist (n=5)
Gender, n (%)

Reason for and Manner of Searches

Of the 99 searches, house officers conducted the most (51/99, 52%), followed by medical students (32/99, 32%), medical officers (10/99, 10%), and specialists (6/99, 6%). Most search activities were directed at junior members of the team, such as medical students and house officers, and self-initiated searches increased with seniority. Most of the search activities were carried out individually, with only a few carried out collaboratively (Table 2). Many participants used simple search strategies that consisted of one or more keywords entered alongside each other without the use of synonyms or any type of Boolean operator.

Table 2. The reason for and manner of searches.

Search type	MS[a] (n=32), n (%)	HO[b] (n=51), n (%)	MO[c] (n=10), n (%)	Specialist (n=6), n (%)
Search initiation

Querying Activity

The querying activity represented the participants' querying patterns during the search sessions. Whenever a query was entered into the search field of the web browser or search engine used to find information, the Morae recordings were observed and recorded. The querying activity's results were presented in terms of participant categories and search types (foreground [FG] or background [BG]). FG refers to the user application and BG refers to the programs that are behind the scene. The results were further classified according to the number of queries issued, average query length, use of medical terms in queries, use of stop words and operators in queries, queries with spelling errors, issuance of ineffective queries, and reissuance of the same query. Table 3 shows the total number of queries issued and average query length.

Table 3. Number of queries issued and average query length of the queries issued.

Query	MS[a] (n=15)		HO[b] (n=19)		MO[c] (n=8)		Specialist (n=5)	
	BG[d] (s=26)	FG[e] (s=6)	BG (s=45)	FG (s=6)	BG (s=8)	FG (s=2)	BG (s=3)	FG (s=3)
Queries issued

Use of Medical Terms

Cross-checking the terms with medical terms in the MeSH library revealed the number of medical terms issued within a query. According to the results, 70.1% (218/311) of the queries issued were medical queries that included some medical terms. The participants used 307 medical terms, with an average of 1.4 medical terms per medical query recorded. The results also revealed that participants who frequently used medical terms in the queries were the house officers, who used an average use of 3.7 medical terms in the queries issued, as opposed to the medical students, medical officers, and specialists, who used a mean number of 2.3, 3.5, and 2.3 medical terms, respectively. The evidence from the participants' verbal utterances suggested that they had included medical terms in their queries to retrieve more relevant results. Table 4 contains information on the medical terms used in the participant queries.

Table 4. Details of the use of medical terms in the queries issued.

Variable	MS[a] (n=15)		HO[b] (n=19)		MO[c] (n=8)		Specialist (n=5)

Use of Stop Words and Boolean Operators

According to the results of the analysis, stop words were used in only 65% (17/26) of the searches. The findings of this study differed from those of previous studies [45,46], which found that stop words were used in 80% of the searches conducted. The remaining searches lacked stop words in their queries, and the vast majority were BG-type searches. When examining the number of stop words used in the queries, FG-type searches had more stop words (1-4 stop words) than BG-type searches (1-3 stop words). The stop words used in this study were "in," "of," "on," "is," "for," "and," and "with." The participants in this study did not frequently use Boolean operators in their queries (Multimedia Appendix 1). Only 4 of the searches had queries issued with Boolean operators, which were issued by the house officers. In this study, the operators used were the double quotation mark, bracket, and AND operator.

Search Activities

A total of 311 queries during 99 search sessions were issued by the participants, with a mean of 3.14 (SD 2.6) queries. Participants who were house officers issued the most queries (51/99, 52%), followed by medical officers (10/99, 10%), medical students (32/99, 32%), and specialists (6/99, 6%). The participants spent an average time of 2.3 hours per day searching for medical information, with a single medical information search lasting 21 minutes on average. The average number of queries issued by all participants ranged between 2 and 4 queries. The mean number of queries issued in the BG- and FG-type search categories differed slightly, with FG-type searches recording 3.5 (SD 2.7) queries, slightly higher than BG-type searches, which recorded 3 (SD 2.6) queries.

In total, 307 distinct medical-related keywords were used in the searches. The length of the participant queries were then checked. The length of a query was calculated based on the number of terms/words used in a single query. The average query length in this study was 3.9 (SD 1.76) words. Specifically, the mean query length for FG-type searches was 5.2 (SD 2.6) words, which was higher than the mean query length of BG-type searches, 3.71 (SD 1.4) words. Query length averages issued by house officers and medical officers were comparable, at 3.6 and 3.7 terms, respectively. Multimedia Appendix 2 depicts the issuance of queries with spelling errors, ineffective queries, and the reissuance of the same query. A total of 4% (4/99) of searches used Boolean operators, with "AND" being the only one. Spelling errors were found in 6.8% (21/311) of the queries. Participants were aware of the errors made after the search and reran the searches with the correct spelling.

Result Viewing Activity

The number of results and sublinks clicked, number of tabs used to view results, and control functions used in searches were used to analyze participant result viewing activity. When participants used the search engine to access a specific link or webpage after the queries were issued, the number of results clicked was displayed (Multimedia Appendix 3). According to the findings of this study, 377 results were clicked when looking for information. Of these, 302 came from BG-type searches and the rest from FG-type searches. The mean number of results clicked in this study was 3.81 (SD 3.11). According to the data, the mean number of results clicked in FG-type searches was 4.41 (SD 3.043), while the mean number of results clicked in BG-type searches was 3.68 (SD 3.13). This indicates that there was a higher level of result viewing activity when searching for FG-related information.

When participants proceeded to click on the links presented in the result clicked/webpages visited, the number of sublinks clicked was recorded. In this study, the mean number of sublinks clicked was 1.27 (SD 2.43), with the mean value being higher in FG-type searches (1.82, SD 3.067) compared to BG-type searches (1.16, SD 2.29). The participants' verbal utterances revealed that they clicked on the sublinks during the FG-type searches because of progressive searching within a result/webpage to gain a better understanding of the subject matter being searched.

An interesting pattern in the use of multiple tabs during searching was discovered during the analysis of the result viewing activity (Multimedia Appendix 4), which depicts the number of tabs opened and control functions used by participants. Of the total searches observed, 65.6% of participants viewed their results in more than one tab. The mean number of tabs used was 3.15 (SD 2.86). The mean number of tabs in FG-type searches was 4.29 (SD 3.53) compared to 2.91 (SD 2.66) in BG-type searches. This indicates that more tabs were opened during the result viewing process in FG-type searches than in BG-type searches. Participants who used control functions indicated that they were successful in finding the information they were looking for.

The analysis of the result viewing activities of the participants revealed the use of control functions when viewing results or webpages. In the postsearch interview, participants who had used control functions in their searches were asked why they had done so. Their responses were: "to improve the searching process" and "to skim through important content only." In their result viewing activity, only 4 BG searches by a medical officer and 3 by medical students used control functions. CTRL-F (in 2 searches) and CTRL+ were the control functions used in this study. The CTRL-F function was used to search the information on the results page for terms like "defin," "1P," "size," "mm," and "pda." In the results presented, the CTRL+ function was used as a zoom-in function to improve the viewing of images and text.

Discussion

Principal Findings

Previous studies evaluating search practices in health care trainees and practitioners relied heavily on participant perceptions of previous searches [13,23,44-47,50-52]. There have been no studies that have assessed search activities in an acute clinical setting based on direct observation of real-time searches as far as we are aware. Despite limitations in the period of engagement due to restrictions related to the nature of the NICU and disruption of the study period, our observations yielded useful information. The majority of those who took part were house officers who had been ordered by their superiors to

conduct searches, usually alone. There were 3 queries per search session on average, with 4 words used in each query. Relevant evidence appeared to be found in more than three-quarters of cases, and in roughly two-thirds of cases, there was more than one source of relevant evidence. Junior members of the clinical team who were tasked with conducting searches to answer multiple questions posed by senior team members in a short time may encounter difficulties in locating the best evidence. This included ownership of queries, content expertise, search techniques, and the absence of another person to provide input into the search process. Due to time constraints or a lack of clarity in terms of the questions posed, the challenges may have resulted in errors and ineffective searches that were not followed up on. Identifying the best evidence among multiple sources could also be difficult, although this study did not assess how the searchers dealt with this. It has been demonstrated that increasing the use of medical terms in queries increases the likelihood of retrieving the desired information [45,46]. If well chosen from a focused clinical question, the average query length of 4 words in this study was usually sufficient for an effective quick search to retrieve some relevant evidence, either in a repository of primary studies such as PubMed or in preappraised resources such as the Cochrane Library [53].

There have been no previous studies that have reported findings on the result clicking behavior among medical students in terms of result viewing activity. In this study, the medical students used search tabs more frequently when looking for FG-related information. In addition, when compared to house officers, medical officers, and specialists, medical students used the most tabs while searching. When viewing the results of the click, the control functions were also used. In terms of the number of sources accessed, medical students accessed the fewest in the BG-type searches. The medical students indicated PubMed and MEDLINE as their preferred sources of information based on the searches they conducted.

In this study, house officers demonstrated the most active search behaviors. When compared to medical students, medical officers, and specialists, they conducted the most overall searches (54.5% of the total searches recorded in this study). During searches, house officers had the most querying activity (the highest average number of queries issued, the highest number of stop words used in queries issued for FG-type searches, the highest number of queries issued with spelling errors, and the most ineffective queries). The findings of this study contradict previous findings, which indicated a lower number of queries issued when participants searched for EBM-related information [44,45,47].

The medical officers' search behaviors in this study were straightforward. They had completed 10.1% of all recorded searches, with 80% yielding successful outcomes. In their querying activity, they demonstrated simple search behaviors by issuing a higher average number of queries and a longer average query length. They also used the fewest stop words in both their FG- and BG-type searches, had no spelling errors in their queries, and included medical terms in all of their FG-type searches. Although the simple search behaviors demonstrated by medical officers were effective in producing successful outcomes, the findings of this study do not agree with previous research findings. Previous research found that the number of queries issued was lower and the average query length was shorter [44,45,47].

In this study, the specialists displayed 2 types of searching behaviors: uncertain and expert. The specialists' uncertain behavior was mirrored in their querying activity. Specialists issued the most queries in FG-type searches compared to BG-type searches, the longest average query length in BG-type searches, the fewest medical terms used in FG-type searches, and the most stop words used in all BG-type searches. In addition, specialists issued a greater number of ineffective queries in their BG-type searches than in their FG-type searches. Such behaviors by specialists were classified as uncertain and differed from previous studies, which reported fewer queries issued, a greater number of medical terms used, and the use of stop words to prevent the searcher from searching for their desired information [44-47,54]. This uncertain behavior of the specialists indicates the need for better information retrieval strategies to improve their online searching behaviors during the EBM practice. The findings point to a possible focus on training to improve the effectiveness of searches. These include the target participants of junior doctors and medical students, techniques for converting clinical encounter queries into well-constructed questions with relevant keywords, recognition of types of research that are most likely to answer specific questions, ranking of keywords to determine their order in searches, and appropriate use of Boolean operators.

Limitations

Our study has some limitations. First, our findings may not be generalizable because they were conducted in a clinical practice setting with a specific team structure and facilities. Although most hospitals have a hierarchical structure like the one used in our study, the nature of task delegation, particularly in information retrieval, may differ across countries. Furthermore, because the search sessions recorded in this study were limited to selected morning clinical rounds, the information gathered over a very limited cumulative engagement period may not represent the participants' true search behaviors. The type and amount of prior training received by the searchers may differ, which may result in different search patterns and results. On the other hand, as part of evidence-based practice, the NICU studied was provided with devices conducive to online searching and such facilities may not be widely available in places with limited resources.

Conclusion

In conclusion, our study found that junior doctors were the primary individuals tasked with searching for clinical evidence in the NICU of a tertiary hospital in Malaysia. They mostly searched on their own, using simple, quick search strategies based on a few keywords. In three-quarters of the cases, they recovered what appeared to be relevant evidence, failing in one-quarter of the cases. This suggests that different search behavior profiles are required among the various types of EBM practitioners. The searches recorded in this study were based on clinical problems encountered by the EBM practitioners to reflect the participants' true search behaviors. According to the findings of this study, different online searching behaviors were

observed during the practice of EBM among different types of EBM practitioners. More research should be conducted on the facilitators and challenges of real-time searches in clinical settings, types of questions asked, and quality of evidence retrieved, as well as the association between effective evidence retrieval and the provision of best evidence in guiding care and improvement in patient-important outcomes.

Acknowledgments

We thank the Director General of Health, Ministry of Health, Malaysia for the permission to publish this article. This research was funded by the Ministry of Education in Malaysia under the Fundamental Research Grant Scheme (FRGS/2/2013/ICT02/MUSM/03/1).

Authors' Contributions

NAM, VS, and AD designed the study, performed the data collection, and wrote the first draft of the manuscript. NAM, AI, NSMD, and NC performed the data analysis and wrote the first draft of manuscript. NML supervised the study and wrote the first draft of manuscript. All authors have reviewed the manuscript.

Abstract

Background: Psychological factors (eg, depression) and related biological and behavioral responses are associated with numerous physical health outcomes. Most research in this area relies on self-reported assessments of psychological factors, which are difficult to scale because they may be expensive and time-consuming. Investigators are increasingly interested in using social media as a novel and convenient platform for obtaining information rapidly in large populations.

Objective: We evaluated the feasibility of obtaining Facebook data from a large ongoing cohort study of midlife and older women, which may be used to assess psychological functioning efficiently with low cost.

Methods: This study was conducted with participants in the Nurses' Health Study II (NHSII), which was initiated in 1989 with biennial follow-ups. Facebook does not share data readily; therefore, we developed procedures to enable women to download and transfer their Facebook data to cohort servers (for linkage with other study data they have provided). Since privacy is a critical concern when collecting individual-level data, we partnered with a third-party software developer, Digi.me, to enable participants to obtain their own Facebook data and to send it securely to our research team. In 2020, we invited a subset of the 18,519 NHSII participants (aged 56-73 years) via email to participate. Women were selected if they reported on the 2017-2018 questionnaire that they regularly posted on Facebook and were still active cohort participants. We included an exit survey for those who chose not to participate in order to gauge the reasons for nonparticipation.

Results: We invited 309 women to participate. Few women signed the consent form (n=52), and only 3 used the Digi.me app to download and transfer their Facebook data. This low participation rate was observed despite modifying our protocol between waves of recruitment, including by (1) excluding active health care workers, who might be less available to participate due to the pandemic, (2) developing a Frequently Asked Questions factsheet to provide more information regarding the protocol, and (3) simplifying the instructions for using the Digi.me app. On our exit survey, the reasons most commonly reported for not participating were concerns regarding data privacy and hesitation sharing personal Facebook posts. The low participation rate suggests that obtaining individual-level Facebook data in a cohort of middle-aged and older women may be challenging.

Conclusions: In this cohort of midlife and older women who were actively participating for over three decades, we were largely unable to obtain permission to access individual-level data from participants' Facebook accounts. Despite working with a third-party

developer to customize an app to implement safeguards for privacy, data privacy remained a key concern in these women. Future studies aiming to leverage individual-level social media data should explore alternate populations or means of sharing social media data.

Introduction

Substantial research has demonstrated that psychological factors (eg, depression and optimism) and their related biological and behavioral responses are associated with physical health and the risk of chronic diseases of aging [1-3]. The majority of research in this area relies on self-reported assessments of psychological factors, which can be difficult to scale because they can be expensive to administer and time-consuming to complete, and therefore impose substantial burdens on participants and investigators. As a result, investigators are increasingly interested in social media as a novel and convenient platform for obtaining information efficiently in large populations. Developing such low-cost low-burden methods for unobtrusively obtaining assessments of psychological factors at the individual level, which can then be linked with individual health and other types of data, may expand capacity and efficiency for examining how psychological factors impact health.

A small but growing body of research suggests that various psychological factors can be measured using machine learning–derived algorithms that harness social media "big data." For example, a recent study leveraged text from 5100 public Facebook status updates and built models to assess an individual's level of psychological well-being (characterized by positive emotions and meaning/purpose in life) embedded within any particular Facebook status update. When comparing algorithm-derived scores with scores annotated by human raters, investigators found moderate correlations of 0.4-0.6 [4]. In another study of 66,732 Facebook users using anonymous data, researchers created an algorithm to estimate other psychological factors similar to Big 5 personality measures; correlations between self-reported and algorithm-based scores derived from social media similarly ranged from 0.4 to 0.5 [5]. Moreover, research has suggested that measures of psychological functioning derived from social media can be used to predict health status. One study examined Twitter posts in 1347 US counties, covering 88% of the US population, and derived measures of psychological functioning using machine learning [6]. Each county was then scored according to levels of negative and positive psychological factors (eg, anger, anxiety, positive emotions, and engagement), and cross-sectional analyses evaluated if these factors were related to county-level rates of heart disease mortality. The psychosocial measures derived from Twitter language were strongly associated with heart disease mortality rates.

However, most studies using social media data to assess psychological functioning in relation to health are ecological (eg, county-level psychological and health data) and cannot link individual-level psychological measures derived from social media to individual-level health outcomes [7,8], a critical methodological element for making causal inferences. Thus, it is important to test the use of social media platforms for individual-level research in cohort studies, where information on demographics and lifestyle, as well as longitudinal data on chronic diseases are available, and enable both the identification of direct relationships and control of potential confounding factors. In particular, Facebook is the most widely used social media platform in the world, with over 2.7 billion users [9]. It has the potential to provide a substantial amount of data on individuals who are posting large quantities of text over extended periods. Moreover, while the majority of Facebook users are young adults, 22% of users are over 45 years of age [10]. To our knowledge, social media approaches to psychological measurement have not been applied in prospective cohort studies of midlife and older adults. Linking psychological factors derived from social media with rich epidemiological data from large prospective studies of midlife and older adults could enable the rigorous and efficient understanding of new perspectives on psychological factors and health outcomes. Therefore, we leveraged the Nurses' Health Study II (NHSII), an ongoing cohort study of women aged 56 to 73 years in 2020, to examine the feasibility of obtaining participant Facebook data to derive measures of psychological factors.

Methods

Study Population

The NHSII is a prospective cohort study that was launched in 1989 among 116,429 US female nurses aged 25 to 42 years at the study onset. At baseline, all participants completed a questionnaire including basic sociodemographic characteristics, lifestyle factors, and medical conditions. The cohort was originally followed using biennial mailed questionnaires to update information on these factors and further assess psychosocial factors. Approximately 60,000 of the women now complete questionnaires online; the follow-up rate since study inception is nearly 90% [11].

The 2017-2018 online questionnaire assessed psychosocial factors, such as optimism, depression, and social support. Items also requested information regarding participants' use of social media. Specifically, the questionnaire included the following items: "Do you regularly post updates or information on social media (rather than just viewing or *liking* posts)?" Among women who answered "yes," a follow-up question asked which of the following sites participants used: (1) Facebook, (2) Instagram, (3) Twitter, and (4) other. Ultimately, 18,519 participants reported regularly posting on Facebook. Very few (7%) reported

using other social media outlets. Thus, in April 2020, we initiated the study to request Facebook data.

Protocol

Obtaining Facebook Data

When collecting any type of individual-level data, privacy is an important concern, and this concern is potentially magnified when collecting information on individuals that was not originally intended for use in a scientific study. At the time this study was initiated, Facebook was not sharing personal data for investigators to use in the context of scientific research. Thus, such data could only be obtained directly from participants. To reduce privacy concerns, we chose to ask participants only for text from Facebook posts they wrote and did not ask for any other content, including photos, links, or posts written by friends. We worked with third-party software developers at Digi.me to modify a program that would enable participants to obtain their own Facebook data and then to send the text of their posts only to our research team securely. The original Digi.me app enables individuals to obtain and store their own digital content from various sources (eg, finances, health, and social). For our study, we customized the original app, including a process by which Facebook text could be securely transferred from each participant to the NHSII server. We also developed simple instructions for use. The NHSII Digi.me app transferred only the text of participants' Facebook posts.

Ethics Approval

The Brigham and Women's Hospital Institutional Review Board and Information Security Office conducted an ethical review and a security review of the modified app, as well as the research protocol, and granted approval for the study (2018P002265).

Participant Recruitment and Consent

An email invitation was sent to a random subset of the women who reported being regular Facebook users in 2017-2018. The email included a brief description of the study and an informed consent form. If consent was given, participants received an email with instructions for using the NHSII Digi.me app. The app enabled them to (1) securely and privately download their individual Facebook posts, and (2) encrypt and securely send their Facebook text to NHSII servers, to be stored behind a firewall. Participants were informed that Digi.me only enables the secure transfer of information and does not see data at any point.

Recruitment Waves

We conducted 3 waves of recruitment. In the initial data collection (Wave 1) occurring in April 2020, we invited a random subset of 40 eligible participants by email. We began the work slowly by inviting a small random subset of eligible participants instead of inviting all participants at once because the Facebook study involved new technology (eg, Digi.me) and potentially large amounts of data transfer. In the second data collection wave (Wave 2), occurring between June and September 2020, we sent the invitation email to a further 269 randomly selected eligible women. In a separate step in September 2020 (Wave 3), we sent an email to participants who had consented to provide their Facebook text but had not transferred their data. The email contained information describing how we had fixed a technological issue, simplified the instructions for the use of Digi.me, and explained that anyone still interested could try to send their Facebook text.

Measures

Our primary outcomes were the following 2 feasibility measures: the percentage of invited participants who consented to share their Facebook data, and the percentage of invited participants who ultimately provided their Facebook posts. We also conducted an exit survey for eligible women who declined to participate in the Facebook study. These women received a single multiresponse question by email. Women were asked to indicate the reasons why they refused to participate with the following 5 response options: (1) lack of time due to increased work responsibilities, (2) lack of time overall, (3) discomfort using Digi.me because of privacy concerns, (4) discomfort using Digi.me because of dislike of technology/apps, and (5) discomfort about sharing Facebook posts. An open-ended response option was also provided. We chose to do an exit survey to gather data on recruitment and participation in the least burdensome way possible for participants.

Statistical Analysis

We conducted descriptive analyses (ie, percentages, means, SDs, and frequency tables) examining the demographic characteristics of participants who were eligible for the study, the percentage of women who consented to send Facebook data, the percentage of women who provided Facebook posts, and the responses to the exit survey.

Results

Descriptive Data

Among the 18,519 women who reported regular Facebook use (Table 1), ages ranged from 56 to 73 years, with a mean age of 65 years (SD 4.7 years). Overall, 93.8% (17,361/18,519) were White, 73.2% (13,549/18,519) were married, and 82.4% (15,261/18,519) lived in an urban area. The median census home value was US $165,000 (SD US $115,000).

Table 1. Characteristics of women eligible for the study to collect Facebook posts (Nurses' Health Study II, 2020; N=18,519).

Characteristic	Value
Age (years), mean (SD)	65.4 (4.7)
Race, n (%)	
White	17,361 (93.8)
African American	160 (0.9)
Other	998 (5.4)
Marital status, n (%)	
Married	13,549 (73.2)
Divorced/separated	3,506 (18.9)
Widowed	739 (4.0)
Missing	725 (3.9)
Median home value (census tract; US$), mean (SD)	165,000 (115,000)
Urbanicity of residence, n (%)	
Urban	15,261 (82.4)
Suburban	1,830 (9.9)
Small town/rural	1,424 (7.7)
Missing	4 (0.0)

Wave 1 Data Collection

Of the 40 women invited, only 4 (10%) participants signed a consent form. Given the low initial participation rate, we paused recruitment to consider potential reasons and modify our strategy accordingly. We identified several possible concerns regarding the initial lack of participation: (1) the first surge of cases due to the COVID-19 pandemic crisis was occurring at the time, and this may have impacted participation among our nurse participants, and (2) the brief invitation email may not have adequately addressed possible participant concerns regarding the technological burden and personal data sharing involved in the Facebook study. Thus, we modified the study in several ways. First, we excluded women who reported on the 2019 NHSII questionnaire that they were active health care workers. Second, we developed a Frequently Asked Questions factsheet and included it as a link in the invitation emails; this factsheet included more detailed information regarding the steps required to use the technology and the actions we had taken to maximize data security and privacy (eg, encryption). Finally, as described previously, we also included the exit survey inviting women who did not want to participate to provide their primary reasons for not participating.

Wave 2 Data Collection

Of the 269 randomly selected participants invited in Wave 2, 48 women (17.8% of Wave 2 invited participants) completed a consent form to participate in sharing their Facebook posts. Among these 48 women, 3 used the Digi.me app to send their Facebook posts (1% of Wave 2 invited participants). Further, 23 women who did not complete the consent form responded to the brief exit survey describing their concerns about participation (Table 2). Each participant could provide more than one response. Of the 23 women, 3 (13.0%) noted that they did not have time to participate, 8 (34.8%) indicated they had concerns regarding privacy, 1 (4.3%) indicated not liking the use of apps, and 12 (52.2%) indicated they did not want to share all the information in their Facebook posts. In addition, 6 women (26.1%) provided written comments in the space for "other concerns;" these mostly involved comments that they had stopped using Facebook or used it only in a very limited way. Further, on receiving the Facebook text from 3 participants, we identified some problems in the data transfer; the 3 women also emailed that they found the directions for using Digi.me somewhat complex. Thus, before initiating a third wave of invitations, we fixed the data transfer issue and also simplified the instructions for using Digi.me.

Table 2. Reasons for choosing not to participate in the study to send Facebook text (Nurses' Health Study II; N=23).

Reason provided in the survey[a]	Value, n
I am working more than usual and do not have time	2
I would have been interested in participating if I had more time	1
I don't feel comfortable using digi.me because of privacy concerns	8
I don't feel comfortable using digi.me because I do not like technology/apps	1
I don't feel comfortable sharing my Facebook posts	12
Other	6

[a]Women were requested to mark all responses that were relevant to them.

Wave 3 Data Collection

In the third data collection that occurred in September 2020, we sent an email to a total of 49 women (15.9% of all invited participants) who had consented to provide their Facebook text but had not transferred the data. The email explained that we had fixed a technological issue and simplified the instructions for use of Digi.me, and that anyone still interested could send their Facebook text. However, we received no additional data transfers.

Of the 309 participants invited overall, 52 consented (16.8%) and 3 attempted to transfer data (1.0%). On carefully considering the low rate of participation, we decided to end the Facebook study and did not send invitations to the remaining eligible women.

Discussion

The goal of this study was to examine the feasibility of using social media data to assess psychological factors, and ultimately examine if these passively measured factors were associated with health outcomes. We queried middle-aged to older women in an ongoing cohort study, the NHSII, on their use of social media. A substantial number reported regularly posting on Facebook (approximately 28%), and few reported using other platforms (eg, 5% Instagram and 2% Twitter) [12]. Working with an industry partner, we developed a customized app to enable participants to download their Facebook data and to transfer Facebook text to the cohort servers using highly secure processes. However, despite providing information about their health and behavior for over three decades on biennial questionnaires and giving biospecimens (eg, blood and toenails) on more than one occasion, very few women agreed to share their Facebook data for cohort research. On exit surveys, women noted that the key issues were concerns about sharing social media data and worries about privacy.

Much of the research to date considering social media data in relation to health has relied on ecological-level data, namely using county-level aggregated social media data from Twitter and linking the data to measures of health status from the same counties [6,13]. Other work has used a computational approach to identify publicly available social media data from the profiles of users who self-disclose health status information in some way, without any means to verify the health information [14,15] and with little available information on other potential confounding factors (eg, sociodemographics, health status, and lifestyle factors). Such work can provide important insights and novel strategies for identifying public health concerns (eg, rising rates of depression) [16]. However, additional insights may be gained by linking social media–derived measures of psychological or behavioral functioning with individual-level health outcomes.

The few early studies seeking to collect this type of data seemed encouraging. For example, in a study of patients in an emergency department, researchers approached individuals over a 26-month period to invite participants to share Facebook postings as well as data from medical records [17]. Of 11,224 individuals who were approached, 2903 consented and were eligible. Among these, 1175 participants (44%) were able to log into their Facebook accounts and share their data with the investigators through an app. Notably, the mean age of consenting individuals was 29 years, and the majority were Black women. Another study recruited 223 participants, primarily psychiatric patients, to participate in a study examining if Facebook data could differentiate participants with different psychiatric diagnoses, drawing on individual-level psychiatric data from medical records [14]. The mean age of the participants was 24 years, with majority being female and White individuals. In a similar study, other authors recruited participants from an emergency room to obtain social media data and access to their electronic health records. Of the 5256 individuals approached, 2717 (52%) were Facebook and/or Twitter users, and among the social media users, 1432 (53%) agreed to participate in the study. Of these participants, 1008 (71%) consented to share their social media data for the purpose of comparing the data with their electronic medical records [7]. Participants who were willing to share their social media data were younger (29.1 years among sharers vs 31.9 years among nonsharers), more likely to be Black, less likely to be White or Asian, and more likely to frequently post on social media. Clearly, there are many differences between these studies and our study, from the average age of participants to the very short-term requirements and data storage of these studies (ie, in contrast to NHSII research in which data are continually stored and utilized for decades).

In a recent study seeking to characterize the willingness of individuals to share 19 different types of digital data (eg, email, fitness tracker, voting history, and Google search) [8], of 595 individuals at an academic urban emergency department who were invited to participate, 206 consented and about half of

these expressed willingness to share some form of digital data. The majority of participants were young (70% were less than 44 years old), female, and Black. However, it is worth noting that among those who did participate, fewer than 50% of participants reported current willingness to share Facebook (or similar) digital data, and many identified substantial concerns around potential data and privacy breaches related to sharing digital data in general. As noted in this study, concerns about privacy may have been exacerbated after 2018, when the public learned that some companies were able to access the data of many millions of individuals' Facebook accounts without their permission.

In this study, many of the women who did consent to provide Facebook data subsequently did not download and send their data to the cohort. In the typical NHSII protocol, women provide data by filling out a detailed questionnaire every other year, which can be sent via mail or completed online. In the substudy, women needed to engage in multiple steps to provide their data, including downloading an app, creating an account on a cloud provider, linking this account to the app, and downloading and then transferring their data to the NHSII servers. Thus, the process for participating in this study required comfort with digital interfaces more than most prior data collection activities in the cohort.

In addition, women identified privacy concerns as a barrier to participation. Prior to conducting this research, we were highly sensitive to potential concerns women in our cohort might have about data privacy, particularly in the aftermath of reporting on breaches of data privacy in the context of Facebook in 2018. To reduce concerns about breaches, we worked with Digi.me, a company dedicated to facilitating individuals' control and use of their own digital data with safeguards for privacy. The app made it possible for women to download their Facebook data and then to securely transfer the relevant data to our research database. As noted above, to reduce concerns about privacy, we committed to obtaining only text, rather than images or posts from friends. Together with Digi.me, we invested substantial time and effort to customize the app to make it possible to curate the data we obtained, as well as to provide simple instructions and maximize data privacy and security. Despite these efforts, the participation rate in our study was low. Thus, it is possible that social media research may be better suited to populations who more frequently use digital apps, which may explain the higher participation rates in previous studies of younger populations [7,14,17].

The limitations of this study include the potential lack of generalizability of our findings to other populations. Our study population was made up of women who were 56 to 73 years of age, primarily white, and educated professionals. Therefore, care should be taken in extrapolating our results to other demographic groups. In addition, the potential participants were members of a long-term cohort, who have provided a large amount of personal and health data to the study previously, which may have influenced their willingness to contribute Facebook data. However, as the participants, who have developed a relationship of trust with the research for decades, did not feel comfortable sharing their Facebook data, the results would plausibly be worse in newer cohorts. Our exit survey was brief and therefore somewhat limited in that we could not tease out the exact or specific reasons why participants did not feel comfortable sharing their Facebook posts. Eventually, in this type of research, one limitation of deriving psychological factors from Facebook data is that Facebook, or other organizations, may commoditize the data for uses that are not directed toward benefitting society, for instance, targeted advertising. Although our study protocol was not successful in obtaining Facebook data or developing algorithms for deriving psychological factors using Facebook data, other researchers should be aware of the potential ethical implications of building these tools and using these data for research. Finally, another limitation of our approach is that recruitment took place during the COVID-19 pandemic. That said, the study protocol was entirely web-based, and we excluded nurses who were active health care workers, so it is unclear how the pandemic might have affected participation.

The question remains as to the range of paths for scientific research to leverage individual-level social media data to inform our understanding of health and well-being among midlife and older individuals. Future work seeking to leverage social media data to understand health will need to carefully consider the populations under study, especially barriers in recruiting older individuals who may be less familiar with such technology, and solutions for enhancing participation. In addition, researchers should conduct qualitative work to understand better how participants interact with social media, including what type of information they are willing to disclose and how they might curate their image on social media. Besides the challenges we identified, social media platforms and apps are changing rapidly, and the frequency of use and the tools developed for accessing platforms may evolve quickly. This is an area of research that must be fast-paced by definition, while infrastructure (especially processes for ensuring ethical research practices) for conducting medical research necessarily moves much more slowly. In conclusion, individual-level research using social media data will best proceed with a clear understanding of the barriers and challenges existing in specific populations and in doing research in a rapidly changing data environment.

Acknowledgments

This work was supported by National Institutes of Health grants R01AG053273, R00CA201542, K99AG055696, U01CA176726, and R01CA67262. This work was also supported by funding from the McLennan Family Fund at Harvard TH Chan School of Public Health (Developing novel social media-derived measures of psychological well-being and other health assets for studies of health and longevity). CTF received salary support from the Lee Kum Sheung Center for Health and Happiness. We thank the participants and staff of Nurses' Health Study II for their valuable contributions. We thank the Channing Division of Network Medicine for their support.

Abstract

Background: Just-in-time adaptive interventions (JITAIs) provide real time *in-the-moment* behavior change support to people when they need it most. JITAIs could be a viable way to provide personalized physical activity (PA) support to older adults in the community. However, it is unclear how feasible it is to remotely deliver a PA intervention through a smartphone to older adults or how acceptable they would find a JITAI targeting PA in everyday life.

Objective: The aims of this study are to describe the development of *JitaBug*, a personalized smartphone-delivered JITAI designed to support older adults to increase or maintain their PA level, assess the feasibility of conducting an effectiveness trial of the JitaBug intervention, and explore the acceptability of JitaBug among older adults in a free-living setting.

Methods: The intervention was developed using the Behavior Change Wheel and consisted of a wearable activity tracker (Fitbit) and a companion smartphone app (JitaBug) that delivered goal-setting, planning, reminders, and JITAI messages to encourage achievement of personalized PA goals. Message delivery was tailored based on time of day, real time PA tracker data, and weather conditions. We tested the feasibility of remotely delivering the intervention with older adults in a 6-week trial. Data collection involved assessment of PA through accelerometery and activity tracker, self-reported mood and mental well-being through ecological momentary assessment, and contextual information on PA through voice memos. Feasibility outcomes included recruitment capability and adherence to the intervention, intervention delivery *in the wild*, appropriateness of data collection methodology, adverse events, and participant satisfaction.

Results: Of the 46 recruited older adults (aged 56-72 years), 31 (67%) completed the intervention. The intervention was successfully delivered as intended; 87% (27/31) of the participants completed the intervention independently; 94% (2247/2390) of the PA messages were successfully delivered; 99% (2239/2261) of the Fitbit and 100% (2261/2261) of the weather data calls were successful. Valid and usable wrist-worn accelerometer data were obtained from 90% (28/31) of the participants at baseline and follow-up. On average, the participants recorded 50% (7.9/16, SD 7.3) of the voice memos, 38% (3.3/8, SD 4.2) of the mood assessments, and 50% (2.1/4, SD 1.6) of the well-being assessments through the app. Overall acceptability of the intervention was very good (23/30, 77% expressed satisfaction). Participant feedback suggested that more diverse and tailored PA messages, app use reminders, technical refinements, and an improved user interface could improve the intervention and make it more appealing.

Conclusions: This study suggests that a smartphone-delivered JITAI is an acceptable way to support PA in older adults in the community. Overall, the intervention is feasible; however, based on user feedback, the JitaBug app requires further technical refinements that may enhance use, engagement, and user satisfaction before moving to effectiveness trials.

mobile health; mHealth; sedentary lifestyle; digital health intervention; intervention design; feasibility study; aging; mobile phone

Introduction

Background

The importance of physical activity (PA) for healthy aging is well recognized. Alongside a reduced risk of mortality [1], cardiovascular disease [2], and metabolic disease [3], engagement in PA and exercise has been linked with lower levels of depression [4] and elevated quality of life and well-being [5]. Long-term PA has been shown to protect against vascular decline in old age [6], and there is convincing evidence that PA can reduce risk of falls [7] and prevent osteoporosis [8] in older adults. Despite these wide-ranging health benefits, approximately 1 in 4 adults is insufficiently physically active [9]. Given that PA levels tend to decline with age [10], older adults are among the least physically active segments of the population, leaving them at greater risk of chronic conditions and disability.

Interventions designed to promote PA in community-dwelling older adults are effective in increasing PA as well as improving self-efficacy and quality of life [11,12]. Most interventions have incorporated lifestyle counseling and health education elements, typically delivered face-to-face in the home, general practice, or community setting and supported by scheduled remote contact to encourage further involvement in PA [11]. However, such approaches are resource intensive, likely inaccessible to those from remote communities, and cannot fully support the dynamic nature of PA behavior. Furthermore, the recent COVID-19 pandemic has highlighted the need for scalable interventions that do not rely on face-to-face delivery.

Digital health behavior interventions have emerged as a solution to some of these challenges. Early internet-based studies have demonstrated some success in increasing PA and reducing sedentary behavior in both adults [12,13] and older adults [14]. More recently, focus has shifted to mobile health (mHealth) interventions, which offer additional advantages, including on-demand tailored support and the potential for broad reach, scalability, and cost-effectiveness in comparison with face-to-face approaches [15]. Just-in-time adaptive interventions (JITAIs) are a type of mHealth intervention that provide real time *in-the-moment* behavior change support to users when and where it is needed and depending on an individual's changing needs [16]. The principle is that JITAIs can be more effective than standard mHealth approaches by addressing the dynamic nature of behavior and capitalizing on the changing states of *vulnerability* (need), *opportunity* (namely heightened susceptibility to positive behavior change), and *receptivity* (when someone is able and willing to receive and process just-in-time support) [17]. To do this, JITAIs typically rely on data from the Internet of Things, sensors, connected smartphone apps, or other environmental or contextual inputs.

In the context of PA, JITAIs use activity-tracking data collected through smartphones or wearables to deliver personalized PA prompts at the right time. However, an effective JITAI requires continuous updates from an activity tracker, which represents a significant technical challenge. Currently, only commercially available activity trackers can meet this need. Although activity data can be leveraged from consumer-grade devices such as smartphones, smartwatches, and activity trackers [18], modification of proprietary algorithms is not usually possible. As such, researchers are often forced to develop interventions that match the app's features, rather than developing an evidence-based intervention and then planning features to align with the intervention [19]. To use data from consumer-grade devices in a theoretically robust mHealth intervention, it is necessary to build a stand-alone but complementary mode of intervention delivery, such as a smartphone app.

Research on JITAIs has, to date, been limited to young or middle-aged populations and community settings such as the workplace, universities, and secondary care [16]; none has targeted older adults in a free-living setting. To address this, as well as the aforementioned issues, we developed a JITAI delivered through a bespoke companion mobile app to help older adults increase or maintain PA levels. This was particularly pertinent because we developed the app in response to the first COVID-19 pandemic–induced lockdown in the United Kingdom, and older adults were identified as being at higher risk from COVID-19 complications than their younger counterparts.

Objectives

The aims of this paper are three-fold: to (1) describe the development of the *JitaBug* app and intervention, (2) examine the feasibility of conducting a larger definitive trial on the effectiveness of the JitaBug intervention, and (3) explore the acceptability of the intervention among older adults in a free-living setting. We hypothesized that it would be possible to use a commercial app for continuous activity–monitoring purposes, while also being able to deliver our own JITAI, grounded in behavior change theory, with custom messaging, and tailoring variables through our companion app.

Methods

Development and Design

The JitaBug intervention was developed during the COVID-19 pandemic in 2020 to maintain or improve PA behaviors in at-risk older populations. The intervention was developed using the

Behavior Change Wheel [20], a theory-driven framework based on several models of health behavior that facilitates the systematic development of behavior change interventions. It is underpinned by the *COM-B model*, which is based on 19 existing frameworks of behavior and consists of three necessary conditions for a given behavior to occur: (1) capability, (2) opportunity, and (3) motivation. The development process involved six steps: (1) defining the problem (in this case reduced PA in older adults because of COVID-19–related restrictions), (2) selecting and specifying the target behavior (increasing daily PA levels at home), (3) identifying the COM-B components and psychological determinants to be addressed for behavior change (behavioral diagnosis), (4) using the APEASE (Acceptability, Practicability, Effectiveness, Affordability, Side-effects, and Equity) criteria to identify appropriate intervention functions, (5) selecting appropriate behavior change techniques (BCTs) by using the BCT Taxonomy (version 1) [21] to deliver intervention functions, and (6) identifying the mode of delivery for the intervention. Following these steps, we designed an intervention incorporating a bespoke smartphone app (JitaBug) combined with a wearable activity tracker (Fitbit [Google LLC]) that would allow users to (1) set PA or exercise goals, plan activities, and set reminders; (2) self-monitor PA levels and receive feedback on behavior; and (3) receive just-in-time adaptive prompts (push notifications) with personalized and actionable messages using motivational language to encourage users to meet PA goals. We chose to use a Fitbit device, given Fitbit's popularity with consumers and therefore the increased potential for future scalability of the intervention and because of the availability of an application programming interface (API), allowing remote data tracking (described in the following sections).

Intervention Components

Using a combination of self-regulatory BCTs, including goal setting, prompting self-monitoring, providing feedback on performance, and reviewing goals, has been shown to increase the effectiveness of PA behavior change interventions [22].

Goal Setting

Goal setting is considered a fundamental component of successful behavior change and is the most frequently used component in health behavior interventions [23]. Evidence from systematic reviews and meta-analyses has shown goal-setting interventions to have small [24] to moderate [25] positive effects on PA. As part of the initial *onboarding* of the JitaBug app, we implemented a goal-setting feature that allowed participants to choose a step count or activity minutes goal depending on their preference. In total, three options were offered—500, 750, or 1000 steps more per day—relative to baseline step count. These targets were informed by evidence that pedometer-based studies typically elicit an increase of 775 steps per day (or effect size of 0.26) in older adults [26]. The activity minutes goal also offered three options—10, 20, or 30 minutes more per day—relative to baseline activity. These goal options were offered to allow participants to gradually increase their PA levels in a realistic and achievable way. Once a goal was selected, participants could rate their level of self-efficacy in achieving their goal by responding to the following question: "On a scale of 1-10, with 1 being not very and 10 being very, how confident are you that you can make some good progress toward your goal?" In addition, participants could review and revise PA goals and reassess their self-efficacy in achieving their goal at any point on the app home screen and were prompted to review their goals every 2 weeks.

Planning and Reminders

Action planning, or prompting the user to make specific plans about when and where they will increase their activity, has been suggested as a useful tool to motivate people to change PA behavior [27]. Evidence from systematic reviews has shown action planning to be one of several effective BCTs in increasing both self-efficacy and PA [28,29]. However, experimental evidence concerning the impact of specific BCTs or combinations of BCTs on PA has suggested that action planning only increases PA when combined with coping planning [30]. A planning feature within the JitaBug app allowed participants to plan activities and when and where to perform them. Participants could log activities for a specific date and time, and the app would deliver an activity reminder as a notification. Given that weather is a common barrier to PA [31], a scrollable 7-day weather forecast (presented in 3-hour blocks) was made available on the same planning screen, using the GPS location of the smartphone to assist participants with coping planning; for example, planning indoor or outdoor activities.

Self-monitoring and Feedback on Behavior

Self-monitoring is considered an essential technique for PA behavior change and is more effective when combined with one or more other techniques derived from control theory (eg, goal setting, feedback on performance, and reviewing goals) [32]. PA interventions with self-monitoring are more effective than those without and more effective again when combined with action planning and coping planning [30]. We designed the JitaBug app to work alongside a wrist-worn Fitbit activity tracker to allow users to self-monitor PA and progress toward activity goals by viewing summary feedback on the device and on the associated Fitbit app.

We included a *snippets* feature within the app that allowed participants to record voice memos concerning PA behavior using the smartphone microphone. Participants were first asked to indicate ("Yes" or "No") if they had engaged in PA that day. Depending on the option selected, participants were given guidance on what to record in the snippet, such as the type, duration, and location of PA, as well as reasons for being active or not, feelings about their PA, and any PA barriers experienced.

JITAI Messaging

Personalized PA messaging was delivered by the JitaBug app to encourage participants to meet their daily PA goal. Messages were tailored to participants' context based on (1) real time PA level (from Fitbit data repository), (2) chosen activity goal (step count vs exercise), (3) time of day (anytime, 12:30 PM, 5:30 PM, or 8:30 PM), and (4) good weather versus bad weather from the *OpenWeather* API (good weather defined as <50% chance of rain). A set of 13 decision rules linked to 3 possible intervention options (Table 1) were developed to dictate what message the participant received and when. A total of 136

unique messages were developed (10-14 for each of the 13 decision rules), and depending on whether the participant chose a *step* goal or *activity minutes* goal, they could receive up to 75 unique messages across the intervention period. The time points incorporated into the decision rules were chosen as possibly opportune times to make PA suggestions (ie, to encourage an activity break around mealtimes or to plan an activity for the following day). Once a JITAI message was received by a user's device, a notification was shown on the lock screen (if locked) or home screen (if unlocked). Clicking on this notification would open the JitaBug app and present the message screen to the user. The message screen displayed the text, any images, and any hyperlinks to resources included in the message. The message screen also included a message-rating question, *Was this useful?*, whereby users could respond by clicking on either a thumbs up or thumbs down image (but not both).

Table 1. Just-in-time adaptive intervention option examples.

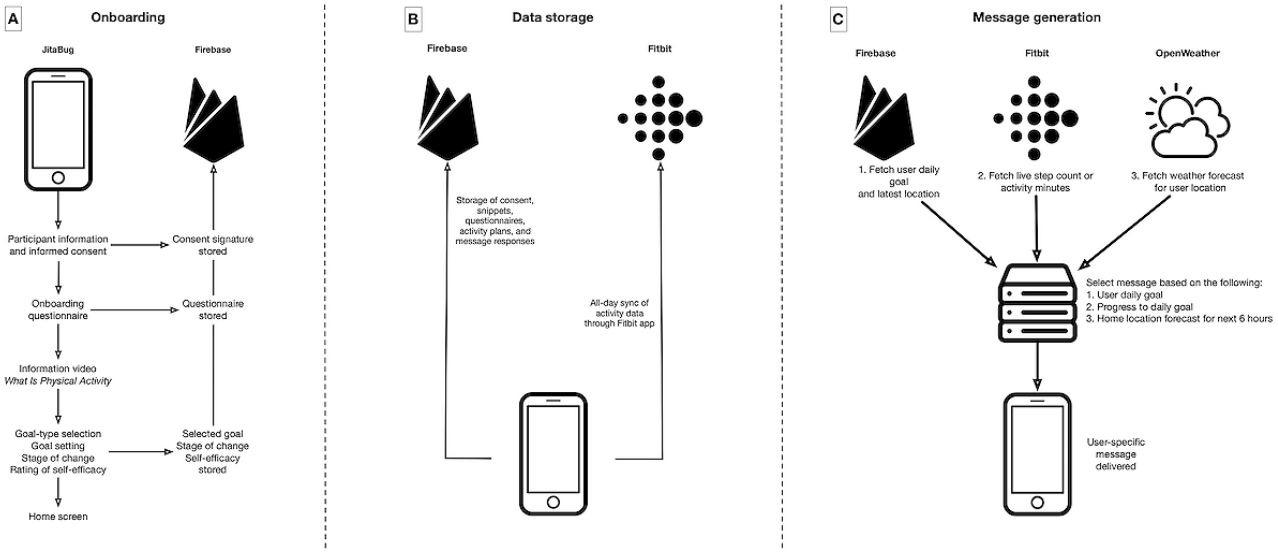
Scenario	Goal of message	Example
Intervention option 1		
When a participant meets their daily step or activity minutes goal	Provide positive feedback and encouragement to repeat the behavior	Well done [NAME]! You reached your goal for today! Aim for the same again tomorrow .
Intervention option 2		
When a participant has not yet reached their daily step goal and the time is between 12:30 PM and 5:30 PM or between 5:30 PM and 8:30 PM and the weather is good	Provide a brief update on goal progress and a message that (1) highlights the benefit of taking an activity break and (2) suggests an activity	You've not reached your step goal for today yet, but there's still time! The weather looks good for this afternoon . How about a brisk walk?
When a participant has not yet reached their daily activity minutes goal and the time is between 12:30 PM and 5:30 PM or between 5:30 PM and 8:30 PM and the weather is bad	Provide a brief update on goal progress and a message that (1) highlights the benefit of taking an activity break and (2) suggests an activity	Don't forget that building muscle strength is just as important as aerobic activity; it helps to maintain functional fitness and prevent falls. How many times can you stand up and sit down from a chair during TV ad breaks?
Intervention option 3		
When a participant did not meet their daily step goal and the time is later than 8:30 PM and the weather is bad	Provide a brief update on goal progress and a prompt that encourages them to plan activity for the following day to meet the goal	The weather is pretty bad tomorrow. But there's some great online workouts available to try. Does anything take your fancy? [33]
When a participant did not meet their daily activity minutes goal and the time is later than 8:30 PM and the weather is good	Provide a brief update on goal progress and a prompt that encourages them to plan activity for the following day to meet the goal	Let's make sure you reach your step count target tomorrow . It's going to be dry so why not plan something outdoors?

Technical Implementation

The technical implementation of the mobile app is depicted in Figure 1. The app was developed using the Dart programming language and the Flutter development framework. This framework has the advantage of enabling apps to be compiled for both Android and iOS platforms with a substantial amount of shared code. Consequently, the final app *JitaBug* was released onto the Apple App Store and Google Play Store shortly before the start of the study intervention (September 2020).

To deliver personalized JITAI messages to each user, we used a separate remote server to automate messaging. This was written using the Python programming language (version 3.7; Python Software Foundation), the Firebase Admin Python package [34], and an open access Fitbit API package [35]. Personalized messages could be compiled by accessing three data sources for each user: (1) a Firebase repository that held data, including the user's first name, home postal code, chosen activity goals, and mobile phone unique ID; (2) a Fitbit data repository that held the user's current activity metrics; and (3) the *OpenWeather* API that pulled the weather forecast for the next 4 hours at the user's home location (based on home postal code). The messaging algorithm ran in 2 parts. Every hour, between 9 AM and 8 PM, the server would check the Fitbit repository to determine whether the user had met their daily activity goal; if yes, it would process and send a motivational *congratulations* message (Intervention option 1; Table 1). In total, three times per day (12:30 PM, 5:30 PM, and 8:30 PM), the server would access the 3 aforementioned data sources and send a personalized message based on the decision rules.

Figure 1. Technical model of the JitaBug intervention, summarizing (A) the onboarding process, (B) how data were stored, and (C) the generation of just-in-time adaptive physical activity messaging.



Feasibility Study Design

We tested the feasibility and acceptability of the JitaBug intervention in a 6-week 1-group pretest-to-posttest trial using a mixed methods approach. The study was conducted entirely remotely across the United Kingdom between September 2020 and November 2020. Participants completed a 7-day monitoring period (baseline), a 4-week intervention (weeks 2-5), and a follow-up 7-day monitoring period. As this was a feasibility study, a sample size calculation was not necessary [36]. Sample size targets were defined by practical and resource considerations, limiting us to recruit 40 older adults.

Ethics Approval

The study was approved by the Health and Life Sciences Research Ethics Committee of the University of the West of Scotland (13212).

Participants

Participants were ambulatory, community-dwelling older adults who use a smartphone but not a wearable activity tracker. They were recruited through social media posts from the research teams' personal accounts (Twitter and Facebook), university newsletter, research recruitment websites [37], community groups (Men's Shed), and word of mouth. Those interested were emailed a participant information sheet, including contact details for the study team in case they wished to ask questions, and a consent form. After informed consent, participants were asked to provide contact details so that a member of the research team could arrange for the delivery of the study equipment through courier (accelerometer, Fitbit activity tracker, and accessories). In addition, they were sent study enrollment videos and user manuals describing each stage of the study onboarding process.

Procedure

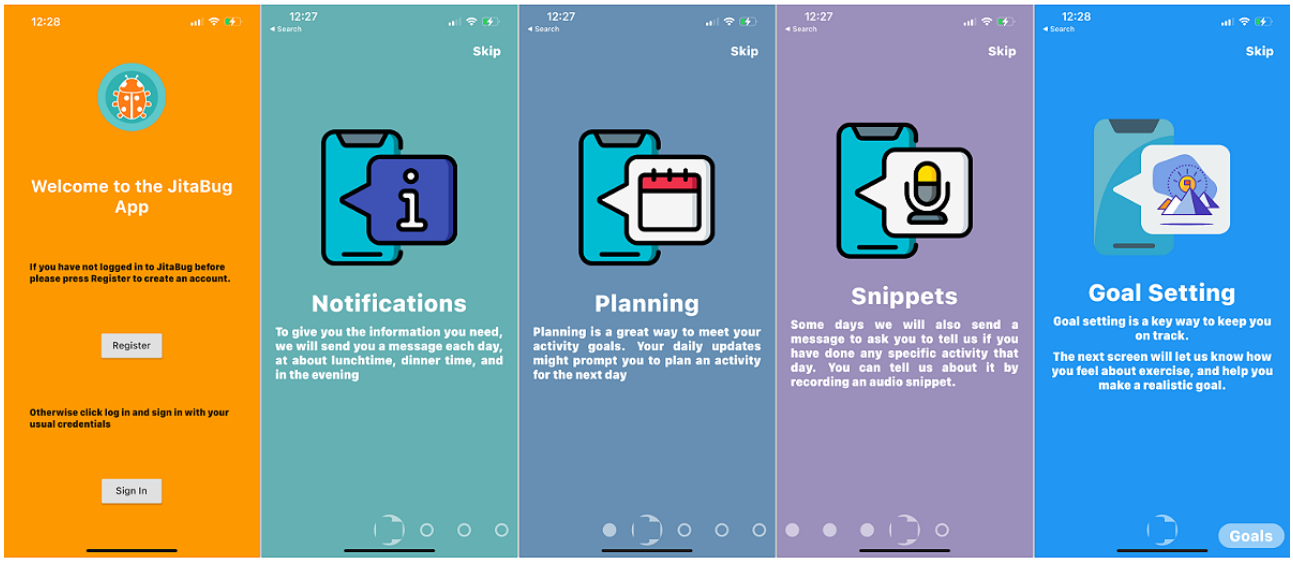
Fitbit Onboarding

Participants were couriered a Fitbit activity tracker (Fitbit Charge 4) for use during the study. The Fitbit trackers were preregistered so that the Fitbit user ID for each device was available to the research team. Notifications were turned off on the Fitbit tracker, the *do not disturb* mode was enabled, and all *exercise* options were removed from the tracker, with the exception of *walk*, before sending to participants to avoid contamination with the JitaBug intervention. Participants were asked to download the Fitbit app and log in using the study username and password provided to them. After logging in, participants were guided to turn off all push notifications and to connect the Fitbit tracker to their smartphone through Bluetooth. They were required to keep Bluetooth turned on for the duration of the study to ensure uninterrupted data upload to the Fitbit data repository (approximately every 15 minutes). This allowed our server to access each participant's most recent activity data to inform the JITAI decision rules. All participants inputted their date of birth, height (cm), body mass (kg), and sex (male or female) into the *personal* profile section of the Fitbit app.

JitaBug Onboarding

Upon downloading the JitaBug app, participants were asked to reconfirm consent to participate in the research study and log in using the study username and password. Participants then completed a survey to provide personal, anthropometric, demographic, and socioeconomic information. They were then guided through a summary of the app and its key features (Figure 2) including notifications (prompts), planning, the *snippets* feature (described in the following section), and goal setting.

Figure 2. JitaBug onboarding screenshots.



Main Intervention

After onboarding, participants were directed to the *goal-setting* feature. First, they were shown a short in-app video clip to describe what PA is, what the current PA guidelines are, and how to distinguish between intensity levels. The key message of the video was *any activity is better than none and more is better still* [38]. After they had watched the video, participants were asked to indicate their stage of change [39] with respect to PA from a list of five options:

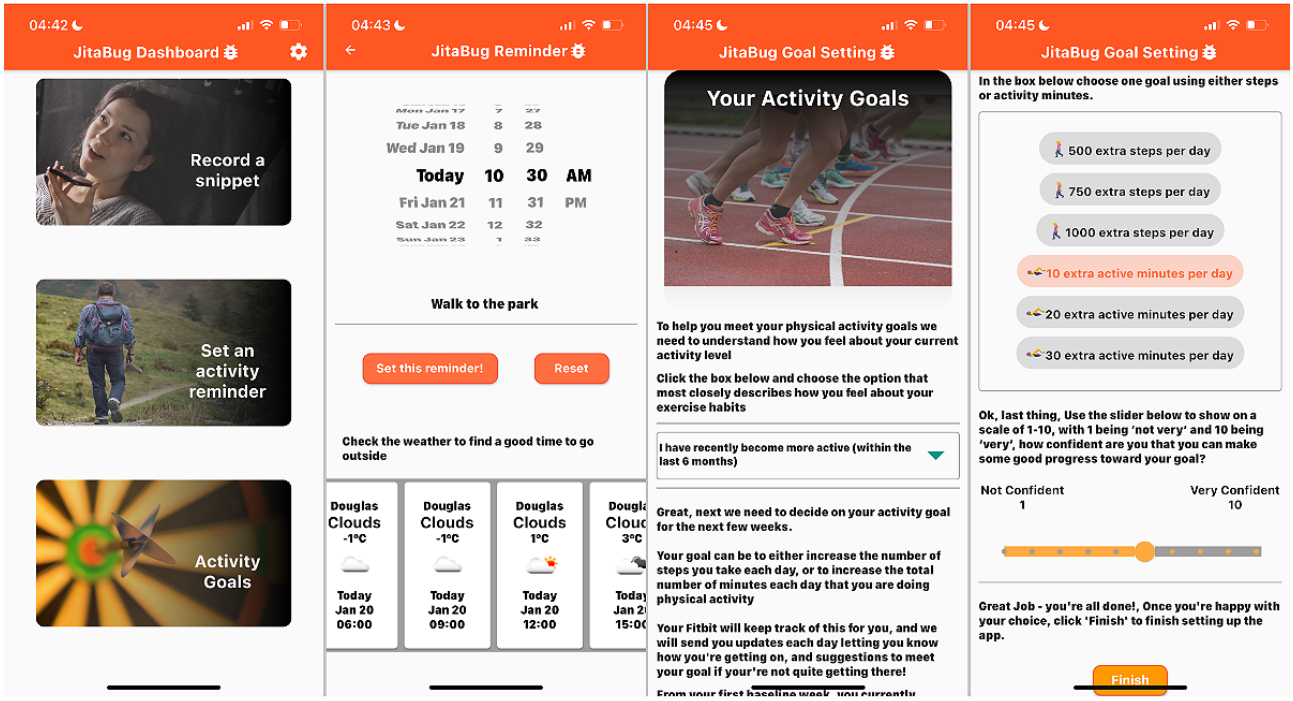
1. I've been physically active for more than 6 months and I am maintaining my activity level (maintenance).
2. I have recently become more active (within the last 6 months; action).
3. I have definite plans to improve my physical activity level in the next month (preparation).
4. I'm seriously intending becoming more physically active in the next 6 months (contemplation).
5. I know I should improve my physical activity level, but I don't intend to (precontemplation).

Next, participants were shown their average step count and activity minutes from the previous week (baseline). They were then asked to choose either a personal step count goal (500, 750, or 1000 more steps than the average step count during the preintervention period) or an activity minutes goal (10, 20, or 30 more *active minutes* than during the preintervention period) based on their baseline activity level. Finally, self-efficacy in achieving the selected goal was assessed with the following question: "On a scale of 1-10, with 1 being not very and 10 being very, how confident are you that you can make some good progress toward your goal?"

The JitaBug app was designed to mainly run *in the background* with minimal user input. The app automatically delivered PA message prompts (push notifications), in line with the predefined JITAI decision rules, to encourage the participant to meet their goal. Some message prompts encouraged participants to use the activity-planning feature, but they could also access this feature at any point during the intervention. At certain time points throughout the intervention, participants were also prompted to record ecological momentary assessment (EMA) *snippets* to reflect on their progress and describe contextual aspects of their physical activities. After 2 weeks and again after 4 weeks, participants were prompted to review and revise their activity goal or continue with their original goal. Screenshots of the app's main screens, including the dashboard, planning feature, and goal setting, are shown in Figure 3.

On completion of the study and after safe return of all devices, participants were provided with a £20 (approximately US $26.80) voucher from a reputable retailer as a thank you for their time and effort during the study.

Figure 3. JitaBug app screenshots.



Outcome Measures

Proximal Outcome

The proximal outcome of interest was defined as daily PA goal achievement measured using the Fitbit tracker. The Fitbit tracker was worn throughout the entire study on the nondominant wrist and only removed for charging purposes.

Distal Outcome

The main distal outcome of interest was change in time spent in low-, moderate-, and vigorous-intensity PA (minutes per day) and sedentary activities (minutes per day) between baseline and postintervention follow-up. Given the current limitations with wearable activity tracker validity [18] and the need to accurately measure intervention effectiveness in a later definitive trial, we chose to measure PA at baseline and follow-up by research-grade accelerometer. Participants were provided with an ActiGraph wGTX3-BT accelerometer (ActiGraph LLC) and instructed to wear it on their nondominant wrist, distal to the Fitbit tracker when both were worn, for 8 consecutive days, 24 hours per day, during the baseline and follow-up periods, removing it only for bathing or showering. The accelerometers were synchronized with GMT, initialized to capture data at 100 Hz, and programmed to commence data collection at 6 AM on the day after delivery. Participants were instructed to wear the accelerometer on the day it was received to ensure full data capture.

Other Outcomes

Sociodemographic and anthropometric characteristics, including gender, age, location within the United Kingdom (postcode), marital status, employment status, key worker status, number of people in the household, household income, education level, number of dependents, dog ownership, bicycle ownership, past activity tracker ownership, and PA preferences, were obtained by means of a survey during the onboarding process to describe the sample recruited.

Self-reported contextual information on PA types, locations, domains, reasons for being active, and barriers experienced was gathered throughout the intervention using the snippets feature that doubled as a voice-based EMA approach. Participants were sent notifications to *record a snippet* at two time points (12:30 PM and 5:30 PM) on two random days of the week (1 weekday and 1 weekend day) each week of the 4-week intervention (16 in total).

We also explored mental well-being and mood responses to the intervention using this approach. On the same day the snippet notifications were delivered, participants were also prompted in the evening (8:30 PM) to complete two questionnaires: the short Warwick-Edinburgh Mental Wellbeing Scale [40] and the short version of the Multidimensional Mood State Questionnaire [41]. The questionnaire screen used a touch interface 6-point (Multidimensional Mood State Questionnaire) or 7-point (Warwick-Edinburgh Mental Wellbeing Scale) Likert scale with a visual indicator of the selected response.

Finally, participants completed a postintervention user experience survey to assess overall experience, app usability and satisfaction with the technology (using relevant questions from the mHealth App Usability Questionnaire [42]), perceived effect on behavior, and views on the intervention as a whole.

Data Processing

ActiGraph data were downloaded using ActiLife (version 6.14.3; ActiGraph) and saved in raw format as .gt3x files. The files were subsequently converted to time stamp–free .csv files and

exported into R (version 3.6.3; The R Foundation for Statistical Computing) for processing using the GGIR package (version 2.1.0) [43]. Briefly, this processing method detected nonwear time as well as abnormally high values and autocalibrated the raw triaxial accelerometer signals using local gravity as a reference [44]. As this was a feasibility study, we were interested in reporting the number of participants who met our proposed wear time inclusion criterion of 4 days, including 1 weekend day, of valid wear (defined as ≥16 hours per day) [45].

Analysis

The analyses reported here focus on the trial feasibility and acceptability of the intervention. Feasibility outcomes include (1) recruitment and retention within the study; (2) intervention delivery in the wild; (3) completion rates and usable data from the app, the Fitbit wearable activity tracker, and the ActiGraph accelerometer; and (4) adverse events. Results are summarized narratively and descriptively (means, SDs, and proportions) based on data from researcher notes, app analytics, and the user experience survey.

Acceptability outcomes are summarized descriptively based on data from the user experience survey and include three categories: (1) satisfaction with the research overall; (2) satisfaction with the technology (JitaBug app and Fitbit tracker together); and (3) satisfaction with, and usability of, the JitaBug app itself. Likert-scale responses were scored (1=strongly disagree, 2=disagree, 3=neutral, 4=agree, and 5=strongly agree). An overall score for each acceptability category (research overall, technology components, or app components) was calculated by summing the mean score for each question within the respective category. Open-ended responses were coded and categorized into themes. Data are presented as mean (SD), unless otherwise stated.

Results

Feasibility

Recruitment and Retention

Recruitment advertisements resulted in 75 people contacting the research team about the study. Participants responded through Twitter (2/75, 3%), a research recruitment website [37] (41/75, 55%), existing contact lists (6/75, 8%), or after hearing about the study through word of mouth (26/75, 35%).

After they were provided the study details, 64% (48/75) of the respondents volunteered to participate. Of these 48 volunteers, 46 (96%) met the study inclusion criteria and provided informed consent to participate (exclusion reasons: residing outside the United Kingdom, 1/48, 2%, and current knee injury, 1/48, 2%). Of the 46 participants who consented to participate, 5 (11%) withdrew from the study before receiving the study equipment (Fitbit tracker and accelerometer). Reasons for withdrawal at this point included family emergency (1/46, 2%), other commitments (2/46, 4%), deciding not to take part (1/46, 2%), and unable to download the JitaBug app to an older iPhone (iPhone 5; 2012; 1/46, 2%). Of the remaining 41 participants, 8 (20%) either withdrew or dropped out from the study after having received the equipment. Reasons included no response to study emails/unable to contact the participant (4/41, 10%), issues setting up the JitaBug app (1/41, 2%), did not like the look of the ActiGraph accelerometer (2/41, 5%), and deciding not to take part (1/41, 2%). After completion of the baseline monitoring week, of the 33 remaining participants, 2 (6%) withdrew because of Fitbit syncing issues with their smartphone. Therefore, of the 46 older adults initially recruited, 31 (67%) participants aged 65.5 (SD 5.4) years started and completed the feasibility study. Table 2 summarizes the sociodemographic profile of the final sample.

Table 2. Participant characteristics (N=31).

Characteristics	Participants, n (%)
Sex	
Male	14 (45)
Female	17 (55)

Action	10 (32)
Maintenance	7 (23)
No response	5 (16)

Intervention Delivery

All participants received the study equipment through courier within 2-5 days of dispatch without issue. All participants were able to download the JitaBug app from the relevant app store (Apple App Store or Google Play Store) independently, but 3% (1/31) of the participants required further assistance from the research team because their device used an operating system that was older than the one the initial design of the app would work with (JitaBug was initially only compatible with Android software development kit version 23 onward). To retain the participant in the study, the research team developed a bespoke version compatible with Android software development kit version 21.

Of the 31 participants, 27 (87%) were successfully onboarded, chose an activity goal, and completed goal self-efficacy at baseline. Goal self-efficacy ratings were generally high (median 8, range 2-10), suggesting that participants were confident in achieving their chosen goal. Of the 31 participants, 14 (45%) reviewed and changed this goal at least once during the intervention period, whereas 4 (13%) required assistance from the research team with onboarding because of lack of mobile data access at the time of onboarding.

Of the 2390 JITAI messages sent throughout the intervention, 2247 (94%) were delivered successfully; of these, 188 (8.37%) were goal-achievement messages from Intervention option 1 (Table 1). To send the right type of message at the right time, the 13 decision rules relied on accurate and up-to-date data from the Fitbit activity tracker and the weather API. Overall, 99% (2239/2261) of the Fitbit, and 100% (2261/2261) of the weather, data calls were successful. Of the 31 participants, 3 (13%) reported that they either “did not receive any notifications” or “received very little information” during the intervention, suggesting that some did not receive this intervention component. These participants were likely those who had difficulty with onboarding because, on investigation, it became apparent that if the process was interrupted or not completed (eg, by closing the app halfway through), then the decision rules would not function because of missing information, namely the activity goal choice. As a result, the participant would not receive any PA messages. The issue was identified and resolved for these participants during the intervention.

Data Collection and Missing Data

In terms of accelerometer data, valid and usable data were obtained from 90% (28/31) of the participants at baseline and follow-up. At baseline, of the 31 devices, 30 (97%) were returned for processing, with 29 (97%) files subsequently processed; we were unable to process 1 (3%) device for an unknown technical reason, and 2 (6%) participants failed to meet the minimal wear time criterion. At follow-up, of the 31 devices, 30 (97%) were returned and 30 (100%) files were successfully processed; 3 (10%) files were removed from subsequent analysis for not meeting the minimal wear time criterion. Researcher notes indicated that 6% (2/31) of the participants did not wear the accelerometer while sleeping. The average number of valid days of data was 7.1 (SD 0.5) at baseline and 7.9 (SD 0.7) at follow-up.

Of a possible 496 snippet recordings, 212 (43%) valid recordings were obtained. On average, participants recorded 50% (7.9/16, SD 7.3) of the snippets, 38% (3.3/8, SD 4.2) of the mood assessments, and 50% (2.1/4, SD 1.6) of the well-being assessments through the app. The user experience survey distributed at the end of the study had a 97% (30/31) response rate.

Adverse Events

There were no adverse events reported during the study.

Acceptability

Acceptability data are available in Multimedia Appendix 1.

Satisfaction With Research Process

The overall acceptability score for the research process was very good (4.00/5.00, SD 0.73; 80% satisfaction). Most of the participants (27/30, 90%) agreed or strongly agreed that they were satisfied with the research conducted. Most (21/29, 72%) were satisfied with the measurements taken and the amount of data gathered.

Satisfaction With Technological Components

The overall acceptability score for the technology components of the intervention was very good (3.86/5.00, SD 0.59; 77% satisfaction). Most of the participants agreed or strongly agreed that they felt comfortable using the technology (21/30, 70%), that it required little effort to use (23/30, 77%), and that it was easy to learn how to use (25/30, 83%). Very few participants agreed that using the technology caused them embarrassment (2/29, 7%). Participants were moderately satisfied with the usefulness of the technology (15/30, 50%) and the accuracy of the data provided by the technology (18/30, 60%).

Satisfaction With App Components

The overall acceptability score for the JitaBug app components was good (3.36/5.00, SD 0.72; 66% satisfaction). Most of the participants agreed or strongly agreed that the app was easy to use (22/30, 73%), that the amount of time involved using the app and answering questions within the app was reasonable (18/30, 60%), and that the app’s PA goals were realistic (20/30, 67%). Overall, 59% (17/29) of the participants said that they were satisfied with the app; however, only 43% (13/30) of the participants agreed that they would use the app again. Lower satisfaction (agreement) was also observed with respect to the interface of the app (12/29, 41%), frequency of notifications (16/30, 53%), relevance of notifications (12/30, 40%), usefulness of the information presented within the app (12/30, 40%), and appropriateness of the notification timing (13/30, 43%). Of the 19 questions, 2 (11%) scored high *neutral* responses—satisfaction with the way the app presented feedback and information (17/30, 57%) and satisfaction with the time interval between setting new goals (16/29, 55%)—suggesting that several participants may not have received these aspects of the intervention. Finally, only 33% (10/30) of the participants agreed that the app had all the expected functions and capabilities.

Satisfaction With the Intervention

Responses from the open-ended questions of the user experience survey are summarized in Table 3. The feedback identifies potential improvements to the intervention and recommends specific elements that could enhance user engagement in mobile app–based behavior change interventions for older adults going forward. The collective feedback is categorized into themes and links to positive and negative outcomes.

Table 3. Summary of qualitative feedback from the user experience survey (N=30).

Theme and positive comments, n (%)	Negative comments, n (%)
Goals	
Motivated to do more, 2 (7)	—[a]
Felt good when achieving goals, 1 (3)	—
Self-monitoring and feedback	
Receiving feedback on behavior, 8 (27)	Fitbit did not track low-intensity activities, 1 (3)
Tracking and visualizing behavior patterns, 7 (23)	Unreliable and inaccurate, 1 (3)
Comparing with past performance, 4 (13)	Dislike wearing a second watch, 1 (3)
Raised awareness, 6 (20)	—
Prefer passive data collection, 1 (3)	—
JITAI[b] messages	
Took on advice and formed a new habit, 1 (3)	Ignored, 1 (3)
—	Annoying, 1 (3)
—	Too many, 1 (3)
—	Repetitive, 3 (10)
—	Irrelevant, 1 (3)
—	Too simple or patronizing, 4 (13)
—	Inappropriate times, 3 (10)
Setting activity reminders	
Established a new routine so no longer needed reminders, 1 (3)	Not useful, 3 (10)
—	Felt bad when unable to follow through with plans, 3 (10)
—	Too time consuming, 1 (3)
—	Most difficult part, 1 (3)

[a]None reported.

[b]JITAI: just-in-time adaptive intervention.

Participants liked using the Fitbit tracker the most (22/30, 73%), followed by receiving feedback on their activity (5/30, 17%). Participants liked using the Fitbit tracker and its associated app to track data on their activity and sleep patterns and visualize their progress over time. This seemed more useful than receiving feedback on behavior through the JITAI messages. Participants felt that the intervention raised their awareness of their PA level and gave them encouragement to be active and meet their goals. There was a suggestion that the passive activity detection offered by the Fitbit tracker was preferred over self-reporting through *snippets*; however, a limitation is that some lower-intensity physical activities are either not detected or do not contribute to steps or activity minutes. Example quotes are as follows:

> *I think that wearing a tracker automatically makes you more aware of periods of inactivity and progress towards goals, even though it was at times unreliable and didn't record activities such as tai chi and yoga towards my daily goal.* [Participant 2]

> *Fitbit provides immediate feedback on a wide range of health metrics, so enabling more direct tracking of progress, if not against targets, then against historic data.* [Participant 4]

> *I was able to see what I was doing and compare days and what my sleep pattern was like. It reported to me on the activity I was doing and my sleep rather than asking me to report what I was doing and then suggest options.* [Participant 21]

Some participants commented that they found the PA message content to be repetitive and the timing of the messaging was not always appropriate. For example, some reported receiving a message to be active immediately after an activity bout and some mentioned that they were not able to act on the message *in the moment*, which made them feel bad:

> *They never came in at the right times usually after I had been exercising.* [Participant 30]

> *I couldn't always guarantee to do it and there wasn't anything I could do about it. So it made me feel bad about myself.* [Participant 22]

In addition, some mentioned that the language used in the messages was too simplistic and, at times, *patronizing*, and they may be more suited to very inactive people:

> *...I enjoyed all the information, goals and targets provided with the Fitbit app, so that the JitaBug was really not necessary. One night it did tell me to get out for a walk in the dark, which I did and have continued to do so if I haven't got my steps in through the day. That was one definite piece of advice from the JitaBug that I responded to. A lot of it was a bit lightweight for me, I feel. I can see that it would be appropriate for some people though (possibly older and less able).* [Participant 13]

Improvement Suggestions From Users

Participants offered several suggestions for improvements to the JitaBug app, predominantly centered around usability. They advised that the PA message notifications should be more obvious (eg, adding a red dot to the app icon on the home screen when a new notification is received) and accessible because messages were not always seen in the notification center. It was suggested that reviewing and setting PA goals should be easier and that there should be more flexibility with the app features (eg, avoid forced completion of EMA questionnaires). Participants suggested that having more content and resources would encourage people to use the app more and that PA messages should be used as an opportunity to provide educational content. Finally, participants suggested that the app should integrate with, and offer more than, existing health apps.

Discussion

Principal Findings

This study demonstrates for the first time that a smartphone-delivered JITAI using data from a wearable activity tracker is an acceptable approach to increase PA in older adults in a free-living setting. A main finding is that by using a companion app (and server), it is feasible to leverage the technical benefits of commercial activity trackers and still deliver a theory-led JITAI with bespoke tailoring variables and messaging. Overall, the acceptability of the intervention was very good (23/30, 77% expressed satisfaction). Participants were comfortable with the technology and found the app easy to use. Furthermore, given the intervention completion rate of 67% (31/46), the successful delivery of the intervention *in the wild* as intended, the acceptable levels of accelerometer data collection, and the absence of adverse events, we propose that after some minor usability improvements, the JitaBug intervention is feasible to run in a larger, fully powered trial to ascertain its effectiveness in changing PA behavior and improving health and well-being.

Concerns regarding the acceptability of mobile technology in studies with older adults are largely historical, and our data on the acceptability of the JitaBug intervention confirm what has been reported elsewhere. Hawley-Hague [46] assessed the acceptability of a mobile app to support falls rehabilitation, reporting that older adults had few issues with the technology and were comfortable with using it for exercise advice. Similarly, several studies have reported that older adults find wrist-worn activity trackers acceptable [47,48]. Nevertheless, it is worth noting that the evidence to date is likely subject to sampling bias, given the need for people to own an up-to-date smartphone capable of running new apps and syncing with wearable devices. Indeed, our participants were predominantly well educated, retired, and with reasonable household income. Therefore, more research is needed, across a wider demographic, to understand whether mHealth solutions can truly reach harder-to-reach groups such as those from lower socioeconomic backgrounds and therefore achieve their full potential.

Overall, the JitaBug intervention was well received, the app was easy to use, and participants were comfortable with the technology. However, we noted that participants were less satisfied with the features and content within the JitaBug app and the PA messages in terms of timing, relevance, and repetitiveness. We propose that this was partly due to disparity between the study aims and participants' expectations of the app. The JitaBug app was designed to run in the background with minimal user input to reduce user burden and limit intervention fatigue [17]. However, participants reported that they wanted more content and interaction and felt that they often had little reason to open the JitaBug app. We intended to avoid recreating the Fitbit app; therefore, we did not include updates on activity minutes or step count within JitaBug. However, to ensure fidelity to the JITAI messaging and BCT approaches, we also requested participants turn off notifications from the Fitbit app. Consequently, participants felt that the JitaBug app offered insufficient information regarding progress toward their goals each day. Future studies should address this and include some feedback on activity data within the companion app if the Fitbit (or another proprietary) app might compromise study fidelity.

Regarding timing, relevance, and repetitiveness of PA messages, specific tailoring variables within decision rules may have influenced delivery of appropriate messages. For example, time lags between the Fitbit wearable activity tracker syncing with the JitaBug servers may have resulted in incongruence between real time PA and the message received concerning current PA. The JitaBug app called the Fitbit server every hour, but this was dependent upon an internet connection and the frequency with which the phone synced data with the Fitbit server. Another variable that could influence message content was weather conditions. Given that the study was delivered in the autumn in the United Kingdom when average rainfall is at its highest and the decision rules determined good versus bad weather depending on rainfall, it is likely that far fewer message options were delivered than intended. Thus, the geographical location and season in which an intervention is delivered may have profound implications for intervention delivery and user acceptability. Finally, we used predefined windows of time, chosen as possible opportune moments to intervene on PA behavior, to send JitaBug notifications. However, event-based timing, for example, when someone has been sedentary for a prolonged period of time, might be a more effective approach

[17]. Furthermore, the timing of JITAI messages may be enhanced by detecting a user's state of receptivity [49] with additional data inputs such as location, device interaction, and battery level [50]. Future studies should expand on the number and type of tailoring variables relevant to PA, which in turn will facilitate the development of more intuitive and nuanced messaging rules.

We anticipated at the outset that creating PA messages that are equally meaningful to participants with different backgrounds, reading abilities, and expectations was likely to be one of the most challenging parts of the study. The language used in our messaging was aimed at a reading level equivalent to 6th grade (12 years of age) in line with guidance on the reading level of patient education and health literacy materials [51]. Nevertheless, participants commonly described the messages as overly simplistic and occasionally patronizing. The same feedback has been reported in another JITAI study targeting substance abuse in adolescents and young adults [52]. Developing meaningful messages is complex, multidimensional, and requires the incorporation of a variety of concepts and theories [53]. It is possible that co-designing messages with intended users might increase satisfaction with this aspect. Moreover, it may be possible to target messages to specific user groups, for example, based on demographics or further tailor messages for individual users based on preferences, baseline activity levels, and even personality traits [54]; however, this would inevitably require significantly greater resource commitment.

In terms of feasibility, web-based, email, and referral recruitment strategies were successful in reaching 75 people over a 9-week period, with 48 (64%) of them then volunteering to participate. Of the 46 volunteers who were eligible, 31 (68%) enrolled onto the study, suggesting a good level of interest in the intervention. These recruitment and retention findings are similar to other PA-focused mHealth studies using apps and commercially available activity trackers in adults [55,56]. Given that the apps used in these previous studies have undergone extensive testing and development over several years to maximize engagement, finding comparable recruitment and retention rates with the JitaBug intervention is promising and further supports the feasibility of the intervention. Furthermore, this study was conducted in the context of COVID-19 restrictions, which required us to develop an intervention that could be delivered wholly remotely. Thus, unlike earlier work, our retention data did not benefit from face-to-face induction of participants onto the study. Indeed, critical aspects of the intervention, including the aims and functionality, which might usually be undertaken by the research team, had to be incorporated into the app *onboarding* process. Nevertheless, retention was relatively unaffected; therefore, the encouraging recruitment and retention data suggest that a high proportion of older adults can feasibly use the JitaBug app remotely.

The feasibility of PA data collection by accelerometer and wearable activity tracker was excellent. We also assessed the feasibility of collecting longitudinal changes in participants' mood and well-being using an EMA-based questionnaire and contextual information about PA behavior using a voice-based EMA approach, both integrated within the JitaBug app. According to a recent systematic review of smartphone-based EMAs [57], this is the first study to combine qualitative data collection with an EMA approach and only the second to evaluate the feasibility of EMA in older adults. de Vries et al [57] report that although compliance in EMA studies is infrequently reported, it ranges between 43% and 91%, with longer studies trending toward lower compliance. Our compliance of between 38% and 50% is relatively low and is perhaps not surprising, given the length of EMA collection. Nevertheless, our qualitative EMA approach through audio snippets provides a novel and feasible way to gather contextual information about PA behavior, which is currently lacking in device-based PA measurement studies [18]. It is also worth noting that additional reminders when participants miss EMA recordings have not previously been feasible because researchers had to wait until the end of the study to retrieve the EMA data. However, we have demonstrated herein that it is feasible to remotely collect and store snippets, making them immediately accessible by researchers; therefore, EMA reminder notifications are possible and could further increase the feasibility of this data collection method.

Limitations

There are several limitations of this study that should be noted. Our proximal outcome was achievement of daily PA determined by the Fitbit tracker. This was because the JITAI component of this study was dependent on continuous activity–updating of Fitbit servers to enable remote tracking, a feature not available on research-grade accelerometers. Although validity and reliability of commercial activity trackers for step counting in older adults have been reported as good to excellent [58,59], they are still considered less valid than research-grade accelerometers in measuring PA of different intensities [18,60]. We sought to overcome the limitations with the measurement device by simultaneously determining the feasibility of remote deployment and recovery of research-grade accelerometers in the week before and the week after the JITAI. The accelerometer data loss of 10% (3/31) is encouraging, suggesting that it is feasible to measure PA using ActiGraph in community-dwelling older adults; therefore, this approach can be used to strengthen the validity of efficacy data. A second limitation is that muscle-strengthening activities are not accurately captured through device-based measurement, particularly when step counting is used over heart rate–based activity goals [61]. The importance of muscle-strengthening activities in addition to aerobic PA has been well established, but fewer older adults meet the daily recommendations [62]. Thus, including a means for recording muscle-strengthening activities in the JitaBug app is an area for consideration. Third, we did not collect location data or use other contextual data (such as calendar appointments, device use, and battery status) within our decision rules. These data may improve the timing of, and receptivity to, JITAI messages [50] and should be considered in future versions of the intervention. Finally, the participants recruited were predominantly well educated, retired, and with reasonable household income; therefore, the feasibility of the intervention in other population groups, including those from lower socioeconomic backgrounds, may be required before implementation.

Conclusions

This study demonstrated that a smartphone-delivered JITAI using a wearable activity tracker (JitaBug) is an acceptable way to support PA in older adults in a free-living setting. Moreover, the intervention was feasible, although the app will undergo further technical refinements that may enhance use, engagement, and user satisfaction before effectiveness trials. Finally, we present a novel and feasible approach to capture qualitative insights into PA behavior alongside quantitative measurement, which may advance the PA measurement capabilities of future smartphone-delivered mHealth approaches.

Acknowledgments

This study was funded by the Chief Scientist's Office, Scotland.

Authors' Contributions

NS and JLM conceived of the study and designed the intervention. NS developed the app and managed the technical implementation of the app. AKC recruited participants and collected the data. JLM analyzed the data and wrote the manuscript. LDH and NS contributed to the manuscript writing. DSB analyzed the ActiGraph data, and both DSB and CE provided methodological guidance and reviewed the manuscript. All authors reviewed and approved the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Enhanced communication with health care providers (HCPs) can improve symptom management and health-related quality of life (HRQoL) for patients with chronic health conditions. Access to appropriate communication venues is needed to improve communication, however. As such, digital communication interventions mediated by patient portals carry the potential to support patient-provider communication and interaction and through this, also facilitate shared decision-making (SDM). The *InvolveMe* intervention was designed to provide patients with the opportunity to communicate symptoms and informational needs prior to consultation via digital assessment, including prioritizing what is most important to discuss with their HCPs, as well as to interact with HCPs through secure messages between outpatient visits.

Objective: The aim of this study was to assess the feasibility of the *InvolveMe* intervention by investigating acceptability, demand (ie, system use), and limited efficacy.

Methods: The study was designed as a single-arm, pre-post feasibility study combining quantitative and qualitative methods for data collection. Patients from an endocrine outpatient clinic were invited to use the *InvolveMe* intervention for 3 months, and HCPs administering *InvolveMe* were invited to participate in a focus group. Guided by descriptions of how to design feasibility studies by Bowen et al, feasibility was tested by exploring (1) acceptability, using data collected during recruitment from patient participants and nonparticipants (ie, declined to participate or did not meet study requirements), HCP experiences with recruitment, and the System Usability Scale (SUS); (2) demand via exploration of system use through extraction of system log data and HCP experiences with system use; and (3) limited efficacy testing, via exploration of potential effects from the Short-Form Health Survey (RAND 36), Hospital Anxiety and Depression Scale, and Health Literacy Questionnaire.

Results: Patient participants (N=23) were a median 54 (range 26-78) years old and primarily male (14/23, 61%). Nonparticipants (N=16) were a median 73 (range 55-80) years old and primarily male (12/16, 75%). The average SUS score was 72.2, indicating good system usability. Assessments were completed by 8 participants from home prior to outpatient visits. The assessments entailed various bodily symptoms and needs for information. Participants sent 17 secure messages related to patient administrative matters, symptoms, and challenges. Focus group participants (N=4) were all female and registered nurses. Data were analyzed

in 2 predefined themes: Acceptability and Demand. Acceptability included the subthemes intervention attractiveness and intervention suitability. Demand included the subthemes elements of SDM and intervention challenges and opportunities. All patient participants completed outcome measures at baseline, and 19 (19/23, 83%) completed outcome measures at 3 months. These preliminary efficacy findings were mixed and inconclusive.

Conclusions: The study design provided findings from both patient and HCP perspectives and supported feasibility of the *InvolveMe* intervention. The investigation of acceptability and demand supported the potential for remote SDM mediated by patient portals using assessments and secure messages.

Introduction

Living with a chronic health condition is demanding, as chronic health conditions often cause a variety of symptoms (eg, anxiety, depression, fatigue, loneliness, and sleeping problems) that may negatively affect health-related quality of life (HRQoL) [1-4]. In order to manage the various symptoms they experience, patients need to be able to communicate and interact with health care providers (HCPs) [5,6]. However, experiences with poor communication and interaction between patients and HCPs are common, which may interfere with symptom management and help-seeking [7,8]. Shared decision-making (SDM) may, with its focus on the patient and HCP working together to understand and address the patient's situation, carry the potential to improve patient-provider communication and interaction [9-11]. Traditionally, SDM has taken place in physical patient-provider encounters. However, information and communication technology (ie, eHealth) has provided new opportunities for SDM to be explored by improving access to care, enabling information exchange, supporting patient-provider communication, and building relationships [12].

Remote SDM may provide benefits by helping HCPs to understand which aspect of the patient's problem requires action and, together with the patient, identify the action required to solve the problem [13]. Patient portals present one way to engage patients and providers in remote SDM [14]. A patient portal provides patients with secure online access to their own health information, such as HCP's journal notes, medication lists, and opportunities for communication with their HCPs via secure messaging [15]. A review of patient portals [14] found that use of portals supported information sharing, improved preparation before visits, and supported patient-provider communication. Furthermore, portal use was found to encourage engagement in self-management of chronic disease [14,16] and empower patients in SDM [14]. However, the review rated the evidence related to portal use for improved communication, information sharing, and patient-provider relationships as low [14]. Secure messaging was identified as the most commonly reported portal feature, with patient-generated data by remote patient-reported symptoms (ie, assessments tools) less frequently reported [14].

Secure messages can also be an integral part of SDM, providing patients and HCPs with opportunities for contact, and benefits to patient-provider communication from using secure messages have been implied [17-19]. A review identified patients' main triggers for sending secure messages as accessibility to HCPs, self-management, and unmet needs [20]. Furthermore, the review highlighted that consequences of patient-provider secure messaging included patient empowerment, health promotion, and acquisition of uncertain answers [20]. Another review, focusing on use of secure messages, reported improved or comparable patient health outcomes for patients with chronic conditions when using secure messages compared with in-person care, describing quality of care as equivalent or improved for chronic conditions [21]. Use of secure messages among cancer patients has also been associated with improved survival and reduced treatment-related admissions, as well as reduced emergency visits [22]. In addition, the use of secure messages has been associated with improved glycemic level among patients with diabetes [23].

Remote assessment in preparation for health care visits can support symptom management [24], which is an important and integral part of chronic health care. Collecting patient-reported symptom data remotely can provide an opportunity to address the individuality and variability in symptoms over time among patients. Remote collection of patient-reported symptoms can also make the clinical workflow more efficient by not requiring patients to complete assessments in the waiting room or report symptoms within the limited time for consultation with HCPs [24]. A recent review found that there were few published studies examining integrated systems (ie, more than one system act together as one) for remote patient-reported symptoms, primarily feasibility and pilot studies, and subsequently limited evidence exists related to care and outcomes from using such integrated systems [24]. However, results from standalone systems (ie, a system that functions independently of other systems) for remote patient-reported symptoms are promising. The use of such systems has been reported to reduce symptom burden [25-27] and decrease emergency visits and in-hospital admissions [28]. Also, a review found improved symptom control, HRQoL, patient satisfaction, and patient-provider communication when patient-reported symptoms were used in feedback to patients [29]. A review on the effectiveness of

digital assessment tools to improve SDM [12] also found that communication, especially information sharing related to the patient's HRQoL and social aspects, as well as provider management of the patient's condition, improved through use. The review highlighted that digital assessment tools can be especially important for people with chronic health conditions [12].

Even though benefits of patient-provider communication and patient outcomes from the use of secure messages and remote patient-reported symptoms have been reported, research examining digital interventions combining secure messages and remote patient-reported symptoms through patients' portals to facilitate SDM is scarce. There are also patient barriers to the use of patient portals, such as lack of user-friendliness, technical support, education, and access to the internet [16,30]. Patient age may also play a role [30], and tailoring digital patient-provider communication interventions through the involvement of stakeholders representing end users (eg, patients or HCPs) appears crucial [31,32]. Stakeholders can provide insight to help tailor interventions to suit the local context (eg, hospital setting) and thus make interventions more acceptable, user-friendly, and less complex [31,32]. There are several factors that may impact intervention implementation, both relating to population and individuals [33]. For example, adaptation and tailoring to context are acknowledged as important implementation strategies [34], and creating an understanding of the context in which the intervention will be used can hence help avoid development of interventions that may fail during evaluation [33].

Seeking to address some of the issues raised by existing research, the current research team designed and developed a digital patient-provider communication intervention, called *InvolveMe*, aiming to support patients living with chronic health conditions, such as patients with nonfunctioning pituitary adenomas (NFPA) [35]. This single-arm pilot study aimed to assess the feasibility of the *InvolveMe* intervention by exploring acceptability, demand (ie, system use), and limited efficacy using a combination of qualitative and quantitative methods.

Methods

The *InvolveMe* Intervention

The *InvolveMe* intervention was developed to support SDM in the follow-up of patients with chronic health conditions, by being tailored to suit the patient group [35]. The intervention was further tailored to suit the intended context (ie, endocrine outpatient clinic) [36], in this study, patients with NFPA. *InvolveMe* provides patients with the opportunity to remotely report symptoms, needs, and preferences for care by completing an assessment (ie, predefined symptom list) in the hospital's patient portal. In addition, patients can use the secure messaging feature in the patient portal to interact with HCPs about symptoms and needs between hospital visits [35]. To allow for integration in patient portals, the *InvolveMe* assessment feature was developed as a Single Page Application (ie, web-technology) in line with the HL7 FHIR standard (ie, a specification for health care interoperability) [37]. The assessment part of *InvolveMe* is organized in 4 categories: (1) *bodily symptoms* (eg, pain, fatigue), (2) *psychosocial challenges* (eg, anxiety, loneliness), (3) *the need for work-related support* (eg, work-related understanding, whether the job exacerbates health), and (4) *the need for information* (eg, medication side effects, treatment change). The system allows for all symptoms and needs to be marked. In the first 3 categories, patients can rate how bothersome they find the symptom, while in *The need for information* category of the assessment, patients can request information from a predefined list. All symptoms and needs can be prioritized according to patients' preferences for care, on a scale from 0 to 10. The completion of the assessment generates a summary that is sent to the patients' HCPs (ie, as an attachment via the secure message feature).

In this study, the assessment was used as preparation prior to upcoming in-person outpatient consultations, as well as for feedback during the consultations. Secure messages were sent from, and received in, a shared message inbox managed by a dedicated moderator (ie, registered nurses). Routines for the moderator were established in dialog with the registered nurses to suit daily clinical workflow. The moderator would send a secure message through the patient portal approximately one week prior to the planned visit with an invitation for patients to complete an assessment (See Figure 1). *InvolveMe* was accessed by patient participants through the hospital patient portal and could be used on smartphones, tablets, or PCs. The shared message inbox had an automated message response, providing patients with contact information in case of medical emergency, response time, and contact information for the endocrine outpatient clinic. See Figure 2 for selected screenshots of the *InvolveMe* assessment feature from the patient interface. HCPs accessed the shared message inbox through hospital computers. See Figure 3 for screenshots showing the HCP interface of a completed, received assessment. The *InvolveMe* intervention was provided as an addition to standard care.

Figure 1. Invitation to complete the *InvolveMe* assessment from the patient interface.

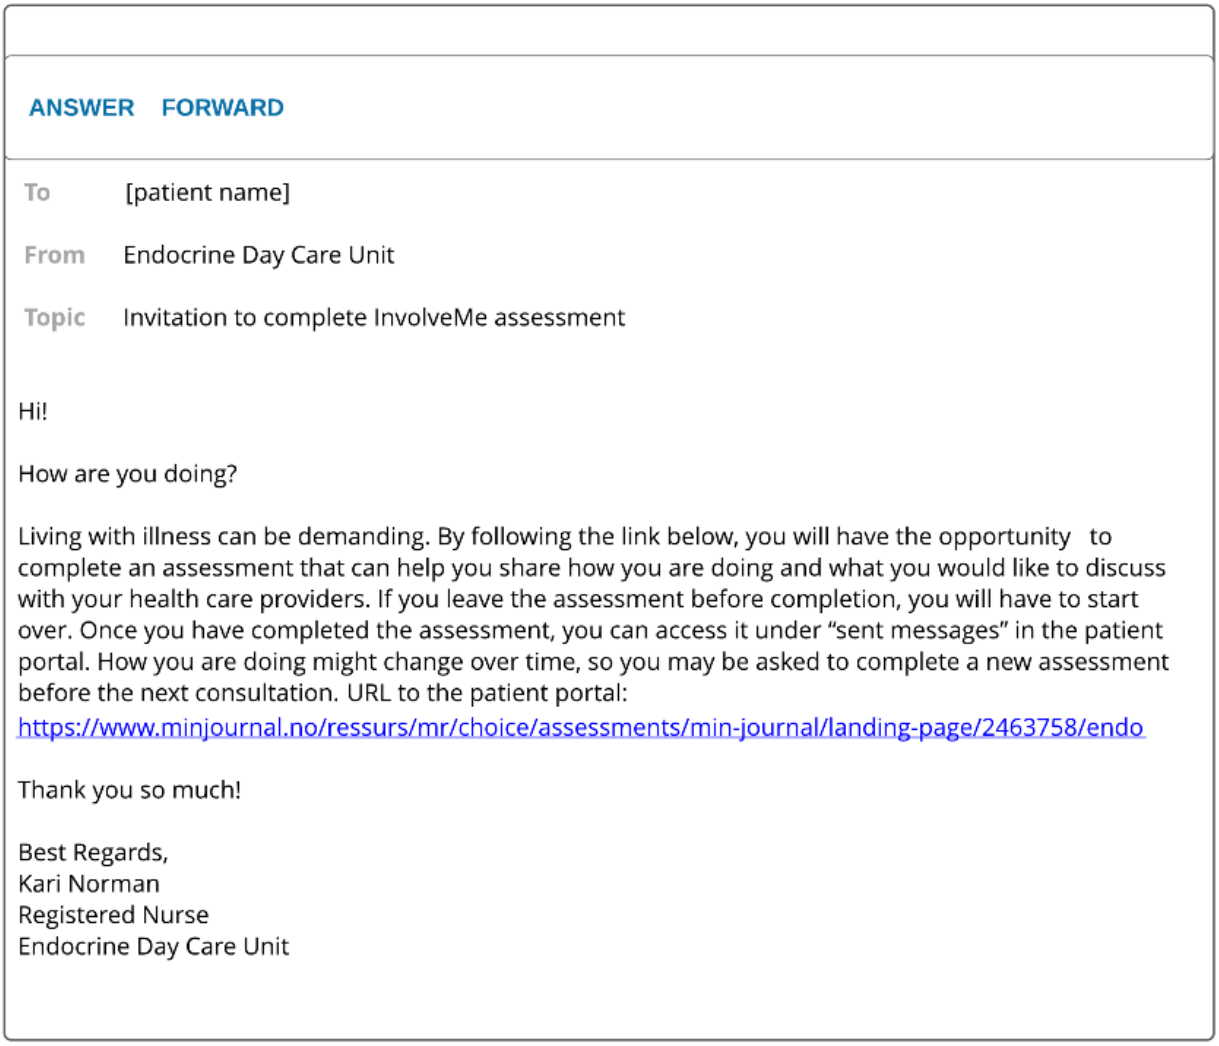

Figure 2. Screenshots of the *InvolveMe* assessment feature from the patient interface.

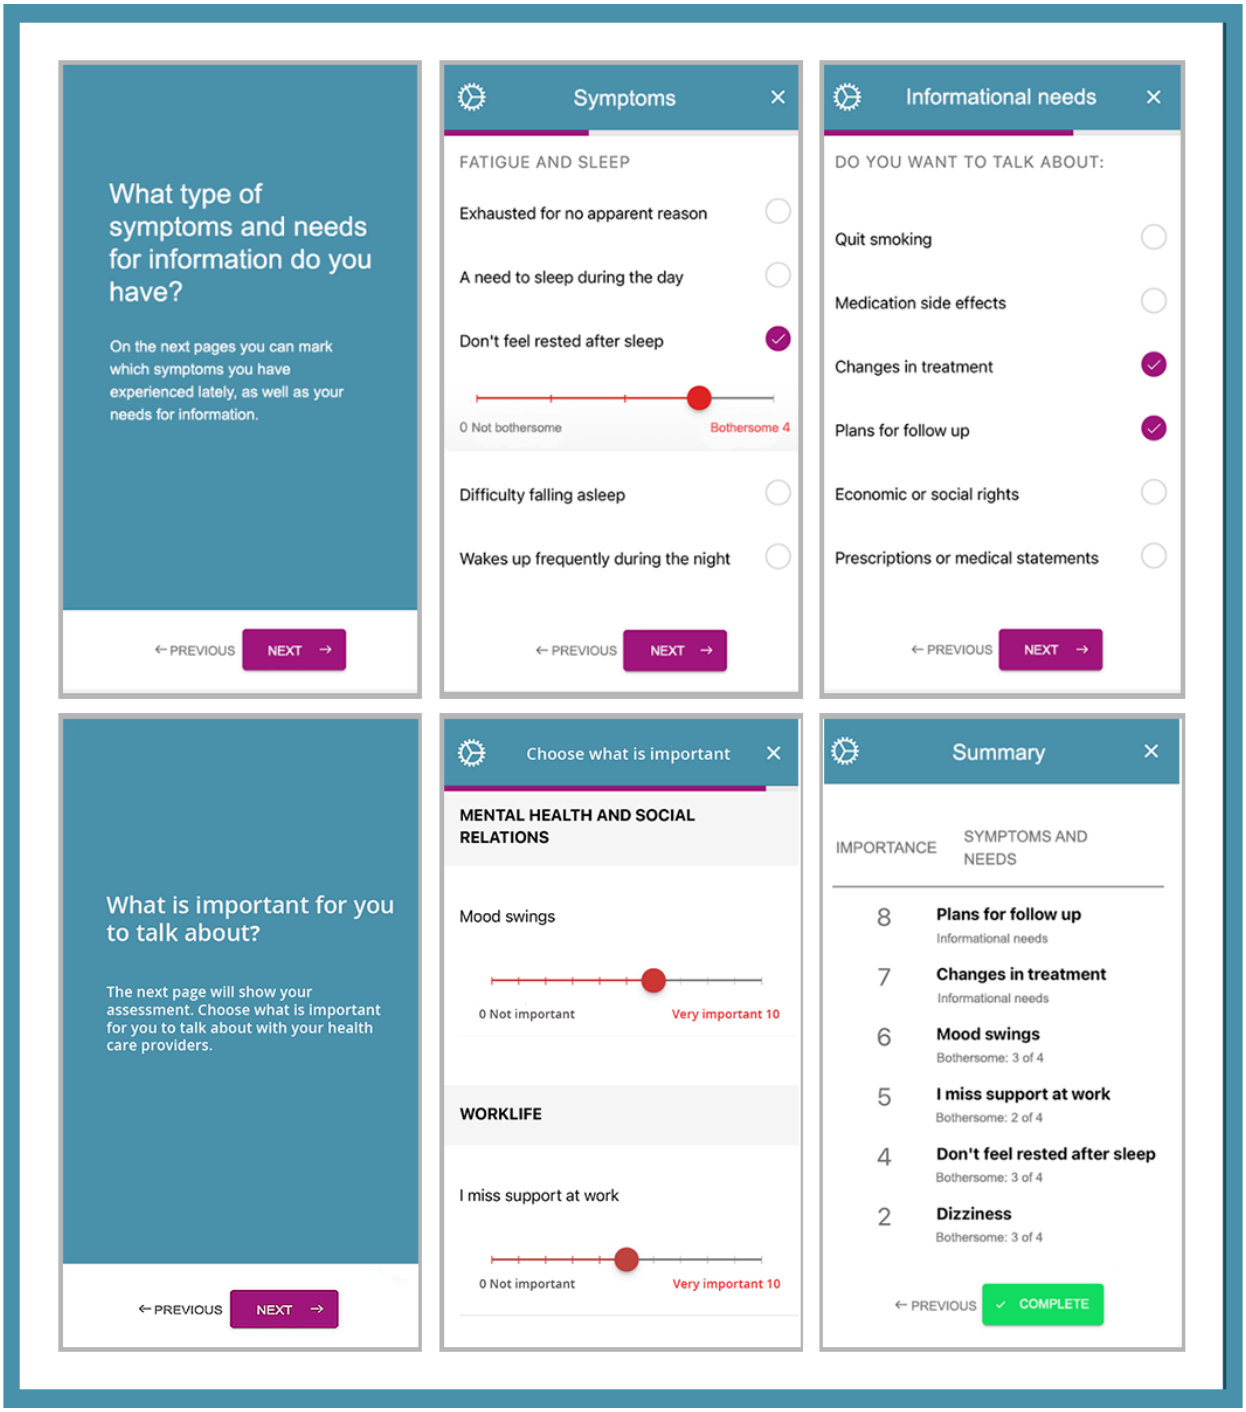

Figure 3. Completed assessment received from the health care professional (HCP) interface.

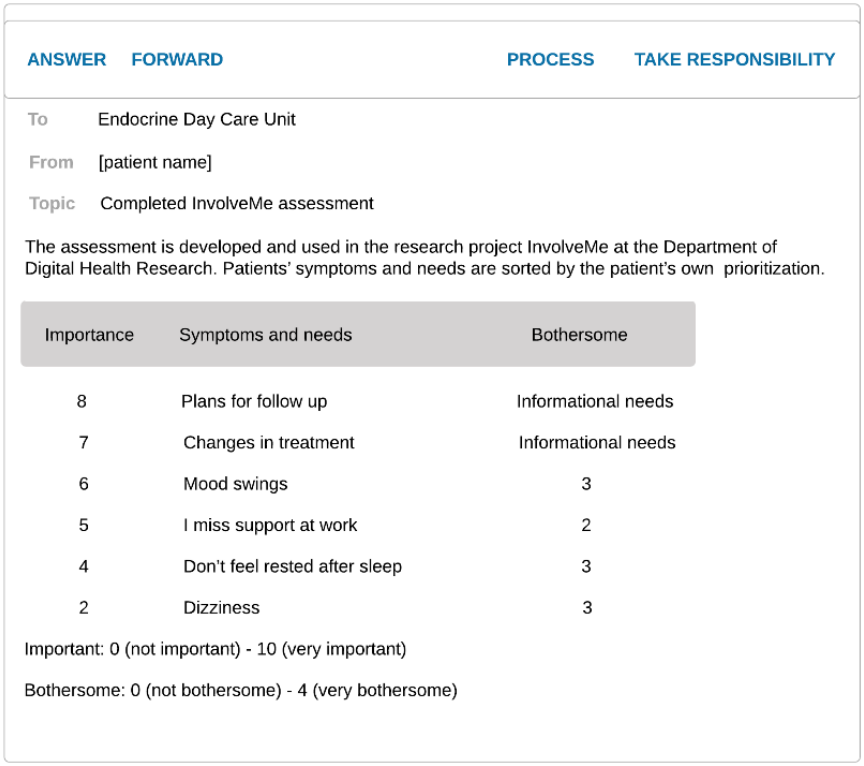


Study Design

In order to evaluate the effectiveness of complex interventions, initial testing and refinement of the intervention to ensure its feasibility are recommended [38]. Feasibility studies are important for producing findings that can be used to tailor interventions and examine recruitment settings [39]. This study was therefore designed as a pre-post feasibility study, with all patient participants receiving the *InvolveMe* intervention. In addition to the perspective of patients, the perspective of nonparticipants (ie, patients who declined to participate or did not meet study requirements) was included in this study to elaborate on potential barriers for use of eHealth interventions, which are of special interest for universal health care delivery, as provided in Norway. In addition, the perspective of HCPs was included to gain an understanding of intervention delivery and use in clinical practice. Feasibility conceptualization was guided by Bowen et al [39], exploring (1) acceptability (To what extent is *InvolveMe* judged as suitable, satisfying, or attractive?), (2) demand (Exploration of the actual use of the *InvolveMe* intervention and experiences with use from the HCP perspective), and (3) limited efficacy testing (Does the tool show promise of being successful with the intended population?) [39]. For the study purpose, this study combines quantitative and qualitative methods for data collection.

Setting, Participants, and Recruitment

The participants in this study were patients with NFPA and HCPs recruited from an endocrine outpatient clinic at a university hospital in Norway. NFPA are benign pituitary tumors, with which patients frequently experience a long period of slow deterioration of their health status before undergoing surgery, and they usually experience a variety of symptoms in the aftermath [40-42], which negatively impacts HRQoL [41,42]. Patients experience individuality and variability in symptoms, including pain, fatigue, sleeping problems, anxiety, and depression, and they may also face challenges related to visual limitations, fear of recurrence, distressing thoughts, loneliness, and frustration [41,43]. Patients with NFPA need and receive long-term follow-up in outpatient care after surgery. The initiative to include this patient group came from the endocrine outpatient clinic participating in this study, which recognized a need to improve patient follow-up after surgery.

Eligibility criteria for inclusion of patients in the study were (1) a diagnosis of NFPA (anywhere in the disease trajectory); (2) receiving treatment and follow-up from the study endocrine outpatient clinic; (3) ≥18 years of age; (4) able to understand oral and written Norwegian; (5) access to a smartphone, tablet, or personal computer; (6) access to the internet with a secure access key (BankID).

Participating HCPs were registered nurses responsible for care and follow-up of NFPA patients at the endocrine outpatient clinic. Some of them had previously participated in studies related to the development and intervention tailoring of *InvolveMe* [35,36].

Ethical Considerations

The study was approved by the Regional Committee for Medical and Health Research Ethics (2018/2201) and the Oslo University Hospital Institutional Review Board equivalent function (2017/9223). Informed consent was obtained from all participants.

Study Procedure

Registered nurses and physicians at the endocrine outpatient clinic identified eligible patient participants based on study inclusion criteria, and the registered nurses asked if these

patients were interested in receiving information about the study. Some of the patients were contacted and asked prior to upcoming consultations; others were asked during consultations. Those interested in receiving more information were contacted by the first author (BS) by phone and provided with information about the study purpose and procedures. Those interested in study participation signed a digital information and consent form. Patient-reported outcome measures were collected online through a secure server at Services for Sensitive Data (TSD; University of Oslo). After completing baseline outcome measurements, patient participants were contacted by the first author and informed how to register and log into the patient portal to access the *InvolveMe* features. After the first log on, HCPs sent a welcome message with information about the project to the patient participant. Patient and HCP participants could contact the first author by phone during the day on weekdays in case of questions. All contacts with participants were logged. The patient participants were informed to direct emergency issues or non-study-related questions to their primary care team or the nearest hospital or urgent care treatment unit.

HCPs at the endocrine outpatient clinic were provided with information about the study, and those willing to participate were included.

Data Collection and Outcome Measures

Timeframe

Data collection from patient participants was carried out from April 2020 until October 2020, when an unexpected incident led to the closure of the hospital patient portal and subsequently closure of the study before the planned study period completion. Outcome measures were collected from patient participants prior to them receiving access to *InvolveMe* and after 3 months of access. Numbers of assessments and secure messages, as well as the content in the secure messages, were also collected. Data from HCP participants were collected through a digital focus group in December 2021.

Sociodemographics and Disease-Related Measures

Information about patient participants' age, sex, level of education, work, income, and year of diagnosis and whether participants had received surgery were collected at baseline. HCP participants were all female registered nurses working in the endocrine outpatient clinic.

Acceptability—Patient Perspective

To explore to what extent the intervention was judged as satisfying or attractive, the first author's experiences from introducing patient participants to the *InvolveMe* intervention, including registration and login procedures in the patient portal, were written down. In addition, patient participants completed the System Usability Scale (SUS), a 10-item survey that provides a comprehensive assessment of subjective usability [44], at the 3-month follow-up. The SUS is a widely used subjective rating tool with acceptable reliability and validity [45-47]. Data from patients who declined to participate in the study (ie, nonparticipants), including age, sex, and reason for not participating in the study, if given unsolicited, were collected.

Demand (System Use)—Patient Perspective

Details of actual system use of the *InvolveMe* intervention were extracted from the patient portal. These data included the number and content of secure messages sent by patient participants, number of assessment invitations sent from HCPs, and number of and content in the assessments completed by patient participants. In addition, reasons for noncompletion of assessments were collected by the first author by phone (ie, written down).

Acceptability and Demand—HCP Perspective

The HCP participants were invited to share their experiences in a focus group that was conducted digitally due to national in-person meeting restrictions during the COVID-19 pandemic. The focus group interview guide consisted of open-ended questions based on operationalization of acceptability and demand [39] after dicussions and consensus of the research team. To explore to what extent the intervention was judged as attractive, suitable, and satisfying (ie, acceptability), participants were asked questions about experiences with recruitment and system usability. To explore experiences with system use (ie, demand), participants were asked questions about the use of secure messages and assessments. The focus group was facilitated by the first (BS) and last (EB) authors, lasted 45 minutes, was recorded with a digital voice recorder, and was transcribed verbatim by the first author.

Limited Efficacy Testing

To explore the feasibility of outcome measures and whether *InvolveMe* could show promise of being successful with the intended population, as well as explore preliminary indications of the potential impact of using *InvolveMe*, participants completed the following outcome measures: anxiety and depression, HRQoL, and health literacy.

Anxiety and depression were measured with the Hospital Anxiety and Depression Scale (HADS), a 14-item measure of anxiety and depression [48]. Items were rated on a 4-point scale (0-3), with a total score ranging from 0 to 42. The HADS is divided into 2 subscales: anxiety (HADS-A; 7 items) and depression (HADS-D; 7 items).

HRQoL was measured with the noncommercial RAND 36 survey, a 36-item HRQoL measure of physical, emotional, cognitive, role and social functioning, physical health, and general and global health [49,50]. Scores can range between 0 and 100 for all subscales, with lower scores indicating higher disability (0=maximum disability, 100=no disability).

Health literacy was measured with the Health Literacy Questionnaire (HLQ) [51]. The 44-item questionnaire includes 9 independent scales, with each scale including 4 to 6 items. The first 5 scales (Part 1 of the HLQ) are scored using response options indicating the level of agreement to items (1=strongly disagree, 2=disagree, 3=agree, 4=strongly agree), while the 4 remaining scales (Part 2 of the HLQ) report on the capacities to undertake different tasks (1=cannot do or always difficult, 2=usually difficult, 3=sometimes difficult, 4=usually easy, 5=always easy) [51].

Statistical Analysis

Statistical analyses were completed using SPSS version 25 (IBM Corp, Armonk, NY). Data on baseline characteristics and perceived usefulness are presented as medians and ranges for continuous variables and as proportions with percentages for categorical variables. Dependent paired *t* tests were used to analyze pre-post intervention changes. All tests were 2-sided, and *P* values <.05 were considered statistically significant.

Qualitative Analyses

Data from secure messages sent by patient participants and data from the focus group with HCP participants were analyzed using thematic analysis inspired by Braun and Clarke [52]. The analysis process was led by the first author (BS) in close collaboration with the last author (EB). Data from 17 secure messages (ie, written text) were read by the first and last authors and coded inductively by the first author [52]. Quotes (ie, written text) to illustrate the content of the secure messages were then chosen by the first and last authors and discussed within the research team.

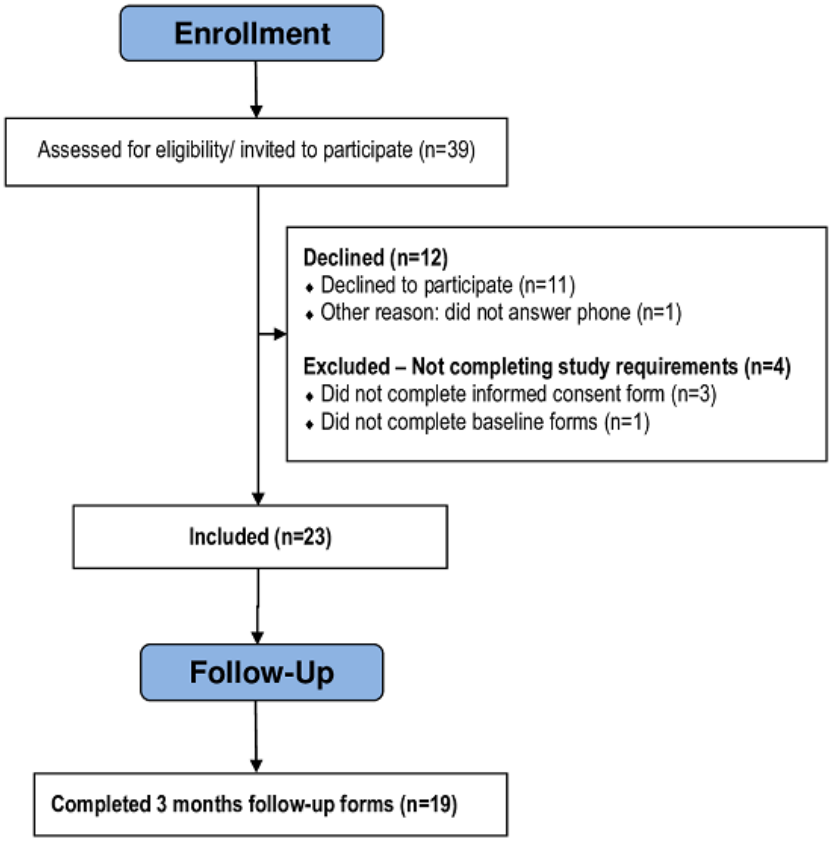
The first and last authors read the transcript from the HCP focus group to become familiarized with the data [52]. Then, the 2 authors used the interview guide to code the transcript deductively into 2 predefined codes: (1) acceptability and (2) demand. Next, subthemes within each main theme were identified. Themes and subthemes were then re-examined, and quotes to illustrate each subtheme were finally chosen and discussed within the research team [52].

Results

Recruitment, Participant Flow, Sample Description

Of 39 patients with NFPA who were assessed for eligibility, 23 (59%) agreed to participate (ie, patient participants), and 16 (41%) declined or did not meet study requirements (ie, nonparticipants). The 23 participants who were included in the study completed baseline measures and received the *InvolveMe* intervention. Of these, 19 participants completed the 3-month follow-up outcome measures. Due to technical issues with the hospital patient portal, the study closed after 6 months, which meant that 4 of the final included participants had limited time (ie, 1 to 4 weeks) to use *InvolveMe*. These 4 were hence not invited to complete the 3-month follow-up outcome measures. One of these participants completed and returned a secure assessment, but none of them used the secure message option in *InvolveMe*. Figure 4 provides details of the study recruitment and participant flow.

Figure 4. Recruitment flowchart.



Patient participants (N=23) were a median 54 (range 26-78) years old at inclusion. Of these, 17 (74%) had completed surgery. Participants were mostly male (14/23, 61%), and almost one-half (10/23, 44%) noted elementary school as their highest level of education (see Table 1 for details). The nonparticipants (N=16) were a median 73 (range 55-80) years old and mostly male (12/16, 75%). HCP participants (N=4) were all female and registered nurses working at the endocrine outpatient clinic.

Table 1. Patient participants' baseline demographics and illness characteristics (N=23).

[b]n=17.

Acceptability—Patient Perspective

Among the 23 patients receiving the *InvolveMe* intervention, 7 (30%) needed additional technical support and assistance beyond the 2 planned contacts during study inclusion to be able to complete study requirements (ie, to complete the digital consent form, complete the digital baseline forms, or register in the patient portal). There were no questions from participants related to completing outcome measures after the initial guidance on how to complete the digital forms. At the 3-month follow-up, the 19 participants also completed the SUS. Mean system usability (ie, SUS) score was 72.2 (SD 14.6), which equals good system usability [44]. Of the 16 nonparticipants, 4 (25%) were positive toward participating but did not complete study requirements such as informed consent or baseline outcome measures. Reasons for declining were mainly described as not having a smartphone (7/16, 44%), feeling overwhelmed (2/16, 13%), or that they thought the intervention would be difficult to use (2/16, 13%). Some stated that it could be challenging to participate in a digital intervention, and some were not familiar with certain terms such as “smartphone.”

Demand (System Use)—Patient Perspective

During the 3-month study period, 43% (10/23) used the *InvolveMe* intervention (ie, used the secure message, completed the assessment, or both) before study closure.

Secure Messages

Of the included patient participants, 4 (4/23, 17%) sent a total of 17 secure messages (ie, assessments not included) during the study. HCPs responded to all, mainly by messages, some by phone or in-person in the upcoming consultation. The content of the messages from participants were sorted into 2 codes: (1) Patient Administrative Matters and (2) Symptoms and Challenges.

For the “Patient Administrative Matters” code, the 9 secure messages mainly concerned a change in the scheduled time of a hospital appointment, prescriptions for medications, or other practical matters. One participant wrote:

> *I have called the pharmacy for a while, but they have not received my medicine. Think the medicine is called something like [medication name]. I was advised by*

> *the doctor to take it during my appointment in May. Have called you too, but no answer.* [Participant 11]

For the "Symptoms and Challenges" code, the 8 secure messages concerned various symptoms and challenges experienced by the participants. The messages centered on a need for guidance (ie, including information and advice) regarding how to manage various symptoms and how to live with the chronic health condition. One participant wrote:

> *What should I feel or look for when I work with challenging things over time, or to see the degree to which I can work-out. Previously I have been told to double the dose of [medication] when needed, but when is that? What are the risks associated with the procedures that have been performed?* [Participant 5]

Another participant wrote:

> *I am still on sick leave, as I feel VERY and UNUSUALLY tired. I get easily tired after doing something. Have also had strict restrictions about making sure I take it easy, not bending forward, sleeping in at least a 30 degrees upwards position, not just showering hot, not eating hot/spicey food etc. (...) Have today raised hemoglobin to [X], as I have lost a lot of blood which may have affected the situation? (...) I'm not quite sure what to do to feel better?* [Participant 16]

Assessments

HCPs sent invitations to complete intervention assessments to all patients with upcoming consultations. Of the 13 invitations sent, 8 (62%) participants completed the assessments prior to the scheduled consultation. In a phone conversation, 1 patient said about the assessment:

> *So incredibly beneficial to be enabled to meet prepared.* [Statement, Participant 17]

Patient participants marked their symptoms and needs in all 4 assessment categories. The categories *Bodily symptoms* and the *Need for information* were marked in all assessments. The most prevalent need for information was about the disease trajectory, marked by 7 (7/8, 88%) participants. The number of marked symptoms and needs varied from 3 to 17 (median 6.5). See Table 2 for an overview of content in the completed assessments.

Table 2. Overview of the content in completed assessments (n=8).

Assessment main categories	Completed individual assessments							
	1	2	3	4	5	6	7	8
Bodily symptoms	Y[a]	Y	Y	Y	Y	Y	Y	Y
Psychosocial challenges	N[b]	Y	Y	Y	Y	N	Y	Y
The need for work related support	N	N	Y	N	N	N	Y	N
The need for information	Y	Y	Y	Y	Y	Y	Y	Y

[a]Y: yes.

[b]N: no.

Reasons for not completing the assessment varied: The upcoming consultation was rescheduled; the assessment was not received by the user due to technological difficulties; and one participant "felt fine" and felt no need to complete an assessment. Two participants did not receive an assessment notification in the patient portal and were therefore not aware of the assessment invitation. Patients had to register their contact information in the hospital patient portal in order to receive notifications there, and a failure to do so could potentially explain why these participants did not receive a notification.

Acceptability and Demand—HCP Perspective

Findings from the focus group with HCP participants were analyzed into the 2 predefined themes of Acceptability and Demand.

Acceptability

Participating HCPs provided a variety of feedback on the intervention, constituting 2 subthemes: (1) Intervention Attractiveness and (2) Intervention Suitability.

In the Intervention Attractiveness subtheme, HCP participants described their experience with the intervention in favorable words and phrases. They described the availability that the intervention provided for the patients as favorable, being able to contact HCPs when they needed to. They also stated that the intervention provided a unique option, especially for patients with complex health issues or heavy symptom burden. They stated that they would have liked to use the intervention for a longer period than the actual study period and said they would like to be a part of and use the intervention in a potential future clinical trial. Regarding recruitment of patient participants, the HCPs described most patients as interested and easy to recruit for this study. As one HCP stated: "...it was not difficult to recruit patients at all, they were, many were positive..."

In the Intervention Suitability subtheme, participating HCPs described the need for a secure and safe place for patients and HCPs to be able to communicate digitally and stated that the intervention was suited for this purpose. They highlighted that their, as well as the patient participants', previous involvement in the process of intervention development and tailoring was an important factor to make the intervention suited to purpose. However, based on experiences of recruiting participants for the pilot study, the HCPs were not entirely convinced that the intervention was suitable for older patients. One HCP stated

that older patients sometimes lacked the necessary equipment (eg, a smartphone) to participate, and reflecting on this, other HCPs contemplated whether a pre-educational group could be useful for eligible patient participants that needed guidance on how to use the intervention. The participating HCPs described themselves and the participating patients as satisfied with the *InvolveMe* intervention and described how patients had provided positive feedback to them about the intervention. One HCP stated that "...the participating patients gave the impression of being very satisfied, they thought it was exciting, and nice, that they could send questions."

Demand

The participating HCPs described the actual use of the *InvolveMe* intervention, and findings constituted 2 subthemes: (1) Elements of SDM and (2) Intervention Challenges and Opportunities.

In the Elements of SDM subtheme, HCPs described how the assessment helped patient participants sort their thoughts before the hospital visits and stated that it acted as a way of providing information about common symptoms and needs. One HCP described the assessments completed prior to consultation as making it easier to address sensitive topics in in-person conversations with patients. This was supported by the other participating HCPs. Some of them described how patients' identification and prioritization of topics important to them contributed to a focus in the consultation conversation, centering around what was most important to discuss for the patients. The HCPs described how the assessments had contributed to change their perspective on what was important to discuss with patients and said that, through this information exchange focusing on patients' current situations, a more individualized follow-up was facilitated based on the patient's needs. As described by one of the HCPs:

> *...the most important thing is that it is user centered, that patients dare to raise issues that are important to them, so that we can focus on what is important, for them to benefit the most from the health care service, this is very important and very rewarding.*

Also, one HCP described how the intervention provided support and contact for patients who felt unprepared for the aftermath of surgery. This was also supported by the other participating HCPs.

In the Intervention Challenges and Opportunities subtheme, participating HCPs described the intervention as time-consuming initially, as they had to learn a new system (ie, hospital patient portal) and develop new routines to be adapted into the daily clinical workflow. However, they stated that, after having learned to use the system, it was no longer time-consuming but rather something that could be executed in between other daily tasks. As stated by one HCP:

> *...we had to learn a new system, which we spent some time on, but I think it was quite easy to learn the system, and it quickly became the routine.*

One participating HCP also stated that they spent some time between themselves discussing potential responses to patients before replying to the secure messages from patients. They reported considering this as something positive, providing quality-assured responses to patients and also contributed to the development of care though contributing to professional discussions. One participant stated that the assessment could potentially even provide support for new HCPs with little prior knowledge about the patient group. They also highlighted, based on feedback from patients, that access to the intervention was valued, even by the patients not using the intervention (ie, participating nonusers), stating that interventions were often used the most by those with complex health issues or heavy symptom burden.

Limited Efficacy Testing: Pre-Post Intervention Results

Pre-post intervention findings at the 3-month follow-up revealed statistically significant increases in symptoms of anxiety (mean difference [MD] 3.9, 95% CI 2.3-5.5) and depression (MD 2.7, 95% CI 0.9-3.8) for the participating patients. Time since surgery had no impact on these results. HRQoL findings indicated a statistically significant improvement for the "Role Physical" subscale (MD 25.0, 95% CI 3.0-47.0) but not for the 7 other subscales. There was a high degree of heterogeneity in the data, with large variance and subsequently broad CIs for the HRQoL subscales (eg, the "Role Emotional" subscale improved by 17.5, but due to the large variance, the findings were not statistically significant). Scores related to health literacy remained stable, with no statistically significant changes from baseline to follow-up. See Multimedia Appendix 1 for details.

Discussion

Principal Findings

Findings from this feasibility pilot study gave insights related to the acceptability and demand of the *InvolveMe* intervention. Exploration of intervention acceptability identified good system usability, and the findings also provided insights regarding patients' reasons for not participating, as well as demographic factors impacting intervention participation (eg, older age among nonparticipants). Furthermore, some participants appeared to struggle with understanding terms used to describe study participation. The examination of demand (ie, system use) suggests that completed assessments and use of secure messages may respectively act as preparation for upcoming visits and provide patients with the opportunity to request guidance on symptom management. The limited efficacy testing showed mixed findings in terms of HRQoL, anxiety, and depression but indicated a study population with high health literacy.

This study provided insight into opportunities for remote SDM through use of secure messages and digital assessments mediated by a patient portal. During the study period, only 17% of participants used the secure message feature. However, simply having the access and opportunity to communicate with HCPs may be of benefit to patients, even without using this option [53]. This was as expected and also suggested in focus group with HCPs. About half of the secure messages sent in the study contained questions related to symptom and treatment complication guidance, which may indicate that the secure messages were used by those who experienced a heavy symptom burden at the time. This was also pointed out by the HCPs during the focus group.

Existing research has found patients to be interested in using secure messages with their HCPs and that patients prefer the convenient and asynchronous aspects provided by secure messaging through portals [14]. The modest use of secure messages in the current study could have been due to the brief study timeframe, and providing patient access over a longer period of time could have provided increased knowledge and experience related to the use of secure messages. Some patients may also lack interest in communicating through portals as they are satisfied with the existing in-person communication [14]. Health literacy is another factor that may play a role in patient portal use, as research has pointed to patients with lower literacy skills as being less likely to use patient portals [14]. However, the participants in this study did not have low literacy skills, quite the contrary.

The assessments collected prior to consultation in this study revealed a wide range of symptoms and needs experienced by the patient participants, which may help identify important topics and priorities for patient-provider discussions and SDM, as also pointed out in the focus group with HCPs. Such assessments may address the individuality and variability in symptoms, aiding patients with communicating their symptoms, needs, and preferences for care to their HCPs [54,55]. In all completed assessments, the study participants used the opportunity provided to request information. This could help improve the provision of tailored information to suit the patients' situations and thus support patients in making choices about their lifestyle, when ready to do so. It has been suggested that, when patient preferences are asserted, HCPs may manage patient concerns and health conditions more effectively [12]. In line with SDM, the *InvolveMe* assessment feature, providing insight into patients' current situations, may facilitate collaboration between the patient and provider to mutually understand and address the patient's situation [9-11].

In this study, 41% of the eligible patients declined to participate or did not complete study requirements (ie, nonparticipants), which is a low percentage of people declining compared with similar studies examining eHealth interventions (ie, 60%-68%) [56,57]. However, evidence on how patients accept eHealth interventions is limited [58], and increasing knowledge related to reasons for nonparticipation (eg, user friendliness, complexity) is necessary in order to improve intervention acceptance.

Nonparticipants in this study were older (median 73 years) than the participants (median 54 years), corresponding with findings from existing research [56,59]. Increased age has been described as contributing to lower levels of digital skills [60,61], a known barrier for adopting new technology [30,62]. Along these lines, a review pointed to substantial health equity disparities in patient portal use, where older persons, persons with low socioeconomic status, persons with low health literacy, and persons with chronic health conditions appear to use portals less often [62].

In this study, some of the eligible patient participants struggled to understand some of the terms used to describe the study participation in detail. Use of technology may inadvertently create health equity concerns by not paying sufficient attention to the social determinants of health during the implementation process [62]. Instead of focusing on barriers for portal use, which may place responsibility on patients already experiencing health disparities, one should focus on developing interventions that are easy to use in order to reduce disparities [62,63]. Findings from this study, as well as existing research on strategies to minimize potential disparities in use [14,63,64], point to the need to develop strategies to increase the number of participants in future studies.

System usability was rated as good but not excellent in this study, which indicates room for intervention improvement. However, using the SUS [44] to measure usability may not have been ultimate in this study, as participants most likely rated the overall system usability, including all the features of the hospital patient portal, not the specific features of the *InvolveMe* intervention alone. When aiming to measure usability and evaluate features integrated into an existing system, the SUS may not be specific enough, and other or additional usability measures should be considered.

The psychosocial outcome measures in this study were primarily included to test feasibility of the measures (eg, are they easy to answer digitally, do they capture changes). Even though some participants initially struggled with completing the outcome measures, all 19 participants receiving the 3-month follow-up measures completed these. There were no questions from the participants related to outcome measures after the initial guidance on how to complete these, indicating satisfactory study routines for this aspect. The noted statistically significant increases in anxiety and depression during the 3-month study period were unexpected. These findings could however be related to the ongoing pandemic during this study, and a recent study revealed that the general population was almost 3 times more likely to suffer from symptoms of anxiety and depression due to the pandemic [65]. The current study period coincided with a national decrease in COVID-19 cases around baseline (ie, May 2020 to June 2020) and a national increase in cases around the 3-month follow-up (ie, August 2020 to September 2020), which might explain the pre-post increase in symptoms of anxiety and depression. However, given the feasibility nature as well as the limited number of participants in the study, efficacy conclusions cannot be made.

Compared with indicators of health literacy (ie, *Active engagement with HCPs* and *Read and understand health information*) from a population-based survey (ie, including people with chronic health conditions) [8] as well as general population participants [66], health literacy scores from this study indicate a study population with high health literacy. Reasons for these findings are not evident, although participants in this study were younger compared with nonparticipants, and higher age has been associated with lower health literacy [60,67].

Even though the closure of the hospital patient portal during this study caused premature study closure, the software development of the *InvolveMe* assessment feature is in accordance with a standard enabling the completed assessment to be sent as an attachment via the secure message feature in the national patient portal [68] as well. Use of standards for provision of eHealth systems has been recognized as a key factor

for successful implementation [31,32], and the importance of developing new software features and systems according to established standards are clearly emphasized through this feasibility pilot study.

The COVID-19 pandemic brought an urgent need for remote care through secure, technical systems and as such, boosted the use of the national patient portal [68] in various ways. For example, as of March 2020, all COVID-19 test results were accessible to Norwegian citizens through the national patient portal, and a number of HPCs, including general practitioners, began using the national portal for most nonurgent care and follow-up. This increase in use of eHealth systems as a consequence of the pandemic has also been identified through a recent review, highlighting how the transformation of care from in-person to virtual or remote accelerated during this time [69]. The *InvolveMe* intervention, incorporated into the national patient portal, may provide features currently not used in the national portal, further promoting patient-provider communication and interaction and serving the need for remote care systems.

Study Limitation and Strengths

This study has several limitations. First, the study was designed to assess the feasibility of a digital patient-provider communication intervention to support patients with NFPA. All patient participants received access to the intervention, without randomization, and statements regarding the effectiveness of the intervention cannot be made. Efficacy testing was however not a major part of this feasibility pilot study. Second, the participants were recruited through a collaborating partner (ie, endocrine outpatient clinic), and it may therefore be assumed that the participating sample were highly motivated and the study cannot conclude whether patients with NFPA in general would be interested in, or benefit from, such an intervention. Indications on feasibility are however promising. Third, the urgent closure of the hospital patient portal led to an unpredictably shortened study period, which might have affected study outcome. Fourth, the focus group with HCPs was conducted 1 year after the pilot study was finished, and all HCP participants were registered nurses. This might have affected recall of experiences, and other additional professionals could have elaborated even more on questions asked in focus group.

This study also has several strengths. First, both patient and HCP perspectives are included in the study, underlining the importance of stakeholder involvement when aiming for real world implementation [30-32]. Second, all eligible patients were invited for participation. This provided insight into who would be interested in the opportunity to assess symptoms and information needs prior to consultations and use secure messages to communicate digitally with HCPs between consultations, as well as reasons for nonparticipation. Such information could be used to tailor educational material and study routines for participant follow-up during the study. Third, the data collection related to acceptability and demand provided essential information for tailoring of the *InvolveMe* intervention as well as study routines in preparation for a future clinical trial.

Future Directions

Through exploration of acceptability, demand (ie, system use), and limited efficacy testing, this study established feasibility of the digital patient-provider communication intervention *InvolveMe*. Findings provided ideas and suggestions for further tailoring in order to prepare for a future clinical trial, such as the development of study-specific questions (ie, in addition to SUS) [44]; use of simple, plain language in the recruitment processes and patient education material; as well as having a dedicated support person involved in the study. In the study, some participants struggled with completing study requirements. Future research should aim to incorporate ways to help adults not familiar with technology to become familiar with and adopt digital interventions.

The increasing number of persons living with chronic health conditions entails, in addition to individual personal challenges, increases costs and demands for resources, representing a major challenge for health care services. Therefore, future research should continue to explore how assessments and secure messages mediated through patient portals can promote and support remote SDM in a variety of chronic health conditions.

Finally, in order to examine actual effects of digital patient-provider communication interventions such as *InvolveMe*, larger-scale clinical trials are needed.

Conclusions

This feasibility pilot study explored how a digital patient-provider communication intervention, *InvolveMe*, could be of use for patients living with chronic health conditions, such as patients with NFPA. Feasibility was established, and the importance of developing software according to given standards was highlighted. Given the findings showing that patient participants used the secure assessment and messages to communicate about bodily symptoms, needs for information, and challenges they experienced, the use of patient-provider interventions such as *InvolveMe* has the potential to facilitate SDM by enhancing accessibility and information exchange and to strengthen the patient-provider relationship for patients living with chronic health conditions.

Acknowledgments

This study was funded by the Norwegian Nurses Organization (Grant #847382; principal investigator EB). The authors would like to thank the patients who participated in the study. The authors would also like to thank the heads of the participating departments, Aud E. Stenehjem and Jens Bollerslev, as well as the health care providers at the Endocrine Day Care Unit, Rikshospitalet, Oslo University Hospital, for their support and encouragement in the research process. Also, the authors would like to thank the patient representatives participating throughout. Finally, the authors would like to thank the research team

members, especially Marianne Ollivier and Elise Flakk Nordang from the content development group and the design and software team by Per Tømmer, at the Department of Digital Health Research at Oslo University Hospital, for their contribution throughout the project process.

Conflicts of Interest

None declared.

Abstract

Background: Digital health technologies such as continuous remote monitoring and artificial intelligence–driven clinical decision support systems could improve clinical outcomes in intensive care medicine. However, comprehensive evidence and guidelines for the successful implementation of digital health technologies into specific clinical settings such as the intensive care unit (ICU) are scarce. We evaluated the implementation of a remote patient monitoring platform and derived a framework proposal for the implementation of digital health technology in an ICU.

Objective: This study aims to investigate barriers and facilitators to the implementation of a remote patient monitoring technology and to develop a proposal for an implementation framework for digital health technology in the ICU.

Methods: This study was conducted from May 2018 to March 2020 during the implementation of a tablet computer–based remote patient monitoring system. The system was installed in the ICU of a large German university hospital as a supplementary monitoring device. Following a hybrid qualitative approach with inductive and deductive elements, we used the Consolidated Framework for Implementation Research and the Expert Recommendations for Implementing Change to analyze the transcripts of 7 semistructured interviews with clinical ICU stakeholders and descriptive questionnaire data. The results of the qualitative analysis, together with the findings from informal meetings, field observations, and previous explorations, provided the basis for the derivation of the proposed framework.

Results: This study revealed an insufficient implementation process due to lack of staff engagement and few perceived benefits from the novel solution. Further implementation barriers were the high staff presence and monitoring coverage in the ICU. The implementation framework includes strategies to be applied before and during implementation, targeting the implementation setting by involving all ICU stakeholders, assessing the intervention's adaptability, facilitating the implementation process, and maintaining a vital feedback culture. Setting up a unit responsible for implementation, considering the guidance of an implementation advisor, and building on existing institutional capacities could improve the institutional context of implementation projects in the ICU.

Conclusions: Implementation of digital health in the ICU should involve a thorough preimplementation assessment of the ICU's need for innovation and its readiness to change, as well as an ongoing evaluation of the implementation conditions. Involvement of all stakeholders, transparent communication, and continuous feedback in an equal atmosphere are essential, but leadership roles must be clearly defined and competently filled. Our proposed framework may guide health care providers with concrete,

evidence-based, and step-by-step recommendations for implementation practice, facilitating the introduction of digital health in intensive care.

Introduction

Background

In intensive care medicine, digital health technologies promise to improve outcomes by reducing the patients' length of stay or preventing complications [1-3]. Continuous remote monitoring allows early detection of deterioration in intensive care unit (ICU) patients and therefore rapid therapeutic intervention [4]. Algorithms used in clinical decision support systems and early warning scores can analyze the large amounts of data generated by ICU monitoring devices to decrease ICU mortality and the risk of complications such as prescription errors [5,6]. Despite the potential, the digital transformation of health care is lagging in numerous countries for reasons that can be ascribed at every level of the health care system. At the macro level, weak national internet infrastructures, high market fragmentation, and lack of legal frameworks, financing models, and interoperability play a significant role [7-9]. At the meso and micro levels, cumbersome operation, high costs, lack of interoperability, information governance uncertainty, and organizational resistance block digital health technology implementation [10-13].

Implementation science, as an increasingly evolving discipline, has brought about the publication of numerous guidelines and recommendations for the implementation of digital health technologies in health care settings by various institutions and researchers [9,14-17]. However, still scarce is the evidence regarding meso- and micro-level implementation and the guidelines for the successful integration of digital health technologies into specific clinical settings [16,18-20]. Successful and sustainable implementation in health care requires a holistic concept to be followed, applying meaningful strategies at all levels [21-23]. In particular, the implementation processes of digital health tools in German ICUs are poorly explored, apart from the concept *tele-ICU*, which involves augmenting local ICU capacity with external expertise through video consultation, remote monitoring, and web-based access to patient data management systems [1,24,25].

Five domains are essential for the implementation of digital health in various health care settings: (1) the individual digital health technology (eg, remote patient monitoring systems), (2) the outer setting (eg, external regulations, laws, and patient needs), (3) the inner setting (eg, the direct implementation environment, social factors, networks, and communication), (4) the individual health professionals, and (5) the implementation process [11]. These domains were first outlined in the Consolidated Framework for Implementation Research (CFIR), a well-proven tool to evaluate the implementation of an intervention into health care settings [12,13,26-29]. Targeting the improvement of implementation performance, the Expert Recommendations for Implementing Change (ERIC) provide a comprehensive compilation of strategies to boost implementation in clinical practice [30,31]. The CFIR domains and ERIC strategies are coherent and synergistic and provide meaningful guidance for implementation researchers and practitioners; however, they require more use cases and documentation of applications in a specific context and setting. In addition, the present literature on implementation strategies for digital health technologies in health care settings and particularly the ICU is extensive and unstructured, and the strategies reported are often poorly conceived [20,32,33].

It is unclear whether the aforementioned barriers and facilitators to digital health implementation can be transferred into the ICU context, given that it is a very specific setting: multiple professional groups work together, many different technologies are already in place, and staff stress levels are also high because of critically ill patients requiring acute treatment, high alarm frequency, and staffing and capacity constraints [34-36]. Concrete implementation strategies for digital health technologies in intensive care settings are still lacking.

Objectives

This study aims to (1) investigate barriers and facilitators to the implementation of a remote patient monitoring technology and (2) develop a proposal for an implementation framework for digital health technology in the ICU.

Methods

Overview

To assess the barriers and facilitators to implementing a remote patient monitoring system, we explored stakeholder perspectives using an abductive qualitative approach. This research design, combining inductive and deductive elements, included semistructured interviews with ICU leaders and key stakeholders in the implementation process, as well as field observations and regular feedback discussions within the research team. To develop the presented implementation framework for digital health technology in the ICU, we conducted a deductive analysis by matching the collected data to the CFIR and ERIC domains. Using the CFIR-ERIC mapping tool, we filtered out relevant strategies to improve implementation performance. In a final step, the strategies were ordered in a temporal sequence and visualized in a figure [37]. The Standards for Reporting Qualitative Research were consulted to report this research [38].

Ethics Approval and Consent to Participate

The ethical approval for this study was granted by the Ethics Commission of the Charité–Universitätsmedizin Berlin (EA1/031/18). Participation in the survey was voluntary. Before the study, all participants provided their consent.

Context and Technical Setup

We conducted this study with ICU staff from a German university hospital over the course of the implementation of the Virtual Patient Monitoring Platform Vital Sync (version 2.4; Medtronic plc). The device remotely monitored ICU patients from portable tablet computers at the hospital premises and was supplemental to the primary patient monitoring system, the IntelliVue patient monitoring system (MX800 software version M.00.03; MMS X2 software version H.15.41-M.00.04; Koninklijke Philips N.V.). The primary Philips IntelliVue monitoring system displayed the vital parameters on stationary touchscreen displays at the bedside and on a monitor at the central nurse station. COPRA (version 6; COPRA System GmbH) was used as the patient data management system (PDMS); however, no data transmission from the Vital Sync system to the primary monitoring system or PDMS occurred.

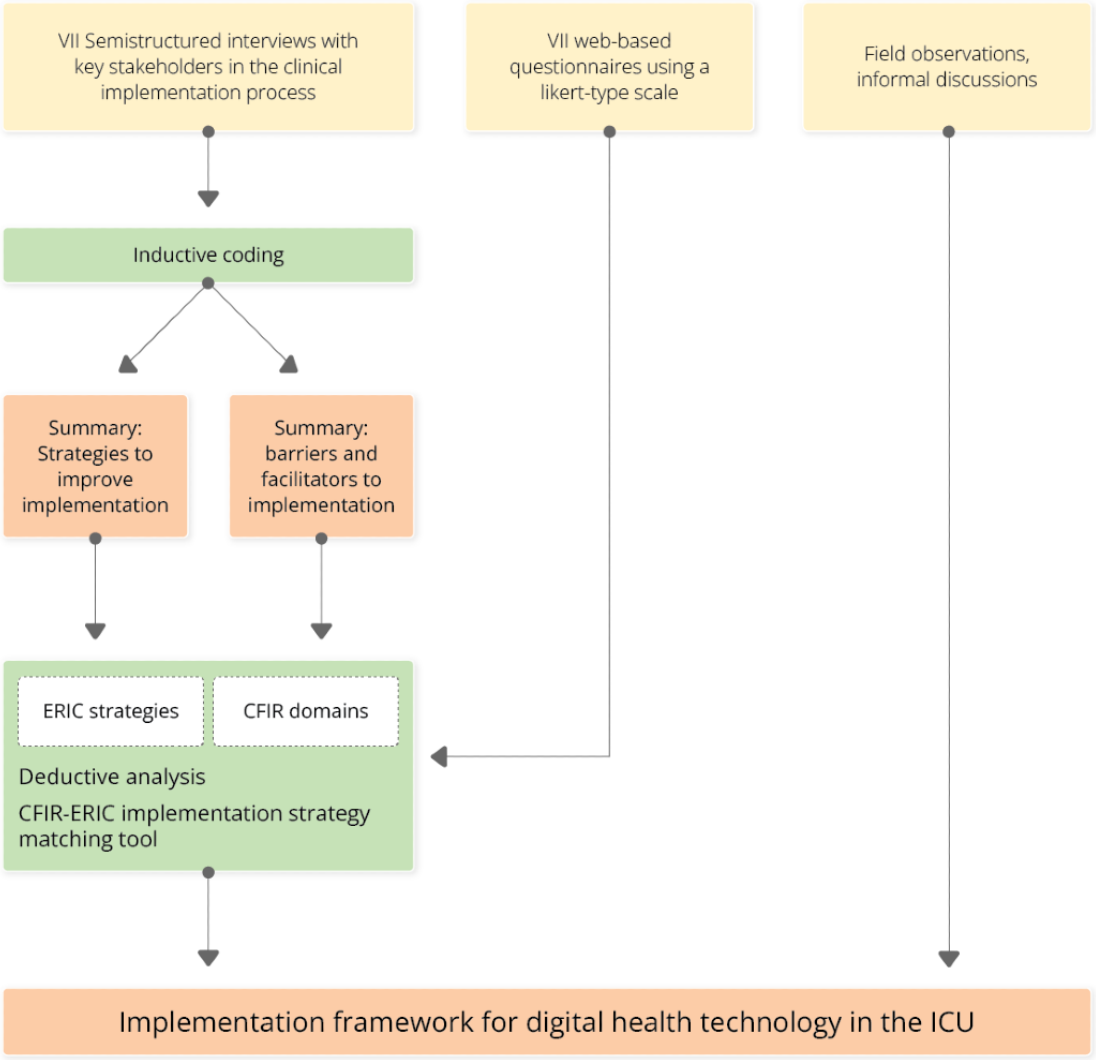
The remote monitoring system was installed between May 2018 and June 2019 in 50% (5/10) of the beds of the postanesthesia care unit, an ICU mainly for postoperative patients that need short-term intensive care treatment and monitoring. The system included 2 sensors (the pulse oximetry and the capnography) that registered peripheral capillary oxygen saturation, pulse rate, end-tidal carbon dioxide level, and respiratory rate at a frequency of 1 Hz. The vital parameters were displayed on a monitor at the central nurse station and were retrievable from 6 tablet computers (2 large 10.2“ iPad tablets [9th generation; Apple Inc], 2 iPad mini 4 tablets [Model A1550; Apple Inc], and 2 Surface Pro 4 laptops [Microsoft Corporation]). A 6-digit code protected the iPad access, and the data were accessible after logging into the Vital Sync website. A username and a password protected the access to the Microsoft Surfaces. Technical instructions of ICU staff (ie, physicians, nurses, and respiratory therapists) into the device were conducted over a period of 1 month. In addition, 2 workshops were conducted for hands-on training. Additional assistance was provided as needed. Further technical description and use of the software can be found elsewhere [39,40].

Study Design and Research Team

This qualitative exploratory implementation study is based on an abductive research approach, as described by Dubois and Gadde [41] and Zainal [42]. The abductive approach of systematic combining (containing inductive and deductive analysis methods) specifies existing theories, refining them according to the individual case and context. We considered this approach essential to derive practical recommendations for the implementation of new technology in the ICU. The transcripts of 7 semistructured interviews and web-based questionnaires with key stakeholders in the clinical implementation process, the results of field observations and informal discussions among the research group, and findings from previous explorations in the context of the implementation were analyzed and applied to the CFIR domains and ERIC strategies to develop the proposed implementation framework (Figure 1) [43].

The research team consisted of an MD candidate (LKM); a postdoctoral researcher with a background in anesthesiology, intensive care medicine, digital health, and geriatrics (ASP); a professor for digital health, who is a consultant anesthesiologist and a computer scientist (FB); a psychologist (HK); a head nurse (MS); an ICU senior consultant (SWC); and the department’s head of staff (CS).

Figure 1. Overview of the data collection and analysis for the derivation of the proposed implementation framework for digital health technology in the ICU. CFIR: Consolidated Framework for Implementation Research; ERIC: Expert Recommendations for Implementing Change; ICU: intensive care unit.



Data Collection

Our data included interview transcripts and quantifiable results of a questionnaire with key stakeholders in the ICU, informal meetings and discussions among the research group, field observations, and the results of previous explorations [39,43]. The outer setting and manufacturer's perspective were not part of this study because we could not evaluate these domains with the data given.

From June to November 2019, we conducted 7 semistructured interviews with ICU staff members, including 3 physicians, 3 nurses, and 1 respiratory therapist. We used purposive sampling with the aim of including all stakeholders who were closely involved in the implementation process and in leading positions in the ICU and presenting all professional groups. The identified study participants were key stakeholders (eg, head nurse, senior physician, and staff member with high working time in respective ICU) of the ICU and had closely experienced remote patient monitoring implementation, overseeing the implementation process, receiving feedback regarding the system from other staff members, and using the system in their own clinical practice.

The interview guideline was deduced on the findings of a previous study from our research group [43] and was oriented toward the categories of the CFIR (Multimedia Appendix 1 [44]). Pilot interviews with associated intensive care physicians did not alter the questions. The interviews were performed either before or after patient care and were recorded and transcribed verbatim.

The semistructured interview guideline included web-based questionnaires containing 47 items and a technology commitment scale [44]. We conducted face-to-face pilot testing with ICU staff with a focus on clarity, relevance, and order of the items. We used a 5-point Likert-type scale as an ordinal response format, with the options *not correct at all*, *not quite correct*, *partly correct*, *quite correct*, and *completely correct*. The study data were collected and managed using Research

Electronic Data Capture (REDCap) tools hosted at Charité–Universitätsmedizin Berlin [45,46]. Data resulting from the questionnaire responses were collected in an overview table.

To gain auditability and enhance reflexivity in the research process, informal meetings and discussions among the research group and field observations occurred from the start of the implementation in May 2018 until March 2020. These methods helped gain a more objective perspective and minimize potential biases that naturally arise when using a qualitative research approach, as described by Noble and Smith [47]. Results of the field research were published by Poncette et al [39].

Data Analysis

For qualitative analysis, we applied a hybrid approach combining inductive and deductive coding elements, as described by Fereday and Muir-Cochrane [48].

First, the interview transcripts were analyzed using a thematic analysis approach, applying an inductive coding process, meaning that themes and codes were iteratively developed and applied to all transcripts [49]. The resulting content of the codes was summarized to obtain the main findings and serve as the basis for the deductive analysis, as described by Crabtree and Miller [50].

Second, for deductive analysis, we used as code system templates the CFIR domains and ERIC strategies, which were grouped into 9 clusters [30,31]. Summaries from the inductive analysis and the findings of the questionnaires were coded according to templates (Multimedia Appendices 2 and 3). That is, data from the web-based questionnaires were not analyzed with quantitative methods. Specifically, the CFIR template was used to analyze the summaries regarding implementation performance, whereas the ERIC strategies served as a template for analyzing the summaries of staff's suggestions on implementation process improvements. All coding was performed using the MaxQDA 2020 qualitative data analysis software [51].

Finally, the proposal for an implementing framework for digital health technology in the ICU was derived from the results of the CFIR- and ERIC-guided analyses. The CFIR-ERIC Implementation Strategy Matching Tool supported the prioritization of the derived recommendations [52]. Findings from the informal meetings, discussions, and field observations supported in situating the results and the interview suggestions in the context of implementation and in supplementing objective characteristics. We ordered the findings into a temporal perspective.

Results

Overview

Inductive analysis of the interview transcripts revealed the two major categories *perceived performance of the implementation* and *perceived factors improving implementation*, which contained 4 and 3 subtopics, respectively. According to the interviewed stakeholders, the remote patient monitoring system's implementation was insufficient owing to a lack of staff engagement in the process and little perceived benefit from the novel solution in its current version. Factors suggested improving implementation were targeting staff training, features of the technology itself, and implementation setting.

Deductive coding revealed four major CFIR domains: *intervention characteristics*, *inner setting*, *individual characteristics*, and *process*. Regarding perceived factors improving implementation, seven clusters of the ERIC framework were mapped: *use evaluative and iterative strategies*, *provide interactive assistance*, *adapt and tailor to context*, *develop stakeholder interrelationships*, *train and educate stakeholders*, *support clinicians*, and *change infrastructure*.

Implementation Process

Staff Involvement and Training

The interviewees identified staff involvement and training as being more targeted toward nursing staff, although they were not in charge of the implementation project. According to the interviewed stakeholders, staff members of all professional groups lacked a feeling of responsibility to continuously apply the remote patient monitoring system. In addition, the staff was unable to identify a leading member in charge of the implementation process and longed for more regular staff training and information sessions. Interviewees reported that opinion leaders' communication created a negative peer pressure not to use the system.

Interviewees said that they felt well informed about the project initially; however, the information flow decreased equally. Training did not reach all staff members because of a complex shift system and a big pool of staff for 2 ICUs, whereas the system was implemented only at 50% (5/10) of bedsides on 1 ICU. Staff perceived the system as an imposition from outside the ICU and felt that it did not have any influence on the implementation.

Additional Benefit

Staff did not perceive the system's added value as high for four reasons: First, the ICU already had a monitoring system offering remote functions (eg, displaying vital parameters of different patients on all bedside monitors), although it did not offer a portable monitoring device. However, according to interviewees, this made an additional system superfluous. Second, the high staff presence in the ICU decreased the need to remotely monitor patients. Third, high patient turnover in the ICU was associated with frequent connecting and disconnecting of patients to and from the system, resulting in an increased workload for nurses. Fourth, remotely monitoring patients while being on a different ward or performing a clinical intervention would make a necessary immediate reaction to an alarm impossible.

Intervention Features

Interviewees highlighted that the limited number of vital parameters monitored by the system was not sufficient to satisfactorily evaluate the patient's condition. Furthermore, the system's dependency on a stable wireless network connection raised concerns. Interviewees perceived the tablet as too large and inconvenient to use and carry in the tunic pockets. Finally, the device would not allow patients' monitoring during their transportation.

Attitude of Staff

Interviewees said that they were satisfied with the current monitoring system and did not see the need for a change. ICU staff did not use the system because they lacked the habit and routine of using a remote patient monitoring technology. They were afraid of losing break times when applying the system and of an increased workload (eg, system setup). They feared that reduced patient contact and false alarms might increase stress levels and endanger patient safety. Overall, the staff saw no additional benefit in the technology. Figure 2 presents an overview of the factors influencing the implementation process from the perspective of interviewed staff members.

Figure 2. Implementation performance: 4 major categories were identified (inner ring), divided into themes (middle ring), and further specified (outer ring). ICU: intensive care unit.

Mapping of CFIR Domains

The summaries of the staff interview transcripts and descriptive data from the questionnaire responses were coded and assigned to four major domains of the CFIR: intervention characteristics, inner setting, individual characteristics, and process (Textbox 1 and Multimedia Appendix 2 [44]).

Textbox 1. Mapped Consolidated Framework for Implementation Research domains and subdomains.

Intervention characteristics

- Intervention source
- Evidence strength and quality
- Relative advantage
- Adaptability
- Trialability
- Complexity

Inner setting

- Structural characteristics
- Networks and communication
- Implementation climate: tension for change, compatibility, relative priority, and learning climate
- Implementation readiness: leadership engagement and access to information

Individual characteristics

- Knowledge and beliefs about the intervention
- Self-efficacy
- Individual stage of change

Process

- Planning
- Engaging: opinion leaders and formally appointed implementation leaders
- Executing

Strategies to Improve Implementation

Staff Engagement and Communication

According to the interviewed stakeholders, persistent leadership engagement and nomination of specific responsible persons for the implementation process were essential, especially in a busy environment such as the ICU. Staff training should be conducted continuously and was particularly critical in the early implementation stages. The quality of instructions was considered essential to influence the staff's opinion toward the implementation. Feedback discussions with staff, project leaders, and a well-functioning team would increase staff engagement. Communication of the project should be encouraging and motivating.

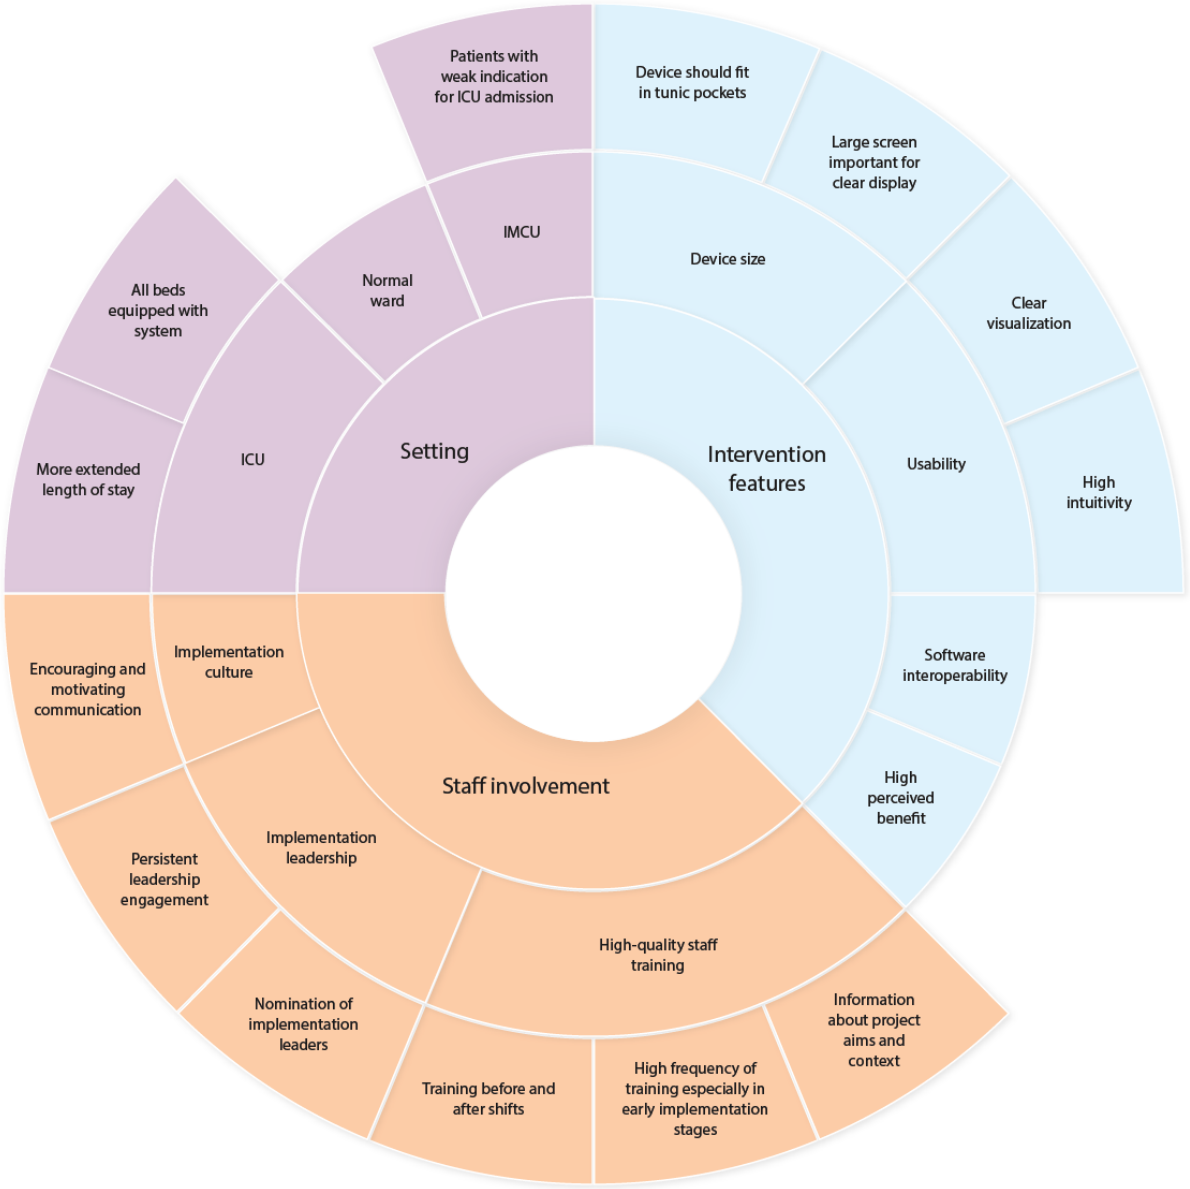
Setting

It was reported that equipping all beds in the ward with the technology and all staff members with portable monitoring devices would increase the implementation performance. A normal or intermediate care unit (IMCU) could be more suitable for a remote patient monitoring technology owing to a lower staff presence and scarcer technical facilities. Interviewees suggested that patients with a relatively weak indication for admission to the ICU could be admitted to a normal ward or IMCU and be monitored remotely. The implementation of technology concerning ICU patients would be more straightforward in a ward with more extended patient stays, as short stays imply more work to install the system.

Intervention Features

High intuitiveness would be crucial for effective implementation, as stated by the interviewees. A monitoring solution without cables would increase usability and perceived benefit. Opinions on the device size varied; a clear visualization needs a large screen, but interviewees favored a device that fits into the pocket of a tunic. Software interoperability with other devices (eg, the respirator or the PDMS) would be essential. Figure 3 presents an overview of the strategies to improve the implementation of digital health technologies according to the interviewed staff members.

Figure 3. Perceived factors improving implementation: 3 categories were identified (inner ring), divided into subcategories (middle ring), and enriched with concrete suggestions (outer ring). ICU: intensive care unit; IMCU: intermediate care unit.



Mapping of ERIC Strategies

Of the 73 ERIC strategies, 19 (26%) were mapped to the summary segments concerning staff suggestions for implementation and quantifiable questionnaire responses (Textbox 2 and Multimedia Appendix 3). The segments were assigned to 78% (7/9) of the clusters of the ERIC framework.

Textbox 2. Mapped Expert Recommendations for Implementing Change clusters and strategies.

Use evaluative and iterative strategies

- Purposely re-examine the implementation
- Develop a formal implementation blueprint
- Audit and provide feedback

Provide interactive assistance

- Facilitation
- Provide clinical supervision

Adapt and tailor to context

- Promote adaptability

Develop stakeholder interrelationships

- Identify and prepare champions
- Organize clinician implementation team meetings
- Recruit, designate, and train for leadership
- Inform local opinion leaders
- Model and simulate change
- Involve executive boards

Train and educate stakeholders

- Conduct ongoing training
- Make training dynamic
- Use train-the-trainer strategies
- Conduct educational meetings

Support clinicians

- Facilitate relay of clinical data to providers
- Remind clinicians

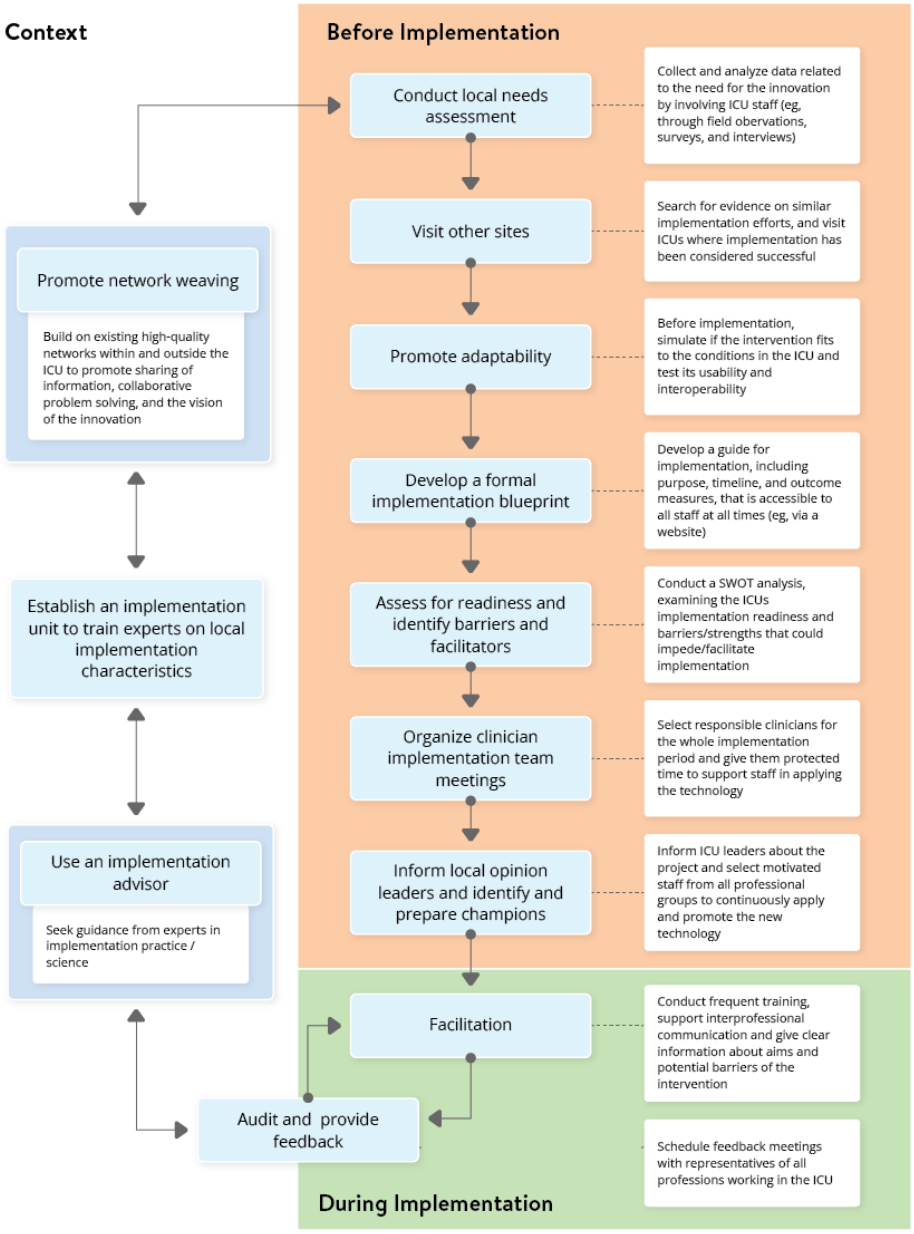
Change infrastructure

- Change physical structure and equipment
- Change service sites

Proposal for an Implementation Framework for Digital Health Technology in the ICU

The developed implementation framework includes 11 recommendations derived from ERIC strategies belonging to 4 clusters of the ERIC framework. A temporal perspective was added, and recommendations were specified to the ICU environment (Figure 4). Our recommendations are targeted toward hospital administrations, leading clinicians in the ICU, and implementation researchers—individuals responsible for the implementation process of new digital health technology in the ICU. Before implementation, 7 strategies, such as *conduct local needs assessment*, *visit other sites*, or *promote adaptability*, should be completed. During the implementation process, we recommend applying the ERIC strategies *facilitation* and *audit and provide feedback* continuously. The strategies *promote network weaving* and *use an implementation advisor* should optimize the implementation setting's context. Optimally, an implementation unit with experts for the local implementation characteristics should be established. Several factors influence the choice of the time to start the implementation process, and an implementation advisor should be consulted to adapt these factors to the context and local needs. Regular feedback by ICU staff regarding the implementation process, illustrated in Figure 4, through the feedback loop can lead to a further need for innovation and ideas to implement digital health technologies. The implementation is a circular process; therefore, we did not include an *after implementation* phase. Continuous re-evaluation triggers a new entry into the implementation strategy and thus leads to a sustainable implementation environment that is always adapted to new needs.

Figure 4. Strategies resulting from the CFIR-ERIC Implementation Strategy Matching Tool and the mapping of staff suggestions for improving implementation to the ERIC strategies before (orange) and during (green) implementation and in the general context of the implementation (yellow). CFIR: Consolidated Framework for Implementation Research; ERIC: Expert Recommendations for Implementing Change; ICU: intensive care unit; SWOT: strengths, weaknesses, opportunities, and threats [52].



Discussion

Principal Findings

Taking the example of a remote patient monitoring system, this study confirmed critical barriers to the implementation of new digital health technologies in the intensive care setting [11,13,53]. The proposed implementation framework for digital health technology in the ICU includes practical strategies to overcome these barriers while using facilitators from the ERIC clusters that can be applied before and during implementation and in the general context of an implementation.

Before implementation and in the general context, sharing use cases and building upon existing best practices are crucial strategies to adapt and choose the technology that best fits the local settings (ie, *visit other sites*, *promote network weaving*, and *use an implementation advisor*) [13,21]. Initiators of an implementation project should lay out its details, aim, and context before implementation (*develop a formal implementation blueprint)*. Transferable discoveries from these strategies and the strategies we propose to be applied before implementation (*promote adaptability*, *conduct local needs assessment*, *assess for readiness*, and *identify barriers and facilitators*) could be used to improve the adaptability and needs orientation of the intervention. Adaptability and user-centered design have been identified as key facilitators of digital health implementation in other settings [11,53,54]. To create the respective conditions, developers and providers of digital health technologies should actively participate in the implementation processes by taking

advantage of the valuable feedback from clinical stakeholders and adapting their products in the spirit of user-centered design [55-57]. Therefore, our proposed implementation framework suggests several strategies to enhance the involvement of clinical stakeholders directly (*organize clinician implementation team meetings*, *inform local opinion leaders*, and *identify and prepare champions*), in line with the proposed strategies for other implementation settings [58,59].

During implementation, ensuring a transparent communication of the project's aim and context (*audit and provide feedback*) is as critical as an effective *facilitation* to improve staff involvement and to promote and sustain implementation.

Sustainable implementation practice means to include the aforementioned aims and strategies in the general context of implementation practice. We propose the strategies *use an implementation advisor* and e*stablish an implementation unit* to improve the implementation environment and the local conditions for a fast, efficient, and sustainable implementation of technology that focuses on the needs of users and patients and adds value. These processes should always be re-evaluated to readapt interventions following the changing needs [58,60,61].

Implementing Technology in the ICU

For decades, the ICU has been equipped with high technology to support staff with continuous monitoring of patients' vital signs, application of medication, documentation (eg, PDMS), or diagnostics (eg, ultrasound and bronchoscopy). However, the implementation of innovative technology in a demanding and hectic environment such as the ICU is a challenge [62]. This has been prominently shown by various projects, more recently, through the rise of telemedicine in the ICU [63], necessitating frameworks for the implementation of such endeavors.

Reported digital health implementation efforts in the ICU rarely involved the use of developed implementation frameworks [64]. This could be due to a lack of both implementation expert consultation and framework transferability into clinical routine. Current frameworks for the design and implementation of digital health technologies are based on best practices and, if evidence-based, need to be validated [30,65]. Our study provides an explicit approach to target implementation challenges and optimize innovation flows and adaptability in the complex environment of an ICU. Further optimization by saturating theories with practical experiences from clinical translation is crucial for the development of a scalable and agile framework for the implementation of digital health technology in the ICU.

Internet of Things, Interoperability, and Data Security

Especially in ICU settings, where various technical devices continuously generate data, the amount of data that can be analyzed and processed is growing rapidly [66-68]. With growing amounts of data to analyze and process, the adoption of the Internet of Things (IoT) in health care is a promising approach to alleviating issues such as high staff stress levels, alarm fatigue, and even medical errors [69,70]. ICUs, in particular, use many different end devices that could be integrated into a fog-, edge-, or cloud-based IoT network for fast and efficient data processing [71,72].

To enhance the capacities of cloud systems, interoperability has become increasingly important, especially in relation to IoT infrastructures [73,74]. Holistically implemented, interoperable technologies could alleviate the burden on staff by reducing documentation time, and easier data retrieval can facilitate therapy and diagnosis [75]. The lack of interoperability of the remote patient monitoring system may have presented a barrier to its implementation. Consistent with findings from other research [55,76], our results show that health care staff support the implementation of interoperable, intelligent monitoring interfaces.

When harnessing the potential of interoperable IoT networks and implementing them in health care settings, a secure and reliable IT infrastructure is required [77,78]. Cybersecurity in health care organizations should be fostered through the definition of cybersecurity duties, sufficient funding, and the application of state-of-the-art measures to reduce the risk of cyberattacks [79,80]. For instance, blockchain technology combined with IoT-enabled smart devices using interoperable fog/edge and cloud computing networks can enable secure, instantaneous data transmission and processing while reducing costs and network delays [70,71].

Implementation Units

With aforementioned promised benefits, health care providers will experience the need to implement new digital health technology into their infrastructures in the decades to come [63,81-83]. They have to be abreast of the latest digital health technologies to select the appropriate technology for the specific area of application and to plan and execute the implementation process, requiring an effective and efficient approach to implementation.

The question arises as to which staff position is responsible for overseeing, evaluating, and adapting recent evidence and strategies in implementation science to the local context. As suggested, internal and external implementation experts should be involved as early as possible [30]. With the introduction of a unit for implementation as a central starting point for any implementation project, resources for redundant project planning or ineffective implementation could be spared and invested elsewhere. The extent to which these units will be involved in the ICU design, for example, should be assessed individually. Beyond the consultation and proposal regarding innovations, such a unit could assess the usability of devices and the adaptability of the intervention before procurement [84] or foster exnovation and deimplementation of outdated or useless technology.

Implementation Frameworks

Implementation science is a young discipline that has developed over the last 2 to 3 decades [85]. Nonetheless, numerous implementation frameworks, either for specific health care settings or for general guidelines, have been published during this period [26,64,86-88]. Other implementation frameworks and strategies for health care are nonspecific in terms of either the intervention targeted [26,64], as they refer to evidence-based

practices [89], or technology [90-92]. Looking at intensive care medicine, implementation frameworks are widely limited to the implementation of evidence-based practices [93,94]. Explicit guidelines for the implementation of novel digital health technologies in the special ICU environments are lacking.

The implementation framework at hand was developed through an interdisciplinary approach, is specific to the ICU setting, and considers relevant particularities in terms of digital health technology implementation.

Limitations

The research team was only able to obtain a limited view of the entire implementation project. The decision to implement the system was made before the study began, which prevented conducting front-end exploration of the implementation setting or evaluation of the external setting and vendor perspective. It was not possible to pursue a user-centered design and implementation in this specific context. However, our study provides valuable insights into the process of implementing digital health technology in the ICU and highlights important application strategies while planning an implementation project. In particular, we identified explicit pitfalls for implementation processes in the specific clinical environment of an ICU and solutions to overcome them.

The interpretation of the results should consider that the CFIR-ERIC mapping tool needs further validation and evidence. Thus, the mapping of strategies to the major barriers might not reflect the best strategy to tackle the respective barrier. We sought to overcome this limitation through profound discussions at meetings within the research team, extensive field research, and analysis of suggestions from staff to improve the implementation performance.

A limitation to the study's scope is that the ERIC strategies do not include changes in intervention characteristics, which would be essential when aiming to improve implementation performance in a user-centered design. ERIC only covers the last stages of implementation (planning and executing the implementation of the finalized intervention) but does not include the readaptation of the intervention as part of the development process.

Finally, the fact that every ICU has unique structural and sociotechnical features, as well as the number of interviewees, could limit the general validity of derived findings. As we investigated an explicit use case in an ICU, potential interviewees were limited because we identified and interviewed the key stakeholders throughout the study. This study depicts an implementation project in intensive care medicine that is close to the standard practice in Germany, where implementation science is still an evolving discipline. However, it is specific to the setting in which it was conducted (ICU, country, and health system), and translation of our findings to other contexts is limited and should be done with these specificities in mind. In terms of continuous reassessment, our proposed framework may need further validation and evaluation in ICU or IMCU settings to fully realize its potential for optimization of implementing digital technologies.

Conclusions

We propose an implementation framework for digital technology in the ICU, which entails practical and evidence-based strategies to improve the implementation process. The ICU provides an exceptional setting for the introduction of digital health technology: the stress level of staff is high, and the ICU team is composed of multiple different professions using the same technologies.

The proposed framework outlines strategies to be applied before and during implementation and in the general context of implementation. Before implementation, the need for innovation and potential interventions should be carefully assessed by involving all clinical stakeholders with clear implementation leadership. Interventions should be needs-oriented, user-centered, and adaptable to changing circumstances. During implementation, a clinical implementation team should ensure transparent, inclusive, and motivating staff communication regarding the project and continuous feedback through local opinion leaders and champions. To ensure efficient management of resources and time, we recommend optimizing the general context of implementation practice in the ICU and the health care institution by involving an implementation advisor, ideally in consultation with an implementation unit of the same institution. Our proposed framework should encourage health care institutions to implement modern digital technology in ICUs and facilitate clinicians and implementation advisors in the practical execution of implementation projects in ICU settings.

Acknowledgments

The authors would like to express their gratitude to the intensive care unit staff for their participation in the study. They acknowledge support from the German Research Foundation (DFG) and the Open Access Publication Fund of Charité – Universitätsmedizin Berlin. The authors would like to thank the Einstein Center Digital Future. They would also like to thank Medtronic for providing the study devices free of charge and Francesca Cappellini for copyediting the manuscript.

Data Availability

The data sets generated and analyzed during this study are not publicly available because of data privacy; however, they are available from the corresponding author (FB) upon reasonable request.

Authors' Contributions

CS had the idea for shared decision allocation and initiated the implementation of remote patient monitoring in the intensive care unit. The study was conceived by ASP, CS, FB, and LKM. LKM conducted data acquisition and analysis, supported by ASP. LKM and ASP wrote the manuscript. HK contributed to the study's methodology and interpretation of results from a psychologist's point of view, and MS (nurses' perspective) and SWC (physicians' perspective) contributed the perspective of the intensive care unit where this study was conducted. FB supervised all parts of the study. All authors critically reviewed and approved the manuscript.

Conflicts of Interest

CS and FB report funding from Medtronic. FB also reports grants from German Federal Ministry of Education and Research, grants from German Federal Ministry of Health, grants from Berlin Institute of Health, personal fees from Elsevier Publishing, grants from Hans Böckler Foundation, other from Robert Koch Institute, grants from Einstein Foundation, and grants from Berlin University Alliance outside the submitted work.

Abstract

Background: There is a global emphasis on expanding data collection for joint replacement procedures beyond implant attributes and progression to revision surgery. Patient-reported outcome measures (PROMs) are increasingly considered as an important measure of surgical outcomes from a patient's perspective. However, a major limitation preventing wider use of PROMs data in national data collection has been the inability to systematically collect and share electronic information with relevant stakeholders in a comprehensive and financially sustainable manner.

Objective: This study reports on the development of an electronic data capture and reporting system by a national registry for the collection of PROMs and the processes used to identify and overcome barriers to implementation and uptake. The study also aims to provide a cost breakdown of establishing and maintaining a nationwide electronic PROMs program.

Methods: Between 2018 and 2020, 3 governance and advisory committees were established to develop and implement a PROMs pilot program nested within a nationwide joint replacement registry. The program involved electronic collection of preoperative and 6-month postoperative data for hip, knee, or shoulder replacement surgery from 44 Australian hospitals. Resource requirements for the program included a project manager, software developers, data manager, and statistician. An online platform was tested, refined, and implemented for electronic PROMs collection with scalability considered for future expansion to all Australian hospitals and additional data fields. Technical capabilities included different access for multiple user types, patient registration, automatic reminders via SMS text messages and email, online consent, and patient outcome real-time dashboards accessible for different user groups (surgeons, patients, hospitals, and project stakeholders).

Results: During the PROMs pilot period there were 19,699 primary procedures undertaken with 10,204 registered procedures in the electronic system. This equated to 51.80% of people who had a joint replacement at participating hospitals during this period. Patient registration and data collection were efficient (20-30 seconds and 10-12 minutes, respectively). Engagement with the reporting dashboards (as a proportion of those who viewed their dashboard) varied by user group: 197/277 (71.1%) hospital administrators, 68/129 (52.7%) project stakeholders, 177/391 (45.3%) surgeons, and 1138/8840 patients (12.9%). Cost analysis determined an overall cost per patient of Aus $7-15 (approximately US $5-12) for 2 PROMs collections per joint replacement procedure once the program was established.

Conclusions: Successful implementation of an orthopedic PROMs program with planned scalability for a broader national rollout requires significant funding and staffing resources. However, this expenditure can be considered worthwhile, given that

collection and reporting of PROMs can drive health care improvement processes. Further consideration of strategies to improve stakeholder engagement with electronic reporting dashboards (particularly for patients and surgeons) will be critical to the ongoing success of a national PROMs program.

Introduction

Orthopedic registries and health care service groups around the world are gradually expanding from routinely reported surgical data to include data on the self-reported health status of patients undergoing joint replacement surgery. Patient-reported outcome measures (PROMs) provide an indicator of surgical thresholds and treatment effects, with the potential to improve health care outcomes within the health care sector for these increasingly common and resource-intensive procedures. Guidelines have been produced regarding the types of PROMs that should be collected [1,2]. However, a major limitation preventing the wider use of PROMs data in population-based studies has been the inability to systematically collect and share electronic information with all relevant stakeholders in a comprehensive and financially sustainable manner.

There are major challenges in effectively collecting and utilizing patient-reported data in a population-based setting. Timing of data collection, optimal selection of PROMs instruments, consent and data collection processes, acceptable levels of data completeness, data security concerns, approaches to delivering stakeholder feedback, and the financial implications are some of the considerations. To date, orthopedic registries that collect PROMs have implemented varying approaches to address these considerations [1-3]. To ensure the effective implementation of a national PROMs collection program, there is a need to systematically design, develop, and test an approach that addresses all of these considerations and does so in a cost-effective manner [1].

In this paper, we report on the establishment of a bespoke electronic PROMs data collection and reporting system and the processes used to overcome identified barriers. This system was developed to facilitate a PROMs pilot program nested within the Australian Orthopaedic Association National Joint Replacement Registry (AOANJRR). We discuss project design, governance, resourcing, infrastructure, and multistakeholder engagement considerations. A comprehensive cost breakdown of establishing and maintaining an ongoing PROMs program nationally is provided to assist other researchers and clinicians who may be considering implementing a PROMs program in their jurisdictions.

Methods

Establishment of a PROMs Pilot Project

The primary purpose of the PROMs pilot program was to design, develop, and test a comprehensive approach to electronically collect PROMs data that could be effectively rolled out nationwide by the AOANJRR. Ongoing development of the purpose-built online platform, known as *RAPID* (Real-time Automated Platform for Integrated Data capture), continued throughout the pilot in response to learnings and stakeholder feedback. This continual refinement of processes and systems was undertaken to best position the PROMs program for a planned nationwide rollout.

Governance, Funding, and Program Approval

Establishing project governance is considered a safeguard to protect patient data and to promote efficiency in the delivery of a PROMs program [4]. For this program, 3 separate groups were established to provide oversight. A Project Steering Committee was established and met quarterly to provide support and guidance for the program. The high-level support from the committee involved a multistakeholder approach including leadership across the Australian Orthopaedic Association (AOA), AOANJRR, orthopedic surgeons, partners, consumer representation, and project funders. An International PROMs Instrument subgroup was established to provide expert advice regarding selection of PROM instruments, additional items, and the timing of data collection [1]. Lastly, a PROMs Working Group was established and met regularly to provide expert advice around project implementation and troubleshooting support for practical issues identified during day-to-day operations.

Ethical Approval

Relevant ethics and hospital governance approvals were obtained, consistent with local requirements [5]. The following Australian ethics committees approved the pilot program from which the data presented in this study were obtained: University of South Australia Human Research Ethics Committee (HREC; 200890), Sydney Local Health District Ethics Review Committee (Royal Prince Alfred Hospital Zone, HREC/18/RPAH/90), Calvary Health Care Adelaide HREC (18-CHREC-F004), Mater Misericordiae Ltd HREC (HREC/18/MHS/45), St Vincent's Health and Aged Care HREC (HREC 18/14), University of Tasmania HREC (H0017292), Calvary Health Care Tasmania HREC (010418), St John of God HREC (1408), and Calvary Health Care Australian Capital Territory (25–2018). Furthermore, licensing requirements for use of the selected PROMs instruments were addressed.

Staffing Requirements

Initially, a project manager oversaw the pilot program and a software developer commenced the design and build of the *RAPID* platform infrastructure. As data collection commenced,

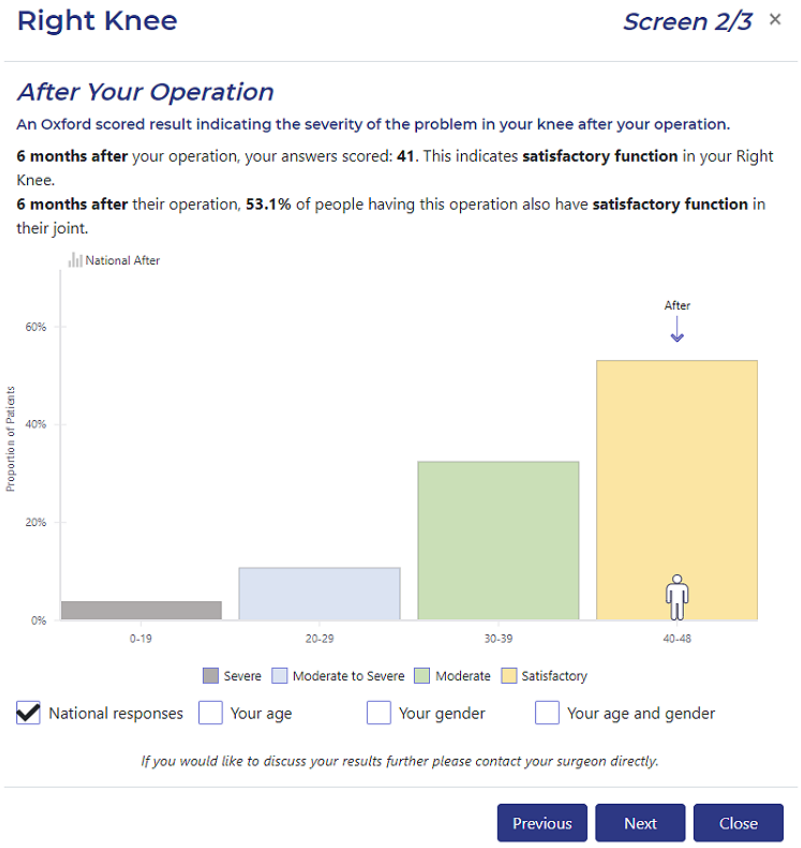
additional staffing resources were required and further team members were sourced (2 additional software developers, a data manager, and a statistician).

Infrastructure: Software Development

During the initial design phase, available off-the-shelf software solutions were deemed not fit for the purpose of the Registry's electronic PROMs collection. This was due to the lack of customizability, particularly pertaining to the layout of patient dashboards and reporting functionality, and concerns regarding ongoing costs and support. Developing the software in-house allowed for technical solutions to be developed for problems identified during the design, testing, and data collection phases. Lastly, *RAPID* was designed from the outset to be scalable for national data collection and included the capability to run multiple research projects simultaneously nested within the Registry.

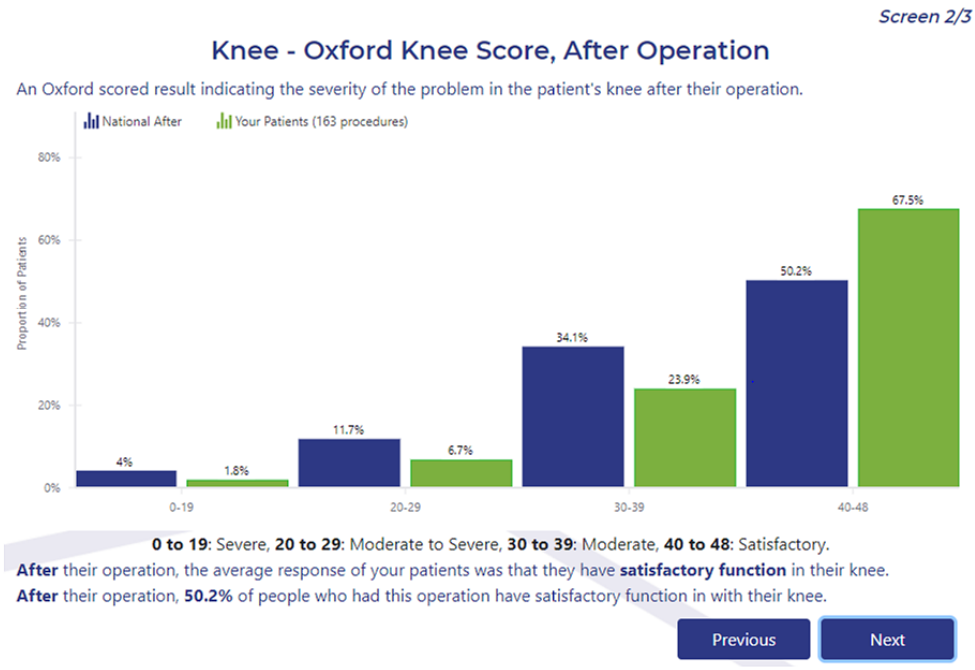
RAPID included the ability for patients to provide online electronic consent, complete their preoperative/postoperative PROMs, as well as incorporate real-time dashboard reporting for patients to view their PROMs responses to compare their own responses as well as with national averages (Figure 1). Critical to the design of *RAPID* was to make the system usable for the specific patient population undergoing joint replacement who are predominantly elderly. Therefore, it was important to make the system as simple, user-friendly, and intuitive as possible. The number of "clicks" required was minimized, 1 question was displayed at a time, and, where possible, the PROMs questions were presented without the need for scrolling (this feature also enhanced viewing ease via a smartphone or other portable devices). Patients were provided with the option to go backward and review or change their answers if they wished to do so. However, the system did not allow for responses to questions to be left blank. Screenshot examples of *RAPID* can be found in 2 published AOANJRR reports [5,6].

Figure 1. Example screenshot from a patient's dashboard within the RAPID platform. RAPID: Real-time Automated Platform for Integrated Data capture.



Orthopedic surgeons had access to identified individual patient responses via *RAPID* when the patient consented to share their responses (12,236/12,874 [95.04%] preoperatively and 4653/4780 [97.34%] postoperatively). In addition, surgeons were able to download patient responses in a Microsoft Excel format. Dashboards were provided to all surgeons and these graphically displayed their patient recruitment data and PROMs outcomes, as well as comparisons with national averages (Figure 2). Surgeons were able to filter their patient cohort based on age or sex and compare different hospitals in which they operate. Designated hospital staff could also obtain similar data for the hospital cohort, following the provision of appropriate consent. Specific reporting dashboards were also designed for project stakeholders who were provided with aggregated national-level data.

Figure 2. Example screenshot from a surgeon's dashboard within the RAPID platform. RAPID: Real-time Automated Platform for Integrated Data capture.



An additional software feature of *RAPID* was the ability to integrate PROMs data collected by third parties so that some hospitals and surgeons could continue to collect data in their systems. This was deemed necessary due to the length of time some of the previous data collection systems were in place. The AOANJRR developed a standardized template for use by hospitals to send PROMs data via *RAPID*. Integration of the data into *RAPID* was conducted by the data management and statistical teams following a manual review of the data file. Any data discrepancies were queried and addressed prior to upload. However, this feature proved to be a highly resource-intensive process and opportunities to streamline this will be considered for the national rollout.

Software Architecture and Security

The major components of the *RAPID* software architecture are a user interface built on the React web framework, with back end services using Spring Boot and a PostgreSQL database. These components were chosen due to their popularity within the software development community, breadth of documentation and community support, ease of development, and no licensing costs.

To securely log into *RAPID*, user access is role based for designated administrators, with access tailored depending on each role's scope of responsibility within the system. For other users (such as surgeons and hospital staff), access is tailored based on their roles within various hospitals and other projects in *RAPID*. Additional security measures in *RAPID* include session timeouts, password expiries, minimum password strength limits, restrictions on password reuse, lockouts when the number of successive incorrect password attempts reaches a threshold, and a secure password hashing algorithm (PBKDF2). Access to the raw data (ie, in the database) is limited to data managers, statisticians, and information technology staff through firewall and access control measures.

Results

Engagement: Participation, Recruitment, Data Collection, and Quality

Hospital Participation

The pilot program included a broad cross section of public and private hospitals from all Australian states, of all sizes (small [<100 beds], mid-range [100-499 beds], and large [>500 beds]) and from urban and nonurban areas. Hospital representatives either volunteered to participate in the pilot PROMs program, were recruited following surgeon recommendation, or were invited to participate based on previous collaborative projects. In total, 44 hospitals provided pilot data.

Patient Recruitment and Hospital Training

Patients scheduled for primary or revision hip, knee, and shoulder replacement procedures were eligible. Patients under the age of 16 and patients with a cognitive impairment that impacted their ability to provide informed consent were excluded. Initial patient recruitment involved registration into *RAPID* via the collection of limited data including patient name, date of birth, postcode, contact details (1 or more of the following: email, mobile phone, and home phone), joint, side, surgeon (optional, if known), and hospital. Patients registered themselves or were registered by an administrator, via the *RAPID* platform. Administrators were provided training in *RAPID* by the project team and had on-site visits (or when not possible on-site, online training). Once registered, patients were able to provide electronic consent and then PROMs could be completed, either immediately or at a later time. Once registered, patients were provided with an electronic patient information

sheet that detailed information about the Registry and the pilot program. A hard copy study information card was also provided to patients. If patients did not wish to participate, they were able to select "decline to participate" within *RAPID*, which deleted all identifying information recorded at registration from the system. However, only a small number of patients declined participation (944/14,890, 6.34%). SMS text messages and email reminders were effective in maintaining patient participation once patients were successfully registered in the electronic system [5]. Feedback provided by administrators and patients highlighted the efficiency of the patient registration and data collection system, indicating that it took 20-30 seconds to register a patient and 10-12 minutes for patients to complete their PROMs.

Data Collection

Automated email and SMS text message reminders were sent to patients via the *RAPID* platform as a reminder to complete their PROMs both preoperatively and 6 months postoperatively. The system allowed for a set number of reminders to be sent pre- and postoperatively, depending on the contact details provided at registration. Patients who had not completed their PROMs after 2 automated reminders appeared on a list for phone call follow-up. Phone call follow-up was trialed as part of the pilot and patients' responses were entered directly into *RAPID* by a member of the phone call follow-up team. Comparisons of demographic information determined no substantial difference between patients who required phone call follow-up and those that responded to electronic reminders. Given this finding and associated costs, phone call follow-up was later phased out.

Data Quality

Throughout the data collection phase, the project manager communicated with orthopedic surgeons and personnel assisting with patient registration to ensure hospitals were well supported. A data summary was distributed regularly (containing both patient registration and procedure registration at each hospital), and hospitals were also directed to their *RAPID* reporting dashboards. If a hospital was identified as having low registration of patients, it was contacted so that processes could be reviewed and refined. Through this process, the AOANJRR determined that hospital registration improved over the pilot period, where more than 60.2% (441/733) of procedures undertaken at pilot hospitals were registered within the *RAPID* platform after 12 months of data collection, compared with 44.85% (2366/5275) in the first 3 months of data collection [5]. By examining learnings from hospitals that improved registration rates, the AOANJRR was able to implement the same processes to improve the performance of less satisfactory hospitals.

Surgical procedure forms received from each hospital were entered into the AOANJRR database as part of routine Registry processes. The patient information from the procedure form was then matched with the patient information in *RAPID*. This process assisted with determining the proportion of joint procedures registered at each hospital as well as identifying any data entry errors. It was also required for electronically triggering postoperative data collection reminders based on the procedure date. Reports were produced on patient registration and procedure registration rates at each hospital.

Cost Analysis

Establishment Costs Associated With a PROMs Program

A multistakeholder approach to funding was established to foster a wide leadership base and to maximize engagement across the health care sector. Expenditure for the pilot PROMs program (n=14,890) was largely attributed to staffing costs as well as to the establishment of *RAPID*.

Staffing Costs

While the PROMs pilot was in the design and development phase, staffing costs were kept to a minimum by drawing on the expertise and experience of existing Registry staff. As the pilot developed and the scope increased, additional resources were required to establish PROMs collection within the pilot hospitals. This included the project manager (1.0 full-time equivalent [FTE]), software developers (2.5 FTE), data manager (0.8 FTE), and a statistician (0.6 FTE).

Information and Communications Technology Development Costs Associated With RAPID

A large portion of establishment costs was associated with the software development phase of *RAPID*. In addition to the information and communications technology (ICT) staffing costs, running costs included software licensing, servers (including nonproduction servers used for development and testing), and website certificates (Aus $27,000 [~US $20,000] over 2 years). Furthermore, to ensure secure storage of sensitive patient data, a security design review was conducted during the design phase and a follow-up software penetration test was conducted prior to launch (Aus $14,000 [~US $10,000] over 2 years). While these costs substantially contribute to the overall budget, the security of patient data is at the forefront of consideration in health care settings [7].

Trial of Tablets for Patient Registration Within Hospitals

A total of 70 tablet devices (specifically iPads) were purchased by the Registry and provided to 41 pilot hospitals to mitigate potential barriers relating to patients not having access to electronic devices and to encourage hospital participation. The total cost including providing cellular data for the devices was Aus $31,000 (~US $23,000). Data indicated that hospitals only intermittently provided patients with the tablets for patient self-registration and survey completion [5]. With this in mind, it has been decided that tablets will not be provided when the PROMs program rolls out nationally in Australia.

Cost of Telephone Follow-Up

During the pilot period, 1148/14,926 (7.7%) procedures registered in *RAPID* had a landline telephone only (predominantly patients aged ≥85 years) [5], precluding patient follow-up via SMS text messaging. Extrapolating the cost of Aus $65,000 (~US $48,000) for telephone follow-up in the pilot (involving about 15% [n=44] of available hospitals) to a broader national rollout produces an estimate exceeding Aus $450,000 (~US $336,000) annually. This was deemed to be financially unsustainable. Throughout the pilot and since its completion,

AOANJRR has encouraged hospitals to obtain the contact details of a proxy individual (eg, a family member or friend) to receive reminders on the patient's behalf and assist with the electronic completion of PROMs.

Discussion

Principal Findings

Owing to the success of establishing the PROMs pilot program within 44 Australian hospitals, a national rollout of the program is currently underway with ongoing government funding. A large portion of the funding attributed to the national rollout has been dedicated to staffing costs. The PROMs project manager, ICT software developer, data manager, and statistician have been retained. Two additional full-time project coordinators have subsequently been employed to facilitate expansion of the program from 44 hospitals to approximately 320 Australian hospitals, which requires significant engagement with each hospital site. The project coordinators are also responsible for continued engagement with the hospitals that participated in the pilot.

Prediction of Anticipated Ongoing Cost of a PROMs Program Nationally

On completion of the national rollout program, it is anticipated that PROMs staffing costs may decrease with the potential to reduce to 1 project coordinator and 1 software developer while retaining the project manager, data manager, and statistician. Conversely, ICT costs are likely to gradually increase as the size of the *RAPID* platform expands to accommodate for increased accessing, processing, and storage of patient data. Increased server storage and security enhancements as the *RAPID* platform increases capacity are expected. Assuming PROMs data are collected on 40%-80% of joint replacement procedures (a range of ~44,000 and ~88,000 procedures; based on 110,000 primary hip, knee, and shoulder procedures for osteoarthritis and revision procedures for the 3 joints per annum), we estimate a cost per patient of Aus $7-15 (approximately US $5-12). We recognize that cost and governance processes differ between countries and jurisdictions, which makes direct comparisons for implementation in other settings challenging.

Enablers and Barriers to Establishing a PROMs Program

Enabler: Successful Cost Minimization

Nesting the PROMs pilot project within the AOANJRR was key to successfully reducing costs as it allowed for shared staff resources throughout the lifecycle of the project, particularly in the planning and implementation phases of the project. This included utilizing the existing expertise, skills, and relationships of Registry staff to liaise with surgeons and clinicians directly at hospital sites. These relationships assisted with approval for hospitals to participate and reassuring surgeons regarding any process or security concerns. The well-established reputation of the AOANJRR allowed for confidence in data security by patients, surgeons, and stakeholders.

Enabler: Successful Online Electronic Data Collection

Electronic PROMs collection has proven to be a successful means of outcome data collection, as evidenced by other Registries, such as the Functional and Outcomes Research for Comparative Effectiveness in Total Joint Replacement (FORCE-TJR) Registry that has reported high levels of enrollment and data completion via electronic collection [8]. Our pilot has proven similar success in that of the patients who consented within *RAPID*, preoperative PROMs collection was obtained for 97.77% (12,871/13,164) of registered procedures, and 79.05% (4184/5293) of postoperative PROMs were completed [5]. Wilson et al [2] highlighted that paper-based questionnaires can be relatively easy for patients to complete, but issues persist with mail-out, having patients mail them back, following up on missing data, possible data entry errors, or duplications [2]. These issues were mitigated with the use of the *RAPID* platform. Another consideration is potential patient response differences when 1 question is viewed at a time (versus traditional paper-based collection) and the order in which the questions are answered. Some research has indicated that displaying 1 question at a time improves response rates; however, equivalence studies compared with paper-based collection would provide benefit to the orthopedic community [9]. In our pilot study, the small number of patients who were unable to access *RAPID* or could not be contacted via electronic means were encouraged to seek assistance from family or friends to complete their PROMs or to contact the Registry for assistance with online completion. In the pilot study, preoperatively, 10.34% (782/7562) of patients reported seeking assistance from a family member and 0.45% (34/7562) of patients reported seeking assistance from a friend. Technology is increasingly affordable and accessible with internet access in Australian private homes recorded at 86% [10]. Access and technological familiarity will likely continue to improve over time, including for older patients.

Enabler: Successful Customization of the RAPID Platform

The ability to adapt *RAPID* functionality following user feedback and respond quickly to address any identified issues was a critical enabler to improve engagement with hospital sites and optimize patient registration. Hospital staff feedback identified that patients in preadmission clinics are required to attend a variety of appointments during their preadmission review and this made it difficult to complete the survey on the supplied iPad in a single sitting. A system adjustment was then made to implement a "resume" function in *RAPID*. This allowed patients to exit *RAPID* part way through the survey and return to complete the survey within 14 days in their own time on any device.

Administrators identified during the pilot that the electronic consent format was proving onerous for patients as they had to click "I agree" to each consent statement (9 in total) before providing final consent. The system was updated so that the information sheet could be reviewed on a single page with patients consenting to participate in the study once the information was reviewed by pressing 1 button.

Registry staff identified that it would be helpful to generate additional PROMs completion reminders manually when patients requested. *RAPID* was updated to include a manual link that generated additional SMS text messages or email reminders on request.

Such enhancements proved important in facilitating data collection and reducing the burden on patients. This also underscores the importance of continuous software developer resourcing to support additional minor platform refinements, even after a project has launched.

Identified Barrier: Overburdening Hospital Staff and Patients

One of the main considerations for this program was to develop an electronic system that would not overburden hospital and administrative staff. Two pathways for patient registration were therefore developed; patient self-registration or registration of a patient by an administrative user. During the pilot, participant recruitment increased when the patient was registered by hospital staff. For the national implementation of this program, the Registry will continue to encourage the registration of patients by hospital staff.

Frequently reported barriers for patients to complete PROMs are the length of time to completion and difficulty using electronic devices [11]. Early reports from patients suggested that the time taken to complete the PROMs instruments was satisfactory (10-12 minutes for PROMs completion) [5]; however, further exploration of patient burden and preferences is necessary through seeking consumer representation [6].

Identified Barrier: Hospital Staff Turnover

Staff turnover at the hospitals was identified as an issue impacting patient recruitment. Registry staff were often unaware that a hospital staff member trained in using *RAPID* had left the hospital until a decrease in patient registration was identified. In these instances, it was identified that key project details were not communicated or understood when hospital staff handed over the task to new personnel. To alleviate this potential barrier, the Registry has implemented additional reporting strategies to monitor hospital recruitment as well as continuing to provide specific hospital training, education material, and induction documentation to meet the needs of new hospital staff.

Conclusions

Successful implementation of a national PROMs pilot program with planned scalability for a national rollout can be achieved but requires significant funding and resources. However, the expenditure can be considered worthwhile given the high level of patient participation and the potential for PROMs data to drive improvement processes, improve care for patients, and optimize health care efficiency. Importantly, strategies to improve stakeholder engagement with electronic reporting dashboards (particularly for patients and surgeons) need to be investigated further, as this will be critical for the ongoing success of a national PROMs program.

Abstract

Background: The Rosalynn Carter Institute for Caregivers (RCI) offers evidence-based interventions to promote caregivers' health and well-being. Trained coaches regularly meet with caregivers to offer education and instructions to improve caregiver health, build skill sets, and increase resilience. Two of these interventions, RCI Resources for Enhancing Alzheimer's Caregiver Health (REACH) and Operation Family Caregiver (OFC), use a set of caregiver-reported questionnaires to monitor caregivers' health status and needs.

Objective: This study aims to describe how web-based assessment questionnaires are used to identify and monitor caregiver status in the RCI REACH and OFC programs and outlines perceived enhancements to the web-based system that could support caregiver-coach encounters by directing priorities.

Methods: This was a descriptive, qualitative study. Data were collected via semistructured interviews with caregivers and coaches in the RCI REACH and OFC programs from July 2020 to October 2020. During the interviews, participants were asked to describe how the assessment questionnaires were used to inform caregiver-coach encounters, perceived usefulness of enhancements to web-based display, and preference for the structure of score results. The interviews were recorded, transcribed, and coded using structural and interpretive codes from a structured codebook. Qualitative content analysis was used to identify themes and summarize the results.

Results: A total of 25 caregivers (RCI REACH: 13/25, 52%; OFC: 12/25, 48%) and 11 coaches (RCI REACH: 5/11, 45%; OFC: 6/11, 55%) were interviewed. Most caregivers indicated that the assessment questions were relevant to their caregiving experience. Some caregivers and coaches indicated that they thought the assessment should be administered multiple times throughout the program to evaluate the caregiver progress. Overall, caregivers did not want their scores to be compared with those of other caregivers, and there was heterogeneity in how caregivers preferred to view their results at the question or topic level. Coaches were uncertain as to which and how much of the results from the self-reported questionnaires should be shared with caregivers. Overall, the results were very similar, regardless of program affiliation (RCI REACH vs OFC).

Conclusions: Web-based and procedural enhancements were identified to enrich caregiver-coach encounters. New and enhanced strategies for using web-based assessment questionnaires to direct priorities in the caregiver-coach encounters included integrating figures showing caregiver progress at the individual caregiver level, ability to toggle results through different figures focused on individual versus aggregate results, and support for interpreting scores. The results of this qualitative study will drive the next steps for RCI's web-based platform and expand on current standards for administering self-reported questionnaires in clinical practice settings.

KEYWORDS

caregiver; web-based questionnaires; self-report questionnaires; caregiver outcomes; intervention technology; patient-reported outcome measures

Introduction

Background

One in five adults in the United States provides unpaid caregiving; these adults are also known as family caregivers [1]. Responsibilities for unpaid caregivers are wide-ranging and include interacting with clinicians on behalf of the care recipient, transportation, housework, shopping, paperwork, managing finances, helping with personal hygiene, and administering medical therapies [2]. Caregiving responsibilities often accumulate over time as the care recipients' health status worsens, and caregivers must manage the changing needs of their care recipients. For family caregivers, caregiving is associated with higher levels of depression and anxiety, worse self-reported physical health, and increased risk of early death [3].

The Rosalynn Carter Institute for Caregivers (RCI) offers evidence-based interventions to promote the health and well-being of caregivers and provides training on coping skills [4]. RCI coaches regularly meet with caregivers to offer education and training to improve their health, build skill sets, and increase resilience. During these one-on-one meetings, caregivers and coaches touched on a variety of topics, including the burden of caregiving, self-care techniques, problem solving, and community support. Two of these interventions, RCI Resources for Enhancing Alzheimer's Caregiver Health (REACH) and Operation Family Caregiver (OFC), use a set of caregiver-reported questionnaires to monitor caregivers' health status and needs.

RCI REACH is a coach-led one-on-one program for caregivers that focuses on building caregiver skills in stress and mood management, as well as problem solving. Caregivers in this program care for individuals with Alzheimer's disease and related dementia. The RCI REACH includes 12 in-person or web-based sessions with a coach. On average, it takes approximately 7.5 months for caregivers to complete the program depending on the spacing of the sessions. A preliminary single-group observational study showed that RCI REACH participants had a decrease in depression and caregiver burden, and caregivers reported being less troubled by care-recipient behavioral problems [5].

The OFC is a coach-led one-on-one program for caregivers of active-duty military personnel or veterans. Sessions were conducted in person or via a web-based video platform including FaceTime (Apple Inc) or Zoom (Zoom Video Communications) over the course of 8 sessions (average time to complete the sessions was 5.4 months). Coaches help caregivers recognize challenges, identify solutions, and develop problem-solving skills. Using a single-group, pre-post study design, Easom et al [6] showed that caregivers who participated in the OFC had decreased depression and feelings of caregiver burden, as well as increased life satisfaction and positive problem-solving skills.

Included in each of these RCI programs are a set of web-based questionnaires that are used to provide RCI with information on caregiver outcomes, otherwise known as *the assessment*, which consists of a variety of validated questionnaires, such as the Center for Epidemiologic Studies Depression Scale—Revised [7] to measure depression and the Zarit Burden Interview [8] to evaluate caregiver burden. Other questionnaires validated for caregivers were used to evaluate caregiver work performance [9], work-family conflict [10], self-efficacy for caregiving [11], problem-solving ability [12], life balance [13], caregiver perceived financial stress [14], and community support [15]. As the challenges and needs of caregivers in RCI REACH and OFC are different, the assessment also asks caregivers to report concepts specific to each program. For example, caregivers in the RCI REACH program are asked specific questions about caring for an individual with dementia, including care recipients' memory and behaviors [16], how bothered they are by their care recipient's memory status or behaviors, home preparedness and safety, and desire to place the care recipient in a nursing home or assisted living facility [17]. For the OFC, the assessment inquired about problem solving [12] and child anxiety for children living in the caregiver's household [18].

The web-based assessment is currently administered when caregivers enroll in the program (T1) and when they finish it (T2). Historically, this assessment was primarily used to evaluate the impact of the programs on caregiver outcomes at the aggregate level. However, the RCI was interested in learning what opportunities there might be to expand the usefulness of the assessments and results to coaches and caregivers.

Coach-caregiver encounters are similar to clinician-patient encounters in routine clinical care. Self-reported questionnaires, often referred to as patient-reported outcome (PRO) measures, are administered in clinical care to obtain information on patient status. Significant evidence supports the integration of PROs in clinical care with processes that report scores to patients and clinicians. PROs are associated with improved patient quality of life outcomes, patient-clinician communication, patient satisfaction, and facilitation of meaningful and focused conversations between patients and clinicians [19-30]. The rationale for this study is that, by exploring an analogous process in caregiver-coach encounters, RCI's web-based assessment could provide real-time feedback about progress on intervention targets and can serve as an intervention strategy to more directly tailor the intervention to improve caregiver-coach communication, support the coach in identifying and prioritizing caregiver needs, and achieve better intervention-related outcomes for caregivers.

Objectives

We conducted a qualitative study to describe caregiver and coach perspectives and proposed enhancements to the web-based assessment that could support caregiver-coach encounters. Specifically, we were interested in how the assessment would optimally integrate into the coach-caregiver encounter, including how often outcomes should be evaluated, which format of outcome presentation would be most helpful and to whom, how stakeholders would like to see outcomes presented (eg, figures and text), and what specific features of the assessment would support the encounter and shared decision-making about caregiver needs or successes. This project provides foundational knowledge for designing a web-based system that could support caregiver-coach encounters by providing timely feedback on caregiver needs.

Methods

We conducted a qualitative descriptive study including 1-hour one-on-one semistructured interviews with caregivers and coaches associated with RCI's REACH and OFC programs from July 2020 to October 2020.

Data Collection

Semistructured interview guides were developed to standardize the topics discussed during the interviews. The caregiver and coach interview guides were developed separately because of the different perspectives shared by each type of participant. Interview guides were iteratively developed before data collection began and included open-ended questions and scripted probes. During data collection, the team refined the interview guides by modifying the way questions were worded or adding probes to improve the flow of the interview and gain insight into specific sections.

During the interviews, participants were asked to describe how the T1 and T2 assessments were currently being used, how frequently they thought the assessment should be administered, perceived usefulness of enhancements to web-based displays, and preferences for the structure of self-reported score results. Caregivers and coaches were asked how they would prefer to see the results in figure format. To facilitate discussion about the format of the results, some caregivers and coaches were provided with example figures for discussion.

All interviews were conducted via Zoom with video being disabled. With participants' permission, the interviews were audio recorded and transcribed. The caregivers were given a US $25 gift card as compensation for their time. During and after the interviews, interviewers took notes describing patients' responses and impressions using semistructured debriefing forms.

Ethics Approval

This study was reviewed and exempted by the Duke University Institutional Review Board (protocol number Pro00105250).

Inclusion Criteria

Adults aged >18 years who completed at least 1 session with a coach in either the RCI REACH or OFC program were invited to participate. Eligible coaches included RCI REACH and OFC coaches who had coached at least 1 RCI-affiliated caregiver.

Recruitment, Consent, and Sampling

Recruitment was conducted in 2 ways. First, the Duke study team met with the RCI coaches on the web during a regularly scheduled coach meeting to introduce the study. At the meeting, coaches were provided with information about the study, which included an information sheet and a link to a secure web-based questionnaire (via REDCap [Research Electronic Data Capture; Vanderbilt University]), where coaches and caregivers could review written information about the study and answer screening questions. The coaches were asked to share the study information and REDCap link with caregivers. If an individual was eligible after completing the screening, the Duke study staff reached the coach or caregiver to provide more information and schedule the interview.

The participants were also recruited from the contact list provided by the RCI. Duke study team members reached out to potential participants via email and telephone to provide information about the study and subsequently enrolled the individual if they were eligible and expressed interest in participating in the study. Eligibility and screening responses were recorded via REDCap for both strategies.

During the recruitment process, the study team obtained information about the duration of caregiving, type of caregiving (child, spouse, or parent), time participated as a coach in the RCI REACH or OFC programs, and basic sociodemographic information. This information was used to ensure the diversity of experiences in the study sample. Purposive sampling was used to achieve a balanced representation of interviewees from each existing program (OFC and REACH), the duration of caregiving, caregiver type, and time enrolled in the program.

Analysis

Descriptive statistics were used to summarize the characteristics of the study participants. Qualitative content analysis was used to analyze the participant transcripts. The team used NVivo (version 12 for Windows; QSR International) qualitative data analysis software [31] to apply codes to transcripts, segmenting sections of the transcripts that were associated with particular concepts discussed in the interviews.

The analysts created a codebook (Multimedia Appendix 1) starting with deductive codes created from the interview guides and adding inductive codes identified during the initial review of the debriefing forms. To establish intercoder reliability, 3 analysts (NL, ED, and CS) independently coded 2 transcripts and then met to reconcile them. Discrepancies in coding were resolved through discussion and the codebook was refined. Next, the 3 analysts (NL, ED, and CS) divided the remaining number of transcripts and independently coded them. The analysts met once a week (including TC) throughout the process to check the coding process and refine the code definitions, as necessary. If significant changes to coding definitions or new codes were added, all transcripts were reviewed and recorded based on the latest definitions and codebooks. Once the coding was complete, the 3 analysts (NL, ED, and CS) reviewed the code reports and summarized the findings. The team compared

the results of the caregivers and coaches. Structural and qualitative content analyses were used to identify themes and summarize the results.

Results

Description of Study Participants

In all, 25 caregivers (RCI REACH: 13/25, 52%; OFC: 12/25, 48%) and 11 coaches (RCI REACH: 5/11, 45%; OFC: 6/11, 55%) were included in the study. Table 1 presents the sample characteristics. Most participants were women; 52% (13/25) of the caregivers and 45% (5/11) of the coaches had graduate degrees.

Table 1. Background characteristics of the study participants.

Demographic characteristics	Overall caregivers (n=25)	RCI[a] REACH[b] caregivers (n=13)	OFC[c] caregivers (n=12)	Overall coaches (n=11)
Age (years), mean; median (minimum-maximum)	55; 53.75 (34-74)	64.31; 65 (44-79)	45.6; 42.5 (24-69)	40.5; 40 (24-66)

[b]REACH: Resources for Enhancing Alzheimer's Caregiver Health.

[c]OFC: Operation Family Caregiver.

[d]N/A: not applicable.

Most caregivers cared for their spouses or partners (20/25, 80%) or parents (4/25, 16%). The average length of time for caregiving was 4.1 years for RCI REACH (median 4.5; minimum-maximum 21-9) and 4.8 years for OFC (median 4.5; minimum-maximum 0.7-13). Most caregivers (24/25, 96%) lived with their care recipients. Approximately one-third of the coaches had experience coaching in other programs, either within or outside the RCI (4/11, 36%). The average number of caregivers' coaches who were coached simultaneously was 11 (median 10; minimum-maximum 3-22).

Mode of Survey Completion

Coaches often administered the assessments to caregivers verbally and entered caregiver responses into the web-based

system. The majority of coaches (8/11, 72% of the coaches) used Zoom to administer the assessment, and 27% (3/11; all OFC coaches) conducted the assessment over telephone. A few coaches indicated that before the COVID-19 pandemic, they administered the assessments in person, with the caregivers. Some coaches had the caregivers fill out the assessment in their presence to mitigate the burden of reading aloud every question while also being able to observe important nonverbal cues from the caregivers.

Overall, most caregivers appreciated taking the first assessment with their coach, whether it was via Zoom or telephone. Several caregivers mentioned that taking the assessment with their coach felt more personal, allowed them to share their caregiving story, and build rapport with their coach. There was agreement that the benefit of taking the first assessment with a coach lies in the caregiver's ability to share their stories. A coach described the first assessment (T1) as follows:

> *I think you can just garner a lot from what is being said and things that are not being said at T1, and I think that's where I focus. That's how I get to know them, and I don't know whether you're going session by session with the information, but I think a couple of things. I think the first session should be more of a get to know you session, and although I do tell them about the program in the first session, I focus more on letting them tell their story because I think that's how: 1) You build the relationship; but then 2) How you're able to assess the real need at hand.*

Two caregivers preferred to take the assessment on the web by themselves, and 3 coaches suggested that caregivers take the assessment on the web by themselves for at least the second assessment. Most caregivers appreciated taking the assessment with their coach to build rapport, so it is unclear if there is a significant value in having the caregiver fill out T2 with their coach because at that point, rapport would already have been formed.

Frequency of Survey Administration

The assessments were administered in the first (T1) and last (T2) sessions for the RCI REACH and OFC programs. The coaches and caregivers were asked if more frequent assessments would be useful. There was significant interest among caregivers and coaches of both programs in adding assessments midway through the program. Specifically, approximately 40% of the caregivers felt that it would be helpful to take the assessment again midway through the program, in addition to the current pre-post format. Participants generally agreed that the assessment could be used to evaluate the progress and assess the needs of caregivers. A RCI REACH coach said the following:

> *I think that it would be helpful to maybe even do it at the halfway point. That may help get some more scores then and to see if something needs to be reassessed or re-evaluated in how we continue the program for the caregiver. That way if there is something else that has come up or if we see a significant change in score, we can reflect that with the caregiver and decide how to proceed with the rest of the program.*

The importance of assessing caregivers' needs frequently was highlighted by 2 RCI REACH participants, who emphasized that their care recipients' needs would change frequently (weekly or monthly). One major detractor for not wanting to add a midway assessment was how long it would take (ie, coaches and caregivers believed it would add burden). Some caregivers and coaches suggested that the middle assessment should be condensed or completed on the web without the coach.

How the Assessment Scores Were Used

The caregivers were asked how they and their coaches used their assessment responses. The assessment did not include the functionality for caregivers to see their scores on their own. However, most caregivers remembered going over their assessment results to their coaches. Many caregivers remembered that their coaches provided them with resources after reviewing the assessment results. A caregiver said the following:

> *...We focused a lot on the ones that I was scoring the least on. And she tried to give me pointers and other resources if I wanted to take a look at them on my own.*

Of the few caregivers who did not recall the results of the assessment with their coach, there was agreement that this practice would be helpful. A caregiver said the following:

> *Yeah, but would I have appreciated it or gotten something out of it? Yeah! I answered questions for over an hour, so if somebody had sent me a printout or talked to me about it – ...It would have been helpful to get that feedback about that very first hour.*

At the time of data collection, the assessment tool provided score reports only to the coaches, and these score reports were available only at the topic level. Coaches said they use assessment responses to structure encounters, as well as identify where and what caregivers are struggling with so they can provide resources and support. Coaches also confirmed what caregivers speculated: that the baseline assessment was used to initiate dialogue between the coach and caregiver, build rapport, and gain a sense of how the caregiver is doing.

A few coaches expressed dissatisfaction with how they currently see results, namely that formatting is not helpful or user-friendly, and that the results do not provide much useful information about what to do next. A coach said the following:

> *I think most definitely having more information about what they responded and why it's a concern, and what would be the proper steps to take would be very beneficial because right now we have, we see that happy face and it gives us an explanation. The answers they gave us are concerning, but then that's all.*

Some coaches had trouble with the assessment tool or did not value it. For example, 2 coaches said that they had to take good notes during the assessment administration because they could not access the results. A RCI REACH coach said that they

administered the assessment because it was a requirement but did not use the assessment responses at all; they felt that they could gain the information they needed through conversations with the caregiver during the coaching sessions.

Facilitating Score Report Review in the Future: Caregivers

Caregivers and coaches were asked what score report features would be most useful in the future to inform coach-caregiver encounters. Caregivers were asked if they were interested in seeing individual questions or topic-level scores from the assessments. Table 2 shows caregiver preferences for viewing scores from the assessments (one REACH participant was not asked this question and another REACH participant indicated that they were not interested in seeing their results on the assessments at all).

Table 2. Caregiver preferences for viewing assessment results.

	Topic scores only, n (%)	Individual scores only, n (%)	Both scores, n (%)
RCI[a] REACH[b] (n=11)	3 (27)	3 (27)	5 (45)
OFC[c] (n=12)	4 (33)	2 (17)	6 (50)
Total (N=23)	7 (30)	5 (22)	11 (48)

[a]RCI: Rosalynn Carter Institute for Caregivers.

[b]REACH: Resources for Enhancing Alzheimer's Caregiver Health.

[c]OFC: Operation Family Caregiver.

Of the 7 participants who expressed wanting to see only topic-level scores, 5 (71%) mentioned that they felt that going through the individual item scores would be too burdensome because of the length of the assessment. One caregiver remarked, “I think it’s just a better quick snapshot of where you’re at in things, rather than an overwhelming individual number for every question.”

Of the caregivers who wanted to be able to see both the topic-and individual-level scores, more than half (6/11, 55%) wanted to see topic-level scores first so they could see overall progression, regression, or change over time; then, if certain areas did not change or scores regressed, they wanted to be able to view individual question scores for more details: “After seeing it by topic, if I have questions – then we can dive in for the question for that particular topic.”

Of the 23 caregivers, only 5 (22%) wanted to see individual item scores. One reason for this was that some caregivers wanted to see “all the details” and changes at the individual item level.

Most caregivers were interested in seeing the results and changes in their scores over time, but only a few caregivers were interested in seeing the scores that improved. Two caregivers were not interested in viewing the scores on the assessments that worsened (they only wanted to see scores for the topics or individual questions where they improved). These caregivers said that seeing worsening scores would not make them feel good about their progress. Some caregivers also mentioned that seeing the scores on the assessments would provide extra validation to help them see the program really helping them. When asked if reviewing the scores on the assessment would be helpful, a caregiver responded as follows:

> *[Yes], because I think it’s a little bit more concrete, a more visual way to understand where you’re at. Gosh, I scored really high or I scored really low or maybe things aren’t as bad as I thought they were...*

A few caregivers emphasized the importance of being able to interpret figures showing the results of their scores. For example, some caregivers mentioned that the figures needed to have clear legends to indicate which scores were good or bad or if they were moving in a positive or negative direction.

Facilitating Score Report Review in the Future: Coaches

Most coaches also wanted to see both topic level and individual item scores (7/11, 64%). In all, 3 coaches did not want to see individual item scores; 2 of them being OFC coaches who felt that going through individual item scores would be too burdensome because of the length of the assessment. Three coaches indicated that they would only want to look at individual item scores for specific high-risk topics such as safety or depression. Coaches were open to multiple formats and felt that sharing results with caregivers would be helpful in showing caregiver progress. A coach noted the following:

> *...I think it would be really cool for us to show them at the end of the program or even if another period of assessment’s introduced, checking in with them whenever that’s done, just to show them progress and how we’re doing.*

Overall, most coaches thought it would be beneficial to share all changes in assessment results with caregivers (scores that improved, worsened, or remained the same). A coach said the following:

> *And at the end, I just want to know if they’ve improved or if they’ve gone down then I can refer resources or do what I need to do at that point.*

However, 2 of the coaches were concerned that some caregivers may be discouraged or more stressed if they were told that their scores worsened or did not improve over the course of the program. One of these coaches said the following:

> *I think it would depend on the caregiver. I think some would find it stressful that they’re not meeting their goal, but others might find it motivating.*

However, overall, both caregivers and coaches felt that seeing and sharing the caregivers' improvement scores would make them caregiver and coach feel validated. A few coaches were not interested in sharing scores with caregivers; instead, they felt that the dialogue they would have with the caregiver would be more important in explaining how the caregiver has changed from T1 to T2. Two coaches suggested that the scoring be optional to the caregiver or used for goal setting.

Overall, both caregivers and coaches were extremely interested in reviewing scores on assessments throughout the RCI programs, with particular interest in how scores changed over time, and whether caregivers improved in certain areas or still needed support in others. Some wanted to see topic scores for a quick summary, whereas others wanted to delve into the details to see exactly where the changes were happening. Most of the coaches and caregivers were open to either option.

Comparing Caregivers

Caregivers were asked if they were interested in seeing how their scores on the assessments were compared with other caregivers in their respective programs. Across both programs, most caregivers (approximately two-thirds) said that they were not interested in seeing how they were compared with the other caregivers. One of the main reasons given by caregivers in both programs was that every caregiver is different and in a different situation, so comparing oneself to another was not useful. A caregiver said the following:

> *I don't think that [comparing caregivers] would be helpful because...in caregiving everybody's situation is different, everybody is caring for somebody different, and it's probably not relevant to you.*

The other main reason caregivers were not interested in seeing how they compared with the other caregivers was that they feared that it would cause them stress and anxiety and make them feel worse. A caregiver stated the following:

...If I had bad scores, then I'd be feeling like, "Okay, why are my scores not as good as theirs? Like, what am I doing wrong as a caregiver?" So, I wouldn't want to compare.

Of the caregivers who were interested in seeing how their scores compared with the other caregivers (8/24, 33%), the reasons for this were curiosity and getting a sense of where they stand compared with the other caregivers. Overall, coaches were less certain about whether they would like to compare caregiver scores on the assessments, and opinions varied according to the RCI program. Some OFC coaches noted that it would be helpful to compare caregivers because they could look at average scores and identify any trends or patterns. RCI REACH coaches were less enthusiastic about comparing caregiver scores on assessments. In general, they provided the same reasons as caregivers (ie, every caregiver's situation is different, and it is not useful to compare one to another). In addition, RCI REACH coaches were concerned that sharing score information with caregivers would cause more stress. A few OFC coaches (2/5, 40%) also shared the concern of adding additional stress, so they would keep this information to themselves and not share it with caregivers. The other 3 OFC coaches believed the opposite (ie, that it would actually be helpful for caregivers to see how they compare with others; it could be a learning experience and help validate their feelings).

Discussion

Principal Findings

This study aimed to describe how a web-based assessment is currently being used to identify and monitor caregiver well-being in 2 RCI programs and describe perceived enhancements to the web-based system that could support caregiver-coach encounters by directing priorities for the encounters.

Although the questionnaires included in the assessments were self-administered, RCI coaches used the questionnaires to elicit conversations and get to know the caregivers in their programs. Most assessments were administered verbally via Zoom or telephone, a practice that was likely initiated due to the COVID-19 pandemic but was also well accepted by caregivers and coaches. Coaches valued being able to observe the caregivers on Zoom while administering the questionnaires because they could pick up on nonverbal cues. At least 1 coach indicated that they preferred to share the questionnaire with their caregivers during the assessment.

Historically, the assessments were administered twice: once at the beginning and once at the end of each program. Coaches and caregivers generally agreed that more assessment administrations would be useful because they could receive feedback on caregivers' status and adjust the program as needed. The frequency of change in the care recipient should be considered when deciding the assessment frequency to pick up on new caregiver needs and have coaches able to address these needs in a timely manner. The primary concern regarding the addition of assessment administrations was the length of the assessment. One potential consideration for further refinement of the assessment is to prioritize topics that need to be specifically evaluated by individual caregivers and administer those topics only. Another way to reduce the time required to complete assessments is for caregivers to complete the follow-up assessments on their own because they have already built rapport with coaches; one risk of this approach is that caregivers may not complete a lengthy follow-up assessment on their own. Coaches could encourage caregivers to complete the assessment before the last meeting with their coaches.

Assessment scores were visible to the coaches but were not accessible to the caregivers. Most caregivers agreed that having access to scores would be useful for viewing their status and identifying areas where they needed the most help from their coaches. Caregivers who do not remember going over the assessment results with their coach may become frustrated with the assessment process if they do not think their coach is looking at the results. A formal portal for caregivers to review their own scores or review their scores in tandem with their coach would allow the process of reviewing scores with coaches to be more memorable and useful.

In general, coaches valued the assessments and indicated that they used the scores to identify areas where caregivers found them difficult. A number of coaches were unhappy with the

current functionality of the assessment score results format and emphasized the need for a clear interpretation of the assessment results. Coaches and caregivers provided a wide range of feedback on how they preferred to see assessment scores in the future and what would be most useful to them. Overall, most caregivers and coaches were interested in seeing the score results over time, indicating improvement or worsening. Most caregivers and coaches prefer access to topic- and question-level scores. There was considerable heterogeneity in how caregivers described why they preferred different levels of detail in their score reports. Coaches and caregivers were generally in support of viewing changes in scores in figure format. Some concerns about this practice were mentioned, such as caregivers feeling discouraged about a lack of progress or worsening. This opens an opportunity to reframe the assessment as a tool or intervention to identify needs rather than weaknesses. Most coaches and caregivers were not interested in comparing caregiver scores across other caregivers in the programs, although a few felt that it might be useful. Conflicting perspectives by both caregivers and coaches on whether they would like to compare caregivers to other caregivers demonstrate the importance of providing options for assessment result displays. The heterogeneity in preferences for the format of the results highlights the need for flexibility in the functionality of the assessment tool, with the ability to toggle higher- or more specific-level information, or whether improvement or worsening scores are displayed. One way to address this in the context of the program would be for coaches to ask caregivers about their preferences and adjust the score output for each caregiver's perspective.

The importance of being able to understand and interpret the assessment result figures was mentioned by a few participants. Building on the work that has been accomplished in the interpretation of figures in clinical care settings [32-35], additional research could evaluate the key features of figures that influence interpretation and understanding. Clear figure and score interpretation is critical for coaches and caregivers to determine which needs should be prioritized.

Building on This Study

Future steps for refining the assessment could include developing individualized functionality or features for caregivers and coaches. For example, it is possible that some caregiver characteristics, such as caregiver status (eg, caregiver is doing well or finding it difficult) could be associated with preferences for assessment functionality. Future research could investigate these characteristics and use them as predictors for the presentation of assessment functionality to individualize the assessment experience for caregivers. Another opportunity for individualizing assessment functionality is to set goals and track outcomes toward these goals. The goals of the programs were individualized for each caregiver based on the coach-caregiver encounters, and assessment scores were used to track these goals. Assessment score reports may need to be individualized to draw attention to the outcomes that are most important to the caregivers. Clear interpretation of guidelines for scores is also important. For example, the goal of the coaching intervention may be more protective in nature; therefore, caregivers should expect to see relatively consistent scores over time rather than an improvement.

Strengths

A key strength of this study was that the qualitative interviews included perspectives of the interventionists (coaches) and individuals receiving the interventions (caregivers). Stakeholder interviews are often conducted in clinical care contexts but focus on the individuals receiving interventions: patients. By including both stakeholders in the qualitative study design, we compared the results, resulting in a holistic set of insights and suggestions for the next steps. Another strength is that we had the opportunity to interview caregivers who were currently enrolled in RCI programs, as well as caregivers who had completed their RCI program. The results of this qualitative study will drive the next steps for RCI's web-based platform and expand on current standards for administering self-reported questionnaires in clinical practice settings. The results of this study could potentially be useful for health organizations when building or upgrading web-based portals for patients and clinicians.

Limitations

The results of this study should be considered in light of its limitations. First, the interview participants were only from RCI coaching programs; the generalizability of the functionality of the tool may be limited. Second, all coaches included in the interviews actively participated in the RCI programs; therefore, their interviews may reflect a more positive outlook than coaches who were no longer with RCI. Finally, the caregivers and coaches who dropped out of the program were not included in the study; consequently, the results may reflect a more positive view of the assessment.

Conclusions

We conducted qualitative interviews with the coaches and caregivers in the 2 RCI programs. Web-based and procedural enhancements were identified to enrich caregiver-coach encounters. New and enhanced strategies for using web-based assessments to direct priorities in the caregiver-coach encounters included (1) integrating figures showing caregiver progress at the individual caregiver level, (2) ability to toggle results through different figures focused on individual versus aggregate results, and (3) support for interpreting scores. The results of this qualitative study will drive the next steps for RCI's web-based platform and expand on current standards for administering self-reported questionnaires in clinical practice settings.

Acknowledgments

The authors acknowledge the time and commitment of the caregivers and coaches who participated in this study. The authors would also like to acknowledge Amy Clark for project management, Erin Campbell for her editorial support, and the colleagues from Rosalynn Carter Institute for Caregivers for facilitating data collection.

This study was funded by the Rosalynn Carter Institute for Caregivers and the Bristol-Myers Squibb Foundation.

Authors' Contributions

TC drafted the manuscript, interpreted the results, and was responsible for designing and conducting the study. NL contributed to the completion of the regulatory tasks (creating recruitment materials, reviewing or editing institutional review board application, managing staff effort on project, managing participant compensation, and managing audio files or transcripts) and participated in interview guide creation, conducted interviews, trained staff on interview techniques and qualitative data analysis, developed the codebook, managed the master NVivo file and ran the interrater reliability, coded and analyzed qualitative data, and participated in manuscript writing. ED contributed to the recruitment of caregivers and coaches and scheduling interviews, participated in interview guide and other study material creation, conducted interviews, coded and analyzed qualitative data, and participated in manuscript writing. CS contributed to the recruitment of caregivers and coaches (cold calling or emailing potential recruits, calling after completion of REDCap [Research Electronic Data Capture] eligibility, reviewing study information and materials, and scheduling interviews) and conducted interviews, completed the analysis for demographics (Table 1), coded and analyzed qualitative data, and participated in manuscript writing. KW contributed to the facilitated recruitment of caregivers and coaches and participated in the interview guide and codebook review and in manuscript writing. JO contributed to the facilitated recruitment of caregivers and coaches and participated in interview guide and codebook review and in manuscript writing. Abstract

Background: HIV disproportionately impacts Black men who have sex with men (MSM), and targeting the primary relationship (ie, couples) using mobile technology for health holds promise for HIV prevention. Web-based recruitment of MSM is commonly employed in HIV prevention and intervention research. However, little known about recruiting Black MSM couples on the internet in the United States.

Objective: This study describes the process of recruiting Black MSM couples over social networking and dating apps frequented by MSM. We describe the activities for recruiting, screening, and enrolling participants as part of a randomized trial employing a multipronged recruitment approach.

Methods: Black MSM in couples were recruited via three apps (ie, *Jack'd*, *Adam4Adam*, and *Growlr*) between May 2020 and March 2021 during the COVID-19 pandemic in the United States. Black MSM couples were eligible if one or both partners are Black, MSM, and living with HIV, and if both partners were 18 years or older, and have been together for at least 2 months in what they both consider a primary relationship (ie, one in which both partners reported feeling most committed to over any other partner or relationship).

Results: A total of 10 Black MSM couples (n=20) were enrolled via social networking apps. App recruitment activities were a combination of passive (eg, in-app advertisements) and active (eg, direct messaging of users) engagement. Recruitment approaches varied by the social networking app owing to differences in app features. A full-time recruiter experienced challenges such as bugs (ie, technical errors in computer program or system), navigating technical requirements specific to each app, and web-based harassment.

Conclusions: Despite challenges, it was possible to recruit Black MSM couples virtually into research as part of a multipronged recruitment strategy. We identify tips for using web-based dating and other social networking apps as part of a recruitment strategy in future research with Black MSM couples.

Introduction

HIV remains a global health issue requiring continued efforts in prevention and intervention in low-, middle-, and high-income countries [1,2]. Within the United States, HIV disproportionately affects men who have sex with men (MSM). This health disparity is even greater among Black or African American (hereafter "Black") men [3-6]. Half of all Black MSM are estimated to acquire HIV in their lifetimes compared to one in 11 for White MSM [7]. The primary romantic relationship is an intervention target given high rates of seroconversion among MSM in these relationships [8-11]. Among Black MSM, nationwide estimates indicate that one-third to a half of those with HIV are in a primary relationship [12-14]. Therefore, research on couples remains crucial in HIV/AIDS prevention and intervention.

Location-based dating and social networking apps have become an option for participant recruitment in HIV/AIDS and sexual health research [15-17]. The advantages of app-based recruitment in HIV research are recently highlighted by the COVID-19 pandemic whereby in-person recruitment was prohibited owing to physical distancing and other public health measures [18]. Recruiting couples on the internet requires special consideration for relationship verification and data validation [19-21]. Emergent studies have used apps and other social media (eg, Facebook and Instagram) to recruit MSM couples [22,23]. However, knowledge gaps exist for using dating and social networking apps to engage racial or ethnic minority MSM couples.

Recruiting Black MSM couples into research studies presents important considerations and is challenging for myriad reasons. Distrust of research and medical institutions and cultural stigma concerning race, sexual orientation, and HIV status are barriers to research participation for Black MSM [24,25]. MSM in couples may have a diverse range of agreements regarding sex with others outside of their relationship. Sexual agreements are the mutual understanding between primary partners regarding what sexual behaviors are allowed [26]. These agreements are prevalent among 58% to 99% of same-sex male couples [27], with 11% to 64% of these agreements including sex with outside partners [27]. Given that some MSM have agreements regarding outside partners, dating and social networking apps provide a way to reach partnered MSM that may use apps to socialize or find potential sexual partners.

Few studies have presented details on using dating and social networking apps to recruit Black MSM couples, highlighting a potential knowledge gap on methods for engaging couples into research. Thus, the goal of this study is to describe the process of using dating and social networking apps to recruit same-sex couples to inform future trial designs. This study is part of a multipronged recruitment approach of a pilot randomized controlled trial (RCT) with Black MSM couples with HIV.

Methods

Study Overview

The dating app recruitment process described herein was part of a multipronged recruitment approach of a pilot RCT to test the feasibility and acceptability of a mobile app intervention for improving HIV care and treatment among Black MSM couples living with HIV. We targeted recruitment efforts on dating and social networking apps frequented by Black MSM: *Jack'd*, *Adam4Adam* (*A4A*), and *Growlr* [19,28-31]. Qualitative data particular to each app are described below to highlight the unique success and challenges experienced using this underutilized recruitment approach. To maximize engagement with Black MSM, we hired a Black, cisgender, same-gender-loving–identified man as the study recruiter who performed all recruitment activities and documented the recruitment process. Recruitment occurred between May 2020 and March 2021. Black MSM couples were eligible if one or both partners are Black, MSM, and living with HIV, if both partners were 18 years or older, and have been together for at least 2 months in what they both consider a primary relationship (ie, one in which both partners reported feeling most committed to over any other partner or relationship).

Owing to differences in user engagement requirements by app, we used different engagement approaches by app. On *Jack'd*, recruitment was conducted through their in-app advertisements. Interested candidates who clicked on the advertisement were directed to a Qualtrics prescreener questionnaire that obtained basic qualifying information (eg, current place of resident, race, relationship and HIV status, and length of time on antiretroviral medications for HIV). Study staff then contacted eligible candidates via SMS text message using the telephone number provided.

Recruitment on *A4A* was carried out by sending private SMS text messages to potential participants using the in-app messaging feature. The recruiter identified potential participants using the app's search filters which allowed users to filter through other users' profiles on the basis of set criteria such as their race, HIV status, and relationship status. The study recruiter identified users whose race or ethnicity was set to Black, African American, or mixed. We included "mixed" race because many Black MSM may identify as mixed race given the diversity among Black communities. We also found that some users identify their race as mixed to avoid being filtered out by users who filter out Black-identified users within the app. The study recruiter identified users whose HIV status was set to HIV-positive, undetectable, or unanswered. Users who left their HIV status unanswered were considered for the study as it would encompass anyone who has never been tested or chose not to disclose their serostatus on the internet. Finally, the study recruiter identified users whose relationship status was set to dating, partnered, open relationship, polyamorous, or married.

Once potential participants were identified, the study recruiter privately messaged each individually. *A4A* has a message delivery report in its platform, which allowed recruiters to know if a message has been read or not. Users who read but did not respond within 48 hours of the first message being sent were

sent a follow-up message asking if they were still considering participation in the study or were no longer interested. The messages that remained unread would require no follow-up as those users were likely inactive. Users who communicated interest then were asked to complete a phone screener with a study staff to determine eligibility.

Recruitment on *Growlr* was carried out by sending private messages to potential participants using the in-app messaging feature and in-app advertisements contained the weblink to a Qualtrics prescreener. A *Growlr* paid service, the "SHOUT!" feature, allowed the recruiter to send the study information to multiple people in a specified vicinity.

A total of 10 couples (N=20) recruited via apps were enrolled in the trial, including 7 same-race Black couples and 3 interracial couples.

Ethical Considerations

This study received ethics approval from the institutional review board of University of California, San Francisco (IRB#15-18042). All participants provided informed consent to participate in the study.

Results

Results Overview

Individual- and couple-level characteristics of the couples recruited via apps are reported in Tables 1 and 2, respectively. The following outlines findings resulting from the process of recruiting participants via each app.

Table 1. Individual-level participant demographic characteristics of couples recruited from dating apps (N=20).

Characteristics	Values
Age (years), mean (SD), range	36 (13), 20-54
Length of relationship (months), mean (SD), range	5.7 (9.3), 2-336
Ethnicity, n (%)	
Hispanic or Latino	3 (15)
Not Hispanic or Latino	17 (85)
Race, n (%)	
African American or Black	15 (75)
White	3 (15)
More than one race	2 (10)
Serostatus, n (%)	
Living with HIV	15 (75)
Not living with HIV	5 (25)
Cohabitation, n (%)	
Living together	16 (80)
Not living together	4 (20)

Table 2. Couple-level characteristics by HIV serostatus and race (N=20).

Status	Same-race participants, n	Interracial participants, n	Couples, n (%)
Seroconcordant-positive (both members are HIV-positive)	4[a]	1	5 (50%)
Serodiscordant (one partner with an HIV-positive status and the other with an HIV-negative or unknown status)	3	2	5 (50%)
Total	7 (70%)	3 (30%)	10

[a]There was one serodiscordant-positive couple in which both partners are multiracial. They identify as African American or Black and another race (eg, Latinx and Native American).

Jack'd

Overall Findings

In-app advertisements on *Jack'd* were used for recruitment on the platform. Eligible candidates who completed the Qualtrics prescreener questionnaire through the study advertisement and were contacted by recruiters via SMS text message with the telephone number they had provided. If the candidate did not respond to the SMS text message within 24 hours, a recruiter would follow up with a telephone call and leave a voicemail message if there was no answer. Potential candidates had 1 week to respond before another attempt to make contact was made. This pattern of correspondence continued until either the candidate indicated that he/she was no longer interested or the telephone number was no longer in service. Interested and

eligible candidates who completed the Qualtrics prescreener would then complete a telephone screener. Participants were scheduled for an interview once they provide informed consent to participate.

A total of 35,912 unique impressions, or the number of times the study advertisement was displayed to a user for the first time, occurred on *Jack'd* in 4 major cities (Atlanta, Georgia; Los Angeles, California; Houston, Texas; and Washington, District of Columbia). Of these views, 924 users clicked on our advertisement at least once. Consequently, the click-through rate, or number of unique clicks divided by the number of unique impressions, ranged between 0.85% (Atlanta, Georgia) to 1.16% (Houston, Texas).

Character Limits for Advertisement Placement

Though recruitment on *Jack'd* was carried out through in-app advertisements, imposed character limits made it difficult to fully describe the target population and goals of the study. One solution was to include part of the study description into the image selected for our profile at an extra cost (Figures 1 and 2). *Jack'd* removed our advertisements and stated that adding more text to our recruitment advertisements would be an extra cost. Our team elected to pay the additional fee to include more description in our in-app advertisements so that interested applicants had more information prior to completing the prescreening measure.

Figure 1. Inclusion of part of the study description into the image selected for our profile at an extra cost in the app interface.

Figure 2. Screenshot of the image selected for our profile in the app.

Adam4Adam

Technical Bugs

The recruiter experienced functionality issues with the web-based browser and mobile app versions of *A4A*. The web-based version was designed to look like the app, but there were technical bugs with several functions. For example, the recruiter made edits to the profile on the web-based version; however, these edits were not always reflected in the app version. Moreover, blocks of text from the recruiter profile would often be removed without notification or explanation, which would leave out key details of the study and regular monitoring would be required to ensure that information published to the app profile was not deleted by the app. Unfortunately, when information was deleted from the profile no error messages or warnings had been communicated to the recruiter. As such, there may have been times when potential candidates missed vital information about the study.

Potential candidates were contacted on the basis of their eligibility potential, which was determined by using app search filters (eg, candidate identified race, relationship, and HIV status). Additionally, recruiters scanned through details on their candidates' profiles for information that may qualify or disqualify them for the study. A total of 292 potential candidates were contacted on *A4A* across 15 different states. Searches were conducted across all large geographical regions of the United States including the West (California, Nevada, Arizona, and Washington), Midwest (Ohio, Illinois, and Wisconsin), South (Mississippi, Texas, Georgia, Florida, North Carolina, and Tennessee), and Northeast (Massachusetts and New Jersey). Participants contacted in accordance with the state were as follows: Arizona (n=10), Georgia (n=17), Illinois (n=34), Massachusetts (n=7), Mississippi (n=14), Nevada (n=10), New Jersey (n=12), North Carolina (n=45), Ohio (n=19), Tennessee (n=18), Texas (n=25), Washington (n=9), and Wisconsin (n=3). Owing to an unexpected account suspension, we were unable to breakdown numbers between California and Florida (n=69).

Existence of Bots

Successful engagements with potential participants on *A4A* could be improved simply by the recruiter distinguishing

themselves from automated "bot" profiles that function to send spam and are often ignored by app users. The recruiter found positive changes in user responses when he developed rapport with other users. For example, one user had a profile photo with a dog, prompting the recruiter to comment, "Cute dog, it reminds me of my childhood pet," followed by a self-introduction. In another successful recruitment interaction, the recruiter started a conversation inquiring about the reference of a song in a user's profile name. The shared knowledge between the user and recruiter about the song lead to the user's interest in further discussion. After sharing the recruiter's role with the study, the user chose to enroll in the study.

Inability to Track Profiles and Messages

Tracking contacts on *A4A* were not straightforward and required additional steps. *A4A* offers a feature to "favorite" users, allowing their profile to be bookmarked through an in-app list. This list enabled the recruiter to stay connected to contacts even if they changed their username. However, the feature did not allow for more than one person to be added owing to technical bugs. Thus, the recruiter used the web-based version to save the URLs of users' profiles for tracking purposes. Additionally, the chat function only allows for a limited number of messages to be sent before older messages are lost. To save relevant information, the recruiter tracked and recorded usernames, dates of interaction, follow-up dates, user profile URLs, and other notes in Microsoft Excel.

Removal of Flyer Image From Recruiter Profile

During the recruitment process on *A4A*, the recruiter received an automated message indicating that the study's flyer image—which had been uploaded to the recruiter's profile—was removed because it violated the app's standards. The recruiter then changed the study's profile picture to a photo of himself. Thereafter, when potential participants expressed interest in the study through private SMS text messaging, the recruiter would send the flyer image directly to them.

Harassment

The recruiter experienced racially and politically charged verbal abuse during the height of the Black Lives Matter protests in 2020. Racial epithets (eg, "mountain caucus monkey") were used by an app-user without provocation. Romantic and sexual harassment were common.

Growlr

Similar to *A4A* and *Jack'd*, *Growlr* recruitment procedures involved both active and passive approaches. The study recruiter identified potential participants through the app's search filters and messaged eligible users privately; in-app advertisements with the study information also contained a weblink to the prescreener. A *Growlr* paid feature "SHOUT!" was used to send the study information to multiple users in a specified region. We paid for "SHOUT!" broadcasts in 4 separate cities (eg, Charlotte and Raleigh, North Carolina; Nashville, Tennessee; and Cleveland, Ohio). Users within a 25-30–mile radius were able to see these advertisements and resulted in 2955 total views.

Similar to *A4A*, the recruiter experienced verbal abuse and harassment. *Growlr* removed the study flyer from the recruiter's profile, with a message indicating that it violated company guidelines against in-platform solicitation. However, after a new flyer was posted that excluded any mention of the study participants being paid, it was nevertheless removed again, and *Growlr's* customer service did not respond to our inquiries about the second flyer removal. Owing to the technical bugs and low success rate (no eligible couples were found), the recruiter discontinued efforts on the platform after 2 weeks.

Discussion

Principal Findings

HIV incidence among Black MSM in the United States continues to be disproportionately high [3,4] with one-third to half of Black HIV-positive MSM to be in a primary relationship [13,14,32]. Nonetheless, societal stigma, distrust of research and medical institutions, and other systemic barriers negatively impact HIV prevention and treatment for this underserved community [24,25]. As such, novel approaches to recruiting Black MSM couples are needed.

There are relatively few dyadic HIV research studies with Black MSM couples (eg, time and staffing). Little information exists detailing the successful strategies for web-based recruitment of Black MSM couples into HIV research. While dating and social networking apps have been commonly used to recruit single MSM for research studies [19], no research has used dating apps to explicitly recruit couples of MSM. This study demonstrated the feasibility of dating and social networking apps for recruiting Black MSM couples as part of a pilot RCT of a couples-focused app for improving HIV care engagement. Recruiting MSM couples through dating and social networking apps is a necessary recruitment strategy given the prevalence of sexual agreements among MSM couples [27].

Consistent with previous research, this sample of couples contained predominately same-race Black partnerships [32]. The search and filter functions in the apps, such as filtering users on the basis of their reported relationship status, helped to identify potential participants per the eligibility criteria. *A4A* and *Growlr* offered the functionality to filter through user-identified race or ethnicity categories, which reduced the time needed to search for eligible users. Paid advertising campaigns through *Jack'd* and *Growlr* were an opportunity to recruit passively, instead of actively searching through users and initiating conversations to determine eligibility and interest.

Although the strategy of privately messaging potential participants on *A4A* was a successful recruitment strategy, it was not without challenges. Our Black, same-gender-loving–identified recruiter reported multiple episodes of harassment of various types (eg, sexual, racial, and political). Additionally, app-specific guidelines for study advertisements varied (eg, character limits and other rules). Regular check-ins between the principal investigator and recruiters and careful attention to the guidelines for each app are necessary.

Limitations

Our study recruited for a one-time interview, and we do not know how these findings generalize to other, longer-term

research requirements. Further, biases in the sample skew toward nonmonogamous couples owing to the generally sexual purposes of MSM using the apps. Finally, given the evolving nature of the software, some of the app features reported during the time of publication may or may not reflect what is currently available.

Comparison With Prior Work

Apps designed for MSM have become increasingly popular and users on those platforms may visit them frequently (eg, daily) [33]. Research has recruited single MSM [19,34-36] and Black MSM [37-39] via apps. Given high HIV transmission rates between MSM primary partners [8-11], recent studies have also recruited MSM couples through a combination of web-based engagement (eg, Facebook and gay websites) and apps [10,40-44], but not exclusively on apps. No research documents the utility of app-based recruitment for Black MSM couples [45,46]. Given the disproportionate rates of HIV [6,7,47] and the importance of coordinating HIV prevention, care, and treatment [45,48,49] within this community, there is urgency to finding novel approaches to recruiting Black MSM couples for HIV prevention studies.

Conclusions

Dyadic HIV research with Black MSM couples is important but knowledge gaps remain. Challenges to research with this population include participant recruitment, which can be resource intensive, underscoring the need for recruitment strategies that have been demonstrated to be feasible and acceptable. We discuss our strategies for engaging Black MSM couples via social networking apps, and associated technical challenges, including issues with harassment directed at our recruiter. We have identified a way forward with using social networking apps to engage Black sexual-minority couples to inform future research.

Abstract

Background: The gap between mental health needs and resources for Aboriginal and Torres Strait Islander people, the Indigenous people of Australia, is most marked in the prison population. Indigenous people are overrepresented in Australian prisons. In prison, this group experiences mental disorders to a greater degree than non-Indigenous prisoners. This group has also been found to experience mental disorder at a higher rate than Indigenous people in the community. In addition to pre-existing determinants of poor mental health, these high prevalence rates may reflect poor engagement in mainstream interventions or the efficacy of available interventions. In community populations, the use of digital mental health resources may help to increase access to well-being support. However, culturally appropriate digital tools have not been available to Indigenous people in prisons. The absence of feasibility and efficacy studies of these tools needs to be addressed.

Objective: The aim of this study is to determine the feasibility of the Stay Strong app as a digital well-being and mental health tool for use by Indigenous people in prison.

Methods: Dual government agency (health and corrective services) precondition requirements of implementation were identified and resolved. This was essential given that the Stay Strong app was to be delivered by an external health agency to Indigenous prisoners. Then, acceptability at a practice level was tested using postuse qualitative interviews with clients and practitioners of the Indigenous Mental Health Intervention Program. All Indigenous Mental Health Intervention Program practitioners (10/37, 27%) and client participants who had completed their second follow-up (review of the Stay Strong app; 27/37, 73%) during the study period were invited to participate.

Results: Owing to the innovative nature of this project, identifying and resolving the precondition requirements of implementation was challenging but provided support for the implementation of the app in practice. Acceptability of the app by clients and practitioners at a practice level was demonstrated, with nine themes emerging across the interviews: satisfaction with the current Stay Strong app, supported client goal setting, increased client self-insight, improved client empowerment, cultural appropriateness, enhanced engagement, ease of use, problems with using an Android emulator, and recommendations to improve personalization.

Conclusions: The Stay Strong Custody Project is a pioneering example of digital mental health tools being implemented within Australian prisons. Using the app within high-security prison settings was found to be feasible at both strategic and practice levels. Feedback from both clients and practitioners supported the use of the app as a culturally safe digital mental health and well-being tool for Aboriginal and Torres Strait Islander people in prison.

Introduction

Background

Mental disorders are a leading cause of the nonfatal global burden of disease. Commonly accepted estimates are that 21.2% of years lived with disability and 7.1% of disability-adjusted life years are experienced by people with mental disorders, but some researchers argue that these figures underestimate the true impact [1]. However, the picture is even more bleak for Indigenous people. Indigenous populations in western nations such as Canada, the United States, New Zealand, and Australia are particularly impacted as they have higher rates of mental disorder, substance misuse, and suicide than their non-Indigenous population [2-10]. The rates of incarceration are also higher for Indigenous people than for non-Indigenous populations, with this cohort shown to have a particularly high prevalence of mental disorders [11,12].

Aboriginal and Torres Strait Islander people, the Indigenous people of Australia, experience a burden of disease 2.3 times more than that experienced by the non-Indigenous Australian population, with mental disorders and substance use disorders accounting for 19% of this total disease burden [13]. Compared with non-Indigenous Australians, Indigenous Australians have higher rates of suicide (2 times) [13], higher rates of hospitalization for self-harm (2.7 times) [14], higher levels of psychological distress (2.6 times) [14], and higher rates of depression and anxiety [15] and are overrepresented in the mental health system (3 times) [16]. Differences in prevalence rates between Australia's Indigenous and non-Indigenous populations suggest an increased presence of determinants of poor mental health and well-being, a lower rate of engagement in interventions, and a reduced efficacy of the interventions available for Indigenous people in Australia. Indigenous Australians are 14 times more likely to be incarcerated than non-Indigenous Australians [17,18]. Although Indigenous people represent 3.3% of the Australian population, they constitute 29% of all prisoners [17,18]. As a breakdown of the overall prison population, Indigenous women constitute 36% of the female prisoner population and Indigenous men constitute 28.9% of the male prisoner population [17,18].

The gap between mental health and well-being needs and resources is at its most marked for Indigenous people in prison [19]. It is estimated that in Australia, the 12-month prevalence of mental disorders in Indigenous women in prison is 86% and in Indigenous men in prison is 73% (including substance use disorders). This is very high compared with the 12-month prevalence of mental disorders in the general Australian population, which is 22% for women and 18% for men [12,20]. This discrepancy is evident in other western colonized countries such as New Zealand, the United States, and Canada [19], where Indigenous people experience poor mental health [2,4,9], increased risk of substance misuse [2-4], higher rates of suicide [2,5,10], and overrepresentation in the prison population [21-23]. Although there is an improving commitment to the health and welfare of First Nations people, in these jurisdictions, there is limited Indigenous-specific well-being or mental health interventions for prisoners and limited published evaluations of these interventions [19].

The Correctional Investigator of Canada, Truth and Reconciliation Commission of Canada, and Canadian parliamentary commissions called on government to improve First Nations prisoners' access to culturally relevant intervention [24-26]. This aim is also reflected in New Zealand's Hōkai Rangi strategy to address the overrepresentation of First Nations people in prison [27]. Within this strategy, scaling up successful interventions, developing new Indigenous-specific interventions, and deciding how best to support their delivery have been identified as key challenges [27]. In Australia, the National Agreement on Closing the Gap aims to eliminate the gap between the health and welfare of Indigenous and non-Indigenous people [28-30]. Among the priority targets to be addressed through this agreement are reducing the rates of incarceration and improving Indigenous prisoners' social and emotional well-being (SEWB). This may be achieved in part through access to culturally safe, Indigenous developed and delivered, evidence-based interventions [28,30].

Although it is possible to develop and deliver culturally safe well-being interventions specifically for Indigenous people in prison, there is a lack of access for prisoners to evidence-based interventions [19]. There is a need for equity-oriented evidence-based interventions that engage a population with complex needs in a restrictive prison environment. The development of innovative, culturally safe, and effective interventions that make efficient use of the finite resources available to support prisoners would address the growing gap between need and service.

As a step toward achieving this vision, since September 2015, the Stay Strong Custody Project (SSCP) has been trialing culturally safe digital mental health resources with Aboriginal and Torres Strait Islander women and men in prison. This has been achieved through the use of these tools by the Indigenous Mental Health Intervention Program (IMHIP; Queensland Health's Forensic Mental Health Service). IMHIP is an SEWB service specifically for Indigenous people in prison, offering culturally safe early intervention and support for Indigenous people in custody and for up to 6 months after their release from prison. IMHIP's innovative service delivery model enabled the service to become an early adopter of digital mental health assessment and intervention tools within the high-security prison environment. The SSCP adapted a collection of 5 digital mental health tools to support the assessment of and intervention with IMHIP clients in prison. Internationally, digital tools or information and communication technology (ICT) are being used to support prisoners in completing day-to-day tasks,

enhancing education and vocation skills, accessing family and support, and videoconferencing as a platform for psychiatry and psychotherapy sessions. However, these ICT examples are the exception rather than the rule. Where these limited programs have been introduced in Europe, United Kingdom, Canada, and the United States, they have typically involved low-security prisons, which have fewer restrictions on internet access and ICT support [31].

Internet access is prohibited or extremely restricted within prisons in most countries to prevent breaches of security. These limits are extended to devices that have the potential for communication with contacts outside the prison, such as smartphones, tablet PCs, and laptops. Restrictions on devices and internet use place limitations on the availability of digital mental health and well-being tools to prisoners, both in Australia and in other countries.

Despite this challenge, the use of digital resources to support mental health and well-being in prison is likely to increase in the coming years, given the degree to which it is already influencing the delivery of mental health support in the general community [32-34]. As this occurs, access to digital mental health support within prisons may begin to more closely mirror the level of access available in the outside community. This extension of access will be enhanced by establishing a body of evidence supporting the feasibility and efficacy of digital mental health interventions in a prison context. A concerted effort in creating, evaluating, and raising the awareness of credible digital mental health apps, programs, and services is essential.

Capitalizing on the rapid advancement and widespread adoption of digital technologies, researchers and developers have written and tested digital interventions related to a range of mental health issues, resulting in a substantial evidence base supporting their efficacy. The most widely evaluated group of digital interventions include those that target depression and anxiety in the general population, with greater support for guided digital interventions than unguided [35-41]. However, the benefit of unguided interventions is their ease of accessibility for the general population. The evidence base for digital mental health tools and systems, guided or unguided, for Indigenous people is practically nonexistent, especially for Indigenous prisoners, which limits the generalizability of these results to this population [42].

An exception is the Stay Strong app, which is used as a guided or therapist-facilitated mental health and well-being intervention tool for Indigenous clients. The app was based on the original paper-based version of the Stay Strong Plan, which has been in use since 2007 and has demonstrated significant improvements in client well-being, life skills, and alcohol dependence [43]. An iOS (Apple) version of the Stay Strong app was developed in 2013, making it the first digital mental health app specifically for the First Nations people of Australia [44]. Both the Stay Strong Plan and the app combine motivational interviewing and problem-solving strategies within a brief, strengths-based assessment and intervention tool, developed specifically for Indigenous Australians and for promoting Indigenous cultural values and self-management. Studies have demonstrated the feasibility of the app for use with Aboriginal and Torres Strait Islander people in the community to address mental health and substance misuse issues [44,45]. The app provides a structured evidence-based process to improve engagement with clients and overcome the gap in service access for Aboriginal and Torres Strait Islander clients [44]. For this project, the app is adapted to an Android version, and only this version is used in this study.

Objective

This study assesses the feasibility of the Stay Strong app as a digital well-being and mental health tool for use with Indigenous people in prison. This study also describes the implementation of the Stay Strong app as a digital well-being and mental health tool for use with Indigenous people across 3 high-security prisons in Queensland, Australia.

Methods

Overview

In this section, we first explain the setting and preparatory work required to implement this project. Then, we describe the intervention itself, including the adaptations and recruitment of participants. Finally, we describe the procedure for implementing and evaluating the intervention.

Setting

IMHIP is an SEWB and mental health service provided in prisons by Queensland Health. The IMHIP team is led by an Indigenous project manager and has a staffing profile of 8 Indigenous health worker and practitioner positions, all filled by Aboriginal and Torres Strait Islander staff. The team includes social workers, psychologists, and other Indigenous health workers specializing in mental health and SEWB. Support is also provided to IMHIP clients, as needed, by a non-Indigenous forensic psychiatrist. The IMHIP service is provided within 3 high-security Queensland prisons (Brisbane Women's Correctional Centre, Southern Queensland Correctional Centre, and Woodford Correctional Centre)—2 women's prisons and 1 men's prison. Where possible, clients are matched with IMHIP staff of the same gender, in line with recommended cultural practice. The IMHIP service is offered to Indigenous prisoners on their point of entry into one of these correctional centers, with the level of service determined by the client's level of need.

The Brisbane Women's Correctional Centre is a high-security women's prison with a built capacity for 264 prisoners and current state of 276 prisoners (as of May 4, 2021). The Southern Queensland Correctional Centre is a high-security women's prison with a built capacity for 300 prisoners and current state of 302 prisoners (as of May 4, 2021). The Woodford Correctional Centre is a high-security men's prison with built capacity of 988 prisoners but is currently over capacity with 1426 prisoners (as of May 4, 2021), making it the largest prison in Queensland.

Differences in terminology can occur internationally when describing various security levels of prisons. In Queensland, there are three prison security levels: maximum, high, and low. High security is the most common classification provided to prisoners upon entry into the prison system, including those on

remand, with 94% (9176/9752; as of May 3, 2021) of prisoners being accommodated in a high-security prison. Prisoners on a high-security classification can only be accommodated in high-security prisons. In some jurisdictions, this security classification would be referred to as maximum security. In Queensland, maximum security refers to an uncommon classification applied to no more than 38 prisoners at any point of time, with all of them isolated in individual cells. A prisoner is placed under a maximum-security order only if his behavior is considered as a threat to the safety of other prisoners and staff or the security of the prison. Prisoners under a maximum-security order are placed in maximum-security units, which are separate from the main accommodation areas. Only Woodford Correctional Centre and Brisbane Correctional Centre have maximum-security units.

Contextual Preparation

Overview

To our knowledge, the SSCP is the first use of digital mental health tools in Australian prisons. The project's innovative mode of delivery required the research team to develop new pathways and protocols for delivery in prisons, from inception to implementation. IMHIP's ground-breaking model of service delivery presented numerous challenges that were overcome through the support, consultation, and involvement of community groups and key Indigenous stakeholders.

Implementation Process

Textbox 1 outlines the implementation process undertaken from conception to sustained adoption of the Stay Strong app within the IMHIP service.

Textbox 1. Steps in implementation of the Stay Strong app in a prison setting.

Step 1: Conception and initiation

- Identification of client base, app, and context.
- Scoping potential for project with stakeholders.

Step 2: Definition, planning, and approval

- Development of project plan and evaluation protocol.
- Gained support from the Indigenous Mental Health Intervention Program (IMHIP), Queensland Forensic Mental Health Service, leadership team of Brisbane Women's Correctional Centre, and Menzies School of Health Research.
- Gained approval from the health and correctional government agencies for implementation of Stay Strong app into service and for evaluation.
- Gained approval and adapted Stay Strong app to the Android custody version.
- Gained approval and adapted outcome measures from paper versions to Android apps.
- Development of feedback app (Android version).
- Development of the locked down tablet interface for project.
- Practitioners trained in Stay Strong app and in the use of the app in the context of IMHIP service.
- Tested functionality, user interface design, compatibility, performance, installation, and offsite and onsite security.

Step 3: Launch

- September 2015—first use of Stay Strong app by an IMHIP client (Brisbane Women's Correctional Centre)

Step 4: Performance and support

- Provision of technical support, clinical supervision, support in output production (practitioner reports, client cards, and management data), and continued training for practitioners.
- Introduction of Android emulator with change to Windows-based tablet PCs.

Step 5: Project transition into sustained adoption

- Evaluation of Stay Strong app's feasibility and efficacy with Indigenous prisoners.
- Management of transition of technical support from research team and tool developer to health agency.
- Continued use of the Stay Strong app as part of the formal IMHIP service delivery model.

Preparation for Expected Challenges

Attempting to bridge the digital divide in mental health interventions in prison involved a range of challenges: prisoners being denied access to internet, lack of access to technologies, and competing philosophies of the correctional environment (security and containment) with the external health service. For the SSCP, this required approvals and protocols for the use of digital mental health strategies and technology as part of IMHIP service delivery. This included acquiring ethics and security approvals across both correctional and health agencies, the leadership teams of the relevant prisons, the Queensland Forensic Mental Health Service, and the IMHIP team responsible for the delivery of the service. The approvals and

the training of IMHIP staff and those involved in the broad care of IMHIP clients ensured engagement and support for the project. From inception and acceptance-testing to implementation, this process took approximately 18 months, with the first use of the Stay Strong app and associated project apps by IMHIP clients occurring in September 2015.

In preparation for implementation, processes and safeguards were put in place to meet the security requirements of the prisons and ensure confidentiality of client data. These included the safe and secure storage of tablet PCs within health facilities and during transport from health facilities to prison facilities. It was agreed that upon entry into the prisons, practitioners would proceed through entry checks with devices being logged against practitioners' names in permanent entry logs for officer reference. Permanent entry logs are records of what items specific staff and visitors are permitted to bring into a prison. To obtain the approval for the study, we also had to agree that, once in the prison, practitioners would abide by the security restrictions placed upon the use of tablets, supported by the use of lockdown software on devices. This was to ensure that the digital environment met security requirements.

Given the research team's experience in working across both agencies and within a range of correctional environments, they were able to expediate many processes: pre-empting issues of security and communication; movement of digital devices through centers; concern over prisoners' access and use of devices; management of confidential prisoner or client information; use of audio recording apps on devices for client feedback; device charging, maintenance, and ICT support; staff and stakeholder training; stakeholder and leadership engagement and approval; client's willingness to consent to providing feedback and having their interviews audio recorded; and logistics of printing and sharing of the prisoners' Stay Strong app client cards with prisoners and their prisoner property for use upon release.

The software developer, principal researcher, and IMHIP team completed the key elements to support adaptation and implementation: functionality, user interface design (walk-through of general design heuristics), compatibility (operating system device, screen, and plan for no connectivity), performance (memory and battery), installation, and security testing (data flow with broad agency security requirements).

Apps were password-protected to ensure client confidentiality; practitioners had to re-enter passwords to wake devices from sleep mode or to reopen the app and when accessing existing data. Tablets were also controlled using lockdown software (SureLock software; 42Gears Kiosk lockdown software for Android devices) to meet the security and confidentiality requirements of the health and correctional agencies responsible for the care of IMHIP clients.

Project Support

Financial support for the purchase of technology, development of software, and ICT support was critical to the project's success (refer to the *Acknowledgments* section). Throughout this process, it was essential that partnerships across health, correctional, academic, and software development sectors were developed and maintained. Without these relationships, the project would not have developed and formed a precedent for digital mental health strategies in Australian prisons.

Intervention

The Stay Strong app and 4 other apps adapted or developed specifically for this project provide a collection of digital mental health tools to support IMHIP clients. The Kessler Psychological Distress Scale [46], the Warwick-Edinburgh Mental Well-being Scale [47], and the Growth and Empowerment Measure [48] were used as outcome measures along with the semistructured interview app to inform the intervention and support the subsequent efficacy evaluation of the Stay Strong app. All use of digital resources was through tablet PCs, facilitated by the practitioners and used as an extension of their assessment and intervention resources (Figure 1). All the outcome measures, semistructured interview app, and the Stay Strong app were completely stand-alone apps owing to the internet connectivity restrictions placed upon the project. Consequently, all the apps used in this project were able to work offline (ie, not requiring network connection to function), thereby meeting both the security requirements of the prisons and the client confidentiality requirements of the health service.

Figure 1. Home screen of the tablet PC showing the Stay Strong app and other related apps.

Approval was given by the original developers of the Stay Strong app to adapt the original iOS community version to an Android custody version. Subsequently, the community version has been superseded by a hybrid version (for use on both iOS and Android devices). Similar to the community version, the steps of the custodial adaptation are ordered to enhance engagement while using a holistic approach for assessing a client's well-being and mental health needs. This 11-step app aims to engage clients and provide a nonthreatening approach to the discussion of their well-being and mental health. A comparison between the stepped intervention process of the custodial version and the recently updated community hybrid version is presented in Multimedia Appendix 1. The stepped intervention process of both versions includes the following: (1) collecting demographics, (2) talking about family, (3) talking about a client's strengths, (4) identifying a client's worries, (5) setting first goal for change, (6) setting second goal for change, (7) tips to enhance emotional and physical well-being, and (8) tips to manage substance misuse (Multimedia Appendix 1).

Key differences in the custody version when compared with the community version of the Stay Strong app are the removal of the client photo option, research *collect information* tick box option on the demographics page, and email option on the completion page of the Stay Strong app. Removal of these options from the community version was needed to meet the client confidentiality requirements of both the health and correctional agencies for implementation of this project in 2015. Figures 2 and 3 show steps 2 to 9 of the custodial version, which is nearly identical to the community version, with the exception of the additional *my support* page.

Figure 2. Custodial version of the Stay Strong app—steps 2-5.

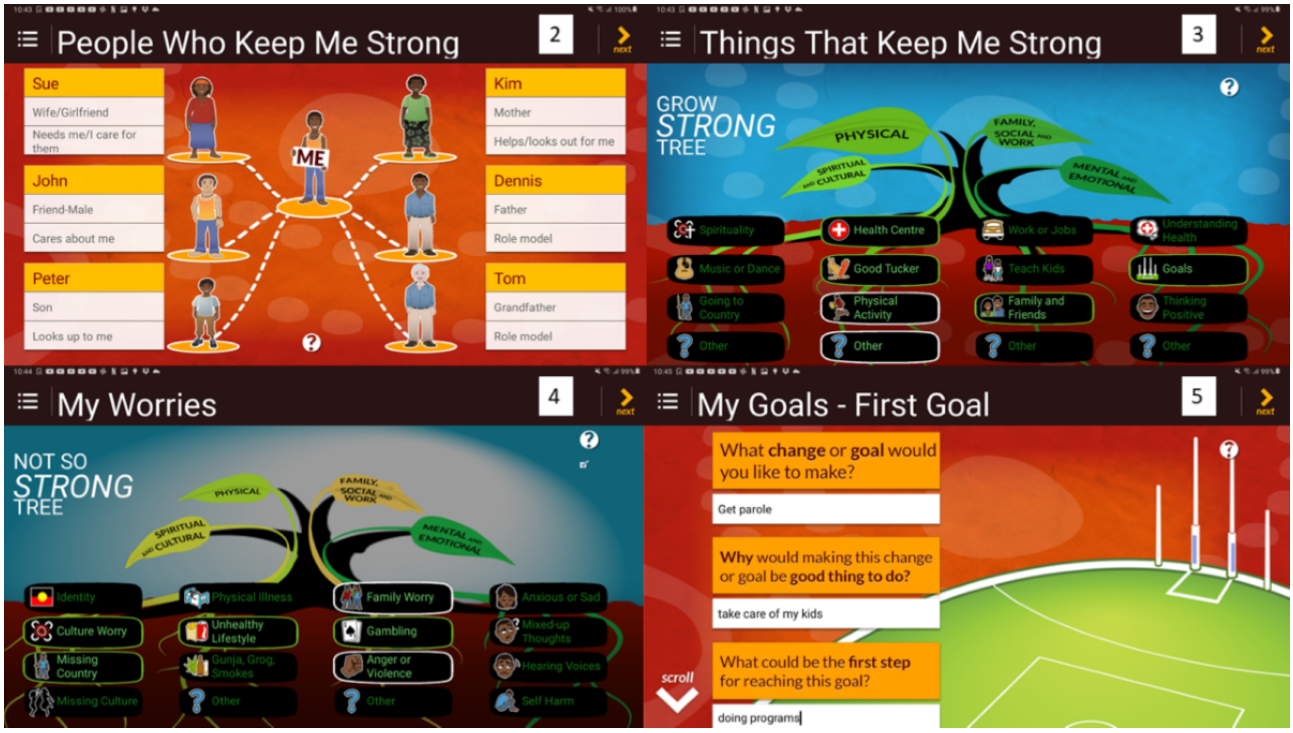

Figure 3. Custodial version of the Stay Strong app—steps 6-9.

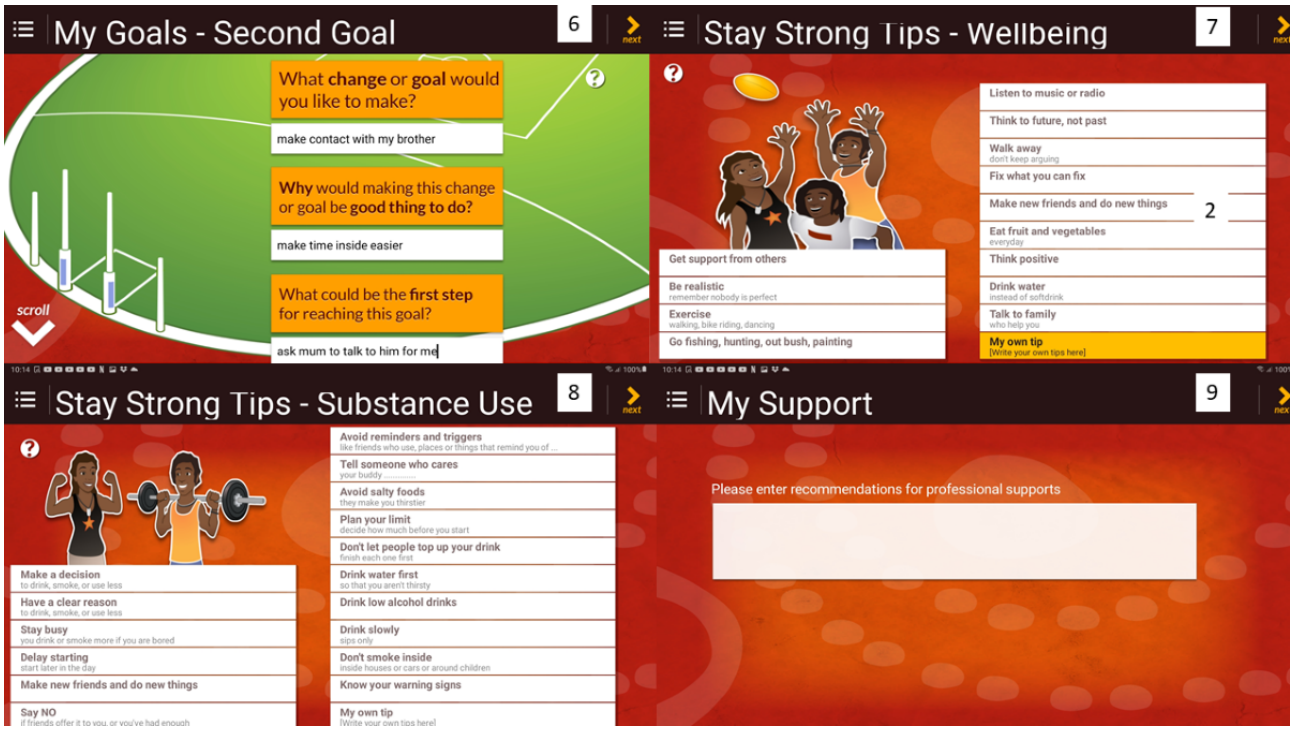

In the custodial version of the Stay Strong app, step 9 is the *my support* page in which discussion with clients occurs regarding professional supports that may be of benefit during custody and upon release. This is important, given the risks and challenges experienced by people during their first 6 months after release from prison [49,50]. Contact details are listed in this section, which are then automatically copied to the client's summary (step 10) and client card (step 11).

The client summary is a pictorial summary of each step, which then can be made into the client card (Figure 4), which is a wallet-sized, folded, and laminated card version of the client summary. Clients were provided with 2 copies of their cards, one for use while in custody and another that was stored with other personal property for use upon release. The cards were also folded in a way that allowed prisoners to display the pictorial representation of their support network easily in their prison cells.

Figure 4. Custodial version of the Stay Strong app—Stay Strong client card (step 11).

Recruitment

Client Participants

Participants were recruited from the client base of IMHIP between January 2017 and September 2019 (19/27, 70% women and 8/27, 30% men). All IMHIP clients were from one of the 3 high-security adult Queensland prisons (2 women's prisons and 1 men's prison). The IMHIP staff recruited clients who had the capacity to consent to their involvement in the project and who were regarded as not presenting any safety concerns. An invitation to participate in the program involved both written and verbal explanations of the study and consent forms. Before their release from prison, only clients who completed the baseline and follow-up assessments were invited to participate in a semistructured feedback interview with an IMHIP practitioner. All IMHIP practitioners at the time of the study were involved in conducting the semistructured interviews with clients.

Practitioner Participants

During the same period, IMHIP practitioners were invited to participate in semistructured feedback interviews with the principal researcher (6/10, 60% women and 4/10, 40% men). Similar to that for the client participants, practitioners' invitations involved both written and verbal explanations of the interviews and written consent was obtained.

Initial training for all practitioner participants involved either a 2-day trainer or 1-day Stay Strong app workshop. The process also involved shadowing of colleagues as part of the staff induction processes and Stay Strong app supervision by the principal researcher for the period of the study. The accredited Stay Strong app training package was provided by recognized trainers, and workshop content was summarized, for ongoing reference, in the Aboriginal and Islander Mental Health Initiative Stay Strong Planning Brief Treatment Manual [51].

Ethics Approval

The study was approved by the Darling Downs Hospital and Health Service Human Ethics and Research Committee (clearance #HREC/14/QTDD/65), the Behavioural and Social Sciences Ethical Review Committee of the University of Queensland (clearance #2015000360), and the Queensland Corrective Services Research Committee (no clearance number provided) before the IMHIP clients and practitioners were invited to participate. Client participants did not receive any financial compensation for participation in the study. Payments were not allowed by the prisons in which the participants were accommodated.

Procedure for Implementation and Evaluation

The study synthesized feedback from client and practitioner semistructured interviews to determine the feasibility of integrating the Stay Strong app into an SEWB and mental health service for Indigenous prisoners.

Delivery of Intervention

Steps within the Stay Strong app were completed by clients with their trained IMHIP practitioners as part of the IMHIP service delivery model. This was facilitated and supported by practitioners in session. During the project, clients completed the Stay Strong and outcome measures apps (Kessler Psychological Distress Scale, Warwick-Edinburgh Mental Well-being Scale, and Growth and Empowerment Measure) at 3-month intervals (at intake, first follow-up, and second follow-up) if still in custody. All participants who were in custody for their second follow-up were offered semistructured feedback interviews with practitioners.

Semistructured Interviews

Following their use of the intervention, participating clients and IMHIP staff were invited to provide feedback on the effectiveness of the Stay Strong app, its mode of delivery, and the service context for its use. The purpose of the interviews was to evaluate the use of the Stay Strong app and identify benefits and areas for improvement. The questions for the client semistructured interviews about their experience with the Stay Strong app are reported in Textbox 2, and those for practitioner interviews are reported in Textbox 3. The Stay Strong app went through a name change during this project, dropping *plan* from its title; thus, users were asked about their use of the Stay Strong Plan in reference to what is now known as the Stay Strong app (Textboxes 2 and 3).

Textbox 2. Stay Strong app's client questions used during semistructured interview.

Questions

- What were the best things about working on a tablet?
- What were the best things about developing your own Stay Strong Plan?
- What were the worst things about working on a tablet?
- What were the worst things about developing your own Stay Strong Plan?

Textbox 3. Stay Strong app's practitioner questions used during semistructured interview.

Questions

- What has it been like working with the tablets?
- What has it been like using the Stay Strong Plan with women/men?
- What would you suggest we do differently?
- How would you explain the tablets and Stay Strong Plan to other practitioners?
- How do you explain the Stay Strong Plan to the women/men you work with?

Before the interviews, of the 27 client participants, 24 (89%) clients consented to have their interviews audio recorded and the remaining 3 (11%) clients entered their responses directly into the tablets in response to the interview questions. All the (10/10, 100%) practitioners consented to having their interviews audio recorded.

Analysis

Audio recordings of the feedback interviews were transcribed verbatim by the principal researcher (EP). Following transcription, researchers (EP and KH) used the constant comparison method [52] as a framework for conducting the thematic analysis, as used in previous qualitative analyses [53]. There were 2 iterations of the qualitative coding. Practitioner and client data were coded separately. On the first pass through the data, the 2 coders independently identified themes that arose from >1 respondent across the questions in >1 interview. Then, the themes were agreed upon by the research team and coded independently for each question and each respondent (yes=1; no=0). There was no limit on the number of themes that could be coded for each response. Data were entered directly into SPSS data sets, and direct quotes reflective of each of the themes were collated. At this stage, any theme that did not reach satisfactory interrater reliability were discussed until consensus between coders was attained. Following agreement on themes within practitioner and client data, EP compared the 2 sets of themes and identified commonalities between both practitioner and client themes; these were then checked by KH.

Results

This section outlines both themes emerging from feedback interviews and responses to unexpected challenges experienced during the project.

Stay Strong App Themes Emerging From Client and Practitioner Feedback Interviews

Overview

Interrater reliability across themes was moderate to strong (κ ranging from 0.71 to 1). The prominent themes identified across both client and practitioner interviews include the following: general satisfaction with the Stay Strong app in its current format; support of clients' goal setting, self-insight, empowerment, cultural development, and engagement in intervention; ease of use of the Stay Strong app; and initial problems with using an Android emulator. These themes are

discussed below and include example responses by both clients and practitioners.

Satisfaction With the Current Stay Strong App (General Positive Statements or No Recommended Changes)

There was clear support from both clients and practitioners who voiced their satisfaction with the Stay Strong app in its current format, providing general positive statements or specifically identifying that there was no need for any change in the app.

Responses from clients included the following:

> *Oh, I thought it was one of the best things ever.*
>
> *Gives me some bit of hope in myself that you know.*
>
> *Liked being able to tell my story and explain it.*

Responses from practitioners included the following:

> *I would say ninety nine percent of the clients that I worked with them on the tablet have really enjoyed it. It's been something that they haven't done before. You know, it's exciting because they're allowed to touch a computer. I think they've enjoyed it.*
>
> *It's amazing. It's very, it's, it's kind of fun. It's exciting. You feel like you've got this. You're like technologically advanced, it's something. You know, new and exciting, yeah, it's quite, it's user friendly, too, and I know it just kind of makes you, you look deadly and you, you know.*
>
> *Then they love [sic] piece of technology that they can use, but they probably don't get to use at all while they're incarcerated, something different to do.*

Supported Client Goal Setting

All participants welcomed the Stay Strong app's support for clients' in developing and learning the process of goal setting. Responses from clients included the following:

> *It got me thinking about goals, my goals.*
>
> *To know that you have got goals and that you can believe in making your goals; and just being yourself and believe.*
>
> *Working out a lot of my goals and things about myself that I didn't know.*

Responses from practitioners included the following:

> *I think it helps them gain an understanding of how to work through goals that probably never had that opportunity. Never had that experience so actually understanding the process and how to work through steps in a goal.*
>
> *That it is a very useful tool for building that rapport with the client and helping them identify their future goals and their strengths and weaknesses and their support systems.*
>
> *It's a cultural intervention tool used to establish, how do I say that? To establish, to help focus the kind of future goal settings and, and a, identify their support systems, strengths, weaknesses, future goals in a way that's not too invasive.*

Increased Client Self-insight

The Stay Strong app was recognized by both clients and practitioners as enhancing the development of client's self-insight and self-reflection. Responses from clients included the following:

> *So going through the app, it makes, it makes me realise that I've got a lot of good things about me and like I didn't even think of it, you know. And just going through it makes me realise that I do have some positive.*
>
> *I know how to think about things now before acting on it now, you know in positive ways.*
>
> *You can actually see my progress like on the tablet, which is pretty good. I spun out a bit.*
>
> *I think in the beginning, there's so much I didn't realise, how sad and how bad my mental health was...yeah. Very confronting.*

Responses from practitioners included the following:

> *It sort of draws their attention to thinking and reflecting on those aspects in their, in their lives.*
>
> *It is a very good reflective tool.*
>
> *It's helpful for people that are leaving prison to sort of revisit and understand what their risks are. So that hopefully when they are released and back in the community that they can continuously be aware of those.*

Improved Client Empowerment

There was agreement between clients and practitioners that the Stay Strong app represented a client-led and directed tool that enhanced clients' confidence, view of self, and empowerment. Responses from clients included the following:

> *You know, in the long run, with those little steps in between. That you get, you know, you feel like you're really proud of actually getting there.*
>
> *Knowing that I can actually do it. You know like because I always doubt myself.*
>
> *It helped me though, you know, it helped me through a couple of rough times.*

Responses from practitioners included the following:

> *It's definitely client focused, client based. It's their story. It's a chance for people to tell their story about, you know, the things that keep them strong, the things that take away their strength. It's a, it's a, it's an opportunity for people to start thinking about ways that they can, their path to recovery.*
>
> *It's client led, client driven.*
>
> *Really helpful for people who are needing to gain empowerment in their lives and get their lives back on track and understand more deeply what their strengths are, and what their worries are, and help them inform goals and form a plan.*

Cultural Appropriateness

Clients and practitioners alike identified the Stay Strong app as a culturally safe tool that supported clients. Responses from clients included the following:

> *Doing that Stay Strong Plan [referring to Stay Strong app] made me come out of my shell because I didn't think that I was a person, not just any person, but also identifying myself as Aboriginal.*
>
> *All of the support in bringing back the culture.*
>
> *Helped me identify doing something spiritual. So thinking of my spirituality. It's helping me try to connect even though it's not like outside connections in here [prison].*

Responses from practitioners included the following:

> *It's very culturally friendly. They, they are able to complete it fairly easily.*
>
> *This is an opportunity for the Aboriginal or Torres Strait Islander person, the First Nations person to identify their story, to identify and acknowledge the network that they have that does support them in their recovery and healing.*
>
> *So, this is really a document or a process that is, that gives an Aboriginal or Torres Strait Islander person an opportunity to use their own, their own ways and their own words in identifying what makes them strong. What takes away their strength and identifying their steps to recovery. What they need to do.*

Enhanced Engagement

Both clients and practitioners identified the Stay Strong app as engaging and supportive of rapport between clients and practitioners. Responses from clients included the following:

> *The visual, the visual thing, as opposed to, the before counselling things, like it's words, reports, it never, never got anywhere, it never hit home.*
>
> *It's more. You can relate to the pictures that to come up on it.*
>
> *It was fast, better than paper, you can talk.*

Responses from practitioners included the following:

> *When we spit out the cards and all that at the end of it and give it to the client, and they can see that, you know, that visual. We're very visual people.*
>
> *I think that the tool actually helps with rapport building and helps them focus on that stuff and breaks the ice a bit and actually helps you, you know, break down some of the walls.*
>
> *The focus of the app is to support that narrative approach, to support that talking space and that's really, really important or as we call it, the yarning space.*

Ease of Use

Both clients and practitioners voluntarily stated that the Stay Strong app was easy to use, with some saying that it was easier than the typical paper assessment and intervention processes. Responses from clients included the following:

> *It's a lot easier because again like up, working on paper would, I'll probably find it more difficult because not being able to read or write properly and probably get really frustrating, probably would have. I find it is a lot easier on the tablet.*
>
> *You don't have to fill out paperwork that I might not understand.*
>
> *Much easier to understand and to communicate my feelings.*

Responses from practitioners included the following:

> *Before the Androids, we were doing the paper-based, so which is not as cool as doing it on a touch screen, it's actually not. Yeah, some people, some of the clients didn't mind writing into the stay strong plans [referring to the paper-based version of the plan]. You know, they keep diaries and journals and things like that. But generally speaking, completing the Stay Strong Plan on an Android tablet is very user friendly.*
>
> *It's easy, you know, you know in a culturally appropriate way which is interactive.*
>
> *They like the design. It's really simple, easy, it's easy to use.*

Problems With Using Android Emulator

When the project moved from Android tablets to Windows-based tablets, it required the use of an Android emulator software program on the new devices. The emulator software allowed the app to run on a Windows-based device. A few problems were associated with the use of the emulator: interaction with the health agency computer system, lack of technical agency support for emulator use, and inclusion of additional steps to facilitate the download of client material. Feedback from both clients and practitioners supported the return to the earlier modes, with devices being matched to the app (Android app on Android tablet PC). Responses from clients included the following:

> *Losing all of the information.*
>
> *Saving and crashing.*

Responses from practitioners included the following:

> *The old ones we didn't have a problem with [referring to original Android tablets]. So simple. There was never an issue with them.*
>
> *Wouldn't need to log into that second tablet thing, emulator.*
>
> *It's written for an Android then maybe we could just get fast track it to using Androids. I think it will resolve a lot of issues with updates and things on that.*

Other Prominent Themes From Practitioner Interviews

Recommendations to Improve Personalization

Although no clients provided recommendations to improve personalization of avatars within the Stay Strong app,

practitioners recommended being able to alter the client's avatar, add pets to client's support network, and further change the clothing of all avatars. Only the custody version of the Stay Strong app uses an avatar to represent the client, as images of prisoners are not permitted owing to prison security requirements.

Responses from practitioners included the following:

> *Some of them, you know, they will have a giggle when they're clicking on the cartoon pictures to around, you know, their mum or sister. They like, you know, my brother here looks kind of like this. You know, it's, it's, it's, they enjoy that and it's quite...and it's personal. And they've chosen that themselves. But yeah, it would be cool to do the middle picture. And then they could choose their pet dog or cat or something like that. That would be kind of cool as well. Yeah. Yeah.*
>
> *I'd probably make it more interactive so they could actually, you know, pick the cap they put on the child's head or do the hairstyle, you know.*
>
> *I would love to see pets being added to, you know, the support, the support section. I think that would be really cool. Also, the ability to change the centre picture, but that might just be on my own.*

Responses to Unexpected Challenges

There were several challenges that were not apparent at the inception of the project. Limitations were placed on the type of devices the project could purchase through the health agency, which initially conflicted with the security requirements of the correctional system. There were costs associated with in-agency information technology support for devices and limitations placed upon initial devices' access to secure Wi-Fi, requiring practitioners to manually connect tablets to their workstation PCs to download outputs. Workplace health and safety requirements conflicted with secure storage requirements and charging of tablet PCs. There were issues with staff retention in the IMHIP service, which was seeking permanent funding at the time of the project.

As the project progressed, prison officials recognized the effectiveness of safeguards and protocols. Then, this allowed the IMHIP service to move from locked down Android tablets to Windows-based tablets that had access to the secure Queensland Health network within prison facilities. This change in device capability and access to secure networks via Wi-Fi allowed the new tablets to be used by practitioners as mobile workstations within and outside the prisons. Thus, although the restrictions for use remained the same for prisoners during appointments, practitioners' use of devices between sessions expanded, enhancing the administration efficiencies for staff. Although overall this was a positive outcome, there were issues in gaining ICT support for the app emulator software needed for continued use of the new Windows-based tablets.

Discussion

Principal Findings

To our knowledge, this paper describes the first project to successfully implement the use of digital mental health apps in prisons in Australia, with its use by the first client occurring in September 2015. The description and evaluation of this project through this paper provides an example to other jurisdictions that seek to implement digital mental health solutions within the prison environment; it also provides evidence of acceptance and engagement by First Nations prisoners with a culturally safe digital mental health app.

The Non-adoption, Abandonment, Scale-up, Spread, and Sustainability [54] domains provide a framework to understand and reflect on the implementation experience and participant feedback. Below, we use this framework to discuss challenges and successes and make recommendations for the long-term sustainability of the Stay Strong app in prison.

A long-identified consideration for successful implementation in the digital health domain is the relationship between users (clients, practitioners, and developers), technology (including design), and organizations or wider systems with their economic realities [54,55]. For this project, a shared vision was held by practitioners, management, research team, and agencies that focused on improving the mental health and well-being of Indigenous prisoners. Although the correctional agency and leadership within the forensic mental health service allowed for innovation in the adoption of the app at a service level, there was tension between this and the wider health agency support for technology change. The health district only supported iOS apps, and therefore, to overcome issues of software incompatibility, the Android emulator was used, which was itself problematic at times. Although the custody version of the app was developed without funding, further development in a hybrid format (for use on both iOS and Android devices) may offer a more stable and valued proposition for funders. With development of the new hybrid version of the app and precedents set in other health districts for use on Android devices, it is hoped that these issues are less likely to pose barriers to dissemination and upscaling, if the IMHIP service expanded. Thus, it is evident that development and implementation would have benefited from cross-disciplinary involvement being extended to ICT policy makers from the beginning of the project.

The new hybrid version of the app allows for greater flexibility in use. However, given the restrictions placed upon the use of technology within high-security prisons, there is still a need for a custody version. Therefore, without customization of the hybrid or iOS Stay Strong app, Android is the only operating system for which there is a custody version. Ultimately, the value of the app is defined by its clinical relevance to users—its health benefits and financial viability [56]. Although client and practitioner feedback confirmed that the Stay Strong app's design aims to promote client well-being, the financial investment needed to overcome the innovation-system conflict remains a hindrance to the sustained adoption in the Australian custodial environment.

Feedback through interviews revealed that the visual appeal, interactive interface, and ease of use supported clients' engagement. Although client engagement is the natural focus of app development, practitioner acceptance has been demonstrated to be the strongest determinant of health technology adoption [54]. Peer support for the appropriateness of the technology and credibility of the tool is key to practitioner acceptance [54,57]. This project has been an example of peer influence supporting sustained adoption of digital technologies through training (including the onboarding of new staff), acknowledgment of the tool's credibility by a national index of Australian evidence-based digital mental health resources [58]), support from the management and practitioners, and inclusion of the tool into the formal IMHIP service delivery model. Typical reasons for practitioners' resistance to new health technology include implementation requiring policy change, inefficiency of the technology, risk of compromised practice, and negative change to client relationships [54,59]. By ensuring that these key areas were addressed, the likelihood of sustained adoption of the app was increased.

To protect against the risk of compromised practice, the knowledge domain was another focus for sustained adoption. This domain extends beyond practitioners' and clients' direct knowledge of how to use the app. The broader knowledge required for its use involved understanding how best to facilitate its adoption. For the SSCP, and therefore IMHIP, this has required understanding of the app's use in clinical practice within a context involving both health and correctional agencies. This involved understanding the technical requirements of use and an ability to provide and receive clinical supervision. Deficits relating to an implementation facilitator's broader knowledge of the service, technical support, organizational readiness, and ability to provide ongoing supervision have been identified as reasons for poor adoption rates after training by other services [60,61]. In contrast, one of the most important driving factors for this project's sustained implementation has been the support and direction provided by its internal facilitators. The SSCP is an example of a project that involved continued training from developers, technical support from project software developers, supervision and project management by the principal researcher, and support in service delivery from the IMHIP service and forensic mental health service management. The benefit of implementing this digital mental health tool within a small developing service is the flexibility within the service delivery model to determine the most efficacious use and the support available from internal facilitators. The successful implementation and use of the app by IMHIP for >5 years at the time this paper was written demonstrates the feasibility of its use with Indigenous people in prison and, more broadly, the implementation of digital mental health tools within the prison environment. The app has evolved in use and content over this period. Both clients and practitioners value its functionality, engaging appeal, cultural appropriateness, and clinical value in goal setting, insight, and empowerment.

Limitations

The study used implementation and interview data only. To enhance sustained adoption by and value proposition for users and agencies, there is a need for additional research into the efficacy of the Stay Strong app with Indigenous people in prison. We hope to build toward this with the future publication of a pilot efficacy study.

The project was also limited to 3 sites covered by the IMHIP service; therefore, although the user population is representative of the broader Aboriginal and Torres Strait Islander population, the number of participants was limited. The fact that IMHIP itself was a temporary project at the time meant that the service periodically experienced high staff turnover and shortages. The periods of low staffing resulted in delays in intakes and follow-ups and in combination with the short periods of imprisonment for most IMHIP clients, reduced the overall number of participants who made it to their second follow-up before release. This ultimately limited the number of IMHIP clients who were able to be included in this evaluation. However, the sample size of clients who participated in this study is comparable with other qualitative studies assessing feasibility [62-64].

The other limitation to this sample was the relatively low proportion of men participating in the program and evaluation. The main reason for this was that the participants were recruited from 2 women's prisons and 1 men's prison. Therefore, our sample does not reflect the higher proportion of men than women in the prison population. Future research could examine barriers to and enablers for engagement in such a program from the perspective of gender.

Conclusions and Future Directions

The aim of this study is to determine the feasibility of the Stay Strong app as a digital well-being and mental health tool for use by Indigenous people in prison. The app was successfully implemented and it provided support, as expected, for client treatment and transition planning (transitioning from prison back into the community). It offered a culturally safe tool, delivering a match between the aims of the app and clients' needs.

Successful implementation of this digital mental health tool required the coordination of gatekeepers (management), users (practitioners and clients), and systems (agencies, environment, and technology). This innovative project demonstrated the meaningful, manageable, and sustainable adoption of digital mental health technologies into the high-security prison environment; it provides an example for other jurisdictions that are considering the implementation of digital mental health solutions for First Nations people in prison. The thematic synthesis of client and practitioner feedback on the Stay Strong app confirmed that it was culturally appropriate and helpful in developing clients' empowerment, self-insight, and goal setting. Users described the tool as easy to use, engaging, and supportive of client disclosure.

As discussed, previous community-based implementation studies of the Stay Strong app identified the complexity of digital mental health tools needing more than training, external follow-up, and external supervision [60]. Using the Non-adoption, Abandonment, Scale-up, Spread, and Sustainability framework [54], this study identified additional factors, which supported

its implementation success. Key elements of the project's success were the match between the app and client needs, the benefits for users of app outputs, and having internal facilitators that drive the implementation and sustained adoption of the app.

Within the SSCP, the activity of supporting adoption of this app was a deliberate social process focusing on practice change through the support and training of practitioners, removal of barriers to implementation, provision of resources, monitoring of progress, and promotion of change [65]. Ultimately, the implementation steps that the project took to achieve this success provide a framework for other agencies and jurisdictions that want to implement either the app in prison or, more broadly, digital mental health tools within the prison environment. The project has demonstrated that the Stay Strong app and other digital mental health tools provide a novel and innovative opportunity for health and correctional agencies to bridge the divide in First Nations prisoners' mental health and well-being.

Acknowledgments

The authors acknowledge the support of the Menzies School of Health Research in the training of Indigenous Mental Health Intervention Program (IMHIP) staff and researchers to use the Stay Strong app and the permission they provided for adaptation of the app to the custody version for this project. The development of the Stay Strong app also paralleled its use within the IMHIP, and although not directly invested in its use by Queensland Health, Menzies provided training and access to the app at no cost to support broader use. In addition, the support provided by the IMHIP practitioners, Queensland Forensic Mental Health Service management, management teams of the Queensland Corrective Service prisons involved, and the project's software developer was key to the success of this project.

Abstract

Background: Web-based tools developed to facilitate a shared decision-making (SDM) process may facilitate the implementation of lung cancer screening (LCS), an evidence-based intervention to improve cancer outcomes. Veterans have specific risk factors and shared experiences that affect the benefits and potential harms of LCS and thus may value a veteran-centric LCS decision tool (LCSDecTool).

Objective: This study aims to conduct usability testing of an LCSDecTool designed for veterans receiving care at a Veteran Affairs medical center.

Methods: Usability testing of the LCSDecTool was conducted in a prototype version (phase 1) and a high-fidelity version (phase 2). A total of 18 veterans and 8 clinicians participated in phase 1, and 43 veterans participated in phase 2. Quantitative outcomes from the users included the System Usability Scale (SUS) and the End User Computing Satisfaction (EUCS) in phase 1 and the SUS, EUCS, and Patient Engagement scale in phase 2. Qualitative data were obtained from observations of user sessions and brief interviews. The results of phase 1 informed the modifications of the prototype for the high-fidelity version. Phase 2 usability testing took place in the context of a pilot hybrid type 1 effectiveness-implementation trial.

Results: In the phase 1 prototype usability testing, the mean SUS score (potential range: 0-100) was 81.90 (SD 9.80), corresponding to an excellent level of usability. The mean EUCS score (potential range: 1-5) was 4.30 (SD 0.71). In the phase 2 high-fidelity

usability testing, the mean SUS score was 65.76 (SD 15.23), corresponding to a good level of usability. The mean EUCS score was 3.91 (SD 0.95); and the mean Patient Engagement scale score (potential range 1 [low] to 5 [high]) was 4.62 (SD 0.67). The median time to completion in minutes was 13 (IQR 10-16). A thematic analysis of user statements documented during phase 2 high-fidelity usability testing identified the following themes: a low baseline level of awareness and knowledge about LCS increased after use of the LCSDecTool; users sought more detailed descriptions about the LCS process; the LCSDecTool was generally easy to use, but specific navigation challenges remained; some users noted difficulty understanding medical terms used in the LCSDecTool; and use of the tool evoked veterans' struggles with prior attempts at smoking cessation.

Conclusions: Our findings support the development and use of this eHealth technology in the primary care clinical setting as a way to engage veterans, inform them about a new cancer control screening test, and prepare them to participate in an SDM discussion with their provider.

Introduction

Background

Shared decision-making (SDM) is a valuable and, in some settings, mandated approach to helping patients make informed and value-aligned decisions in medical care. SDM is especially useful in decisions of equipoise when the benefits of intervention do not clearly outweigh the harms and when the value patients assign to these attributes vary [1,2]. Lung cancer screening (LCS) is an evidence-based intervention that meets these criteria [3,4]. However, despite expert guidelines dating from 2014 that recommend LCS for eligible persons [5], LCS uptake and adherence to follow-up protocols have remained low [6]. A number of SDM tools for LCS have been developed [7-10]; however, the implementation of SDM in practice has been limited [11], and the uptake of LCS remains low [12]. A participatory design approach, including patient end users such as US veterans, may increase the uptake of SDM tools and support value-aligned decisions regarding LCS. A user-centered design of SDM interventions guided by usability metrics is required to advance the integration of web-based SDM tools into clinical practice [13].

LCS with low-dose computed tomography has proven effective in decreasing lung cancer mortality in two large randomized controlled trials: the National Lung Screening Trial in the United States [4] and, more recently, the Dutch–Belgian LCS trial [3]. The trials reported a decrease of 20% and 25% in lung cancer mortality among those screened compared with control populations for the United States and Belgian studies, respectively. However, clinical trials also reported harms, including false positive tests, significant incidental findings, and an excess incidence of lung cancer cases indicative of overdiagnosis. False positive tests require follow-up imaging and, in some cases, invasive diagnostic procedures that can cause harm. False positive rates vary across trials and decrease in the later years of screening. The National Lung Screening Trial reported false positive rates of 26.3 %, 27.2 %, and 15.9% at baseline, year 1, and year 2, respectively. The Dutch–Belgian trial reported false positive rates of 19.8 %, 7.1 %, and 9.0% at baseline, year 1, and year 3, respectively [14].

Decision aids (DAs) are structured tools that include a description of decision options, evidence-based benefits and harms associated with each option, a value clarification exercise, and support for a SDM conversation with one's health care provider [15]. In systematic reviews, DAs have been found to improve the quality of decision-making with respect to the outcomes of knowledge, preparation for decision-making, and value-aligned decisions [16]. However, the implementation of DAs has been limited. A primary barrier has been their integration into the flow of clinical practice [17-19].

Objectives

Veterans of the United States military are at a higher risk of developing lung cancer than the general population because of older age, higher rates of smoking, and environmental exposures [20]. Veterans are also at higher risk for mental health conditions, including anxiety and posttraumatic stress disorder (PTSD), which increase the burden of LCS, thus affecting the balance of benefits and potential harm from LCS [20]. To address these challenges, we used a user-centered design to develop a veteran-centric LCS decision tool (LCSDecTool) for use in a primary care setting. This tool was designed to be used independently by the patient before the clinic visit (either at home or in the waiting room) with the option of sharing some components with the clinician during the clinic visit. In this study, we report an iterative process of usability testing of a prototype tool and a revised high-fidelity version, with the latter conducted as part of a hybrid type 1 effectiveness-implementation trial. Usability assessment is a key component in the development of web-based decision support tools. Common methods used in usability testing include observation, cognitive interviews, and self-reported feasibility and usability with validated scales [21]. We seek to determine whether veterans find the tool useful to use in the context of a clinical visit and elucidate key aspects of the user experience that had an impact on usability.

Methods

Description of the LCSDecTool

We developed the LCSDecTool using the Promoting Action on Research Implementation in Health Services (PARiHS)

implementation framework. The PARiHS framework includes the domains of evidence (scientific evidence supporting intervention efficacy), context (the setting in which the intervention is delivered), and facilitation (training and support needed to deliver the intervention) [22,23]. Systematic reviews have established the efficacy of decision aids in improving the process of medical decision-making, as indicated by an increase in knowledge, perceptions of being informed, accuracy of risk perceptions, and clarity about values [24]. We were guided by criteria from the PARiHS framework in the tool design and usability testing for the prototype and high-fidelity LCSDecTool, both of which were evaluated among eligible veterans receiving primary care in Veteran Affairs (VA) Medical Centers and later in the context of a clinical visit. Both focused on the support needed by veterans to access and navigate the tool. The development and usability assessment were also informed by the Technology Acceptance Model (TAM) [25,26]. The TAM posits that people need to perceive the technology as useful and easy to use to continue using it. This model supported our choice of the quantitative outcome measures of the System Usability Scale (SUS) and the End User Computing Satisfaction (EUCS) measure, which include questions in these domains [27-29].

Stakeholder focus groups (clinicians) and structured interviews (veterans) further informed the content and features of the prototype LCSDecTool [30]. The LCSDecTool was designed to (1) use in advance of or during a primary care clinical visit where LCS may be initiated, (2) ensure that veterans understand the key benefits and potential harms of LCS, (3) help veterans weigh the benefits and potential harms of LCS, (4) provide resources for smoking cessation and mental health treatment, (5) support communication with their provider regarding this decision, and (6) include a clinician portal to streamline the use of the tool with a clinician in the clinical setting. The tool was designed for the primary platform of a tablet but has compatibility with a computer or mobile phone. The stakeholder inputs that informed these goals are summarized in Table 1. The data collection form with illustrations from the prototype version of the LCSDecTool is available in the supplemental materials (Multimedia Appendix 1).

Table 1. Feedback from veteran and clinician stakeholders to support the design of the lung cancer screening shared decision-making tool.

Features and content and description	Supportive data from stakeholder interviews	
	Veterans (n=32)	Clinicians (n=9)
Computer based		
Accessed by a URL link on devices: tablet, desktop, laptop, and smartphone	• 12 (38%) recommended the lung cancer screening shared decision-making tool be computer based; some wanted paper instead of digital	• 6 (67%) supported a web-based module • 5 (56%) supported a phone app • 4 (44%) supported an app for a tablet
Overview of LCS[a]: simulated discussion between patient and provider		
Simulated dialog with questions and answers about LCS	• 8 (25%) recommend a web-based tool that is engaging and interactive to hold attention; one suggested that they could ask a question, and it would be answered back	• Only 2 (22%) indicated they thought patients were knowledgeable about LCS
Overview of LCS: clickable knowledge boxes		
6 knowledge boxes, each covering a key LCS content area; must click on all boxes before advancing to the tool	• 17 (53%) recommended a simple user-friendly website, suggested simple words, examples, and graphs; break knowledge down into topic categories, and have limited words on each page	• Only 2 (22%) indicated they thought patients were knowledgeable about LCS
Evidence-based outcomes: pictograph		
Main outcomes from the National Lung Screening Trial displayed in pictograph: lung cancer deaths and deaths averted, false positives, biopsies, and complications	• 17 (53%) commented they wanted understandable graphics • 10 (31%) commented they wanted updates in research	• 4 (44%) wanted graphical representation of risks and benefits
Value elicitation—rating scale 1 and rating scale 2 and Cancer Screening Attitudes Rating Scale		
Ratings to indicate value attributed to LDCT[b] attributes; high-fidelity version used rating scale 2	• Qualitative analysis of 23 (72%) veteran interviews indicates wide variation in how LCS attributes are valued and that attitude and beliefs about LCS may affect value ratings [30]	• 4 (44%) noted that LCS is not a priority for veterans compared with their other concerns
Veteran-centric content—smoking cessation and mental health		
VA[c] resources highlighted with an option to request consultation	• 12 (38%) wanted to include smoking cessation options in the tool • 19 (59%) indicated that LCS might increase their anxiety or worry	• 6 (67%) wanted to use LCS discussions to promote smoking cessation • 4 (44%) noted that LCS might increase patient anxiety and worry about having cancer
Enter questions for the provider		
Free text option; questions inserted on the summary sheet	• 8 (25%) stated that they wanted the tool to be engaging and interactive	—[d]
Summary page		
Includes ratings of values and attitudes; ability to print, save, or email page	• 10 (31%) veterans stated the tool should prepare them for a discussion about LCS with their provider	—
Clinician portal		
Link from entry page to features for use at the point of care: pictograph, value and attitude assessment, and summary page	—	• 5 (56%) noted they did not have time to participate in shared decision-making about LCS. • Clinicians indicated that the tool must be short and easy to use in the clinical setting.

[a]LCS: lung cancer screening.

[b]LDCT: low-dose computed tomography.

[c]VA: Veteran Affairs.

[d]Data not available.

Approach to Usability Testing

We used both quantitative and qualitative methods for usability testing. The SUS and the EUCS scales have been widely used and well-validated to assess interventions in the domains of ease of use and usefulness [28,29,31-36]. The SUS is a 10-item scale developed for the assessment of a broad range of products; scores (ranging from 0=low usability to 100=high usability) correspond to the following adjective descriptors: worst imaginable, awful, poor, okay, good, excellent, and best imaginable [27,37]. The EUCS scale is a 12-item scale that captures the domains of content, accuracy, format, ease of use, and timeliness relevant to a computer application. Scores range from 1=low satisfaction to 5=high satisfaction [28,29]. The Patient Engagement (PE) scale has been used to assess engagement in web-based programs in the medical setting [38,39]. The PE scale assesses engagement in the domains of caring for one's health, concerns addressed about LCS, understanding LCS guidelines, and understanding information about LCS. Scores on the PE scale range from 1=low engagement to 5=high engagement.

To better interpret the results of the quantitative measures, we used qualitative approaches, including observations of the testing sessions and brief interviews at the completion of the testing sessions. These qualitative approaches have been applied in usability testing to identify barriers to the effective navigation of tools and processing of information [40,41]. The research assistants (RAs) who obtained the qualitative data underwent formal training in qualitative interviewing before the study. This process included 8 hours of training in qualitative methods in the Mixed Methods Research Lab at the University of Pennsylvania for our senior RAs (JP: Bachelors of Science with Major in Biology; JI: Bachelor of Science with a major in Neuroscience). Our junior RA was trained by the senior RAs on the observation of interviews and feedback (JM: Bachelor of Arts with a major in Psychology).

Phase 1 Prototype Usability Testing

Phase 1 Study Participants and Recruitment

Veterans were eligible if they were aged 55 to 80 years, had a 30 pack-year history of cigarette smoking, and continued smoking sometime within the past 15 years. The exclusion criteria were cognitive impairment; a life expectancy of <2 years, as determined by their primary care provider; and having received LCS within the past 18 months. The participating sites were the Michael J Crescenz VA Medical Center in Philadelphia, Pennsylvania, and the West Haven VA Medical Center in West Haven, Connecticut.

We used the Corporate Data Warehouse to identify eligible veterans based on age, an algorithm of indication of tobacco use based on primary care visits and dental visit structured fields in the computer record, and pharmacy records of the use of smoking cessation medications, as well as having an upcoming primary care appointment. We sent recruitment letters with follow-up phone calls to confirm eligibility. Veterans who were interested were then scheduled for a study visit. Recruitment for the phase 1 protocol study occurred between August 2018 and January 2019. A voucher for US $50 was offered to compensate the participants for their time. The recruitment goal for veterans was 16 from each site (total of 32)—a sample size that has been validated in the literature for usability testing [42,43].

Phase 1 Prototype Usability Testing Procedures

Following informed consent and the completion of a baseline survey to assess demographic information, participants were individually seated in a room with an RA. Participants were provided with a tablet device to use the LCSDecTool. The session was audio recorded and transcribed. Following the use of each section of the tool (Table 2), the RA asked the participants to describe their user experience. The RA documented field notes during the session to highlight responses to specific sections. At the completion of the tool, the participants completed the SUS and EUCS scales [27,29].

Table 2. Qualitative feedback in phase 1 prototype usability testing.

Features and content of the LCSDecTool[a]	Feedback from phase 1 prototype testing	
	Veterans	Clinicians
Computer based		
Accessed by a URL link on devices: tablet, desktop, laptop, and smartphone	• Users varied in preferred device: tablet, laptop, phone	—[b]
Overview of LCS[c]: simulated discussion between patient and provider		
Simulated dialog with questions and answers about LCS	• Users found this engaging • Most recognized that it was a physician and patient discussion and found this engaging • The scrolling function was intuitive to most • Recognized the format as similar to texting • Easy to navigate • One did not realize it was a physician–patient discussion	• Consider adding audio • Clarify who is speaking • Dialog seems natural • Shorten • Define CT[d] scan • Change *Nodule* to *Spot* • Liked clarification that a false positive is not a mistake • Change *Doctor* to *Provider* • Indicate most nodules are small
Overview of LCS: clickable knowledge boxes		
6 knowledge boxes, each covering a key LCS content area; one must click on all boxes before advancing to the tool	• Most found this to be more informative and easier to navigate than simulated dialog • Some noted that the repetition of some content in this format reinforced the information that was being conveyed • The pictures on each box were engaging	• Add a box for *what is a CT scan?* • Navigation may be confusing • Symbols would be better than pictures • Be careful about using relative risk reduction for mortality benefit • Consider the pictorial representation of statistics • Add a box for *what happens if my scan is abnormal?* • Agree with bringing up annual screening; include that interval cancers may occur
Pictograph		
Main outcomes from the National Lung Screening Trial displayed in pictograph: lung cancer deaths and deaths averted, false positives, biopsies, and complications	• Users (except for 1) understood that the 2 side-by-side pictographs were comparing outcomes between screened and not screened populations • Understood dots to represent people and colored dots to represent outcomes • Some needed to be guided through the pictograph to understand	• Good color contrast • Would use with patients • Helpful visual aid • Describe a major complication • Clarify screened and unscreened groups
Value elicitation—rating scale 1 and rating scale 2		
Rating scale 1 response scale: much less likely to much more likely to want screening; rating scale 2 response scale: not at all concerned to extremely concerned	• For most users, rating scale 2 was easier to use and demonstrated greater variation in ratings among benefits and potential harms of screening. • One user found rating scale 1 to be more relevant and helpful in evaluating these attributes	• Less user friendly than the attitudes section • Shorten • Explain that answers go to the summary page • Lacks assessment of cost • Prefers scale 2 • Carry over stem to each question
Cancer screening attitudes—rating scale		
An assessment of general cancer screening attitudes and beliefs	• Questions were intuitive and easy to answer	• Reads well • Clarify what *repeat testing* means • Clarify why these questions were asked
Veteran-centric content—smoking cessation and mental health		

Features and content of the LCSDecTool[a]	Feedback from phase 1 prototype testing	
	Veterans	Clinicians
VA[e] resources highlighted with the option to request a consultation	• Most acknowledged that these were important, and some clicked boxes to request consultations. • One user cautioned that raising the issue of anxiety may discourage a veteran from LCS	• Provide phone numbers in a handout • Note that the risk of lung cancer decreases after smoking cessation • Change the description to *mental health or behavioral health provider* • It is important to include smoking cessation to emphasize benefit, even with LCS • State that smoking cessation is more effective than LCS in preventing lung cancer deaths • Loved mental health access • Include information specific to veterans • Integrates well with the tool
Enter questions for the provider		
Free text option; questions inserted on the summary sheet	• Users all supported this feature	—[b]
Summary page		
Includes ratings of values or attitudes; able to print, save, or email page	• Users all supported this feature	• Clarify where the email goes • Simplify and shorten • Title value responses with “Why I want screening” • Clarify that it goes to the provider • Improve that format of presenting scale results; use color coding • Give suggestions to providers about how to address concerns; goal to distinguish beliefs from misunderstandings • Like how it looks; will be helpful to providers
Clinician portal		
Link from entry page to features for use at the point of care: pictograph and value and attitude assessment	—	• Name *Clinician* or *Provider* rather than *Physician* portal • Add picture with active link to the portal • Make more accessible to the clinician • Use term save *document* versus *PDF* • Like that the provider has quick access to patient summary

[a]LCSDecTool: lung cancer screening decision tool.

[b]No information emerged for this feature.

[c]LCS: lung cancer screening.

[d]CT: computed tomography.

[e]VA: Veteran Affairs.

Phase 1 Prototype Analytic Plan

Quantitative Analysis

Descriptive statistics were used to summarize the following outcomes: (1) time in minutes for completion of the tool, (2) participant characteristics, and (3) scores on the SUS and EUCS scales. Participant characteristics included sex, race, ethnicity, age, and education level.

Qualitative Analysis

Members of the research team (MS, JP, and JM) reviewed the transcripts of the user sessions with veterans and the field notes documented by the RAs from provider interviews. Comments were summarized for each section of the LCSDecTool to indicate feedback from veteran users and clinicians regarding the features and content of the LCSDecTool (Table 2).

Phase 2 High-Fidelity Usability Testing

Phase 2 Study Participants and Recruitment

Usability testing of the high-fidelity version was conducted as part of a pilot type 1 hybrid effectiveness-implementation trial that compared the LCSDecTool with a control web-based intervention providing general education about cancer screening. The participating sites were the Michael J Crescenz VA Medical Center in Philadelphia, Pennsylvania, and the West Haven VA Medical Center in West Haven, Connecticut. Eligibility criteria

for veteran participants were identical to the phase 1 prototype usability testing protocol with the following exceptions: (1) the additional exclusion criteria of a prior diagnosis of cancer (except for stable prostate cancer or nonmelanomatous skin cancer) and (2) the additional inclusion criteria that the veterans' primary care provider consent to participate in the study. Recruitment for the phase 2 high-fidelity usability study occurred between March 2019 and February 2020. Participants received a US $50 voucher for the baseline visit, which included usability testing.

Phase 2 High-Fidelity Usability Testing Procedures

Following informed consent and the completion of a baseline survey, participants were given a tablet that was open to the first page of the LCSDecTool. Participants were instructed to navigate the tool on their own. The RA observed the session, took field notes to document observed difficulties in navigation, and answered the participants' questions during the usability session. The time from when the participant started to interact with the tool until the summary page was reached (ending the session) was documented by the RA.

Upon completion of the use of the tool, the RA conducted a brief interview with the participant, which included the following questions:

1. What were your general impressions of the LCSDecTool?
2. Did you have any trouble using the tool, and if so, describe (if the RA had noticed any issues in navigating the tool that were not mentioned, they would prompt by adding "I noticed you had trouble with...")?
3. Do you have suggestions for improvements?
4. On the page that has boxes with knowledge content, do you think that it should be required to click on every box to move forward?
5. Did you find the tool repetitive in any way?

When the user responded affirmatively, follow-up questions were asked so that the patient could further elucidate.

Upon the completion of the usability testing session, participants proceeded to their scheduled primary care appointments. A postclinic survey was completed directly after the primary care appointment. The postclinic visit survey included the SUS, EUCS, and PE scales. The study was approved by the institutional review boards of the participating sites.

Phase 2 High-Fidelity Analytic Plan

Phase 2 Quantitative Analysis

Descriptive statistics were used to summarize participant characteristics, including sex, race, ethnicity, age, annual household income, and comorbidity. Descriptive statistics were used to summarize the responses to the SUS, EUCS, and PE scales.

Phase 2 Qualitative Analysis

We used a thematic analysis to analyze the qualitative data from the following sources: (1) notes taken by the RA while observing usability testing and (2) documented responses to the brief interview that followed the user session. Thematic analysis is an approach for identifying, analyzing, and reporting themes or patterns within a set of data using standard methods for qualitative research [44]. We used an inductive approach to identify themes pertaining to the user experience with the tool. A total of 2 members of the study team (JP and JM) initially reviewed the data and created an initial coding scheme. The data and codes were reviewed and finalized with input from additional members of the study team (MS and DK). Final coding was conducted by 2 independent coders, with differences resolved by consensus.

Ethics Approval and Informed Consent

The study was approved by the institutional review board of the participating sites. Participants provided informed consent to complete the baseline survey in phase 1, and the clinicians of participating veterans signed informed consent forms in phase 2 at the time of enrollment in the study. IRB approval obtained from the Michael J Crescenz VA Medical Center, Philadelphia VA (IRB# 01635, IRB #01721, IRB#01780) and the VA Connecticut Healthcare System (MIRB# 02071, MIRB#02240).

Results

Phase 1 Prototype Usability Testing

Phase 1 Study Participants

A total of 70 recruitment letters were mailed to the Philadelphia VA Medical Center. Of the 70 veterans, 12 (17%) had confirmed eligibility by phone interviews and were enrolled in the study. A total of 101 letters were mailed to the West Haven VA Medical Center. Of these 101 veterans, 6 (5.9%) were confirmed to be eligible and were enrolled in the study. Of the 18 participants, 15 (83%) were male, 8 (44%) were African American, and 15 (83%) had up to a high school–level education. Additional participant characteristics are presented in Table 3.

Table 3. Description of study populations.

Participant characteristic	Prototype cohort[a] (n=18)	High-fidelity cohort (n=43)
Sex, n (%)		
Male	15 (83)	39 (91)
Female	3 (17)	4 (9)
Race, n (%)		
African American or Black	8 (44)	27 (63)

Heart disease	—[a]	4 (9)

Participant characteristic	Prototype cohort[a] (n=18)	High-fidelity cohort (n=43)
Other	—[a]	4 (9)

[a]The prototype cohort did not have an assessment of income or comorbidity.

[b]There were no self-reports of race in these categories.

[c]One participant selected *Other* and *White*.

[d]GED: General Educational Development.

[e]No self-reports of education in this category.

Phase 1 Prototype Quantitative Results

In the phase 1 prototype usability testing, the mean of the SUS score (potential range: 0-100) was 81.90 (SD 9.80), corresponding to an excellent level of usability. The mean of the EUCS score (potential range 1-5) was 4.30 (SD 0.71; Table 4).

Table 4. Quantitative outcomes for phase 1 prototype and phase 2 high-fidelity usability.

Categorization	Prototype cohort (n=18), mean (SD)	High-fidelity cohort (n=43), mean (SD)
SUS[a,b]: total (0-100); individual items (0-10)		
Total	81.90 (9.80)	65.76 (15.23)
I think I would like to use this tool frequently.	7.64 (2.18)	7.09 (2.11)
I found the tool unnecessarily complex.	8.75 (2.46)	7.09 (2.11)
I thought the tool was easy to use.	8.47 (152)	6.40 (2.45)
I think that I would need the support of a technical person to be able to use this tool.	8.06 (2.79)	7.03 (2.33)
I found the various functions in this tool were well integrated.	8.75 (1.29)	6.91 (2.17)
I thought there was too much inconsistency in this tool.	8.75 (1.96)	6.57 (2.25)
I would imagine that most people would learn to use this tool very quickly.	7.92 (2.46)	7.26 (1.79)
I found this tool very cumbersome to use.	7.92 (3.12)	6.22 (2.52)
I felt very confident using the tool.	8.47 (1.94)	7.44 (1.87)
I needed to learn a lot of things before I could get going with this tool.	7.22 (3.31)	5.11 (2.67)
EUCS[c,d] measure (score 1-5)		
Total	4.30 (0.71)	3.91 (0.95)

Does the web tool provide the precise information you need?	4.17 (0.99)	3.81 (1.11)
Does the web tool information content meet your needs?	4.28 (0.89)	3.74 (1.03)
Does the web tool provide help that seemed to be just about exactly what you need?	4.22 (01.17)	3.67 (1.06)
Did the web tool provide sufficient information?	4.33 (0.84)	4.02 (1.01)
EUCS accuracy subscale	4.25 (0.83)	3.87 (1.10)
Was the web tool accurate?	4.22 (0.88)	3.86 (1.10)
Were you satisfied with the accuracy of the web tool?	4.28 (0.89)	4.05 (0.95)
EUCS format subscale	4.28 (0.69)	3.97 (1.00)
Did you think the web tool information is presented in a useful manner?	4.28 (1.02)	4.05 (0.95)
Was the web tool information clear?	4.28 (0.83)	4.05 (1.05)
EUCS ease of use subscale	4.53 (0.70)	4.0 (1.02)
Was the web tool user friendly?	4.5 (0.86)	4.05 (0.10)
Was the web tool easy to use?	4.56 (0.62)	3.95 (1.13)
EUCS timeliness subscale	4.25 (0.83)	3.88 (1.06)
Did you get the web tool information you needed quickly?	4.28 (0.96)	3.86 (1.08)
Did the web tool provide up-to-date information?	4.22 (0.88)	3.91 (1.11)
PE[e,f] tool (score 1-5)		
Total score	—[g]	4.12 (0.67)
How well did the tool support you in caring for your health?	—	4.00 (0.70)
How well were your concerns about lung cancer screening addressed?	—	4.27 (0.77)
How well did you understand the guidelines for lung cancer screening?	—	4.12 (0.76)
How well did you understand the information provided about lung cancer screening?	—	4.14 (0.83)

[a]SUS: System Usability Scale.

[b]The SUS is a 10-item Likert scale with individual item scores ranging from 0 (low usability) to 10 (high usability) and a total score ranging from 0 to 100.

[c]EUCS: End User Computing Satisfaction.

[d]The EUCS is a 12-item scale measuring domains of content, accuracy, format, ease of use, and timeliness.

[e]PE: Patient Engagement.

[f]The PE scale includes four items assessing whether the tool (1) supports users in caring for their health, (2) addresses health concerns, (3) informs users about lung cancer screening guidelines, and (4) informs users about lung cancer screening. Scores on the PE scale range from 1 (low engagement) to 5 (high engagement).

[g]Patient Engagement was not assessed on the prototype cohort.

Phase 1 Prototype Qualitative Results

The veterans' and clinicians' qualitative feedback for the prototype testing are summarized in Table 2. Key feedback received from veterans included the following: (1) the dialog feature was engaging; (2) the knowledge boxes were an effective way of presenting information and reinforcing content introduced in the dialog feature; (3) the pictograph effectively conveyed a comparison of outcomes among screened versus nonscreened groups; (4) the value elicitation questions using a response scale measuring level of concern regarding potential harms were more intuitive to most than the response scale assessing if the attribute made it more or less likely for the veteran to have LCS; and (5) there was enthusiasm among users about the interactive features, including a text box and summary sheet to ask questions and share questions, values, and preferences with their provider. Clinician feedback included recommendations for simplifying the terminology used and enthusiasm for the pictograph as a visual aid to support provider–patient communication about LCS.

Modifications Made in the High-Fidelity Version

Results of the phase 1 testing informed changes made to the prototype in the development of the high-fidelity version, including the following: (1) use of a color scheme aligned with the US Department of Veterans Affairs branding, (2) replacement of stock graphics with icons and symbols, (3) use of directions and well-placed buttons to improve self-navigation, (4) a more prominent link from the entry page to the clinician portal, (5) simplified text and definitions, (6) single value clarification exercise, and (7) improved graphics and format of summary page to increase the visual impact and clarity. A link to the LCSDecTool is found in Multimedia Appendix 2. The dialog, knowledge box, pictograph, and value elicitation features are illustrated in Figures 1-4.

Figure 1. Illustration of the dialog feature in the lung cancer screening decision tool (LCSDecTool).

Figure 2. Illustration of the pictograph feature in the lung cancer screening decision tool (LCSDecTool). CT: computed tomography.

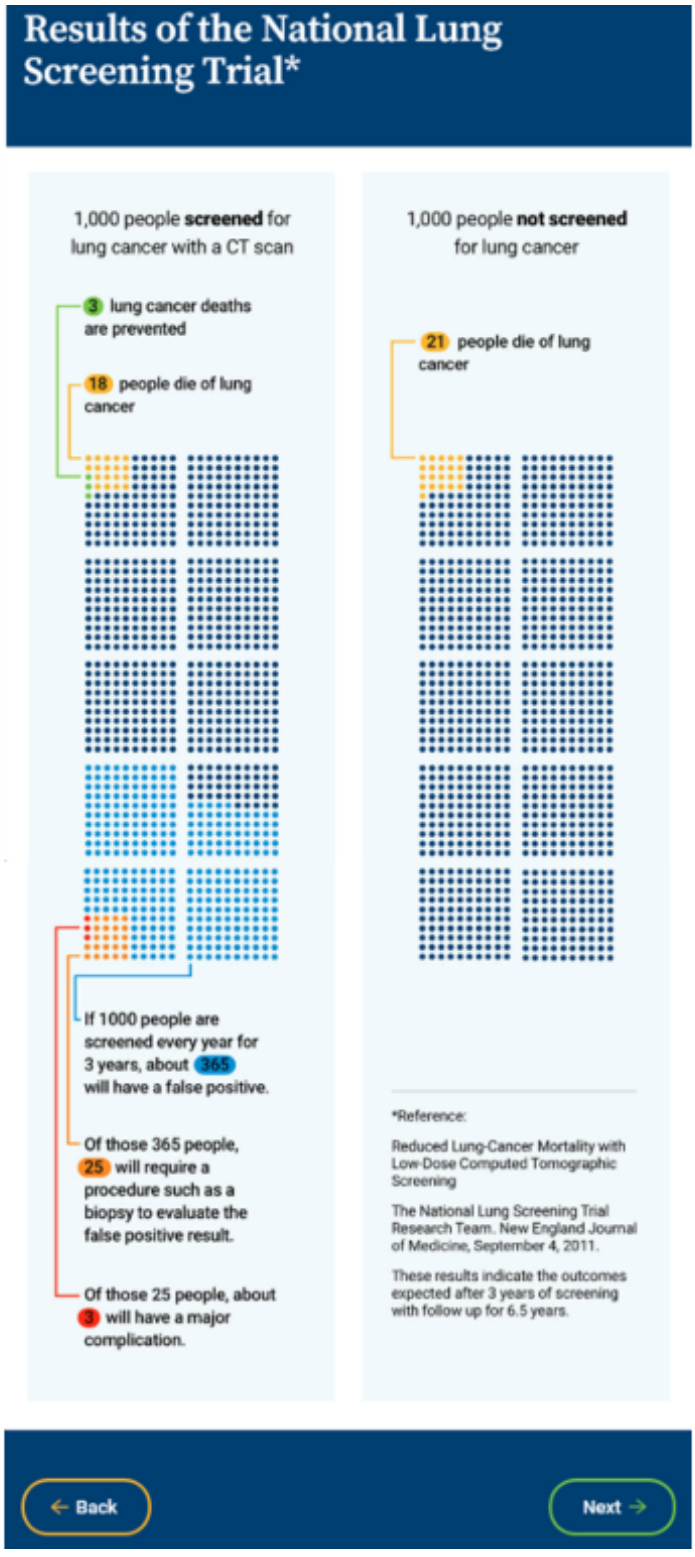

Figure 3. Illustration of the knowledge box feature in the lung cancer screening decision tool (LCSDecTool).

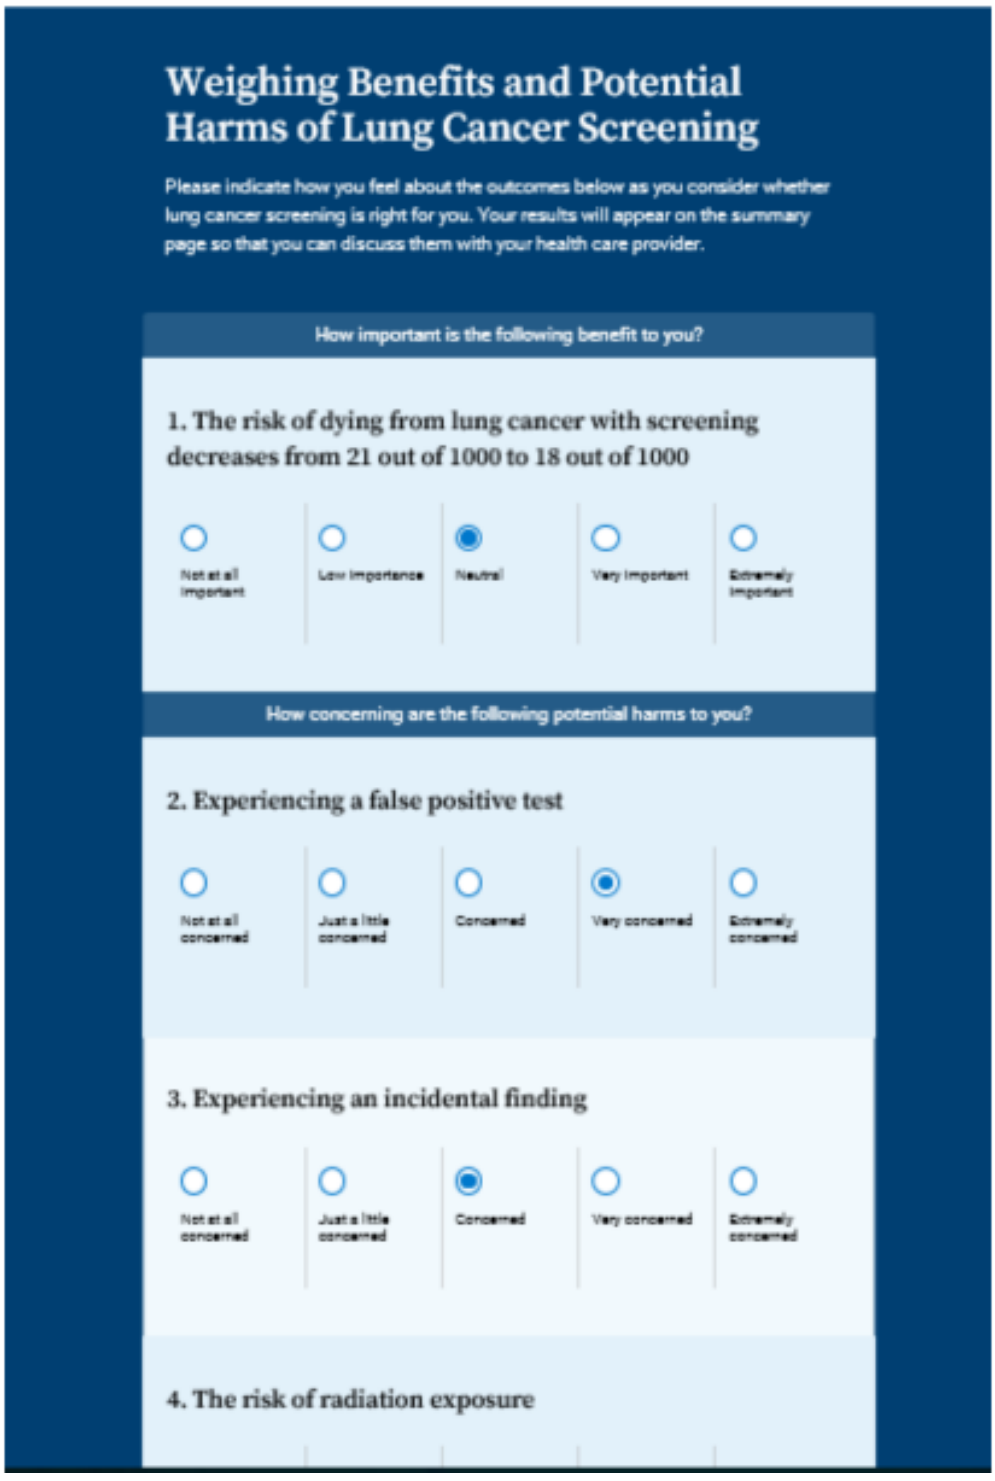
Figure 4. Illustration of the value elicitation feature of the lung cancer screening decision tool (LCSDecTool).



Phase 2 High-Fidelity Testing

Phase 2 Study Participants

At the Philadelphia VA Medical Center, 465 recruitment letters were sent. Of these 465 persons, 376 (80.9%) were reached by phone, and 281 (60.4%) were confirmed to be eligible for the study. Of the 281 eligible persons, 80 (28.5%) were enrolled in the study, with 42 (53%) in the experimental arm and participating in the usability analysis. At the West Haven VA Medical Center, 136 letters were sent. Of these 136 individuals, 96 (70.6%) were reached by phone and found to be eligible for the study. Of the 96 eligible persons, 5 (5%) were enrolled in the study, with 1 (20%) in the experimental arm and participating in the usability analysis. Of the 43 participants, 27 (63%) were African American or Black, 39 (91%) were male, and 41 (95%) had up to a high school–level education. Additional demographic details are presented in Table 2.

Phase 2 High-Fidelity Quantitative Results

In the phase 2 high-fidelity usability testing, the mean SUS score was 65.76 (SD 15.23), corresponding to a good level of usability. The mean of the EUCS score (potential range 1-5) was 3.91 (SD 0.95). The mean PE score (potential range 1-5) was 4.12 (SD 0.67; Table 3). The median time to completion in minutes was 13 (IQR 7-30; Table 4).

Phase 2 High-Fidelity Qualitative Results

A total of five themes related to usability emerged from the qualitative analysis of the field note–documented observations and responses to the short interview. These themes were as follows: (1) a low baseline level of awareness and knowledge about LCS increased after using the LCSDecTool; (2) users sought more detailed descriptions about the LCS process; (3) the LCSDecTool was generally easy to use, but specific navigation challenges remained; (4) some noted difficulty understanding medical terms used in the LCSDecTool; and (5) the LCSDecTool evoked veteran struggles with prior attempts at smoking cessation (Textbox 1).

Textbox 1. Qualitative feedback from phase 2: high-fidelity usability testing.

Qualitative feedback from phase 2

Thematic analysis

- Theme 1: low baseline awareness and knowledge about lung cancer screening (LCS) that increased after use of the LCS decision support tool (LCSDecTool)
- Theme 2: users sought more detailed descriptions about the LCS process
- Theme 3: the LCSDecTool was generally easy to use; however, specific navigation challenges remained
- Theme 4: some noted difficulty understanding medical terms used in the LCSDecTool
- Theme 5: the LCSDecTool evoked veteran struggles with prior efforts at smoking cessation

Navigation challenges

- Scrolling for physician–patient dialog (n=15)
- Advancing through knowledge boxes (n=10)

Negative affective responses of using the tool

- Worry about cancer risk
- Reading about the harms are scary
- Difficulty of smoking cessation

Genuineness of tool

- Dialog seemed scripted (n=1)

Ease of understanding

- Needed help to understand pictograph (n=1)

Veteran-specific features

- Resources for smoking cessation: some veterans were already familiar with the resources
- Mental health consultation: comment that a mention of anxiety related to LCS would discourage veterans from ever having LCS (n=1)

Theme 1 indicates a need for more information about LCS among this population. A participant stated that they “learned a lot and didn’t know much about LCS and lung cancer before using the tool.” Another stated that they “didn’t know that the VA even had a screening test.” This feedback supports our finding of high PE scores in the quantitative testing. Theme 2 reflects the desire for more information about the LCS process, with one of the participants asking, “What actually is a CT scan?” and another questioning, “if it is painful?” This theme indicates what information could be added to the tool to increase the content domain of the EUCS measure. Theme 3 indicates that the tool was generally easy to use; however, navigation was challenging for some of the features. For example, a participant described the tool as “helpful, with a lot of information, easy to use.” However, specific navigation problems were identified. A participant indicated that they “did not know how to scroll through the Dialogue,” and an RA observed and commented that another user was “stuck on Box page until I told him he had to click on the boxes.” Some participants had difficulty using the radio buttons on the value elicitation feature. Theme 4 indicates that some users struggled to understand the medical terminology. A participant stated that “some wording can get you twisted up” and provided feedback to “keep it simple and use plain language.” For example, the meaning of the words “nodule,” “CT Scan,” and

"Overdiagnosis" were not understood by some users. This theme is relevant for interpreting the SUS scores in the format domain.

Theme 5 indicates that the tool evokes veterans' struggles with prior attempts at smoking cessation. One of the specific veteran-centric features included in the tool highlighted the importance of smoking cessation and mental health. Users could click a radio button to request to speak with a primary care provider about smoking cessation or a mental health provider about either smoking cessation or LCS. Some users stated that they were already familiar with these resources or had successfully quit smoking. Others commented on the difficulty of smoking cessation, recalling multiple efforts to do so. A participant commented that he quit smoking for 1 year but recently restarted, stating, "don't ask me why I started again, I don't have a reason, I just did it," and another commented, "I have tried the smoking cessation classes here at the VA but they don't work." Other users clicked the boxes conveying an interest in speaking about these topics to a provider.

Discussion

Principal Findings

The LCSDecTool was designed to create an engaging experience, inform veterans about LCS, support a value-aligned decision, and facilitate communication with their provider about LCS. We found that usability among veterans was good when administered in the context of a primary care clinical visit. These results provide evidence that an older group of US veterans can navigate tablet-based DAs. Our study was noteworthy for engaging veterans in the design of a decision support intervention in a meaningful way. In creating a veteran-centric tool, we involved veterans at every step of development and incorporated their feedback in an iterative process of tool development. Veterans were able to help determine the components of the SDM process and provide reactions and comments that could help other veterans. The motivation to provide feedback to help other veterans reflects a military culture of caring for and deriving satisfaction from helping other veterans [45].

Given that veterans in this age group may not have been familiar with technology, usability testing was particularly important to ensure that they could interact with and understand the information in the tool. Our usability findings were strengthened by conducting the assessment in the setting of a primary care visit where the LCSDecTool was designed to be used. Through this evaluation, we identified areas of strength and areas that require further refinement and modification.

The qualitative feedback obtained from our findings revealed 5 underlying themes. Two of these themes (low baseline awareness and knowledge about LCS that increased after use of the tool and the desire for more detailed descriptions of the LCS process) indicate that usability testing increased awareness of LCS. This is a key step in the process of adopting this evidence-based and provides preliminary evidence that the tool will increase awareness of LCS. Two additional themes (the tool was generally easier to use, but navigation challenges remain and difficulties in understanding some medical terminology remained) indicate the importance of veteran feedback in creating a tool that veterans are able to understand and use. These themes will guide further refinements of the tool. A final theme indicates that the tool may enhance discussions with providers about smoking cessation and mental health. This theme reinforces that veterans perceive a relationship between mental health, smoking cessation, and LCS and further supports the decision to address this relationship in the LCSDecTool.

Our study sample was a particularly vulnerable population in terms of sociodemographic factors (low level of education and income) and health status. Among those in the phase 2 high-fidelity cohort, 47% (20 out of 43) reported a diagnosis of PTSD. Rates of PTSD are known to be higher in veterans than in the general US population. Furthermore, among veterans, the rates of PTSD are higher in those receiving VA care than those who do not [46]. Veterans who receive care in the VA are also known to have lower education and income than veterans receiving care outside of the VA. Given these differences in socioeconomic status and health status, usability testing among a sample of veterans receiving VA medical care focuses our study on a more vulnerable population of veterans.

We observed a decrease in the usability measures from the prototype testing cohort to the high-fidelity testing cohort. There are several potential reasons for these differences. First, in the prototype cohort assessment, quantitative usability measures were collected immediately after completing the tool. In contrast, in the high-fidelity cohort, the user experience and quantitative usability assessment were separated by a clinic visit. The goal of this study was to assess the usefulness of the tool when used in the clinic setting. However, the intervening clinic visit may have decreased the salience of user experience. Of note, the purpose of the primary care visit was not limited to the topic of LCS, although addressing age and risk factors for appropriate cancer screening is an expected component of a primary care visit. Second, the study directed RAs to be more engaged with participants in the earlier prototype testing than in the high-fidelity testing. For example, in the prototype testing, the RAs discussed the participants' experience with each section of the tool before progressing to the next section. The increased level of RA engagement during the prototype user session may have positively affected user experience.

According to the TAM, users need to perceive the technology as useful and easy to use to continue using it. Our qualitative data provide additional insights on participant perceptions of the tool regarding usability and usefulness. The design of our value assessment measures was based on qualitative studies conducted with veterans regarding how they perceived and valued the potential benefits and harms of LCS [30]. In usability testing, the value assessments were completed without difficulty, with some participants commenting that they enjoyed responding to these scales and found them helpful. Our PE survey indicates that users of the LCSDecTool felt engaged in the decision-making process, a primary goal of any SDM intervention, as in the development of other eHealth applications [35,36]. Our results suggest that users perceived that the tool supported them in caring for their health, addressed their concerns, and informed them about LCS.

Comparison With Other Work

In our study, we observed that 100% of the participants completed the use of the LCSDecTool. Completing the tool included moving through all sections, responding to the value assessment questions, and submitting the summary page. In a recent Cochrane review, which was a subgroup analysis of 105 studies involving >31,000 participants, the median effect of a DA on the length of a medical consultation was to lengthen the consultation by 2.6 minutes in comparison with usual care [24]. Although the length of the LCSDecTool did not emerge as a concern among users in our qualitative feedback, the time required to complete the tool could have contributed to lower scores on the SUS and EUCS scales. Our qualitative data suggest that improving navigation and allowing users to choose which sections to review would decrease the time to completion of the LCSDecTool without compromising usability and effectiveness.

Prior studies on cancer screening DAs provide a comparison of the usability scores for the LCSDecTool. Carter-Harris et al [8] developed an LCS DA that included audio and video features and scripts tailored to the user's smoking status. The tool, named *Lung Talk*, reported mean SUS scores of 75.7 (SD 7.9), indicating a good level of usability [8]. Coe et al [47] developed a breast cancer screening DA for use among multi-ethnic women. This tool, named *Real Risks*, reported mean SUS scores of 80.0 (range 50.0-95.0) and 66.3 (range 55.0-75.0) for the English and Spanish versions, respectively [47]. Our study design is unique in reporting usability scores prospectively as the tool moved from the evaluation of a prototype to the evaluation of a high-fidelity version within a clinical setting. In our study, the SUS scores decreased when the tool was integrated into the clinical setting but remained at an acceptable level of usability.

Our LCSDecTool differs from existing LCS DAs in several respects. It was developed using the principles of user-centered design to increase engagement with the tool among a veteran population. This includes the look and feel of the tool, such as using the Department of Veterans Affairs branding, content that acknowledges the mental health conditions that may affect LCS, and smoking cessation referrals specific for veterans receiving care in VA medical centers.

Limitations

Our study has some limitations. First, data for the phase 2 high-fidelity version were obtained in the context of a pilot hybrid type 1 effectiveness-implementation trial. In this research setting, participants were able to ask an RA for help with the tool if needed. This may not be feasible in routine care outside the context of a research study. Second, the LCSDecTool was tested on a limited number of veterans and clinical sites. Our population reports high rates of mental health conditions and other comorbidities and has particularly low levels of education and income. The findings may not be generalizable to a broader population of veterans or the general US population. Despite these limitations, the strengths of our study include the evaluation of the usability of the LCSDecTool among veterans who are diverse in race, meet eligibility criteria for LCS, and are receiving care in a VA primary care setting.

Conclusions

In conclusion, our study found that a web-based LCS decision support tool developed for and tested among US veterans receiving care in a VA medical center demonstrates an acceptable level of usability. We designed the LCSDecTool for use before and during a clinical visit, incorporating content, formats, and functions that can be used across these settings. The decision regarding LCS requires patients and their providers to consider scientific evidence of benefits and harms, as well as patient values, priorities, and beliefs. Given these complexities, it is important to conduct usability testing of this patient-centered LCSDecTool in its target population. Our findings support the use of this eHealth technology in the primary care clinical setting as a way of engaging veterans, informing them about a new cancer control screening test, and preparing them to participate in an SDM discussion with their provider. Our study further indicates that involving veterans in all phases of the development of the tool extends veteran involvement to the design of SDM processes. Future work is needed to fully address the information and decision support tools that will help veterans understand and apply the principles of SDM for LCS in the context of a comprehensive health care program.

Abstract

Background: Human papillomavirus (HPV) can cause several types of cancers and genital warts. A vaccine is available to prevent HPV infections, and several efforts have been made to increase HPV education and, eventually, vaccination. Although previous studies have focused on the development of messages to educate children about HPV and the existence of the HPV vaccine, limited research is available on how to help children better communicate with their parents and health care professionals about the HPV vaccination. In addition, limited research is available on the target audience of this study (Italian children).

Objective: This manuscript describes a study assessing the feasibility of using an evidence-based animated video and a web-based game to help children (aged 11-12 years) participate in discussions about their health—in particular when such conversations center around the HPV vaccination—and improve several HPV-related outcomes. The study also compares the effects of these 2 educational multimedia materials on children's knowledge and perceptions of HPV prevention.

Methods: A mixed methods approach consisting of focus group discussions and an experiment with children (N=35) was used to understand children's experiences with, and perceptions of, the animated video and the game and to measure possible improvements resulting from their interaction with these materials.

Results: Both the animated video and a web-based game increased children's knowledge and positive perceptions about HPV and HPV vaccination. Any single message was not more effective than the others. The children discussed aspects of the features and characters they liked and those that need improvements.

Conclusions: This study shows that both materials were effective for improving children's education about the HPV vaccine and for helping them to feel more comfortable and willing to communicate with their parents and health care professionals about their health. Several elements emerged that will allow further improvements in the design and development of the messages used in this study as well as the creation of future campaigns.

Introduction

Background

Engaging children and preteens in conversations about their health is important for their well-being and future health behaviors [1,2]. However, children and preteens are often not included in such conversations, even when they express a specific interest in being involved, because both parents and health care professionals consider such conversations particularly challenging [3]. Furthermore, research aimed at understanding and improving children's engagement in health discussions is limited [4-6]. As a consequence, children's

information needs are often unmet, despite evidence showing that children can actively participate in health discussions and decision-making processes [4], as well as benefit from being included in them [1,2,6]. Some health-related conversations are perceived as more challenging by both parents and their children; for example, conversations about sexual health or cancer [7,8]. A conversation concerning HPV vaccinations is one such because it shares barriers faced by both sexual health–and cancer-related discussions. Human papillomavirus (HPV) can negatively affect the human body by causing several types of cancers and genital warts [9]. Today, HPV is known to be the most frequently diagnosed sexually transmitted disease [10]; yet, vaccination hesitancy remains a problem. To limit the risk of contracting an HPV infection, children should receive the HPV vaccine at age 11-12 years [11,12].

Given children's need to receive health information and the communication challenges they may face, recently researchers developed and assessed several educational strategies targeting in particular preteens and adolescents in the United States [13-15]. In addition to improving attitudes and knowledge, these educational materials seem to support an increased rate of HPV vaccinations over methods that target parents only [14,16]. These promising results and the barriers that children and preteens face to communicate about their health indicate the importance of developing evidence-based interventions and message strategies to educate children about specific health topics such as HPV and support them in discussing these health topics with their parents and health care professionals [17]. These interventions need to take into consideration the cultural background of the children and the perceived social norms because these can influence the way children and adolescents talk about health with their family and the way they conceptualize health [18,19].

Interventions using communication technologies have shown the potential to improve HPV vaccination behaviors [20]. These interventions can allow for customization of information to individuals' needs [20] and culture [21]. However, only limited research exists on how communication technology can support children's learning about health [14,22,23]. Even less research is available on the role that communication technology–based interventions can have in empowering children and preteens to discuss their health or the HPV vaccine [7].

Communication Technologies for HPV Education and Vaccination

Research and interventions about HPV vaccinations have adopted several communication technologies such as videos, Facebook pages, SMS text messages, and emails [20], as well as mobile apps [24,25]. However, when communicating with children, preteens, or adolescents specifically, researchers have tested mainly videos and SMS text messages focused on HPV [14,20], despite the fact that several other strategies have been shown to be promising for educating children about health [23,26,27]. For example, serious games and educational animations can encourage adolescents' engagement in health decision-making [26,28-33]. Thompson et al [28] developed and assessed a serious videogame about the HPV vaccine for adolescents. The game increased adolescents' likelihood of receiving the vaccine and aided the participants in personal health decision-making. Similarly structured videogames have also been used for other health-related behavior changes in terms of, for example, diet and exercise [13,29,33]. In addition, there is evidence that supports the use of educational animations to communicate about several health-related topics [30,32,34].

A systematic review of adolescent-targeted HPV educational animations found that the animations significantly increased motivation toward receiving the HPV vaccination [30]. However, the analysis also showed that the interventions were not effective with regard to attitudes or behavior in the long term [30]. These findings indicate that more research needs to be conducted to determine how to design such messages and the effects these messages may have on individuals' outcomes and health conversations [30,32]. In addition, more research is necessary to understand the effects these interventions can have on diverse audiences [20].

Rationale for This Study

This study describes the development and assessment of two theory-based multimedia messages (an animated video and a game) to communicate with children about HPV and the HPV vaccine. The format and content of these messages were created based on the insights of children collected through previous formative research [35,36]. The study's aims are as follows:

1. Understand children's acceptability of the messages.
2. Measure the effects of the messages on children's HPV-related outcomes.
3. Verify whether children's confidence and willingness to communicate with their parents and health care professionals about the HPV vaccine increased after message exposure.

This study was conducted in Italy. In this country, HPV vaccination rates for middle school children are worryingly dropping. The most recent data indicate that the HPV vaccine coverage rates for females in 2015 were 66.64% and 56.26% for the first and second dose, respectively, but in 2018, the rates dropped to 61.68% and 40.36%, respectively. For males, the situation is even more severe. In 2018, the vaccination rate was very low: 44.05% for the first dose and 20.82% for the second one. Official data from 2015 are not available for males [37].

Methods

A multidisciplinary team composed of experts in health communication, social science, and interaction design used (1) a human-centered–design approach to develop the game and the animated video and (2) a mixed methods design consisting of focus group discussions and an experiment with Italian middle school children to evaluate the effects of 2 multimedia messages (animated video and game).

Ethics Approval

Ethics approval was received by the University of Kentucky IRB (institutional review board application number 54851).

Participants and Recruitment

Once ethics approval was received, Italian middle school children from a large public school in north Italy were invited to join the study. Teachers distributed a leaflet and the informed consent documents to all the parents of children (aged 11-12 years) enrolled in the second year of middle school. Children whose parents signed the informed consent document were considered to have given child assent. In total, 35 middle school students participated in the project. Most of the participants were female (20/35, 57%). All the students recruited were attending the second year of middle school at the time of the study. This sampling decision was made because in Italy the HPV vaccine is provided for free to all children in their 12th year of life (aged approximately 11-12 years).

Procedures

Overview

Focus groups were conducted in January 2020. All focus groups were conducted in Italian by the same moderator (AO) for purposes of consistency. Considering the number of children recruited, 9 focus groups were scheduled and randomly assigned to either the animated video or game conditions. Children recruited for this study were then randomly assigned to 1 of the 9 focus groups. After an initial ice-breaking exercise, the children were asked to complete a preintervention questionnaire. Next, they watched the animated video (20/35, 57%) or played the game (15/35, 43%). After watching the animated video or playing the game, the children were asked to complete a postintervention questionnaire. The measures used in the preintervention and postintervention questionnaires were the same. This choice allowed us to evaluate differences in responses due to being exposed to either of the 2 messages. Once all the children completed the postintervention questionnaire, the focus group discussion on the animated video or game began. The children were asked a few questions about the message they interacted with. The questions concerned (1) the purpose of the animated video and game, (2) what they thought children would like about the animated video and game, (3) what they thought children would not like about the animated video and game, (4) their opinions of the characters in the animated video and game, and (5) how (and if) they would use the animated video and game to talk with other people about health and the HPV vaccine. After this discussion, the children were invited to interact with the experimental message that they had not been randomized to (either the animated video or the game). They were then invited to discuss the same questions for the second message as well. The procedures used to analyze the focus group discussions and the experimental data are described in the following sections.

Questionnaire Measures

Knowledge

Knowledge of HPV was measured with an 8-item scale adapted from Forster et al [38]. Examples of the items included *Males cannot get HPV* (False) or *HPV can cause cancer* (True). Participants could answer on a scale ranging from 1 (strongly disagree) to 5 (strongly agree).

Attitudes

Attitudes were measured using a 5-point semantic differential scale with 3 pairs of opposite adjectives regarding vaccinating against HPV: bad and good, harmful and healthy, and cannot protect me from some cancers and can protect me from getting cancers. The scale showed good reliability (Cronbach α=.76).

Intention to Talk

Intention to participate in the conversations about the HPV vaccine was measured by 1 item: *I feel I will be invested in deciding whether to have the HPV vaccine.* The children could answer this item on a scale ranging from 1 (strongly disagree) to 5 (strongly agree).

Self-efficacy

Self-efficacy was measured using a 5-item scale from Forster et al [38]. Examples of the items included *I feel comfortable talking to my parents about whether to have the HPV vaccine* and *I feel comfortable asking my physician any questions I may have before receiving my HPV vaccination*. The scale showed medium reliability (Cronbach α=.50).

Subjective Norms

Subjective norms were measured using the 4-item scale from Forster et al [38], with each item measured on a scale ranging from 1 (strongly disagree) to 5 (strongly agree). Examples of the items included *My parents think that getting the HPV vaccine is important* and *My friends think that getting the HPV vaccine is important.* The scale showed good reliability (Cronbach α=.70).

Fear

Fear was measured using the 6-item scale from Forster et al [38]. Examples of the items included *I expect that the HPV vaccination will be very painful* and *I am worried about the side effects of the HPV vaccine.* The scale showed medium reliability (Cronbach α=.56).

Enjoyment

Enjoyment was measured with 2 items: *I had fun watching the animation* or *I had fun playing the quiz game* and *I found the animation pleasant to watch* or *I found the quiz game pleasant to play*. The children could answer each item on a scale from 1 (strongly disagree) to 5 (strongly agree). This measure was used in the postintervention questionnaire only.

Involvement With the Message

This construct was measured with 2 items that the children could rate on a scale from 1 to 5: *The animation I watched was important to me* or *The quiz game I played was important to me* and *The animation I watched was interesting to me* or *The quiz game I played was interesting to me*. This measure was used in the postintervention questionnaire only.

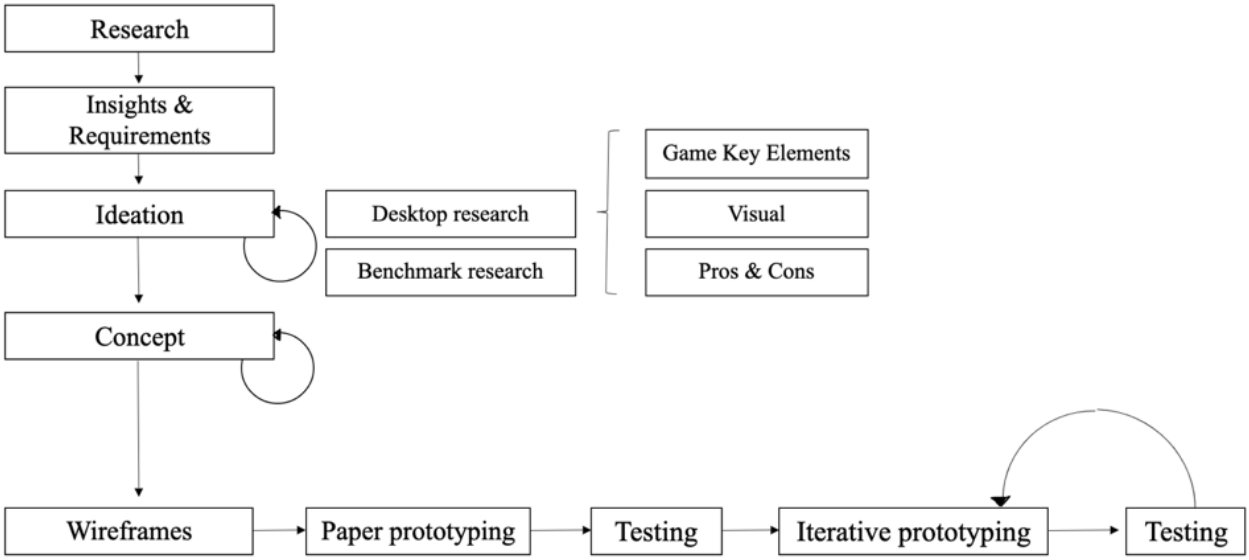
Development of the Game and the Animated Video

Overview

The content and format of the messages were informed by previous formative research that (1) explored Italian children's understanding of, and concerns about, HPV and the HPV vaccine; and (2) investigated channels, sources, strategies, and

characters that may be acceptable and useful to learn and talk about HPV and the HPV vaccine with their parents and health care professionals [35,36]. This formative research indicated that a promising approach to work with Italian children would be to develop multimedia materials that children could access both at school and at home. Such materials needed to focus on a few key questions the children had about HPV and the HPV vaccine to help them find an answer to key questions they identified as important [35,36]. The findings from the formative research and key constructs from the theory of planned behavior (TPB) [39], social cognitive theory (SCT) [40], and the gamification approach [41] were used to create the text and characters of the animated video and to design the logic of the game. The development of the game logic followed a human-centered–design approach, indicated in Figure 1.

Figure 1. The human-centered–design approach followed in this project.



The TPB [39] identifies intentions to perform a behavior as the main predictor of the behavior. To positively influence intentions, it is necessary to work on individuals' attitudes toward the behavior, their perceived social norms, and perceived control over the behavior [39]. The SCT argues that we learn to perform a behavior by observing other people doing it and by looking at the outcomes of such behavior [40]. The gamification approach identifies several affordances that support and promote the value that an individual will assign to a game [41].

The TPB helped us to identify the key constructs to include in our game and animated video to help children engage in conversations about the HPV vaccine. We considered the insights from the SCT in designing the scenes of the animated video and game. Specifically, we showed children in the act of discussing the HPV vaccine with a health care professional, showing the positive outcomes of such a discussion and the strategies to address the challenges of engaging in such conversations.

Animated Video

The animated video *Salute e HPV* (Health and HPV) aims to guide 2 middle school children (characters in the animated video) to discover the guidelines to be healthy. The video introduces the HPV vaccine to the children as a standard activity (such as practicing physical activity or eating a healthy diet) that they should pursue at their age to remain healthy. The video shows several scenarios in which the children practice physical activity, eat a healthy diet, and brush their teeth, along with their parents. The video also mentions the importance of sleeping at least 8 hours per night. At the end of these scenarios, the narrator (a health care professional) highlights that children also need to take the HPV vaccine to remain healthy. The choice of including this activity among several that children in Italy are typically comfortable with was made to reduce the fear and stigma associated with the HPV vaccine [37] and to stress the importance of getting vaccinated during the middle school years, as per the recommendation of the Italian ministry of health [35]. At this point in the video, the health care professional appears on screen and starts answering questions from the children about the HPV vaccine. First, the health care professional describes HPV and the diseases that it can cause. Second, the health care professional focuses on the safety of the vaccine, showing scientists in a laboratory studying and evaluating the vaccine. Third, the health care professional describes how the procedure for getting vaccinated works. The health care professional is shown talking with the 2 children, one of whom raises some concerns and explains that they are scared. The health care professional reassures them, telling them that it is common to "be scared" and to "talk about" these feelings. The health care professional also identifies some strategies the children can follow to reduce their fears. After this interaction, the children feel encouraged and receive the vaccine. Fourth, the health care professional explains that the vaccine is available for free and recommends that the children talk with their parents and physician to obtain more information. The health care professional and the children together indicate some sources that children and their parents can use to obtain more information. The video is available on YouTube [42]. Figure 2 shows a screenshot from the animated video.

Figure 2. Screenshot from the animated video.

Game

The game *Salute e HPV* (Health and HPV) was designed following the human-centered–design approach indicated in Figure 1. This approach, successfully adopted in several health-related interventions [43], helps to design interfaces and web-based platforms able to meet the needs of the audience (in this study, Italian middle school children). The approach includes several iterative phases. In the ideation phase, several insights on children's needs and preferences were gained. We collected these insights through a series of focus groups conducted in the year before the development of the game [36,37]. After developing a greater understanding of children's perspectives, concepts were identified by the designers in collaboration with the researchers who conducted the preliminary focus groups. The proposed solutions were then developed and improved through the refinement and testing of several prototypes [43,44]. The research team tested the prototypes multiple times before using the final prototype adopted in this study.

The game is a web-based quiz available on the web that can be played by children alone at home or in a group if at school. In this study, children played in groups of 2 because of the limited number of computers available. The game gives children the opportunity to choose a character to play with (the options are a boy or a girl, the same used in the animated video). The characters' names were Francesco and Giulia, the most common names given to newborns the year the children in this study were born. This choice was made to help the children better identify with the characters. For the health care professional, the same character as in the animated video was used. The role of the health care professional was to provide children with correct information. Children could not choose to play with the health care professional character.

The content of the game was consistent with the content of the video. The game included the same key questions and information as in the animated video. For each of the 5 questions, the children were shown 4 pairs of statements related to the question. Each pair included 1 correct and 1 incorrect statement for the children to choose from. Once the children read the objective of the game and instructions for playing it, they could start the game. The game was designed to include several motivational affordances (Textbox 1).

These motivational affordances were selected because they can influence gamers in several ways. In particular, *points and achievements* and *feedback* were included in the design of the game to support children's autonomy and competence [45]. A *clear goal* and the *progress bar* were included to provide children with a means to measure their performance [46]. Ultimately, previous research indicates that these motivational affordances can influence the enjoyment of, and engagement with, the game experienced by gamers [46]. Figure 3 shows a screenshot of the game.

Textbox 1. Motivational affordances included in the game.

Points and achievements

• Numbers and medals were used to reward children for successfully progressing in the game

Progress bar

• Stars were used to show children at which point of the game they had reached

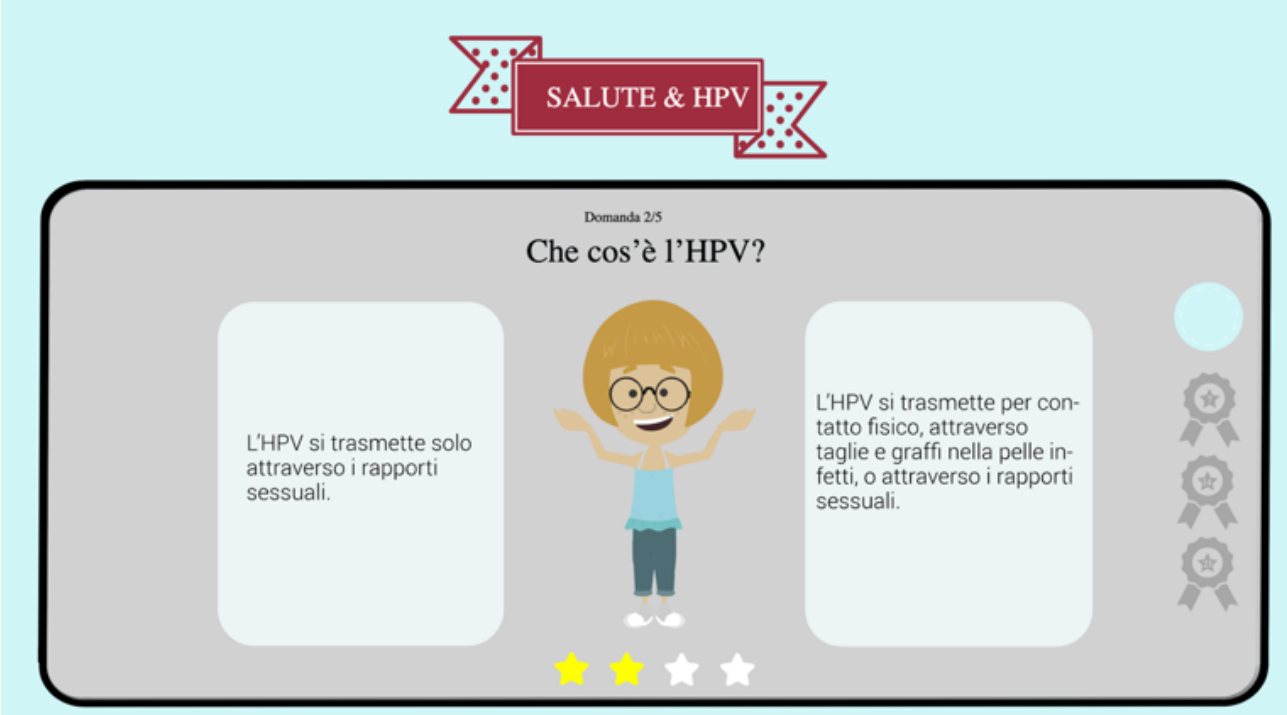
Clear goal

• The goal of the game was described at the beginning of the game, along with the instructions for playing the game

Feedback

• Children received feedback through the use of colors (green for correct answers and red for incorrect ones) and the physicians' statement, provided at the end of each level (after each of the board's 5 questions)

Figure 3. Screenshot from the web-based game. HPV: human papillomavirus.



Data Analysis

Focus Group Discussions

The focus group discussions were audio recorded and transcribed verbatim in their original language. The real names of the children were deleted and substituted to protect their identity. The transcripts were uploaded in NVivo (version 12), a qualitative data analysis software (QSR International). The analysis of the discussions proceeded through several steps. First, the researcher (AO) familiarized herself with the transcripts. This process included reading the transcripts several times and considering the notes taken for each of the focus groups. Second, the transcripts were coded line by line [47], following a constant comparative method [48]. Third, recurring themes were identified and further refined. Fourth, the transcripts were recoded to include the changes made for each specific category. Finally, data were compiled in brief summaries. The brief summaries are reported in the *Results* section.

Experiment

A series of analyses of covariance were run to verify whether the animated video and the game were effective in improving the children's attitudes, knowledge, subjective norms, self-efficacy, intentions, and emotions regarding the HPV vaccine. Preintervention scores were inserted as covariates. Analyses of variance were run to measure the children's enjoyment and involvement with the animated video and the game.

Results

Focus Group Discussions

Overview

Several themes emerged from the focus groups. First, the children discussed the knowledge they acquired or retained from watching the animated video or playing the game. Second, the children explained what they liked and what should be improved upon in the animated video and the game. Third, the children reflected on the characters in the animated video and the game.

Finally, the children commented on how they would use the information from the animated video and the game in their lives.

Knowledge Acquired

After watching the animated video or playing the game, the children tried to summarize the information they remembered the most. In particular, they mentioned the association between the virus and some types of cancers, as well as the fact that the vaccine is an effective strategy to prevent cancer:

> *I'd heard about this vaccine, but I didn't really know much. I knew it was transmitted through sexual intercourse and that's all, but I didn't know it could cause cancer.* [Mia]

Next, the children remembered that the vaccine is available in many countries around the world, and that in Italy, it is given for free to every child aged 12 years. According to the children, this was a very important insight that could also help parents:

> *This vaccination in Italy is also free of charge, so parents may be less worried about possible costs.* [Luke]

Features Children Liked

The children indicated several features of the video and the game that they liked. For both the animated video and the game, they mentioned the colors, which they described as "bright" and "attractive":

> *The designs are very clear but are not exaggerated, they are stylized, beautifully colored.* [Marzia]

The children also commented on the strategies used to present the information. In particular, for the animated video, the children appreciated the use of the *whiteboard* to illustrate the concepts presented by the health care professional. They specifically liked the fact that both the health care professional and the images of what she was describing were shown at the same time, and this aided their comprehension:

> *It's nice that there's the tarp [whiteboard] with the projector.* [Lia]
>
> *It's very detailed.* [Peter]
>
> *You see the images at the same time as the doctor explaining, there's not just the voice.* [Lia]

Regarding the game, they appreciated the summary of the information provided at the end of each question. They felt that they could still learn from the game even if they did not know much about HPV or the HPV vaccine before playing it:

> *It's pretty clearly explained. It's nice that every time it asks you a question, you get the summary afterward. Even if you haven't seen the video, maybe you can get most of the answers wrong, but then with the summary, you understand.* [Thomas]

In the end, when asked which of the 2 materials they preferred, the children said that they liked the animated video and the game equally. They said that children should use both these educational materials because, although they included the same information, they felt that the 2 materials complemented each other:

> *They are two things that talk about the same subject, but they are different because in the game you had to think about what you understood, whereas the video serves to confirm your hypothesis.* [Azzurra]

Features That Need Improvement

The children recommended that a few elements could be improved in both the game and the animated video. In particular, the children felt that there was some missing information:

> *The length [of the video] is right, but maybe you could add a part explaining what the consequences are if you don't get this vaccine.* [Tia]

More specifically, the children indicated that they wished they had been able to learn more about the possible side effects of the vaccine as well as the symptoms of an HPV infection, besides the risk of getting cancer:

> *Always add, as in the video, always add what can happen if you don't get the vaccine.* [Marzia]
>
> *And what are the side effects.* [Tia]
>
> *Also because we could convince more people that this infection isn't a small thing, so it's much better to prevent it with the vaccine.* [Marzia]

Characters

Overall, the children liked the characters in both the animated video and the game for several reasons. The most liked character was the health care professional, appreciated for both her caring attitude and for the type of information she provided:

> *I [liked] the doctor because even [though] the children are afraid of the needle, she advises them to close their eyes, she's thoughtful.* [Lia]
>
> *She also gives them advice on how to feel less pain, have less anxiety.* [Peter]

The children also liked the 2 young characters, both their design as well as their personality. Regarding the overall design, some children also mentioned the presence of diversity as a positive characteristic that they valued and helped them to better identify with the characters:

> *I liked that the children were of different ethnicities.* [Tobias]
>
> *She [the doctor] looks like me!* [Mara]

Regarding the personalities of the characters, one of the moments the children appreciated the characters the most in the animated video was when the children visit the physician's office to receive the vaccine, and 2 different emotional reactions were displayed:

> *Then the characters are nice, they make the idea. The boy was worried about the vaccination while the girl wasn't, it indicates that there are different kinds of people.* [Luke]

A negative comment about the characters concerned the size of the children. For some of the children, this contributed to making the characters look as though they were younger than the children:

Maybe looking at them like that, the characters being too short may look like children. They don't look like children my age to me. [Philip]

Use of the Animated Video and Game

The children mentioned that one of the most interesting elements they liked about the video and the game was that they could use these tools to learn more about HPV and the HPV vaccine:

This game is instructive. It can be the litmus test [literally prova del nove (test of 9) in Italian] to see if you understand. [Duccio]

It's like some kind of test, and it makes you realize what you've figured out but it doesn't make you feel anxious at least. [Agata]

The children expressed the desire to talk more about these topics with adults as well as with their friends. This concept emerged consistently in each of the focus groups, either explicitly or in the form of the questions asked by the children. For example, the children asked whether they could show the video to their parents or have a say in the decision to receive the HPV vaccine:

But is it something that parents choose, or can I choose too [to get the vaccine]? [Elia]

What do you think? [Moderator]

I'd like to make the decision too, because it's about me, and if I want to do it, I can do it. [Elia]

The children consistently mentioned that the video could be a means to facilitate the discussion with the parents. It could be something that parents could use to talk to their children about HPV:

It could be good for the parents, too. You say there's this disease, it can also cause tumors, my daughter has to be cured, I have to give her vaccinations. So, it might help the conversation a little bit. [Azzurra]

The children also wished that the video and the game were available on the web on several social media platforms so that both they and their parents could access them easily:

Can we find it online? To show it to our parents? [Sarah]

I would go to see the video on YouTube, as a platform that would be great, but also Instagram and Facebook, where there are many adults who could make the decision to have their children vaccinated. [Maria]

Experiment

Several analyses of covariance were run to understand the effects of the messages assessed in this study. The dependent variables used were, in turn, postintervention knowledge, attitude, intention, self-efficacy, subjective norms, and fear scores. The independent variable was the modality used (animated video vs game). Participants' preintervention scores were used as covariates. Both the animated video and the game were effective in changing some of the key variables explored to improve children's knowledge and perceptions of the HPV vaccine, but any single message was not statistically more effective than the others. For the animated video, significant changes from pre- to postintervention scores were observed for most of the variables assessed, with the exclusion of attitude and subjective norms. For the game, the only statistically significant change from pre- to postmessage exposure was observed for knowledge and intention. The results for each of the variables for both the animated video and the game are shown in Table 1.

These results reinforce what emerged from the focus groups data: the children retained the information from both educational strategies (animated video and game) and enjoyed watching, and interacting with, them.

Table 1. Results and descriptive statistics for study variables by experimental condition (N=35).

Condition	Time point				*t* test (*df*)	*P* value	Mean difference

Discussion

Principal Findings

This study adopted a mixed methods approach consisting of focus group discussions and an embedded experiment to assess the feasibility of 2 educational multimedia materials on HPV and the HPV vaccination. The purpose of these educational materials was to educate children and provide them with the skills to discuss these topics with their parents and health care professionals. Both the qualitative findings and the results from the experiment indicated that the 2 educational materials were well received and improved children's intention to discuss the HPV vaccine from pre- to postmessage exposure. Children liked the characters presented in the animated video and the game and provided several suggestions on how to improve these materials. By educating children on the HPV vaccine, researchers and practitioners have the potential to aid in the promotion of personal health decision-making, strengthening communication about personal health, and enhancing personal health behaviors, including developing more favorable attitudes toward receiving the HPV vaccine [7].

This study took place in Italy, a country where the field of health communication is still underdeveloped, and it represents a pioneering effort to engage and represent a relatively understudied audience: Italian children. The study provides evidence in support of the use of multimedia interventions such as animated videos and web-based games to improve child-parent communication and HPV-related discussions. It indicates how communication and behavior change theories can be integrated into the human-centered–design approach. It also describes the working process used by the interdisciplinary team of communication scholars and interaction designers who created and evaluated the educational multimedia materials.

This study suggests that animated videos and web-based games can be effective multimedia strategies to improve children's knowledge about the HPV vaccination and their intention to discuss their health, in particular the HPV vaccine, with their parents and health care professionals. During the focus group discussions, the children indicated the features they appreciated in both the animated video and the game, which included in particular the personality and caring attitude of the characters. This finding suggests that showing positive examples of

communication exchanges may be important to help children feel comfortable when discussing the HPV vaccine and looking for health-related information. The children also expressed the desire to show the 2 messages to their parents and friends, indicating that multimedia messages should be easily retrievable and shareable in possible future campaigns to support children's discussion and information needs.

The experiment allowed observation not only of the improvements in knowledge of HPV and the HPV vaccine but also of the different changes in the outcome variables, depending on the message the children interacted with. When considering the emotional reaction to the vaccine, the animated video seemed to have an advantage over the web-based game. It is possible that, by showing enacted behaviors, animations may reduce children's fear while improving their self-efficacy with regard to health discussions. These findings are significant, considering that children encounter several challenges to engaging in conversations about their health, particularly when such discussions include a sexual-education component [49,50]. It is important to note that the children participating in this study felt that the video and game complemented each other, and that by using both, they were able to learn and test their knowledge. The children also suggested that the animated video and the web-based game would also be helpful to parents in providing an explanation of HPV to their children.

Limitations and Future Directions

There are some limitations to this study that should be mentioned. First, data were collected at only 1 school in the northern part of Italy. It is possible that children from different areas of Italy would have different perceptions and previous experiences that may affect how they receive the animated video and game. Second, parents' and physicians' comments about the game and animated video were not collected, limiting our ability to contextualize the children's experiences. Third, the scales used in this study were translated from English to Italian, but the translated questionnaire had not been previously validated with an Italian audience.

Future research is necessary to further extend this preliminary investigation to control for the effects of the specific features of the game by increasing the number of children exposed to these educational multimedia materials. A greater sample of children would allow researchers to evaluate the possible role of mediators and moderators to explain the effects of the animated video and the game to improve children's self-efficacy and attitudes. Future studies should also aim to measure improvements in the conversations between parents and their children resulting from the exposure to the game and the animated video through observations of dyadic conversations. Furthermore, it would be beneficial to understand whether the animated video and game are useful tools to help parents begin a discussion with their child about HPV. Future studies should also better explore the effects that educational multimedia messages have on children's conversations with their teachers and peers to inform the design of school-based interventions. Future studies should also control for the HPV vaccination status of the children and consider targeting the messages to it. Ultimately, future studies should integrate and evaluate these materials and educational modules in comprehensive health education packages that include information on several health issues relevant to children aged 11-12 years.

Conclusions

Engaging children in discussions about their health in general and HPV and the HPV vaccine in particular is important for empowering children and meeting their information needs. The animated video and web-based game evaluated in this study were well received by the children and were shown to be promising messages to improve several outcomes. We hope that the findings of, and procedures used in, this study will inspire other researchers to continue this line of research and further identify and develop strategies and campaigns to engage children in their health care.

Acknowledgments

The authors wish to thank all the children who participated in this study; the school that helped with the recruitment of the children and offered the spaces to conduct the focus groups; the Rotary Club del Seprio, which supported the project and created a connection with the school; and the designers who worked on the animated video (Michela Burzio) and the videogame (Giorgio Ratti). The publication of this manuscript was supported by the National Cancer Institute Cancer Center Support Grant (P30 CA177558).

Abstract

Background: Widespread vaping and e-cigarette use is a relatively new phenomenon. Youth vaping peaked in 2019, with over 25% of high school students currently vaping. e-Cigarettes are used where smoking is not permitted or as an alternative smoking cessation treatment instead of Food and Drug Administration–approved options. Vaping and e-cigarette use has the potential to harm health, including causing adverse respiratory effects and nicotine addiction. Health care professionals need skills training to help their patients with this relatively new and evolving health problem.

Objective: The aim of this study is to understand health care professionals' training needs in this subject area to determine the focus for web-based continuing education training.

Methods: We reviewed the literature on clinical aspects of vaping and e-cigarette use. Using the results and our experience in substance use continuing education, we created a list of key clinical skills and surveyed health care professionals about their training needs. We also asked about their interest in a list of related topics. We recruited individuals who completed our web-based courses on substance use, members of health care professional–related groups, and experts who had published an article on the subject. Half of the 31 health care professionals who completed the survey were physicians and the remainder were primarily nurses, social workers, and counselors. Participants self-identified as nonexperts (n=25) and experts (n=6) on vaping.

Results: Participants who were nonexperts on average agreed or strongly agreed that they needed training in each of 8 clinical skills (n=25; range 3.7-4.4 agreement out of 5). The top two skills were recommending treatments for patients (4.4 out of 5, SD 0.49) and evaluating and treating the health effects of vaping and e-cigarette use (4.4 out of 5, SD 0.50). Experts agreed on the importance of training for health care professionals in all skills but rated the need for training higher than nonexperts for each topic. Over half of the participating health care professionals (44%-80%) were interested in nearly all (9/10, 90%) vaping-related topics on a checklist. The topics participants were most interested in were the pros and cons of vaping versus smoking and the health effects of second- and third-hand vaping. Primary care physicians showed more interest in vaping-related topics than nonprimary care physicians (t_{13}=2.17; P=.02).

Conclusions: This study confirmed gaps in health care professionals' vaping-related clinical skills identified in the literature by identifying a perceived need for training in related skills and health care professionals' interest in key topics related to vaping prevention and cessation. This study provides specific guidance on which clinical skills training is most needed and which topics are most interesting to health care professionals.

clinical skills; vaping; e-cigarettes; nicotine; brief interventions; addiction treatment; health care professionals; continuing education

Introduction

Background

The growth of e-cigarette devices, after their initial promotion as safer alternatives to traditional cigarettes, brought about a disturbing trend of youth vaping, fueled in part by marketing directed to this age group [1] that minimized potential harm [2]. Whereas current cigarette use by high school students steadily decreased in the past 20 years to only 9.4% by 2019 [3], vaping, especially nicotine vaping, was on the rise. By 2019, when we conducted this study, 27.5% of high school students were vaping [4-6]. Vaping by youth later continued at a significant rate of 11% in early 2021 despite less time spent inside schools owing to the pandemic [7]. Many adults who use e-cigarettes as smoking cessation treatment alternatives to Food and Drug Administration (FDA)–approved options end up using both forms of nicotine [8].

Nicotine's harmful health effects were already known to medical science when nicotine vaping became popular, including nicotine's addictive properties [9,10] and harmful cardiovascular effects [11-13]. Other harmful health effects became evident over time, including a greater potential for nicotine overdose with vaping than with cigarette smoking, as well as harm to the lungs related to the inhalation of toxic chemicals in vaping liquids [10,11,14,15]. The serious lung disease, e-cigarette or vaping product use–associated lung injury, primarily associated with a vaping liquid additive, underscored the potential for respiratory damage, affecting over 2000 individuals and causing 68 deaths, mainly in the latter half of 2019 [16]. The long-term effects of inhaling various harmful ingredients are not yet fully understood.

With the addictive potential and health effects of vaping and e-cigarette use and increased use by their patients, health care professionals need to know how to prevent and address the use of these products. In the absence of large-scale studies on the best approach to preventing and treating vaping and e-cigarette use, many health care professional societies and addiction specialists recommended following existing evidence-based guidelines for tobacco cessation [17-21]. For example, the questions of the 5 As approach often recommended for tobacco cessation can be modified to pertain to the differences between vaping and e-cigarette use and other tobacco use, such as the nicotine delivery method and typical patterns of use [22]. Professionals also need sufficient knowledge to provide patient and parent education. Tobacco interventions by primary care providers are effective, including for adolescents [23,24]. Educational programs on best practices in this area need to be fluid, as further research gathers data on the best clinical approach to preventing and treating vaping and e-cigarette use by patients. Similarly, the use of e-cigarettes by many people to help with tobacco cessation requires further research [25]. Health care professionals need to understand that the FDA has not approved e-cigarettes as an aid to quit smoking and respond to patients who are using them for this purpose [26].

As a group, the authors brought significant experience in developing nicotine and cigarette addiction cessation training programs [27] and substance abuse cessation training for health care professionals [28-35]. With this experience, we were familiar with the evidence that health care professional screening and interventions effectively improve patient outcomes for substance use problems [36,37], including for tobacco cessation in children and adolescents [38,39]. This experience formed a solid basis to begin developing a curriculum and content.

To address the challenge of determining health care professionals' greatest needs and interests, we conducted a literature review to identify evidence-based protocols and current thinking on clinical skills thought to be effective for addressing patient vaping and e-cigarette use. We refined the list of skills that we identified with input from expert consultants in vaping and e-cigarette use and using our experience with addiction treatment education. We followed this with a needs analysis using a web-based survey asking health care professionals about the clinical skills training they most needed and topics of most interest to them.

Objectives

This study aims to determine the need and interest health care professionals have in training on clinical skills to address vaping and e-cigarette use by their patients. We also aim to prioritize the needs and determine differences by groups of clinicians or level of expertise.

Methods

Literature Review

The newness of widespread vaping and e-cigarette use and the emerging recognition of the associated adverse health impacts and limits as a tobacco cessation tool created a challenge in developing an evidence-based continuing education program for health care professionals on the topic. To address this challenge, we completed an extensive literature review from 2014 to 2019. Using PubMed, Google Scholar, and PsycINFO, we searched for research-based articles on vaping and e-cigarette use, covering the topics of brief interventions, epidemiology, motivations, prevention, risk factors, health effects, psychosocial impact, addiction, knowledge and practice gaps, clinical guidelines, vaping products and ingredients, and regulations. We used standard internet searches to identify available training for health care professionals on the topic, Centers for Disease Control and Prevention updates, clinical guidelines, and news. Additional keywords used in the internet and web-based searches included *gateway drugs*, *e-cigarettes*, *vaping*, *e-liquid*, *vaporizers*, and variants of these terms. We also searched for previous studies examining health care professional' perspectives and knowledge on e-cigarette use and vaping and current, evidence-based recommendations for a prevention and treatment clinical protocol. We created survey questions from the clinical skills and related topics most recommended in the literature.

Ethical Considerations

This research was considered exempt from institutional research board review because it involved survey procedures, and the information obtained could not be linked to the participants and did not place them at risk (approval number: 2019/007).

Recruitment

Owing to the formative, exploratory nature of this study and a condensed time frame required by the funding mechanism, we used a convenience sample. We recruited and enrolled participants from October 21, 2019, to November 14, 2019, via direct email. Recruitment efforts included contacting the first 100 health care professionals who had taken a Clinical Tools addiction-related continuing education activity a year previously and inviting participants to share the invitation with colleagues. We also contacted approximately 100 health care professionals using social media and email lists. We modified recruitment to achieve participant diversity similar to the distribution in health care professionals. To obtain input from experts in the field, we also emailed 50 authors of research articles on the clinical aspects of vaping and e-cigarettes. We linked to the human participants' or institutional review board exemption information in the emails. Completing the survey after reviewing that information signified enrollment. Identifying information and study data were stored separately. Participants completing the web-based survey received a US $20 gift card. We checked IP addresses for any duplicate submissions from the same computer.

Data Collection and Analysis

We developed survey questions on potential clinical training needs and key topics by gathering recommendations from the existing literature on how to address patient vaping [17,18,40] and substance use interventions [41-45], as well as our experience of providing training on addiction for health care professionals for over 20 years. Questions were based on evidence-based clinical skills and topics recommended most frequently; gaps in knowledge, skills, and practice; and general principles of addiction assessment and treatment, particularly for tobacco cessation. Question types included Likert-style questions (5-point agreement) about the perceived need for training in key clinical skills, a checklist of topics related to patient vaping, an open-ended question asking whether they had other related needs and interests, and multiple-choice knowledge questions about common vaping myths. Survey questions included a not applicable or do not know option; all survey questions were required. We administered the needs analysis web-based survey from October 21, 2019, to November 16, 2019.

We asked about the need for clinical skills training, interest in vaping topics, and knowledge of several common myths about vaping. We also asked participants to identify their level of expertise in the field of vaping and e-cigarettes (expert or nonexpert) and whether or not they worked in primary care. We asked both experts and nonexperts about the training needs of nonexperts by changing the question stem for each group.

We calculated average Likert rating scores and their SDs for the skills and knowledge data, plus the percentage of participants rating each item with *agree* or *strongly agree*. For the topic interest data, we calculated the percentage of participants who endorsed each topic. We calculated *t* scores and *P* values to compare the overall results in the groups (expert vs nonexpert and primary care physicians vs not primary care physicians). Descriptive statistics were used to analyze and compare the results for the individual questions across groups. A single response to the optional open-ended question is reported without analysis.

Results

Literature Review

The literature review identified several gaps in health care professionals' medical knowledge, clinical skills, and practice related to vaping and e-cigarettes [46-50]. The gaps in health care professionals' knowledge were of health effects [48,49], vaping methods, products, and patterns of use; recommended interventions; and the effectiveness and safety of e-cigarettes to aid smoking cessation. Gaps in clinical skills or practice were evident in health care professionals' infrequent practice of screening [51], following up on screening results [52], and providing interventions [48,49]. Health care professionals screen patients for the use of noncigarette products and advise quitting them less frequently than they do for cigarettes [46]. Health care professionals also need to be prepared to provide patient education and recommend resources, such as social media or SMS text messaging support for vaping or e-cigarette cessation [53].

The clinical guidance from national professional organizations available at the time of this search in September 2019 was limited and included guidelines by the American Academy of Pediatrics recommending tobacco cessation counseling and FDA-approved tobacco dependence pharmacotherapies [20] and clinical tips sheets by the American Academy of Family Physicians [54]. Another resource was the Surgeon General's report on e-cigarettes and young people [10]. Several journal articles drew conclusions about effective prevention interventions, identified youths and young adults at greater risk, and recommended counseling interventions based on the available evidence [40,50,55-57]. The search also revealed only a few, often expired, web-based trainings for health care professionals on the topic [40,58-62]. Boston Medical Center and Montreal University subsequently published a guideline based on tobacco cessation interventions and expert opinion [18]. As of this study, there were no nationally recognized clinical guidelines for vaping cessation treatment (2020). However, a curriculum was developed subsequently for pediatricians by the American Academy of Pediatrics in 2021 [63].

We consolidated the literature review results to produce a list of skills and topics generally considered by experts in the field as important for clinicians to understand. This list is reflected in the survey questions.

Participants

A total of 31 health care professionals participated in the needs analysis surveys and self-identified as nonexperts (25/31, 81%) or experts (6/31, 19%) in vaping. Nonexperts included physicians (15/25, 60%), nurses (4/25, 16%), social workers or counselors (3/25, 12%), and other health care professionals (3/25, 12%). Self-identified experts on vaping were physicians (3/6, 50%), a psychologist (1/6, 17%), an epidemiologist (1/6, 17%), and a social worker (1/6, 17%). Physicians were divided

nearly evenly between primary care (8/15, 53%) and nonprimary care (7/15, 47%).

The diversity of the sample reflected ethnic and racial percentages of the professions in US physicians and nurses [64,65], except for low representation by Black participants. The demographics, voluntarily described by participants, were Asian 19% (6/31), Black 0% (0/31), White 68% (21/31), >1 race 10% (3/31); other 3% (1/31), and Hispanic or Latino 3% (1/31; prefer not to answer 3/31, 9%). More participants were women (22/31, 71%) than were men (9/31, 29%).

Survey Results and Analysis

Clinical Skills Training Needs

For clinical skills training, we asked participants to rate their perceived need for training in 8 clinical skills, listed in Table 1, using a Likert-type survey with a 5-point agreement scale.

Table 1. Health care professionals' perceived need for clinical skills training on vaping (N=31).

"I or Healthcare Professionals NEED MORE TRAINING in how to"	Nonexpert (n=25)		Expert (n=6)	
	Rating[a], average (SD)	Agree or strongly agree, n (%)	Rating[a], average (SD)	Agree or strongly agree, n (%)
Recommend treatments for patients who vape or use electronic cigarettes (e-cigarettes)	4.4 (0.49)	25 (100)	4.8 (0.41)	6 (100)
Evaluate and treat health effects in patients who vape or use e-cigarettes	4.4 (0.50)	25 (100)	4.7 (0.52)	6 (100)
Provide brief interventions for patients who vape tetrahydro-cannabinol	4.3 (0.69)	22 (88)	4.8 (0.41)	6 (100)
Helping patients who are using e-cigarettes to quit smoking	4.1 (0.78)	21 (84)	4.5 (0.82)	5 (83)
Talk with parents about vaping prevention or helping their adolescent child quit	4.1 (0.85)	20 (80)	5.0 (0)	6 (100)
Counsel patients about how to quit vaping or e-cigarette use	4.0 (0.75)	21 (84)	4.8 (0.52)	6 (100)
Motivate patients to quit vaping or e-cigarette use	4.0 (0.79)	20 (80)	4.8 (0.52)	6 (100)
Assess vaping and e-cigarette use in patients	3.7 (0.95)	20 (80)	4.3 (0.82)	6 (100)

[a]Likert rating: 1=strongly disagree, 2=disagree, 3=neither agree nor disagree, 4=agree, 5=strongly agree.

Participants generally agreed that they need training in clinical skills to address their patients' vaping or e-cigarette use. The ratings by all participants are presented first, followed by comparisons of expert opinion versus nonexpert opinion and primary care physicians versus nonprimary care physicians.

A majority of participants agreed that clinicians need more training for all 8 clinical skills listed (Table 1). The skills that health care professionals who were not experts on vaping (n=25) most often agreed that they required training were as follows: (1) recommend treatments for patients who vape or use e-cigarettes (average 4.4, SD 0.49; 25/25, 100% agree or strongly agree) and (2) evaluate and treat health effects in patients who vape or use e-cigarettes (average 4.4, SD 0.5; 25/25, 100% agree or strongly agree).

Nonexperts (n=25) and experts (n=6) generally agreed about the need for training in the same clinical skills. However, nonexperts' average ratings ranged lower than experts' ratings (3.7 to 4.4 out of 5 vs 4.3 to 4.8 out of 5).

Experts agreed that all skills listed were needed, rating none of the skills below 4 (agreement). According to experts, the skills needed the most were as follows: (1) talk with parents about vaping prevention or helping their adolescent child quit (average 5.0, SD 0; 25/25, 100% agree or strongly agree) and (2) four other skills were rated nearly as highly (average rating 4.8, SDs 0.41-0.52; 25/25, 100% agree or strongly agree). These pertained to patient counseling, motivating patients to quit, recommending treatment, and providing brief interventions for patients who vape tetrahydrocannabinol (THC).

The clinical skills with the largest rating differences between the expert and nonexpert groups (0.8-0.9 points) were talking with parents about vaping prevention or helping their adolescent child quit, counseling patients about how to quit vaping or e-cigarette use, and motivating patients to quit vaping or e-cigarette use.

The clinical skills that primary care physicians (n=8) on average agreed most strongly that they need training in were as follows: (1) evaluate and treat health effects in patients who vape or use e-cigarettes (average rating 4.8 out of 5, SD 0.46; 8/8, 100% agree or strongly agree), (2) recommend treatments for patients who vape or use e-cigarettes (average rating 4.6 out of 5, SD 0.51; 8/8, 100% agree or strongly agree), (3) provide brief interventions for patients who vape THC (average rating 4.6 out of 5, SD 0.52; 7/8, 88% agree or strongly agree), and (4) counsel patients about how to quit vaping or e-cigarette use (average rating 4.4 out of 5, SD 0.74; 7/8, 88% agree or strongly agree).

Primary care physicians on average agreed more strongly that they needed training in the 8 clinical skills listed than did nonprimary care physicians, averaging 4.3 out of 5 (SD 0.34) versus 3.9 out of 5 (SD 0.37; t_{13}=2.56; 95% CI for the difference 0.0734-0.8266; *P*=.01).

Topics of Interest

We asked nonexperts in vaping (n=25) to indicate which topics relevant to vaping interested them on a checklist of 10 topics, listed in Table 2. Most of the nonexpert participants indicated an interest in most (9/10, 90%) of the topics listed, with the percentage of participants interested in each topic ranging from 52% to 80% (Table 2). Topics endorsed most often were *Pros and cons of vaping versus smoking*, selected by 80% (20/25) and *Health effects from second- and third-hand vaping*, selected by 76% (19/25).

Table 2. Number of health care professionals who are not experts on vaping who indicated an interest in vaping-related topics (n=25).

Topics related to vaping and e-cigarettes (in order from most often selected to least)	Health care professionals endorsing interest in topic, n (%)
Pros and cons of vaping vs smoking	20 (80)
Health effects from second- and third-hand vaping	19 (76)
Risks of vaping specifically	18 (72)
Vaping and e-cigarette devices, liquids, and their ingredients	17 (68)
Vaping prevention	16 (64)
Biology of endocannabinoids and pharmacology of tetrahydrocannabinol	16 (64)
Special needs regarding vaping because of cultural, racial, ethnic, or socioeconomic differences	14 (44)
Pathology and radiology of e-cigarette and vaping-associated lung illness	13 (52)
Patient and parent resources on these topics	13 (52)
Biology of the nicotine system and pharmacology of nicotine	13 (52)
None of the above	1 (4)

Physicians (n=15), all of whom were not experts in vaping, were most often interested in *Health effects from second- and third-hand vaping* (n=13, 87%) and *Pros and cons of vaping versus smoking* (n=12, 80%). The fewest physicians were interested in the topics *Special needs regarding vaping due to cultural, racial, ethnic, or socioeconomic differences* (5/15, 33%) and *Biology of the nicotine system and pharmacology of nicotine* (5/15, 33%).

Primary care physicians (n=8) on average showed interest in significantly more topics than nonprimary care physicians (n=7): 5.5 topics (55%, SD 1.51%) versus 3.6 topics (36%, SD 1.4%; t_{13}=2.168; *P*=.02).

We also offered participants the opportunity to add skills or interests that were not included via an open-ended question. In response to this optional, open-ended question, a hospital staff participant identified “negative consequences of vaping.” No other participants responded to this question.

Vaping Knowledge

We asked participants to indicate their level of agreement with 3 myths about vaping, described in Table 3, using the same Likert-type survey style.

Table 3. Health professionals’ agreement with myths about vaping.

Question: rate your agreement or disagreement with the following statements about vaping	Nonexpert (n=25)		Expert (n=4)	
	Rating[a], average (SD)	Disagree or strongly disagree, n (%)	Rating, average (SD)	Disagree or strongly disagree, n (%)
Vaping or electronic cigarette use is a good option for smokers trying to quit (correct answer is 1-2, strongly disagree or disagree).	1.8 (0.94)	14 (56)	1.8 (0.96)	3 (75)
Vaping tetrahydrocannabinol is the main problem. Vaping of nicotine and flavored liquids is not significant clinically (correct answer is 1-2, strongly disagree or disagree).	1.8 (0.75)	22 (88)	1.5 (0.58)	4 (100)
Helping patients who vape is just like helping smokers or drug users (correct answer is 1-2, strongly disagree or disagree).	3.5 (0.85)	3 (16)	2.2 (1.26)	3 (75)

[a]Likert rating: 1=strongly disagree, 2=disagree, 3=neither agree nor disagree, 4=agree, 5=strongly agree.

In response to 3 Likert-type agreement–style knowledge questions, both vaping expert and nonexpert participants were fairly knowledgeable about several common myths about vaping. Their responses aligned with the correct answer, which was to disagree with the inaccurate statements (Table 3). Experts disagreed more strongly with the statements. Differences were not statistically significant on average. However, 1 statement, “Helping patients who vape is just like helping smokers or drug users,” had a relatively larger difference (1.3 out of 5) between

nonexperts and experts, suggesting a larger gap in the knowledge about this topic.

Participants were also asked, "Compared to quitting cigarettes, quitting vaping of nicotine is (easier, same, harder)." Most participants (24/31, 77%) said it was the same; 19% (6/31) said it was harder, and 6% (2/31) said it was easier to quit vaping. The ratings for experts and nonexperts were similar.

Discussion

Principal Findings

To confirm and prioritize health care professional training gaps in clinical skills and knowledge related to vaping and e-cigarette use, we conducted a needs analysis with health care professionals and experts in vaping. We asked about their need for training in clinical skills and their interest in related topics. To explore whether there was a knowledge gap, we also asked whether they agree with common myths regarding vaping.

Most health care professionals participating in this study agreed that they needed training in key clinical skills on helping patients with vaping, as identified via a literature review. A majority were also interested in learning about a list of key topics related to vaping culled from the literature review. Participant responses to myths about vaping not only showed some awareness of their inaccuracy but also identified areas of misunderstanding. Together, these results suggest that health care professionals perceive a need for training in vaping-related clinical skills, are interested in learning about related key topics, and have a gap in some related knowledge. Results from experts confirmed the need for the clinical skills training and education in key related topics.

The clinical skills that participating health care providers agreed they need involve providing brief interventions, including counseling and motivating on quitting and prevention, recommending treatments, and evaluating and treating the health effects. The finding that training is needed across the range of skills identified in this study highlights the broad training needs of health care professionals in the evolving patient use of vaping and e-cigarettes and associated health concerns.

Experts more strongly agreed that health care professionals need training in each of the clinical skills needed to help their patients with vaping when compared with health care professionals who were not experts on vaping. The reasons for this difference might include health care professionals not being as aware of a training need, providers being better prepared than experts realize, or other reasons, which would require further research to understand.

A majority of participating health professionals who were not experts on vaping were interested in nearly all the vaping-related topics listed in this study. This indicates widespread agreement on what general areas to cover in a vaping training program. The topics with the highest rate of interest, *Pros and cons of vaping versus smoking* (20/25, 80%), *Health effects of second- and third-hand vaping* (19/25, 76%), and *Risks of vaping* (18/25, 72%) can be emphasized.

Further research could explore the reasons for high and low ratings for need and interest to distinguish between lack of interest, lack of relevance for their practice, or already having a particular skill or knowledge.

Participants' relatively higher agreement with a myth that there are no differences between interventions for vaping and other substance use points to an understanding of the similarities but a knowledge gap about the differences that do exist. This confirms knowledge and skills gaps identified in the literature review. Nonexperts in vaping need a better understanding that there are some differences in clinical treatment for vaping and e-cigarette cessation versus smoking cessation to respond to the reinforcing effects of flavoring, different patterns of use, peer influence, and the ability to vape or use e-cigarettes discretely and in more environments [9,10,17,66,67].

The topics physicians were most interested in differed somewhat from those of participating health care professionals as a whole. They showed greater interest in the health effects of vaping and e-cigarettes, recommending treatments, and providing brief interventions for vaping THC. As might be expected from their patient population, primary care physicians rated the need for training higher than nonprimary physicians (average 4.3, SD 0.34 vs 3.9, SD 0.37, out of 5; P=.01). They also indicated more interest in vaping-related topics, endorsing an average of 5.5 versus 3.6 topics (P=.02).

The results support a training for health care professionals on vaping and e-cigarettes that emphasizes the primary care setting and the identified skills and topics. However, fairly low SDs throughout the study, despite over half of the participants being nonphysicians and nonprimary care, support the development of a universally applicable training. The training activities must be flexible enough to address the minor differences in needs based on the health care professionals' work setting and patient population.

Applications

Subsequent to this research, a few more clinical practice guidelines on vaping and e-cigarettes emerged. For example, in 2021, the American Academy of Pediatrics published an e-cigarette curriculum and poster for pediatricians only accessible to members [63]. As adolescents and young adults use these products more than other age groups, and as that young demographic is less likely to see the physician than older individuals, nonphysician health care professionals need this training in addition to pediatric physicians.

Although our work was specific to vaping cessation, some takeaways can be applied to continuing education development for health care professionals in general. Programs on substance use should include content related to health impacts to increase physician engagement and interest. In addition, content related to clinical skills should focus on specific areas where this research demonstrated gaps between the health care professionals' self-perceived understanding of their training needs and real-world outcomes, such as the need to adapt counseling and interviewing techniques to the specific substance and cultural, racial, ethnic, and socioeconomic differences. In addition, health care professionals may need to be persuaded

that topics favored more highly by experts on a topic are relevant to their practice and patient population.

After identifying health care professionals' training needs and practice gaps, we developed 3 case-based web-based training activities focused on the clinical skills identified. These activities are currently available in the studies by Rossie [68-70]. In an early evaluation of that program with 78 health care professionals, most users indicated improvement in their knowledge (74/78, 95%) and competence (66/78, 85%). The learners gave high ratings for their vaping-related self-efficacy (4.3 out of 5), intended behavior (4.3 out of 5), and attitude (4.3 out of 5) following the completion of the program. An analysis of the educational impact of the activities is ongoing.

e-Cigarettes and vaping are not the *safe alternative* to cigarette use, as initially presented by the industry. Patients who vape, use e-cigarettes, or are considering using them will benefit from health care professionals who are able and ready to intervene with prevention, evaluation, and cessation strategies. Health care professionals who are adequately trained regarding patient vaping and e-cigarette use will decrease the burden of nicotine, THC, and harmful chemicals used in these products on patient health.

Key Findings

Most participants agreed that clinicians need more training on vaping across a list of clinical skills commonly used to address substance use. However, experts' agreement was stronger.

Health care professionals without expertise in vaping understood their need for training in clinical skills related to vaping, as was evident by selecting similar needs to what experts selected. However, expert agreement on needs was significantly stronger, on average.

Health care professionals agreed most strongly that they need clinical skills training in recommending treatments for patients who vape or use e-cigarettes and evaluating and treating health effects in patients who vape or use e-cigarettes.

There was strong interest by most participants who were not experts in vaping in learning about most topics on a list of key topics about vaping. The strongest interest was in the pros and cons of vaping versus smoking and the health effects of second- and third-hand vaping.

Physicians in primary care more frequently expressed interest in topics related to vaping and e-cigarette use than those not in primary care. Physicians had greater interest in the health impact of vaping than other health care professionals.

Participants showed a moderately good understanding of myths about vaping from a clinical perspective but need better awareness of the differences between treating a patient for vaping and other substance use.

Limitations

This research was limited by searching only 3 major databases of journals in our literature review, PubMed, Google Scholar, and PsycIINFO. For example, we did not search for Scopus and CINAHL, which have relevancy because of the clinical nature of this topic. We may have missed some topics mentioned in articles indexed only in the sources not used.

Limitations related to sampling may have affected the results. We elected to use a convenience sample owing to the time frame and funding available. Thus, the participants may not represent the health care professionals as a whole.

Several limitations are related to study participants. We directed half of our recruitment efforts to a list of health care professionals who had taken our other substance use courses because we wanted to understand the needs of our typical audience. Consequently, participants may have more interest in and knowledge about substance use than the average health care professional. An honorarium provided to participants may have introduced a bias toward participation or more positive feedback. The small number of experts in this study limits comparisons of experts with nonexperts. Although we had participant recruitment efforts that specifically sought to increase the diversity of the sample, African American health care professionals were not represented.

Finally, questions were not randomized owing to limitations of the software used, which may have resulted in items near the top of the checklist being chosen more often than they would have otherwise.

Conclusions

Using a survey derived from a literature review and expert knowledge, we identified health care professionals' perception of their need for training in clinical skills, their interests, and their knowledge related to vaping and e-cigarette use by patients. The list of clinical skills training needed and topics of interest for health care professionals identified in this study confirms the need identified in the literature and adds prioritization according to which skills and topics had the greatest need and interest. This information can contribute to the effective focus of the growing body of training on helping patients who vape or use e-cigarettes or considering use. Combining literature review with expert opinion and health care professionals' interest enabled us to develop a targeted curriculum to address the clinical skills gaps and the evolving health concerns of vaping and e-cigarette use. The results suggest that vaping and e-cigarette use is an area where health care professional training would benefit.

Acknowledgments

This project was supported entirely by funding from the National Institute on Drug Abuse of the National Institutes of Health (grant R43DA050401). The Clinical Tools Institutional Review Board reviewed all participants' activities and determined that the project was exempt from an ongoing review.

Conflicts of Interest

The authors are employees of Clinical Tools, the small business that received the National Institute on Drug Abuse grant to perform this needs analysis. BT is the principal investigator of the grant and owner of Clinical Tools, Inc. Clinical Tools may profit from products created as a result of the grant.

Abstract

Background: Biomedical research requires health care institutions to provide sensitive clinical data to leverage data science and artificial intelligence technologies. However, providing researchers access to health care data in a simple and secure manner proves to be challenging for health care institutions.

Objective: This study aims to introduce and describe Medical-Blocks, a platform for exploration, management, analysis, and sharing of data in biomedical research.

Methods: The specification requirements for Medical-Blocks included connection to data sources of health care institutions with an interface for data exploration, management of data in an internal file storage system, data analysis through visualization and classification of data, and data sharing via a file hosting service for collaboration. Medical-Blocks should be simple to use via a web-based user interface and extensible with new functionalities by a modular design via microservices (*blocks*). The scalability of the platform should be ensured through containerization. Security and legal regulations were considered during development.

Results: Medical-Blocks is a web application that runs in the cloud or as a local instance at a health care institution. Local instances of Medical-Blocks access data sources such as electronic health records and picture archiving and communication system at health care institutions. Researchers and clinicians can explore, manage, and analyze the available data through Medical-Blocks. Data analysis involves the classification of data for metadata extraction and the formation of cohorts. In collaborations, metadata (eg, the number of patients per cohort) or the data alone can be shared through Medical-Blocks locally or via a cloud instance with other researchers and clinicians.

Conclusions: Medical-Blocks facilitates biomedical research by providing a centralized platform to interact with medical data in collaborative research projects. Access to and management of medical data are simplified. Data can be swiftly analyzed to form cohorts for research and be shared among researchers. The modularity of Medical-Blocks makes the platform feasible for biomedical research where heterogeneous medical data are required.

Introduction

Health care institutions are increasingly challenged by the need to balance the increasingly complex clinical pathways and socioeconomic costs. Digital transformation in health care is expected to address this challenge [1]. More accurate and rapid diagnosis, management, and treatment are anticipated through personalized and precision medicine [2,3]. However, combining health care data with biomedical research proves to be difficult and cumbersome for health care institutions, even if the researchers are based at the institutions itself.

Most health care data are available at the level of the health care institutions, often only accessible by clinical personnel and not by biomedical researchers themselves. The availability of data is even more complicated for multicenter research, which is preferable because of the increased sample size, statistical power, and improved generalizability of research [4]. Even if data are available, regulations make data sharing difficult and hinder collaborative research. Although federated learning promises to alleviate the challenge of data sharing, it is a rather new concept that requires expert knowledge, and it is not straightforward to implement. Therefore, the accessibility and sharing of data originating from single or even multiple centers to biomedical research would be advantageous for today's evidence-based medicine [2,5,6].

Besides the availability of data, the complexity and heterogeneity of data in health care make data-driven biomedical research even more difficult [7-10]. Answering research questions and characterizing diseases often involves diverse and interdisciplinary data [11], ranging from metadata (eg, demographics), clinical information (eg, clinical history and cognitive scores), biological specimens (eg, blood samples), physiological data (eg, electroencephalography), and imaging data (eg, magnetic resonance) to other auxiliary data; that is, multi-omics research. Using such diverse data, a more comprehensive understanding of the diseases and drawing stronger conclusions might be possible [9,12]. However, preparing, handling, and curating heterogeneous data can be tedious and costly [2] before even a single hypothesis can be tested. Knowledge of the available data and means of simple and fast extraction and management of the data from health care institutions are, therefore, key to successful biomedical research.

The development of software platforms facilitating data exploration, management, analysis, and sharing for biomedical research is ongoing, as some previous reviews [9,10,13-15] summarize. Among the numerous existing platforms, those that are most relevant to this work, which are presented on the use case of medical imaging, are summarized hereafter. XNAT (Extensible Neuroimaging Archive Toolkit) [16] is a platform that allows the storage, processing, and sharing of data in biomedical research, with an emphasis on medical images. The virtual skeleton database [17] allows sharing of data in a web-based repository. GIFT-Cloud (Guided Instrumentation for Fetal Therapy and Surgery) [18] is a data sharing and medical image–sharing platform that simplifies the transfer of data from clinics to research. JIP (Joint Imaging Platform) [19] tackles data sharing using a federated approach, which enables the decentralized use of medical images for algorithm development. KETOS [20] is a platform for data analysis, training, and deployment of artificial intelligence (AI) methodologies in health care settings. PRISM (Platform for Imaging in Precision Medicine) [21] handles medical images and associated clinical data, allows the creation of cohorts, and provides image curation functionalities in the setting of the Cancer Imaging Archive. However, most of the available platforms require data to be extracted and curated beforehand and are nonmodularizable; that is, the platforms usually do not provide support if researchers want to use uncommon types of data.

We present Medical-Blocks, a platform that enables exploration, management, analysis, and sharing of data in biomedical research. On the basis of the increasing demand to share and analyze health care data for research, we hypothesize that Medical-Blocks enables swift and secure data exchange. Medical-Blocks can be used as a cloud application or a network of local instances in multi-institutional research, or as a local instance at a single institution, depending on the data sharing and protection regulations. It is adaptable and modularizable to the needs of the particularities of the biomedical research conducted and, hence, the required data.

Methods

Overview of Medical-Blocks

Medical-Blocks allows the exploration of data available at clinical systems, management and analysis of these data for research, and sharing of data between institutions for collaborative research. To this end, Medical-Blocks can be connected to data sources of clinical systems (eg, databases such as electronic health records [EHRs] and picture archiving and communication system [PACS]) at health care institutions by blocks. Users can explore the data in the clinical systems through Medical-Blocks, without interfering with the clinical workflow. After identifying data that are suitable for further investigation (eg, within a clinical study), the data can be imported to and managed within Medical-Blocks. Medical-Blocks allows analysis of the data through data visualization, editing, and (automatic) classification by labeling the data such that it becomes research-friendly. By classification of the data, metadata of the data becomes available to the users (eg, number of patients and number of images of a certain type). Therefore, Medical-Blocks allows swift exploration and management of the available data for biomedical research at health care institutions. Furthermore, the metadata or data can be shared through Medical-Blocks from instance to instance or via the cloud in research collaborations.

An exemplary use of Medical-Blocks in a research collaboration between hospitals is illustrated in Figure 1. Medical-Blocks operates both in the cloud and locally at an institution. In both cases, it features the same functionalities. The cloud instance allows users to connect to Medical-Blocks and to perform management and analysis of data from all over the world. Metadata and data can be shared to this cloud instance either from local instances of Medical-Blocks at health care institutions or data can also be imported directly to the cloud, if compliant

with the legal regulations (eg, only anonymized data). At health care institutions, Medical-Blocks can be directly connected to the data sources of the clinical systems.

Medical-Blocks is implemented as a web application that relies on a client-server model. The implementation of the front end is illustrated in Figure 2. The React library [22] is used to build the user interface (UI) with its web components (tables, combo boxes, etc), which are based on the Material-UI library [23]. The Redux library [24] oversees variables that are used by the web components of the UI and notifies them upon changes in the data. The Axios HTTP client library [25] is used to query, upload, and download data between the web components and the back end's application programing interfaces (APIs) such as GraphQL and representational state transfer (REST) APIs.

The back end is based on the ExpressJS framework [26] that exposes two end points (Figure 3): a GraphQL and REST download end point. The GraphQL [27] end point is implemented using the Apollo server library [28], which handles the query, mutations, and upload events triggered by the clients. Owing to the limitations of the Apollo server library in handling file download events, a download end point was created. The implementation of the download end point was based on the RESTful API. GraphQL ensures communication with the local SQL server through the Sequelize NodeJS library [29]. Files were redirected to an internal files system using NodeJS [30]. To notify clients about events (variables, messages, and new files), we used the subscription system of GraphQL in conjunction with a Redis database [31]. A NodeJS Docker API was implemented to handle the communication to the Docker containers [32]—the so-called blocks. The Docker containers can connect to the APIs of the clinical systems. Details on the technical implementation, such as the PACS and EHR connections, are provided in Multimedia Appendix 1 [27-30,32-38] and referenced accordingly in the subsequent sections.

Figure 1. Illustration of the use of Medical-Blocks in a research collaboration between 2 health care institutions via the cloud or direct connection. At each health care institution, a local instance of Medical-Blocks is set up, which accesses the data sources of the health care institution (eg, electronic health records and picture archiving and communications system). Researchers and clinicians can explore, manage, and analyze the available data through Medical-Blocks. For collaboration, metadata (eg, number of patients per cohort) or the data itself can be shared through Medical-Blocks via a cloud instance with other researchers and clinicians. Metadata and data can also be shared directly between local instances of Medical-Blocks from institution to institution.

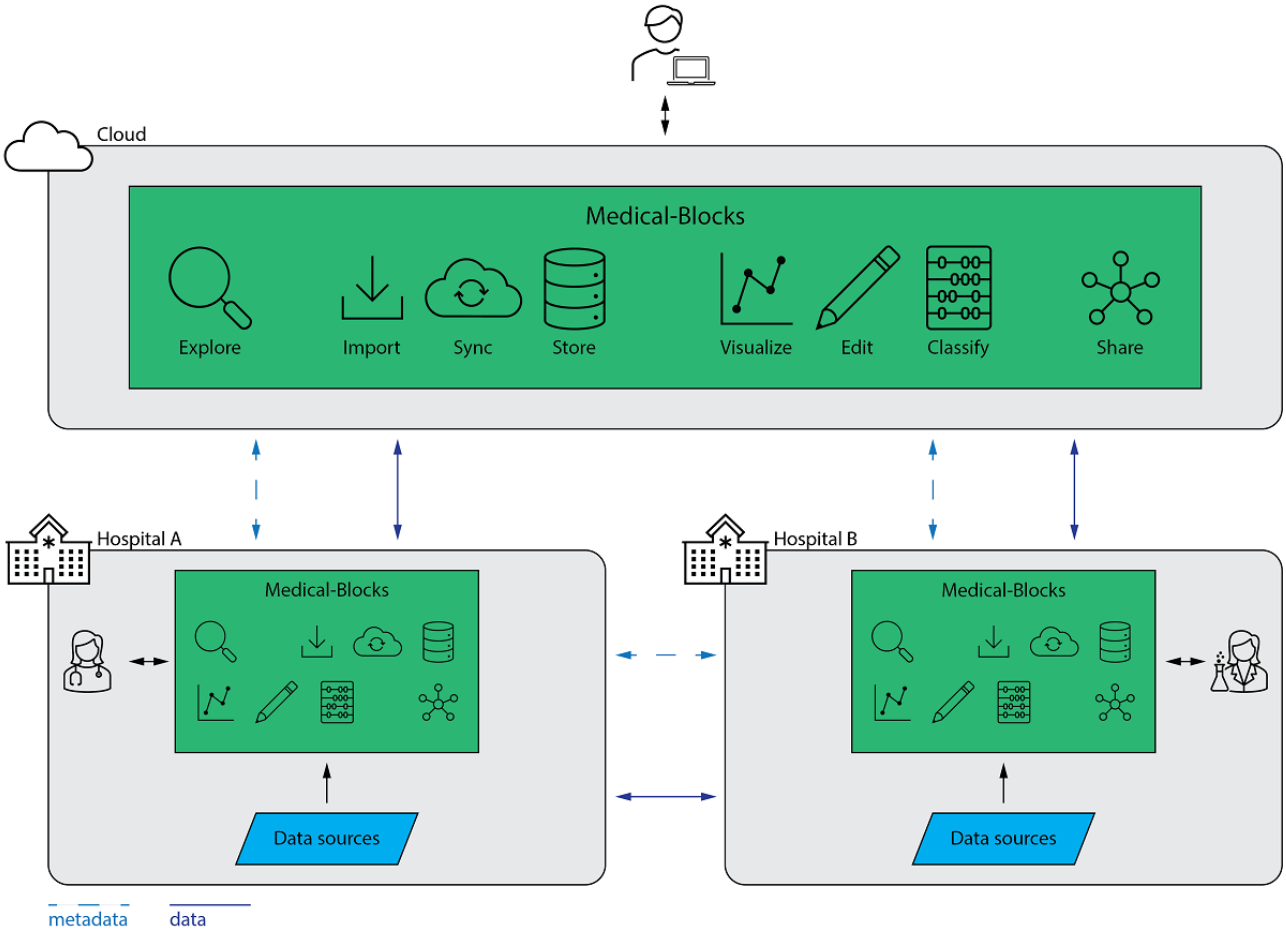

Figure 2. The front end of Medical-Blocks is built using the React library with Material-user interface web components. An Axios HTTP client communicates with the back end of Medical-Blocks. UI: user interface.

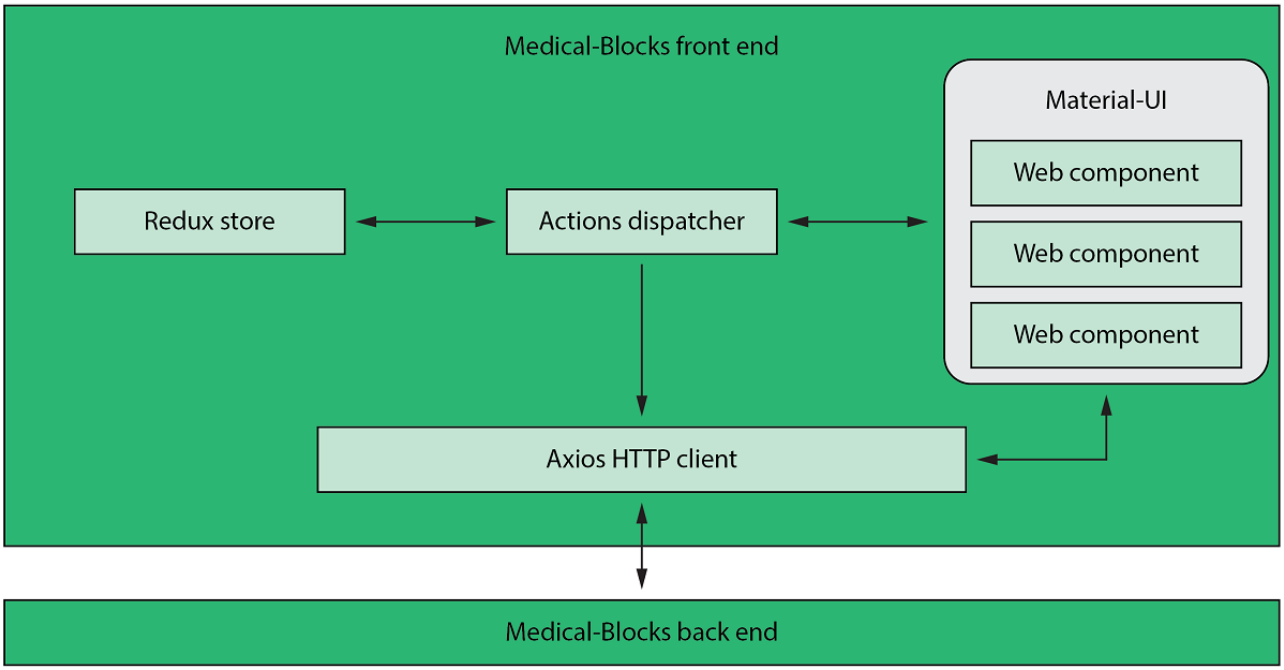

Figure 3. The back end of Medical-Blocks is based on ExpressJS and exposes a GraphQL and download end point. NodeJS is used to communicate with Docker containers—the so-called blocks—that can connect the clinical systems. API: application programming interface; REST: representational state transfer.

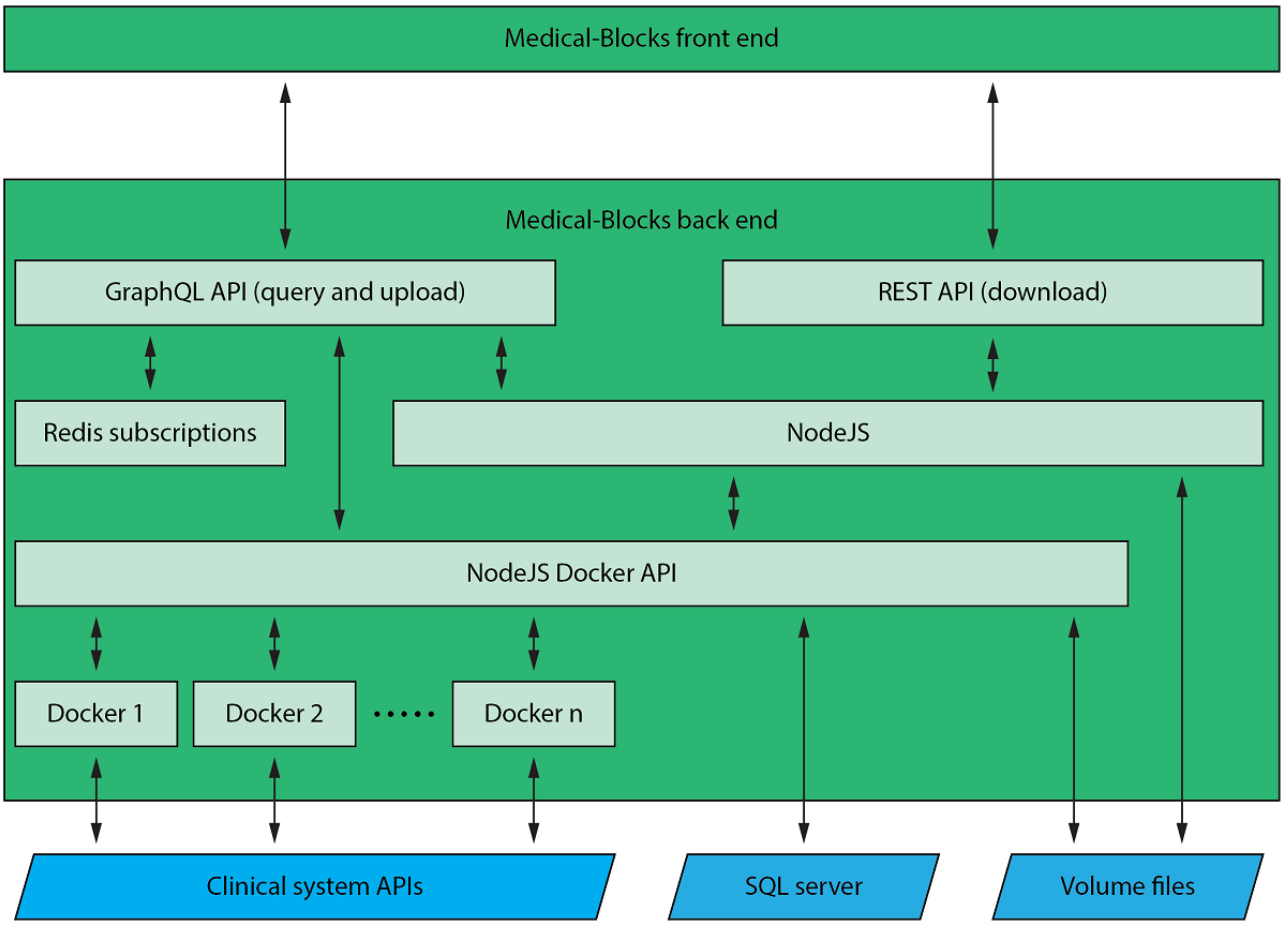


Main Features

The main features of Medical-Blocks can be broken down into data exploration, data management, data analysis, and data sharing.

Data Exploration

Medical-Blocks can be connected to the data sources of clinical systems, which allows users to explore the data available within an institution. The type of connected data sources, that is, systems and databases, depends on the type of research being conducted. Currently, Medical-Blocks is connected to PACS, EHR, and electroencephalography data sources (section S1 in Multimedia Appendix 1). The connections to the individual systems of the data sources are established through the APIs of these systems by Docker containers (*blocks*) specific to each connected clinical system.

Data Management

Medical-Blocks allows the management of data for research, which includes the import of data from data sources to its internal storage system. Data import is possible in three ways: manually by a user over the web UI, semiautomatically using standalone applications (through MB-Connect and MB-Sync described later), or automatically via blocks triggered upon new data being available. For example, the clinical PACS automatically sends a copy of the data (medical image in Digital Imaging and Communications in Medicine [DICOM]) format) to Medical-Blocks. The block processes data into the required format, such as anonymization (eg, removing patient-related information) and conversion to another data format (eg, DICOM to MetaImage conversion). For uncommon data types, the modular architecture of Medical-Blocks allows the integration of new blocks (section S2 in Multimedia Appendix 1).

Medical-Blocks stores data files and information in its own internal system (SQL server and volume files in Figure 3). Storing the data separately allows modification of data such as anonymization and conversion without altering the original data in the institution's system. The platform provides permanent storage of data prepared for research, which makes the data easily accessible for future research and, therefore, lowers the effort of data collection and preparation. This is in line with the FAIR data principles [39]; that is, findability, accessibility, interoperability, and reusability. Furthermore, the importation to Medical-Blocks lowers the number of requests to the institution's systems to the minimum, which is only accessed during data exploration and import.

Data Analysis

Medical-Blocks allows the analysis of stored data through metadata. Metadata becomes available through analysis blocks that automatically classify and label newly stored data upon import or by manual triggering. Such metadata could be, for instance, the type of disease or the imaging sequence, which is described further in section S3 in Multimedia Appendix 1. As the analysis depends on blocks and the modularity of Medical-Blocks allows the integration of new blocks (section S2 in Multimedia Appendix 1), the type of analysis performed, and therefore the metadata, is user- and project-specific. If an automatic extraction through blocks is not possible, metadata can also be added by the user manually. Data can also be visualized and inspected using the built-in viewers in the platform (eg, image viewer for images).

The metadata provides a research-friendly summary of the available data via a dashboard. This summary might facilitate the creation of potential cohorts for research, which is often a time-consuming process. Therefore, metadata offers the potential to explore the available data in a more research-driven manner. Such exploration is usually not provided by clinical systems, which rarely come with features that facilitate research, as they function at the level of individual patients rather than cohorts.

Data Sharing

Data sharing is one of the core features of Medical-Blocks. A built-in file hosting service via the cloud permits sharing of data, similar to well-known file hosting services such as Dropbox. The extent of sharing is freely configurable by providing individual users, groups of users, and even users from other institutions access to the cloud. Therefore, Medical-Blocks meets the requirements of biomedical research, where collaboration is often key to success.

The data can be shared on two levels: (1) sharing of metadata and (2) sharing of full data. The sharing of metadata allows the exchange of summaries of the available data based on the data analysis performed in Medical-Blocks. Therefore, researchers can explore the available data without sharing the actual underlying data. In research involving multiple groups and multicenter research, sharing metadata allows exploring potential collaborations regarding aspects such as data set size and data composition. As only metadata are shared, the potential abuse of data is prevented. As soon as all stakeholders agree, Medical-Blocks then allows researchers to exchange the full data that underlies the metadata.

Design Principles

The design of Medical-Blocks adheres to five principles: (1) simplicity, (2) flexibility, (3) modularity, (4) scalability, and (5) security.

Simplicity and Flexibility

Medical-Blocks is accessible via a web UI, which allows researchers to interact with various data formats available at health care institutions within one interface. Domain knowledge regarding clinical systems and access to software specific to data formats (eg, PACS use and access) is not required for researchers. Furthermore, the web UI makes the platform agnostic to specific hardware and operating systems requirements.

Metadata simplifies the exploration of potential cohorts for research through a dashboard view of the UI. This contrasts with accessing different clinical systems to search for potential cohorts, which can be a tedious process depending on the number of clinical systems involved. Beyond the dashboard, technically versed users can also use the GraphQL playground for exploration (section S4 in Multimedia Appendix 1).

Data sharing and access to data are further facilitated by standalone sync applications that can be installed on PCs, which

reduces interactions with the web UI and allows files to be uploaded to Medical-Blocks via the file explorer. Their functionality is very similar to well-known file hosting services; that is, shared data are directly synchronized to the file system and are accessible via the file explorer of the operating system. There are two versions of the sync application: a full version (MB-Sync) and a lightweight version (MB-SyncLight). The lightweight version works only unidirectionally; that is, data are only synced from the platform to the client. This also allows sharing of data with users who are not registered users of Medical-Blocks by providing a token for access. The full version works bidirectionally; that is, data can be synced from Medical-Blocks to the client, and vice versa. The sync applications are available for the operating systems Windows, macOS, and Linux. Details of the technical implementation are provided in section S5 in Multimedia Appendix 1.

Medical-Blocks offers various features that facilitate project management, as synchronizing the communication between multiple researchers and keeping track of the current state of a research project are often cumbersome. This is further complicated if multiple institutions and researchers are involved in multiple projects. Medical-Blocks facilitates project management through a communication, notification, and activity logging system. Users can access the status of a project and review what other users have been doing in the project, if new data are available, among others. Using the communication system, users can communicate with each other and with the teams to which they are assigned.

Modularity

Medical-Blocks is modularizable to adequately cope with the complexity of the information technology (IT) ecosystems of modern hospitals, such as multiple vendors, different APIs, and security restrictions. Individual patient data are typically stored in various systems at an institution (eg, clinical, laboratory, and radiology). To obtain an entire view of the electronic medical record of a patient, the data needs to be pooled from these individual systems, which can be a cumbersome process for researchers because of the different interfaces to access the systems. Medical-Blocks simplifies access to data by using blocks tailored to connect to the clinical systems through their APIs. These blocks allow a flexible adaptation of Medical-Blocks to the IT ecosystem of the health care institutions and for different research projects. Depending on the type of research project, a block can be integrated to access data from a previously unconnected clinical system.

Scalability

Medical-Blocks is intended for use at various levels of operations. The first level is the use as a cloud instance or local instance at a health care institution without any connection to clinical systems; that is, data are imported manually through the web UI. The next level is the connection to the clinical systems of the health care institution. Further levels are then the connection to other Medical-Blocks; that is, from institution to institution and to the cloud. The connection to the clinical systems is possible in two ways: (1) by directly connecting a Medical-Blocks instance and (2) by using MB-Connect. Connecting Medical-Blocks necessitates a local instance running on a server, which may not always be desired and feasible. Therefore, MB-Connect, a software plug-in, can be used at health care institutions as a bridge to a cloud instance of Medical-Blocks (section S6 in Multimedia Appendix 1). Therefore, the use of Medical-Blocks can be adjusted depending on the requirements of the health care institutions and the size of the research collaboration.

Scalability is directly linked to the available resources Medical-Blocks runs on. To ensure scalability, Medical-Blocks leverages operating system virtualization; that is, the main core of Medical-Blocks is designed as containers that store and run their corresponding functionality. Using Kubernetes (Cloud Native Computing Foundation), the containers can be scaled according to the live demand of resources. Depending on the estimated maximum resource requirements, Medical-Blocks can run on low-cost hardware such as Raspberry Pi (Raspberry Pi Foundation) to enterprise products such as Google Cloud (Google Inc). Hardware can be locally installed, virtualized, and cloud-based. Easy scalability is especially important as big data and data-driven methods are becoming more prevalent in biomedical research [3,5,10], which will result in an increased demand for the storage and management of data. Furthermore, having the possibility of running instances at a smaller scale allows the inclusion of smaller institutions and their data owing to relatively flexible hardware requirements.

Security

Security is a key requirement for software that interacts with health care data. The security and privacy of health care data are usually regulated at the national or international level; for example, in the United States through the Health Insurance Portability and Accountability Act of 1996 and in the European Union through the General Data Protection Regulation. Therefore, software interacting with health care data must adhere to the regulations of the countries in which the software is being deployed. In Switzerland, the management of health care data for research requires at least three main security features (Ordinance on Clinical Trials in Human Research 810.305; Article 18): (1) restricted access, (2) user rights, and (3) traceability of operations.

Medical-Blocks provides restricted access, user rights, and traceability of operations performed on data. Restricted access is enforced by a secure log-in to the platform (section S7 in Multimedia Appendix 1). Rights can be assigned at the user level to prevent unwanted import, access, and modifications. All operations (ie, import, access, and modifications) performed on the data by the system and users are logged and saved for a potential audit. Therefore, Medical-Blocks adheres to the common legal and ethical regulations in biomedical research. It must be noted that such features are not necessarily implemented in clinical systems (eg, clinicians often have access to all patients without specific restrictions).

The user management of Medical-Blocks allows to define roles from the level of projects to teams, down to the level of single users. The principal investigator can define the data, teams, and users involved in a project. To simplify user management, teams of users can be formed with team-wide rights, which can be assigned to projects. Rights can also be defined at the user level;

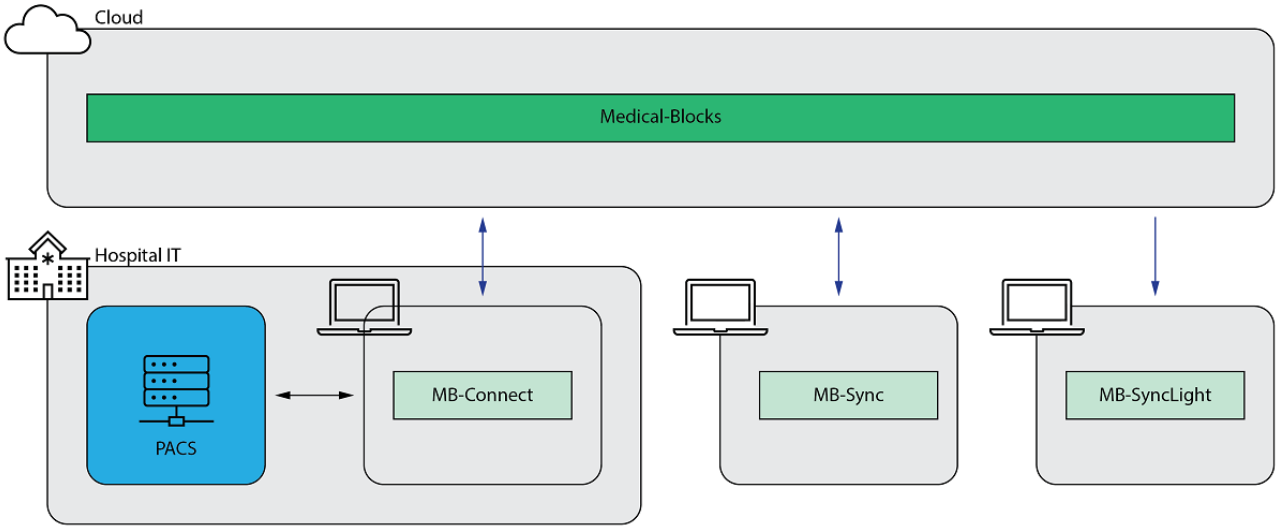
for instance, clinicians can access deanonymized data, whereas researchers can only access anonymized data. Generally, data imported into Medical-Blocks gets assigned to the user who performs the import, which is the first measure to prevent abuse of data as it is only accessible by this user. Furthermore, data exploration and import are restricted to specific users to prevent unauthorized access to clinical systems. Users can be restricted to only see metadata instead of the true underlying data. Similar to exploration and import, data sharing is also restricted to specific users.

Medical-Blocks at the Inselspital

We present Medical-Blocks on the use case of medical imaging and how the platform is currently being used at the Inselspital (University Hospital of Bern, Bern, Switzerland). This use case encompasses mostly research in the field of quantitative medical image analysis, involving the processing of medical images using AI developed to extract quantitative imaging biomarkers for monitoring of treatment response and as an outcome measure. To do so, researchers need to have access to medical images acquired in daily clinical routine to develop and evaluate AI methodologies on real-world data. To date, this process has been tedious because it involves accessing the PACS of the hospital to query and retrieve medial images of potential cases in the DICOM format. Subsequently, researchers had to anonymize and convert the DICOM images to a regulatory-complying and research-friendly format. Furthermore, the medical images had to be linked to complementary (clinical) information such as demographic variables and diagnoses extracted from other clinical systems.

Medical-Blocks was integrated into the IT imaging ecosystem at our hospital (Figure 4). We opted to use Medical-Blocks as a cloud instance, which does not necessitate the installation of Medical-Blocks at the hospital but, in turn, necessitates that all data contained in Medical-Blocks must be anonymized to comply with the legal regulations of the responsible authorities. Therefore, we use MB-Connect to access the unanonymized data of the PACS, anonymize the data, and send the data to Medical-Blocks in a semiautomatic manner. MB-Connect was integrated into an in-house DICOM viewer as a plug-in (MB-Viewer; section S6 in Multimedia Appendix 1). Upon import, the users of Medical-Blocks can access the data via the web UI from anywhere. Furthermore, the data can be synchronized and shared with any computer by two synchronization applications: MB-Sync and MB-SyncLight.

Figure 4. Overview of Medical-Blocks as used at our hospital. Owing to legal regulations, the picture archiving and communications system cannot be directly connected to Medical-Blocks as patient-identifying would be shared over the internet. Therefore, we use the MB-Connect plug-in within an in-house Digital Imaging and Communications in Medicine viewer for uploading anonymized medical images to Medical-Blocks. Users of Medical-Blocks can access the data via the web user interface. Synchronization of data to the user's file systems is possible by two synchronization applications (MB-Sync and MB-SyncLight). IT: information technology; PACS: picture archiving and communication system.



Results

We present the results of the development of Medical-Blocks separated into the main features of data exploration, data management, data analysis, and data sharing.

Data Exploration

The dashboard with a summary of the metadata is presented to the user upon log-in into Medical-Blocks (Figure 5). The number of cases, studies, and series available become directly visible to the user. It also presents summaries on anatomical regions, sequence, and the type of pathology. Furthermore, the dashboard presents the latest activities within the project to the user. Moreover, only the metadata and activities of the project or projects to which the user has access are shown.

Exploring available data in the clinical systems at the institution and in Medical-Blocks is possible in the Query/Retrieve section (Figure 6). Querying of data is similar to that in commercial PACS software: querying by patient name, patient ID, accession number, date of birth, study description, unique identifiers, and image properties. The query can be refined by date, image modality, and image properties options. A query will list all results that match the search criteria. If Medical-Blocks is not directly connected to the PACS of the hospital, it only retrieves results from the data contained within the platform. If Medical-Blocks is connected to a PACS, a query lists the results

from the PACS that can be explored and imported without the need of having access to the actual clinical systems (the PACS viewer in this case). This feature can be limited to certain users of Medical-Blocks to prevent abuse. Medical-Blocks further ensures that all queries and imports are logged.

Figure 5. Dashboard of Medical-Blocks shown upon log-in to the platform. The dashboard visualizes the metadata; that is, it provides a concise summary of the available data.

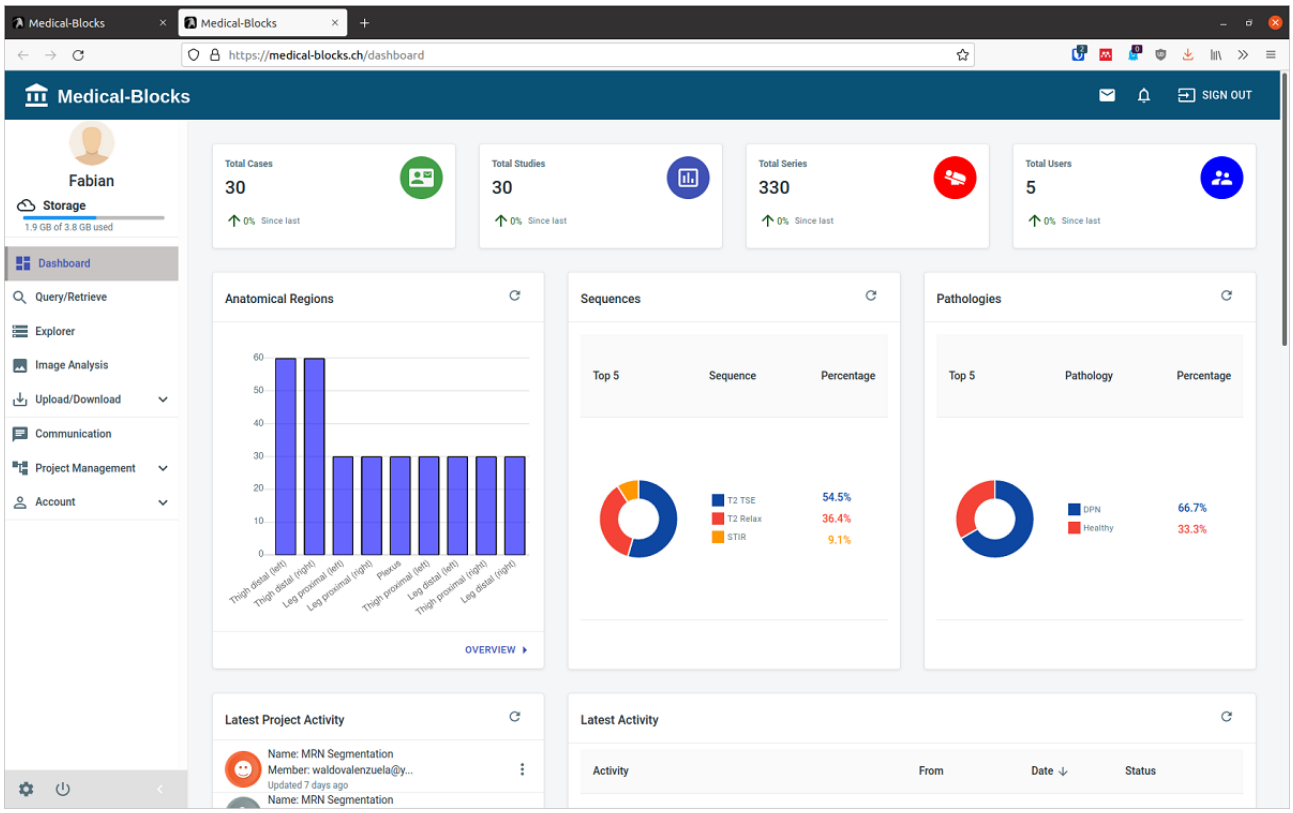


Figure 6. Data exploration through the Query/Retrieve section. Upon entering a patient name, the available data in Medical-Blocks search for matching entries, which are listed in the query results. The query can be refined by restricting it to a certain date or a range of dates, imaging modalities, and image properties.

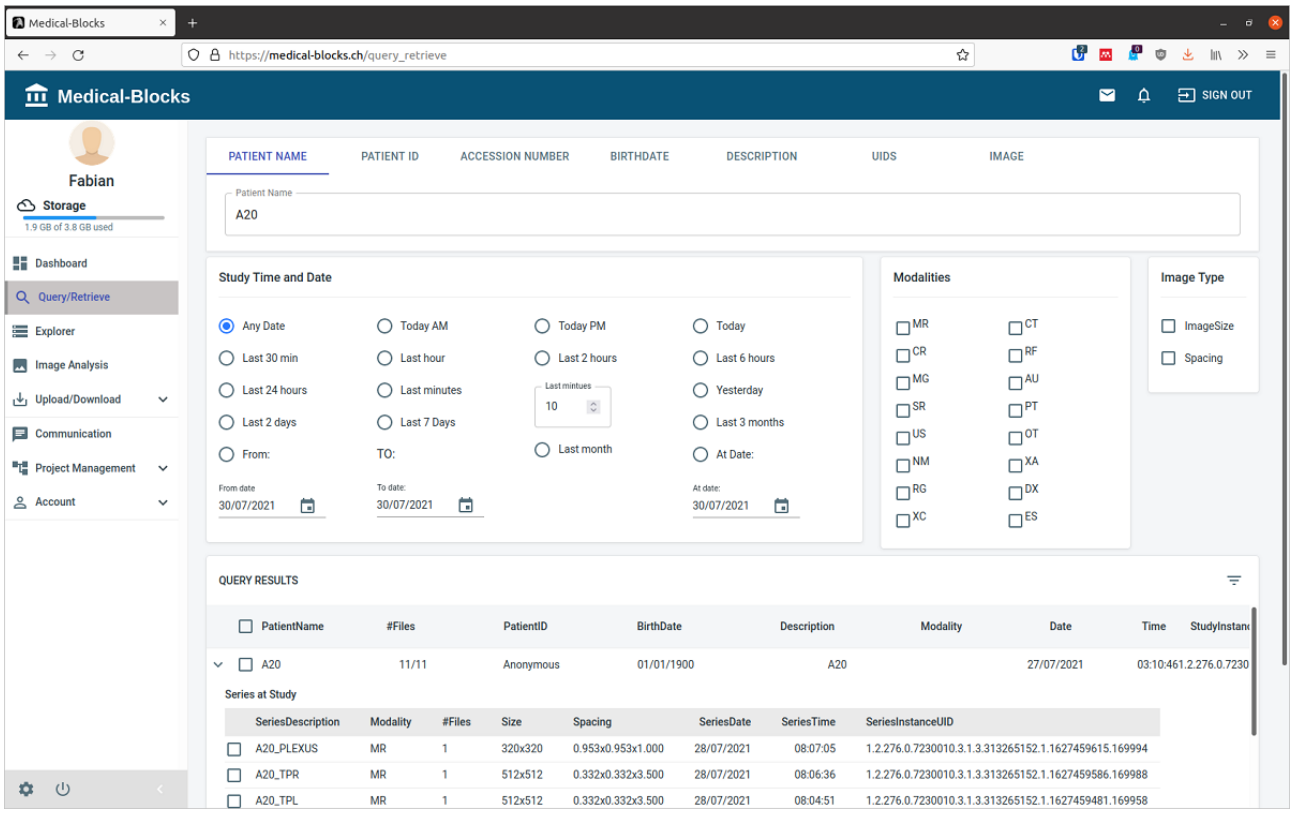

Data Management

The Explorer section of Medical-Blocks allows the inspection of available data in the platform (Figure 7). The Explorer section works like explorers known from today's operating systems. It allows the user to rearrange files into folders, copy files, cut files, paste files, and remove files. The explorer is agnostic to the type of data; that is, electroencephalography or text documents are also displayed in the Explorer section. Furthermore, the explorer has a drop feature that allows users to import a file directly in the Explorer section, facilitating the way of moving files to Medical-Blocks for sharing.

Import of data to Medical-Blocks is possible through the Query/Retrieve section (if Medical-Blocks is connected to a clinical system), MB-Connect, MB-Sync, and manually. The manual Upload/Download section (Figure 8) extends the import capabilities of the explorer to multifile import. The file or files to be imported can be selected from the file system of the computer by a file system dialogue or directly imported by dropping to the Upload/Download section. Once imported, the files become visible in the explorer.

Figure 7. Overview of the available data in Medical-Blocks through the Explorer section. The explorer allows files to be managed in a manner similar to that of file explorers in current operating systems. Here, 30 folders containing image data, 1 CSV file, and 8 electroencephalography files are present.

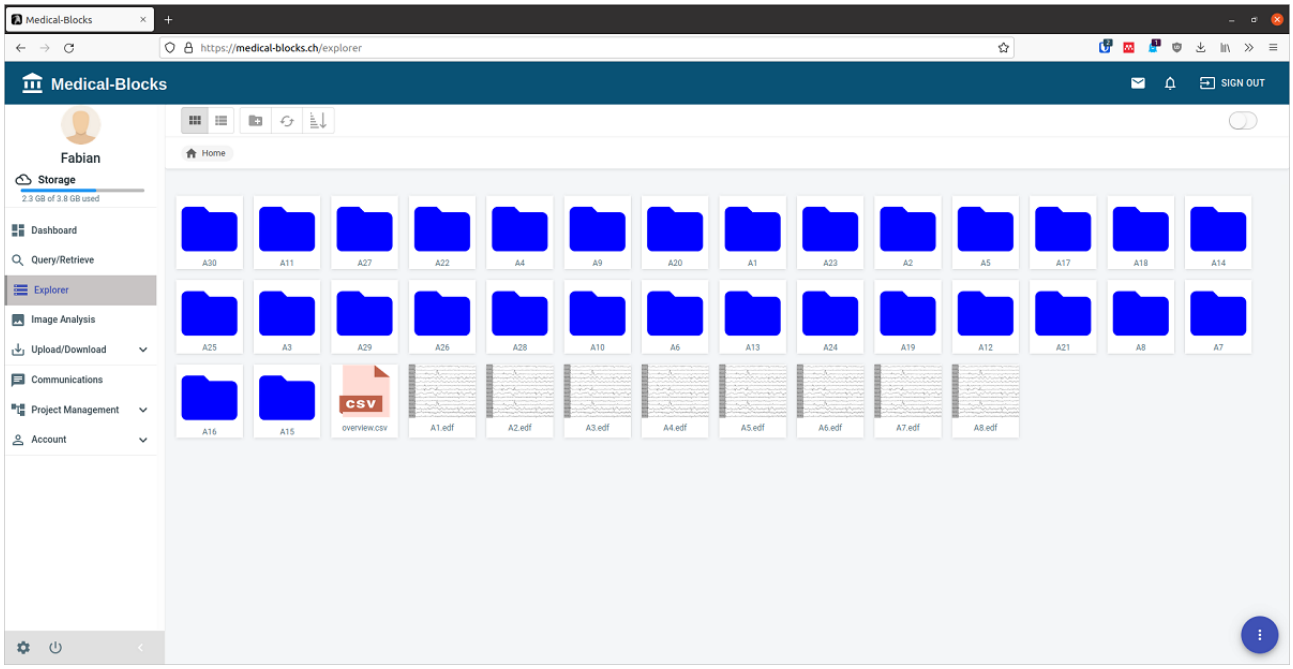

Figure 8. Manual import of data to Medical-Blocks. Files to be imported can be selected using a file system dialogue or by dropping the files to the user interface of Medical-Blocks.

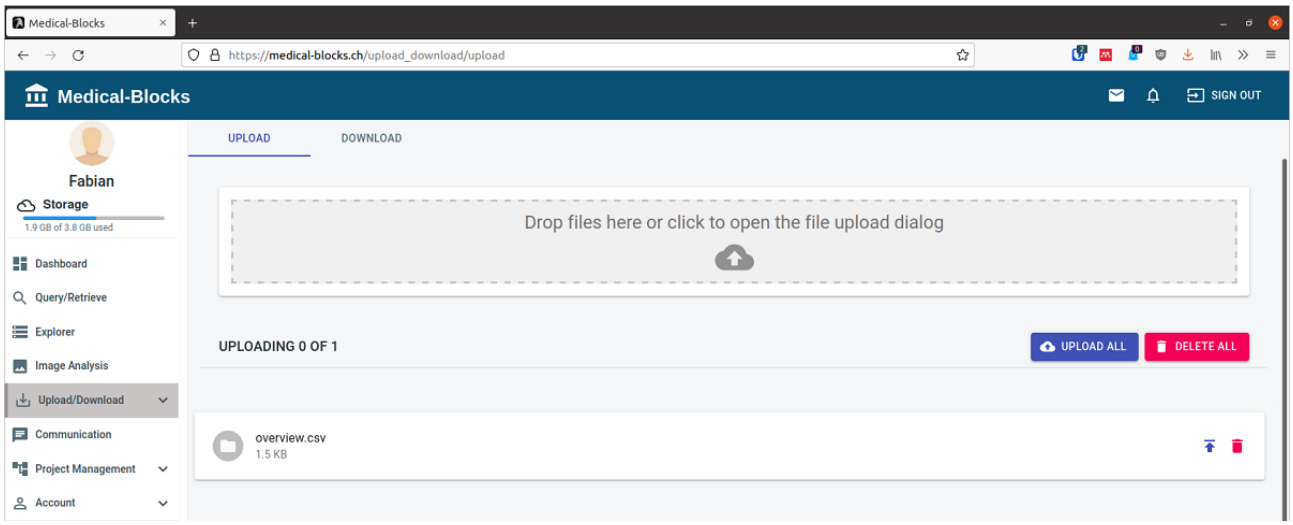

Data Analysis

Medical-Blocks presents a summary of the data available in the form of metadata in the dashboard of Medical-Blocks (Figure 6), which allows a high level of automation in the data analysis. Furthermore, the built-in viewer allows, for example, the inspection of medical images directly via the web UI (Figure 9). A section for manual classification appears when selecting a file (Figure 10). This section allows to correct wrong classifications and to add user-defined classifications that are not automatically extracted by the blocks.

Figure 9. The built-in viewer allows to inspect the different image slices of a medical image within Medical-Blocks.

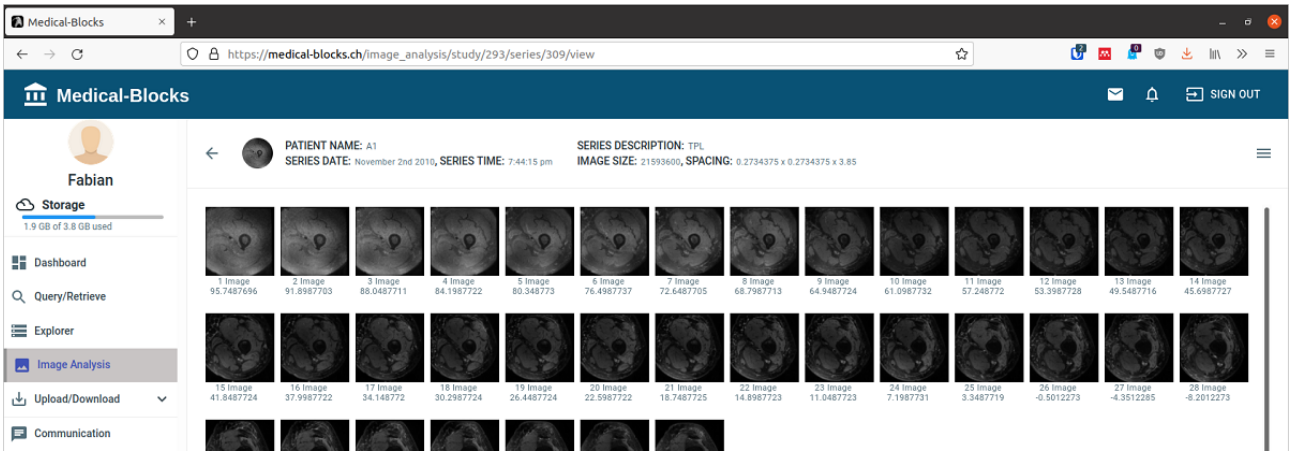

Figure 10. The process of manually classifying data in Medical-Blocks. By selecting a medical image, it can be classified according to anatomical region, image focus, investigated side, pathology, and sequence.

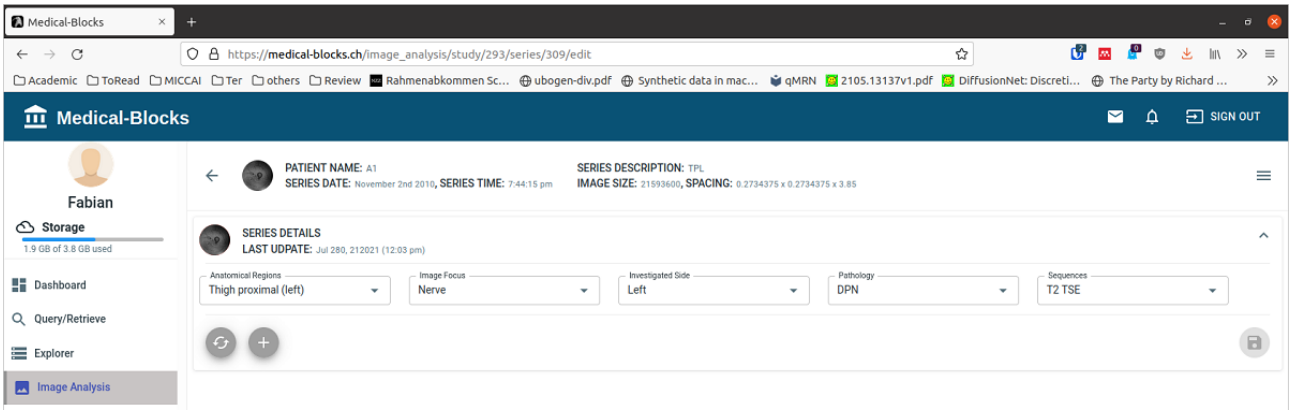

Data Sharing

Sharing of data via Medical-Blocks is possible in multiple ways. First, users see the metadata of the available data in Medical-Blocks on a project-level in the dashboard by default (Figure 5). Second, the owner can provide access to the data to other users or projects in a corresponding dialogue of the explorer or by generating a share link, as shown in Figure 11. As soon as access rights are granted, data will appear in the explorer of the other user or users. Third, synchronization applications MB-Sync and MB-SyncLight can be used for sharing.

Using the synchronization applications, data from Medical-Blocks can be synchronized to any computer's file system, as shown in Figure 12. Access to data can be granted on a folder level in the explorer; that is, by sharing a link to a user of the synchronization application (Figure 11). Data access can also be granted to people who are not users of Medical-Blocks by generating a SYNC CODE (Figure 12). This code can be used with MB-SyncLite to retrieve data from Medical-Blocks without being a user of the platform.

Figure 11. The sharing of data in Medical-Blocks. (A) The owner of the data within the explorer gives read access to the data to another user (Waldo Valenzuela) and a project (MRN Segmentation). The files will now appear in the explorer dialogue of the user Waldo Valenzuela and for all users assigned to the project MRN Segmentation (with appropriate user rights to view data). (B) Share links for direct sharing of data can be automatically generated.

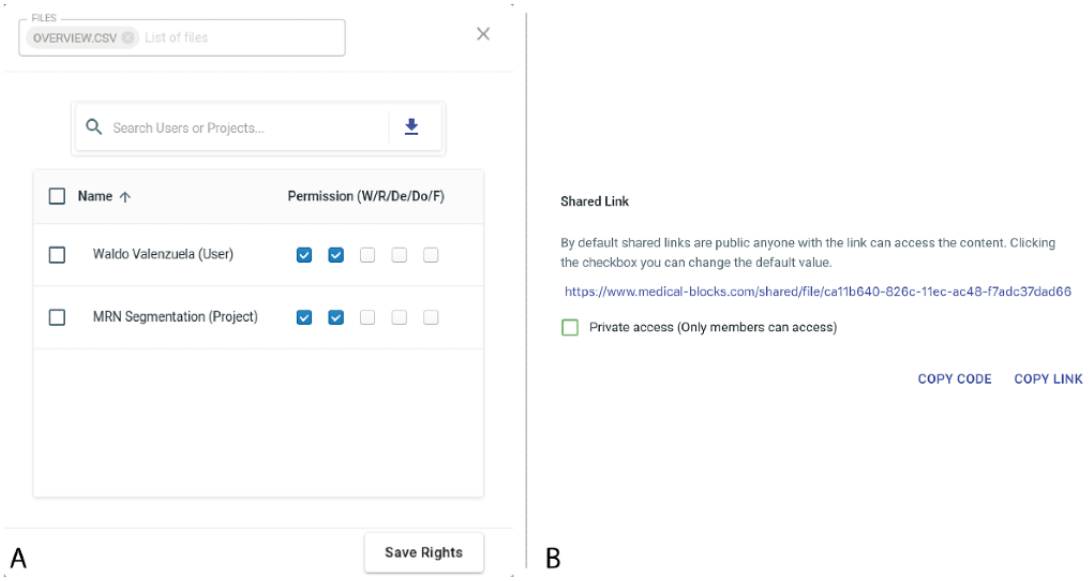

Figure 12. The synchronization applications MB-Sync (A) and MB-SyncLite (B). For MB-Sync, the user uses the log-in credentials of Medical-Blocks and selects which data to sync and to which location. For MB-SyncLite, a person receives a synchronization code (SYNC CODE) that grants access to a specific folder (here HGGB). In both cases, the data are synced to the file system and are accessible via the explorer of the operation system.

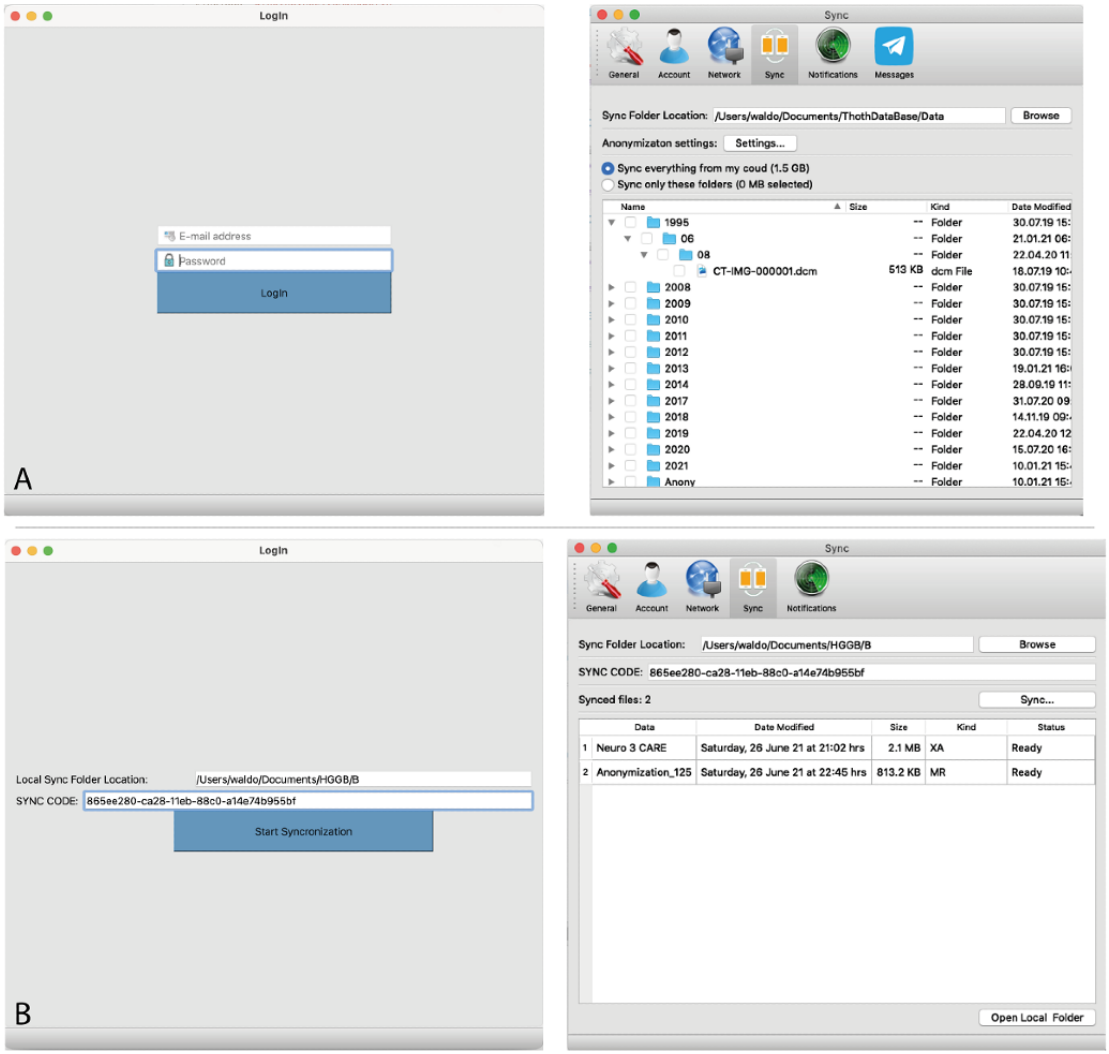
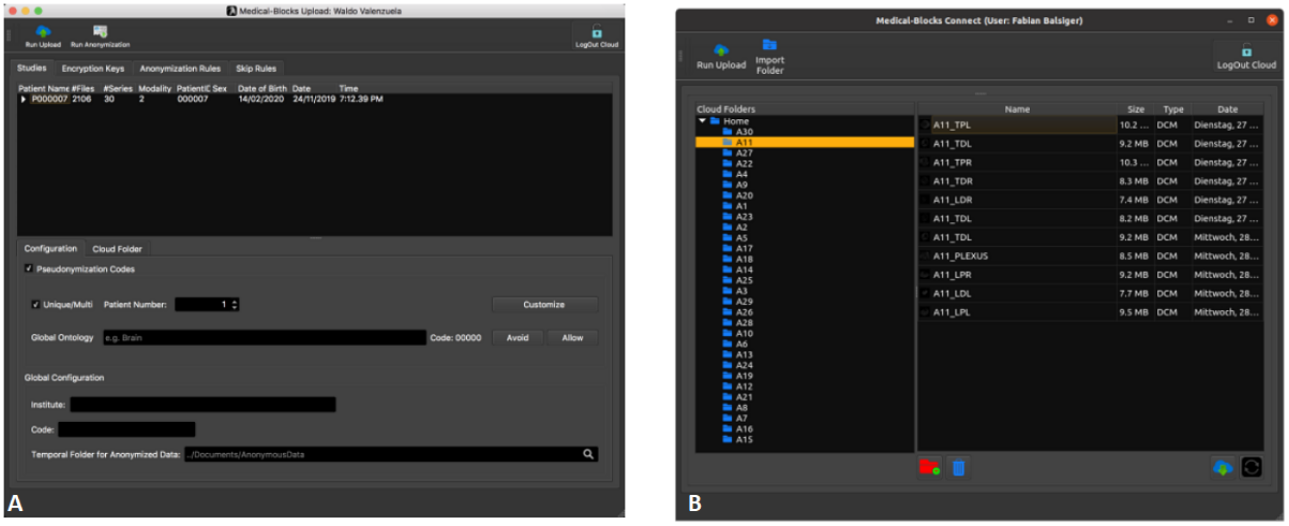


MB-Connect

MB-Connect is used to import data to the cloud instance of Medical-Blocks (Figure 13). MB-Connect was integrated as a plug-in into an in-house DICOM viewer called MB-Viewer (section S6 in Multimedia Appendix 1). By default, the DICOM files to be imported are anonymized using a predefined template (eg, the date of birth is set to January 1, 1900). If required, the user can edit and modify the anonymized information, that is, which DICOM tag fields will be anonymized according to what rules, through the anonymization dialogue (Figure 13A). For the import to Medical-Blocks, the user can select the directories to which the medical image or images will be imported (Figure 13B). By default, the medical images will be uploaded to the user's home directory, as with the Upload/Download section in the web UI (Figure 8). The directories on Medical-Blocks can also be directly modified within the upload dialogue such as editing the directory name as well as creating and deleting directories. Anonymization is mandatory before the upload of medical images to Medical-Blocks such that no patient-identifying information is being uploaded to the cloud instance of Medical-Blocks.

Figure 13. The anonymization (A) and upload (B) dialogues of MB-Connect integrated into our in-house Digital Imaging and Communications in Medicine (DICOM) viewer MB-Viewer. Before the upload of medical images to Medical-Blocks, the DICOM tag fields need to be anonymized by using the dialogue shown (A). The user specifies to which directories on Medical-Blocks the medical images are uploaded to by using the dialogue shown (B).



Discussion

We conceptualized and devised Medical-Blocks to enhance the exploration, management, analysis, and sharing of data in collaborative biomedical research. The platform can be connected to clinical systems for direct exploration of data for potential research. Data imported into and managed by Medical-Blocks are available to other researchers for further analysis. Visualization and classification of data allow the formation and analysis of potential cohorts for research. As Medical-Blocks can run as a cloud application, sharing of metadata and data with collaborators is easily possible, enabling multicenter research. An ecosystem of complementing software such as MB-Connect and synchronization applications MB-Sync and MB-SyncLight further extend the applicability and usability of Medical-Blocks. Medical-Blocks is accessible for use on the web [40]. New users must register, and access is granted upon reasonable request.

Data analysis and data sharing are two key features of Medical-Blocks. The automatic analysis of data allows the convenient exploration of data to form new cohorts for research through metadata. This metadata allows further exploration of potential collaborations with other researchers by sharing the type and extent of data available without sharing the underlying data. Once cohorts are defined, the underlying data can easily be shared with collaborators. The synchronization applications MB-Sync and MB-SyncLight make sharing and synchronizing data to the file system straightforward.

By connecting the medical systems of a health care institution, medical data become accessible to researchers who usually do not have direct access to such systems. This allows the exploration of available data for potential research without interfering with the clinical workflow. By managing the data with Medical-Blocks, the data are handled in a standardized manner independent of proprietary data formats. Researchers are likely to spend less time on converting and managing data because the platform can automate such processes.

The integration of computational blocks into Medical-Blocks is a feature that is currently lacking. In the use case of medical imaging, computational blocks can, for instance, leverage AI for medical image analysis. Such computational blocks can be used in different ways to classify data for metadata and research purposes. For the classification of metadata, AI can automatically predict the investigated side, which would further automate the data analysis if not simply possible through DICOM tag fields. For research purposes, AI is used for medical image analysis such as segmentation [41,42], brain morphometry [43], and reconstruction [44,45]. By executing such blocks when new data are synchronized from the PACS and when a user imports new files, AI can be tested on real clinical data acquired in everyday clinical practice. Therefore, a novel AI can be

deployed in a shadow-mode–like environment for the continuous validation of AI [46].

A major hurdle in developing Medical-Blocks was its integration into the hospital IT infrastructure. Directly connecting Medical-Blocks to the PACS of the hospital underlies legal restrictions related to cloud-based data transfer. Running Medical-Blocks as a local instance and connecting it to the PACS was possible without any problems, as the use of MB-Connect highlights. Nevertheless, to develop and leverage data sharing—a key feature of the platform—we opted to use Medical-Blocks as a cloud instance. We believe that this was the right trade-off; that is, fully leveraging data sharing while restricting the connection to clinical systems. This setting also shows that Medical-Blocks can be used without having a local instance running, but only by using MB-Connect integrated into a DICOM viewer for the data exploration and upload of data from the PACS to a cloud instance of Medical-Blocks. This setting might further make it simple to convince smaller institutions to participate in a multicenter research project, as no local instance of Medical-Blocks needs to be run in the institution's IT infrastructure.

We will address several shortcomings with the next release of Medical-Blocks. First, we aim to certify the platform such that it can manage unanonymized medical data in the cloud; that is, a certification as a medical device. A direct connection to the clinical systems at our hospital without intermediate software such as MB-Connect might then be possible. Having unanonymized data available for multicenter research might benefit the classification, cohort exploration, and ultimately the conclusions of the research projects. Second, we aim to apply Medical-Blocks beyond the use case of medical images. A first step in this direction was already made by starting a project involving electroencephalography data, but a more diverse set of types of data would be favorable for research involving multiple medical disciplines. Third, the integration of computational blocks involving AI is a key strategy for future releases (section S2 in Multimedia Appendix 1). Researchers should be able to add their AI as blocks to the platform and run these blocks directly on the newly imported data. Such a possibility could hopefully facilitate the application of novel AI in shadow mode before translating it to clinical practice. Finally, we believe that the ongoing and increasing use of Medical-Blocks will likely reveal several aspects we currently do not think about but are key to better user experience and more accurate and faster biomedical research.

In conclusion, we introduced Medical-Blocks that facilitates biomedical research by providing a centralized platform to interact with medical data in collaborative research projects. Medical-Blocks simplifies access to and management of medical data. Data can be analyzed swiftly to form cohorts for research. Finally, data can be shared among researchers. The modularity of Medical-Blocks makes it possibly applicable to various types of biomedical research involving heterogeneous medical data.

Abstract

Background: As health care becomes more fragmented, it is even more important to focus on the provision of integrated, coordinated care between health and social care systems. With the aging population, this coordination is even more vital. Information and communication technology (ICT) can support integrated care if the form of technology follows and supports functional integration. Health TAPESTRY (Teams Advancing Patient Experience: Strengthening Quality) is a program centered on the health of older adults, supported by volunteers, primary care teams, community engagement and connections, and an ICT known as the Health TAPESTRY application (TAP-App), a web-based application that supports volunteers in completing client surveys, volunteer coordinators in managing the volunteer program, and primary care teams in requesting and receiving information.

Objective: This paper describes the development, evolution, and implementation of the TAP-App ICT to share the lessons learned.

Methods: A case study was conducted with the TAP-App as the case and the perspectives of end users and stakeholders as the units of analysis. The data consisted of researchers' perspectives on the TAP-App from their own experiences, as well as feedback from other stakeholders and end user groups. Data were collected through written retrospective reflection with the program manager, a specific interview with the technology lead, key emailed questions to the TAP-App developer, and viewpoints and feedback during paper drafting from other research team members. There were 2 iterations of Health TAPESTRY and the TAP-App and we focused on learnings from the second implementation (2018-2020) which was a pragmatic implementation scale-up trial using the Reach, Effectiveness, Adoption, Implementation, and Maintenance framework at 6 primary care sites across Ontario, Canada.

Results: TAP-App (version 1.0), which was iteratively developed, was introduced as a tool to schedule volunteer and client visits and collect survey data using a tablet computer. TAP-App (version 2.0) was developed based on this initial experience and a desire for a program management tool that focused more on dual flow among users and provided better support for research. The themes of the lessons learned were as follows: iterative feedback is valuable; if ICT will be used for research, develop it with research in mind; prepare for challenges in the integration of ICT into the existing workflow; ask whether interoperability should be a goal; and know that technology cannot do it alone yet—the importance of human touch points.

Conclusions: Health TAPESTRY is human-centered. The TAP-App does not replace these elements but rather helps enable them. Despite this shift in supporting integrated care, barriers remained to the uptake of the TAP-App that would have allowed a full flow of information between health and social settings in supporting patient care. This indicates the need for an ongoing focus on the human use of ICT in similar programs.

integrated care; information and communication technology (ICT); program evaluation; older adults; primary care

Introduction

Background

Currently, health care is provided by multiple providers across various disciplines and through different organizations. With patients receiving care from multiple people, it is crucial to have a system that can integrate providers and information horizontally and vertically across the health care system. The concept of integrated care is to deliver coordinated care that brings together services from across health and community-based social systems [1]. This type of care also aims to close the gap between health and social care [2] as it is seen as a way to bridge the gap among acute care, primary care, and community and social services [3]. Evidence shows that integration, coordination, and person-focused care are core features by which primary care achieves better population health outcomes [4]. To effectively integrate care, providers must ensure the continuity of sharing information about patients while allowing patients to remain at the center of their own care [5]. Therefore, this type of care relies on infrastructure to support the bridging of these traditionally siloed services and the centering of the patient in any intervention.

Information and communication technology (ICT) is an important enabler that supports the delivery of integrated and coordinated primary care [6,7]. ICT includes any health information technology that aids in the collection of health information and its processing, storage, and exchange [8]. There is evidence that ICT can support integrated care systems by fostering greater care efficiency and enhancing information exchange [9-11].

With the growing population of older adults in Canada and globally, the need to provide care that wraps around patients is even more important. In shifting to more integrated care, the changes that organizations make will need to be supported using all available resources. ICT can connect users across organizations and disciplines to share information. Appropriate communication to enhance these connections is critical for successful integrated care systems [5]. However, there are knowledge gaps in the literature describing the processes of introducing ICT into existing health and social care settings and in understanding how ICT changes work and information flows. Given the challenges that the introduction of anything new can present when incorporated into existing systems, careful planning and evaluation of these infrastructures are necessary.

Health TAPESTRY (Teams Advancing Patient Experience: Strengthening Quality) offers an opportunity to describe the development and evolution of ICT as part of a pragmatic complex intervention rooted in primary care. The program creates connections among trained community volunteers, interprofessional primary health care teams, novel technology, and community engagement and connections through improved system navigation [12,13]. The aim is to help older adults stay healthier for longer in the places where they live. A total of 2 evaluations have been completed through a randomized controlled trial. The study showed that patients who received Health TAPESTRY walked more (mean difference 1.13, 95% CI 0.31-1.95), had fewer hospitalizations (incidence rate ratio 0.37, 95% CI 0.18-0.77), and saw their primary care team more (mean difference 1.52, 95% CI 0.84-2.19) [12,13].

The key ICT within Health TAPESTRY is the Health TAPESTRY app (TAP-App), a web-based application that has 3 interfaces (briefly described below). In Health TAPESTRY, trained volunteers conduct visits in older adults' homes to discuss the clients' health and life goals, while identifying their health and health-related social needs using validated tools or surveys adapted by the research team. These surveys were administered by volunteers, facilitated by and recorded in the TAP-App on tablets through the volunteer interface. During the visits, the volunteers had the opportunity to answer client questions and provide relevant information on community programs and services that may be of interest to the client. After visits, volunteers write *social context* information on the TAP-App about their own perspectives of the client. Volunteers were also invited to write narratives on the TAP-App, which were stories of their own experiences with the potential to be used for research or program development purposes, as needed. A volunteer coordinator at each site handled the management and scheduling of volunteer and client visits through the TAP-App (ie, the volunteer coordinator interface).

The TAP-App creates an automated PDF TAP-Report that is shared with the huddle team at the patient's primary care site through a huddle interface. The huddle is a subgroup of people within the primary care team who meet weekly to discuss with clients in the program. The huddle is composed of at least 3 providers from different disciplines (eg, physician assistant, occupational therapist, nurse, and physician). The huddle members view TAP-Reports from their own interprofessional lens and work together to create individualized plans of care for clients based on the information collected. The huddle teams are then able to document a summary of their review and plan of action on each TAP-Report through the huddle interface. They also have the option to send volunteers back to clients through the huddle action checklist, which contains a list of options for engaging volunteers in the plan of action, including discussing changes in clients' health needs, planning the achievement of goals, or connecting clients to community-based health and social services. These recommendations are communicated to volunteers via volunteer coordinators who receive this information on the TAP-App. After volunteers follow-up with clients, they communicate any new information back to the huddles through the Follow-Up Report, another automated PDF report created by the TAP-App. A detailed description of Health TAPESTRY is in the published protocol [12].

Objectives

In this paper, we describe the development and evolution of a specific ICT in Health TAPESTRY, the TAP-App. This story

is presented as a case study to share the lessons learned during its development, evolution, and implementation.

Methods

Design

The case under study is the TAP-App itself, and the units of analysis are the perspectives of end users and stakeholders [14]. We used the Stake understanding of case studies [15], including a focus on qualitative results, involvement of researchers' impressions as key sources of data, detail provided to assist in naturalistic generalization, and lack of a specific start or end time of data collection and analysis. Although our case was partly bounded by the start and end dates of the randomized controlled trial that was conducted (described elsewhere), the TAP-App went beyond these temporal boundaries; hence, we describe development and vision both before and after. The settings that bound our case were numerous and are described in the *Setting* section below.

Data Collection

The data in this study came from the direct perspectives of key members of the research and implementation team, who are also represented as authors in this paper. The lessons learned in this paper constitute the key themes from the team's perspectives in implementing the TAP-App in Health TAPESTRY. Specific data sources to understand how the TAP-App was implemented in its 2 phases were a written retrospective reflection from the program manager, an interview with the technology lead (facilitated by SD and JG), and key questions administered via email to the software developer.

Although the lessons learned in this paper came directly from the program team, their understanding of the implementation of the TAP-App was informed by the feedback that the team received from many other stakeholders and end users (including Health TAPESTRY clients, community volunteers, volunteer coordinators, primary care providers, and administrative or other primary care team members). This feedback came to the team via email, volunteer *lunch and learns*, volunteer narratives submitted via the TAP-App, and during verbal debriefs with volunteer coordinators. Furthermore, we gathered viewpoints and feedback from other research team members who developed and implemented the TAP-App at each of the 2 main stages. SD and JG collected this information and combined it with the direct observations of the research team to add detail and clarity to understanding the lessons learned in this work.

Data Analysis

Although there was no traditional qualitative data set for this study's data because of the structure of data collection, the project team members (ie, the authors and key informants) discussed lessons learned throughout and after project implementation. LL and SD developed the initial *Lessons Learned* section in this paper based on the key themes that continued to arise in these project conversations and their own perspectives as implementers. JG and SD then edited the lessons learned after collecting more information from key informants (ie, the interview with the project lead and key questions to the developer). Throughout this process, member-checking was continued, that is, feeding back the written lessons learned to the key informants, to ensure that the written representation fit their understanding of the process.

Methods to Improve Rigor

We used several methods to enhance rigor in this case study. We worked to enhance credibility and confirmability through triangulation of various data sources (ie, respondents), data collection methods, and individual interpreters of the data [16,17]. We further enhanced credibility by prolonged engagement of respondents while ICT was used in a multi-year program [16]. Finally, although this case study focused deeply on a specific ICT, we used a thick description that may aid in understanding the potential for transferability or naturalistic generalization of the results to other settings and ICTs [15,16].

Setting

The TAP-App was developed, hosted, and driven by an academic university department, McMaster University's Department of Family Medicine. The department includes subgroups—2 of which are devoted to information technology and research—and were the 2 areas of the department that managed the TAP-App. During the implementation of Health TAPESTRY–Ontario (2018-2020), which is the period of focus of this study, the TAP-App was used in 6 family health teams (FHTs) across the province of Ontario, Canada to support older adult clients. FHTs are primary health care teams that bring traditional family physician–led practices together with an array of interprofessional providers such as nurses, social workers, dietitians, pharmacists, and others [18]. Interprofessional providers in an FHT may be colocated or located at different sites. The FHTs, as well as the communities they serve, vary in size, with populations ranging from 2710 to 536,917 as of the 2016 Census [19,20]. In addition to its use by FHTs, as described above, the TAP-App was used by trained community volunteers working in clients' homes and by the organizations and individuals that supported both these volunteers and the communication exchange among elements. A national humanitarian charitable organization supported 4 of the 6 sites with 4 volunteer coordinators. A coalition of multiple agencies focused on community health supported the final 2 sites with 1 volunteer coordinator.

Development and Evolution of the TAP-App

TAP-App (Version 1.0)

The first version of the TAP-App was programmed in-house at McMaster University's Department of Family Medicine, using Java. The technology was still in active development at the start of implementation, which led to an iterative nature of development and the opportunity to integrate feedback from users. During the initial implementation of Health TAPESTRY that took place at just 1 FHT in Ontario (2014-2015), the technology was a single log-in webpage with different interfaces for volunteers and administrators (ie, volunteer coordinators and research staff) and for the 2 clinical sites within this FHT. The volunteer interface was where surveys for each client could be accessed during home visits. Upon completion, the automatically generated PDF TAP-Report was not shared with the primary care team via a huddle interface; instead, the

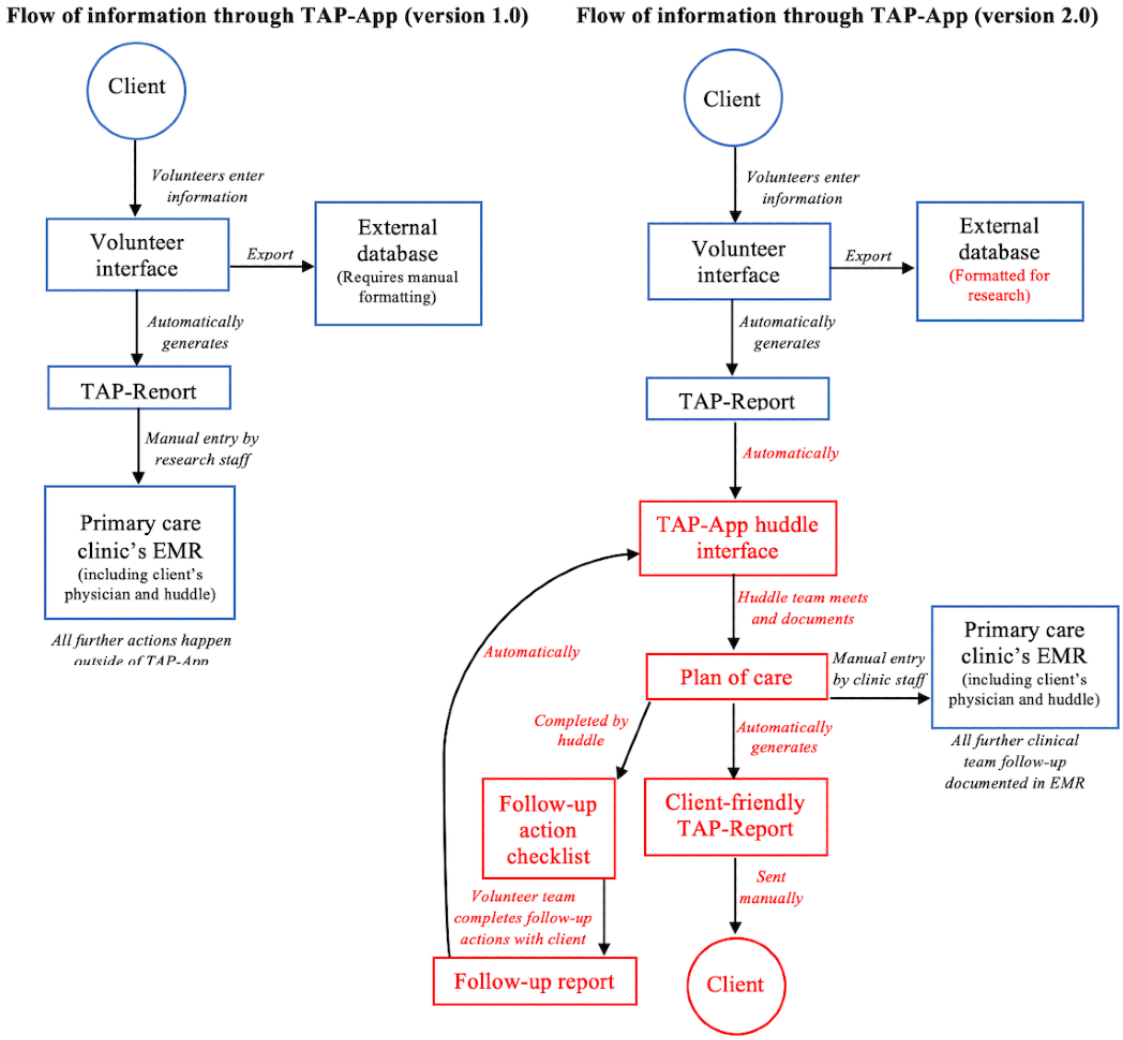
research staff uploaded the TAP-Reports to the clients' electronic medical records (EMRs) for the primary care team to review. Therefore, they also did not have the huddle action checklist, nor did volunteers have the follow-up visit or Follow-Up Report options, though volunteers did conduct preplanned 3-month follow-up visits which were not a part of the second implementation of Health TAPESTRY. As in the second version of the TAP-App, the volunteer coordinator interface held client and volunteer information but also had a scheduler for coordinating volunteer availability and visit times. The question data could be extracted from the TAP-App for research purposes, although it was not in the ideal format for data analysis.

TAP-App (Version 2.0)

Building on the initial Health TAPESTRY experience, the McMaster University Department of Family Medicine invested in a new iteration of the technology that would be supported on Research Enterprise Management of Information (REMI), a new multi-tenant software platform built using Java and Angular to facilitate collaborative research initiatives. The second large-scale implementation of Health TAPESTRY at 6 sites (2018-2020)—enabled by the TAP-App—was the first department project to use REMI, with modifications specific to the program.

There were several advancements in the existing technology with the goal of establishing a 2-way versus 1-way flow of information between clients and interprofessional huddle teams (Figure 1). First, a huddle interface was created, which allowed TAP-Reports to be generated directly in the huddles. This new interface provided huddle a place where a client's plan of care could be documented. From here on, the huddles could use the new huddle action checklist. The huddle interface also allowed huddles to create a client-friendly version of the TAP-Report, including a plan of care that could be mailed to clients. Finally, to improve the flow of information, this iteration of the TAP-App enhanced the functionality of exporting data to allow them to be uploaded to other data storage locations (eg, REDCap [Research Electronic Data Capture; Vanderbilt University] electronic capture tools) and be easily reported to sites to support quality improvement, quality assurance, or research purposes.

Figure 1. Health Teams Advancing Patient Experience: Strengthening Quality (TAPESTRY) application—TAP-App (version 1.0) versus TAP-App (version 2.0). EMR: electronic medical record; TAP-App: Health TAPESTRY app.



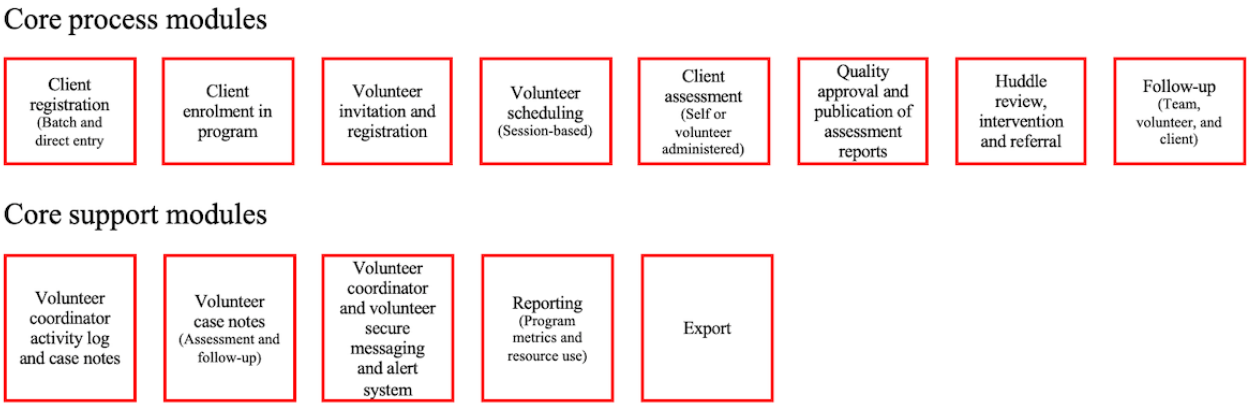
Note: The text boxes in red represent what was added to TAP-App (version 2.0) compared to TAP-App (version 1.0)

The design was again iterative and implementation was stepwise in nature, as rollout of the program and technology did not occur in all 6 FHTs simultaneously. Each site was able to customize its survey packages based on community or clinic needs and preferences. The TAP-App was still in active development when implementation began on the first site, which allowed the team to solicit and receive feedback from users (as described in the *Data Collection* section).

The Tap-App ICT: Bringing a Vision to Life

Although the TAP-App was first introduced as a tool to schedule volunteer and client visits and collect survey data with tablet use in focus, a broader vision underpinning this ICT was further developed during implementation. As outlined earlier, within the department, there was a desire to create a *program management tool* that could underpin all aspects of a complex intervention such as Health TAPESTRY. This shift led to the creation of a tool (the TAP-App hosted on REMI) that provided organizational support, management of clinicians and community partners, logic in data collection, and the opportunity for information to flow among users in a scalable and customizable tool that could support research and education enterprises (see Figure 2 for a detailed look). At the time of writing, the vision for the technology included some elements that had not been fully introduced, such as enhanced volunteer management and tracking and the opportunity for others in the department to use the technology.

Figure 2. Research Enterprise Management of Information (REMI): powering the Health TAPESTRY (Teams Advancing Patient Experience: Strengthening Quality) app and more.



Contributing to Integrated Care Through the TAP-App

Models of integrated care are centered on the values of *collaborative*, *coordinated*, *comprehensive*, and *holistic care* [21]. By the end of the implementation, we were able to design a technology that made strides toward supporting these core values of integrated care through ICT. The TAP-App provided a platform that enabled communication between primary care providers and 2 community-based volunteer agencies, as well as their community volunteers, to support *collaboration* between the health and social sectors. This technology allows for the *coordination* of information within and across teams by using trained volunteers to collect data for clinicians and volunteer agencies, allowing for the expanded coordination of services for clients. The follow-up action component of the TAP-App was not extensively used by primary care teams to request volunteer support, in part because some of the items on the follow-up checklist did not mirror real-life patient needs; for example, items did not include specialist or hospital referrals as the primary care teams managed those themselves. Regardless, some clients experienced the *comprehensiveness* of having multiple providers and services across disciplines involved in their plan of care in a more integrated and less fragmented manner. Finally, this technology was embedded into a person-centered program with a focus on what mattered most to clients rather than what was the matter with clients. This introduced components of a *holistic* approach, as the TAP-App was used to support this aim and collect health as well as social, socioeconomic, emotional, and other dimensions to create a plan of care that would reflect client needs across the health and social spectrums.

Results and Discussion

Participants, Positionality, and Reflexivity

The authors of this paper were the participants from whom the themes of the lessons learned came. The roles they held in Health TAPESTRY were research assistant, research associate, technology (digital health) lead, program manager, research coordinator, practice model lead, software developer, data manager, executive lead, and evaluation lead. Of the 10 authors, 5 (50%) were women, 4 (40%) were men, and 1 (10%) was gender nonbinary. Of the 10 people, 7 (70%) were present in both phases of the Health TAPESTRY program, and 3 (30%) were present only in the second phase.

As developers, implementers, and evaluators of the technology under study, we had an implicit bias in the shared hope for program success. However, the 2 phases of project work allowed us to reflect on our unique position and further develop the app to overcome barriers and maximize its success. Beyond that, we aimed to take a pragmatic approach to understanding our lessons learned, considering both what worked and what did not work.

Lessons Learned

Iterative Feedback Is Valuable

The introduction of any new technology will inevitably have both expected and unexpected effects on operations and workflows, even beyond the initial implementation. Therefore, continuous iterative feedback is necessary from users throughout. Given the many end users (or, in some cases, stakeholders who did not actively use the technology themselves) involved in a complex program such as Health TAPESTRY, there is a need to develop a process for managing feedback. It is also important to prioritize suggestions into high-, medium-, and low-priority categories. Some potential questions and guidelines that we found helpful—and encourage others to consider using in determining the end users' needs—during our implementation are as follows:

1. Would this alter the mechanisms in which data moved among users?
2. Would this require retraining for end users?
3. Would this change the way in which a client experienced the program?
4. Was this outside of the scope and capacity of the technology?

A key to the successful implementation of ICT is the involvement of end users. Buntin et al [10] highlighted the *human element* being a critical component of health technology implementation, which emphasizes the importance of provider feedback and *buy-in*. As the literature has identified, it is important to plan ICT early and deliberately, with monitoring and end user involvement throughout [8]. The involvement of end users appears to be a necessary element for the successful implementation of technology [5] because the implementation of ICT will create new tasks and processes. Iterative feedback will help move the implicit experience of an end user into explicit knowledge as ICT will likely introduce new ways of working at various levels by numerous people. See Table 1 for an overview of the 5 key lessons learned from our implementation of the TAP-App.

Table 1. Five key domains to consider when implementing a new information and communication technology (ICT) to support integrated care.

Domain	Why is it important	When is it important
Iterative feedback	Iterative end user feedback is vital for successful implementation of an ICT as different stakeholders involved have different needs and workflows that need to be considered.	Throughout implementation
Purpose of the ICT	An ICT that will be used for research, in addition to program implementation, must consider the needs of both purposes.	Development of the ICT
Integration into existing workflow	The ICT should support and enable existing workflows to facilitate the normalization of the ICT into practice.	Throughout implementation
Interoperability	Interoperability has both advantages and disadvantages. There is a need to consider the feasibility and practicality of an ICT being interoperable with other software; it is also possible that interoperability should not be the goal.	Development of the ICT
Limitations of technology	On the basis of the program being implemented; an ICT may be unable to complete all tasks within a program or the ICT may not be the best option to complete those tasks; a human element may be required.	Development of the ICT

If ICT Will Be Used for Research, Develop it With Research in Mind

Computer-assisted data collection for research use has been considered acceptable and has been widely adopted for at least 25 years [22]. However, when developing an ICT with the key purpose of being part of a program (rather than a research study), the research needs to evaluate whether the program can sometimes be overlooked. This is exactly what happened within the development of TAP-App (version 1.0), which made it very difficult to manage the spreadsheet of data as the output. We identified the problem and remedied it during the development of TAP-App (version 2.0) by including an embedded researcher (LL) in the ICT development team. The only way to scale a technology that may be used for research purposes (eg, understanding pre–post changes in participant outcomes or for general program evaluation) is to have a usable downloadable file (or way to develop summary reports), ideally one that can be converted into the appropriate file types for statistical software programs. Although this is not a common key learning in the literature in this field, other authors have emphasized the importance of being aware of concurrent changes to other systems when implementing a new ICT system [23]. Although these authors referred to technology systems, it is just as important to consider any system of work, including program versus research needs.

Prepare for Challenges With Integration of ICT Into Existing Workflow

The integration of ICT into existing practices and workflows takes time and requires an understanding that there will be challenges until it becomes a normalized part of the regular experience. This is not a new learning on its own; the literature in the field describes how introducing new ICT introduces new ways of working, which organizations and providers may be resistant to and often, an inadequate understanding of the clinical work environment causes new ICT systems to fail [5,24,25]. We have worked to understand how to manage these barriers. Although the normalization process theory was not fully used as an underpinning for this project, we considered the elements of normalizing a new technology into the existing workflow as we implemented the TAP-App. Normalization process theory states that new interventions must interact with the service organization, practices, and ways in which providers engage

with patients to be successful [26]. Along with existing work processes, implementation must interact with the existing *information ecology*, the activities in which users are already served by technology, such as the current channels of communication and storage of information [5].

Therefore, technology needs to support and enable the workflow of clinicians and not dictate it. By developing a new iteration of the TAP-App on REMI, the technology's ability to achieve a level of flexibility and scalability allows the technology to be implemented in multiple existing contexts. However, despite including flexibility, scalability, and the human element of feedback within our development of the TAP-App in both iterations, there were still some difficult areas when fitting it into the usual practice. One of these was the log in to a secondary website by providers, that is, the use of the huddle interface. This additional step added time, already at a premium for health care providers, and an issue that can be a major constraint in introducing new ICT into practice [8].

It is also important to implement ICT that is flexible enough to change per the local context, but neither the technology nor the end users can be too rigorous in the application of the technology. Although end users need to see value in adopting a new ICT [23], its developers and implementers cannot expect too many users and users cannot expect too much ICT. Steele Gray et al [24] recommended that adopting ICT into integrated care models requires a balance between a user-focused model and disruptive innovation, as ICT will inevitably introduce new ways of working for each user. However, the literature on innovation adoption suggests that users are likely to only support components that reflect practice as usual [27], a contradiction that can be difficult to navigate. Implementation of the TAP-App resulted in similar findings, as providers ended up adopting components of the technology that were useful to them and not the parts that added work or changed the workflow.

Ask Whether Interoperability Should Be the Goal

In the adoption of ICT, the concept of interoperability, specifically between external software and EMRs, will likely always need to be considered and is often seen as the end goal for any new health-related technology [28]. Interoperability is "the ability of health information systems to work together within and across organizational boundaries" [29]. Although there is evidence to support the benefits of ICTs that are interoperable with EMRs [30], the TAP-App was not intended to be fully interoperable during this implementation. It was not feasible, given the sheer number of EMR systems currently in use across Canada, including the 6 sites for this study. This may be a common barrier when implementing ICTs and may make them interoperable with EMR systems. This barrier is even larger with the implementation of programs such as Health TAPESTRY, which would require information systems that spanned the health and social sectors. The lack of interoperability among systems has been considered a key barrier in other studies [24]. However, because it was not feasible to fully integrate the TAP-App into an EMR, it does not mean that more integration would not be appreciated by providers. If providers have something similar to an embedded link in their EMR that takes them only a single click to access, they may not see it as a distinct site or different from their usual workflow.

Even if we had pushed for full interoperability between the TAP-App and EMRs, it may have addressed some of the disruptions in workflow. However, it has been shown that providers need to first see a great enough value in the ICT to fully integrate it into their work. In Health TAPESTRY, the value of ICT is not only the TAP-App itself but also the program elements that the huddle can access with the TAP-App, which introduces an additional barrier to access, as the primary care team should see a great enough value in the information contained in the TAP-Report and in the work of volunteers who are following up with their patients. In observing the challenges of integrating new health ICT, Planitz et al [23] found that the adoption of health ICT relied on providers identifying the functionality of new systems and that they were reluctant to change work processes during adoption. Therefore, the consideration of how well human factors are considered in introducing new ICT, and how well the ICT's functions are suited to end users may actually provide more value than the consideration of the interoperability of an ICT into an EMR. The human element is the key.

Know That Technology Cannot Do it Alone...Yet

There are inherent benefits and growing knowledge of the importance of developing human-centered ICT, including both the uptake and usability of the technology, which has been described in this case study and in other literature [31,32]. At the core of Health TAPESTRY are community volunteers administering surveys directly to clients, building rapport, and viewing clients in their own spaces, with their visits and questions facilitated by the TAP-App. This element is a benefit of the program and it would be remiss to suggest that technology could do this *instead*. Technology as the solution is not a true solution, as a human element is important in programs such as this; form should follow the function for an ICT to be successful.

Another human touch point within Health TAPESTRY was the addition of volunteer coordinators to interprofessional huddles, which further enabled the practice of integrated care, helping reach out to the community beyond the volunteer organizations themselves. While the TAP-Report to the huddle team provided necessary information, the volunteer coordinator was able to provide further narrative. In addition, this connection allowed the huddle teams to liaise directly with volunteer coordinators about possible follow-up actions for volunteers and resources to connect with patients. It also allowed the volunteer coordinator to remind the huddle teams of the community-based health and social-service options within their context and the role volunteers can play in connecting patients to these, as well as helping with any TAP-App–related issues. However, although this was an in-person activity, the volunteer coordinators' connections to the huddles were fully internet-based. As the entire world shifted to a more internet-based environment during the COVID-19 pandemic, we have seen many fields turn to more internet-based methods of connection. Through internet-based inclusion of community-based partners in interprofessional primary care huddles, we could keep the human element of connection, using it to further humanize the use of

technology [33], while still working to provide personalized, wrap-around care for clients.

Limitations

We acknowledge several limitations to this study. First, the authors of this paper understand the development and implementation of the TAP-app were themselves the developers and implementers of this ICT. This may introduce bias. However, we were not aiming for an entirely unbiased picture. Instead, we were directly looking to further understand perspectives of the people closest to the technology. We also practiced reflexivity in understanding our position in the project. Another limitation was that there was no direct data set with actual quotes that could be used. This was a restriction of the way we set up the evaluation. Finally, while there were a great number of stakeholders who provided perspectives to the authors throughout implementation, these perspectives were filtered through authors' understanding and positionality.

Conclusions

Although ICT systems are used to support coordinated and integrated care through information sharing, access to care, and continuity of services [5-7,24,34], there is a limited understanding of the process of introducing ICT into existing health and social care settings [24]. We have contributed to reducing this gap in the literature by describing the development and implementation of a specific ICT, the TAP-App, within the Health TAPESTRY program. The TAP-App helped enable the human-centered elements of Health TAPESTRY. However, despite the advancements made in the design of the TAP-App, there remain barriers to achieving the uptake of technology to allow for a fully improved flow of information between health and social settings. The key lessons for introducing ICT to enhance information exchange across sectors are that a system of iterative feedback to inform the design is important and that introducing a new ICT will inevitably cause implicit and explicit changes to existing workflows. In addition, human perspectives, interactions, and relationships may be more vital than ensuring interoperability between ICTs and EMRs. Maintaining a human-centered approach to integrated care is still key, whether a human-centered approach can also be brought in through internet-based communications or other technology.

Acknowledgments

We gratefully acknowledge the many team members who allowed us to implement and evaluate Health TAPESTRY (Teams Advancing Patient Experience: Strengthening Quality) and its associated elements (including the Health TAPESTRY application [TAP-App]) in 2 separate implementations in Ontario, Canada. Specifically, we would like to acknowledge Raied Siddiqui, Ernie Avilla, and Linda Xie for their hard work in conceptualizing, developing, and implementing TAP-App (version 1.0); Lisa Dolovich who co-led the first Health TAPESTRY implementation; Sivan Bomze, Samina Talat, Alex Macmillan, and Yana Almeida from the Canadian Red Cross for their contributions to the development of the TAP-App (version 2.0) volunteer functions; the Health TAPESTRY volunteer coordinators Cherie Gagnon, Mackenzie Berthiaume, Nelson Ruiz–Blanco, Danielle Mischkot, Jaclyn McKenna, Louisa van Lith, and Samantha Woodcroft, as well as huddle members Kiska Colwill, Sundée Himburg and Kim Culp for providing feedback and testing new features; Rebecca Clark in supporting the finalization of this manuscript; and our Health TAPESTRY governance team for guidance during TAP-App (version 2.0). Overall, we want to issue a big thank you to all Health TAPESTRY volunteers, clients, volunteers, primary care teams, and staff for contributing to the study and providing valuable input on their experiences using the TAP-App. We also gratefully acknowledge our funders. Between its 2 implementations, Health TAPESTRY was funded by Health Canada, the Labarge Optimal Aging Initiative, the McMaster Family Health Organization, the Department of Family Medicine at McMaster University, the Ontario Ministry of Health and Long-Term Care, and David Braley. None of the funders had input regarding the design, implementation, or analysis of Health TAPESTRY. Additional financial support was provided during the second implementation by the Canadian Red Cross, a partner agency, specifically to support the development of volunteer-focused functions within the TAP-App.

Abstract

Background: Embodied conversational agents (ECAs) have been proposed as a promising interaction modality for the delivery of programs focused on promoting lifestyle changes. However, it is not understood what factors influence the health effects of ECAs or their use.

Objective: We aimed to (1) identify whether ECAs could persuade community-dwelling older adults to change their dietary behavior and whether ECA use could decrease loneliness, (2) test the pathways to these effects, and (3) understand factors influencing the use of ECAs.

Methods: A randomized controlled trial was conducted. The intervention group received access to the PACO service for 8 weeks. The waitlist group started PACO use after waiting for 4 weeks. Two primary outcomes (eating behavior and loneliness) were assessed via online questionnaires at intake, upon joining the waitlist, after 4 weeks, and after 8 weeks. The third primary outcome (use) was assessed via data logs. Secondary outcomes were measured at the same time points, via questionnaires or an optional interview.

Results: In total, 32 participants completed the intervention. We found a significant correlation between use in minutes on the one hand, and perceived usefulness (r=0.39, P=.03) and enjoyment on the other (r=0.38, P=.03). However, these did not predict use in the full regression model ($F_{2,29}$=1.98, P=.16, R^2=0.12). Additionally, PACO use did not lead to improvement in eating behavior (χ^2_2=0.34, P=.85) or a decrease in loneliness (χ^2_2=0.02, P=.99).

Conclusions: Our study did not provide any concluding evidence about factors that are linked to the use or health effects of ECAs. Future service design could benefit from either creating a functional design catering to the predominant stage in the precaution adoption process model of the targeted population, or by personalizing the service based on an intake in which the end user's stage is determined.

Introduction

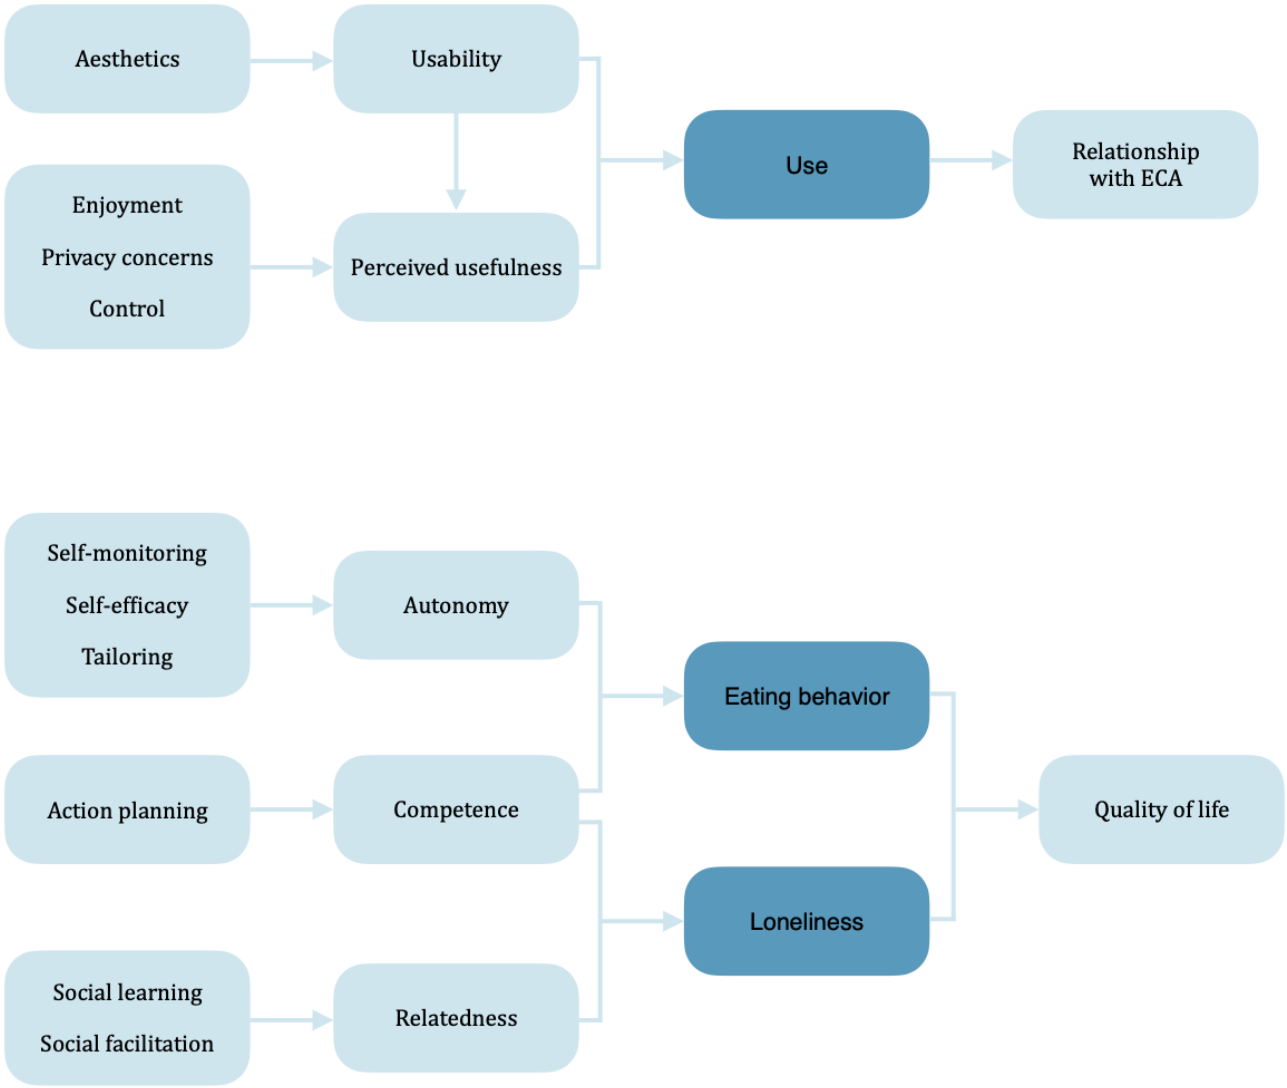
Background

Embodied conversational agents (ECAs) have been proposed as a promising interaction modality for the delivery of programs focused on promoting lifestyle changes [1], such as physical activity [2-4] and nutrition [5,6], and preconception care [7,8]. ECAs often have a human-like appearance and communicate via prewritten dialogue. They also have the ability to establish and maintain an empathic relationship by using empathic behavior, both verbal, via text or speech, and nonverbal, via facial and gaze expressions and hand and body gestures [9]. These behaviors may make them more engaging than traditional eHealth interventions [10,11]. Results are promising, as ECA interventions have been found to be easier to use [5] and used more frequently [5,11-13] than interventions without an ECA. Nonetheless, ECA use does decline over time, limiting long-term health effects [1,14-17]. Moreover, it is unknown what factors influence use of an ECA. When designing an ECA, designers are advised to select the right role for the ECA, combine the most important personality characteristics, and use informational, nonjudgmental language [18]. In addition, a scoping review identified which use-related factors were assessed when evaluating the effect of ECAs on promoting healthy lifestyles. These factors included usability and user satisfaction, further specified as factors including liking and trusting the ECA and the desire to continue using the ECA. However, evidence for the effect of these factors on ECA use is limited. Furthermore, there is scarce and inconclusive evidence for the health effects of ECAs and the pathways to these effects [1].

In order to assess the pathways to effects and understand ECA use when evaluating an ECA, conceptual models can be used (as shown in Figure 1; further details were reported in the research protocol for this study [16]). The conceptual model explaining ECA use is based on existing human-computer interaction literature, including the technology acceptance model (TAM) [19]. The key variables in TAM are perceived usefulness and perceived ease of use. Systematic reviews have shown that these 2 variables typically explain about 40 percent of an individual's intention to use a technology in a variety of contexts [20-22]. However, there is mixed evidence regarding whether intention predicts actual use [23,24]. Since actual use, rather than intention to use, is deemed necessary to achieve any health benefits, use is at the center of the conceptual model. Increased use is expected to improve the intensity of the relationship with the ECA, because of the capacity of ECAs to establish and maintain an empathic relationship. Usability and perceived usefulness are hypothesized to act as antecedents for use, whereas increased usability is expected to result in increased perceived usefulness.

The conceptual model explaining health effects occurring after the use of an ECA starts with behavioral change techniques (see Multimedia Appendix 1), which are expected to lead to an improvement in the 3 basic psychological needs: autonomy, competence, and relatedness. [25]. Ultimately, improved health behaviors will lead to a better quality of life. This model is primarily based on self-determination theory [25] and has an explorative character. By contrast, the classification system of Teixeira et al [26,27] is used to form hypotheses to explain which techniques improve which needs. Hence, the objectives of this study were to (1) identify whether ECAs could persuade community-dwelling older adults to change their dietary behavior and decrease their loneliness, (2) assess the pathways to these effects, and (3) understand ECA use.

Figure 1. Conceptual models explaining embodied conversational agent (ECA) use and health effects.



Methods

Study Design

This study used a randomized controlled trial design. Participants in the first cohort received access to the 8-week intervention immediately, while participants in the second cohort served as a control group, receiving access to the intervention after being placed on a 4-week waiting list.

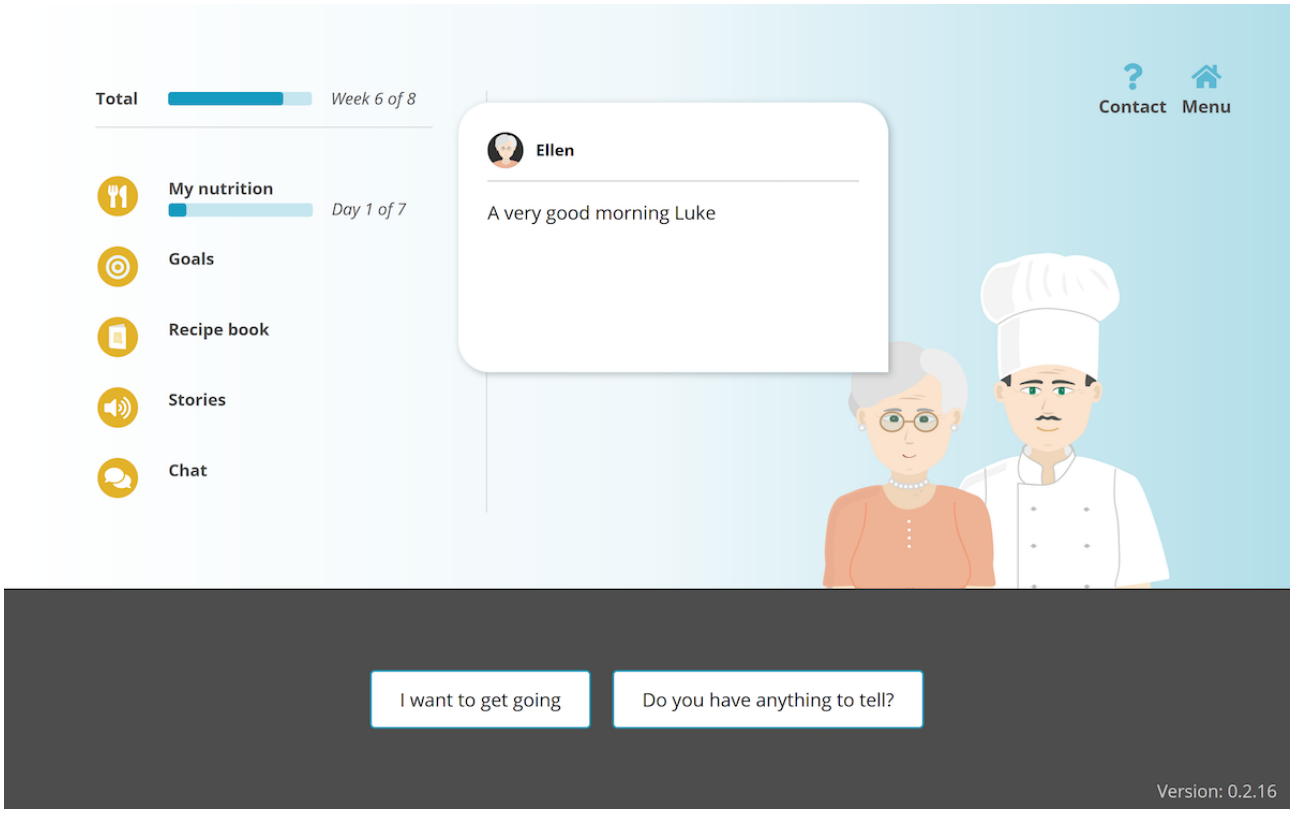
Participants and Procedure

We aimed to include a total of 60 participants with a 1:1 ratio of participants per cohort. Participants were deemed eligible if they were aged 65 years or older, not in paid employment, and lived alone and independently at home. In addition, participants needed to speak Dutch, be able to use a tablet or computer by themselves, and have a wireless internet connection. The project members recruited participants via research panels, flyers, newspapers, and social media. After providing informed consent, the participants were invited to complete the intake questionnaire. They were asked to report their demographics (gender, age, educational level, health conditions, risk of malnutrition [28], and eHealth literacy [29]), their possession of a device to use for the study, and their motivation to participate. All participants were asked to complete the baseline questionnaire (T0) after creating an online account and complete another questionnaire after 4 (T1) and 8 (T2) weeks of use. Participants in cohort 2 were asked to complete an additional waitlist questionnaire (Tw) 4 weeks before T0. In the last questionnaire, participants were asked whether they were open to an interview by phone.

Intervention

The intervention, PACO, is a web-based eHealth service in which 2 ECAs engage in dialogue with an older adult to provide motivation for improving eating behavior and decreasing loneliness. The service consists of 5 modules, each one applying a different behavioral change technique (Figure 2, Multimedia Appendix 1). The user can engage in dialogue with Herman (the cook, who provides nutritional advice) and Ellen (the peer, who provides social advice). The ECAs are represented as 2D humans in cartoon style, are not animated, and use text as the means of communication. During the onboarding process, the ECAs introduce themselves and explain the PACO program.

Figure 2. PACO home screen.



Outcomes

The primary outcomes include use of the service, eating behavior, and loneliness. Use was assessed via log data collected on the PACO back end. Eating behavior was self-assessed by 3 open questions about the previous day's fruit, vegetable, and liquid intake and loneliness was assessed via a validated questionnaire (Table 1 shows further details). The experience and the willingness to pay for PACO were measured via a self-compiled scale. All other outcomes were measured via validated online questionnaires. In an interview of approximately 30 minutes, participants were asked further questions about their experiences with PACO and any behavioral changes.

Table 1. Study outcomes measured via questionnaires in each study phase.

Outcome	Scale	Tw	T0	T1	T2

[a]ECA: embodied conversational agent.

[b]N/A: not applicable.

Data Analyses

We created a single score for each scale and checked the test assumptions. Due to the violation of the linearity assumption, we deviated from the original protocol by using nonparametric tests. Relationships between demographics and the main study outcomes were calculated using Spearman ρ and, for gender, Mann-Whitney *U*. Differences between Tw and T0, and in health-related outcomes over time, were compared using the Friedman test. Differences in the strength of the relationship with the ECA over time were compared with a repeated-measures ANOVA. Spearman ρ was used to calculate the correlations between use- and health-related outcomes. Linear regression analysis was used to calculate the multivariate relationships between use, eating behavior, loneliness, and significant outcomes. The statistical significance level was $P<.05$. Recordings of the interviews were transcribed and thematically analyzed by LLK and BCM.

Ethics Approval

This study was preregistered at ClinicalTrials.gov (NCT04510883) and approved by the medical ethics committee of Wageningen University (number NL73121.081.20). We refer to the study protocol article for all details on the protocol, the development process of the intervention, and the conceptual models [16].

Results

Drop-out, Baseline Characteristics, and Motivation

In total, 51 participants met the inclusion criteria. Nineteen participants did not use the PACO service for 14 consecutive days and were treated as dropouts. Among participants who dropped out, 7 did not respond to emails or telephone calls, 3 dropped out due to illness, 3 due to lack of time, 2 due to lack of motivation, 2 due to difficulties with the service, and 1 due to internet issues. Eight participants who dropped out had created an account, of whom 4 had completed T0. The mean age of the 32 participants was 73.00 years (SD 5.33, range 65-85); 18 (56%) were women. In total, 12 (38%) had completed high school or an associate degree and 19 (59%) had completed college or university. The mean eHealth literacy score was 29.25 (SD 4.36, range 15-34), and the risk of malnutrition was 9.69 (SD 1.35, range 7-11). None of the demographic characteristics were significantly associated with use, eating behavior, or loneliness, and there were no significant differences in health-related outcomes between Tw and T0. During intake, participants stated that they were mainly motivated to participate because they were interested in research and in new developments and thought it was important to contribute. Some participated because they were interested in nutrition and wanted to stay healthy or improve their habits.

Health Effects

The ECAs were not able to persuade users to change their fruit, vegetable, or liquid intake ($\chi^2_2=0.34$, $P=.85$) or decrease

loneliness (χ^2_2=0.02, *P*=.99). There were also no significant differences over time in quality of life (χ^2_2=2.99, *P*=.22), autonomy (χ^2_2=0.34, *P*=.85), competence (χ^2_2=2.32, *P*=.31), or relatedness (χ^2_2=2.46, *P*=.29). Table 2 shows all descriptive health outcomes.

During the interviews, most participants indicated that they thought they had a healthy diet. Nonetheless, a majority mentioned that the food diary helped them to become aware of their food intake. Some people were even shocked by the observation that they had such a fixed eating pattern and described PACO as a wake-up call. About half of the participants mentioned that they did introduce changes into their diet, such as cooking with more fresh ingredients, baking bread, eating more fruits and vegetables, and eating less meat. With respect to loneliness, most participants mentioned that they already had ample social contacts, even though some stated that they were feeling rather lonely. Apart from the unfortunate timing of the pandemic, 4 participants mentioned making changes in their social network because of PACO. For example, 1 participant created a list of everyone he knew and contacted them occasionally. Also, the chat connected a few people with each other and resulted in one-on-one contacts.

Table 2. Descriptive health outcomes.

	Scale	Tw, mean (SD)	T0, mean (SD)	T1, mean (SD)	T2, mean (SD)
Eating behavior	0-300	237.04 (45.33)	215.84 (72.12)	215.70 (65.92)	223.01 (71.28)
Loneliness	1-5	2.27 (1.71)	2.47 (1.78)	2.62 (1.91)	2.44 (1.92)
Quality of life	13-65	54.93 (4.93)	56.09 (5.60)	55.47 (6.56)	54.78 (5.85)
Autonomy	1-5	4.11 (0.42)	3.99 (0.54)	4.05 (0.60)	4.07 (0.56)
Competence	1-5	4.24 (0.37)	4.05 (0.58)	4.19 (0.52)	4.22 (0.57)
Relatedness	1-5	4.21 (0.38)	4.33 (0.56)	4.31 (0.53)	4.34 (0.51)

Pathways to Effects

Following our conceptual model for health, we expected to find a significant correlation between minutes spent on the different modules and eating behavior. However, this was not the case (*P*>.05, see Table 3 for all correlations). With respect to the other pathways, we found that competence correlated with eating behavior (*r*=–0.38, *P*=.03) and that it predicted eating behavior over time ($F_{1,30}$=4.30, *P*=.047, R^2=0.13). Quality of life (*r*=–0.60, *P*<.001), autonomy (*r*=–0.38, *P*=.03), relatedness (*r*=–0.59, *P*<.01), and number of chat messages (*r*=0.72, *P*=.03) correlated with loneliness, but did not predict loneliness ($F_{4,8}$=1.32, *P*=.40, R^2=0.14).

Table 3. Spearman correlations for health-related outcomes and PACO modules.

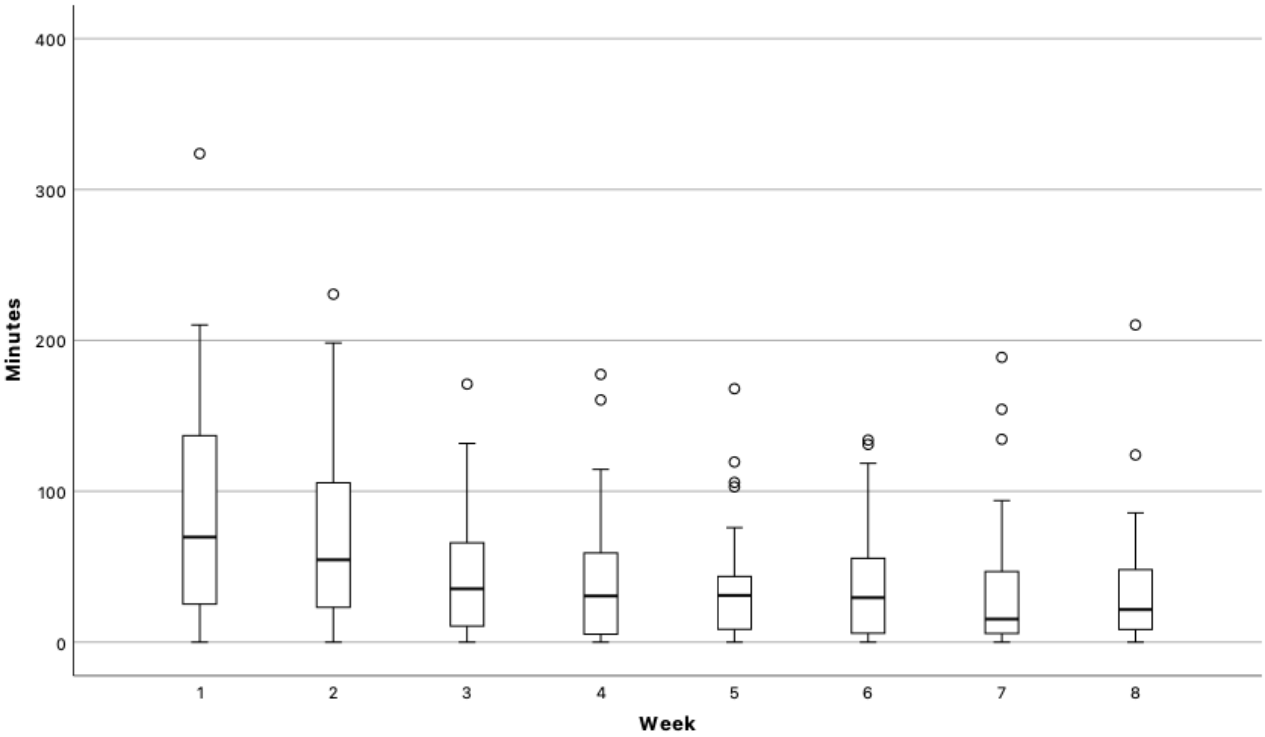
Understanding ECA Use

Use of PACO and Trends Over Time

On average, participants logged in 39.97 times (SD 37.38, range 10-197). Minutes per week decreased from a median of 69.66 in week 1 to 21.57 minutes in week 8 (Figure 3). The Friedman test confirmed this decline over time, showing a significant difference in use between weeks (χ^2_7=31.46, *P*<.001). The median time for using PACO was 15 h, 15 min, and 05 s. The average total time spent on PACO was 6 h, 30 min (SD 05 h, 54 min, 01 s), and the time spent per session was 11 h, 10 min (SD 05 h, 44 min). The average number of modules used per session was 2.39 (SD 0.34). The most time was spent on the food diary (85.45%), followed by the recipes (6.36%), goals (4.58%), and stories (3.61%). In total, 11 participants signed up for the chat. They sent a mean of 27.78 messages (SD 15.55, range 13-67). During the final interaction, the module used most

often was the food diary (41.67%), followed by the chat (25.00%), goals (16.67%), recipes (12.50%), and stories (4.17%).

Figure 3. Minutes per week.



Use-Related Outcomes

Usability, aesthetics, privacy concerns, and perceived control were rated above the midpoint of the scale (Table 4). The enjoyment and usefulness of PACO were rated below the midpoint of the scale, and perceived usefulness was rated relatively low. In total, 30 (94%) participants indicated that they were not willing to pay for PACO. With respect to the amount they would be willing to pay, results were contradictory, with 28 (88%) not willing to pay anything, and 4 (13%) willing to pay €5 (US $5.50). Following our conceptual model for ECA use, we found that aesthetics correlated significantly with usability (r=0.44, P=.01) and enjoyment correlated with perceived usefulness (r=0.48, P=.005). Although we found that perceived usefulness (r=0.39, P=.03) and enjoyment (r=0.38, P=.03) correlated with use in minutes (Table 5 shows all correlations), in the full regression model, these did not predict use ($F_{2,29}$=1.98, P=.16, R^2=0.12).

During the interviews, participants stated that although they read the module content, they did not truly engage and often reported that the content was not helpful. For example, participants listened to stories and read recipes, but did not act. In some cases, this was due to issues of tone, such as storytellers being seen as patronizing or the discomfort of endorsing dining alone. In other cases, such as the chat, participants simply did not wish to speak to people they did not know, or, if they did do so, the conversations felt shallow.

Table 4. Descriptive use outcomes.

	Scale	Outcome, mean (SD)
Usability	0-100	64.53 (17.98)
Enjoyment	1-7	3.26 (0.81)
Aesthetics	1-7	4.82 (1.21)
Privacy concerns	1-7	5.14 (1.28)
Control	1-7	4.78 (1.20)
Perceived usefulness	1-7	2.56 (0.99)

[a]ECA: embodied conversational agent.

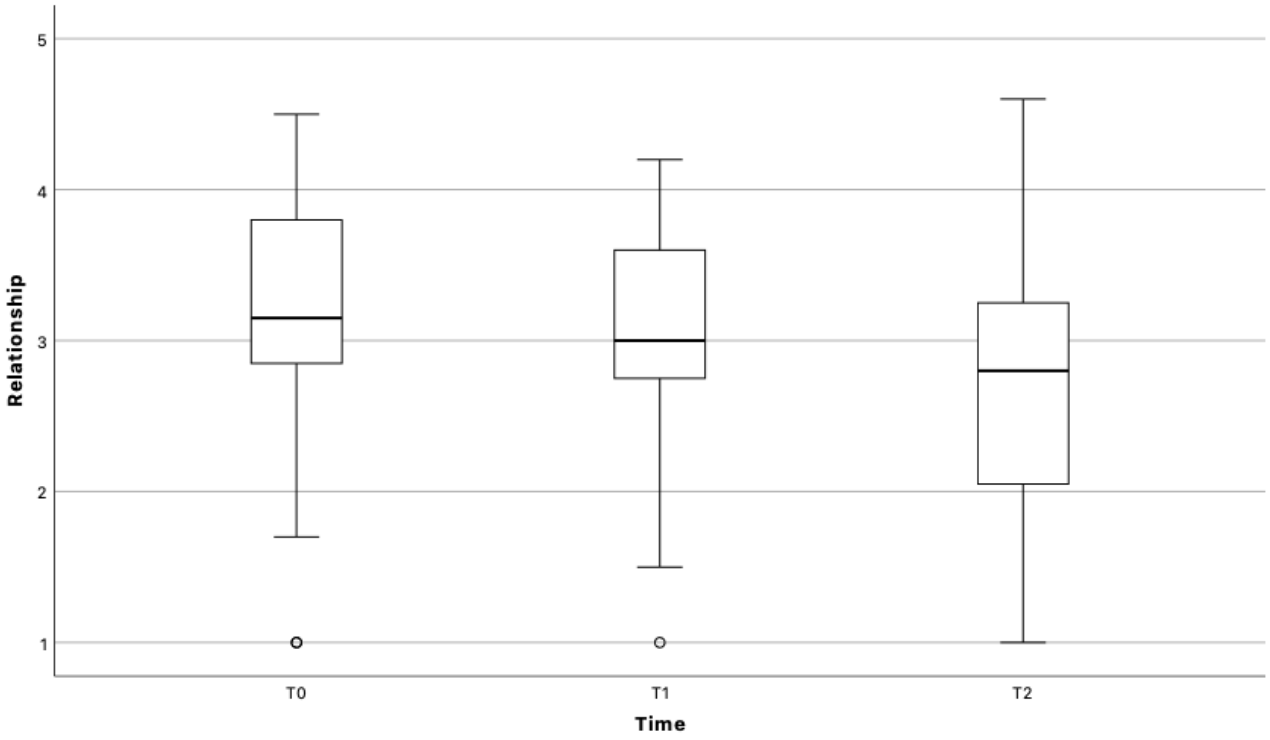
[b]Not applicable.

Relationship With the ECAs

The strength of the relationship with the ECAs decreased over time ($F_{1.72,53.33}$=4.22, *P*=.02; more details shown in Figure 4). Posthoc analysis with Bonferroni correction showed that the difference between T1 and T2 was significant (*P*=.047). Contrary to our expectation, the relationship did not correlate with use (*r*=–0.13, *P*=.47).

During the interviews, most participants were neutral about the ECAs, or reported not having noticed them. Six participants mentioned that the ECAs made PACO easier to use, more engaging, or more enjoyable compared to plain text, or even described them as “fantastic.” On the other hand, 3 participants found the ECAs to be childish and unreal and the participants considered themselves too rational to regard the ECAs as actual people.

Figure 4. Relationship with the embodied conversational agents over time.



Discussion

This study used a randomized controlled trial to investigate the effectiveness, the pathways to effects, and the mechanisms that underlay the use of an ECA targeting eating behavior and loneliness among older adults. The results showed that neither the ease of use of the PACO service nor the user experience explained the extent to which it was used. Furthermore, the use of PACO did not result in improved fruit, vegetable, or liquid intake or reduced loneliness. Our findings might, on first sight, contradict our hypotheses, and add to the mixed evidence base on nutritional ECAs [5,6,44]. On the other hand, we can also take these results as valuable lessons for the future design of eHealth services.

Participants did become more aware of their eating behavior due to the self-monitoring tool, and thus also became more aware of behaviors they could improve. In the terms used in the precaution adoption process model (PAPM) [45], they were "deciding about acting." However, in the interviews, participants expressed high self-perceived health and no need for change. This suggests users might well have been in the stage of "decided not to act." It is known that the PAPM stage plays a significant role in the perceived persuasiveness of different behavioral change techniques [46]. Hence, different needs should have been nurtured in our participants, as they were still in an earlier stage of the model. If this was the case, then the design of future services could benefit from either creating a functional design catering toward the predominant stage of the targeted population or personalizing the service based on an intake process that considers the stage of the end user.

To our knowledge, we are among the first to study factors that help understand ECA use. Surprisingly, we found that the use of PACO could not be explained by its usability, privacy concerns, perceived usefulness, or level of enjoyment. Furthermore, positive ratings on aesthetics and perceived control were not associated with time spent using PACO, although these factors did have a positive correlation with usability. Instead of arguing that these factors are not relevant for the development of an ECA, we argue that a certain threshold might be necessary for a service to be used. This is in line with other work on ECAs among older adults, which has shown that technical problems have a negative impact on use, adaptiveness, usefulness, and trust [47]. It has yet to be determined what factors positively influence the use of an ECA. Instead of focusing on traditional use-related factors, as we did in our conceptual model explaining ECA use, future research might benefit from examining certain threshold scores in earlier stages of development. Furthermore, the PAPM might help understand ECA use. If users do not intend to change their behavior, for example, it can be expected that they will not engage with the ECA. Research has indeed shown that this is true for the adoption of nutrition and fitness apps among the general population [48].

This study has limitations. First, we received a very low response to our flyers, social media posts, and advertorials. Newspaper interviews and phone calls to potential participants by the research panels resulted in a greater, yet still limited, response. Because of this nonresponse, we do not know why more older adults did not want to participate in this study. In total, 5 potential participants indicated that they did not want to participate on the consent form. One unintended effect of this method of obtaining informed consent could have been that people who were unable to provide consent were excluded. As a result of the small sample size, the overall power of this study was low. We consider that not measuring the PAPM stage was a second limitation of this study. We suspect that PAPM stage

is a factor that might provide more insight into both the use and effectiveness of the service (ie, participants who use the service more frequently and report health-related effects might be more likely to act). Finally, the ongoing COVID-19 pandemic might have influenced our results. We did rewrite the content of PACO to match the current situation and focused on online alternatives for engaging in social interactions. Nonetheless, participants felt they were not able to be more socially active due to government restrictions. Indeed, loneliness increased in our target group during the pandemic [49]. This might have counteracted the decrease in feelings of loneliness that we expected.

In conclusion, this study illustrates how to use a conceptual model to guide the evaluation of an ECA service in terms of both its level of use and its health effects, although it did not provide us with any conclusive evidence of its actual effectiveness. Nonetheless, our results provide valuable directions for future studies in this emerging field.

Acknowledgments

This work was supported by the Netherlands Association for Health Research and Development and its associated Create Health program (grant 40-44300-98-110). We would like to thank Dennis Hofs for developing the software, and MSc students Willine van den Brink and Iris Bijvelds for their assistance in performing the trial.

Conflicts of Interest

LvV works at Roessingh Research and Development, the company that developed PACO. There are no other conflicts of interest.

Abstract

Background: Accurate self-reported symptomatic toxicity documentation via the Patient-Reported Outcomes version of the Common Terminology Criteria for Adverse Events (PRO-CTCAE) is essential throughout cancer treatment to ensure safety and understand therapeutic efficacy. However, the capture of accurate toxicities from patients undergoing radiation therapy is challenging because this is generally provided only at the time of scheduled visits.

Objective: This study seeks to establish the usability and feasibility of a mobile PRO-CTCAE Administration System (mPROS) to capture toxicities related to radiation therapy.

Methods: English-speaking adult patients who were undergoing radiation therapy for cancer were enrolled and given a brief demonstration of the Say All Your Symptoms (SAYS) and Symptom Tracking Entry Program (STEP) interfaces of the mPROS app, followed by a patient-use phase where patient actions were observed as they navigated mPROS to enter toxicities. Patient feedback was captured via a semistructured interview and brief questionnaire.

Results: We enrolled 25 patients (age: mean 60.7 years; females: n=13, 52%; White patients: n=13; 52%; non-Hispanic patients: n=19, 76%; college graduates: n=17, 68%). Patients almost equally preferred the SAYS (n=14, 56%) or STEP (n=11, 44%) interfaces, with 21 patients (84%) agreeing that they would use mPROS to report their symptoms to their health care team and 19 patients (76%) agreeing that they would recommend mPROS to others.

Conclusions: The mPROS app is usable and feasible for facilitating the patient reporting of radiation therapy–related symptomatic toxicities. A revised version of mPROS that incorporates patient input and includes electronic health record integration is being developed and validated as part of a multicenter trial.

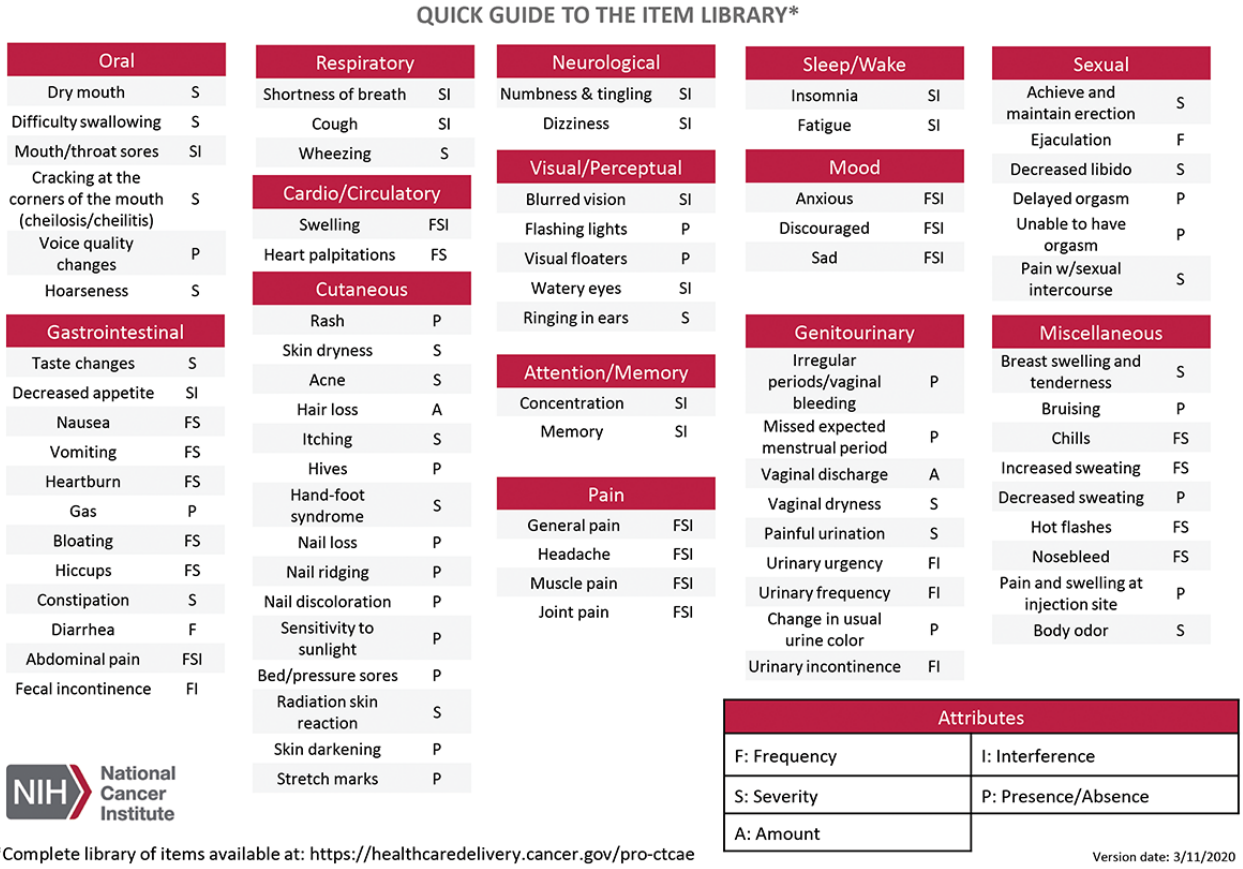
Introduction

Toxicity reporting via the Common Terminology Criteria for Adverse Events (CTCAE) of the National Cancer Institute (NCI) is mandatory in oncology clinical trials to monitor patient safety and to understand the toxicity profiles of treatments [1]. Several studies have shown that symptomatic toxicities associated with anticancer treatments (eg, nausea and vomiting) are frequently underreported by health care providers, even when prospectively collected within clinical trials [2-5]. To address the issue of underestimating symptom toxicities related to cancer treatment, the NCI supported the creation of the Patient-Reported Outcomes (PRO) version of the CTCAE (PRO-CTCAE), referred to as PRO-CTCAE [6-10]. Version 1.0 of the PRO-CTCAE item library can be administered electronically [11] and includes 124 individual items representing the 78 toxicities, with multiple attributes captured for a given toxicity attribute question (eg, frequency, severity, and interference with usual or daily activities), as shown in Figure 1.

Figure 1. Patient-Reported Outcomes of the Common Terminology Criteria for Adverse Events item library version 1.0.



Although the PRO-CTCAE has preliminarily demonstrated promise in several areas [12-17], with the broad electronic delivery of the PRO-CTCAE showing clinical utility [18-21], this tool has not yet enjoyed widespread use in the radiation oncology setting [22-24]. The exposure of surrounding healthy tissue to the radiation field is largely unavoidable for patients with cancer who are treated with radiation therapy, making patient reports of symptomatic toxicities particularly important for this population. One barrier to using the PRO-CTCAE is that each radiation oncology clinic must develop infrastructure and support to administer a PRO-CTCAE assessment [25]. For example, administrative personnel in clinics creating custom PRO-CTCAE assessments using paper forms require additional time to enter the patient responses into digital systems. If the PRO-CTCAE is administered on a clinic-provided digital platform (eg, tablets), administrative support is required to answer questions from patients who do not routinely use technology (eg, for changing passwords) [26,27]. Although these complications are manageable, they may be reduced or eliminated through the development of mobile apps that do not require clinics to provide digital assessment platforms.

Categories of PRO-CTCAE items have not yet been established for commonly used cancer radiation treatments, necessitating that radiation oncologists select PRO-CTCAE items for a given treatment based on their clinical experience rather than a uniform standard. Additionally, the current practice is such that PRO-CTCAE assessments are not tailored to patient characteristics, previous assessment responses, or the area(s) of their body where they are receiving radiation therapy. Such patient-centered specificity in toxicity reporting would provide clinicians with crucial context that will assist in their interpretation of this patient-reported information. Further, for patients reporting PRO-CTCAE toxicities between visits or otherwise outside of the clinic setting, there is currently no means to remotely deliver relevant self-care information and suggestions (eg, strategies for treating mild skin symptoms). Patients may be more likely to engage in and complete the

assessments if they know that they will learn something about their symptoms and how to treat them.

Despite the importance of leveraging the electronic capture of between-visit PRO information that can be incorporated directly into the electronic health record with respect to improving medical decision-making and prolonging overall patient survival [28-30], there are no cancer-specific mobile health apps available for this purpose [31,32]. Therefore, this study sought to complete a cross-sectional assessment of the usability and feasibility of the Mobile PRO-CTCAE Administration System (mPROS), an iOS- and Android-based smartphone app designed to address the aforementioned barriers through the tailoring of PRO-CTCAE assessments specifically to patients undergoing radiation therapy for cancer.

Methods

Recruitment

Patients with appointments in the radiation oncology clinics at Memorial Sloan Kettering Cancer Center (MSK), a tertiary NCI-designated Comprehensive Cancer Center in New York, NY, were screened by a clinical research coordinator (CRC) for initial eligibility. Patients were originally eligible for approach if they spoke English; were receiving radiation therapy in the head/neck, breast, or pelvic areas; and were aged 18 years or older. Delays related to patient accrual required the expansion of participant enrollment to those receiving radiation therapy for any disease type, despite mPROS only being equipped to address symptoms related to radiation in the head/neck, breast, and pelvic areas. The physicians attending to the patients were contacted for permission to approach patients who were determined to be eligible. Enrolled patients were given the option to end the study session at any time. Documented informed consent was not collected, as this study was deemed exempt by the Institutional Review Board at MSK.

Mobile App

The mPROS app uses 2 PRO-CTCAE assessment interfaces to collect data. The structured interface, called the Symptom Tracking Entry Program (STEP), delivers multimedia-supported PRO-CTCAE items relevant to the patient's radiation therapy (Figure 2). The second interface, Say All Your Symptoms (SAYS), leverages a virtual clinical assistant in the form of a chatbot to engage the patient in a text-based conversation to elicit patient responses to relevant PRO-CTCAE items in a comforting manner (Figure 3). Both interfaces are programmed to be responsive to symptoms related to radiation in the head/neck, breast, and pelvic areas for male and female patients.

Figure 2. Symptom Tracking Entry Program interface.

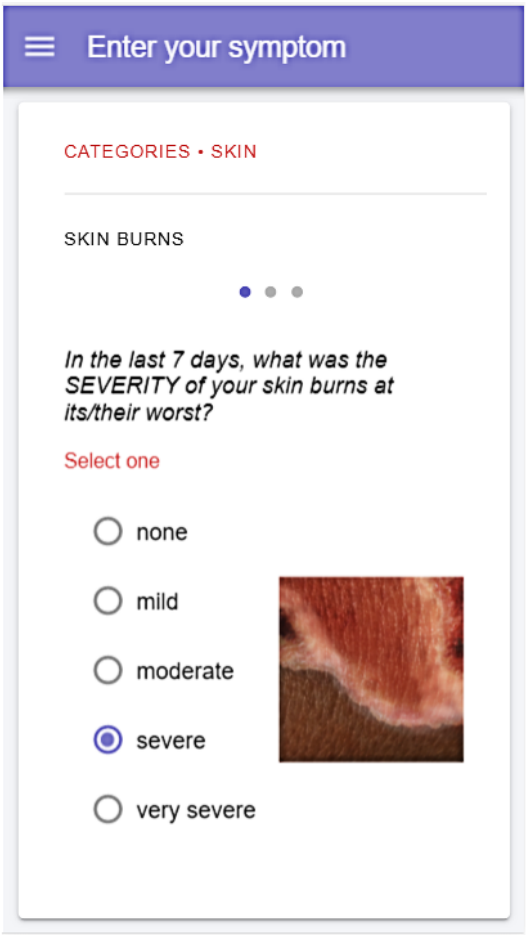


Figure 3. Chatbot on the Say All Your Symptoms interface.

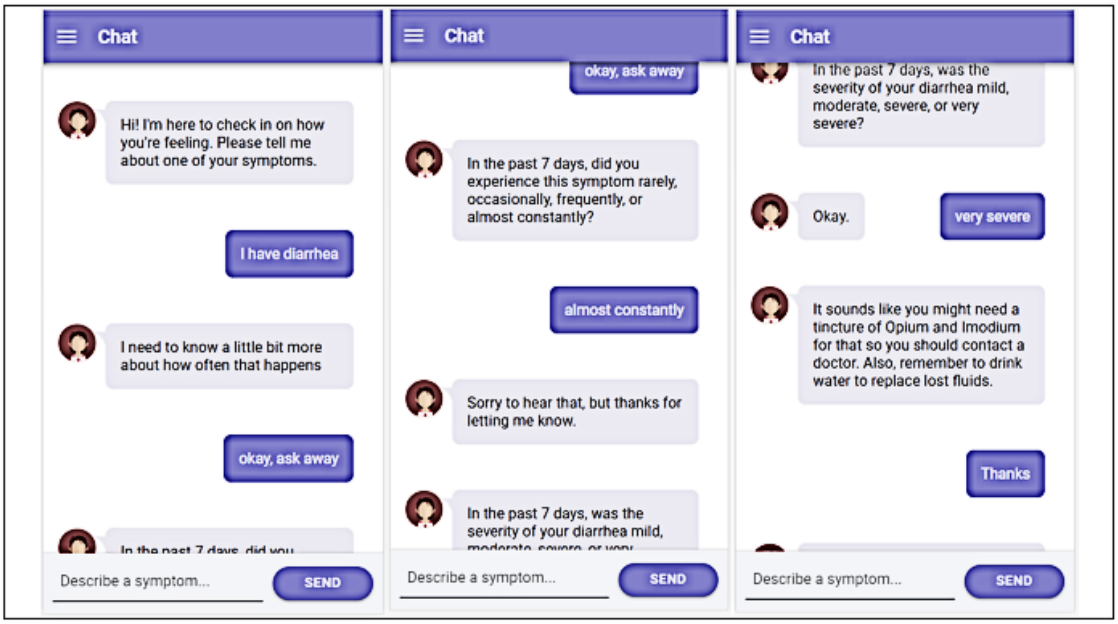

Procedure

The interactions during this research session took place in a quiet, private space in the MSK radiation oncology clinics and were audio-recorded to support the generation of a summary report. The CRC confirmed eligibility and determined if the patient was able to use a study-provided iOS- or Android-based smartphone on which the mPROS app was installed. Upon enrollment, the CRC collected demographic and treatment characteristics (eg, gender, age, education, race and ethnicity, the radiation treatment region, and the frequency of mobile phone app use) and provided an explanation about how mPROS works. Patients were then asked about their preferred operating system (ie, iOS or Android), the part of the body where they were currently being administered radiation, and 1 to 3 symptoms that they were currently experiencing or had recently experienced. This was followed by a brief (8-10 minutes) demonstration on how to use both interfaces of mPROS, with the CRC using symptoms not mentioned by the patient to avoid redundancy. Patients were given the opportunity to ask questions about mPROS and request a repeat demonstration of either mPROS interface.

Following the completion of the demonstration, patients were provided with the study smartphone based on their preferred operating system (ie, iOS or Android) and asked to use the mPROS app for approximately 5 to 10 minutes. The patients were asked to choose which interface they wanted to use first (ie, STEP or SAYS). The CRC guided the patients to progress through each interface but was instructed to provide additional assistance only when requested by the patients.

The patients' explicit and implicit actions were observed and documented by the CRC (eg, the ability to switch between interfaces without assistance, issues related to progression through the app, app crashes, etc), and any aspects that appeared to be frustrating or time consuming were noted for the follow-up interview. All patient interactions with the mPROS app (ie, click location and time per page/interface in milliseconds) were captured by the mPROS system.

Upon completing the patient-use portion of the study within mPROS, the CRC conducted a semistructured interview in which patients were asked the following questions: (1) What features of mPROS did you like the most? (2) What features of mPROS did you like the least? (3) What suggestions do you have to improve mPROS? (4) Which mPROS interface did you prefer and why? (5) What symptoms or features of symptoms did you want to report in mPROS but could not? (6) How frequently do you think you would use the mPROS application? (7) What could we add to the mPROS application to make it more useful to you? (8) How would an application like mPROS help you in discussing your symptoms with your doctors? (9) Is there anything else that you would like to tell us about your experience with the mPROS application?

Patients were then asked to complete a brief 7-item questionnaire to indicate the degree to which they agreed with the following statements: (1) I would use the mPROS application to report symptoms to my health care team. (2) I would recommend mPROS to others. (3) I use other smartphone applications to track my symptoms. (4) I use other smartphone applications to track my daily activity and experiences. (5) I would be interested in connecting with other radiation patients through the mPROS application to share experiences. (6) I would like for the mPROS application to show me my symptom history over time. (7) I would like for the mPROS application to give me an option to use the phone camera to take a picture of my symptomatic area (eg, skin, mouth) to send to my doctor.

After the research interaction, patients were thanked for their participation, reimbursed US $50 for their time, and given the opportunity to spend additional time using the mPROS app if it was of interest to them. All audio recordings were destroyed within 48 hours of the research interaction.

Results

Patient Characteristics

A total of 124 patients were screened for eligibility between May and August 2019. Among them, 91 patients (73.4%) were found to be eligible; the CRC approached 65 (71.4%) of these 91 patients (Figure 4). The primary reason for not approaching patients was due to the rescheduling of appointments (n=20). Of the 65 approached patients, 29 (23.4%) accepted enrollment in the study, with a total of 25 patients (20.2%) completing the research interaction session. Further, 20 patients who were eligible did not show up for their scheduled appointment and thus could not be approached for participation, whereas 19 patients were approached and agreed to participate if they could complete the session during a future visit. The reasons for refusal included not enough time for the study (n=11, 64.7%), not interested/irrelevant (n=4, 23.5%), not using a smartphone (n=1, 5.9%), and not keen to use an app like mPROS (n=1, 5.9%).

The enrolled patients (age: mean 60.7 years; range 34-80 years) comprised 52% females and were mostly highly educated (68% college graduates or postgraduates), White (52%), and non-Hispanic (76%). The radiation regions included the brain (n=4), breast (n=4), chest/thorax (n=4), head/neck (n=4), lungs (n=2), lymph nodes (n=2), adrenal gland (n=1), liver (n=1), pelvic region (n=1), spine (n=1), and thighs (n=1), of which only 9 (ie, breast, head/neck, and pelvic region) were the targets for the current version of mPROS. All but 3 (12%) of the 25 patients indicated that they sometimes used smartphone apps, with 12 patients (48%) indicating that they “always” used smartphone apps. Furthermore, 20 patients (80%) currently use and prefer the iOS operating system, whereas 5 patients (20%) preferred using Android devices. The sample characteristics are included in Table 1.

[a]Cancer type specifically targeted in the current mPROS (Mobile Patient-Reported Outcomes version of the Common Terminology Criteria for Adverse

Events Administration System) app.

Demonstration Phase

Patients generally understood the use of mPROS during the demonstration phase; no patients requested a repeat demonstration of the mPROS features. However, 3 patients had questions regarding treatment management suggestions (eg, 2 types of ibuprofen suggested for pain rather than 1 type), and 1 patient asked whether text had to be entered into the final open-ended text box for gastrointestinal symptoms for the symptom form to be "complete."

Patient-Use Phase

The mean time to complete the patient-use phase was 19 minutes and 33 seconds (range 7 minutes and 22 seconds to 39 minutes and 17 seconds). All but 2 of the participants were able to navigate between STEP and SAYS without assistance from the CRC.

Semistructured Interviews

Table 2 includes a summary of patient preferences, perceived mPROS benefits, suggestions for mPROS improvement, and general feedback on the app. The majority of the patients indicated they would use mPROS on a regular basis (n=12) or when they noticed a marked change in their symptoms (n=13). Patient statements included "I would use it every day because of my chronic symptoms."

When asked about their suggestions to improve mPROS, 8 patients suggested the addition of a feature to send mPROS communications directly to their doctor, preferring a 2-way confirmation of data sent and received. The addition of a feature for patients to enter lifestyle-related information (eg, current medications, treatments, diet, mental health, and exercise routines) was suggested by 7 patients. Another suggestion given by 4 patients was to have an alert system in place for any instance of a symptom being reported as "very severe," and 3 patients spontaneously suggested adding a feature to upload photographs of their skin. The inclusion of a spell-check feature in the SAYS interface was suggested by 3 patients. Of these 3 patients, 2 suggested having SAYS confirm a symptom entry before advancing to the related questions or having it suggest a symptom if the user's input was not recognized (eg, "you said 'headache' – did you mean head pain?"). Two patients suggested including legal language before reporting symptoms (eg, "If you are experiencing an emergency, please call 911 or contact your doctor"). One patient suggested a "sent confirmation/read receipt" feature be added to the app, and another patient suggested the addition of an option to enter medications or treatments already taken for a given symptom.

With respect to using mPROS to help with discussing symptoms with their doctor, 14 patients mentioned the advantage of being able to record and recall symptoms over time, with 9 patients indicating that mPROS would help them to report symptoms over time, 7 mentioning that using mPROS would help their doctor or treatment team, and 4 stating that they are currently recording and maintaining their own physical set of symptom notes that would otherwise be documented in the mPROS app.

The mPROS app provided artistically rendered images to help patients understand the skin burn severity levels (mild, moderate, severe, and very severe). When asked about the skin severity images, 17 of the 25 patients (68%) found these to be helpful, and 18 patients indicated that the binary (ie, light versus dark) skin tone was insufficient, with 2 patients spontaneously raising this point prior to the interview question. The inclusion of additional context was requested by 3 patients when selecting skin color during patient setup, as the images do not appear until later, and they appear only if skin symptoms are included in the STEP interface. Another patient suggested asking the skin color question only when specifically indicating that a patient is experiencing a skin-related symptom. Additionally, 6 patients did not find the skin images to be helpful, citing that the skin burn images were not relevant to them either because the choices within skin effects did not include burns or because the reference images did not represent their healthy skin color. These patient responses included "I didn't find these to be helpful – I have discoloration, not burns. It would be better to upload pictures of your skin as you go through radiation" and "No – they don't look like skin to me. Light and dark skin was not specific enough. You need more gradations or have us pick from a continuum."

Table 2. Patient preferences, perceived benefits, general feedback, and suggestions for improvement identified from the semistructured interviews (N=25).

Survey items	Value, n (%)
Interface choice	
Used SAYS[a] first	13 (52)
Used STEP[b] first	12 (48)
Interface preference	
SAYS	14 (56)
STEP	11 (44)
Interest in future use	
Would use mPROS[c] on ad hoc basis depending on symptom changes	13 (52)
Would use mPROS on regular basis	12 (48)
Perceived benefits of mPROS	
Ability to record and recall symptoms over time	14 (56)
Assistance with recording symptoms over time	9 (36)
Will assist treatment team	7 (28)
Most liked feature	
SAYS chatbot	9 (36)
Specifying body areas	6 (24)
Speed/convenience of completing symptom reporting using the app versus completing it in the doctor's office	5 (20)
Ability to choose between methods of reporting symptoms	3 (12)
No response	2 (8)
Least liked feature	
mPROS not recognizing symptom	7 (28)
Confusion over when to swipe/tap “next” to enter more attributes	6 (24)
Texting	4 (16)
No response	8 (32)
Patient suggestions to make mPROS more useful	
Ability to send reports directly to clinicians	8 (32)
Ability to enter medications, treatments, diet, mental health, and exercise	7 (28)
Alert system for very severe symptoms	4 (16)
Less verbose questions/chat language	4 (16)
Spell-check for SAYS chatbot	3 (12)
Ability to upload skin photos	3 (12)
SAYS confirmation of symptom entry	2 (8)
Inclusion of legal language before reporting symptoms	2 (8)
Send confirmation/read receipt to clinicians	1 (4)
Specifying skin tone for skin-related symptoms	1 (4)
Use of a 1-5 scale rather than asking patients to type verbal descriptions	1 (4)
Additional safety features for logging into the app	1 (4)
Severity image feedback	
Binary skin tone (ie, light versus dark) insufficient	18 (72)
Images generally helpful	17 (68)
Not relevant due to lack of burns or not representing healthy skin color	6 (24)

Survey items	Value, n (%)
General feedback and issues	
Confused about right-swipe navigation of attribute questions	18 (72)
Helpful completion icons	9 (36)
Attempted to enter symptoms not associated with mPROS radiation sites	7 (28)
Struggled with text entry	6 (24)
Body areas too large to show where symptoms occurred	3 (12)
Problems finding home screen	2 (8)

[a]SAYS: Say All Your Symptoms.

[b]STEP: Symptom Tracking Entry Program.

[c]mPROS: Mobile Patient-Reported Outcomes version of the Common Terminology Criteria for Adverse Events Administration System.

Patient mPROS Questionnaire

Among the 25 patients, 21 (84%) agreed or strongly agreed that they would use the mPROS app to report their symptoms to their health care team, and 19 (76%) agreed or strongly agreed that they would recommend mPROS to others. Approximately half the patients do not currently use other mobile apps to track their symptoms (n=12, 48%), with the majority indicating they do not use other mobile apps to track other activities (n=16, 64%). When asked whether they would be interested in connecting with other radiation patients through mPROS, only 10 (40%) patients were interested in such a feature. Except for 1 patient, the remaining 24 (95%) would like for mPROS to show symptom history over time and provide an option to send a photograph of their symptomatic area using the phone camera.

Discussion

Principal Findings

The underreporting of symptomatic toxicities throughout the course of radiation treatment can lead to the underestimation of the absolute rate of toxicity, which can immediately impact clinical decision-making. More accurate patient-tailored reporting of toxicities can lead to improved personalized care and quality of life for patients with cancer having difficulty with any treatment. This study sought to establish the usability and feasibility of mPROS, a mobile app that was designed to measure symptomatic toxicities via PRO-CTCAE and was specific to patients undergoing radiation therapy, in a sample of patients from radiation oncology clinics at a tertiary cancer center. The mPROS app was generally liked, with the majority of patients indicating they would use the app to report symptoms to their health care team. Some patients indicated that they liked the speed or convenience of reporting symptoms on their phone versus doing it in the doctor's office. Others liked having a choice of how to report symptoms.

Using mPROS to capture patient-reported toxicities is feasible; only 17 of the original 91 (18.7%) patients who were determined eligible for the study refused to participate (Figure 1). Of the 25 patients who participated, 21 (84%) indicated that they would use this app to report symptoms to their health care team and 19 (76%) stated that they would recommend mPROS to others. Limited training (ie, 8-10 minutes) is required for orienting patients to use mPROS; no patients requested additional demonstrations of the mPROS app prior to initiating the patient-use phase. Despite our patients' median age of 63.5 years and the inclusion of 11 patients aged 65 years or older (range 34-80 years), we observed no age-related challenges in the use of mPROS. This is consistent with recent work that established the feasibility of electronic geriatric health assessment in patients aged 65 years or older in a multi-institutional setting [33].

Using a qualitative methodology to establish the usability of mPROS is a strength of our study [34]. These patient-centered interactions provided important feedback for the refinement of mPROS and demonstrated that there is a need to have a personal app for reporting symptoms; moreover, the SAYS chatbot is desired by patients who are comfortable with texting, and there are symptoms that are not caused directly by radiation that patients still experience and want to report, such as headaches and nausea. Additionally, the majority of patients indicated that the skin severity images were insufficient and did not represent their healthy skin color. Suggestions were made to replace the binary (ie, light versus dark) skin tones with a sliding skin tone scale. The next version of mPROS will contain other recommended features that will make it more useful to the patients.

There are a number of limitations to this study. This was a single-site study completed in a tertiary cancer center with a mostly highly educated study sample with limited Hispanic representation. Additionally, delays related to patient accrual necessitated the expansion of eligibility criteria to any English-speaking patient aged 18 years or older who was receiving radiation therapy for any disease type. The version of mPROS that was used for testing only included body map selections and symptoms related to receiving radiation in the breast, head/neck, or pelvic region. Enrolled patients who were receiving radiation in a different region (n=16) were asked to select a region that was proximal to their radiation site, and several of their suggestions involved expanding mPROS to include their specific radiation sites (n=4). Despite this version of mPROS not including their radiation sites, all but 1 (n=15, 94%) of these participants indicated that they would use this app to report symptoms to their health care team. Finally, as mPROS was evaluated on a study-provided smartphone during a single session with each participant, we did not consider it

appropriate to assess the acceptability of the app at this time; acceptability will be analyzed as part of an ongoing multicenter clinical trial.

Conclusions

The mPROS app is a usable and feasible tailored assessment for patients to report symptomatic toxicities related to their radiation therapy. Using patient input from this study, a revised version of mPROS that includes electronic health record integration is being developed and validated as part of a multicenter clinical trial (National Institutes of Health/NCI Small Business Innovation Research Phase 2 Contract #75N91020C00027). The seamless electronic documentation of these patient-reported symptomatic toxicities will ensure that this information is considered as part of the clinical decision-making process, and this may ultimately improve patient outcomes.

Acknowledgments

This project has been funded in whole or in part with federal funds from the National Cancer Institute, National Institutes of Health, Department of Health and Human Services (under contract no. HHSN26120180013C) as well as the National Institutes of Health Support Cancer Center Support (grant P30-CA008748-53), which partially supports the Patient-Reported Outcomes, Community-Engagement, and Language Core Facility used in carrying out this investigation.

Conflicts of Interest

JU received funding, and authors SM, AR, and AK each received stipends from the National Institutes of Health and National Cancer Institute for developing the Mobile Patient-Reported Outcomes version of the Common Terminology Criteria for Adverse Events Administration System (mPROS) through the Phase 1 Small Business Innovation Research contract (HHSN26120180013C).

Abstract

Background: Despite the potential of digital mental health to provide cost-effective mental health care, its adoption in clinical settings is limited, and little is known about the perspectives and practices of mental health professionals regarding its implementation or the factors influencing these perspectives and practices.

Objective: This study aims to characterize in depth the perspectives and practices of mental health professionals regarding the implementation of digital mental health and explore the factors affecting such perspectives and practices.

Methods: A qualitative study using in-depth semistructured interviews with Portuguese mental health professionals (N=13)—psychologists and psychiatrists—was conducted. The transcribed interviews were thematically analyzed.

Results: Mental health professionals deemed important or engaged in the following practices during the implementation of digital mental health: indication evaluation, therapeutic contract negotiation, digital psychological assessment, technology setup and management, and intervention delivery and follow-up. Low-threshold accessibility and professionals' perceived duty to provide support to their clients facilitated the implementation of digital mental health. Conversely, the lack of structured intervention frameworks; the unavailability of usable, validated, and affordable technology; and the absence of structured training programs inhibited digital mental health implementation by mental health professionals.

Conclusions: The publication of practice frameworks, development of evidence-based technology, and delivery of structured training seem key to expediting implementation and encouraging the sustained adoption of digital mental health by mental health professionals.

Introduction

Background

Digital mental health may be understood as the use of digital technologies to support and improve mental health conditions and provide mental health care, including screening, health promotion, prevention, early intervention, treatment, and relapse prevention [1-3]. It encompasses a wide range of modalities, including internet research [4], monitoring and assessment [5], videoconferencing counseling and psychotherapy [5], internet interventions [6], and professional training (e-learning and e-supervision) [7]. In this regard, various technologies (telephone, mobile devices, apps, videoconference and chat software, psychological assessment, support and intervention platforms, artificial intelligence, virtual reality, serious games, wearable devices, etc) may be used to improve health outcomes or facilitate health care service delivery [1,2].

Owing to the potential of digital mental health to increase access to mental health care, eliminate disparities, and reduce costs of treatment delivery, interest and research in the field have grown exponentially in the past years [8]. Numerous randomized controlled trials have been conducted, and a strong body of evidence of efficacy has been generated [9,10], particularly in the domains of internet interventions [11] and videoconferencing counseling and psychotherapy [12].

Internet interventions are self-help, guided or unguided, technology-enabled interventions that aim to provide health and mental health–related assistance [11]. They have been found to be more effective than treatment as usual and as effective as face-to-face therapies for various conditions [13] (eg, generalized anxiety disorder [14], depression [15], and cancer-related distress [16]). The impact of guidance on the efficacy of internet interventions has also been examined. Although previous studies suggest that guided interventions are superior to unguided interventions [17], there is still a lack of research comparing the outcomes of blended treatment outcomes with classic face-to-face or nonblended treatments [18]. Internet interventions have also been found to be cost-effective when compared with various control conditions, such as active, attention, or waiting list control groups [19].

With regard to counseling and psychotherapy delivered via videoconference, previous systematic reviews [12,20] have reported that they can be effective across different populations (eg, children, adults, and older adults), geographies (eg, urban and rural), care settings (eg, primary health care settings and clinics), and mental health conditions (eg, anxiety, depression, and distress). Previous studies have reported that the effects are comparable with both in-person treatment and blended care approaches [20], and evidence on videoconferencing counseling and psychotherapy cost-effectiveness is increasing [21]. However, although sound scientific support favors the use of digital mental health approaches for the treatment of mental health disorders, its adoption by mental health professionals has been slow, and its implementation in clinical settings is still limited [22]. In Portugal, despite a significant mental health treatment gap [23,24], digital mental health initiatives are practically nonexistent [25].

Across the globe, various studies have been conducted to identify potential drivers of and barriers to digital mental health adoption (ie, acceptance, uptake, and use) and investigate mental health professionals' attitudes toward such an approach [26]. In general, findings suggest that professionals' attitudes range from neutral to generally positive [27], and there are several factors affecting adoption. Factors that are often identified as expediting adoption relate to the low-threshold accessibility of digital mental health [28,29], professionals' knowledge and training in the field [30,31], the potential to introduce new treatment alternatives (eg, virtual reality and biofeedback) [32], and professionals' positive attitudes toward digital mental health [28]. Conversely, factors frequently appointed as inhibiting adoption relate to the absence of ethical, legal, and regulatory frameworks for providing web-based mental health care [33-36]; professionals' lack of knowledge and training in the field [28,30,31]; potential confidentiality and security breaches associated with digital systems [37]; and negative attitudes toward digital mental health [28]. Furthermore, greater acceptance of blended care approaches was reported across studies [22,32].

Although previous research provides valuable insight into the factors influencing the adoption of digital mental health by professionals, adoption predictors, and their interrelationships are largely unknown. Most studies with health care professionals adopt a quantitative cross-sectional design, capturing the stance of large samples and listing implementation drivers and barriers but failing to provide an in-depth understanding of therapists' experiences, attitudes, and adoption determinants [32]. Moreover, qualitative studies on the topic often focus on cognitive behavioral therapy–oriented interventions [38,39], specific treatment modalities [39,40], and particular mental health conditions [22,29,39] or include participants of specific research programs [22,29,39,41], failing to characterize in depth the perspectives and practices of mental health professionals regarding the implementation of digital mental health or the factors influencing such perspectives and practices.

Objective

The aims of this study are (1) to characterize in depth the perspectives of mental health professionals regarding digital mental health, (2) to characterize in depth the practices of mental health professionals regarding the implementation of digital mental health, and (3) to explore the factors influencing such perspectives and practices in the context of Portugal.

Methods

Study Design

This qualitative study used in-depth semistructured interviews to characterize the perspectives and practices of Portuguese mental health professionals regarding the implementation of digital mental health and explore the factors influencing such perspectives and practices. A semistructured interview guide (Multimedia Appendix 1) was developed based on a literature review and analysis of data obtained from a previous study by the research team [28]. The interview guide included 33 questions and covered five main domains: (1) professional background and digital technology proficiency, (2) knowledge

and use of digital mental health, (3) attitudes toward digital mental health, (4) advantages and limitations of digital mental health, (5) drivers of and barriers to the adoption and implementation of digital mental health, and (6) therapeutic process and alliance in digital mental health interventions. In addition, follow-up questions were used to clarify participants' perspectives and practices. The COREQ (Consolidated Criteria for Reporting Qualitative Research) checklist was used as a guideline to structure this paper [42].

Sampling and Recruitment

A nonprobabilistic, stratified purposeful sample [43] of Portuguese mental health professionals—psychologists and psychiatrists—was planned to capture variation and ensure the inclusion of participants in different age groups and work contexts; with different academic degrees and theoretical orientations; and reporting different levels of work experience, knowledge, and use of digital mental health. The sample of participants was identified following referrals from researchers and contacts in the health community. A total of 28 mental health professionals were invited to participate in this study via email or telephone. Of the 28 invited professionals, 15 (54%) replied and agreed to participate. Meaning saturation was established as a stopping criterion, which meant that new participants would not be enrolled once novel fieldwork insights stopped significantly changing the analysis [44]. Data collection ended after 87% (13/15) of participants were interviewed, as meaning saturation was achieved during the last interview.

Study Context

This study was conducted in the context of the iNNOV Breast Cancer project (ClinicalTrials.gov NCT03275727) [45]. During the iNNOVBC project, we realized that mental health professionals' attitudes toward digital mental health were significantly associated with previous use of such interventions, potentially affecting program acceptance and implementation. On the basis of this insight, we decided to further investigate the perspectives and practices of mental health professionals regarding the implementation of digital mental health and explore the factors influencing such perspectives and practices using this qualitative interview study.

Ethical Approval

This study was approved by the ethics review boards of Instituto Português de Oncologia do Porto Francisco Gentil, Unidade Local de Saúde de Matosinhos, Entidade Pública Empresarial, the Portuguese Psychologists Association (Ordem dos Psicólogos Portugueses), and the Portuguese Data Protection Committee (approval number 10727/2017). Written informed consent was obtained from all participants before the onset of study procedures.

Data Collection

Interviews took place face to face between November and December 2019 at Fraunhofer Portugal AICOS meeting rooms to ensure a private and facilitating environment. A total of 2 interviewers participated in the data collection (CMS and Ana Alves or Elsa Oliveira). Although both interviewers were free to pose questions and provide clarifications, each interviewer was assigned a main role (ie, principal interviewer or observer). The first author acted as the principal interviewer in all interviews. Interviews were conducted in Portuguese.

A pilot interview was conducted at the onset of the study to test the interview guide and train all the researchers on the research protocol. In total, 13 mental health professionals were involved, resulting in approximately 10 hours of audio recordings. The average duration of the interviews was 49 (range 26-81) minutes. All interviews were audio recorded and stored in a pseudoanonymized format in a secure, password-protected location. Interview recordings were transcribed verbatim (CMS and Ana Alves) using oTranscribe (MuckRock Foundation) [46], an open-source transcription web app. Transcripts were coded and analyzed in parallel with data collection to enable data collection to be driven by analysis.

Researchers' Characteristics and Reflexivity

The research team comprised outsider, hybrid, and insider researchers with multidisciplinary backgrounds (eg, clinical psychology, engineering, and design). Nevertheless, all data collection team members worked within the field of digital health, which may have influenced the conduction of interviews and analysis. As such, several measures were taken to ensure the validity of the study and promote reflexivity.

Before the start of the study, members of the research team were encouraged to write down their expectations regarding the findings and debate them within the team to elicit preconceptions and prejudiced ideas that could influence the analysis. In addition, data collection co-occurred with data transcription to help reveal areas of the data that required more exploration in subsequent interviews and raise awareness of the potential impact that researchers' relationship with the research topic and participants could have on data collection and interpretation. During the study, frequent meetings were conducted to encourage reflection and debate on management and interview analysis.

Analysis

The analysis followed the thematic analysis method of Braun and Clarke [47]. Coding was performed in parallel by 2 researchers (CMS and Ana Alves). After initial familiarization with data through interview transcription and repeated transcript reading, initial codes capturing salient content were independently generated. Scrivener software [48] was used to support the coding of the interview transcripts and the writing of the memos. Regular discussions between the researchers (CMS, Ana Alves, Elsa Oliveira, and FN) were promoted to discuss the results and coding trees, and comparative analyses were performed to ensure reliability. Data patterns were then identified and iteratively organized into themes by clustering and collapsing codes based on similarities and differences. Thematic maps were then assembled and refined as they were applied to the data. Patterns within and across themes were systematically explored and scrutinized until consensus between researchers was achieved, and no additional insights resulted from the analysis of the data. Preliminary and final reports were submitted for participant validation.

Results

Participants

A total of 13 mental health professionals participated in the study. Of these 13 mental health professionals, 2 (15%) were psychiatrists, and 11 (85%) were clinical psychologists. Most participants were female (11/13, 85%), and the median age was 35 (IQR 11, minimum 25, maximum 56) years. Participants had a median of 11 (IQR 11) years of professional experience, and most held a master's degree or higher (9/13, 69%). Most participants were active (12/13, 92%) and working at different universities or research institutions (5/13, 39%), distinct hospitals of the National Health Service (4/13, 30%), and various private practices or charities (3/13, 23%). Most participants (9/13, 69%) developed some sort of clinical practice at the time of the interviews. Approximately 31% (4/13) of participants worked exclusively as clinical and health psychology researchers in the field of digital mental health. Approximately half of our sample had cognitive behavioral therapy orientation (7/13, 54%). Considering the participants' knowledge and experience using digital mental health, the sample was evenly distributed, including nonusers and occasional and regular users (Table 1). Nevertheless, given the embryonic stage of digital mental health in Portugal [28], half of our sample could be considered as early adopters of digital mental health and thus may not be representative.

[a]CBT: cognitive behavioral therapy.

Findings

Digital mental health is not addressed at Portuguese universities, being poorly disseminated in health care institutions and frequently limited to private practice and research organizations. As a result, the participants' understanding of and experience in the field were dissimilar, ranging from sparse to significant and focalized to comprehensive. Although professionals working in private practice were mostly familiar with videoconference counseling and psychotherapy, interviewed researchers had a broader perspective on the various available intervention formats and experience delivering internet interventions and on the web and virtual reality rehabilitation programs. Despite these knowledge and experience decalages, 5 main themes and 16 subthemes became salient in the analysis and characterized the perspectives and practices undertaken by professionals regarding the implementation of digital mental health. These perspectives and practices are listed in the adjacent textbox (Textbox 1) and further described in the following sections.

As the perspectives and practices of participants regarding digital mental health were highly influenced by the purpose of the intervention (psychological assessment, psychotherapy, etc), the selected treatment modality (eg, videoconferencing counseling, internet interventions, etc), and drivers and barriers encountered during the implementation process, the abovementioned practices tended to unfold subsequently but could also co-occur, overlap, be omitted, or assume a recursive nature.

Textbox 1. Themes and subthemes describing participants' salient perspectives and practices.

Themes and subthemes

Indication evaluation

- Assessment of digital mental health uptake drivers
- Appraisal of digital mental health uptake barriers
- Casuistic assessment of the applications and indications of digital mental health

Therapeutic contract negotiation

- Clinicians' credentials presentation
- Therapeutic setting definition
- Therapeutic boundaries framing
- Contingency plan construction
- Privacy, confidentiality, and data protection procedures disclosure
- Legal, jurisdictional, and billing considerations discussion

Digital psychological assessment

- Dealing with the absence of validated technology
- Perceived lack of control over the psychological assessment process

Technology setup and management

- Adapting and conciliating nonclinical software to clinical purposes
- Developing digital mental health technology

Intervention delivery and follow-up

- Appraising the impact of the absence of evidence-based, usable interventions in practice
- Therapeutic alliance establishment
- Perceived lack of control over the therapeutic process

Indication Evaluation

After hearing about digital mental health from a peer, a conference presentation, or a client requesting to be followed remotely, most participants reacted to digital mental health with disquietude. Having received no formal training on digital mental health, participants presented ambivalent predispositions toward this practice, including "apprehension" (P12) and "curiosity" (P1), and felt the need to further explore whether digital mental health could be applied in their practice:

> *I felt that there was a grey area in online psychological interventions because there were many questions that were not being answered [...] my idea was I will not go through with this until it is as transparent as possible* [P5]

Similar to P5, multiple interviewed professionals felt that there was a lack of high-quality guidelines for implementing digital mental health in practice. Professionals had to search thoroughly for legislations and regulations, technical requirements, ethics, and risks of these interventions, and there was an absence of structured intervention frameworks that could be easily adopted. This void required our participants to independently assess who digital mental health could be appropriate for and autonomously delimit digital mental health applications and indications before initiating their digital mental health practice.

According to the participants, digital mental health could be used for prevention, screening, intervention, and rehabilitation purposes. The ubiquitous nature of mobile devices was recognized as an appropriate venue for performing screening and ecological momentary assessments. Complementarily, the low-threshold accessibility, high scalability, and customizable and persuasive design (ie, technology designed for changing users' attitudes or behavior [49]) of digital mental health could potentially leverage prevention (self-care) interventions and rehabilitation programs. Digital mental health was also considered valuable if integrated within a stepped-care health care model, playing an important preventive and supportive role before escalating to more differentiated health care alternatives:

> *[Digital Mental Health] makes sense to me [...] precisely before referral to us [psychiatrists] and not exactly for patients with major disorders. That is, it can and should probably be part of healthcare in [...] early stages of illness [...] I don't want to be too optimistic, but [perhaps] it can effectively prevent future psychiatric illness* [P4]

During the interviews, it became clear that digital mental health was not for everyone; however, the participants believed that many clients could benefit from this approach. Given the accessibility and convenience of digital mental health approaches, implementation was consensual among geographically isolated clients, migrants, and clients at risk of contracting infectious diseases, such as immunodepressed patients. Digital mental health was also considered to support clients presenting mild to moderate psychological disorders or stabilized major disorders and patients with chronic illnesses, as it could support self-care. Conversely, digital mental health was considered generally contraindicated to clients experiencing severe conditions, such as advanced dementia, psychotic outbreaks, borderline personality disorder, suicidal ideation, or history of parasuicidal attempts, because of a high risk of dropout and the difficulties in managing crisis episodes at a distance. According to the participants, special consideration should also be given to clients living in unsafe environments or experiencing domestic violence, as such conditions could not fulfill the minimum setting requirements to establish rapport, compromising the intervention's efficacy and making contingency plans hard to deploy remotely. To be able to benefit from digital mental health approaches, participants considered that potential clients should also present minimal literacy and computer skills, have preserved cognitive function, and be motivated and insightful.

In addition to the abovementioned recommendations, interviewees emphasized that digital mental health implementation should be casuistic, and uptake should depend on the assessment of individual, technological, and contextual factors. In certain situations, digital mental health could configure the unique available alternative to provide first aid psychological support, becoming the indicated approach to even manage situations to which it could be typically contraindicated (ie, suicidal ideation):

> *It's not that I like it very much, but I have several patients [...] who have emigrated [...] and what happens is that it can be crucial and even vital for that person to know that on the other side of the world there is someone who speaks her language, who understands, and who can [...] help her acquire tools to deal with the situation...* [P11]

Awareness of such potential led various health care professionals to consider adoption even when their attitudes regarding such modalities were somewhat negative. According to the participants, complying with their perceived duty to provide psychological support to clients in need was of high importance and often superimposed therapists' preferences, concerns, or digital mental health's identified limitations, being the triggering point for various participants to start delivering digital mental health interventions.

Another important aspect emerging from the interviews was the notion that digital mental health indications could be dynamic and change during the therapeutic process:

> *For example, avoidant people, people with social anxiety [...] we may be reinforcing this way of functioning [using an online medium]. Of course, that if we start like this at an early stage and then afterwards, we bring the person in...but if it's always online and one of the issues is that she's not able to be face-to-face with other people, we are only reinforcing this behaviour with the online intervention* [P13]

As explained by P13, digital mental health interventions could be particularly useful in facilitating access and motivating clients for treatment at some point in the process but could also reinforce dysfunction at a later stage, becoming counterproductive. According to participants, the use of digital mental health implied not only assessing the indication of such an approach at the onset of the intervention but also monitoring the impact that the digital model could have on the therapeutic process.

Therapeutic Contract Negotiation

According to the participants, the delivery of digital mental health interventions should not be a simple transposition of the face-to-face model to the digital format. Appropriate implementations of digital mental health should comply with specific procedural and relational rules that should be clarified and negotiated with clients' ad initium. Although some participants opted to verbally debate with clients on these rules and procedures, others considered this information to be transposed to a written therapeutic contract formalizing the therapeutic relationship being established:

> *You were just asking if there were any rules that were established...I believe that in this type of intervention that's something that should be more demarcated [...] because there is no face-to-face contact. So maybe the intervention should be better delimited, it should be even written, the way things should work [...] the commitment should be established in a more pronounced way.* [P6]

As noted by P6, the high flexibility and informal character of digital interactions could sometimes collide with the structured setting that clinical interventions require, making mental health professionals uneasy. Consequently, participants felt the need to debate with clients about the nature and format of the proposed intervention.

According to the participants, clinicians' credentials should be made available to clients, and the digital setting should be clearly defined. Session or module frequency, structure, and length should be communicated to clients at the onset of the intervention, and the importance of client assiduity and compromise should be emphasized to foster client adherence to the digital therapeutic process. The session's physical space was also a matter of concern. Participants mentioned the importance of guaranteeing a stable and innocuous background environment to underline the professional character of the service being provided. Most participants paid attention to the room dynamic and environmental circumstances in which the session occurred to ensure that no distractions hindered its flow and that confidentiality requirements were met.

Negotiating the therapeutic contract went beyond establishing the setting rules configuring a sort of user manual for both

clients and professionals. According to the participants, when using videoconference, specific guidelines should be followed and provided to clients. Defining who was responsible for establishing the connection was considered important to provide clients with assurance. Complementarily, having a waiting room, as provided in some videoconference software, was perceived as important to welcome clients and mimic the face-to-face model.

Professionals also provided orientations regarding lighting and camera positioning to ensure an adequate assessment of clients' behavior and provided instructions on how to prevent interruptions caused by technology failure. These strategies included turning off other software running in the background and using a cabled network for connection stability. They discussed the diligence to perform in the event of poor audio or image performance, technology failure, or disconnection to avoid impacts on ongoing introspection, ensure adequate therapist feedback, or enable crisis containment. These procedures were perceived as particularly relevant when dealing with crisis situations and became part of a predefined contingency plan. Furthermore, alternative follow-up or communication strategies were identified at an early stage to prevent misunderstandings, promote trust, and make the therapeutic boundaries clear.

Clarifying relationship boundaries during this negotiation phase was capital to most participants:

> *There may be a tendency in some people to think that because it's online...[It] is not really a psychologist-client relationship. The dynamics of power may become slightly blurred. So, to mitigate this problem [...] this initial contract dotted the i's and crossed the t's [...]. Dual relationships...So...How will we treat each other on social networks, you know? "I will not follow you...I advise you not to do it as well to protect your privacy"..."I will not google you..." that sort of...* [P5]

To avoid negatively affecting the therapeutic process, most professionals established strict protocols and boundaries. To avoid dual relationships—situations where multiple relational roles exist between a therapist and a client—most professionals exclusively used institutional accounts or platforms to contact clients and refrained from becoming friends or followers of their clients on social media, thus preserving their clients' privacy and the evolving working alliance.

Professionals also made full disclosures of their data collection and protection procedures, including the storage of personal contacts, health and psychological data, correspondence, or billing data, to assure clients that their privacy was safeguarded. Detailing the costs of each type of interaction (eg, SMS text message, email, and reports) was mentioned as important by participants as it also served the purpose of reinforcing therapeutic boundaries. Finally, our participants discussed the legal and jurisdictional framework that applied to the intervention, especially with clients from abroad and frequent travelers.

Digital Psychological Assessment

Once the therapeutic relationship was framed, therapists were faced with the challenge of case formulation and adaptation of the psychological assessment process to the digital format. In general, interviewees considered the administration of psychological instruments (standardized questionnaires, projective tests, etc) and clinical interviews digitally approachable. Nevertheless, they had reservations about the potential of remote observation and the possibility of performing an accurate and comprehensive psychological assessment using digital mediums.

Regarding testing, most participants expressed high acceptability of systems capable of supporting remote assessment processes and capable of automatically sending, administering, and scoring tests, underlining their time-saving potential. However, none of the participants used such technology in their clinical practice because of the scarcity of dedicated platforms in the market, limited set of instruments, lack of adaptation to Portuguese and digital contexts, or high subscription costs. Having to overcome such barriers significantly affected professionals' practices and possibly the psychological assessment process. While some professionals felt compelled to narrow the scope of the evaluation, relying solely on structured clinical interviews to avoid experiencing a high technological burden in their practice or submitting clients to such a burden, others opted to devise alternative ways of administering psychological instruments remotely:

> *Zoom allowed me to share the screen, so I used to share PQ [a clinical interview] and then clients would see me on the left and the questionnaire on the right and I would fill it out.* [P5]

Professionals commonly used a collaborative approach to administer structured interviews or questionnaires, using videoconference or emailing encrypted questionnaires to overcome distance and software limitations. However, this approach was not considered adequate for all tests (eg, some neuropsychological instruments), and several doubts were expressed regarding the validity of remotely administering paper-and-pencil instruments. In the absence of instruments duly adapted to the digital context, the administration of psychological instruments raised a feasibility dilemma. Participants were often confronted with the conflicting alternatives of trying to administer the assessment protocol they would implement in person versus implementing the most feasible evaluation protocol while considering usability, time, and investment constraints. Moreover, the security and compliance of such procedures with the General Data Protection Regulation and intellectual property rights were questioned, revealing that some participants were uncomfortable with the strategies they implemented.

Regarding observation, some participants expressed concern over the possibility of losing their "clinical sense" (P4) while performing a remote psychological assessment. Owing to limited vision angles and difficulties in assessing nonverbal communication cues, several interviewees rejected this alternative. Other participants recognized that, although this might be a limitation under some circumstances, in other

situations, the digital environment, especially videoconference, could bring an ethnographic dimension to the experience, allowing the therapist to perform a more accurate in loco evaluation of clients' behaviors and contexts:

> *Deep down I completely entered her world, which was a room in a house, in an isolated town. I could see the tidiness and untidiness of her little room [...] Often I could see that she was wearing pyjamas [...] and that was a session mobilizer at times because she was in fact very comfortable, but she was also presenting with depressive symptoms [...] And I was there to watch it like a movie. [...] Well, I believe that we might miss some information, but I also think that there is other information, as in this case, that emerges that perhaps in another face-to-face situation would not appear, right? [...] It ended up being somehow invasive of her privacy...(But) That's right, she was showing it to me.* [P6]

Digital in loco observation, as described by this participant, provided therapists with the opportunity to gather contextual information that is usually unattainable during in-person appointments, such as the hygiene conditions of their clients' homes. It also encouraged clients to behave more naturally and, therefore, facilitated the display of clinically significant signs that otherwise could be hidden. However, as clients' background scenarios and interactions were not under the therapists' control, accessing contextual information passively provided by clients was sometimes felt by professionals as a violation of their clients' privacy. Furthermore, the perception of traveling in an unchartered territory could arise, challenging the therapists' confidence in their web-based assessment capabilities:

> *I get the impression that...I never know the conditions of the environment where the patient is. I don't know if someone is listening to the patient or not, I don't know if what the patient is saying to me is trustworthy or not.* [P11]

As discussed by P11, the impossibility of guaranteeing communication security and discriminating between all environmental factors potentially affecting clients' behaviors during digital appointments sometimes threatened therapists' confidence in using digital mediums for assessment purposes. In addition, the difficulty in discerning if the information conveyed was real or fabricated hindered professionals' perception of control over the digital psychological assessment process. Overcoming such perceptions required adopting a structured assessment framework capable of anchoring professionals' practices and supporting them in providing a comprehensive evaluation of the client.

According to some participants, technology could be helpful in providing such a framework and reinforcing professionals' perceptions of control over this process:

> *It's preferable to have a platform...I would rather be framed by a platform, without a doubt...I prefer to shield myself in a situation like this, than not being safeguarded by a platform. I find it more organized, I find it more coherent, I think it makes a lot of sense to have this type of resource.* [P6]

As mentioned by P6, digital platforms have the potential to integrate several components inherent to the psychological assessment process, facilitate data collection and interpretation, and enable a more comprehensive assessment of the client. Moreover, if designed to comply with data privacy and security requirements, technology could attenuate professionals' concerns about confidentiality and data breaches, increasing therapists' perception of control and security while assessing remotely.

Technology Setup and Management

Being intrinsic to digital mental health, technology plays a determinant role in both psychological assessments and interventions. As each technology (web platforms, mobile apps, chatbots, etc) has its own affordances and characteristics, potentially capturing information and delivering interventions in a distinct way, participants considered that technology should be selected to comply with the characteristics and specific needs of the target population or client. Consequently, professionals were faced with the task of acquiring, adapting, or developing digital technology at some point in the intervention process. The point at which this aspect was addressed depended on the professionals' work context, training, selected approach, and proficiency in the delivery of digital mental health interventions. Although professionals working with more structured approaches, such as internet interventions, usually addressed this requirement at the onset of the intervention process, therapists working in private practice tended to test and adapt various technologies after a preliminary assessment of the client, making adjustments along the intervention process. Regardless of the adopted strategy (ie, purchasing, developing, or adapting technology), pursuing such tasks was often considered a challenge by professionals.

Confronted with the absence of dedicated technology and the obligation to comply with confidentiality, data privacy, and security requirements, professionals were often forced to conciliate and adapt multiple nonspecific software for clinical purposes:

> *I developed, within my limitations because I am not a programmer, an encrypted Excel program...I tried my best to develop something [compliant with GDPR] [...] then I bought a cloud [...] which allowed encryption and stored [the data] there. But I struggled a bit [...] Because there's the excel file and you can put there, some data, but what about the reports? [...] I was forced to handle many different files, all encrypted, with different passwords, then...I had to use a password manager too...And then there's the e-mail part...I subscribed a platform that allows you to encrypt messages without the recipient using [it] as well. But before, we had to share a password. So, in the first session...I asked people to provide a password for the e-mail communications [...] verbally. Okay, so, I was struggling with that and what I would like to have is a platform where I didn't need to manage many passwords, where everything is integrated, where I can communicate with the person in a safe way.* [P5]

Similar to P5, various other participants used nonclinical videoconference software such as Zoom videoconferencing and Skype to conduct remote sessions and administer questionnaires or perform clinical interviews. Encrypted email services were occasionally subscribed to protect therapist-client off-session communication exchanges, and Microsoft Word was used to produce reports. Microsoft Excel was sometimes used to create forms for collecting client data, and some participants mentioned the use of encrypted cloud services for data storage. Implementing and maintaining these technological setups posed a burden on both professionals and clients and compromised therapists' efficiency and satisfaction. Thus, most interviewees agreed on the importance of developing dedicated and comprehensive platforms to implement digital mental health interventions efficiently and cost-effectively.

However, many participants considered that developing digital mental health technology was a "long and challenging process" (P10). According to some participants, there is a tendency to design "one size fits all" (P13) tools and interventions; however, digital mental health technology should capture and portray emotional and relational nuances to fit different clients. Trust and transparency should be embedded in the structure of the software, and empathy should be conveyed through developed assessment and intervention materials. Digital mental health technology should be usable, inclusive, customizable, scalable, and disseminated, but also culturally sensitive, and assume a personalized and dynamic form. Complying with these requirements was considered highly demanding, especially when developing intervention programs such as internet interventions and web-based or virtual reality rehabilitation programs.

According to some interviewees, developing assessment and intervention programs requires the assembly of a multidisciplinary team. Although mental health professionals need to create the content, designers could be required to work on the graphical presentation, and developers could be needed to create a vehicle to deliver the intervention. Our participants also stated that developing digital mental health programs usually entailed performing comprehensive literature reviews and user research (eg, based on interviews, observations, and usability testing) to identify the best medium for treatment delivery and understanding how to structure the content and exercises to be included in the program under development. As a rule of thumb, participants stated that digital mental health programs should be adaptable and responsive to different formats and devices to reach most clients in ways they find appropriate. However, fulfilling this criterion is not always possible mainly because of financial and technical limitations:

> *In an ideal context we could have developed a web and a mobile app version that complemented each other, but at the time it was not possible. So, we had to decide, and the web version seemed more viable to us, it was...[cheaper] and it allowed us to have the content the way we wanted. An app required...shorter content, a different organization that for us was more difficult to develop in a first rehearsal of the program.* [P8]

Creating intervention content was also considered a challenging process. As identified by P8, it required understanding how the characteristics of a selected technology could affect the therapeutic program being developed. The text length, type of audiovisual content, exercises, and features that can be included in each program vary depending on the selected technology, and the impact that its limitations could have on treatment efficacy should be considered. Furthermore, developing interventions' content implied writing to hypothetical personas [50] and steering development to fit clients' characteristics. However, as the act of typifying clients often collided with the casuistic approach most professionals were trained in and adopted in clinical practice, various participants mentioned feeling uncomfortable with such an approach:

> *I found this adaptation very difficult because we know that the strategies are suitable for each person and what works for one, may not work with another. "But how do we get this into the material?" So, what I tried to emphasize was "these are just suggestions, the most important thing is to follow what makes you feel more comfortable, and you should adapt it according to what makes sense to you," and I underline "don't look at this as laws and rules." Specially because when suggested strategies don't work and everything falls apart, patients who follow all the steps may feel cheated, or question their self-efficacy, their skills...[...] So, my biggest concern was not to cause more damage than people were already experiencing.* [P13]

As discussed by P13, developing digital mental health interventions and tools was considered a major responsibility. This implied not only designing personalized evidence-based empathetic programs but also acknowledging the impact such programs could have on clients beforehand. The different possible intervention outcomes had to be anticipated, and strategies to ensure that possible adverse effects were prevented, monitored, and addressed should be integrated into developed interventions to comply with safety and beneficence requirements. In this regard, iterative testing was considered crucial not only to identify unanticipated characteristics of the program with the potential to negatively affect clients but also to guarantee programs under development were "culturally sensitive and adapted to the target-population" (P9).

To achieve such a high level of technology refinement, participants referred to the different development stakeholders—academia, industry, end users, and funding bodies—that needed to be aligned, and that the multidisciplinary development team should be able to communicate effectively, adapt, and collaborate. However, communication within development teams could be difficult because of different backgrounds within the team, dysrhythmic development processes, and the existence of divergent goal-steering development. This "misalignment" (P7) could significantly affect the quality, usability, and sustainability of developed interventions. As a result, an important gap in what concerns high-quality, evidence-based digital mental health technology was identified by participants.

Intervention Delivery and Follow-up

During the interviews, the "absence of evidence-based ready to use interventions" (P4) and the lack of accessible, secure, and comprehensive assessment and treatment tools were identified as the major factors affecting treatment delivery. According to the participants, if not properly designed, handled, and monitored, technology could be experienced as a "barrier" (P7) or "filter" (P6), especially by clients with limited sensory, cognitive, and physical user capabilities. Various participants recognized the lack of usability of existing tools and programs as an important implementation obstacle. Interventions' "high complexity both in terms of structure and content" (P10), as well as the use of noninclusive design approaches, were considered problematic because of the deleterious impact they could have on treatment adherence, outcome, and rapport.

As perceived by various interviewees, establishing a therapeutic alliance on the web is feasible, and the quality of the established bond may be equivalent to that occurring in face-to-face interactions. However, participants considered that such a process could be affected by poor technology design, adaptation, or failure, and specific strategies should be implemented to facilitate rapport.

> *I did not feel much difference, to be honest, between presential and online interventions in terms of therapeutic alliance [...] you can create the bond in the same way. [...] in the first sessions, I keep assessing if and how the person feels me present, so to speak...If we feel connected and sometimes when I realize that the person is looking at the camera a lot, I give the eye contact suggestion "can you distance yourself from the screen, place the program window in a different way so that we can both be looking at each other in the eye without having to be looking at the camera." [...] It works, and I feel well, I feel in tune with the person, something that I thought I would feel more in person.* [P5]

According to the participants, fostering the therapeutic alliance on the web required close monitoring of both the relational and technological dimensions of the therapeutic process. As mentioned by P5, technical instructions such as adequately distancing and positioning the camera or repositioning tabs and windows on the computer desktop while videoconferencing should be followed to ease eye contact, bring authenticity to digital interactions, and strengthen the working alliance being established. In other intervention formats, such as internet interventions, our participants emphasized the importance of using different communication channels (eg, written, verbal, and visual) to convey warmth and empathy during the intervention and provide timely and personalized feedback to the client regarding homework assignments or intervention strategies being implemented. According to participants, the interventions' materials and therapists' written feedback should be made permanently available to extend the therapeutic setting beyond booked appointments, reinforce the evolving working alliance, and potentially accelerate behavior change. The conduction of close follow-up sessions was also identified as important to "promote relationship continuity" (P1). Various participants suggested that an initial face-to-face appointment was important as well to "give a push to the bond and compromise being established" (P3). Nevertheless, the development of such connection could be influenced by clients' personal characteristics—namely, age, information and communications technology literacy, and cultural aspects. Therefore, close monitoring of the evolution of the working alliance should be performed, and, if necessary, alternative and simpler communication mediums, such as face-to-face appointments or telephone calls, should be used to prevent treatment abandonment.

Client dropout or early abandonment was a recurrent concern captured in the interviews, particularly in the context of crisis situations. Digital mental health was regarded as an unchartered territory in what concerned managing crises, as most participants stated not being prepared to handle such situations remotely and required specific training on how to build contingency plans and how to detect risk situations early:

> *Whoever is on the other side must be aware, know [the signs], and be able to detect the moment when risk arises, right? And despite being at a distance [...] even when in different countries, [the therapist] must be able to properly assess and refer the client. But I don't know how much we can contain on this side...* [P3]

Some of the strategies implemented by participants in this regard included restricting the use of digital mental health to mild or moderate conditions, collecting emergency contacts at the onset of the intervention, and mapping local institutions to be activated under crisis circumstances. Nevertheless, because of the limited action range therapists felt in these situations, various participants were hesitant to work exclusively online, and most refused to consult with anonymous clients.

Delivering digital mental health interventions implied "dealing with unforeseen challenges along the therapeutic process" (P2) without having clear guidelines and training on how to pursue such practice and how to deal with problems such as managing adverse events or crises at a distance. Therefore, a perception of a lack of control over the therapeutic process was experienced by some therapists. This perception was reinforced by the generalized notion that information and communications technology systems are susceptible to security and confidentiality breaches and discouraged therapists' sustained adoption of digital mental health.

Perception of control seemed to be influenced as well by the intervention format and type and frequency of communication established between therapist and client. Ranging from residual in unguided interventions to augmented in blended care interventions, therapists' perception of control seemed to increase when guidance was provided, and synchronous interactions with clients occurred:

> *In unguided interventions, our concern relates to the fact that we don't have control over the evolution of the symptoms and the fact that a person can give up anytime...although, this can happen in presential sessions as well, right? But online we have less*

> *information about what's happening on the other side and this can somehow be a matter of greater concern...I don't think it's an impediment, but it is perhaps the issue that concerns me the most [...] being more frequent [...] half face-to-face sessions and half online sessions, it would allow greater progress monitoring... a greater sense of control in some way, even though this perception might be subjective...* [P8]

According to P8, unguided formats of treatment delivery or guided interventions, including exclusively asynchronous communications with clients, could make a proper case formulation difficult and compromise the assessment of treatment outcomes, hindering therapists' perception of control over the therapeutic process and making them refuse or hesitant to use such formats. Consequently, most participants endorsed blended care interventions.

To be encouraged to implement digital mental health interventions, particularly formats other than blended care, various participants referred to the need for structured training on digital mental health:

> *We must have the necessary knowledge and practice to be comfortable working online [...] otherwise my concern will be "I can't do this, I can't do that" and my attention is no longer on the person, on the questionnaire's results and I believe the usefulness of these tools is lost* [P12]

Training was considered instrumental in providing therapists with the necessary knowledge and practice to implement digital mental health interventions confidently. However, the absence of formal digital mental health training programs was transversally identified as a major gap affecting its adoption by professionals.

Discussion

Principal Findings

This study suggests that mental health professionals deemed important or engaged in the following practices while implementing digital mental health interventions: (1) indication evaluation, (2) therapeutic contract negotiation, (3) digital psychological assessment, (4) technology setup and management, and (5) intervention delivery and follow-up. Although these practices tend to unfold subsequently, they could also co-occur, overlap, be omitted, or assume a recursive nature depending on the purpose of the intervention, the selected treatment modality, and the drivers and barriers encountered along the implementation process.

The implementation of digital mental health started with an evaluation of its indication to a given client and involved the appraisal of individual, technological, and contextual aspects. Similar to previous research, our participants perceived digital mental health as indicated only to a subset of clients [26], restricting it to individuals presenting with mild to moderate symptoms [33,51], limited comorbidity [39], and low risk [41]. However, such recommendations were not consensual among all participants in this study, and in reflection, it may be non–evidence based and unethical [52]. A previous meta-analysis showed that digital mental health interventions could be efficacious for individuals presenting with severe symptoms and suicidal ideation, and there is little evidence that these groups present an increased risk of adverse events [53,54]. Furthermore, a recent publication [55] disclosed that at MindSpot, one of the world's largest publicly funded web-based clinics, users' mean symptom scores were in the moderate to severe range, and a quarter presented with suicidal ideation. This reality suggests that digital mental health might be an important mental health care gateway for clients experiencing severe conditions, and as claimed by various participants, a casuistic indication assessment should be performed to comply with equity and beneficence requirements [56].

Professionals' perceived duty to provide support to clients in need was an important digital mental health adoption driver identified in this study, which has been poorly explored in the literature [32]. Such responsibility often superimposes participants' preferences, concerns, and digital mental health's perceived limitations, which is the triggering point for various participants to start delivering digital interventions. Digital mental health's low-threshold accessibility and convenience [28] reinforced such decision, particularly when treating clients living in geographically underserved areas [51] and patients who were mobility impaired [29], a finding that corroborates previous research [26]. However, due to digital mental health's indication dynamic character [57], such an approach was generally not perceived as a standalone alternative but as part of a continuum where different types and degrees of interactions between client and therapist could be operated to fulfill the clients' best interests. As such, digital mental health interventions were frequently understood as potentially following, intersecting with, or culminating in other treatment approaches (eg, face-to-face interventions and pharmacotherapy), better fitting a hybrid mental health care model [58].

However, hybrid mental health care models have been insufficiently addressed in the literature [26], and a lack of structured intervention frameworks presenting clear guidelines on how to implement digital mental health in an ethical, legal, and secure way was transversally identified by participants as a barrier compromising its implementation. Similar findings have been reported in previous studies [33-36]. To compensate for this lack of structure, professionals independently formulated rules and procedures to organize their digital practice, placing great emphasis on the negotiation of the therapeutic contract.

This practice often involved discussing with clients, in a highly structured manner, digital setting rules, confidentiality and data protection procedures, therapeutic boundaries, and contingency plans to be deployed in potential crisis situations. Despite generalized agreement on the importance of debating the abovementioned aspects with clients, various participants were concerned about the impact such high formality could have on the therapeutic process. To the best of our knowledge, this is the first study to document the digital therapeutic contract negotiation procedure; therefore, further research should be performed to assess its impact.

After framing the therapeutic relationship, professionals typically proceeded with digital psychological assessment. Although the methods they used were similar to the in-person process (eg, observation, testing, and clinical interviews), participants reported that this process was highly dependent on technology availability, characteristics, and performance. During the digital psychological assessment, difficulties in assessing nonverbal communication cues became salient, and the inability to fully control the evaluation setting raised concerns over the possibility of performing an accurate and comprehensive psychological assessment on the web. Such concerns echo the findings of previous research [28,35,59,60]. In a recent study, Mendes-Santos et al [28] reported that approximately 60% of psychologists perceived remote psychological assessment processes as inaccurate, increasing the possibility of misdiagnosis. In another study by Gilmore and Ward-Ciesielski [60], 30% of participants identified digital assessment as risky, particularly when evaluating clients at a high risk of suicide. Nevertheless, previous studies have validated telephone-based behavioral assessments [61], and the equivalence between paper-and-pencil and web-based testing has been consistently documented [62,63]. More importantly, a previous study by Godleski et al [64] reported that suicide risk assessment can be effectively completed via videoconference and in-home messaging devices and is as effective as suicide risk assessment completed in person. This discrepancy between participants' stance toward digital mental health and evidence has been previously identified in other studies [28,34] and suggests that an important knowledge gap in this domain hinders professionals' adoption of such an approach.

Another important obstacle identified in this study, which potentially compromised professionals' performance and, therefore, their sustained adoption of digital mental health [40], was the absence of usable, validated, and affordable digital mental health technology. Although these factors have been singled out as potential barriers compromising digital mental health adoption in previous research [65], their real impact on clinical practice is undetermined. Moreover, the strategies used by professionals to overcome such obstacles have been poorly explored. This aspect may be justified by a greater number of studies focusing on specific research trials [22,29,39,41] or web-based clinics that evolved from research programs [38]. As the technological infrastructure required to deliver interventions in these contexts is assembled beforehand, professionals are possibly spared from the difficulties of acquiring, adapting, and developing digital mental health technology.

Nevertheless, the implementation of digital mental health necessarily entails such procedures. Interestingly, the point at which this technology setup occurred depended on the professionals' work context (eg, research and clinical settings), training, selected treatment approach, and proficiency in the delivery of digital mental health interventions. Professionals developing regular digital practices or working with more structured approaches usually addressed this requirement at the onset of the intervention process, consistently using the preselected technological setup along the process. Conversely, therapists making sporadic use of digital mental health tended to blend in-person and digital approaches more often, frequently electing preferential technology for treatment delivery after a preliminary assessment of the client. The tendency to test and adapt various technologies during the intervention process also characterized the latter group. This practice is possibly justified by a confrontation with technology limitations during the intervention, which were initially unforeseen, or the dynamics of the treatment process requiring different technology affordances to be explored according to clients' progress.

Challenged with the limited availability of affordable evidence-based tools capable of comprehensively supporting treatment delivery, professionals were often forced to narrow the scope of their clinical work or devise alternative ways of pursuing such practice. Mirroring other professionals' procedures [66,67], the adaptation of nonclinical software (eg, Gmail and Zoom videoconferencing) for psychological evaluation and intervention purposes was a strategy frequently adopted by participants in this study. As such practice risked noncompliance with the General Data Protection Regulation, intellectual property rights, and good clinical practices, various participants were hesitant to make sustained use of digital mental health, reserving it for extreme situations such as providing support to migrants. In addition, most professionals underlined the importance of expediting the development of evidence-based digital mental health technology capable of framing therapists' digital practices. This potential of technology to structure the clinical process was also found in previous studies [40,68].

Nonetheless, the development of digital mental health technology was often perceived as long, complex, and expensive. Moreover, a misalignment between development stakeholders (eg, terminology, development priorities, and quality assurance criteria) was identified as a major barrier compromising the effectiveness, usability, and transference of developed programs into clinical practice. Such perceptions align with the current discussion around digital mental health development and implementation processes. Previous publications have discussed the need to turn such processes more agile [69], solution focused [1], and integrated into clinical practice [8,70]. Moreover, a paradigm shift toward the design of digital mental health services instead of products seems to be unfolding [1,55]. According to Mohr et al [1], to be widely adopted and fully integrated into health care systems, digital mental health services need to be designed to fit into the fabric of clients' lives, respect professionals' workflows, and be able to accommodate changes in the care environment and technological ecosystem. If not, digital mental health might be experienced as an added burden rather than as an added value, as became salient in this research. Similar results have been reported by Cerga-Pashoja et al [40].

During intervention delivery and follow-up, professionals were often concerned about the negative impact of nonusable, validated, or defective technology on treatment adherence, outcome, and rapport. Similar to other studies, various participants considered that a positive therapeutic relationship could be established and extended on the web [29,57], potentially accelerating the treatment progress [32]. To be able to foster and monitor the therapeutic alliance, most participants recognized that the development of new relational and technical

skills (eg, the management and development of digital technology and engaging with clients remotely) was necessary, a finding that corroborates previous research [39,55].

However, professionals' lack of training in digital mental health has been transversally identified in this and previous studies [28,34,66], and most participants relied solely on research and trial and error experiences of use to develop such skills. As a result, most professionals questioned their self-efficacy [39] to assess and intervene remotely, and a marked perception of lack of control over the implementation of digital mental health interventions prevented them from fully adopting such an approach. This perception of lack of control has been documented before in relation to technology [39], therapeutic settings [71], therapeutic processes [56], and management of crisis situations [35]. However, no study deeply explored this barrier. Adding to previous research, insights from this study suggest that perceptions of lack of control over case formulation; the assessment of treatment outcomes; and the detection, management, and monitoring of treatment adverse events also discouraged adoption. Moreover, professionals' perception of control seemed to be highly influenced by their experience of use and training. As such, capacitating therapists with the necessary skills to implement digital mental health interventions proficiently seems key to building confidence within the class and expediting adoption.

Unfortunately, there is currently no standard method of training therapists in digital mental health, and structured training and supervision initiatives are limited [72]. Moreover, the paucity of research assessing the impact of such programs is concerning [73]. Considering that the skills and knowledge required for effectively delivering digital mental health interventions are considerably different from those required in traditional models of care [55], not addressing this gap menaces both the quality of interventions delivered by untrained professionals, as well as the future sustained adoption of digital mental health.

Strengths and Limitations

This study had various strengths. It involved a purposeful selection of participants with different sociodemographic characteristics, working within different contexts, presenting different levels of knowledge and use of digital mental health, providing an in-depth understanding of the perspectives and practices of mental health professionals regarding digital mental health. Furthermore, data collection was theory informed and co-occurred with data transcription, helping to reveal areas of the data that required more exploration in subsequent interviews, enriching the data set. Continuous reflection and a consensus approach were also adopted during data collection and analysis. This practice raised awareness of the potential research biases affecting the study. Finally, respondent validation and investigator triangulation were used to increase the validity of the results.

Nevertheless, a few study limitations must be considered when interpreting our findings. Although a stratified purposeful sample was selected to capture variation, as in many interview studies, the representativeness of the sample cannot be established. The results are based on an in-depth analysis of interviews provided by a small sample of Portuguese mental health professionals and, therefore, may not be transferable to other contexts. The fact that digital mental health is still at an embryonic stage in Portugal [25] might have influenced participants' attitudes and opportunities to explore digital mental health—namely in what concerns other digital mental health modalities and technologies (eg, artificial intelligence, serious games, wearable devices); therefore, it is unclear whether the same issues would be identified among professionals practicing, for example, in digital mental health frontrunner countries [74]. Another aspect to consider is that the main interviewer was previously known to most participants from her role as a digital mental health researcher or clinical psychologist. This fact may have introduced a social desirability bias, possibly leading interviewees to be less critical of digital mental health. Finally, this study failed to pursue other forms of triangulation, such as method, theory, and data source triangulation, which would have been advisable to test the validity of the obtained results and gain a more comprehensive understanding of the implementation of digital mental health. However, previous research seems to indicate that the insights from this study have ecological validity [28].

Conclusions and Future Research

This study aimed to characterize in depth the perspectives and practices of mental health professionals regarding the implementation of digital mental health and explore the factors influencing such perspectives and practices. Our findings suggest that mental health professionals deemed important or engaged in the following practices to implement digital mental health interventions: (1) indication evaluation, (2) therapeutic contract negotiation, (3) digital psychological assessment, (4) technology setup and management, and (5) intervention delivery and follow-up. Digital mental health's low-threshold accessibility and professionals' perceived duty to provide support to their clients were identified as the main drivers facilitating implementation. Conversely, the lack of structured intervention frameworks; the unavailability of usable, validated, and affordable technology; and the absence of structured training programs negatively affected implementation and, consequently, professionals' adoption of digital mental health.

To overcome the abovementioned barriers and expedite professionals' adoption of digital mental health, the publication of legal, regulatory, and practice frameworks that can be easily transferred to practice seems necessary. These guidelines could be conjointly elaborated by different digital mental health ecosystem stakeholders (eg, policy makers, regulatory bodies, clinicians, and information technology and data protection specialists) to ensure that they are comprehensive enough to provide the necessary structure professionals require to confidently work remotely. Moreover, the co-development of digital mental health technologies and services must be encouraged. Clients and professionals must participate in the development process to guarantee that such services answer their most pressing needs and integrate smoothly into routine care. In this context, user and implementation research is key to streamlining the development and implementation processes. Finally, to guarantee proper implementation of digital mental health, the design of training programs that are structured according to professionals' most pressing needs and that are

assessed, certified, and made widely available to professionals seems of high importance. To incentivize adoption, professionals must be trained in the implementation of digital mental health interventions and in managing the main barriers affecting it. Research on professionals' current unmet digital mental health training needs is necessary to structure this process. Addressing these research action axes could not only empower professionals in the delivery of digital mental health interventions but also expedite adoption and help close the current mental health care treatment gap affecting health care systems worldwide.

Acknowledgments

The authors wish to acknowledge the Erasmus+ Program of the European Union—Phoenix Joint doctoral program on Dynamics of Health and Welfare, Fraunhofer AICOS, and the Foundation for Science and Technology (individual research grant 2020.09045.BD)—for supporting CMS. The authors thank all participants and Elsa Oliveira and Ana Alves for their assistance with data collection and early analysis.

Abstract

Background: Health care provider organizations are complex and dynamic environments. Consequently, how the physical and social environment of such organizations interact with an individual is a primary driver of an individual's experience. Increasingly, the capabilities required for them to successfully interact with those within their care are critically dependent on the information infrastructure they have in place, which enables people, both patients and staff, to work optimally together to deliver their clinical and operational objectives.

Objective: This study aims to design a framework to address the challenge of how to assemble information systems in health care to support an improved sense of coherence for patients, as well as potentially innovate patients' experiences, by connecting and orchestrating the synergy among people, processes, and systems.

Methods: It is necessary to understand the needs of health care providers and patients to address this challenge at a level relevant to information process design and technology development. This paper describes the design science research method used to combine the sense of coherence, which is a core concept within the Antonosky salutogenic approach to health and well-being, with an established information infrastructure maturity framework, demonstrating the coalescence of 2 distinct conceptual perspectives on care delivery. This paper provides an approach to defining a positive and supportive health care experience and linking this to the capabilities of an information- and technology-enabled environment.

Results: This research delivers a methodology for describing the patient experience in a form relevant to information infrastructure design, articulating a pathway from information infrastructure to patient experience. It proposes that patient experience can be viewed pragmatically in terms of the established sense of coherence concept, with its ability to identify and guide resources to modulate a patient's environmental stressors. This research establishes a framework for determining and optimizing the capability of a facility's information infrastructure to support the sense of coherence defined by the experiences of its patients.

Conclusions: This groundbreaking research provides a framework for health care provider organizations to understand and assess the ability of their information infrastructure to support and improve the patient experience. The tool assists providers in defining their technology-dependent operational goals around patient experience and, consequently, in identifying the information capabilities needed to support these goals. The results demonstrate how a fundamental shift in thinking about the use of information infrastructure can transform the patient experience. This study details an approach to describing information infrastructure within an experience-oriented framework that enables the impact of technology on experience to be designed explicitly. The contribution

to knowledge is a new perspective on modeling how information infrastructure can contribute to supportive health-promoting environments. Furthermore, it may significantly affect the design and deployment of future digital infrastructures in health care.

Introduction

Background

Information technology (IT) is increasingly playing a pivotal role in forming an individual's experience within a health system. The way processes are initiated and delivered and how we communicate our choices and needs, even the light and climate in the room, are now mostly interfaced and controlled through IT. Although there has been extensive work on defining an organization's ability to deliver such technologies [1], there is a scarcity of information on how technology influences the experiences of staff, patients, and families in the health systems.

The challenge is to construct health care environments that provide enhanced patient experience while enabling high-quality, accessible, and efficient care. To address this, it is necessary to understand more precisely how information and information systems affect patient and staff experiences both now and in the future.

Experience is a complex concept. Its realization is contextual to a person's environment, current emotional state, past experiences, and future expectations. In health care, the question has always been how to define a good experience and identify the elements of that experience that the hospital and its services can contribute. Significant survey-based work has been conducted to isolate the factors that patients believe contribute to a positive experience. Indeed, most care delivery organizations conduct detailed surveys after an episode of care to understand how well patient needs and expectations are met [2].

However, to date, there has been little research on why patients identify these factors. Understanding the forces driving patients' preferences would provide a clearer picture of how to change the hospital environment to improve the perceived experience. Consequently, we need improved models to shape experiences in health care. These models would include health care system–controlled factors that drive experience and describe how these factors come together.

This research aims to design a framework to address the challenge of how to assemble information systems in health care to support an improved sense of coherence (SOC) for patients, as well as potentially innovate patients' experiences, by connecting and orchestrating the synergy among people, processes, and systems. The resulting framework provides a method for shaping the patient experience through the improved use of a hospital's digital infrastructure and for the assessment of the maturity of this use based on an established digital infrastructure assessment methodology [3].

Literature Review

To clarify the relationship between experience and technology in health care, it is important that our definition of a health care experience is appropriate and that a model for generating experience is established. Through this model, the relationship with technology can be detailed. Health care has adopted a specific definition for experience, in which the actions that generate interactions between a patient and their operational environment (people, place, or process) are defined as the experience, and an individual's personal response to those actions is defined as satisfaction [4,5]. Both of these interrelated elements need to be accounted for when considering concepts such as the SOC to account for the generation of experience. In this review, we look at the definition of patient experience and patient satisfaction separately before bringing them together through the lens of SOC and relating them to information infrastructure through the infrastructure assessment methodology.

Patient Experience

Patient experience has been used to identify the weaknesses and strengths of health care delivery, with a view to driving quality health care improvements and promoting patient choice [6]. Such measures can report on communication and, more importantly, the patient's experience related to their involvement in their own care decisions [7]. Hence, it provides both a utilitarian feedback loop on health care delivery processes and the measurement of humanistic characteristics experienced by patients during their episodes of care.

Studies have found positive associations between patient experience and improved health outcomes, often through improved health care delivery processes [6,8-11]. Despite this, there is no consistent agreement about the quality outcomes, despite patient experience being considered a complementary measure for quality [9,12]. Indeed, several systematic reviews have examined patient experience and an elusive search for a specific definition [6,12-14].

Patient Satisfaction

Patient satisfaction can measure three things [15]: sufficiency of treatment and care received to improve health outcomes; fulfillment of requests from patients and families for treatments and diagnostics that are not clinically needed and may be harmful; and person-centered well-being factors such as communication, dignity, and respect and the associated logistical factors such as ease of making appointments, accessible parking, hospital physical environment and location, and hospital gowns. Arguably, the latter aspects relate to well-being and are intrinsically linked to a personal sense of worth [16]. The high variability of patient satisfaction can be confounded by

non–clinically related factors [9,17], over which the health care team has no control [18].

There are many dimensions to health care and, therefore, how a patient experiences an episode of care; consequently, how satisfied they are with the experience is one measure [19]. However, it is a measure that is variable for everyone and means something different for each person. Worryingly, research has shown that patient satisfaction scoring can have a negative and inappropriate impact on clinical care decision-making and behaviors of clinicians because of patient satisfaction score pressures [15,20,21]. At a superficial level, patient satisfaction scores reflect the manipulatable elements of what patients perceive as satisfactory experiences in defined episodes of care, such as hospital stays. In many cases, this indicates environmental factors such as noise levels. Consequently, there is no consistent agreement on whether this is an indicator of the quality of health care delivered or received [8,9,22-24].

The Integrated Design of Patient Experience and Satisfaction

Understanding how to optimize care delivery requires that both experience and satisfaction be addressed simultaneously. Although there will always be a need to separately understand what has been delivered (patient experience–focused measures) alongside how patients experienced that delivery (patient satisfaction–focused measures) when it comes to designing the environment in which a patient would best thrive in; however, both elements need to be considered. The notion of creating an environment for a patient that is supportive of the broader idea of patient health and well-being, balancing both experience and satisfaction, is an important consequence of using a salutogenic approach and its concept of SOC [25]. Indeed, in response to the conclusions of Dietscher et al [26], this research focuses on the impact of a more patient-centric approach, using IT to improve hospital processes and functioning. It is this broader characterization of experience, as viewed through SOC, which forms the ongoing definition of experience in this paper.

Experience and the SOC Concept

An approach to this broader concept of experience (ie, patient interactions and responses) is to look at concepts that consider how individuals respond to their environment and how they affect their well-being. One such concept is that of *SOC*, which is a constituent of the Antonovsky Salutogenic Model of wellness [25]. The Antonovsky model is based on an understanding of how an individual responds to stress and the coping mechanisms that the individual has, which enables them to better cope with this stress [27]. “The sense of coherence reflects a person’s view of life and capacity to respond to stressful situations. It is a global orientation to view life as structured, manageable, and meaningful” [28].

The assumption in using this approach is that a reduction in environmental stressors for an individual patient is core to a favorable personal health care experience. Indeed, research on the application of salutogenic orientation in hospitals identifies that interventions improving the hospital design and processes can have an impact on physical health [26]. This is further supported by evidence from psychoneuroimmunology research linking stress and physical health [29]. Although this may not constitute a complete or perfect definition of the drivers of health care experiences, it has proven to be helpful in the care of older adults and health promotion environments where the Salutogenic Model and its concept of an individual’s *SOC* have guided interventions for several decades [30,31].

The SOC core concept in the Antonovsky Salutogenic Model proposes that an individual’s ability to cope with environmental factors that could lead to stress depends on the individual’s three characteristics: their perception of the manageability, comprehensibility, and meaningfulness of their environment, as described in the following sections [32]. Correspondingly, an environment can be optimized in terms of how it contributes to an individual’s well-being (SOC) by optimizing the environment’s ability to deliver the following:

- Manageability: the experience of managing day-to-day physical realities; staying warm, dry, clean, rested, and nourished—the behavioral or instrumental component
- Comprehensibility: the experience of making sense of a situation and creating a structure from otherwise disordered and unexpected information—the cognitive component
- Meaningfulness: the emotional meaning of life and willingness to resolve setbacks and address potential causes of stress—the motivational component

An individual’s SOC can be assessed using several survey-based tools and is an established method of determining an individual’s well-being [33]. The environment can be characterized in terms of generalized resistance resources (GRRs) and specific resistance resources (SRRs) using the Salutogenic Model [34]. Both GRRs and SRRs assist in managing, reducing, or avoiding stressors [35]:

- GRRs are characteristics of a person, group, or community that facilitate an individual’s ability to cope effectively with stressors (tension) and contribute to the development of an individual’s SOC [36]. The social determinants of health and cultural, social, and environmental conditions, such as education, living conditions, salary, self-esteem, and neighborhood, are examples of GRRs [37]. GRRs are less sensitive to direct influence through the manipulation of local technology and information infrastructure.
- SRRs are situation specific and can be optimized to reduce stress in a particular environment or situation; for instance, the ability to change the temperature of a room, use support services, or provide supportive environments. SRRs are elements of experience that can be highly sensitive to direct influences through local technology and information infrastructure.

There is no literature on SRR manipulation to support patients’ experiences. However, SOC has been studied as an overarching philosophy in areas such as nursing [38]. In addition, no literature describes how to model SRRs across an organization to influence a whole hospital population rather than specific patients or in response to postepisode patient experience survey feedback. However, the concept of SRRs has the potential to provide a useful construct for relating the physical and social artifacts within a hospital’s operating environment to their likely

impact on the reduction of patient stressors and a change in the SOC-defined experience.

The methodology for this characterization of SRRs in health care, particularly the role of IT in SRRs, is a core component of the intended framework. For information infrastructure design, this work is centered on the assessment of the information infrastructure of a facility in terms of capabilities and our ability to characterize them in terms of their technology composition and their contribution to process outcomes, which in turn generate patient experience.

Information Infrastructure and Its Assessment

Previous research by Williams et al [3] investigated how information infrastructure can align with health care operational processes. This study resulted in the Infrastructure Maturity Assessment (IMA) framework that enables digital hospitals to assess the maturity of their information infrastructure against their desired digital transformation. The framework characterizes a hospital's infrastructure maturity to create a road map for digital transformation aligned to operational requirements while simultaneously identifying weaknesses in information and communications technology infrastructure capability. This framework is now an international benchmark of hospital infrastructure performance adopted by Healthcare Information and Management Systems Society Analytics [39]. In this study, we refer to the individual technical capabilities of the IMA process as technology services.

Previous research into the link between patient experience and technology has largely focused on assessing the *soft* or indirect benefits of technology and is primarily concerned with organizational processes [40-42]. Although the IMA framework has, to date, been used to assess the technological competency of a health care facility for supporting their key operational processes, our application here is to use this framework to define an organization's ability to support the collection of specific process sets that generate desired experiences, as defined through the SOC concept. Hence, the research question addressed is how the patient experience can be supported and improved through the better use of information infrastructure using SOC as a lens to understand the critical areas of technology-responsive improvement.

Methods

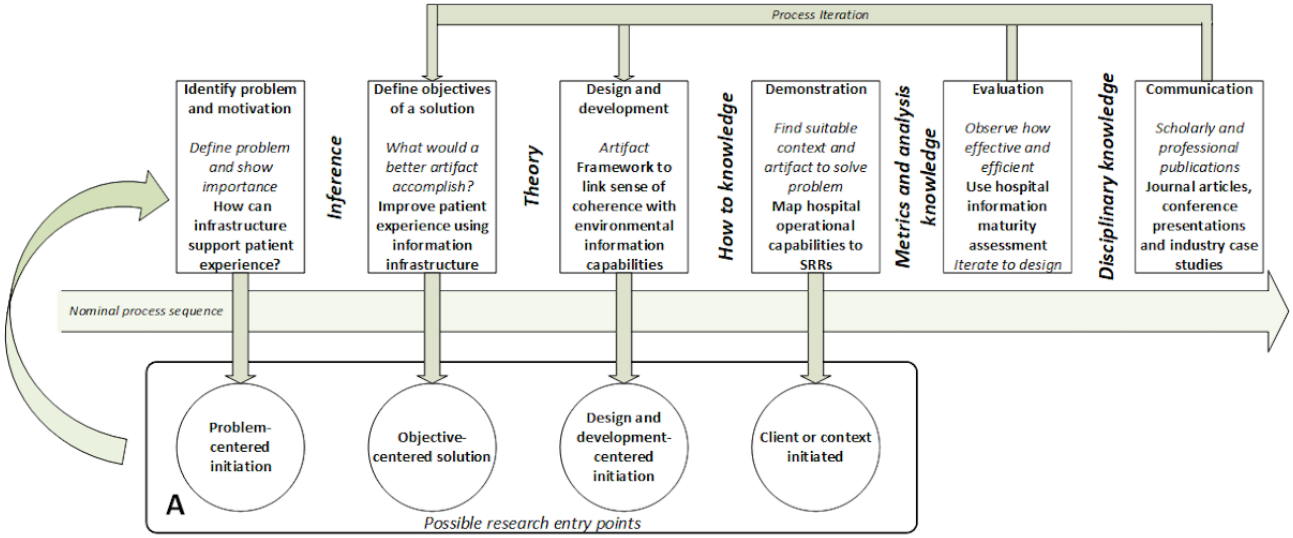
Overview

This research creates a generalizable framework for improving the patient experience through the better use of information infrastructure, which can be implemented in practice. This framework uses existing knowledge to solve the problem of enhancing patient experience underpinned by theoretical learning. This research is positioned in the applied research discipline of information systems (comprising systems, people, and processes). Design science is the chosen research paradigm as it facilitates the construction of problem solving of real-world challenges, applying theory from other disciplines rather than merely exploring, describing, and making sense of the problem [43,44]. This enables the application of multiple theoretical models to be integrated into design science decisions. The resulting framework (artifact) was developed from, and can be applied to, real-world problems in modeling patient experience.

Research Design

The research design defines the contextualization of the methodology for the research question. The application of the Design Science Research Methodology (DSRM) in this research is shown in Figure 1. Each DSRM activity is explained along with its corresponding output in the *Results* section.

Figure 1. Research design based on the Design Science Research Methodology [39]. SRR: specific resistance resource.



Results

The results reflect the steps of each DSRM activity in the research design, as shown in Figure 1.

DSRM Activity 1: Problem Definition

This study had a problem-centered initiation entry point (label A in Figure 1). The underlying problem in many approaches to patient experience is that they hinge on assessing experience using postepisode surveys, targeting only specific processes for

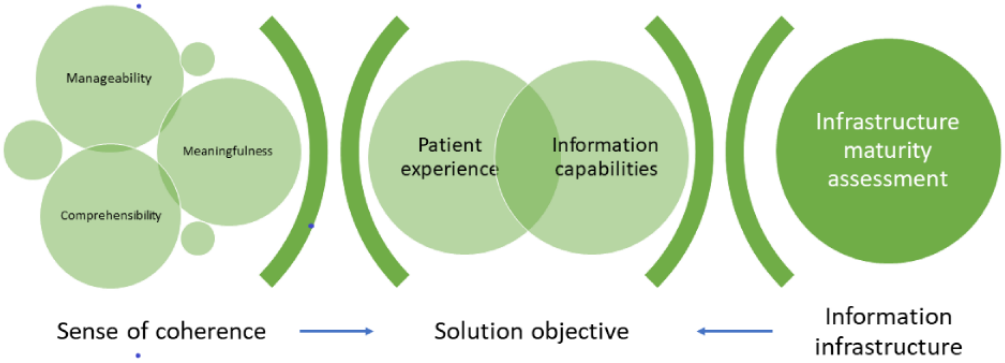
improvement. Postepisode surveys generate little insight into what drives individual patients to form their experiences and what is an optimal experience (a set of interactions and responses) for a patient. The survey approach, although critical in assessment, is insufficient for the purposeful design of patient environments. Experience-based design requires a more holistic model that balances individual patient preferences and benefits. Currently, there is no method for modeling how to improve the patient experience by examining the role of information infrastructure and services in the delivery and support of patient experience. Such a model needs to generate insight into the underlying drivers of such a balanced positive outcome and what influences these drivers. In this study, it was imperative to have those drivers defined in terms relevant to the impact of information infrastructure.

DSRM Activity 2: Solution Objectives

Overview

The solution's objective was to improve the patient experience by reducing environmental stressors for a patient (physical, mental, and social) through the existing hospital information infrastructure. Using the SOC concept as the perspective through which to support care provision in the hospital environment provides a method for defining what a positive and supportive experience looks like and linking this to the information capabilities of the hospital's operational environment. This activity was performed from two sides: defining existing or aspirational patient experiences within the health care environment at one end using SOC and, from the other end, defining how technology comes together to form processes using the IMA framework (Figure 2) that supports those experiences.

Figure 2. Research design: Design Science Research Methodology activity 2—forming the solution objective.



The separate actions in this activity (as shown in Figure 2) were as follows:

1. Mapping the hospital patient experience in terms of the SOC concept, detailing the experience statements that describe the domains of manageability, comprehensibility, and meaningfulness in terms of the operational environments of people, places, and processes
2. Describing how technologies and their combined technological capabilities come together to form information capabilities accessed through the IMA framework
3. Describing how information capabilities combine to form the SRRs that support experience statements.

Mapping the Hospital Patient Experience in Terms of the SOC Concept

The first action involved mapping the hospital patient experience in terms of the SOC concept, detailing the experience statements that describe the domains of manageability, comprehensibility, and meaningfulness in terms of the operational environments of people, places, and processes.

SOC is defined through its three domains: manageability, comprehensibility, and meaningfulness. It is helpful to view these domains in the context of the three environments in which patient experience is often discussed: the operational environments of people, places, and processes. This is the starting point for mapping the experience requirements of a care organization. It is the point at which the organization's vision, mission, and values are distilled into a set of statements that describe the organization, either as it exists at present or as it aspires to be in the future (Table 1).

Each SOC domain can then be articulated relative to these environmental descriptions using a set of experience statements (Textbox 1). These experience statements are not absolute descriptions of the ultimate state of an organization (although, in time, these types of descriptions could evolve); rather, they are distilled from the mission, vision, and values of the organization they describe. In Textbox 1, we articulate a typical set of statements for a modern acute care facility. We have structured the statements to include the condition of the environment (where relevant) and the desired experience, as the condition is an enabler (not a cause) of the subsequent experience. The experience statements are for an individual care organization based on the already defined operational environment descriptions. These statements are defined in collaboration with the facility's clinical and operational staff and their patients and represent either the organization's current state or the future aspirational state of the organization. They are defined for the three operational environments: people, places, and processes.

Table 1. Sample operational environment experience statements for an acute health care organization.

Statements and examples	Place	People	Process
Operational environment experience statements	• "I can individualize my external environment in such a way that best supports my needs." • "The environment is such that there are a minimum number of distractions." • "The environment is responsive to my emotional state and creates a calm and supportive atmosphere." • "The environment can be easily customized to my specific needs, and it reliably stays that way. It produces environmental changes that are traceable, and the logic is transparent."	• "My care team respects my preferences, beliefs, and values, and I have jointly agreed to the goals of care that I can influence in an ongoing way." • "I find working with my carers enriches my life and expands my goals for myself." • "I feel listened to and valued by my carers. There is clear communication between my care team that enables me to feel the I have control." • "There is a close and reliable bond established with the care providers that work with me."	• "I can engage with and appropriately manage the processes and systems to support me in a manner that is optimized to my preferences." • "There is effective coordination between the care team members. There is continuity of care with smooth transitions from one setting to another." • "Processes are responsive to my emotional state and are flexible." • "I feel that the processes are reliable and effective."
Examples	• Temperature, humidity, luminosity, color (hue, saturation, value, and color temperature), noise level, tactile suitability, navigability, cleanliness, enjoyability, comfort, and connectivity	• Friendliness, hospitality, teamwork, cooperation, rapport, transparency, responsiveness, sensitivity, empathy, truthfulness, behavior, professional etiquette, competency (cultural, spiritual, and clinical), accountability, awareness, capability, mastery of the systems (social and technical), respect, and communication	• Interoperability, completeness, reliability, availability, security, resilience, agile, adaptable, simplicity, patient centric, effective, efficient, optimized, empathetic (accommodating to individual circumstance and personalization), well-defined, understandable, engaging (includes user experience), sustainable, acceptable, ethical, legal, fair, equitable, reasonable, coordinated, integrated, safe, and timely

Textbox 1. Sample of typical sense of coherence experience statements.

Environment: place

- "I can individualize my external environment in such a way that best supports my needs."
- "The environment is such that there are a minimum number of distractions."
- "The environment is responsive to my emotional state and creates a calm and supportive atmosphere."
- "The environment can be easily customized to my specific needs, and it reliably stays that way. It produces environmental changes that are traceable, and the logic is transparent."

Manageability

- "I can influence or control the environment."
- "I have sufficient information about the healthcare environment to form reasonable expectations."
- "The environment provides sufficient amenities and facilities to reduce stress and enhance well-being. I feel more able to be in a positive mood due to an environment tailored to my personal preferences."
- "The environment is designed in a way that builds reliability. My environmental needs will be taken seriously. The environment is uniform and consistent with my specified requirements. It is responsive to my needs."

Comprehensibility

- "I understand what I can influence within the environment."
- "The information I have on the healthcare environment is presented in such a way that it is understandable by me (plain language, translated, visual and text)"
- "The absence of excessive environmental demands (noise, crowding, clutter, unclear signage, accessibility) enables a better understanding of the information provided to me."
- "I can direct my attention and focus on what is relevant. The environment reduces the simultaneous demands and minimizes distractions."

Meaningfulness

- "I can exercise my personal preference to build my capacity to make choices about my health now and in the future."
- "Having choices of the environment reinforces my belief in being able to influence my future positively."
- "I feel safe. The environment creates the context for who I am and what I have done. It allows me to interact easily with others creating a greater sense of belonging."
- "The environment supports my exploration of meaning-making by reducing fatigue and stressful demands. It encouraged and supported investigation beyond maintaining daily function. My ability to reliably engage with relevant information sources and share information between key people engenders a high level of trust in the environment."

Describing How Technologies and Their Combined Technological Capabilities Come Together to Form Information Capabilities Using the IMA Framework

A multistage process was used to describe how information capabilities can be formed. The first stage was formed around the IMA, which aggregates technologies into technology services (across the five domains of technical service capabilities of the data center, security, collaboration, mobility, and transport) and structures those services according to a staged maturity matrix [3].

In the second stage, the technical service capabilities of the domain are linked to form *information capabilities* (Textbox 2). Information capabilities are characteristics that information systems require for data actions in end user services. Information capabilities come together to support and create the processes across the three operational environments:

- People (or resources) using the infrastructure (eg, administrators, patients, staff, and equipment)
- Places where the information systems are used (whole hospital, specific hospital units, externally dependent campuses, and car parking)
- Processes that are dependent on information systems (nurse calls, bed management, and task management)

Textbox 2 describes the information capabilities within the operational environments of people, place, and process. Each information capability is defined in terms of the technical capabilities from which it is constructed. The assignment of technical capabilities to an individual's information capability is dependent on the real or aspirational operational objectives of a health care organization. The assignments described in this paper were allocated according to the operational objectives defined for an advanced digital hospital operating at level 8 of the IMA.

Textbox 2. Information capabilities descriptions.

Place

- Accessing: to establish interaction with resources (eg, people, equipment, supplies, information, and systems)
- Controlling: to influence resources (eg, people, equipment, supplies, information, and systems)
- Alarming: to notify the occurrence of a negative (problematic) event
- Alerting: to notify the occurrence of an event
- Measuring: to quantify the characteristics of a resource (eg, people, equipment, supplies, information, and systems)
- Responding: to create an action in response to an event

People

- Sharing: the exchange of data (including textual, image, or graphical information); it can be both synchronous and asynchronous; restricted to permanent and semipermanent file types (retrievable data types)
- Communicating: remote voice and video conversations between individuals or groups; face-to-face gathering of people; the synchronous or asynchronous exchange of textual information in a threaded and persistent form
- Locating: being able to identify how to access resources (eg, people, equipment, supplies, and information) in places
- Recording: the transcription of transient voice and visual information into a permanent record
- Organizing: arranging the schedules of one or a group of people and resources
- Identifying: describing the characteristics of people, places, or things in sufficient detail to uniquely define them
- Analyzing: the processing of information to form insights into decision-making
- Requesting: the identification of a need for a person, place, thing, or process so that it can be supplied at a given time or place
- Interpreting: analysis of current situations or information

Process

- Interoperating: the ability for processes to interact in a way that generates the desired outcome
- Contextualizing: creating information or processes that are relative to an individual's characteristics and the characteristics of the environment around them
- Orchestrating: scheduling, timing, and location of resources to maximize outcomes
- Scheduling: establishing the timing and location of services
- Simplifying: reducing complexity
- Informing: to make people or systems aware of relevant events or information
- Tasking: to assign a specific activity to an individual, group, or process
- Trusting: the creation of secure systems in which information is shared only within the rules established by the organization

Technical capabilities may be considered common (pertaining to all information capabilities within an operational environment) or specific (related to ≥1 but not all information capabilities within an operational environment). In summary, infrastructure-related technologies are used to create technical capabilities, and the aggregation of these technical capabilities forms information capabilities. Using this methodology, we can define an organization in terms of the maturity of its technical capabilities and in terms of the maturity of its information capabilities.

Information capabilities were graded using a modified (4-step) version of the 8-step IMA assessment. The IMA relates to how technology affects processes and is supported by a large volume of data. The 4-step maturity scale in Table 2 reflects a summary of the IMA 8 steps because of the current limited understanding of how hospitals mature in their delivery of the experience. In the future, it may be possible that this scale is expanded as more data are available and more granularity in defining the stages to improve patient experience in hospitals is gained. At this stage, only 4 steps could be assigned with confidence.

The 4-step information capability scale is described in terms of typical outcomes for each level across the operational environments of place, people, and processes (Table 2). This assessment provides organizations with an understanding of the technical strengths and weaknesses of the major operational environments.

Table 2. Information capability maturity—a 4-step maturity scale is used to assess information capability maturity within a health care facility.

Level	Place	People	Process
Level 0: fragmented	Data about the environment, the patient, and the staff may not be accurate or comprehensive because of infrastructure challenges and information capability issues. The format may be understandable but cannot be accessed easily.	It may not be possible for us to share clinical, environmental, and operational information between relevant individuals and groups. Without sharing, we may not be able to add to and refine this knowledge or develop a course of action to achieve our objectives.	An individual or group may not be able to take the plan of action and implement it by delivering physical resources, people, and knowledge to the appropriate places and locations within the organization at the required time. The actions of individuals linked with other individuals and teams coordinated with the assistance of the operational systems within the facility may be compromised.
Level 1: informed	Data about the environment, the patient, and the staff are accurate and comprehensive. It is accessible easily in an understandable format.	One can share clinical, environmental, and operational information between relevant individuals and groups. We can add to and refine this knowledge, developing a course of action to achieve our objectives.	An individual or group can take the plan of action and implement it by delivering physical resources, people, and knowledge to the appropriate places and locations within the organization at the required time. This would encompass the actions of individuals linked with other individuals and teams coordinated with the assistance of the operational systems within the facility.
Level 2: cooperative	Information is in a format and on a system that one feels comfortable using and has sufficient skills to operate effectively. The information is in a language that one is familiar with. One can interpret its content and purpose and gain further insight into the specific situation related to him or her and the course of action that needs to be pursued.	One feels closely connected with their care team, family, and social networks involved with his or her recovery. They understand his or her situation and the ways that they can best support him or her. They feel connected and invested with their situation and action plan. They can seamlessly share information and build collaborative plans to support their objectives.	The operations of relevant systems for delivering one's care are accessible, transparent, and understandable to their care providers and them. They are presented in a way that one can optimize their application for his or her specific outcomes (within the constraints of optimizing the whole of system outputs).
Level 3: systemized	The information is relevant to one's individual needs and future aspirations. The information enables one to cope with his or her daily challenges more effectively, providing a more effective sense of control of his or her outcomes. It allows him or her to craft an understanding of their future that is hopeful yet respectful of challenges that one will face in achieving that future.	Individuals can readily share the information with others to enable them to gain further understanding of their situation and course of action. One can build closer and more supportive relationships with members of his or her team (either patient or clinical) and feel an increased sense of engagement and control because of this.	One feels in control of their care. They understand all the resources at their disposal for optimizing the path to their future objectives. One feels that one has control over those resources, and they coordinate with each other to minimize their intervention in their delivery. They are linked with their care delivery team, and they evolve the services they deliver and how those services are provided, dependent on their progress to recovery.

Describing How the Information Capabilities Combine to Form the SRRs That Support the Experience Statements

The four main classes of information-driven SRRs within a hospital were defined through clinical and operational interviews as follows: teaming and sharing, scheduling and coordinating, monitoring and reporting, and education and training.

Information capabilities are rated according to their relevance to an SRR class. In analyzing an existing facility, the major applications and processes that constitute the SRR classes are defined, and the relevance of the facility's information capabilities is estimated using a 4-step scale (Table 2). This provides a map of SRR classes and their information capability strengths. The relevance of SRRs to the experience statements within the SOC domains (manageability, comprehensibility, and meaningfulness) can then be established using an equivalent relevancy scale. The process of estimating the relevance of both information capabilities to SRRs and SRRs to SOC domains is a critical part of the modeling process that engages a hospital in understanding the information capabilities they have and how they could, or do, affect the patient experience.

DSRM Activity 3: Design and Development

Overview

The design and development activity details the process used and results for each step in the framework creation, leading to the final link between the information infrastructure and patient experience. The solution objective was designed by refining the two ends of the solution (information infrastructure and SOC) into common SRRs that describe both the experiences to be delivered and the technological competency to deliver those experiences.

The experience requirements and technology contributions to the SRRs were described in terms of both their operational environments (people, places, and processes) and the SOC domains (manageability, comprehensibility, and

meaningfulness) using the DSRM 2 outputs of experience (Textbox 1) and IMA-based information capability outputs.

SRR Development

When combined and applied by people in a health care organization, information capabilities result in information-based SRRs and are the aggregation of people with technology to generate processes. The four major classes of information-based SRRs are teaming and sharing, scheduling and coordination, education and training, and monitoring and reporting, as described in Textbox 3. These classes were developed based on an experience study conducted at Fiona Stanley Hospital in Perth on their Enhanced Recovery After Surgery service and were established through extensive discussions with clinicians, technologists, and health care providers.

Through our earlier analysis, we defined the information capabilities that were then quantified through the extension of the IMA process across operational environments (people, places, and processes). In addition, we have experience statements across the operational environments (people, places, and processes) defined at the level of the SOC domains (manageability, comprehensibility, and meaningfulness). It is now possible to link these 2 sets of data together by building specific experience statements for each level of information capability assessment (fragmented to systematized) across each of the SRRs at the operational environment level (Table 3 and Textbox 4). This allows an organization to rank the relevance of its information capabilities to the SRRs they consider most relevant to the type of care they wish to deliver. Table 3 and Textbox 4 show a sample of the process-relevant experience statements for each level of information capability assessment for each of the SRR categories. Equivalent capability level experience statements are created for the information domains of people and place.

An overview of how the technological capabilities and experience requirements were drawn together through the creation of SRRs is depicted in Figure 3. SRRs are described both in terms of their technological components and their inherent experience statements and consequently form a bridge between technology and experience. This forms an overarching *Information Infrastructure to Experience Framework* (presented in the *Discussion* section, together with a discourse on how the framework may be used).

The process flow depicted in Figure 3 can be simplified to the high-level framework description shown in Figure 4. This Information Infrastructure to Experience Framework draws together the three key characteristics of the information infrastructure–driven experience landscape: technology capabilities, experience requirements, and delivery resources. It emphasizes the critical requirement of describing each of these elements within the common operational environments of people, places, and processes. Through this process, it is possible to relate the information infrastructure requirements to support the delivery resources needed to achieve the desired experience.

Textbox 3. Definitions of specific resistance resources.

Teaming and sharing

- Simply and conveniently bringing together clinicians, patients, and carers in the most appropriate format (pairs, groups, teams, and embedded into clinical workflows) to share information and emotion and enable the processes of care delivery and social support, minimizing the barriers of distance and timing

Scheduling and coordinating

- Linking clinical, patient, and carer engagement with scheduling and booking functions within the hospital to enable clear communication and management of activity timing to all participants, staff, and systems in each stage of an individual's patient journey

Monitoring and reporting

- The ability of patients, carers, and clinicians to access, interpret, and add to patient progress data; evaluate patient compliance; and modify the engagement to optimize the clinical and personal outcomes

Education and training

- The provision of education, training, and research materials at the appropriate time and appropriate format, which best supports the patients' clinical and personal needs and the clinician's requirements for decision-making and development

Table 3. An extract of the operational environment characteristics of experience (fragmented to systemized) for each specific resistance resource.

Specific resistance resource	Operational environment information capability maturity level	
	Information capability level 0: fragmented[a]	Information capability level 3: systemization[b]
Teaming and sharing of information contribution	• Task assignment and status are somewhat articulated and are not readily accessible to the individual. • Process structure and status are articulated but may not be readily accessible to the individual. • The skill sets and availability of individuals to accept tasks are articulated but may not be readily available to the individual. • An individual's workload is not readily accessible.	• Individuals have access to technologies that enable them to optimize the allocation of tasks so that they best fit the skill sets, work demands, work environments, and available technologies of the individual to whom the task is assigned. • Individuals have access to the technologies that enable them to define, allocate, and form tasks set into overall processes that sequence around the needs of the individual and the resources that are available within the organization.
Scheduling and coordination of information contribution	• The interactions between component tasks and the overall processes they drive may not be clearly defined and not readily accessible to the individual.	• Individuals and teams can conveniently coordinate tasks, managing those assigned and their sequencing (both in time and with respect to other necessary precursor events).
Education and training of information contribution	• The training and education activities do not articulate the processes that combine to create the required care delivery and how the component activities create the desired outcomes.	• The training and education process enables the individual to understand how to customize their educational resources to their current and predicted future needs, both personal and professional. They enable Individuals to choreograph their education and training programs around an existing potential future commitment.
Monitoring and reporting of information contribution	• How processes deliver upon supporting an individual's culture and values may be monitored and reported on and may not be accessible to all relevant personnel. • How current processes interact to support the quality and reliability of an individual's support services are not regularly monitored and reported on and may not be accessible to all relevant personnel. • How processes deliver upon supporting an individual's culture and values is monitored and reported on to be accessible to all relevant personnel. • How current processes interact to support the quality and reliability of an individual's support services is regularly monitored and reported on so that it is accessible to all relevant personnel.	• The efficiency of processes working in isolation or in more complex systems is monitored and reported, particularly looking to reduce complexity and potential bottlenecks in process execution.

[a]Information capability domain score average: 0.00-0.90; data about the environment, the patient, and the staff may not be accurate or comprehensive because of infrastructure challenges and information capability issues. The format may be understandable but cannot be accessed easily.

[b]Information capability domain score average: 2.41-3.00; an individual or group can take the plan of action and implement it through the delivery of physical resources, people, and knowledge to the appropriate places and locations within the organization at the required time. This would encompass the actions of individuals linked with other individuals and teams coordinated with the assistance of the operational systems within the facility.

Textbox 4. An extract of the operational environment characteristics of experience (experience statements for processes) for each specific resistance resource.

Manageability

- "I can tailor aspects of my care within the larger process of a health organization."
- "The process demands are reasonable and allow for choices and the needs of my life outside the health organization."
- "Tension is reduced because the process is efficient and effective and conforms to my evolving needs."
- "The processes are knowable, reliable, and effective, and I have developed confidence in them."

Comprehensibility

- "I understand my rights and responsibilities within the processes of health."
- "The processes are knowable and predictable."
- "Processes are clearly explained, and I understand my role, and when something is not right, I can voice my concerns and those concerns are heard and responded to"
- "The process is understandable, fair, and equitable for me."

Meaningfulness

- "The choices I make, and the choices offered to me align with my care goals and desired health outcomes."
- "I see the processes as parts that form a whole. They move me closer to my end goal."
- "Despite the volume of processes, I see them culminating in value for my treatment and care goals."
- "I believe that the process aligns with the goals of care and the outcomes I seek."

Figure 3. Process flow for linking experience requirements with technology capabilities to enable the delivery of required SRRs. IMA: Infrastructure Maturity Assessment; SOC: sense of coherence; SRR: specific resistance resource.

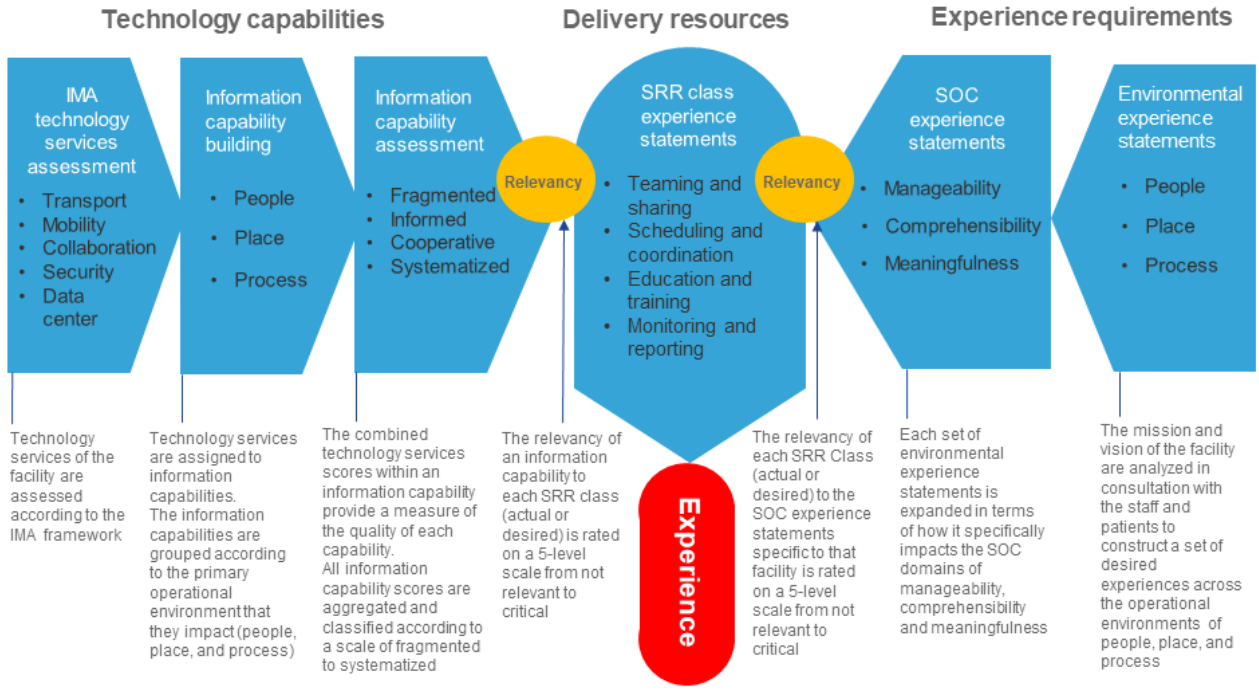


Figure 4. Information infrastructure to experience framework. SOC: sense of coherence.

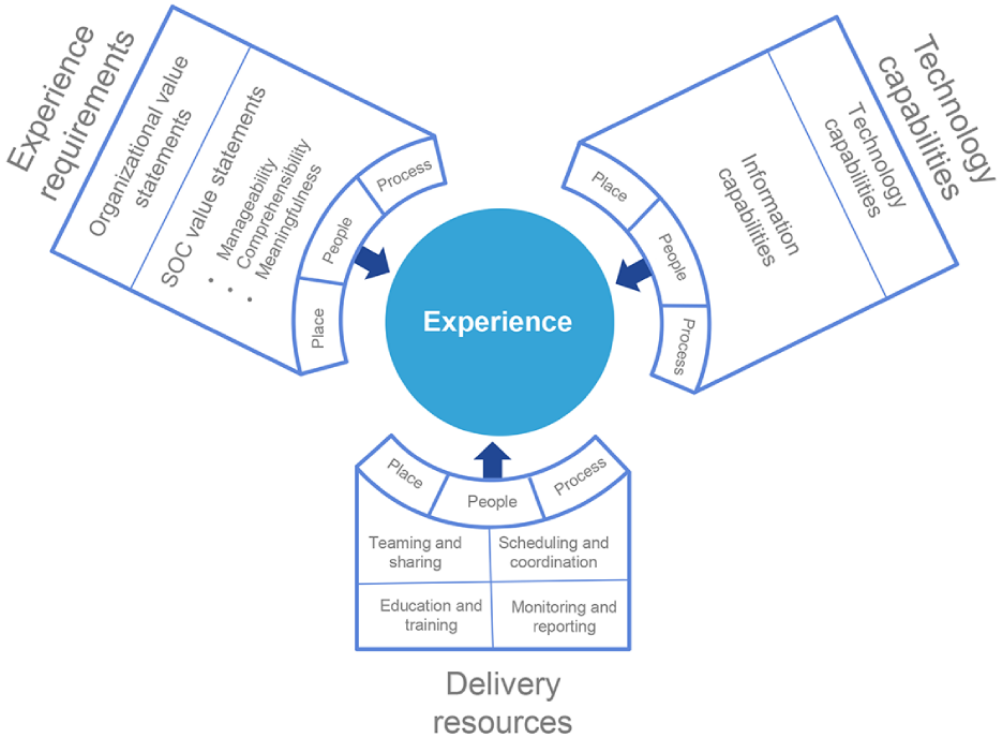

DSRM Activity 4: Demonstration

Through the combination of information capabilities into applications and processes, grouped together as SRR classes (collectively termed delivery resources), the linkage of technology capabilities with experience requirements was assessed to determine how the framework can be applied using existing IMA data. The assessment provided a proof of concept that demonstrated the use of the framework in practice.

Subsequently, there are 2 ways to demonstrate the Information Infrastructure to Experience Framework (Figure 4). First, it can be used in a descriptive fashion to explore the experience requirements (experience landscape) and possible technological responses to the landscape. This is addressed further in the *Discussion* section, along with the potential impact of this approach.

Second, it can be used in an analytical fashion to directly assess the current digital infrastructure's capability to support the organization's experience goals. In this process, an organization's information capabilities are scored using a modified IMA process. The relevance of these information capabilities to the organization's experience landscape is then rated by defining and analyzing the relevance of the organization's SRRs.

The first step of the analytical process comprises defining the information landscape by establishing sets of experience statements at the following levels:

- Operational environment (people, places, and processes)
- SOC domains (manageability, comprehensibility, and meaningfulness)
- Major SRR classes (teaming and sharing, scheduling and coordinating, monitoring and reporting, and education and training)

This defines the experience requirements of the organization as described in Table 3 and Textbox 4.

The second step is the analysis of the information capabilities. The information capabilities, as established for each of the operational environments (people, places, and processes) in Textbox 2, are assigned applicable technology services. These are the same technology services as described in the IMA research [3]; however, these technology services are assessed on a 4-level maturity scale (Table 2) in contrast to the 8-level IMA maturity scale. This generates an assessment of the technological service contribution to each information capability (see the sample in Table 4). Table 4 shows an extract from a much larger matrix that details the technological service requirements to reach a given experience performance level within the operational environments of people, places, and processes. Table 4 focuses on a selection of the IMA transport domain technological capabilities and how they are accessed in the operational environment of place.

Each information capability was then ranked according to its relevance to each of the 4 sets of SRRs, using the relevancy levels described in Textbox 5. The relevancy scale is used to define the level of importance of an information capability to an SRR, thereby indicating its significance in delivering the SRR. A simple 5-level ranking scale was selected as a smaller scale would be insufficiently definitive, and a larger diversity in rank would potentially create unnecessary differentiation in relevancy and would not add value to the relevancy assignment task.

Table 4. Scoring criteria of the Infrastructure Maturity Assessment technological capabilities on the 4-step experience scale.

Technological capabilities	Level 0	Level 1	Level 2	Level 3
Virtualization	Virtual segmentation of campus infrastructure is based on static configuration.	Macro–virtual segmentation of campus infrastructure is based on VLAN[a] trunking protocol propagation and VRF[b].	Micro–virtual segmentation of campus infrastructure is based on VxLAN[c].	Access controlled, policy-based microsegmentation of campus infrastructure is based on VxLAN.
End of support status	End of support status applies to ≤5% of core and distribution layer technologies and ≤30% of access layer technologies.	End of support status applies to ≤5% of core and distribution layer technologies and ≤20% of access layer technologies.	End of support status applies to ≤3% of core and distribution layer technologies and ≤10% of access layer technologies.	End of support Status applies to ≤3% of core, distribution, and access layer technologies.
Wired device grade	Approximately ≤70% of switches and routers are enterprise grade.	N/A[d]	Approximately 71% to 97% of switches and routers are enterprise grade.	Approximately >98% of switches and routers are enterprise grade.
QoS[e]	Fragmented QoS within the health care entity campus has been implemented. Trust boundaries are well defined.	End-to-end QoS has been implemented within the health care entity campus. Trust boundaries are well defined.	End-to-end QoS has been implemented within the health care entity campus and across the WAN[f]. Trust boundaries are well defined.	SDN[g] controllers have been implemented and are used to provide business applications and dynamic end-to-end QoS within the health care entity campus and across the WAN. Trust boundaries are well defined.

[a]VLAN: virtual local area network.

[b]VRF: virtual routing and forwarding.

[c]VxLAN: virtual extensible local area network.

[d]N/A: not applicable.

[e]QoS: quality of service.

[f]WAN: wide area network.

[g]SDN: software-defined networking.

Textbox 5. Relevance of an information capability relevancy to a specific resistance resource.

Rank 1

- Not relevant or rarely involved; the specific resistance resource is not required or provides information contribution based on safety requirements

Rank 2

- Occasionally involved; the specific resistance resource provides information contribution based on safety and timeliness requirements

Rank 3

- Normally involved; the specific resistance resource provides information contribution based on safety, timeliness, and efficiency requirements

Rank 4

- Should always be involved; the specific resistance resource provides information contribution based on safety, timeliness, efficiency, and effectiveness requirements

Rank 5

- Critical, must always be involved; the specific resistance resource provides information requirements based on safety, timeliness, efficiency, effectiveness, equity, and sustainability requirements

The third step establishes the relevance of the SRR classes to the organization's overall SOC-defined experiences within the domains of manageability, comprehensibility, and meaningfulness. This characterizes an organization's technological capability to deliver on the desired SOC experiences. In this process, each of the SRR classes is rated with respect to their relevance to each of the SOC domains (as defined by their experience statements) using the 5-point scale used in Textbox 5. Rating the SRR's technology capability by its relevance to an SOC domain generates an overall capability score (SOC domain-weighted experience capability) for each of these domains. A sample of this process is presented in the following section, *DSRM Activity 5: Evaluation*.

DSRM Activity 5: Evaluation

Overview

The preliminary evaluation used existing Australian data from past hospital infrastructure maturity assessments to ensure that the framework was robust yet flexible when applied to different health care environments. This research had two major outputs: the Information Infrastructure to Experience Framework and the framework scoring.

The initial evaluation tested the process by observing how the model responded to data inputs from the existing IMA data and taking those outcomes through the SOC experience statements. The next step in the evaluation was to perform detailed assessments using a framework with specific hospitals. For this, the first requirement was to define each of the core components of the experience framework across the operational environments of people, places, and processes.

Experience Requirements

This involves the outcome that the organization seeks to deliver through its experiences, described in terms of the patient experience statements for the SOC domains of manageability, comprehensibility, and meaningfulness.

Technology Capabilities

The information infrastructure maturity of the organization derived from the IMA quantifies the maturity of the technology services that are assembled into the information capabilities of the organization.

Delivery Resources

This involves the information-based processes within an organization that can use the information capabilities to deliver patient experience statements. These information processes form the SRRs defined within the concept of SOC.

The second step is ranking the information capabilities in terms of their relevance to the SRR classes and then ranking the SRR classes in terms of their relevance to the experience statements that define the three SOC domains of manageability, comprehensibility, and meaningfulness.

Framework Scoring

A preliminary evaluation of the information capability scoring and its relevance to the SRR classes is provided as a worked example in Multimedia Appendix 1. This example is based on a previous IMA conducted on an Australian hospital. The framework scoring (Multimedia Appendix 1) demonstrates the competency of a facility's information infrastructure to support the technology requirements of a given set of SRRs for each of the operational environments of people, places, and processes. The framework scoring process considers the relevancy of each SRR to each of the SOC domains, as defined by an individual hospital's experience statements, to generate a final SOC domain-weighted experience capability based on their current technology infrastructure.

With an understanding of the technological strength of an organization's SRRs, the final issue is understanding the relevance of SRRs to achieving the experiences the organizations aspire to deliver. This study provides a link between technology and experience. This could be achieved by taking the experience statements derived through discussion and analysis with the organization's clinical staff, operational staff, and patients and ranking the relevance of the SRR groups. The relevance of each SRR to support the desired experience statements within the SOC domains of manageability, comprehensibility, and meaningfulness was estimated using the relevancy ranking in Textbox 5. The framework score reflects the competency of the information infrastructure to support a given level of experience within each SOC domain of manageability, comprehensibility, and meaningfulness.

Future Evaluation

The next phase of the evaluation process will be undertaken from 2022 to 2023 with specific hospitals to validate the framework using expert reviews and, subsequently, implement the framework with a selection of Australian hospitals.

DSRM Activity 6: Communication

The communication of this research is initially through this paper, detailing the complex research process and the body of work. In addition, an industry case study is in preparation, along with a technical report on the use of the framework for the industry. As the framework is designed for practical use, innovation and usability factors are essential for communication.

Discussion

Principal Findings

The developed framework uses the concept of SOC as a lens through which to view and define patient experience in the context of reducing environmental stressors for patients. Through this approach, the framework demonstrates the links among the critical perspectives of experience, supporting information capabilities, and information infrastructure. In addition, the maturity of these supporting capabilities can be measured using a capability maturity assessment model based on the established digital infrastructure assessment methodology [3], and pathways for improvement can be identified.

The purpose of the framework is to assist hospitals in improving their effectiveness regarding patient experience by connecting and orchestrating the synergy among people, processes, and systems using the organization's infrastructure capability. To this end, the framework can be used in two ways: to contextualize and generate conversation for improvement in patient experience and as an assessment tool to evaluate the current information infrastructure.

Contextualization

The concept of SOC provides a pragmatic structure for establishing the overall experience objectives within a health care organization. These guiding principles can then be reflected in the desired experiences at the operational environment levels of people, places, and processes. These, in turn, can contextualize the experience requirements for the way in which IT-driven operational processes (SRRs) interact with the patient. Such an experience map of an organization enables a clear

definition of the information infrastructure requirements to support these desired experiences.

This approach enables the model to tap into the rich archive of survey-based empirical research to guide the experience statements, which are a critical part of the major stages of this model. This framework can be used as a road map for specific improvements, generating discussions on aspirational experiences and how to reach them. In this way, it assists in the design of patient experience road maps rather than journey maps.

Assessment

There are 2 aspects of this assessment. The first is evaluation, and the second is the scoring methodology.

It is possible to use the framework to assess the current capabilities against the draft experience statements contained in the framework or to distill the organization's vision, mission, and objectives into a revised set of customized experience statements. In doing this translation from organizational goals into organization-specific experience statements, it is possible to assess the organization's ability to meet those experience goals, identify gaps, and establish improvement strategies.

The second aspect is to use a scoring methodology to assess the ability of the current information infrastructure to support the desired experience. To score an organization's existing information infrastructure capability, an SOC was established along the lines of a balanced scorecard, with manageability, comprehensibility, and meaningfulness assessed independently. The organization's culture and objectives define the balance of these components. It is particularly insightful to apply the grading detailed in the framework scoring example in Multimedia Appendix 1 at the individual SOC domain level of manageability, comprehensibility, and meaningfulness and reflect it back to the vision of the hospital.

Summary

The final output of this framework is the capability of an organization's information infrastructure to support the desired SOC for the organization and, in doing so, create an explicit set of experiences supportive of positive patient outcomes. The innovation of this research is that, traditionally, SRRs are used when tensions are perceived to create stress [34]. However, our research challenges this perception to prevent the underlying issues in the first place rather than wait until they are perceived as threatening. In this way, it models the prevention of potential threats across the cohort in a unique hospital situation. This ensures that the right SRRs, using the information infrastructure, are available when needed and are not left to chance.

Significance

This research represents a novel approach, which does not currently exist in the literature, in specifying how SRRs can be explicitly designed to support the patient experience. Perhaps, more uniquely, it defines how the facility's information infrastructure can be designed to best support the role of those SRRs.

This study used the SOC concept to construct a bridge between patient experience process measures and patient satisfaction outcome measures. In doing so, we created an integrated model of how information capabilities using technology can enhance the delivery of care, which has not been done before. The development of the Information Infrastructure to Experience Framework as a process capability framework will assist in the practical application of (service innovation) experience-driven improvement, specifically in supporting capability and collaboration development. This contributes to developing operational capabilities and the assessment or measurement of these operational capabilities.

Finally, regarding the research methodology, using the DSRM with additional embedded theory in the design and development arguably demonstrates a more advanced and complex application of the research paradigm than is typically seen.

Future Research Opportunities

The question of the amount of information infrastructure that affects the activities of experience in practical implementation is still to be fully investigated. The type and definition of information capabilities, as well as the classes of SRRs, will benefit from ongoing exploration, together with further testing of the weighting processes in a wider variety of health care settings.

The next step in this research is the validation of the experience statements and case studies in the use of the framework. In addition, the investigation into the use of the framework methodology to define experience using an SOC in other sectors that are looking to take a novel approach to improve the experience is in progress. These include universities and subsets of specific clinical contexts such as cancer survivorship and complex drug therapies. Furthermore, although this research has focused on patient experience, it should be acknowledged that there would be an analogous process for staff experience.

Conclusions

Given the complex nature of experience in health care and to enable the creation of a coherent and simplified framework, we focused our experience definition on the impact of, as well as our ability to manage, environmental stressors. In doing so, we can use the well-established concept of SOC to describe the processes of stressor reduction. We linked this to the established model of information infrastructure service, the IMA, through the concept of information capabilities and the SRRs they support.

Through this approach, this research has demonstrated information infrastructure to experience mapping, taking the theory and characteristics of salutogenic SOC to inform the articulation of a positive patient experience and how this is supported by the information infrastructure. This is defined in both technological and experience terms at the levels of the operational environment (people, places, and processes) and through the delivery resources (SRR classes: teaming and sharing, scheduling and coordinating, monitoring and reporting, and education and training).

Acknowledgments

The authors wish to thank Cisco Systems Australia, which is acknowledged as the sponsor of this research, and Professor Vishaal Kishore, Director of the Health Transformation Lab at the RMIT University, who kindly contributed to our initial discussions on reconceptualizing patient experience.

Conflicts of Interest

None declared.

Abstract

Background: Automated virtual reality (VR) therapy could allow a greater number of patients to receive evidence-based psychological therapy. The aim of the gameChange VR therapy is to help patients overcome anxious avoidance of everyday social situations. gameChange has been evaluated with outpatients, but it may also help inpatients prepare for discharge from psychiatric hospital.

Objective: The aim of this study is to explore the views of patients and staff on the provision of VR therapy on psychiatric wards.

Methods: Focus groups or individual interviews were conducted with patients (n=19) and National Health Service staff (n=22) in acute psychiatric wards. Questions were derived from the nonadoption, abandonment, and challenges to the scale-up, spread, and sustainability framework. Expectations of VR therapy were discussed, and participants were then given the opportunity to try out the gameChange VR therapy before they were asked questions that focused on opinions about the therapy and feasibility of adoption.

Results: There was great enthusiasm for the use of gameChange VR therapy on psychiatric wards. It was considered that gameChange could help build confidence, reduce anxiety, and "bridge that gap" between the differences of being in hospital and being discharged to the community. However, it was reflected that the VR therapy may not suit everyone, especially if they are acutely unwell. VR on hospital wards for entertainment and relaxation was also viewed positively. Participants were particularly impressed by the immersive quality of gameChange and the virtual coach. It was considered that a range of staff groups could support VR therapy delivery. The staff thought that implementation would be facilitated by having a lead staff member, having ongoing training accessible, and involving the multidisciplinary team in decision-making for VR therapy use. The most significant barrier to implementation identified by patients and staff was a practical one: access to sufficient, private space to provide the therapy.

Conclusions: Patients and staff were keen for VR to be used on psychiatric wards. In general, patients and staff viewed automated VR therapy as possible to implement within current care provision, with few significant barriers other than constraints of space. Patients and staff thought of many further uses of VR on psychiatric wards. The value of VR therapy on psychiatric wards now requires systematic evaluation.

KEYWORDS

virtual reality; automated; therapy; inpatient psychiatric care; implementation

Introduction

Potential of Virtual Reality Therapy

Virtual reality (VR) has the potential to be used in the treatment of a range of mental health problems [1]. Aside from the evaluation of clinical effects, there also needs to be consideration of successful implementation in services. A setting where VR therapy may be particularly valuable is psychiatric hospital wards. Pressures on staff time can often lead to limited opportunities for patients to receive psychological interventions or other meaningful activities [2,3]. Clinical symptoms may be reduced upon hospital discharge, but patients are often unprepared for returning to the situations that they had found difficult before admission. VR can provide a safe and controlled setting for patients to practice being in everyday situations. We therefore set out to investigate how VR therapy is viewed by patients and staff in psychiatric hospitals [4].

Objectives

The objectives are 3-fold: first, to obtain initial expectations of patients and staff about using VR headsets and, especially, VR psychological therapy; second, to gain patient and staff views of an automated VR therapy (gameChange). gameChange, which has a user-centered design [5,6], was evaluated in a randomized controlled trial with 346 patients with psychosis [7,8]. Almost all patients were attending outpatient services. The VR therapy led to significant reductions in anxious avoidance and distress, particularly for patients with severe agoraphobic avoidance. In 6 sessions, the aim is to reduce agoraphobic avoidance by presenting graded VR simulations of common everyday situations (eg, getting on a bus and going to a shop) [5,6]. Patients are guided through the program by a virtual coach. The third objective is to consider requirements for implementation. The study design was informed by the nonadoption, abandonment, and challenges to the scale-up, spread, and sustainability (NASSS) implementation framework for health care technologies [9]. Staff and patients were in a position to inform 3 of the framework's 7 domains with regard to implementation of VR therapy: the condition and disorder that the therapy is designed to address, the intended adopters of VR therapy, and the organization where it would be implemented. This is the first implementation study of automated VR therapy in inpatient settings.

Methods

The gameChange Lived Experience Advisory Panel (LEAP), facilitated by the McPin Foundation, contributed to the development of the study. Details of this and other aspects of the study methodology are provided in the full study protocol [4].

Amendment to Protocol

The study was set up before the COVID-19 pandemic. The first focus group was run on March 6, 2020. It had been planned to go on to visit 1-2 inpatient wards at each of 5 National Health Service (NHS) mental health trusts across England, totaling a minimum of 50 participants. However, access to wards and travel across the country became severely restricted. Therefore, we had to reduce the number of sites visited.

Participants

An acute inpatient ward at Nottinghamshire Healthcare NHS Foundation Trust and 2 acute inpatient wards at Oxford Health NHS Foundation Trust took part in the study. Staff working in either the delivery or management of clinical care on the wards were invited to take part. NHS patients staying on the wards were recruited according to the criteria presented in Textbox 1.

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria

- Participant is willing and able to give informed consent for participation in the study
- Aged ≥18 years
- Willing to consent to being audio recorded
- Sufficient English language skills to participate in the focus group or interview

Exclusion criteria

- High levels of associated risk to self or others through participation in the study; for example, actively suicidal
- Photosensitive epilepsy (use of virtual reality is not recommended for those with photosensitive epilepsy)

Procedure

Focus groups were the primary choice for data collection, but an individual interview was offered where a participant preferred it or was unavailable at the time of the focus groups. Focus groups and interviews initially asked questions relating to expectations before all participants briefly tried gameChange and then discussed their opinions on the therapy and its suitability for the ward. Participants could choose which VR scenario they wanted to try out and what level, although patients were encouraged to try out easier levels first. Each VR scenario lasts several minutes, with higher levels typically being slightly longer and more participative. Where there was enough time,

participants could try more than one level or scenario if they wanted.

Topic Guide

The semistructured topic guide was informed by the NASSS framework. Separate but similar topic guides were created for staff and patients. Study authors, including qualitative research experts, and the LEAP members developed the first drafts of the patient topic guide, and both guides were piloted beforehand. The topic guide was reviewed after conducting the first focus group. No significant changes were made, although 2 questions were slightly rephrased (eg, "Who would you like to deliver VR therapy to you?" was changed to read "If this were to be available on the ward, who would you like to be doing it with you?").

Analysis

Focus groups and individual interviews were audio recorded and transcribed verbatim. Field notes from each focus group and interview were also transcribed. Field notes recorded factors such as group dynamic and nonverbal cues to add context to the transcript of the audio recordings. Transcripts were not returned to participants for comment or correction.

A thematic analysis was performed [10] separately for staff and patient data, although similarities and differences between the analyses were then considered. All data were entered into NVivo (version 12; QSR International) [11] to provide a transparent audit trail. The transcribed data were read and reread to ensure familiarity before developing a preliminary coding framework that was discussed and adapted by the first author (PB) during supervision. A number of transcripts were double coded. An extract of the coding and reflexive log, with examples of adaptations made, can be viewed in Multimedia Appendix 1. Details regarding each code were recorded in memos in NVivo. Themes were derived from the data. Diverse cases and minor themes were considered because breadth was considered as important as frequency.

LEAP Involvement in the Analysis

A summary of the analysis was sent to the LEAP members for consideration to assess the validity of the findings in an additional group. LEAP members showed considerable support for the findings. In particular, they highlighted the need to have treatments beyond medication, the potential for VR to be a helpful route to engaging patients who may otherwise not engage with ward activities, and the potential to have alternative VR scenarios and presentations of Nic, the virtual therapist. The importance of VR increasing access to psychological therapy, rather than being a substitute for any existing therapeutic activity, was also emphasized. A LEAP member additionally underscored that limited private space to use the VR would likely be a significant challenge facing many wards.

Reflexivity

All patient focus groups were led by a doctoral student (PB) and cofacilitated by a clinical psychologist (SL, RD, or JJ). All interviews and staff focus groups were either led solely by PB or jointly by PB and a clinical psychologist. Consideration was given to how professional backgrounds may affect data collection and analysis. For example, existing knowledge, expectations, and hopes regarding VR therapy may have affected how the focus groups were conducted. A reflexive log was kept, and to try to minimize these potential biases, the topic guide was closely adhered to because this was created largely from the NASSS implementation framework rather than from personal experience and expectations. Consideration was given to the gender and class of the facilitators and that visible indicators of socioeconomic status could affect participant engagement. Participants were frequently reminded that the aim of the study is to hear and learn from their views and that the facilitators wanted participants to be as honest and open as possible about any concerns or criticisms they may have.

Ethical Considerations

The study had received ethical approval as part of a substantial amendment to the gameChange trial [7]. The trial received ethical approval from the NHS South Central–Oxford B research ethics committee (19/SC/0075).

Results

Overview

In total, 19 patients (n=12, 63% men and n=7, 37% women) and 22 members of ward staff (n=3, 14% men and n=19, 86% women) took part. Participants were from 3 wards across 2 NHS mental health trusts. There were 7 patient interviews and 4 patient focus groups (each with 3 patients) and 3 staff interviews and 4 staff focus groups (each with 2-7 staff members). The numbers of staff and patients recruited from each ward were approximately equal. Participants were predominantly of White ethnicity, with ages ranging from 18 to 60 years for the patient participant group and from 21 to 60 years for the staff participant group. The staff comprised nurses (including clinical leads), health care assistants, a deputy ward manager, a peer supporter, a ward clerk, activity coordinators, occupational therapists, and assistant psychologists. Although analyzed separately to begin with, all themes were shared across staff and patient responses.

Desire for Treatments Beyond Medication and the Value of Psychological Therapy

Many patients described their dissatisfaction with medication being the primary form of treatment available on their ward and the lack of psychological therapy: "How are we going to get better if we're just on meds?...I would really benefit from therapy at this point." [participant 8]; "We just get filled with pills, there's no talking therapies or anything like that" [participant 3]. This desire for treatment beyond medication led to a sentiment of being "up for trying anything" [participant 1]. Patients typically reported a positive view of psychological therapy and a desire for more to be available: "more one to one therapy" [participant 9]; "I think talking's the way forward" [participant 11]. However, there were some exceptions, with an individual saying, "I don't find talking helps" [participant 18] and another individual describing some negative past experiences with a psychologist and suggesting instead that their priority for recovery was seeking safe housing [participant 17]. Notably, many patients were aware of resource limitations contributing to a lack of therapy provision: "The room and the

money is obviously not enough" [participant 2]; "They're under a lot of pressure, you see" [participant 15]. Staff also reported positive views of psychological therapy, seeing it as an important treatment option for patients: "It's always good to have more therapy" [participant 3]; "the most helpful thing for [patients] to have" [participant 19]. Some staff felt that even if therapy could not lead to large clinical improvements, it would nonetheless help patients to have a purpose while being on the ward and help to reduce boredom. There was acknowledgment from a staff focus group that the psychological perspective differs somewhat from the nursing point of view but both are important.

VR Therapy Sounds Rational and Helpful

Before trying it for themselves, patients and staff members reported positive expectations of gameChange. In particular, they felt that the use of technology, graded levels of difficulty within the program, and the automation of the therapy could all be beneficial. Several staff reported expecting the VR therapy to be popular among patients and felt that it would likely help a lot of patients: "It makes perfect sense...it's definitely something that I think could be really useful...just giving them a bit more confidence" [participant 1]. These views were also shared by patients: "If someone struggles with walking down the street and they can do that in chunks and chunks and chunks and gradually build up, like, that's going to be great" [participant 11]. However, some patients did express concern. After hearing about the rationale of gameChange, a patient stated, "Sometimes I wonder whether highlighting these areas can make the issue a bigger thing" [participant 14].

Surpassing Expectations

After trying the gameChange VR therapy for themselves, many staff and patients reported feeling surprised and impressed. In particular, there was considerable discussion by all participants of how surprisingly real the VR therapy felt and how the experience was enjoyable. For instance, a staff member stated, "That was really amazing...it does absorb you into it" [participant 11]. Several participants said that the VR therapy had surpassed their expectations: "It's better than I thought it would be" [staff member, participant 2]; "I was skeptical before coming in, but I get it now" [patient, participant 3]. Several patients also expressed a desire to try more of it and thought it would be very popular on the wards: "I think there would probably be a big line, a big queue, to use it daily I think, to be honest" [participant 4]. However, a member of the staff reported thinking that the VR therapy actually had a strong "sense of unrealism" and that "nothing much" had surprised them [participant 9].

VR Therapy Could Help

The expectation that the gameChange VR therapy would be helpful was maintained after participants tried it. Patients felt that the gameChange therapy could help in a number of ways, including building confidence and reducing social anxiety ("I think it would be helpful to people with anxiety...I reckon it would help" [participant 19]), providing new perspectives and an escape from the ward on the ward ("I already feel as though I've been out today by just being in that experience, and I actually feel better than when I arrived, so it clearly can help" [participant 1]), and preparing for discharge ("It is going to help you to come out into society, out of the hospital, and back into society" [participant 7]). Staff shared patients' views that gameChange could help build confidence, reduce anxiety, and "bridge that gap" [participant 2] between hospital and discharge and also felt that the VR would be particularly helpful for patients who may typically engage less in therapeutic activities available on the ward, as well as for those who struggle with communication and those who find it difficult to leave their bedrooms. A staff member who had seen some of the patients on the ward trying out the VR therapy also noted: "Seeing them afterwards they seemed really pleased with themselves and it was that kind of sense of accomplishment that was really nice" [participant 17]. However, staff and patients acknowledged that the therapy would not suit everyone. For example, it was discussed that some patients may be too unwell to use the therapy or feel that it is not relevant to their needs: "When [patients are] really unwell it's difficult...it would have to be, you know, picked up at the right time in their recovery for it to benefit them" [staff member, participant 8]; "Initially you might not be at the stage to do any talking therapies" [patient, participant 3]. Some patients also said that the therapy would not be of particular help for themselves, even if it would help others: "Social situations as he said, brilliant, but like for self-harming...I can't see that helping in my situation" [participant 2]; "It's not beneficial to me but it would be a massive help for others that are struggling" [participant 13].

Envisioning Implementation

Where the VR could be physically located on the ward, who would support patients to use it, and which patients it might be offered to and when was discussed. Staff and patients thought that the VR needed to be stored away somewhere safe and secure and that a quiet, private room would be needed for using VR for structured therapy interventions such as gameChange. The wards varied as to whether such a space existed already. A staff member suggested that an option to overcome space challenges on the ward would be to have a "dedicated space off the ward to use the [VR therapy]" [participant 4], although this would require patients to be granted leave from the ward, which would not always be possible.

Regarding who would be present to support the patient to use VR therapy, patients and staff stressed the importance of the member of staff being someone the patient could trust and with whom the patient could form a good therapeutic relationship: "someone you feel comfortable around" [patient, participant 5]; "It should be done with somebody that they've got that therapeutic relationship with" [staff member, participant 22]. Unsurprisingly, staff spent longer considering which specific job roles may be most suited to using the VR therapy with patients. Suggestions included assistant psychologists, health care assistants, and occupational therapists. Of the 4 staff focus groups, 2 (50%) noted that it might be important to have staff members who do not have to respond to personal infrared transmitter (PIT) alarms for ensuring that sessions are not disrupted: "If someone has got a VR headset on and all of a sudden this massive alarm is going off...the person facilitating has to run out of the room...that could be really disorientating"

[participant 5]. Although there was agreement that staff would be "very much willing to be trained in it" [participant 1] and would find it enjoyable to be able to "see the benefits" of the treatment [participant 2], it was considered particularly important to ensure an opt-in system, where staff members could sign up to train in the VR therapy if they wanted to but were not required to if they felt that it was not something they would like to do. It was also suggested that, to begin with, it may be helpful to have staff from outside the ward come and "train the whole ward" [participant 1] or even to deliver the therapy to patients, given that external staff would be "more competent and committed" and could then "get the ward staff involved" [participant 2]. When asked about the possibility of a peer professional, that is, someone with lived experience of a mental health problem who has received training in providing psychological support and confidentiality, being present rather than a member of ward staff, patients saw this as a positive option: "They'd be brilliant" [participant 2]; "They're then speaking from experience, aren't they" [participant 4].

Staff members also felt that if VR therapy were to be implemented on the wards, its use by individual patients would need to be discussed within the clinical team and then prescribed in line with the evidence base: "It would have to form part of a care plan...it wouldn't be something that we just get out and go" [participant 11]. In general, staff mostly felt that the therapy could fit well into existing ward routines: "[Staff] set time aside to sort of have one-to-ones with patients...I think you could incorporate it into that hour" [participant 1]; "I take patients out for, like, community assessments and stuff...so the alternative could be doing this" [participant 12].

Concerns About Having VR Therapy on Wards

Both staff and patients raised concerns regarding how VR therapy could be implemented on wards, although the specific concerns varied. Patients discussed whether VR would be seen as a burden by staff because of the need for constant supervision ("Staff could see it as an imposition because they're too busy taking people out on fag breaks" [participant 3]), the headsets getting broken or forgotten about ("It'd get broken" [participant 16]), the therapy becoming a substitute to enable further cuts to funding of existing psychological therapies ("I think the danger of course is that the technology becomes the substitute for government cuts or lack of funding" [participant 1]), as well as needing to ensure that patient data are kept secure and confidential ("I would want to know that my data was secure" [participant 8]). A patient focus group also voiced concern that it could be embarrassing if one were doing something odd in the VR, which tied into desires for using it in a private space with a trusted member of staff. Staff members shared patients' concern about needing to consider how to look after the equipment and prevent it from getting broken: "I could just see the equipment getting ruined" [participant 21]. Staff also raised concerns around whether the headset might be overwhelming or overstimulating for some patients and difficult for those with less spatial awareness.

Barriers and Facilitators to Implementation Vision

Staff thought that having ongoing access to training, the involvement of a patient's multidisciplinary team, and a mechanism for helping patients to continue to use the VR if discharged to the community in the middle of a set of sessions would all be factors that would make it easier to ensure the successful implementation of VR therapy on psychiatric wards. Having a staff member lead the use of VR on the ward, who would, for example, be someone staff members "can report back to with any concerns" [participant 1] and who would be responsible for maintaining the equipment was also raised as a facilitator. In addition, staff and patients stressed the importance of introducing the VR therapy in the right way. Patients primarily spoke about this with regard to how it would be explained to users, for example, providing reassurance regarding its safety, and "explaining it has been developed with people with psychosis" [participant 11] (the gameChange VR therapy was developed with patients using a user-centered design process). Staff primarily considered how it should be explained to staff: "as much information as you could give...why it's going to benefit, what you hope the outcome will be and basically that it could help create a calmer environment on the ward because that's all we want" [participant 8].

In contrast, current barriers to the implementation of VR therapy on wards included staff shortages and the resultant reliance on agency staff, as well as the lack of appropriate space for using the VR therapy on some of the wards, with existing private spaces either being too small, too noisy, or too infrequently available. There was contrast among members of staff within and between wards regarding whether limits on staff time would be a problem. Some members of staff felt that the VR therapy would not add time pressure to staff roles because it could fit into existing routines or that any additional time it would require would likely only bring about savings in time in the longer term ("I wouldn't say the time is a constraint, no, no...if we're spending more time engaging in therapy with someone that can only be a positive" [participant 1], whereas others felt that pressures on staff time would be a greater challenge, and would, for example, "play a part in how frequently somebody could have a session" [participant 16].

Improvements and Potential

Several ways of improving the VR therapy were discussed. Patients and staff thought it would be beneficial to be able to vary the computer characters and, in particular, the virtual coach, Nic, to suit the preferences of the user. A patient focus group also suggested that Nic could be presented as a peer professional, for example, "a patient with your own characteristics that's out in the community" [participant 1], feeling that "if it's presented as a peer supporter, even though it's not real I think that would make you feel a little bit more relaxed" [participant 3]. A number of additional scenarios were also suggested, including a football stadium, a theater, a courthouse, and a workplace. Having some simulated ward environments such as the communal area and a ward round meeting were also suggested by several members of staff and patients: "[Patients] can get really anxious about ward rounds...so I don't know whether or not that could be something in future" [staff member, participant 20]; "a ward meeting where there's loads of people" [patient, participant 16]. Other improvements suggested were having adaptations for individuals with audio or visual impairments and increasing the level of interactivity in the scenarios. Staff

and patients also discussed a range of ideas for further uses of VR headsets. Relaxation and mindfulness exercises were frequently discussed in particular, with other suggestions including helping autistic individuals to practice eye contact; training in STOP anger management techniques; and staff training on what it is like to have certain psychotic experiences, patient assessment and diagnostics, treating posttraumatic stress disorder, and treating obsessional thinking. As a patient stated, "There's sort of endless possibilities" [participant 1]. Because of the limited resourcing many wards face, it was also suggested that patients could use the VR headsets for gaming when available, which might then also help to reduce boredom on a ward.

Discussion

Principal Findings

We report the first qualitative investigation of staff and patient views on the potential of using automated VR cognitive therapy on inpatient psychiatric wards. It was very clear that patients and staff have considerable enthusiasm for trying something new, especially a potentially effective psychological approach, and that participants were impressed by the potential of the automated VR therapy to help patients, while potentially overcoming some of the resourcing challenges that traditional therapies face. Although caveats were expressed, the enthusiasm bodes well for testing and implementing VR therapy on psychiatric wards.

Separate coding frameworks were initially developed, but there was considerable overlap and consensus between patient and staff views. Particularly striking was that nearly all participants felt positively surprised by certain aspects of gameChange, noting that it surpassed their expectations, in particular with regard to how real it felt. In addition, although staff and patients felt that on a patient's immediate arrival to the ward VR therapy may not be so appropriate, psychological therapy is certainly something that was desired by patients and considered by staff to be important for aiding recovery. Patients staying in hospital may often be thought of as being too unwell to benefit from psychological therapy, but this was not the view of the patients and staff from these wards.

Staff and patient participants both shared the belief that VR therapy could be very helpful, and they were keen to consider practical solutions concerning where and with whom it could be used. There was also variation in the discussion by staff and patients. Within the *envisioning practicalities theme*, staff considered in greater detail which professions might be able to feasibly deliver VR therapy, whereas patients understandably discussed in greater detail who they might feel most comfortable in having to support them. Interestingly, a primary concern of the patients centered on whether staff would be willing and have the time to use the VR therapy with them, whereas many staff members did not raise this as a likely problem.

The topic guide covered three domains of the NASSS framework: the condition or illnesses that the technology is designed to help, the intended adopters of the technology, and the organization where it would be implemented. With regard to the condition, the gameChange automated VR therapy is designed to help anyone who may feel anxious or lack confidence in entering everyday social situations. It is for agoraphobic-type anxious avoidance, which occurs in two-thirds of patients with severe mental health conditions [12]. Patients and staff agreed that this would be a relevant treatment target for many individuals on the ward, but they were of the opinion that factors such as severity of clinical symptoms might complicate successful use. Interestingly, wider applications of VR for patients in psychiatric wards were identified. With regard to the intended adopters, a crucial lesson from this study is the clear enthusiasm and positive feedback displayed by all participants. This is particularly of note, given that studies suggest that acceptance by staff can often be the single most important determinant of whether new technologies succeed at a local level [9,13]. However, it must also be recognized that the staff most likely to volunteer their time to take part in an interview may also be those who judge that they have time available or have the most interest in innovation. Self-selection is likely to bias feedback toward the positive. This potential bias may have been mitigated to a degree by running several focus groups in a regular staff meeting slot. However, it is also the case that most of the staff interviewed were not in senior decision-making roles for ward treatment provision. Regarding the NASSS framework domain of organization, most staff reported that their ward would have the capacity and motivation to take on the kind of change entailed by VR therapy. It was judged that the use of VR therapy could fit into existing ward routines such as one-to-one time that staff have dedicated to spending directly with individual patients, although its use in conjunction with real-life practice in outdoor settings may require careful planning.

A number of potential barriers to implementation were raised. Space to use the equipment may be a barrier in some wards. Staff did think that this barrier could be overcome through adapting current spaces or making use of rooms off the ward. Although staff time was not seen as a barrier when wards are working with usual capacities, times of staff shortages was discussed as a potential problem. This might mean that having staff external to the ward, such as peer professionals dedicated to the delivery of VR therapy in addition to training ward staff, could be the most feasible and popular method of implementing VR therapy. This also fits with recommendations within the NHS Long Term Plan to recruit a workforce of peer support workers in acute settings [14,15].

Our experience is that people need to try VR to understand it fully, and this was the case in this study. For implementation, a VR ward facilitator could ensure that as many staff as possible have the chance to try VR. When introducing the technology to patients, it will be helpful to address explicitly the concerns raised by patients in this study; for example, by providing information on the safety of the equipment and whom it was developed by. Resources such as workbooks and summary sheets of the therapy aim and rationale to help consolidate learning may also be useful. It was also notable that VR was seen as something that could be helpful in many different ways on a ward, including for games or mindfulness exercises.

Limitations

There were several limitations to the study. Most significantly, because of the COVID-19 pandemic, recruitment took place on only 3 acute psychiatric wards across 2 NHS mental health trusts, which may limit the generalizability of the findings. The enthusiasm for VR therapy may have been less on wards where, for example, there are more activities and therefore less boredom or on wards that already have psychological therapy available. It is also likely that participants in implementation studies may represent a more highly motivated group who are less representative of the whole population [16]. Multiple stakeholder involvement is important for implementation research [17,18], and there were too few staff participants (eg, consultants and managers) who are typically involved in strategic decision-making. It is also the case that this study did not consider all domains of the NASSS framework. For instance, it will also be valuable to consult individuals with detailed knowledge of the technology to consider supply, support, and future evolution. However, the results of this study indicate that VR therapy has significant potential to be implemented on psychiatric wards.

Abstract

Background: Management of chronic recurrent medical conditions (CRMCs), such as migraine headaches, chronic pain, and anxiety/depression, remains a major challenge for modern providers. Our team has developed an edge-based, semiautomated mobile health (mHealth) technology called iMTracker that employs the N-of-1 trial approach to allow self-management of CRMCs.

Objective: This study examines the patterns of adoption, identifies CRMCs that users selected for self-application, and explores barriers to use of the iMTracker app.

Methods: This is a feasibility pilot study with internet-based recruitment that ran from May 15, 2019, to December 23, 2020. We recruited 180 patients to pilot test the iMTracker app for user-selected CRMCs for a 3-month period. Patients were administered surveys before and after the study.

Results: We found reasonable usage rates: a total of 73/103 (70.9%) patients who were not lost to follow-up reported the full 3-month use of the app. Most users chose to use the iMTracker app to self-manage chronic pain (other than headaches; 80/212, 37.7%), followed by headaches in 36/212 (17.0%) and mental health (anxiety and depression) in 27/212 (12.8%). The recurrence rate of CRMCs was at least weekly in over 93% (169/180) of patients, with 36.1% (65/180) of CRMCs recurring multiple times in a day, 41.7% (75/180) daily, and 16.1% (29/180) weekly. We found that the main barriers to use were the design and technical function of the app, but that use of the app resulted in an improvement in confidence in the efficiency and safety/privacy of this approach.

Conclusions: The iMTracker app provides a feasible platform for the N-of-1 trial approach to self-management of CRMCs, although internet-based recruitment provided limited follow-up, suggesting that in-person evaluation may be needed. The rate of CRMC recurrence was high enough to allow the N-of-1 trial assessment for most traits.

KEYWORDS

mHealth; patient-specific modeling; chronic disease; smartphone; implementation and deployment; facilitators and barriers

Introduction

Chronic recurrent medical conditions (CRMCs) encompass a major proportion of the modern health care burden, accounting for significant costs in the form of both management and lost productive time [1]. For example, chronic migraine headaches affect about 2% of the global population [2], and in the United States alone, cost more than US $20 billion annually [1] to manage. Chronic low back pain accounts for over 5 hours/week in lost productivity by workers, resulting in over US $10 billion in lost revenue per year [1]. Mental health disorders, including depression and anxiety, accounted for 183.9 million disability-adjusted life years and 175.3 million years lived with disability worldwide [3], with an increase of 37.6% over the years from 1990 to 2010 [3].

On a more granular level, CRMCs create a major challenge for today's busy clinician. Although widely variable across providers and practices, the time available for a face-to-face encounter with patients continues to trend downward, despite an increase in the number of clinical items needing to be addressed [4]. As a result, providers have less time available to focus on the range of triggers and contributing factors for any given CRMC. This trend is unfortunate, as for many CRMCs the number and complexity of environmental and lifestyle triggers can be quite robust. For example, sleep changes have been described in about 50% of patients with migraine headaches, although 75% of patients also chose to sleep due to the migraine headache [5]. In addition, a study of 1207 patients with migraine headache identified no less than 16 possible triggers present in at least 5% of these individuals [6]. A similar scale in triggers has also been noted for depression [7], anxiety [8], and chronic low back pain flares [9]. As such, tailored management of patients with these and other CRMCs often requires the provider to take a detailed, longitudinal history with attention to temporal relationships—an approach that fits poorly with the practical constraints of modern clinical practice.

Despite these limitations, there is evidence that an individualized approach to self-management of CRMCs using mobile health (mHealth) apps has potential to improve clinical outcomes. Specifically, the N-of-1 approach to care has been applied to study various interventions for pain [10-14], depression [15-17], anxiety [18,19], and migraine headaches [20-22], and has been incorporated into mHealth technology [23-25]. In 2017, our team developed a prototype semiautomated iOS mHealth app called the iMTracker (Figure 1), which incorporates the N-of-1 platform for patient-entered data to log recurrences of a given CRMC, as well as the opportunity to log possible triggers or suppressors of the CRMC. The iMTracker provides edge-based analysis of symptom correlations, in which data are stored and analyzed on each user's device, without the need to transfer or store data to a central server. However, it is unknown which specific patients with CRMCs would be most likely to use the iMTracker for self-management, and whether the rate of recurrence is high enough to maintain a sufficient level of engagement to draw meaningful associations with lifestyle triggers and to evaluate the impact of interventions on recurrence rate. In this feasibility pilot investigation, we aimed to apply an internet-based recruitment approach to enroll patients to trial the iMTracker app. Our goal in this study was to examine the 3-month adoption rate of the iMTracker app by patients with CRMCs, to understand the patterns and characteristics of the possible CRMCs and users, and to identify design and functional barriers to the use of iMTracker prior to its use. Additionally, we planned to examine the strengths and limitations of the internet-based recruitment approach to development and testing of mHealth apps, and identify areas to address for future prospective studies aimed at improving outcomes.

Methods

Patients

From May 15, 2019, to December 23, 2020, we recruited 180 patients to test the iMTracker app for iPhone for self-management of their CRMCs using an internet-based study design. Inclusion criteria were aged 18 or older, presence of a CRMC, and use of an iPhone. There were no official exclusion criteria, although based on study design and app functionality, patients generally needed to be English speaking and familiar with the use of iPhone apps, as well as the use of email and internet. We started with advertising on social media, such as Twitter, campus-based fliers, and provider word-of-mouth, but found limited recruitment, by which only 2 patients were recruited. We then employed the TrialFacts patient-recruitment company [26] (San Diego, CA, USA) to assist with internet-based recruitment. Patients were provided a small financial stipend for participation, which was paid on enrollment only (nothing additional for follow-up). Written informed consent was obtained for all patients.

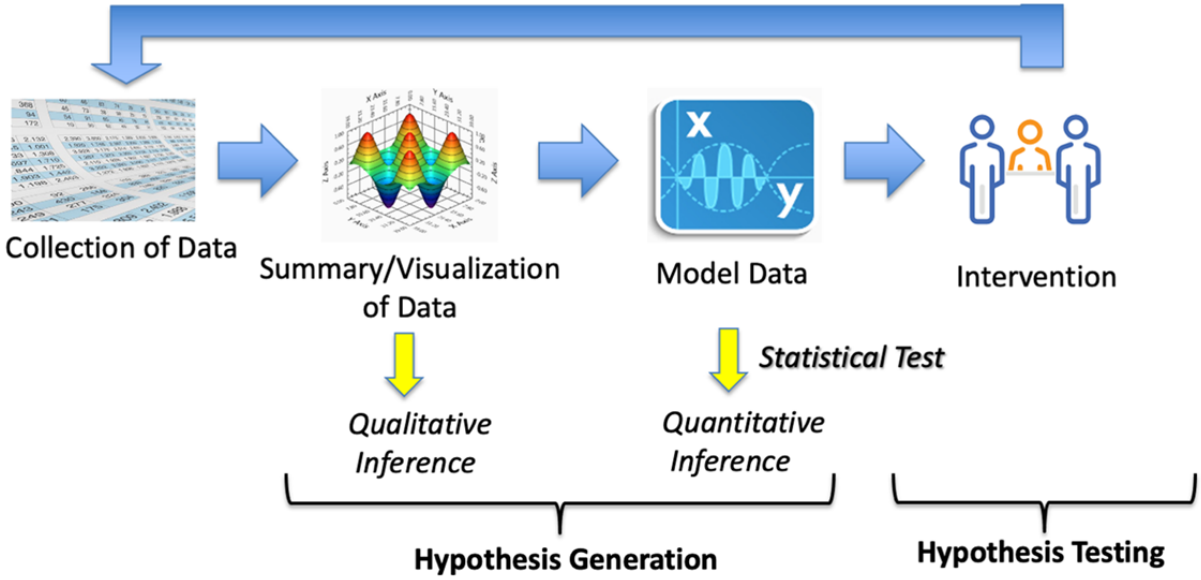
Ethics Approval

The study protocol was approved by the University of Colorado Institutional Review Board (Protocol #18-1000).

mHealth App (iMTracker)

The platform of iMTracker was designed based on an automated N-of-1 trial approach (Figure 2) that includes both hypothesis generation and hypothesis testing, which can be built into the logic of an mHealth app. The iMTracker allows the user to select any problem (outcome) and any potential lifestyle factors (risk factors) or intervention that the user would like to test for an association with the outcome. Through iteration between hypothesis generation (ie, “Is there an association between risk factor A and occurrence of my condition?”) and hypothesis testing (ie, “Does changing risk factor A improve the rate of occurrence of my condition?”), the user is able to self-manage his or her condition toward an overall goal of reducing recurrence. The platform thus provides a semiautomated approach to self-management, in which the analysis provides potential lifestyle/behavioral factors that are associated with the CRMC, but allows users to select which factor to intervene upon to examine impact on CRMC recurrence rate. Importantly, the overarching design of the iMTracker app has been focused on application of edge computing [27,28] strategies that run on the mobile device itself, to allow complete usage of the iMTracker app without the need for transfer or storage of data on a server, which provides patients with a level of privacy and data security [29,30].

Figure 2. The semiautomated N-of-1 approach motivating the iMTracker design.



Data are manually entered by the user, presented in a visual format, and then modeled for correlations between the selected outcome (problem) and potential risk factors (Figure 1). Through built-in notifications, the iMTracker app prompts the user to input data daily, and keeps a running summary of the inputs. This analysis includes correlation between the outcome and risk factors on a daily basis and with 1-day lag to identify risk factors that could potentially cause the outcome on the following day, using the phi statistic for correlation between discrete variables [31]. Although analysis is performed after only 3 days of data collection, users are informed that the accuracy of the correlation is higher with greater amounts of data collection (Multimedia Appendix 1). Once enough data have been collected to form hypotheses about causative associations, users are directed to reset the data collection and select an intervention in the form of a lifestyle modification, from which future data will examine the role of that intervention in reducing recurrences of the outcome.

Survey

Our team designed a brief survey instrument with several goals in mind. First, we wanted to identify which specific CRMCs

users selected for self-management using the iMTracker app. These diagnoses were self-provided, and we did not perform a separate validation with either treating clinicians or chart review. Second, we sought to collect information about the typical pattern of CRMCs—that is, frequency of recurrence—to understand the burden of disease of a possible user of the iMTracker app, and also to guide future work in automating analyses toward sufficient statistical power to detect associated lifestyle conditions and the effect of interventions. Third, we included questions aimed at detecting prior experience with regular data collection (eg, "How often do you weigh yourself?"), information sharing (eg, "How often do you post on social media?"), and electronic engagement with providers using email or secure messaging. Broadly, these questions helped to frame the users' motivation for using this type of technology for self-management of CRMCs. Fourth, we inquired about concerns of using technology for self-management of conditions; specifically, we asked users to rank concerns related to data security, privacy, efficiency (time demand), and efficacy. Finally, we inquired about specific concerns with the iMTracker app, and asked for qualitative input about the design and function. In addition, we collected basic demographic information about categories of age, education, race, and ethnicity.

The follow-up survey was designed to obtain information about the app itself, as well as the process of the N-of-1 approach to self-management of their selected condition, and to assess the 3-month adoption rate to provide a baseline for future clinical trials. Patients were sent a link to the poststudy survey 3 months after the date of enrollment. Patients that provided no answer for the 3-month adoption, but who completed the postsurvey were assumed to have not completed the 3-month adoption. The postsurvey questions are provided in Multimedia Appendix 2.

The study was conducted remotely using email and phone calls with patients. After informed consent was obtained, patients were given a link to the online survey using a REDCap database. Patients were guided through download and use of the iMTracker mHealth app for iPhone (iOS) by a member (AM) of the research team, and given the opportunity to provide qualitative feedback about the app design, outside the survey data. The postuse survey was deployed after 3 months of use (Multimedia Appendix 3).

Analysis

All study data were collected in a REDCap database. Statistical tests of proportions were based on Fisher exact test. The analysis was performed using Stata IC, version 16.1 (StataCorp, Inc.).

Results

Of the 180 patients who completed the preuse survey, 103 also completed the postuse survey (57.2%). Only 2 patients were recruited by the study team outside of use of the TrialFacts company referrals. A total of 172 patients (95.6%) were under the age of 65, with the predominant age range being 31-45 (80 patients, 44.4%; Table 1). Most patients had at least some college (171/180, 95.0%), and most were White (144/180, 80.0%) and non-Hispanic/Latino (161/180, 89.4%).

The most common CRMCs (self-reported) for which patients planned to use the iMTracker app to self-manage were pain (80/212, 37.7%), including low back pain and other musculoskeletal pain syndromes; headaches (36/212, 17.0%), including migraines; gastrointestinal symptoms (17/212, 8.0%), including inflammatory bowel disease flares and irritable bowel disease; and mental health conditions, including anxiety (12/212, 5.7%) and depression (15/212, 7.1%; Table 2). A total of 19/180 patients (10.6%) planned to use the app to monitor more than 1 CRMC. For most CRMCs, frequency was daily (75/180, 41.7%) or multiple times a day (65/180, 36.1%), with few occurring less often than monthly (5/180, 2.8%; Table 3). Patients were allowed to apply the iMTracker app to more than 1 condition, which is why there are 212 listed in Table 2.

To assess overall patterns of self-management and use of media, patients were asked about lifestyle and technology savviness. About one-sixth (28/180, 15.6%) weighed themselves daily, 58/180 (32.2%) weighed themselves at least weekly, 42/180 (23.3%) weighed themselves monthly, and 52/180 (28.9%) weighed themselves rarely or not at all. A total of 49/180 (27.2%) posted on social media multiple times a day, 54/180 (30.0%) posted daily, 49/180 (27.2%) posted weekly, 12/180 (6.7%) posted monthly, 14/180 (7.8%) posted rarely or never, and 2/180 (1.1%) were not on social media; 64/178 (36.0%) communicated with their primary physician regularly using messaging/technology, 66/178 (37.1%) communicated rarely, and 13/178 (7.3%) preferred not to communicate using technology/messaging and only in person. Prior to the study, 74/180 patients (41.1%) said they were very likely to use an mHealth app to self-manage CRMCs, 63/180 (35.0%) were somewhat likely, and 6/180 (3.3%) said they were unlikely to use an mHealth app to self-manage CRMCs. After using the iMTracker app, all patients who said they were unlikely to use an mHealth app changed their answers to neutral (2/6, 33%) or somewhat likely (4/6, 67%).

Patients were asked about concerns for using an mHealth app for self-management of CRMCs both before and after use of the iMTracker. As shown in Table 4, patients were generally more likely to have concerns about effectiveness after using the app, and less likely to have concerns about privacy, data safety/security, or time requirements, after use.

Of the 103 patients who completed the postuse survey, 73 (70.9%; Table 5) said they used the iMTracker app for the planned 3-month period; among those who stopped beforehand, 2/16 (13%) used it for 2 months, 5/16 (31%) used it for 1 month, and 9/16 (56%) used it for less than a month. Among those completing the 3-month use period, only 3/103 (2.9%) failed to enter data on over 50% of days, and 22/103 (21.4%) reported missing less than 5% of days entering data. These patients reported reviewing their data summary weekly or every few weeks in 13/22 (59%) cases, and daily in 3/22 (14%) cases. Finally, 27/103 (26.2%) patients said they were likely or very likely to use the iMTracker app again to self-manage their CRMCs, and 58/103 (56.3%) said they were unlikely to use it without modifications. There was a potential signal for increased levels of education being statistically associated with increased 3-month adoption rate (P=.04; Table 5), although the association did not reach a level of statistical significance after adjustment

for multiple comparisons (Bonferroni *P* for significance [α]=0.05/4=.0125). Among the subjective reasons for not continuing to use the iMTracker app, issues with data sharing and ease of use were most cited, followed by design/display limitations.

Table 1. Demographics of iMTracker users.

Demographics	Value, n (%)
Age (years; n=180)	
Under 30	38 (21.1)

Discussion

Principal Findings

In this internet-based, pilot study of predominantly young and middle-age, educated, White patients, using a semiautomated, edge-based, mHealth app that uses individualized data for tailored management of CRMCs, we made several key observations with regard to both the internet-based recruitment approach to the study of mHealth apps, as well as the specific usage rates and patterns of use by participants. First, we found that while an internet-based recruitment approach was superior to "grass-roots" local methods of recruiting participants on our campus using fliers and word-of-mouth, the 3-month follow-up rates were only slightly above 50% (103/180), indicating that future studies using this type of methodology targeted to achieve a prespecified degree of statistical power will need to account for a high number of dropouts. Second, we found that among those with complete follow-up, the 3-month adoption rate of the iMTracker app was about 70.9% (73/103), with the most common CRMCs that users chose to self-apply the app being chronic pain, headaches, and mental health conditions. This information not only provides conditions and clinical settings in which to target future clinical trials, but also indicates that there may be a need for better tools to manage these conditions beyond what is presently available in clinical practice. Importantly, we found that on completion of this study, more patients had increased perceptions of the safety, privacy, and time demands with the use of an mHealth app for self-management of CRMCs. Finally, we found that the main barrier to use, based on both subjective and quantitative

feedback, was related to the design and workflow of iMTracker itself, which was reflected in the decrease in perception of efficacy noted on completion, and has important implications for future development and testing of this app as well as other mHealth technologies. In other words, this finding indicates that patients are likely to be receptive to the semiautomated N-of-1 trial methodology employed by the iMTracker app, but that greater attention to design and function is needed before moving forward with clinical testing targeted toward improvement in outcomes.

mHealth apps have increased significantly in frequency over the years, with iOS apps including health and fitness groups increasing from 43,000 in 2013 to 98,000 in 2015 [32]. Unfortunately, these tools do not consistently employ best practices for self-management [33], and many of these approaches have failed to reach any meaningful level of adoption across the medical community [32,34], likely due to a lack of formal clinical testing. Our finding that there was an increased concern among patients about the effectiveness of iMTracker is consistent with prior studies of mHealth app for self-management of CRMCs. In a previous investigation, it was found that only 3.4% of apps on the iTunes and Google Play stores promoted for management of depression and anxiety had research to justify their claims of effectiveness, with only 30.4% having expert input in development [35]. A study by Devan et al [36] of 19 apps available commercially for self-management of pain found that only 2 had been validated to improve health outcomes. A similar lack of scientific support for commercially available mental health–targeted [37-39] and pain [25,40] apps has been reported by other investigators. Although we did not inquire about prior use of mHealth apps for self-management, one can infer that most participants in this study had tried prior apps without success. Clinical validation of any mHealth app should be required before integration into the clinical care process, and our study further suggests that while users are optimistic that self-management using an app is possible, follow-up clinical studies will be needed.

Among the characteristics of the specific CRMCs that patients identified for use of an mHealth app, recurrent pain, headaches, and mental health were highly represented. While these diagnoses were self-identified by users, and not validated with clinicians or clinical data (ie, chart review), it does help to identify potential clinics and providers for testing mHealth apps, as would be needed before an app such as the iMTracker could be incorporated into routine clinical care. In addition, the majority of patients noted a high frequency of recurrence of their condition, which is key in determining the number of patients needed for a prospective study to demonstrate efficacy, as a condition that occurred less frequently, for example, once or twice a year, would require an extended amount of time to identify correlation of episodes with other lifestyle and behaviors, or assess the impact of an intervention.

Although our study did not specifically examine clinical efficacy of the iMTracker app in terms of a reduction in the primary CRMC, we did note that there was enthusiasm about future uses, particularly if barriers related to design and function could be addressed. This finding is in line with prior work, such as that by Neuhauser et al [41,42], who noted that participatory methods linked with traditional health communication theory and methods can create effective health communication using artificial intelligence, highlighting the role of design science theory in the development and refinement of mHealth apps. Such insights highlight the challenge that is unique to mHealth, and other health IT apps, in which consideration of user-based preferences and desires must be merged with information and guidance grounded in biology and evidence-based medicine principles. In terms of design life cycles, this requires an integrated design approach with features of both top-down (ie, waterfall) strategies and bottom-up, user-driven design (eg, agile) strategies. Our team has already begun efforts to improve the design and function of the iMTracker app, and future studies will examine the improvement in these changes to make the app more in line with the level of commercial design that many patients have come to expect from all mobile apps, in addition to mHealth.

Despite results to suggest a high degree of potential for clinical application of the iMTracker app, there were several key limitations in our study. First, we generally had a limited amount of follow-up of patients, with roughly half of the patients who enrolled being lost to follow-up. We suspect that this limitation highlighted the challenges of using the internet for recruitment, and the trade-off between use of network-based recruitment methods (ie, online) and in-person clinic recruitment. As an extreme example of the potential of the former, the Apple Watch study recruited over 400,000 participants in an 8-month period using online methods, although only 450 actually returned the confirmatory patches in follow-up [43]. As such, future studies of mHealth technology should consider that the potential benefit in terms of recruitment numbers using internet-based recruitment may accompany a relatively high degree of dropouts. A second limitation was that the population we studied were primarily White, educated, and young/middle age adults; these were individuals who engage regularly with providers using technology, post to social media, and perform self-management with regular weight checks. Missing from our population are older patients, those with less education, and those from underrepresented populations—the type of populations that have also been shown to have less close clinical follow-up for their conditions [44-46], and who might stand to benefit the most from an app that allows self-management. This population bias is critical in considerations of further app development as the design and functionality changes that would typically guide app development would be needed for successful integration with clinical care. Further work is needed on methods to include less represented populations in mHealth studies. Among the issues with biased recruitment was the omission of sex from the baseline variables we collected. Qualitatively (based on the first names of the participants), we suspect recruitment was not heavily imbalanced toward 1 specific sex, although formal assessment would have been beneficial in terms of statistical analysis. In future studies, we plan to examine sex along with other user characteristics in terms of both usage patterns and study participation. Finally, a key limitation of the study was the inability to confirm diagnoses or response to therapy among users of iMTracker. While we have ongoing studies to examine the app prospectively toward clinical outcomes, the findings from this investigation provided important information about

which specific conditions, and which types of clinics, to target for recruitment. This finding was critical as the iMTracker was originally developed toward treatment of recurrent cardiac symptoms (ie, palpitations), and yet we identified other conditions that included chronic pain, headaches, and mental health as being more heavily favored by patients in this investigation.

In future studies we plan to examine the impact of specific design and function improvements on iMTracker, including an examination of the use of industry-standard Agile development life cycles to make iterative improvements to the user interface within the Scrum methodology [47]. Our team has already employed a newer user interface and data entry design based on emojis, although additional work is needed to ensure all users of all levels of education and medical literacy can use the app comfortably. Following this step, we plan to target clinical trials of iMTracker to primary care, neurology, and psychiatry clinics to assess the impact of N-of-1 management on recurrence of chronic pain, headaches, and mental health conditions. Finally, our team has continued work on integration of more sophisticated data management approaches using federated and distributive learning, as well as Bayesian-based analytical frameworks, and we plan to examine the improvement in accuracy with these innovations. Ultimately, much work is needed before the iMTracker app can be used routinely in clinics to manage CRMCs, although feedback from this study has helped target efforts toward high-yield conditions and modifications to improve the chances of success.

Conclusions

In conclusion, in this feasibility pilot study using internet-based recruitment, we found that the primary barrier to investigation was study follow-up, but that among those who were not lost to follow-up, there was generally good adherence to use of the iMTracker app. We identified design and function barriers as being of foremost concern among users, but also noted that the frequency of recurrence of the selected CRMCs should provide ample opportunity to identify a clinical benefit for future studies. We also identified population bias in the patients enrolled using internet-based recruitment alone, and note that additional efforts will be needed to ensure that future studies enroll sufficient numbers of underrepresented populations, specifically older, non-White, and less education populations.

Abstract

Background: Misinformation and conspiracy theories related to COVID-19 and electronic nicotine delivery systems (ENDS) are increasing. Some of this may stem from early reports suggesting a lower risk of severe COVID-19 in nicotine users. Additionally, a common conspiracy is that the e-cigarette or vaping product use–associated lung injury (EVALI) outbreak of 2019 was actually an early presentation of COVID-19. This may have important public health ramifications for both COVID-19 control and ENDS use.

Objective: Twitter is an ideal tool for analyzing real-time public discussions related to both ENDS and COVID-19. This study seeks to collect and classify Twitter messages (“tweets”) related to ENDS and COVID-19 to inform public health messaging.

Methods: Approximately 2.1 million tweets matching ENDS-related keywords were collected from March 1, 2020, through June 30, 2020, and were then filtered for COVID-19–related keywords, resulting in 67,321 original tweets. A 5% (n=3366) subsample was obtained for human coding using a systematically developed codebook. Tweets were coded for relevance to the topic and four overarching categories.

Results: A total of 1930 (57.3%) tweets were coded as relevant to the research topic. Half (n=1008, 52.2%) of these discussed a perceived association between ENDS use and COVID-19 susceptibility or severity, with 42.4% (n=818) suggesting that ENDS use is associated with worse COVID-19 symptoms. One-quarter (n=479, 24.8%) of tweets discussed the perceived similarity/dissimilarity of COVID-19 and EVALI, and 13.8% (n=266) discussed ENDS use behavior. Misinformation and conspiracy theories were present throughout all coding categories.

Conclusions: Discussions about ENDS use and COVID-19 on Twitter frequently highlight concerns about the susceptibility and severity of COVID-19 for ENDS users; however, many contain misinformation and conspiracy theories. Public health messaging should capitalize on these concerns and amplify accurate Twitter messaging.

KEYWORDS

COVID-19; coronavirus; e-cigarette; electronic nicotine delivery systems; Twitter; social media; misinformation; discussion; public health; communication; concern; severity; conspiracy

Introduction

The COVID-19 pandemic has spread rapidly, with over 490 million confirmed cases and over 6.1 million confirmed deaths worldwide at the time of this writing [1]. COVID-19, which can lead to acute respiratory distress syndrome, may be particularly dangerous for nicotine and tobacco users [2]. Emerging evidence suggests an association between the use of electronic nicotine delivery systems (ENDS) and greater incidence of COVID-19 susceptibility and severity, testing, and diagnosis—particularly among US adolescents and young adults [3]. This is concerning considering the increase in the use of these products. Worldwide, approximately 35 million individuals reported ENDS use in 2015, and this number is expected to increase as refillable and disposable ENDS become more popular [4].

The research on the potential associations between tobacco and nicotine use and COVID-19 risk has been mixed. Some published research has indicated that self-reported COVID-19 infection is greater among current cigarette smokers and former smokers compared to nonsmokers [5], that cigarette smoking is associated with higher odds of COVID-19 progression [6], and that ENDS use is associated with increased risk of COVID-19 infection [3]. However, a series of preprints suggesting an inverse relationship between tobacco and nicotine use and COVID-19 risk have also been released, some with substantial reach. For example, a preprint suggesting that cigarette smoking decreases the risk of COVID-19 infection by half was viewed over 56,000 times and has been tweeted 200 times at the time of this writing [7]. Likewise, a preprint suggesting that current cigarette smoking was inversely correlated with COVID-19 mortality has been viewed over 14,000 times [8]. A study using Twitter data found that sentiment toward cigarette smoking and ENDS use became more positive after the release of these preprints and non–peer-reviewed publications, suggesting that tobacco and nicotine users may be at less risk from COVID-19 infection and progression [9].

Likewise, research on the impact of COVID-19 on ENDS use has been mixed. A survey of a small convenience sample of US adult dual cigarette and ENDS users found that approximately one-quarter of participants attempted to reduce their tobacco and nicotine use during the pandemic [10]. Results from a five-country survey, which included the United States, also found an increase in quit attempts due to the pandemic; however, this study also showed little change in actual consumption of tobacco and nicotine products during COVID-19 lockdowns [11]. A qualitative study of ENDS users found that limited availability of ENDS products during lockdowns prompted them to turn to readily available cigarettes [12].

The COVID-19 pandemic has been accompanied by an "infodemic" in which a substantial amount of information has been spreading both online and offline [13]. In particular, misinformation about COVID-19 has been spreading on social media throughout the duration of the pandemic [14,15]. Misinformation about COVID-19 on Twitter has been found to spread virally within a matter of days, often fueling conspiracy theories [14]. Twitter is an ideal platform with which to conduct research on public opinion, conversations, and misinformation related to current health topics, including COVID-19 and ENDS. Most Twitter users maintain public profiles from which data can be obtained using Twitter's Public Streams Application Programming Interface in real time, advancing itself as a tool for "infoveillance" [16,17]. Recently, Twitter data has been used to conduct preliminary work related to discussions around COVID-19 and ENDS, with the authors calling for a more systematic, in-depth qualitative examination of Twitter messages (ie, tweets) related to ENDS use and COVID-19 [18]. Another study examining Twitter data found that individuals who tweeted about ENDS during the pandemic expressed more concern about COVID-19 deaths compared to those who did not tweet about ENDS [19], but an in-depth qualitative analysis into the content of these tweets was not conducted.

Therefore, the purpose of this study was to systematically collect tweets related to COVID-19 and ENDS during the height of the pandemic in the United States and qualitatively analyze them to classify user discussions related to perceived associations between ENDS use and COVID-19. Using a "social listening" approach on Twitter can lead to a better understanding of tobacco-related topics of current importance [20]. Additionally, a qualitative approach allows for an in-depth exploration of discussions and often results in rich data that can be triangulated with quantitative results for a more complete understanding of a phenomenon. This could inform public health messaging and interventions related to ENDS use and COVID-19 misinformation throughout the remainder of the pandemic as well as future investigations of other misinformation related to ENDS and other tobacco products.

Methods

Data Collection and Sampling

We used the open source real-time infoveillance of Twitter health messages (RITHM) framework [17] to collect approximately 2.1 million tweets matching ENDS-related keywords and hashtags (vape, vapes, vaper, vapers, vaping, vaped, e-cigarette, e-cigarettes, e-cig, e-cigs, ecig, ecigs, juul, juuls, juuling) over multiple time points from March 1, 2020, through June 30, 2020, as recommended by Lienemann et al [21]. Of these, approximately half (1 million) were original tweets and the other half (1.1 million) were "retweets" (ie, rebroadcasts of others' content). We then identified tweets containing keywords and hashtags related to the virus SARS-CoV-2 and the disease it causes, COVID-19 (sarscov2, sars-cov-2, covid, covid-19, covid19, corona, coronavirus, the rona, miss rona), which included 67,321 original tweets and 204,603 retweets. We next obtained a random 5% (n=3366)

subsample of original COVID-19–related tweets for human annotation. Previous research has demonstrated that this approach maintains generalizability of the subsample within the context of the full data set [17,22]. This study was approved by the University of Pittsburgh Human Subjects Protection Office.

Codebook Development and Coding Procedures

Initial codebook development involved a separate pool of random tweets (ie, not from the 3366 primary tweets). Individual codes were developed through a hybrid process, using both the themes identified by previous research and an examination by two independent coders of the pool of random tweets [18]. Coders reviewed and annotated these tweets and discussed potential codes with the lead author. After two rounds of this process, an initial codebook containing code and subcode names, definitions, and examples was developed (Table 1).

After initial codebook development, the two coders were provided with a spreadsheet containing the tweet text and a link to each tweet online. The tweet text was initially coded for relevance, defined as discussing a perceived association between COVID-19 and ENDS (eg, "almost 40% of ppl in the U.S. hospitalized for # COVID19 are between 20 and 54. #Vaping may be driving the rise in this" and "I'm going to juul the rona away"). Tweets that discussed ENDS or COVID-19 but not a perceived association between the two were excluded (eg, "coronavirus fears lessening in China as vape production goes back up there"). Coders viewed all relevant tweets that remained publicly available at the time of coding on Twitter so that links to external content could be assessed. However, coders included the text from unavailable tweets to preserve the comprehensiveness of the original data.

Relevant tweets were then coded as to whether they referenced four overarching categories: discussions about associations between COVID-19 severity and ENDS use; discussions about COVID-19 and e-cigarette or vaping product use–associated lung injury (EVALI) symptom similarity; discussions about COVID-19 affecting ENDS use; and discussions about personal or proximate experiences (eg, referencing something the tweeter saw themself or something that happened to someone the tweeter knows). Additionally, substantial misinformation related to COVID-19 and ENDS was found during coding and tweets containing potential misinformation—defined as statements not supported by the current peer-reviewed literature or exaggerations of research findings or public health findings—were identified and tagged by coders. Tweets containing potential misinformation were analyzed by an experienced graduate-level coder and the first author as themes within the major coding categories. All codes and subcodes are described in Table 1.

Codes were not mutually exclusive. For example, a tweet that stated, "Coronavirus attacks the lungs so one of the most important things you can do is to quit smoking and vaping. I'm in day 5 – join me!" would be coded as discussions about the association between COVID-19 severity and ENDS use (subcode: perception that ENDS use is associated with worse COVID-19 symptoms), discussions about COVID-19 affecting ENDS use (subcode: quitting ENDS because of COVID-19), and discussions about personal or proximate experience. We coded both textual and visual (eg, pictures, videos, and emojis) content [17].

The iterative coding process involved double-coding 100 tweets by two independent, experienced Twitter coders that were guided by a senior-level coder. All disagreements were discussed with the senior-level coder and adjudicated with the lead author, after which the codebook was modified accordingly. Interrater reliability was assessed using Cohen κ [23], and it was decided a priori that values above 0.70 would be acceptable. After four rounds of this process, Cohen κ reached acceptable levels of reliability (ranged 0.70-1.00) [24]. The two coders then independently coded the remaining tweets in the data set.

Table 1. Definitions for categorical codes and example tweets.

Code and subcode[a]	Definition	Examples[b]
Discussions about the association between ENDS[c] use and COVID-19 susceptibility or severity	Tweet mentions that ENDS use is associated with contracting COVID-19 or severity of symptoms	
Perception that ENDS use causes COVID-19	Tweet mentions that ENDS use may be a cause of developing COVID-19	• "Vaping may be a cause of coronavirus cases in young people, experts say." • "PSA: vaping is an effective way to spread Covid 19! The viral aerosol mist stays in the air, so lots of your friends can catch the virus."
Perception that ENDS use is associated with worse COVID-19 symptoms	Tweet mentions that ENDS use may be linked to worse COVID-19 symptoms/outcomes	• "People who vape are more likely to experience negative effects from COVID-19." • "That vaping nic eliquid makes the Covid worse! Why do you continue with this?? Until there is data to confirm, just STOP IT! So tired of this!"
Perception that ENDS use protects against COVID-19	Tweet mentions that ENDS use can protect users from COVID-19 or make COVID-19 symptoms less severe	• "If you've ever had vape juice get in your mouth after you take a hit you're immune to the corona virus. I said what I said." • "Juuling and vaping makes you immune to COVID."
Discussions about COVID-19 and EVALI[d] symptom similarity	The tweet discusses both EVALI and COVID-19	
Perception that EVALI is COVID-19	Tweet mentions thinking that EVALI was actually COVID-19	• "Or, we already had the virus and they called it EVALI. CTs of COVID pts and EVALI patients look very similar." • "No ENDS was ever linked to EVALI. EVALI was just COVID a year early."
Perception that EVALI is not COVID-19	Tweet mentions that EVALI and COVID-19 are distinct diseases	• "The first cases of EVALI were reported in April 2019, way before covid. I don't think they are related, but I could see how vaping makes it worse."
Quitting ENDS because of COVID-19	Tweet mentions quitting ENDS use because of COVID-19	• "In the middle of the COVID pandemic of a respiratory disease, smokers and vapers, now is a great time to think abt quitting before the habit kills you." • "Vaping nicotine makes coronavirus worse! Why do you all keep vaping? Until there is more data, just STOP vaping! So exhausted by this!"
Switching from combustible cigarettes to ENDS because of COVID-19	Tweet mentions switching from smoking cigarettes to using ENDS because of COVID-19	• "I have converted so many people from smoking to nicotine vaping during this time of COVID-19!! 18 people have now made a healthier decision to use a harm reduction tool that really works!" • "There are so many people switching to e-cigs and ditching traditional cigarettes. Vaping could help lower the number of people admitted to hospital if they get affected by the coronavirus."
Starting or continuing ENDS use because of COVID-19	Tweet mentions starting or continuing using ENDS because of COVID-19	• "I've just started vaping again as a way to manage stress. I'd quit nicotine for six months up until today...I'm blaming it on the Covid effect." • "COVID really has me back on my high-school diet of juul pods and iced lattes."

Code and subcode[a]	Definition	Examples[b]
Discussions about personal or proximate experiences	Tweet contains reference to something the tweeter saw themself or something that happened to someone the tweeter knows	
Respiratory symptoms	The tweet mentions symptoms that could be from COVID-19 or ENDS use, and the tweeter is not sure which is the cause	• "About once or twice a week I'll wake up with congestion, and I'm like well, I've got covid. And then I'll remember that I burn through like 2 juul pods a day easy." • "He and my friends thought we had something before covid but we're all smokers and thought it was from vaping – who knows?"

[a]Code derived from original codebook; subcode derived from content analysis discussions and adjudications.

[b]Examples are provided for subcodes. Proper names and expletives have been censored. Minor details of tweet content were changed to prevent reidentification of individual Twitter users via direct quotes.

[c]ENDS: electronic nicotine delivery system.

[d]EVALI: e-cigarette or vaping product use–associated lung injury.

Content Analysis

Frequencies and percentages were calculated for each code. A thematic qualitative content analysis approach was used to inductively assess the tweets and refine thematic units within codes [25]. The thematic analysis approach is recognized as a highly flexible qualitative approach that provides a rich and detailed account of data, especially within large data sets [26]. Qualitative themes and quotes around quantitative findings were organized to contextualize associations between COVID-19 and ENDS. Quotes were deidentified, and unique quotes were slightly rephrased while preserving the original meaning of the statement to prevent identification of individual Twitter users [17].

Results

Of 3366 human-coded tweets, 1930 (57.3%) were coded as relevant (ie, discussed a perceived association between COVID-19 and ENDS) and were included in the analysis (Table 2). A total of 1008 (52.2%) tweets discussed the perceived association between COVID-19 susceptibility or severity and ENDS use, with a plurality (n=818, 42.4%) suggesting that ENDS use is associated with worse COVID-19 symptoms. Overarching themes focused on how young people should be concerned about this association because they are more likely to use ENDS than older people and how ENDS use damages the lungs and weakens the immune system. Tweets containing these themes were a mixture of news headlines and personal opinions.

Some tweets (n=120, 6.2%) suggested that ENDS use protects individuals from COVID-19 infection and progression. One theme focused on the potential curative effect of ENDS, with references to early research suggesting the protective effect of nicotine (eg, "Doctors in France recognize the power of nicotine to fight COVID-19 virus. Nicotine & vaping may become a preventive treatment & cure for COVID-19") and the components of ENDS that may cure those with COVID-19 (eg, "Vaping most likely kills COVID because of the propylene glycol content in it"). Other themes suggested that ENDS use protects users from infection and that there was no link between COVID-19 and ENDS (ie, neither protective nor harmful).

Fewer tweets (n=80, 4.2%) suggested that ENDS use actually is the cause of COVID-19, with themes focused on the possibility that the COVID-19 virus was in ENDS liquid (eg, "Remember that mysterious illness caused by vapes in January? A severe respiratory illness. Well the first e cigs came from Wuhan China. What if they put Covid in vape juice, causing the illness and the spread?") and that secondhand vapor might be contributing to the spread of COVID-19 (eg, "Public Service Announcement: Vaping is an effective way to spread COVID-19! The viral aerosol mist stays in the air, and your friends and family can catch the virus. DON'T VAPE").

A total of 479 (24.8%) tweets discussed the perceived similarity (or dissimilarity) of the symptoms of COVID-19 and EVALI. Of these, a greater number of tweets (n=424, 22%) suggested that COVID-19 and EVALI are actually the same disease, with overarching themes focused on government deception (eg, "America is the epicenter and origin of coronavirus, But Trump and American Government have cheated the world since vaping-pneumonia erupted in August 2019. The Covid-19 patient 0 is from Fort Detrick. #TrumpLiedPeopleDied") and similarities of symptoms and medical imaging. A smaller number of tweets (n=57, 3%) focused on distinctions between COVID-19 and EVALI, with overarching themes mentioning how EVALI was not infectious (eg, "If it was true that the vaping deaths were coronavirus, you would see patient-to-healthcare-worker infections") and differences in age groups affected (eg, "Why didn't any old people get EVALI then? It was all young people who vape").

Table 2. Frequencies of coding categories for relevant tweets (n=1930).

Code and subcode	Frequency, n (%[a])
Discussions about the association between ENDS[b] use and COVID-19 susceptibility or severity	1008 (52.2)
Perception that ENDS use causes COVID-19	80 (4.2)
Perception that ENDS use is associated with worse COVID-19 symptoms	818 (42.4)
Perception that ENDS use protects against COVID-19	120 (6.2)
Discussions about COVID-19 and EVALI[c] symptom similarity	479 (24.8)
Perception that EVALI is COVID-19	424 (22.0)
Perception that EVALI is not COVID-19	57 (3.0)
Discussions about COVID-19 affecting ENDS product use	266 (13.8)
Quitting ENDS because of COVID-19	180 (9.3)
Switching from combustible cigarettes to ENDS because of COVID-19	33 (1.7)
Starting or continuing ENDS use because of COVID-19	59 (3.1)
Discussions about personal or proximate experiences	231 (12.0)
Respiratory symptoms	40 (2.1)

[a]Row percentages may not equal 100 due to rounding.

[b]ENDS: electronic nicotine delivery system.

[c]EVALI: e-cigarette or vaping product use–associated lung injury.

Approximately 13.8% (n=266) of tweets discussed a potential relationship between ENDS use behavior and the pandemic. Of these, most mentioned quitting ENDS in response to the pandemic (n=180, 9.3%). The most prominent theme in this category was quitting ENDS because of its effects on respiratory health (eg, “This is an excellent reason to quit smoking and vaping...those habits decrease your lungs' ability to keep clean and fight off coronavirus infection. Do not make it easier to get sick or sicker”). Fewer (n=59, 3.1%) mentioned starting or continuing ENDS because of the pandemic (eg, “corona got me thinkin bout my health so i got a juul for in b/w cigs”) and the perceived health benefits of nicotine (eg, “YOU NEED TO VAPE. Nicotine users are at a lower risk of developing COVID-19 symptoms...”). Finally, 33 (1.7%) tweets mentioned switching from traditional cigarettes to ENDS, with all tweets in this coding category containing the theme of ENDS being a safer alternative to cigarette smoking.

Approximately 12% (n = 231) discussed a personal or proximate experience. Among users who mentioned ENDS use themselves, one theme focused on limiting the sharing of their ENDS because of COVID-19 (eg, “Because of COVID, no you cannot hit my vape”). A total of 40 (2.1%) tweets discussed respiratory symptoms that users believed could be due to either COVID-19 or ENDS use (eg, “Was it it the constant vaping that gave me a sinus infection or do I have the rona”). Another theme focused on possibly having COVID-19 in the past but attributed symptoms to ENDS use at the time. Additionally, some users expressed concern about COVID-19 for friends/family who use ENDS (eg, “I think there's something very serious we need to address regarding Covid-19 and young people, considering 90% of the people I know use e-cigarettes and vapes perpetually”) and relief about not using ENDS themselves in light of COVID-19.

Discussion

In this study, approximately half of the tweets that discussed perceived associations between ENDS use and COVID-19 contained language suggesting the perception that ENDS may worsen COVID-19—specifically that the use of ENDS by predominantly younger individuals may increase risk of severe COVID-19 symptoms. This is consistent with recent research finding that, among those aged 13 to 24 years, current ENDS users and current ENDS/cigarette dual users are 5 and 6.8 times more likely to be diagnosed with COVID-19 compared to nonusers, respectively [3]. This is also consistent with research finding that ENDS may have adverse effects on the cardiovascular and respiratory systems, and increase risk for infections, especially when combined with traditional cigarettes [27]. Likewise, tweets from users indicating a desire to quit ENDS were consistent with research suggesting that approximately one-quarter of US adult tobacco users sought to reduce their use during the pandemic [10].

The themes emerging from this study, combined with previous research, suggest that focusing public health messaging on the potential for worse COVID-19–related health outcomes among ENDS users may resonate with those discussing this topic on social media. Specific strategies, such as magnifying accurate Twitter messages linking ENDS use with COVID-19 and disseminating messages via social media with clear actionable public health advice linked to credible sources may be important health communication tools moving forward [28].

Our findings were also consistent with others who have reported rapid spread of misinformation related to COVID-19 in general [29,30]. In our study, one apparent source of misinformation was the preponderance of preprints of COVID-19–related research that had not yet undergone peer review and were later

contradicted [9,31]. For example, we found that unsubstantiated reports that tobacco and nicotine users were at less risk for COVID-19 complications were being cited by Twitter users as justification to begin or maintain ENDS use [7,8]. Development and dissemination of counter-messaging clarifying the evidence related to ENDS use and COVID-19 may be useful at curtailing this spread of misinformation [32].

Additionally, our analysis uncovered conspiracy theories related to the origins of the virus, its transmissibility, and potential treatments [29,33]. For example, multiple tweets suggested that COVID-19 and EVALI were in fact the same condition. Several other tweets suggested that China engineered the virus and transmitted it to the United States via ENDS. Prior to COVID-19, concerns about EVALI appeared to have contributed to declines in ENDS use among youth [34]. If youth begin to equate EVALI with COVID-19 but do not believe in the dangers of COVID-19 or are no longer concerned about a uniquely vaping-related condition, this trend may reverse. Because the symptoms of EVALI and COVID-19 are similar, it is suggested that clinicians assess ENDS use during all clinical encounters in which COVID-19 is suspected [35].

Several tweets suggested that propylene glycol may kill the virus, thus protecting ENDS users from infection, which relates to a popular misperception of the antiviral and antibacterial properties of propylene glycol gas [32]. Some of these individuals also suggested that regulations around ENDS, including flavor bans, were initiated by the US government in an attempt to hoard propylene glycol for use with COVID-19 treatment. While more research is needed to better understand the relationship between the online spread of conspiracy theories and ENDS use behavior, these findings emphasize the value of using social media to monitor current discourse about various public health crises [13]. The real-time nature of Twitter allows for the capture and analysis of health-related information, misinformation, and disinformation more quickly than traditional methods such as surveys. Additionally, the use of techniques such as social network analysis can help assess the reach and spread of these messages, which can allow for the development of targeted interventions to mitigate the sharing of mis- and disinformation.

Our study was limited in that these results are neither generalizable to non-Twitter users nor the general population. Twitter users tend to be younger and more educated than the general population [36], and the content in the analyzed tweets may reflect that. Moreover, while we endeavored to collect a random sample of tweets, collected tweets are not necessarily representative of all Twitter content on this topic. It is also a necessary limitation that the tweets in this study were coded and analyzed by human coders. However, a series of steps were taken to mitigate this concern. First, we used highly trained and experienced Twitter coders that were guided by a senior-level coder. Second, our codebook was systematically developed and contained specific definitions and examples to guide coders in their interpretations. Third, we conducted four rounds of double-coding until sufficient interrater reliability was reached. At each round, coders discussed inconsistent results with the senior-level coder. A final limitation is that no conclusions about an association between ENDS and COVID-19 can be made from this study. Instead, this study consisted of qualitative analyses of discussions about ENDS and COVID-19.

In conclusion, discussions about the perceived associations between ENDS and COVID-19 on Twitter are often conflicting. These conflicts reflect the lack of consistent health communication messaging, which may have facilitated the spread of speculation and misinformation. The results suggest the need for further research to investigate the spread of information and misinformation about ENDS use and COVID-19, especially on social media platforms. They also suggest potential targets for evidence-based clarifications public health providers can implement.

Abstract

Background: Internet-based treatments for child anxiety may help to increase access to evidence-based therapies; however, user engagement, uptake, and adherence within routine clinical practice remain as challenges. Involving the intended end users in the development process through user-centered design and usability testing is crucial for maximizing user engagement and adoption of internet-based treatments, but so far this has been lacking for internet-based treatments for child anxiety.

Objective: The aim of this study is to develop an internet-based treatment for child anxiety through a process of user-centered design (phase 1) and usability testing (phase 2), based on an existing evidence-based, face-to-face, therapist-supported, parent-led cognitive behavioral therapy intervention. It is intended that the internet-based version of this treatment would consist of a parent website, case management system for clinicians, and mobile game app for children.

Methods: Parents, children, and clinicians who were familiar with the face-to-face version of the treatment were recruited from 2 National Health Service clinics. In phase 1, participants participated in 3 workshops to gain feedback on the overall concept, explore their wants and needs for the websites and game, generate ideas on how the treatment may look, and gain feedback on initial mock-ups of the websites and game. In phase 2, participants attended 3 individual usability testing sessions where they were presented with working prototypes of the website or game and asked to perform a series of tasks on the website (parents and clinicians) or play the game (children). The frequency and details on usability errors were recorded. Participants were asked for their feedback on the website and game using a standardized usability questionnaire and semistructured interviews. The websites and game were iterated after each round of usability testing in response to this feedback.

Results: In phase 1, participants approved the general concept and rated the initial mock-ups of the website and game positively. In phase 2, working prototypes were rated positively and usability errors declined across the iterations and were mainly cosmetic or minor issues relating to esthetic preference, with few issues regarding ability to navigate the website or technical issues affecting functionality. Feedback from the semistructured interviews further supported the positive response of participants to the website and game, and helped identify areas for improvement during the iteration process. The final iteration of the website and game are presented.

Conclusions: Taking an iterative approach to development through user-centered design and usability testing has resulted in an internet-based treatment for child anxiety (Online Support and Intervention for child anxiety) that appears to meet the needs and expectations of the intended users (parents, children, and clinicians) and is easy and enjoyable to use.

Introduction

Background

There is growing interest in providing psychological treatments via the internet to increase access to evidence-based therapies. This is particularly salient for child anxiety disorders as most children who would benefit do not access treatment [1-4]. Internet-based cognitive behavioral therapy (iCBT) for child anxiety is effective and acceptable within research settings [5,6]; however, user engagement, uptake, and adherence remain as challenges within routine clinical practice [7-9].

Involving the intended users in the development process and following a user-centered approach is crucial to maximize service user engagement and adoption of internet-based interventions within routine clinical practice [10,11]. User-centered design is different from the traditional approach of expert-led intervention development *for* users and embraces *active* collaboration *with* users to ensure that the digital solution is usable and meets their needs and preferences [11,12]. Key elements of user-centered design include (1) identifying user needs, preferences, and expectations for the digital solution; (2) actively involving users in the design and prototyping; and (3) conducting usability testing on a working prototype to provide feedback and identify technical and esthetic issues that may affect user satisfaction [10]. User-centered design can improve (1) design quality [13], (2) user adherence [14], (3) usability [15], (4) efficacy and sustainability [16], and (5) stakeholder acceptance and adoption at the system and organizational levels [17]. Recent iCBT development guidelines advocate active collaboration with users [10,18,19], and funding agencies increasingly demand stakeholder involvement.

Despite a clear rationale for user-centered design, few existing mental health digital interventions for young people have incorporated these principles within their development process. However, the number of digital interventions designed with young people is growing, with recent examples for depression [20,21], positive mental health [22], and recovery from mild traumatic brain injury [23]. Others have conducted usability testing of digital interventions for self-harm [24,25], depression [26], positive mental health [27], and recovery from pediatric cancer [28]. To the best of our knowledge, no existing iCBT interventions for child anxiety disorders actively involved users in the design process and only one intervention (*Breathe*, which is focused on adolescent anxiety) conducted usability testing [29]. This study highlighted the importance of involving both young people and clinicians in providing feedback in the iterative usability testing process, and the final iteration of *Breathe* showed improved usability and acceptance following this process.

Aims

The aims of this study are to (1) collaborate with users to design an internet-based treatment for child anxiety disorders (phase 1) and (2) test the usability of this internet-based treatment (phase 2). Existing iCBT interventions for child anxiety disorders involve providing direct support to children or adolescents, via internet-based sessions or modules [5]. However, face-to-face CBT for child anxiety disorders can be delivered in a brief format directly to parents alone [30,31]. Therefore, we set out to design an internet-based treatment based upon a face-to-face parent-led CBT for child anxiety disorders that is effective compared with waitlist [30], is cost-effective compared with another brief psychological intervention (Solution-Focused Therapy [31]), is acceptable and feasible for use within routine clinical practice [32], and is now widely used in early intervention services in the United Kingdom [33]. This brief face-to-face treatment for child anxiety disorders involves the parent reading chapters of the accompanying treatment book [34] and meeting with a therapist for approximately 5 hours of support over approximately 8 weeks, to help apply the CBT strategies with their child and problem solve any difficulties [35]. Although the child is not seen by the therapist during treatment, the parent is encouraged to work through the CBT techniques collaboratively with their child and involve them throughout the process.

Before the design phase, we developed an initial overview plan for the internet-based version of this treatment, in consultation with stakeholders via our research clinic patient and public involvement group. This initial plan specifies that the internet-based version of the treatment would involve a parent website, case management system for clinicians, and a mobile game app for children that could be downloaded onto a smartphone or tablet. The intention is that parents would work through modules containing treatment material adapted from the book, with videos and animations to help demonstrate the CBT strategies. Clinicians would use the case management system to view the parents' responses provided on the parent website and to release the next treatment module after a 20-minute telephone review therapist session. The plan to include a mobile game app for children was developed in response to feedback from our patient and public involvement group that it is important to incorporate opportunities to involve and motivate children in the treatment process. The intention of the game app for children is to help motivate the child in engaging in the treatment strategies such as facing their fears (graded exposure).

Phase 1: User-Centered Design

Methods

Participants

A total of 7 parents (n=6, 86% mothers and n=1, 14% father) and 4 children (n=2, 50% boys and n=2, 50% girls) aged 9-12 years were recruited. Of the 7 parents and 4 children, 5 (71%) parents and 4 (100%) children had recently received the brief face-to-face, parent-led CBT treatment and were recruited from a local child and adolescent mental health service, and 2 (29%) parents had received the face-to-face treatment several years ago as part of a research trial [30]. A total of 11 clinicians (n=7, 64% women and n=4, 36% men) who had experience of delivering the face-to-face treatment were recruited from 2 local child and adolescent mental health services. Sample characteristics are provided in Table 1.

Table 1. Demographic characteristics of phase 1 and phase 2 participants.

Participant group and characteristic	Phase 1	Phase 2

[a]A total of 5 parents participated in both phase 1 and phase 2.

[b]A total of 3 children participated in both phase 1 and phase 2.

[c]A total of 6 clinicians participated in both phase 1 and phase 2.

[d]CBT: cognitive behavioral therapy.

Measures

Participants reported on their technology use using a customized questionnaire. We collected feedback from parents and clinicians on each screen of initial mock-ups of the parent treatment website and clinician case management website, respectively, using an adapted version of the Program Content and Usability Questionnaire (PCUQ). Shortened versions of the PCUQ were administered to children to obtain feedback on various game visuals (character type, environment, and style), existing mobile game app types (story-led games, minigames, and virtual toys), and pen-and-paper mock-ups of the game (see Multimedia Appendix 1 [29,36,37] for full measure details).

Procedure

In all, 3 workshops were conducted separately for each user group (parents, children, and clinicians) approximately 1 month apart. Participants were financially compensated for their time and any travel expenses. Members of the university research team and the website development company conducted the workshops at varied times to facilitate participation.

A breakdown of the content for each of the 9 workshops is presented in Table 2. The workshops for each user group followed an iterative process, whereby feedback from workshop 1 fed into workshop 2 and so forth. In workshop 1, participants provided written consent and completed the demographic (parents and clinicians only) and technology use questionnaire.

Table 2. Phase 1 workshop content.

Participant group	Workshop 1	Workshop 2	Workshop 3
Parents	• Introductions and aim for the workshop • Warm-up exercise • Explanation of the project • Discussion on (1) the treatment itself, (2) how they would use internet-based version, and (3) therapist support: what and how • MoSCoW[a] card-sorting task for functions • Rapid visual prototyping of top 1 or 2 functions	• Introductions and aim for the workshop • Warm-up exercise • Talk through user journey using initial prototype • Feedback (PCUQ[b]) on initial prototype • Group discussion on initial prototype • Rapid visual prototyping of areas identified for improvement	• Introductions and aim for the workshop • Warm-up exercise • Talk through user journey using revised prototype • Feedback (PCUQ) on revised prototype • Group discussion on revised prototype • Read through and discussion of excerpt of treatment content • Feedback on plans for child app
Children	• Introductions and design own name badge • Explanation of the project • Warm-up game • Draw favorite superhero or character • Discussion of (1) what the character would be scared of, (2) how they would face fears, (3) where they would live, and (4) rewards for facing fears	• Introductions and design own name badge • Recap of the project • Warm-up game • Feedback (PCUQ) on game visuals: (1) character type, (2) environment, and (3) style • Feedback (PCUQ) on existing game types: (1) story-led games, (2) minigames, and (3) virtual toy	• Introductions and design own name badge • Recap of the project • Talk through concept of the game and initial designs • Feedback (PCUQ) on mock-up game: (1) character, (2) home screen, (3) dress-up game, (4) challenges, and (5) minigames
Clinicians	• Introductions and aim for the workshop • Warm-up exercise • Explanation of the project • Discussion on (1) concerns and positive aspects about providing the treatment via the internet, (2) issues in the face-to-face treatment, (3) clinician involvement in the internet-based treatment, and (4) digital tools currently used • MoSCoW card-sorting task for functions • Rapid visual prototyping of top 1 or 2 functions	• Introductions and aim for the workshop • Warm-up exercise • Talk through user journey using initial prototype • Feedback (PCUQ) on initial prototype • Group discussion on initial prototype • Rapid visual prototyping of areas identified for improvement	• Introductions and aim for the workshop • Warm-up exercise • Talk through user journey using revised prototype • Feedback (PCUQ) on revised prototype • Group discussion on revised prototype • Read through and discussion of excerpt of treatment content • Feedback on plans for child app

[a]MoSCoW: Must have, Should Have, Could Have, Won't Have.

[b]PCUQ: Program Content and Usability Questionnaire.

The aims of workshop 1 for parents and clinicians were to (1) present the overall concept of the internet-based intervention, (2) explore participants' wants and needs, and (3) generate ideas about what the internet-based intervention might look like and the functionality it may have. Parents focused on the parent treatment website and clinicians focused on the clinician website. The MoSCoW approach (Must have, Should have, Could have, Won't have) [38] was used to gain insight into what the priority of functions should be and what functions were not wanted by users. Participants quickly sketched their ideas for what key functions would look like using rapid visual prototyping [39]. Early prototypes of the websites were created from the learnings from workshop 1 and presented to the participants in workshop 2 to gain their feedback through

discussion and the PCUQ. These early prototypes were interactive screens that could be navigated to represent the intended user experience. This purported to evaluate what the participants liked and what refinements were needed at a very early stage of development. Refined prototypes were presented in workshop 3 and participant feedback was collected through discussion and the PCUQ. The learnings from workshop 3 subsequently informed the development of the working prototype that was used in the usability testing (phase 2).

The aim of workshop 1 for children was to gain an understanding of the kind of character the game should have and how the game could help them face their fears. In workshop 2, children were presented with various game visuals in a colorful booklet and they played different types of existing games on a tablet. Children completed the PCUQ to obtain feedback on what children wanted the game to look like and the type of game they preferred. Pen-and-paper mock-ups of the game were created based on this information and presented to children in workshop 3. Children provided their feedback on the mock-ups through discussion and the PCUQ. This informed the development of a working prototype of the game that was used in the usability testing (phase 2).

During the workshops, detailed field notes were taken to capture the discussion, and visual activities were photographed. Following each workshop, members of the research team and website development company met to collate and summarize feedback from the discussion, activities, and the PCUQ.

Data Analysis

Phase 1 involved gathering information to inform the subsequent development of the intervention, and therefore, no formal statistical analysis was conducted. Key learnings and descriptive statistics for the PCUQ are presented below. The outcomes of phase 1 were a description of the needs and wants of the intended user groups for Online Support and Intervention for child anxiety (OSI) and confirmation that these have been met in the early prototypes.

Ethics Approval

The study was approved by the University of Reading Research Ethics Committee (16/48) and the National Health Service South East Coast–Surrey Research Ethics Committee (16/LO/1598).

Results

Technology Use

As shown in Table 3, all the parents and clinicians had regular access to the internet and a PC or laptop, and most of them had regular access to a smartphone. Parents and clinicians reported feeling confident in using these technologies and endorsed that they liked using them. Most of the clinicians had no experience with delivering internet-based psychological therapies. Children reported regular use of the internet and tablets, with some use of PCs or laptops and smartphones. All children rated themselves as confident in using and liking these technologies.

Table 3. Technology use of participants in phase 1 and phase 2.

Participant group and variables	Phase 1	Phase 2

[d]Rated on a 5-point Likert scale, with higher scores indicating more frequent use.

Workshops

The key learnings from workshop 1 are presented in Textbox 1. Overall, parents and clinicians were positive about the idea of creating an internet-based version of the face-to-face treatment, and children were excited about a game that could help them face their fears.

The functionality proposed for the parent and clinician OSI websites was largely welcomed, with the exception of secure videoconferencing for the therapy sessions. Although clinicians considered this as a *must have*, they had concerns about the technology failing and the implications this could have partway through a therapy session. In contrast, parents did not want the therapy session to be held over a secure videoconferencing system and preferred telephone contact. In response to this feedback from parents, secure videoconferencing was not included in the prototypes presented in subsequent workshops.

Both parents and clinicians suggested additional functionality that they wanted for OSI. For parents, this included a *favorites* section where parents could bookmark key parts of the treatment modules and a written summary of the therapy session. Clinicians suggested that a *welcome* module would be helpful to orientate parents to the treatment approach.

The children wanted to be able to personalize the character in the game through customizable elements such as hair, clothes, and color. They thought the game could help them face their fears if they could earn rewards through it for facing their fears on their *step plan* (exposure ladder).

Initial prototypes of the parent and clinician OSI websites were presented to parents and clinicians, respectively, in the subsequent design workshops (workshop 2 and workshop 3). Overall, the PCUQ results showed that parents and clinicians were positive about the proposed design and functionality (Table 4). Feedback provided during workshop 2 helped to further improve the intervention, as shown by the higher PCUQ ratings during workshop 3.

The main finding from the children's design workshop 2 was that they were largely positive about the game visual options, with a slight preference for a mountain setting and cartoon style for the game app over alternative designs (Multimedia Appendix 2). They liked the concept of having more than one game type to choose from, and their favorite minigame type was *bottle-flipping* [40]. In workshop 3, children were presented with pen-and-paper mock-ups of the game. Children rated all aspects of the game dynamics specified in the PCUQ (game character, home screen, dress-up game, game selection screen, and challenges) as highly liked and easy to use (Multimedia Appendix 3). All the game play options presented were also rated as highly liked and easy to use. Overall, the children agreed that the game developer had understood what they wanted and few changes were needed. On combining feedback from workshops 1 and 2, game option 1 (monster flipping) was selected as the primary game.

Textbox 1. Key learnings from workshop 1.

Key learnings from parents:

- Therapy session to be conducted via telephone and not via secure videoconferencing.
- Include a *favorites* section.
- Clinician should provide a written summary of the therapy session.

Key learnings from children:

- Ability to personalize the character in the game.
- Earn rewards through the game and step plan.

Key learnings from clinicians:

- Not include an instant messaging service with the parent.
- Conduct the therapy session over secure videoconferencing built into system but concerned about technical issues.
- Not include one-way messages of encouragement to the child app.
- Include a *welcome* module to orientate parents to the website and clarify expectations of the treatment approach.

Table 4. Phase 1 parent and clinician feedback on initial mock-ups of Online Support and Intervention for child anxiety.

PCUQ[a] item[b]	Parents, mean (SD)		Clinicians, mean (SD)	
	Iteration 1	Iteration 2	Iteration 1	Iteration 2
It looks easy to use	4.78 (0.32)	4.86 (0.19)	4.36 (0.43)	4.25 (0.32)
It looks easy to navigate	4.75 (0.37)	4.89 (0.15)	4.21 (0.65)	4.37 (0.23)
The words are clear and easy to understand	4.72 (0.35)	4.94 (0.15)	4.23 (0.47)	4.37 (0.45)
This screen has the right amount of information	4.44 (0.57)	4.86 (0.26)	4.04 (0.49)	4.30 (0.46)

It looks clear what to do next	4.37 (0.71)	4.80 (0.34)	3.64 (0.48)	3.92 (0.23)
This page looks user-friendly	4.45 (0.56)	4.85 (0.20)	3.93 (0.47)	4.17 (0.49)
Based on this page, I would return to this website	4.61 (0.34)	4.83 (0.18)	3.93 (0.62)	4.02 (0.60)
The tone of the material is sensitive for parents seeking help for their child's anxiety	4.64 (0.45)	4.86 (0.18)	—[c]	—
The material is relevant for parents seeking help for their child's anxiety	4.61 (0.27)	4.85 (0.19)	—	—
This page meets my needs for an online treatment program	4.64 (0.30)	4.77 (0.29)	3.96 (0.34)	4.18 (0.42)
The page meets what I would want from an online treatment program	4.56 (0.39)	4.82 (0.20)	3.96 (0.30)	4.17 (0.46)
This page meets my expectations as discussed in the workshop	4.57 (0.39)	4.86 (0.16)	3.79 (0.47)	4.05 (0.63)

[a]PCUQ: Program Content and Usability Questionnaire.

[b]Items were scored on a scale of 1 (strongly disagree) to 5 (strongly agree).

[c]Questionnaire item was not relevant for clinicians to answer.

Phase 2: Usability Testing

Methods

Participants

A total of 7 parents (n=6, 86% mothers and n=1, 14% father), 4 children (n=2, 50% girls and n=2, 50% boys), and 8 clinicians (n=4, 50% women and n=4, 50% men) participated in phase 2. Sample characteristics are presented in Table 1. In all, 71% (5/7) of the parents (all mothers), 75% (3/4) of the children, and 75% (6/8) of the clinicians participated in both phase 1 and phase 2. Participants were recruited using the same approach as phase 1.

Measures

Participants completed the technology use and PCUQ questionnaires, as described above and in Multimedia Appendix 1 [29,36,37]. Participants completed the PCUQ in reference to OSI (parents and clinicians) and the game (children) as a whole, rather than specific to each function of the website as in phase 1.

Usability Error Log

Usability errors during use of the parent and clinician websites were logged according to severity metrics common in usability testing [41,42]: (1) level-1 errors refer to cosmetic or minor factors such as typos, legibility, or esthetic preference; (2) level-2 errors are moderate issues; for example, inability to navigate successfully through the site; and (3) level-3 errors are critical or severe issues, such as technical issues that prevents the user from using a function of the site. The frequency of each error severity level was summed for each iteration.

Semistructured Interviews

Semistructured interviews were used to gather further information about the acceptability and ease of use of the website and game. Questions were open and nonspecific to encourage unprompted reports of what was most relevant. Specifically, parents and clinicians were asked the following: (1) What did you think of the website overall? (2) What did you find easy to use? (3) What did you find difficult to use? (4) What did you find easy to understand? (5) What did you find difficult to understand? (6) What did you like about it? (7) What did you dislike about it? (8) What do you think about how long it took to complete a module (parents only)? (9) What would you like to change about the website? (10) What would you like to add to the website? (11) What would you like to remove? (12) What do you think about the colors used? and (13) Is there anything else you would like to say about the website? At this point, we suggested the name, OSI, to parents and clinicians and asked for their feedback. For each element of the game (ie, home screen, monster flip game, and monster dress-up game) children were asked the following: (1) What did you like about the game? (2) What did you dislike about the game? (3) What did you find easy to use? (4) What did you find hard to use? and (5) What would you like to change about the game? Children were also asked what they thought about the sounds and music used in the game. Interviews were audio-recorded and transcribed verbatim for analysis.

Procedure

Participants attended individual usability testing sessions at the University of Reading at a time convenient to them. Parents and clinicians were shown the website relevant to them and asked to *think aloud* (ie, provide continuous commentary) [43] while carrying out a list of tasks (eg, parents were asked to work

through the module and bookmark a page and clinicians were asked to book an appointment for a therapy session) and were provided time to explore the website by themselves. A researcher was present to record the frequency and detail of usability errors using the usability error log. Both the participant and the screen were video-recorded, in case further clarification was required after the testing process. Then, parents and clinicians completed the PCUQ and semistructured interview. Usability testing sessions for the children followed a similar format. Children were asked to explore the game and say out loud what they thought of it as they played it (ie, the *think aloud* method [43]). A researcher was present to record observational notes to obtain a general idea of how children proceeded through the game. Then, the children completed the child PCUQ and semistructured interview.

The research team collated and summarized the feedback on each aspect of the website and the game from the first round of usability testing. Then, the website development company revised the website and the game in response to the user feedback. Then, the second iterations were presented to participants in a second round of usability testing, following the same procedures outlined above. Additional functions were also included in the subsequent iterations of OSI. Feedback from the second round of usability testing was used for further iteration, and a third (final) round of usability testing was conducted as described above. Feedback from the final round of usability testing was used to finalize the website and the game.

Data Analysis

Descriptive statistics were used to analyze the PCUQ responses and the frequency of usability errors for each iteration of the website for both parents and clinicians. Brief summaries of the semistructured interviews were used to identify immediate feedback on each iteration of the website and game that could be used to further iterate OSI. Then, a content-analysis approach was used to analyze interview transcripts across all 3 interactions to capture more detailed insights into the acceptability and ease of use of the website and game. Responses were assigned codes according to whether the comment reflected positive feedback or negative feedback or suggested improvement and the aspect of the design or functionality of the website or game discussed. Then, the codes were organized according to these categories to identify key themes and patterns across the 3 iterations for each set of interviews (parents', clinicians', and children's interviews). The analysis took into account both frequency and severity of usability issues discussed in the interviews. A summary of the key themes along with example quotations from the interviews are presented below.

Results

Technology Use

Parents and clinicians in phase 2 had regular access to the internet and a PC or laptop, and most of them also had regular access to a smartphone (Table 3). Most of the participants reported feeling confident with and liking these technologies. Most clinicians had no experience of delivering internet-based psychological therapies. Children reported regular use of the internet and tablets, with some use of PCs or laptops and smartphones. All children rated themselves as confident in using and liking these technologies.

Usability Testing Sessions

Feedback from parents and clinicians on working prototypes was predominantly positive across the 3 iterations, with mean scores on the PCUQ largely indicating *agree* or *strongly agree* (Multimedia Appendix 4). For most items on the PCUQ, ratings increased across the iterations, suggesting that usability had improved with the changes made to each iteration. Scores for "it is always clear what to do next" stayed within *neutral* to *agree* across iterations for clinicians. Children reported a similar trend for sustained or improved usability scores on the PCUQ for the majority of items (Multimedia Appendix 5); however, some items ("each screen has the right amount of information," "it is easy to use the home screen," and "each screen loaded quickly") showed a slight decline in scores at iteration 3.

Usability errors for parents and clinicians followed a similar pattern across the iterations (Figures 1 and 2). Overall, there were fewer level-3 errors (critical technical issues) than level-2 errors (moderate issues) or level-1 errors (minor or cosmetic issues) for all iterations. Level-3 errors stayed at a low level for parents across all iterations and none occurred for clinicians. Level-1 and level-2 errors tended to reduce across the iterations, with the exception of level-2 errors for clinicians that showed a slight increase at iteration 3, which may be owing to the introduction of new features to the case management system at this stage.

Figure 1. Mean number of usability error types for parents across the iterations of Online Support and Intervention for child anxiety.

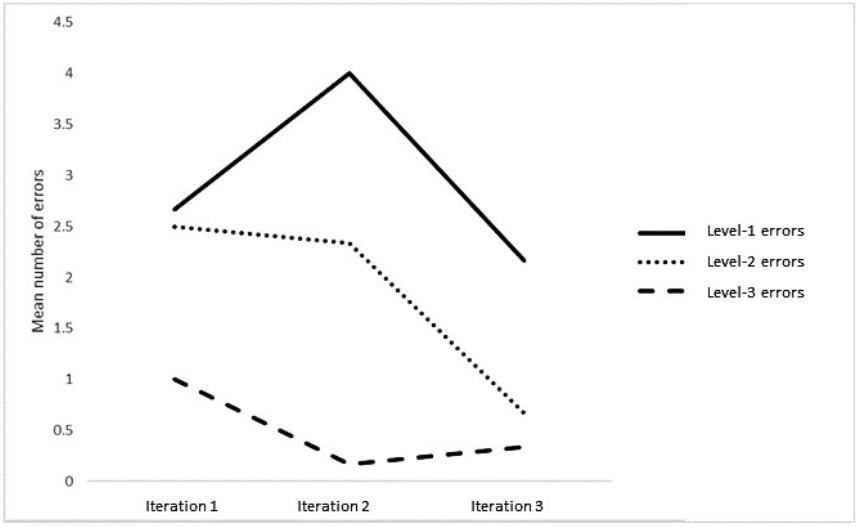

Figure 2. Mean number of usability error types for clinicians across the iterations of Online Support and Intervention for child anxiety.

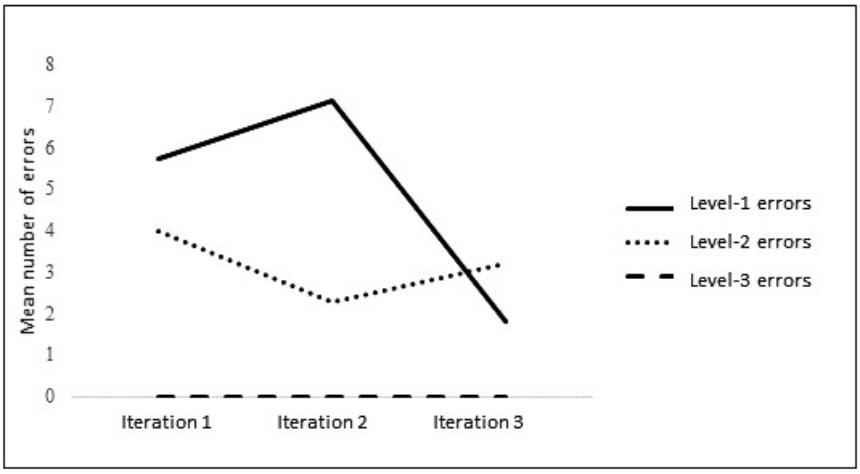

Semistructured Interviews

Results from the semistructured interviews reflected the findings from the PCUQ and usability errors.

Parents

Parents were positive about the overall structure of the website, how the treatment material was presented, and the time required to complete the modules:

> *What I liked about it is it's something I can go back to in my own time when I can't remember exactly how to do something, and it's easier to access and use because it's in nice bite-size chunks, rather than having to flip through the book or my notes from the course.* [Parent 7; iteration 3]

> *I think the information is not too much, straight to the point and also, the fact that you're...it's not just words there are videos, so yes I think that's important. I think it's not long, I think it's a good time.* [Parent 2; iteration 2]

Parents were positive about the website—in particular, that it was easy to use and the materials were accessible:

> *I like the fact that you can at any point stop and go to any other section that you wish to, you don't have to complete that whole section, you can go backwards and forwards as much as you like and it's very quick and easy to do that.* [Parent 4; iteration 1]

> *Well actually, some of the functionality I thought might have been difficult, in other words, adding items to the agenda, moving items around, reviewing bookmarks that I've added, adding in comments and all those sort of things were good.* [Parent 7; iteration 2]

Of note, there was only 1 comment across all the parent interviews relating to technical issues*:*

> *The bit that was a bit frustrating was the, where it sometimes jumped back to the beginning which I think was a Mac-ism.* [Parent 7; iteration 2]

The look and feel of the website were also viewed positively; the OSI name, layout, and language used contributed to this:

> *I like that, OSI. I think it's simple, it's easy to understand and easy to remember. OSI. OSI for this, OSI for that, yeah.* [Parent 2; iteration 1]

> *It's pretty easy to use, it's well laid out so you know where everything is, the menu's quite easy to understand where all the things are, and so yeah. It's easy to navigate.* [Parent 2; iteration 2]
>
> *I think that the text is really good, I think that's gonna help it to be as straightforward and painless as possible.* [Parent 5; iteration 3]

Parents provided some useful feedback on the colors; in the first iteration, a parent noted that, "the blue and white is quite clinical. If I was to pick a colour I'd pick green, because it's restful" [Parent 1; iteration 1]. This feedback was used to develop the website, and at the next iteration, the same parent spoke positively about the revised colors:

> *It's definitely more pleasing to the eye now, with the colours that have been changed from the previous session that I did, the blue just didn't work for me...it just felt too medical and I think when you're in that whole, dealing with the whole anxiety thing it just dominates your whole world, so to be on it when that child is in bed or at school or whatever, to then still be very medical...the green is a lot more relaxing and kind of gently supportive really I suppose.* [Parent 1; iteration 2]

Other useful feedback at iteration 2 were related to the animation and videos:

> *I didn't like the animation. It was too long. And I didn't like the music. With it. Erm, I would have preferred the real people in that bit.* [Parent 4; iteration 2]
>
> *Well apart from the video, I couldn't understand the person talking, and I think subtitles or the optional subtitles might be useful.* [Parent 2; iteration 2]

Changes made at iteration 3 were noticed and elicited positive feedback:

> *I did really dislike the talking heads the last time, I much preferred the true person talking...I much preferred the video, the talking. The real person talking.* [Parent 4; iteration 3]

Parents talked about a key element of the treatment—the step plan, which they were keen to optimize, and they recognized it as something they would want to revisit:

> *I think I had a bit of a challenge with the step plan bit, I think that needs to be a bit finetuned and changing the names of it, and going to steps, but otherwise it's pretty straightforward.* [Parent 2; iteration 1]
>
> *I think if you were going back and you wanted to listen to it again just to pick out the main points, you'd be thinking ugh it's a bit...I think the look was fine, I just, if it was more concise.* [Parent 3; iteration 2]

This feedback was responded to, and at iteration 3, parents reported more favorably about the step plan video:

> *I much prefer the new step plan [video].* [Parent 3; iteration 3]

Children

Overall, children were positive about the game app and found it easy to use. For the monster flip minigame, all of them found the game accessible (eg, "it was easy to use. I like how it explained what to do before, so you knew what to do" [Child 3; iteration 2]), but provided enough challenge to be interesting (eg, "think the hardest part of the game is judging where he's gonna bounce" [Child 4; iteration 2]). As expected, some children found it harder than others to play; a child suggested that "there could be higher levels" [Child 1; iteration 3], whereas another child said that "the extreme one was too hard" [Child 3; iteration 3]; however, they still liked the game overall (eg, "it was a good background. I like how it like, showed where you were at the top" [Child 3; iteration 2]).

Regarding the dress-up game, all the children liked it, and all of them said that there was nothing they disliked about it:

> *I found the buying was easy to use...I like the clothes shop, because it was super easy.* [Child 4; iteration 2]

A child talked about the functionality of the dress-up game in terms of not knowing how to control the activity:

> *There was one thing, when I bought some of the clothes, I didn't realise I had to drag it on, I just tapped it and I thought it would just go on.* [Child 2; iteration 2]

However, the other children found it easy to use. Although this was not a universal problem, the game instructions were refined to address this issue.

Children liked the home screen and commented on particular details:

> *I like the view out the window.* [Child 3; iteration 2]
>
> *I like the ability that you could drag the log to the fire and that you could get a newspaper which would entertain him, and I liked the design of the house, and the buttons are easy to use.* [Child 2; iteration 3]

They asked for more colors to be used, but only in response to a specific question about whether they disliked anything about the home screen:

> *Maybe like, change the colour scheme a bit because it was pretty much all blue, maybe you could paint the house? Or like I said maybe get a new house.* [Child 2; iteration 3]

Others commented positively on the colors:

> *I liked how you could like, go to whichever place you wanted to, and I like the colour of it.* [Child 3; iteration 2]

Feedback on the initial iteration included requests for more options for customizing the character:

> *I don't like the fact that you can't change him, you can't choose his name, you can't choose his colour, you can't choose what he looks like.* [Child 4; iteration 1]

This was addressed in later iterations to the game with the addition of the dress-up game and the random name generator.

Clinicians

Overall, clinicians responded positively to the OSI case management system and acknowledged that any issues they had while using OSI may be because they were a novice user:

> *It was good, I liked it. It's quite easy to kind of navigate, it's quite obvious where to go for things, and when you're actioning something it's quite obvious what you need to do next. Like that it's not too cluttered, it's got kind of just what you need on there.* [Clinician 8; iteration 1]

> *The only thing I'm unsure of is the progress, the notes bit where you take like progress notes, but that's just because I haven't used the system much, after like one week I'd be, I'd know exactly where to go.* [Clinician 7; iteration 3]

Clinicians talked about specific key features of the website, including the calendar feature, the routine outcome measures (ROMs), and the notes function and how risk is managed within OSI (eg, "the week view would be useful. I think it would be helpful to have a month view as well" [Clinician 7; iteration 1]), and later noticed changes to these features without prompting (eg, "I like the calendar view, cos I think that's changed from before" [Clinician 8; iteration 2]).

Clinicians were particularly positive about the ROMs:

> *ROMs bit was the easiest bit, and thinking about new clinicians coming in and being able to see the ROMs all on screen, presented in that way, showing the clinically significant change, whether the scores are above or below the cutoff line, the subscales mapped out with the dates, like I'm struggling to think of how you could display that in an easier way...so that was a nice bit I think. I think for new practitioners, will demystify the process of ROMs.* [Clinician 4; iteration 2]

Some clinicians had suggestions for improvements, but the suggested changes were not necessarily echoed by other clinicians. For example, a clinician found all elements acceptable:

> *...everything was labelled quite clearly, particularly bits in the client information are quite good, so the risks, adding notes and ROMs. I thought all of that information was really clear and easy to access.* [Clinician 8; iteration 2]

By the third iteration, clinicians struggled to identify any further changes they would like to suggest:

> *I don't think there was anything I disliked. Nope. No nothing comes to mind I disliked...Well done. Am I allowed to say well done? Because having used so many unfriendly systems this is like a dream.* [Clinician 6; iteration 3]

> *Really good, really well structured and clean, and yeah it's got the right information.* [Clinician 4; iteration 3]

Final Iteration of OSI

Multimedia Appendices 6-8 show screenshots of the final iteration of the OSI parent website, clinician case management system, and child game app, respectively [44]. Both the parent and clinician OSI websites can be accessed via internet browsers on a computer (desktop or laptop), smartphone, or tablet device.

The parent works through 7 modules (Multimedia Appendix 9) that are released weekly and take approximately 30 minutes to complete. Each module follows the same format with compulsory ROMs, module content, summary of module, homework for the week, module quiz (optional), and module feedback (optional). The ROMs include parent-report versions of the Revised Children's Anxiety and Depression Scale (RCADS) [45], Child Anxiety Impact Scale (CAIS) [46], Child Outcome Rating Scale [47], Goal Based Outcomes [48], brief Spence Child Anxiety Scale [49], and the Session Rating Scale [47]. These ROMs are compatible with the Child and Young People Increasing Access to Psychological Therapies initiative in the United Kingdom [50]. In addition, the CAIS can detect meaningful clinical change in anxiety symptoms and interference [51], and the brief Spence Child Anxiety Scale works well as a brief measure of anxiety symptoms [49]. In line with Child and Young People Increasing Access to Psychological Therapies, all measures are collected weekly, except the CAIS and RCADS, the full versions of which are administered at the start and end of treatment, and a subscale is tracked weekly. Parents can immediately view the scores of the ROMs and information about how to interpret scores via the *your child's progress* tab. Modules are interactive, with questions to answer and worksheets to complete. The treatment material is presented as easy-to-read text, with videos and animations to demonstrate the strategies and provide parent testimonials. Parents can bookmark module pages for quick reference and add notes throughout about their own reflections or experiences. Resources from within and outside OSI are found in a *resources* tab. After completing each module, the parent has a 20-minute telephone review session with their therapist. The telephone session aims to review how the parent applied the strategies with their child and problem solve any difficulties. Details on the therapy session appointment times are found in the *therapy sessions* tab, along with a written summary from the therapist for previous therapy sessions. Parents can add to the upcoming therapist session agenda throughout the relevant module and via the *therapy sessions* tab. They can also reorder items on the agenda to prioritize items that are important to them to discuss.

The OSI case management system allows the clinician to view the service users they are supporting on OSI via the *client list* tab. On clicking a child's name, a detailed view of the child's OSI case file is presented. This includes their personal details and all interactive elements of the parent site. Parent's answers to questions and worksheets are shown under the *homework* tab for clinicians to review before the telephone review session. ROMs are scored and immediately available for review and download via the *ROMs* tab. Appointments for the telephone review session can be booked via the *appointments* tab, which also gives details of past and upcoming therapist sessions. Upcoming appointments can also be viewed via the *calendar* tab. Notes from the therapist sessions are found under *notes*,

and therapists can also add additional progress notes here. Clinicians can view the OSI treatment material presented in a PDF format via the *view treatment* tab. Details on how to contact technical support and frequently asked questions on using OSI are provided for both parents and clinicians via the *help guides* tab. Clinicians are provided with a training video and clinician manual for the OSI case management system.

The child game app is called *Monster's Journey: Facing Fears* and is available to download on smartphones or tablets via the Apple Store and Google Play Store. A registered parent OSI account is needed to access the game (for free). The game aims to help motivate the child to engage in the treatment strategies, and it is an optional part of the OSI treatment program. The game is introduced to families in module 3–*facing fears* and can be used as a reward option when the child faces their fear. Parents can reward their child with virtual coins via a parent portal in the game, which the child can use to unlock various features, such as different minigames, extra levels and modes of the games, and customization options. The game consists of a monster character who the child can name and personalize with different outfits. There are 3 minigames, which the child can choose to play. Each minigame has a range of modes and difficulty levels that can be unlocked using the virtual coins. Children can also earn a nominal number of virtual coins via *challenges* within the games. The home screen acts as a base for the monster and is where the child receives notifications of the reward of virtual coins and other gifts received during gameplay. The game is intended to be motivational and is not intended to be therapeutic in its own right. However, introductions to the minigame includes storylines about helping the monster to face its fears, and there are messages of encouragement to continue playing when the child is struggling with the gameplay and of positive reinforcement when they succeed. Parents are provided with guidance on how to introduce the game and manage screen time.

Discussion

Principal Findings

OSI was developed through a process of user-centered design and usability testing. The results presented here show that by adopting this approach, OSI meets the expectations and needs of the intended users (parents, children, and clinicians). The initial vision for OSI was confirmed and refined during the design workshops in phase 1 of development. This enabled participants to highlight what functions of OSI were important to them and how they would like these to look and work on the website and game. The initial positive ratings of the working prototypes of OSI presented during usability testing (phase 2) suggests that the active collaboration with users at the design stage was a successful and important part of the development process. The 3 cycles of usability testing allowed for further improvement of OSI and by the third iteration, participants reported high levels of satisfaction with how OSI looked, its ease of use, and the functions available.

It is noteworthy that clinicians reported that the OSI case management system was easy to use without any training. This suggests that OSI is intuitive to use; however, most of the clinicians participated in both phase 1 and phase 2 of the development process, and thus, had some degree of familiarity with OSI. Clinician ratings for "it is always clear what to do next" did not show the same degree of improvement across the iterations in phase 2 as the other items on the PCUQ. There was also a slight increase in the number of moderate issues (such as inability to successfully navigate through the site) at iteration 3. This could be owing to the introduction of additional features in the third iteration of the OSI case management system. Feedback gathered in the semistructured interviews highlighted that the clinicians felt that any difficulty in using potentially confusing elements of OSI (eg, the calendar) would resolve with regular use; however, changes were also made to address issues raised, and a clinician training package and clinician manual were subsequently developed to help clinicians to quickly adopt OSI as part of their routine clinical practice.

Parents consistently rated OSI as acceptable and easy to use throughout the design and usability process. This suggests that the initial workshop where parents decided on what features they wanted OSI to have and how they might look was crucial and successfully translated into acceptable and usable initial (phase 1) and working (phase 2) prototypes. Parents were overwhelmingly positive about OSI by the final iteration. It is encouraging that they reported it was simpler to use than they expected, the treatment material was appropriate in tone and presentation, and the time needed to work through modules was acceptable. This feedback is important given that engagement in and adherence to internet-based treatments is associated with treatment outcomes [52-54] but has been low in some previous studies [55-57]. Nevertheless, it will be important to continue to monitor and assess the acceptability of time needed to complete the modules and weekly questionnaires in future research.

Overall, the game app was positively endorsed by children. Some items to assess content and usability did not show a linear improvement across the iterations, and this is likely to be related to the addition of many new features across the usability testing period. Despite this, by iteration 3, children rated the game app as looking good and easy to use and understand, and they reported that they would use the game again. This is encouraging because the aim of the game is to help motivate the child to engage in the treatment strategies by acting as a reward mechanism; thus, a desire to play the game is essential. However, it is worth noting that the game is an optional part of treatment, and future research is needed to determine the extent of its use and whether it successfully motivates children to engage in the treatment strategies and ultimately enhances treatment outcomes. For example, future research could compare outcomes for children who use and do not use the game during treatment.

User-centered design and usability testing are considered as best practice for digital mental health innovation [10,18,19], and developers are encouraged to share their development process to help further understanding of how best to design digital mental health interventions [10]. We hope that the methods we used to develop OSI will provide a model that others can adapt for interventions for other target disorders or age groups. Although our study clearly illustrates the benefits

of user-centered design and usability testing, it is worth acknowledging some of the key challenges associated with the process that will be relevant for others who are developing digital mental health interventions. The process was lengthy, spanning 10 months. It also required careful planning with the technology company that developed OSI to ensure that the timings of the research protocol were achievable and in line with the time taken to develop each iteration of OSI. Time pressures sometimes meant that some features were not available for testing until later stages in the usability testing process. Nonetheless, usability ratings improved over time, suggesting that the collaborative design of these features helped to ensure they were easy and enjoyable to use. It should also be acknowledged that time and budget constraints meant that not all suggestions for improvements could be implemented. Our approach was to respond to anything that caused significant usability issues for most participants or was critical for successful delivery of the treatment. The high acceptability and usability scores indicate that this did not adversely affect ease or enjoyment of use.

Strengths and Limitations

This study has several strengths. Of primary importance, we adopted a bottom-up approach to the development. This allowed the participants to tell us what features they wanted and how they wanted them to look and work, which is the essence of participatory research [58]. By actively involving users at both the design stage *and* usability testing as part of the development process, we were able to not only understand the needs and wants for the website and game but also ensure that it met those expectations and was easy and enjoyable to use. Another strength is that we recruited participants who were familiar with receiving (parents and children) or delivering (clinicians) the treatment that OSI is based on. This enabled a rich discussion of the features that might be helpful in the internet-based translation of the treatment material and management of families receiving this treatment.

Despite the strengths, there are some limitations that should be acknowledged. Participants were predominantly from White British ethnic backgrounds, and parents were well educated and largely employed. The lack of diversity in sociodemographic characteristics means that we cannot be sure that OSI will be satisfactory and easy to use across other sociodemographic groups. Furthermore, the sample did not include those who were not regular internet users, and although 96% of UK adults (aged 16-54 years) report daily or almost daily use of the internet [59], there is marked variation in reasons for internet use and digital skills among the UK population [60]. However, efforts were made to mitigate these issues; for example, the text of the treatment material was considered *easy to read* in readability tests and a range of ethnic backgrounds was represented in the creation of the video and animations. Furthermore, each module has a feedback questionnaire, and thus, OSI can be further iterated based on user feedback from wider research and routine use. The minimum number of participants required for usability testing is often cited as 5 [61]; however, using larger sample sizes and ensuring that participants are representative of the target user group will increase the likelihood of detecting all usability issues [62]. We included >5 clinicians and parents who had experience of receiving and delivering child anxiety treatment, but only 4 children participated and all of them were aged between 9 and 12 years; thus, it is possible that our findings may not be applicable to younger children who might otherwise benefit from the treatment approach [30]. Although our sample size is consistent with previous usability testing of a child anxiety intervention [29], it is possible that there are usability problems that were not detected in this study. Finally, it is important to acknowledge that this study was conducted before the COVID-19 pandemic and associated physical distancing restrictions. It is possible that an increase in the use of digital tools during the pandemic may have changed user preferences and experiences of OSI, and it will be important to assess this through ongoing user feedback.

Conclusions

In conclusion, taking an iterative approach to development through user-centered design and usability testing has resulted in an internet-based treatment for child anxiety (OSI) that appears to meet the needs and expectations of parents, children, and clinicians and is easy and enjoyable to use. Now, it is important to establish the effectiveness of OSI, and further research designed to evaluate OSI in clinical and community settings is in progress. Indeed, it is intended that OSI will continue to iterate further in response to feedback in these settings to ensure that it is helpful to families struggling with child anxiety problems and to clinicians who are supporting them.

Acknowledgments

CC, CH, and TR were funded by National Institute for Health Research (NIHR) Research Professorship awarded to CC (RP_2014-04-018). NIHR had no role in the design of the study; collection, analysis, or interpretation of the data; writing the manuscript; or the decision to submit the paper for publication. CC and LT are supported by the Oxford and Thames Valley NIHR Applied Research Collaboration. The views expressed in this publication are those of the authors and not necessarily those of the National Health Service, the Department of Health, the NIHR, or the Department of Health and Social Care.

Authors' Contributions

CH conceived, designed, and conducted the study and analyzed the quantitative data; CC had overall oversight of the study design and analyses; TR contributed to the development of Online Support and Intervention for child anxiety; and LT analyzed the qualitative data. All authors contributed to the writing of the manuscript.

Conflicts of Interest

CC receives royalties for the book on which this intervention is based; however, none of the authors make any financial gain from the intervention presented in this paper.

Abstract

Background: Within the cultures and societies of the United States, topics related to death and dying continue to be taboo, and as a result, opportunities for presence and engagement during the end of life, which could lead to a *good death*, are avoided. Several efforts have been made to help people engage in advance care planning (ACP) conversations, including completing advance care directives so that they may express their goals of care if they become too sick to communicate their wishes. A major effort in the United States toward encouraging such challenging discussions is the annual celebration of the National Healthcare Decisions Day.

Objective: This study aimed to explore ACP from a sociocultural perspective by using Twitter as a communication tool.

Methods: All publicly available tweets published between August 1, 2020, and July 30, 2021 (N=9713) were collected and analyzed using the computational mixed methods Analysis of Topic Model Network approach.

Results: The results revealed that conversations driven primarily by laypersons (7107/7410, 95.91% of tweets originated from unverified accounts) surrounded the following three major themes: *importance and promotion*, *surrounding language*, and *systemic issues*.

Conclusions: On the basis of the results, we argue that there is a need for awareness of the barriers that people may face when engaging in ACP conversations, including systemic barriers, literacy levels, misinformation, policies (including Medicare reimbursements), and trust among health care professionals, in the United States. This is incredibly important for clinicians and scholars worldwide to be aware of as we strive to re-envision ACP, so that people are more comfortable engaging in ACP conversations. In terms of the content of tweets, we argue that there is a chasm between the biomedical and biopsychosocial elements of ACP, including patient narratives. If used properly, Twitter conversations and National Health Care Decision Day hashtags could be harnessed to serve as a connecting point among organizations, physicians, patients, and family members to lay the groundwork for the trajectory toward a *good death*.

KEYWORDS

advance care planning; National Healthcare Decisions Day; Twitter; good death; hashtag activism; topic modeling; social media; end of life

Introduction

Background

Death and dying are unavoidable realities for all humans but remain taboo and subsequently avoided topics within most Western societies, especially in the United States, which has been referred to as a death-defying culture [1-4]. Prince-Paul and DiFranco [3] argued that death and dying are public health issues [3]. Indeed, complications with end-of-life (EOL) processes extend across the globe as there are social, economic, political, and historic perspectives influencing communication about mortality [4,5]. The stigma surrounding death, lack of awareness, inadequate health literacy, negative public perceptions, systemic barriers, and cultural differences also influence society's reluctance to discuss issues related to potential EOL health care needs and expectations [5-14].

Since as early as the 1960s, many efforts have been made in the United States to promote engagement in advance care planning (ACP) conversations to encourage opportunities to express goals for EOL care and formally document those wishes in a written advance directive (AD) [4,12-14]. According to a (2017) consensus definition from a global panel of experts, "Advance care planning enables individuals to define goals and preferences for future medical treatment and care, to discuss these goals and preferences with family and health-care providers, and to record and review these preferences if appropriate" [13].

Part of this planning process includes the creation of an AD. According to the National Institute of Aging, ADs refer to written legal documents expressing one's values and preferences related to EOL care, which can be modified throughout one's lifetime [14]. This document is then retained and only goes into effect if a person is unable to speak for themselves. Recent efforts to promote ACP in the United States include *My Five Wishes*, *The Conversation Project*, *The Stanford Letter Project*, and *Death Cafes*. However, despite these efforts, low rates of ACP and the completion of ADs persist [15].

Presenting *opportunities* to engage in a public dialog about death and dying to normalize these difficult conversations and reduce the stigma surrounding death may improve public discourse and eventually lead to an improvement in ACP rates [3,16,17]. Specifically, recent work suggests that the presence of high engagement among health care participants throughout the EOL experience can increase the likelihood of a *good death* [17]. Although this does not mean that one's death will be completely painless or without complications, it does help ensure that the dying experience is as good as possible for all parties involved. A particular opportunity to promote engagement in planning and preparing for EOL care in the United States is National Healthcare Decisions Day (NHDD), an observance dedicated to communicating about EOL by advocating for ACP [18].

Scholars have pointed to the potential of the internet, as well as social media platforms, to facilitate discussions, information sharing, and social support around challenging health topics, such as cancer [19-21], and reduce mental health stigma [22]. In particular, Twitter has been studied as a tool for communicating about cancer [20], human papillomavirus vaccines [23], and Alzheimer disease [24]. Recent work has indicated that Twitter can be a useful tool for health care participants to communicate about ACP, suggesting that "Twitter is a new avenue for patients, clinicians, and advocates to engage with each other to better understand each other's perspectives related to ACP" [25]. Key to the diffusion of information and the creation of communities on Twitter is the use of hashtags, which could serve to unify discourse and induce a sense of support and belonging [26,27]. Coupling this with recent calls to reconsider approaches to ACP [9,28-30], we extend this work as this study situates Twitter as a social media tool and relevant NHDD hashtags as a mechanism to engage in conversations related to ACP.

Achievement of a Good Death

Although possibly appearing contradictory in nature, the concept of a *good death* carries a great deal of significance for patients, loved ones, and health care participants alike [17,31]. Although each person's perception may differ on how a good or successful death would be defined by them personally, there are commonalities with what this experience entails. Such experiences are constructed of elements related to physiological, social, existential, and spiritual components [32], which are then reflected in specific actions such as pain management, being in the presence of loved ones, and respecting the patient's values and wishes [33,34]. However, a *good death* manifests itself differently for each person, considering their history, cultural background, attitudes, health conditions, and personal views and attitudes toward death [35]. Although much work has been dedicated to establishing a more positive death experience, the ability to die well continues to be inhibited by several challenges, including poor communication, physical and systemic barriers, lack of knowledge related to the disease trajectory, and discontinuity of care [17]. A recent commission put forth a report to help refocus on and find value in death. Five principles were offered to help re-envision death and dying, including "the social determinants of death, dying, and grieving are tackled; dying is understood to be a relational and spiritual process rather than simply a physiological event; networks of care lead support for people dying, caring, and grieving; conversations and stories about everyday death, dying, and grief become common; and death is recognized as having value." [5]

In an attempt to make sense of the dying process and find value amidst death, we present the *Opportunity Model for Presence During the EOL Process* (OMP-EOLP) and argue that for a quality dying experience to take place, health care participants must be included at every step of a health care journey [17]. Opportunities for presence include integrating such conversations into the sociocultural context of individuals, which helps normalize and reduce the stigma of engaging in EOL conversations. Specifically, the biopsychosocial and spiritual elements of health care participants and their values and culture, including media exposure and language, make up the sociocultural context. As the conversation starts in a sociocultural context, it continues when either a terminal diagnosis is made or returns to a conversation regarding ACP throughout the normal aging process. Additional opportunities for presence during the EOL process include the place of care,

knowledge about family members' health status, and the moment of death. With high engagement at each step of the way and by having a *presence check*, the opportunity to die well is improved. We argue that from a public health perspective, ACP conversations using Twitter can influence engagement throughout the EOL process.

About NHDD

Occurring annually on April 16 in the United States, NHDD exists to inspire, educate, and empower the public by providing information regarding the importance of ACP [18]. First founded in 2008, the NHDD was created with the goal of providing clear, concise, and consistent information related to health care decision-making [36]. Since then, the initiative's goal has been to target the general public, health care providers, and facilities to provide free, simple, and uniform tools to guide this process [37]. Now managed by *The Conversation Project*, started by Ellen Goodman in 2010, NHDD is described as a *public engagement initiative* [18], which was started by Goodman when she and a group of colleagues started sharing personal stories related to *good* deaths or *hard deaths* they had witnessed. The NHDD serves to encourage patients to express their wishes regarding their health care. In turn, this effort also exhorts providers and facilities alike to respect such wishes, regardless of what is expressed or asked for. Although efforts related to NHDD comprise community interventions, interpersonal interactions, and in-person events, such efforts have also been conducted on the web. This includes the integration of web-based toolkits featuring ACP resources, as well as engaging viewers on social media platforms such as Twitter [25].

Hashtag Activism and NHDD's Presence on the Web

Key to the flow of information in web-based campaigns is the use of consistent and widely shared hashtags. From *#BlackLivesMatter* [26,27] to *#OccupyWallStreet* and *#MeToo* [38], hashtags have been used in recent years as an efficient way of solidifying networked activism and diffusing discourse around social issues. Beyond connecting social media users using similar linguistic symbols, hashtags are also useful for broadening discursive communities, for example, by attracting the attention of journalists and other elites [39]. Hashtags have been used to promote public health interventions, causes, and events and facilitate 2-way communication between public health officials and the public on multiple occasions, such as *#LiveFitNOLA* [40] and *#GetUsPPE* [41]. In fact, so potent is the use of hashtags for health campaigns and discussions that in the realm of vaccines, they were used both by those promoting science, such as the provaccine *#DoctorsSpeakUp* [42], and malicious actors who hoped to sow discord among Americans, such as the Russian Internet Research Agency's use of the antivaccine hashtag *#VaccinateUS* [43]. Most recently, Cutshall et al [25] focused on ACP and brain tumor stakeholders with *#BTSM* (brain tumor social media), connecting such hashtag engagement and related activism efforts and extending it to advance efforts toward EOL care, specifically ACP.

Methods

This Study

This study examines the intersection of ACP Twitter conversations surrounding hashtags related to NHDD and how communicated tweets fit into the sociocultural context as an opportunity for engaging in EOL conversations. Specifically, it looks at how EOL, ACP, and NHDD are discussed among Twitter users and what conversations might be able to tell us in terms of individuals' attitudes and potential behavioral intentions regarding ACP. In light of this, we pose the following research questions (RQs):

- RQ1: In regard to *NHDD*, what were the prominent topics of conversation in the tweets?
- RQ2: Who was leading the conversations regarding *NHDD*?

With this, we analyzed tweets published over a full year, between August 1, 2020, and July 30, 2021 (N=9713), to understand how social media had been used as a tool for promoting a day dedicated to making health care decisions, which we call discussions of ACP. For the purposes of this study, we use the term ACP to broadly encompass the whole process of engaging in conversations about EOL goals of care, regardless of whether an AD is completed.

Data Collection

As our theoretical focus is on the unification of language around hashtags, we curated a list of hashtags that were centered on NHDD by reviewing what the holiday was about and which hashtags were used. We also went to Twitter to search for related terms and then collected all tweets containing the following hashtags: *#nhdd*, *#advancecareplan*, and *#goalsofcare*. To identify discourse around the NHDD that did not use hashtags, we also collected tweets using the exact terms *national healthcare decision day*, *advance care plan*, *goals of care*, and *goals-of-care*. Using these keywords, we collected all available tweets published between August 1, 2020, and July 30, 2021 (N=9713) on Twitter using the company's academic application programming interface (7410/9713, 76.27% after removal of duplicates).

Procedure and Measures

Identifying Themes in the Corpus

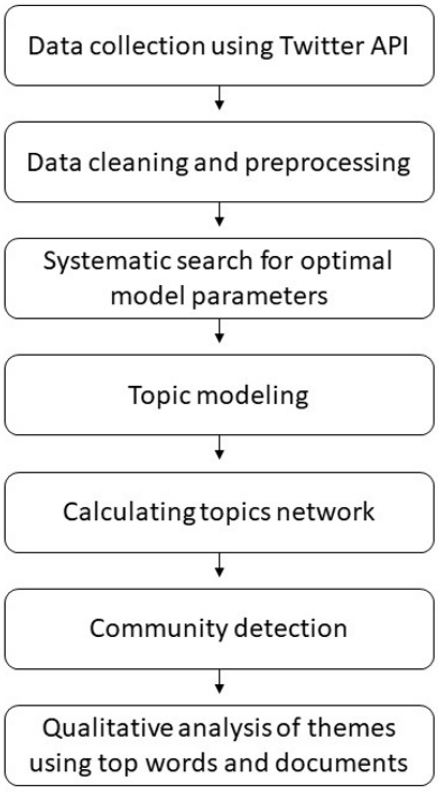
Our inductive modeling of the corpus relied on the Analysis of Topic Model Network (ANTMN) framework [44]. The ANTMN method suggests a four-step process: topic modeling, topic networking, community detection, and qualitative analysis, as shown in Figure 1. Topic modeling (in this case, using latent Dirichlet allocation) is an unsupervised machine learning method that identifies themes in large textual data [45]. The modeling's unsupervised, inductive nature makes it especially useful for work with corpora in which the set of possible topics and themes is not known a priori [46]. Topics are distribution lists of word probabilities based on their co-occurrences in the same documents (in our case, Twitter posts and tweets). Importantly, although the modeling stages were performed inductively and with no reliance on prior theory, after automated modeling, researchers interpreted the results by qualitatively studying the

most common words related to each topic and the most representative documents for each topic. Harnessing the breadth of the data, we also looked at dynamic changes in prevalence topics and themes over time.

Following the standards in communication research [46], we preprocessed the corpus by removing stop words, punctuation, numbers, and symbols and converted all text to lowercase. We refrained from stemming or lemmatization based on the recommended best practices in topic modeling [47]. For hyperparameter tuning, aimed at accounting for the short nature of the texts examined [43], we used 5-fold cross-validation iterating over a range of topic numbers (from k=5 to k=100, in *skips* of 5) and various levels of the α hyperparameter (α=.01, .05, .1, .2, and .5). We found that the model with k=30 and α=.01 offered optimal results based on perplexity scores [43]. Topics were labeled qualitatively by examining the top words, unique words, and documents representative of each topic. To avoid biases in modeling, the topic model was conducted on a sample without duplicates (7410/9713, 76.27%), and analyses of changes over time were conducted on the full sample (N=9713).

In ANTMN's second step, a network of topics was calculated based on the co-occurrence of topics in the same tweets (calculated as the cosine similarity over the document topic matrix). We used these similarities as links in the network where each topic served as a node and their co-occurrence as the link. To remove spurious links and reduce network density, we used a backbone method [48] to discard nonsignificant links. In the third step, we used a community detection algorithm based on the eigenvectors of matrices [49] to group the topics into broader themes. Finally, we qualitatively analyzed the model and its output and labeled each theme based on this close reading. Our qualitative analysis, described in the following section and in the *Results* section, is based on the automated identification of these themes.

Figure 1. Overview of the Analysis of Topic Model Network approach and methodology. API: application programming interface.



Qualitative Analysis

Following the ANTMN approach's fourth step [44], we engaged in qualitative discourse analysis [50], focusing on the language surrounding the making of health care decisions, the meaning surrounding ACP and EOL, and the context in which ACP conversations do or do not take place to understand the nuances of tweets related to NHDD in light of 3 specific theoretical and practical perspectives. The first is the NHDD mission and the ACP explaining the following:

> *National Healthcare Decisions Day [NHDD] exists to inspire, educate and empower the public and providers about the importance of advance care planning. NHDD is an initiative to encourage patients to express their wishes regarding healthcare and for providers and facilities to respect those wishes, whatever they may be [18].*

Second, we focused on Twitter discourse in the conceptual framework of the OMP-OELP [17], specifically the sociocultural context of ACP conversations. Finally, we examined Twitter as a tool that can be used for activism, particularly in advocating for engagement in ACP. A total of 4 authors, 2 of whom were experts in EOL communication and 1 a PhD-prepared registered nurse with specialty certification in palliative and hospice care, reviewed the tweets and model to become familiar with the most representative texts and words associated with each topic.

We were then able to begin to group similar ideas and content together. This process guided the labeling and definition of each topic. The final step in the qualitative analysis was reviewing the discourse for unique cases, defined as "data that demonstrate sharp contrasts with the major pattern that accounts for most of the data" [51,52], or, in this case, outstanding tweets that were relevant in the EOL process but were so exclusive that the nuance was important to take note of to see how the discourse remained thematically in the data set or stood on its own.

Results

Overview

Before analyzing the data in response to our RQs, we examined descriptive statistics indicating the most used hashtags, as well as the most liked and retweeted tweets, to better understand the discourse surrounding NHDD hashtags. Descriptive information of the gathered tweets is shown in Table 1.

Table 1. Descriptive information from the corpus.

Descriptive information	Value, n
Unique users	6974
Unique tweets	1986
Average character length	172

Top Hashtags

We identified multiple shared hashtags related to different goals or aspects involved in or affecting ACP. The first top hashtag we saw was *#NHDD* (728/9713, 7.5%), specifically linking tweets to conversations about NHDD. The second was *#COVID19* (371/9713, 3.82%); the third was *#goalsofcare* (202/9713, 2.08%); the fourth was *#PalliativeCare* (160/9713, 1.65%); and finally, the fifth was *#NationalHealthcareDecisionsDay* (141/9713, 1.45%). It is important to note that there is some overlap in the hashtags used (ie, *#NHDD* vs *#NationalHealthcareDecisionsDay*) because of differences in capitalization, spelling, or abbreviations. The top 10 hashtags used in tweets can be found in Table 2.

Table 2. Frequency of the top 10 hashtags used in tweets from the corpus (N=9713).

Hashtag	Frequency, n (%)
#NHDD	728 (7.5)
#COVID19	371 (3.8)
#goalsofcare	202 (2.08)
#PalliativeCare	160 (1.65)
#NationalHealthcareDecisionsDay	141 (1.45)
#AdvanceCarePlanning	132 (1.36)
#ICU	128 (1.32)
#advancecareplanning	108 (1.11)
#GOCCNJ	106 (1.09)
#hapc	101 (1.04)

Most Liked Tweets

We also analyzed different forms of engagement. This included tweets that received the most likes from other users across the data set. Shared here are the top 3 most liked tweets; the remaining tweets can be found in Table 3. First, the tweet with the greatest number of likes received a total of 893 likes and stated the following:

> *Maybe I'm crazy, but I think surgery interns should do a palliative medicine rotation. I learned how to have successful goals of care discussions from multi-disciplinary meetings where palliative was involved. It's an invaluable skill that most of us don't get formally taught.*

The next most liked tweet was from another individual, which received 594 likes. Here, they stated the following:

> *You need to let them talk and listen carefully. After that, you should try to phrase the goals of care with your own words. "Based on what you told me, we should probably focus on comfort and make sure he doesn't suffer any more."*

Finally, the third most liked tweet was from the same user referenced above. This message received 589 likes and stated the following:

> *One of my favorite consults is goals of care BEFORE high-risk CT [cardio thoracic] surgery. Why palliative care/GOC [goals of care] before surgery? It is because we need to have a high-quality conversation, in very challenging cases. In my opinion, there must be 2 phases of conversations.*

Table 3. Top 10 most liked tweets from the corpus.

Tweet	Likes, n
"Maybe I'm crazy, but I think surgery interns should do a palliative medicine rotation. I learned how to have successful goals of care discussions from multi-disciplinary meetings where palliative was involved. It's an invaluable skill that most of us don't get formally taught."	893
"You need to let them talk and listen carefully. After that, you should try to phrase the goals of care with your own words. 'Based on what you told me, we should probably focus on comfort and make sure he doesn't suffer any more'"	594
"One of my favorite consults is goals of care BEFORE high-risk CT surgery. Why palliative care/GOC before surgery? It is because we need to have a high-quality conversation, in very challenging cases. In my opinion, there must be 2 phases of conversations."	589
"A fun little thing I like to do as a palliative consultant is base my recommendations on the patient's goals of care."	427
"Two most common questions I ask when accepting a patient to the ICU (from any setting): (1) did you address goals of care? (2) can you please turn off the maintenance fluids?"	398
"If you're referring someone to me for a goals of care discussion I give you preemptive permission to discontinue their statin"	391
"A family meeting to determine goals of care over the PHONE (not even video) in a foreign language (with an interpreter) with an unknown number of people is a new kind of hell I hope to not revisit."	347
"#PalliativeCare friends, if you're in the hospital and doing Advanced Care Planning, ask the patient if nursing students can come and listen. In my 4 yrs of nursing school I never learned how to talk about ACP or about goals of care. It's an invaluable lesson to learn. #hapc"	344
"Working in the ICU last month taught me a lot of things. Yes, all providers need more training in end of life discussions. But we also need to unlearn the ableism that influences our goals of care and quality of life discussions."	342
"18. The number of families I updated today. 12. The number of days left on COVID unit 10. The number of minutes I sat down to eat. 6. The number of concurrent goals of care conversations I had in a 2hr span. 1. The one pt who told me she is ready to go. Time to rest for the day."	275

Most Retweets

Finally, another way we examined engagement was by evaluating the number of retweets in Table 2 among messages shared. Once again, we saw consistency in users, as the most retweeted tweets came from the same person with the second and third most liked tweets. As seen previously, this tweet received 127 retweets and stated the following:

> *One of my favorite consults is goals of care BEFORE high-risk CT [cardiothoracic] surgery. Why palliative care/GOC [goals-of-care] before surgery? It is because we need to have a high-quality conversation, in very challenging cases. In my opinion, there must be 2 phases of conversations.*

The second most retweeted message received a total of 123 retweets and was from the *Journal for Geriatrics Clinical Science.* Here they shared the following:

> *Frailty is a key predictor of COVID-19 prognosis, and its assessment alongside measures of acute morbidity, rather than age alone, might help clinicians in offering realistic goals of care in hospitalized patients with #COVID19. #geriatrics.*

Finally, the third most retweeted tweet was from *Intensive Care Medicine*, an international peer-reviewed medical journal for intensive care medicine. With a total of 119 retweets, they shared the following:

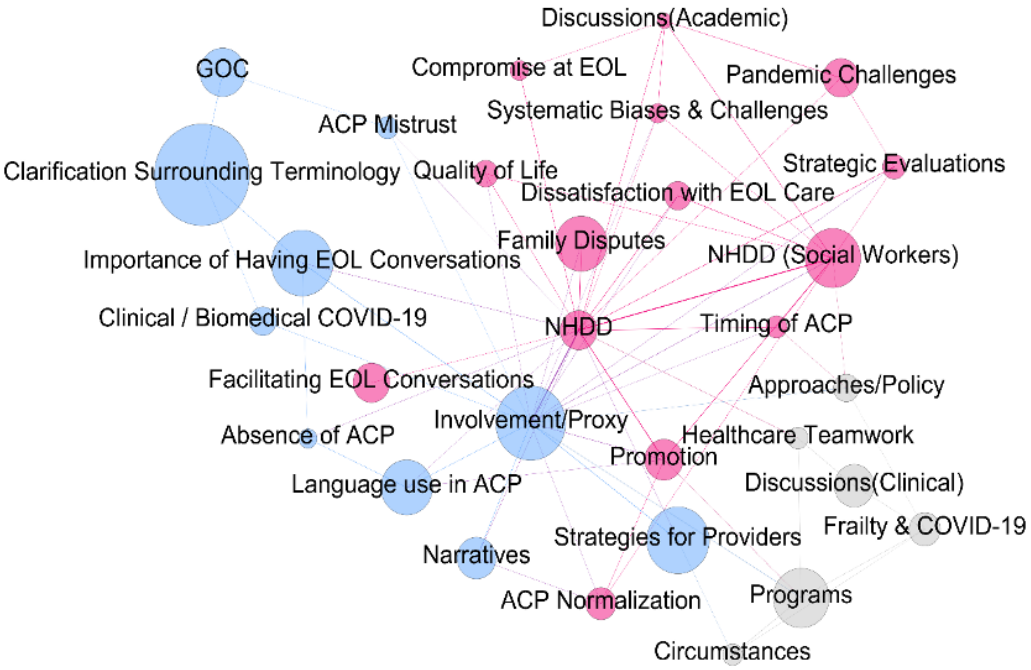
> *Long-term outcome of elderly [= 80y] #COVID19 pts admitted to #ICU: 6-month mortality...72% [likely underestimated] at upper end of recent literature on older critical pts. Data supporting more informed goals-of-care decisions for this #SARSCoV2 cohort*

Addressing the RQs

Overview

RQ1 asked what the prominent topics of conversation were in regard to NHDD during the studied year. A complete list of themes and their corresponding topics is provided in Multimedia Appendix 1. The ANTMN [44] model of 30 topics revealed 3 distinct themes. On the basis of a qualitative analysis of the most representative texts and words, we were able to label each of the 30 topics. Then, upon further qualitative analysis of the 3 themes, we were able to appropriately label and define 3 overarching main themes in the network to encompass conversations. The overarching themes (Figure 2) were *importance and promotion* (red), *the surrounding language* (blue), and *systemic issues* (gray). Each of these is described in greater detail in the following sections.

Figure 2. A topic network using the Analysis of Topic Model Network. The color of nodes indicates the community (theme) associated with each topic. Node size indicates topic prominence within the entire corpus. ACP: advance care planning; EOL: end of life; GOC: goals of care; NHDD: National Healthcare Decisions Day.



Importance and Promotion

The most prominent overarching theme within the corpus was *importance and promotion* (red). Such conversations centered on the notion of NHDD itself, promoting the day among users and highlighting various elements of the ACP process. In addition, in this theme, conversations iterated why ACP is a necessary component of health care interactions, why it should be implemented and not simply limited to the EOL process, and challenges that thwart ACP efforts and success rates.

For example, many users shared information about NHDD and its purpose, such as the following tweets:

> *Today is #NationalHealthcareDecisionsDay. This recognition is designed to educate and empower the public about the importance of ACP. For more information about National Healthcare Decision Day and how to start planning....*
>
> *Advance care planning can reduce a family's anxiety, depression, and stress". #PCC4U*
>
> *Module 4 | Activity 6: Advance care planning and goals of care....*

As shown previously, these conversations aim to increase the audience's awareness that NHDD was taking place; what it was; why it was promoting ACP; and subsequently, why ACP is such a vital component of the health care process.

Conversations using this theme also introduced the idea of creating an AD, including the timing, normalization, and facilitation of and compromises and challenges of EOL:

> *Getting advanced directives is complicated and often generates disagreements w/in family in terms of who has power of attorney. Important to have these in place including goals of care and communicate well.*

The nodes with the highest frequency included NHDD (social workers), family disputes, NHDD, promotion, and facilitating EOL conversations. On the basis of the model, we see that the relationships among NHDD, NHDD (social workers), and promotion is strong. The intersection of the timing of ACP between NHDD (social workers) and promotion illustrates that timing is an important part of the planning process.

The results of the discourse analysis revealed that the promotion efforts using NHDD hashtags reflected the mission of NHDD, which is to educate, inspire, and empower people to have ACP conversations. What we also see is the identification of problem areas or issues with ACP, which can be helpful to those initiating conversations from a clinical perspective and for awareness of the current state of ACP; that is, an agreement that having conversations is important but not that simple. Having one or more conversations about EOL wishes does not guarantee a smooth or high-quality EOL process. This is critical when applied to the OMP-EOLP, and public dialog is related to EOL taking place [3,14,16], in this case, via Twitter. The opportunity for presence is achieved through social media engagement. However, this is only 1 factor in the OMP-EOLP, and the continued high level of engagement of health care participants needs to follow the EOL trajectory. Although we cannot evaluate the success of this in this study, we argue for both academics and clinicians that an understanding of conversation at a public health level is necessary so that future efforts can be tailored more effectively to meet the needs of health care participants. A balance between promoting the positive aspects of ACP and understanding the barriers to ACP, including the ongoing pandemic, is essential.

Surrounding Language

The second theme, *surrounding language* (blue), focused on the language used for clarification and guidance within ACP

conversations. Specifically, we examined the linguistic choices and phrasing used when communicating about ACP. Within tweets using these topics, a large area of discussion described the need for clarification surrounding terminology. For example, dialog encompassed distinguishing goals of care from *code status* (physician orders for resuscitation or *do not resuscitate* [DNR]) and the continuing need to define goals of care for patients or care residents. Even among professionals, conversations noted how there were misunderstandings about what ACP entailed and how it differed from other aspects of care, particularly within the context of the patient's diagnosis, prognosis, treatment options, and care needs. For example, a user tweeted the following:

> *Palliative care in R/R [relapsed/refractory] aggressive lymphomas:*
>
> *- PC ≠ Hospice care or end-of-life care*
>
> *- PC integration is low: too late and less than in solid tumors*
>
> *- Identify triggers for goals of care discussions*
>
> *- Collaboration between specialists.*

Although most of this dialog pertained to clinical conversations (ie, strategies for providers, clinical and biomedical conversations related to ACP during COVID-19, and involvement of health care proxies), there was a small portion of dialog reflecting on patients' experiences with ACP. We found that ACP was discussed in light of personal narratives, noting their experiences and stories of how the presence or absence of ACP affected the dying experience. For example, a user tweeted the following:

> *From a darling, deteriorating, elder contemplating goals of care "Tell me, sweet nurse, shall I die slowly or quickly?" I choked back my tears and replied "How about a goal of peacefully and let time do what it will." Then we just sat in silence and held hands.*

Many narratives, such as the abovementioned one, describe sad, emotional experiences when the patient is either close to death and is forced to consider goals of care and EOL wishes or when a practitioner or loved one reflects on poor death experiences that could have been made better by successful ACP. Shared publicly, these narratives could act as a unique educational tool, harnessing storytelling to emphasize the benefits of ACP, as well as the struggles associated with completing it at later stages. Other narrative efforts included video games or apps developed to make ACP conversations easier, adapting more of an entertainment–education approach to further ACP efforts, which communicates the importance of ACP in a different language rather than in clinical conversations.

The results illustrate another way in which language clarified that the realities of ACP were through expressing mistrust in ACP processes, claiming that if they (patients) filled out ADs, it was an initiative for physicians to reduce their level and quality of care. This is an alarming misperception that emerged from the data. Furthermore, this mistrust appeared to be fueled by the misbelief that engaging in ACP would expedite the dying process for the patient. Such tweets featured charged and accusatory language, which points to misinformation surrounding ACP and EOL processes and provides insights into the potential reception of such information. An example included a health care professional tweeting the following:

> *Sometimes people mistakenly think DNR means "don't do anything." Remember, DNR only goes into effect when a patient codes [cardiac arrest]. A DNR order is not a substitute for a goals of care discussion. They are not the same thing. #MedTwitter #CriticalCare #GoalsOfCare*

This tweet was part of a larger conversation, discussing the misunderstandings of concepts such as a DNR order and how having a DNR order does not mean that physicians will not work as hard to care for them if completed. Identifying such misunderstandings in ACP demonstrates how Twitter can be used as a tool for activism to clarify the purpose, definitions, and information for those in the community.

Our results indicate that the language surrounding ACP tended to portray it as important but not without challenges, as evidenced by the fact that NHDD is a term that is euphemistic in its own right. By avoiding the use of clear terms surrounding death and dying, although well-intentioned, the lack of clarity can perpetuate confusion among health care providers and the public alike. On the basis of qualitative analysis, goals of care were intertwined with ACP, and a point of discussion and disagreement is whether goals of care equate to ACP. Other similar tweets shed light on how various social issues, such as racism and prior negative health care experiences, also fuel this mistrust, which leads to greater barriers that get in the way of the ACP process. The connection with the OMP-EOLP is that the sociocultural factors of health care participants are at play in ACP conversations on Twitter. It is critical for health care providers to be aware of this mistrust in underrepresented communities. For example, the well-documented mistrust of the health care system in the African-American community stems from unethical research practices such as the Tuskegee Syphilis study [53]. Support for this connection is illustrated in the Social Determinants of Health framework, wherein there are factors at play that are not biomedical but instead, a result of where we live, work, and age that influences our health [5,54-56].

Systemic Issues

The third overarching theme closely aligned with language use was *systemic issues* (gray). In examining these conversations, such issues or barriers related to ACP were discussed within clinical settings. The conversations documented issues related to the settings in which care was taking place, disparities in care with regard to socioeconomic groups, and subsequent costs related to care. For example, a tweet explained how "many barriers exist [in ACP] due to implicit bias. Lack of appropriate testing, follow-up, and assumptions about goals-of-care – all leading to poor outcomes...." In other words, owing to perhaps prior negative health care experiences or negative attitudes toward EOL discussions and planning, patients can subsequently experience poor outcomes at the EOL. Issues related to COVID-19 and frailty were also common, which elaborated on care options and decisions related to patients diagnosed with COVID-19. Current research related to ACP and COVID-19

indicates that the number of people filling out ACPs is on the rise; however, that does not equate to a successful EOL experience [57].

On the basis of the qualitative results, we see systemic issues uniquely related to marginalized populations, including prisons, specifically, how these populations faced greater barriers in health care settings, which were exemplified at the EOL [58,59]. Further complicating access to EOL care in prisons is COVID-19, when, for the first time, most prisoners are aged ≥55 years, which also begins to overlap with the most vulnerable population for COVID-19 [60]. For a population that includes those who are most vulnerable to COVID-19, with difficulties in practicing social distancing in addition to chronic illness and access to health care, the barriers to ACP are overwhelming.

Another unique consideration for ACP is in the context of Alzheimer disease and dementia-related care. In our data set of the 30 most representative tweets on each of the 30 topics (900/7410, 12.15%), Alzheimer disease was the only specific disease called out, aside from COVID-19, when discussing ACP. However, only a small number of tweets in our manually coded corpus mentioned this (5/7410, 0.07%). As Alzheimer is a terminal disease that attacks the brain and memory functions, we argue that the need for ACP is much stronger. Previous studies on Twitter and Alzheimer disease indicate that there is a stigma associated with the disease [61]. Topics in this theme called attention to barriers in conversations, as well as the differences in care that emerged. Future work should consider diverse and marginalized populations, their unique needs, and how intervention and communication materials may need to be targeted and/or tailored to make processes, such as ACP, more accessible and achievable. In addition, owing to negative past experiences or distrust in health care–related entities, special precautions and care may be needed to facilitate conversations.

Leading NHDD Conversations

Next, RQ2 asked who was leading these conversations regarding the NHDD. Overall, the users appeared to be mostly health care professionals and health-related organizations. However, only 4.09% (303/7410) of tweets were from verified accounts, wherein the identity was verified from Twitter as a public figure or institution, and the remaining 95.91% (7107/7410) were from unverified users; that is, users promoted NHDD on their own as an individual Twitter user, and the message did not directly come from a public figure or institution. From an activism standpoint, NHDD appears to be common among health care professionals but is not promoted specifically by verified accounts. Although this study cannot draw definitive conclusions about the individuals who were tweeting, the heavy use of medical jargon and references to personal experiences working as clinicians suggest that many users were health care professionals.

From the analysis of tweets, we observed dialog among what appeared to be clinical health care professionals, presumably physicians, discussing the medical treatment plans of patients. We also observed a back and forth in tweets wherein messages were congratulatory in nature or provided shoutouts to other professionals on academic-related achievements (ie, conference presentations and paper publication). Tweets were saturated with heavy medical jargon and abbreviations such as *CT*, which means cardiothoracic; *#pallonc*, which means palliative oncology; *#hapc*, which means hospice and palliative care; and the following example, which is full of medical jargon and is further complicated by shorthand for words and potential typographical errors:

> *Keep sats 90 or higher, dex 6mg for 10d if o2 < 92-94%, early GOC talk, chemical dvt ppx for all, remdes maybe?, if really considering abx check procal (only ~2% have bacterial CAP), keep net neg, trial proning, HFNC?> NIV, more goals of care :(*

Loosely translated, the above passage is referring to treatment for a COVID-19 patient and reads as follows:

> *It is important to keep oxygen saturation above 90%, to administer dexamethasone (which is a steroid) 6 mg for 10 days if oxygen saturation and lt (unclear, could be goal for oxygen saturation level) 92-94%, early goals of care talk, chemical deep venous thrombosis prophylaxis for all, remdesivir maybe? If really considering antibiotics check procalcitonin (only around 2% have bacterial community acquired pneumonia), keep net negative, trial proning (lying face down), high flow nasal cannula & gt (unclear, could be referring to gastrointestinal tube (gt) but it is unclear, could also be typo for gtt (drops)), non-invasive ventilation, more goals of care. :(*

The examples illustrate how such conversations among physicians, scientists, and those with occupations related to the medical field are a part of the conversation, but those without the lexicon are unable to follow and understand the conversation.

On the basis of individuals identifying themselves as social workers in their tweets or tweets from large social work organizations, another profession that appeared to be leading conversations regarding ACP and NHDD was that of social workers. Research indicates a lack of consensus among health care practitioners as to who is best suited to lead ACP conversations [62]; however, we see that social workers are currently a part of this process, which past work looking at ACP may have overlooked. Here, social workers may have a large presence in tweets as their profession generally involves them in EOL conversations and, subsequently, in ACP and the completion of AD forms. An example of the presence of social workers included a tweet from the National Association of Social Workers' Colorado chapter, which stated the following:

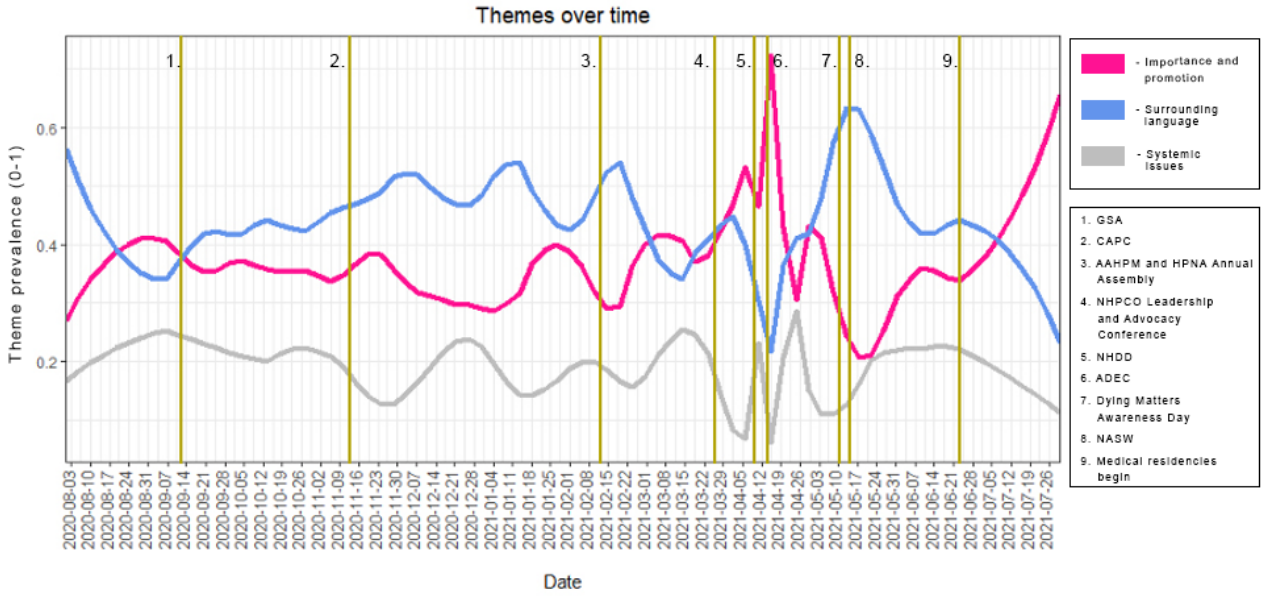
> *April 16th is National Healthcare Decisions Day, which #NASW supports. #NHDD*
>
> *inspires, educates empowers the public and providers about the importance of advance care planning. #Socialworkers have an important role in advance care planning*
>
> *#Covid19.*

By identifying who is leading conversations for NHDD, we can identify a gap in the united front of health care professionals and laypersons advocating for EOL conversations while also educating the public about EOL resources. Knowing who is involved in such conversations is important as it allows us to

better target resources for pre-existing conversations related to EOL wishes and planning. Combining efforts on the part of social workers and other medical practitioners may strengthen and increase the chances of not only AD completion but also following through on adhering to wishes that patients have put forth. We observed a lack of connection in the use of hashtags between clinical (biomedicine) and psychosocial–spiritual providers and family members, perpetuating silos separating the approach and process of ACP.

To examine changes in the composition of tweets over time in terms of thematic use, we examined the frequency and thematic content of tweets throughout the 1-year period and overlaid the major conferences related to NHDD and EOL care (Figure 3). On the basis of this, we can see the spike in tweets around NHDD itself and other conferences taking place throughout the year (indicated in yellow in Figure 3). The problem is that the movement in tweets was not consistent, and presence was more common around professional and academic events than appearing to be a normal or consistent part of the dialog between professionals and laypersons alike, further supporting the notion that ACPs are a siloed effort.

Figure 3. Frequency of themes measured over time from August 2020 to July 2021. Yellow lines indicate professional and academic events coinciding with the timeline. AAHPM: American Academy of Hospice and Palliative Medicine; ADEC: Association for Death Education and Counseling; CAPC: Center to Advance Palliative Care; GSA: Gerontological Society of America; HPNA: Hospice and Palliative Nurses Association; NASW: National Association of Social Workers; NHDD: National Healthcare Decisions Day; NHPCO: National Hospice and Palliative Care Organization.



Discussion

Comparison With Previous Work

NHDD is a niche hashtag that promotes a day in the United States dedicated to educating and empowering people to consider their options for making health care decisions in the event that they are faced with a terminal diagnosis or traumatic event that leaves them unable to speak for themselves. We argue that ACP conversations using Twitter, from a public health perspective, can influence engagement throughout the EOL process. On the basis of the results of the mixed methods study, we argue that who is sharing the information and *how* they do so are important in the engagement process.

The analysis indicated that most tweets were from health care organizations and appeared to be from medical professionals. However, we cannot definitively make assumptions about each user's profession based on the corpus. That said, based on the content in conversations and seeing as it was medically based and filled with technical jargon, we can determine involvement as some form of health care provider or practitioner. In addition, individual users sometimes referenced their own experiences on the job either in hospitals or medical settings, such as medical students or acting physicians. The involvement of such professions in these conversations would make sense, given that Twitter is a social media platform that is used for engaging in public, large-scale, health-related, and oftentimes stigmatized conversations (Tenzek et al, unpublished data, 2022) [19,61]. In practice, this can be helpful for health professionals who need to locate continuing education credits or are interested in attending workshops related to ACP. Furthermore, the social work profession had a large presence in the analysis. Scholars have argued that any health professional could initiate a conversation related to ACP, which is critical in light of COVID-19 [63]. Research suggests that any one of the team members may be the one to engage in a conversation related to ACP with patients, and recently, chaplains have been identified as key professionals in helping with ACP, moving ACP conversations upstream [3,5,57]. We argue that being aware of the opportunities for engagement at different times in the health care experience becomes important for a quality EOL, and collaboratively communicating within the team becomes even more critical to providing quality care [17].

Language, Barriers, and Activism

Next, *how* the message is communicated is also of great importance. Recent work suggests that language choice, including specific words and simplicity, is critical to how people

receive messages related to ACP [64,65]. The results of this study point to the presence of information about this incredibly difficult, complex, and stigmatized topic, which is shared in ≤280 characters. We see in the current results is that it is mostly professionals and clinical terminology about the EOL process from health care providers' perspectives, generally independent from overarching health care facilities or organizations. The professionals who had the right jargon could follow and contribute to the conversation; however, those without the medical dictionary and appropriate hashtag legend to make sense of all the information in tweets may not receive the messages or bypass them if they cannot understand. This means that individual physicians and health care workers are taking this initiative upon themselves to share with and educate others; however, this may be problematic. This study contributes to previous research that argues that engaging in public dialog about ACP must meet the public's perceptions and beliefs about ACP and not of those who already believe ACP is important and have taken action [7]. Furthermore, upon observation, the NHDD hashtag does not directly communicate to audiences that it is an effort to help people plan for death. We should question whether the language choice was intentional in an effort to help audiences be more receptive to a goal-related conversation about health care decisions in general or if the avoidance further reinforces the taboo nature wherein US culture and societies silence this difficult conversation (Tenzek et al, unpublished data, 2022). On a global scale, we see efforts in England called *Dying Matters* and *Good Grief* and *Good Death* in Scotland, where there is no question about what will be discussed. We argue that in the sociocultural context, using language as an opportunity for engagement is critical, and further studies should examine people's perceptions of willingness to talk about dying based on the hashtag being used.

Although the hashtag NHDD promotes ACP conversations, what we also see is the identification of systemic barriers, including sociocultural elements related to literacy levels, misinformation, policies (including Medicare reimbursements), and trust among health care professionals. Our analysis revealed unique ACP considerations, including patients with Alzheimer disease and prison populations, which are complex and stigmatized issues in health care. Using the Social Determinants of Health framework [5,54-56] in connection with the OMP-EOLP, we suggest a shift in ACP conversation to focus more broadly on the issues of literacy, access, and trust in health care as a resource for individuals. A recent study found that although 80% to 90% of people may be aware of ACP and believe that it is important, less than half (10%-41%) actually named a proxy or filled out a form [7]. It appears that education and awareness may not be the biggest barriers to ACP; people are aware that it exists, but there may be little action toward identifying specific wishes for care along the EOL continuum from diagnosis through death [17]. Morrison et al [30] argued that unless the health care system supports goal-centered care and provides resources to follow through with physician-patient conversations and consequential delivery of care, ACP outcomes will fall short of the intended goal; that is, providing the care at EOL that the patient wants. We see this conversation taking place on a global scale, as internationally, there are efforts to bring value back into the EOL [5].

Finally, in terms of activism and based on the argument of having to address ACP at the public health level, Grant et al [7] suggest, "public messaging that introduces these services to the public should differ from the skilled communication that clinicians perform at the bedside of patients with a serious illness" [7]. In doing so, part of the health care experience is ACP throughout a lifetime, not only at EOL, thus shifting ACP conversations upstream [3,66]. This is incredibly important for clinicians and scholars to be aware of as we strive to re-envision ACP so that people are more comfortable engaging in ACP conversations. In terms of the content of tweets, we argue that there is a chasm between the biomedical and biopsychosocial elements of ACP, including patient narratives. Aligning with Cutshall et al [25], if used properly, Twitter conversations and certain hashtags can be harnessed to serve as a connecting point among organizations, physicians, patients, and family members. It is a difficult but worthy effort to lay the groundwork for the trajectory toward a *good death*.

Limitations

Although this study served as an analysis to examine conversations surrounding NHDD, this work explored a snapshot in the time surrounding NHDD in 2021. However, NHDD has been occurring for 13 years. The analysis also captured NHDD hashtags during the ongoing global pandemic, when death was omnipresent across news platforms [5]. We were not able to compare hashtag use in a pandemic, nor were we able to definitively determine the authors of the tweets. On the basis of our findings and a recent report of the *Lancet* Commission to reimagine death, the pandemic may have further stigmatized, instilled fear, or created hesitancy toward engaging in EOL conversations [5]. Future work should explore prior conversations to reveal trends or changes in conversations over time and delve further into the implications that COVID-19 has had on how we discuss dying. Our observation is that the tension between recent efforts at reimagining and upstreaming ACP, both in the United States and on a global level, and the negative impacts of COVID-19–related deaths present new challenges in finding the value in dying.

A second limitation is that the tweets examined were only from publicly shared accounts. This means that other conversations about NHDD and ACP could exist that we could not capture. This may explain why most tweets were from professionals or organizations where the day was promoted and known within the context of EOL. The key is figuring out how to continue to promote and inform the public in the United States about NHDD and, subsequently, about ACP. As the use of social media continues to be part of our daily lives, we argue that Twitter can also be used to promote EOL processes. Third, although Twitter is becoming more popular as a way of engaging in discussions encompassing diverse perspectives without geographical boundaries, current trends in social media use indicate that other social media platforms such as Facebook and Instagram have more users. In addition, with the rise of TikTok during the COVID-19 pandemic [67], researchers should consider moving toward building a bridge that connects social media messages related to ACP across platforms and users alike. Finally, future studies may go beyond the text of tweets to

examine external links [68], visual communication [69], and communication across different social media [70].

Conclusions

Overall, this study explored Twitter conversations surrounding the NHDD and, subsequently, ACP. Twitter conversations were centered on topics related to promotion, language, and systemic issues. Tweets portrayed ACP as a crucial and necessary tool, especially within the EOL context; however, Twitter users also raised concerns and criticisms about ACP that require additional research to disentangle and create specialized campaigns to address barriers and bias in the health care system. Although several prominent conversations did occur across Twitter, the present analysis shows that there is still work to be done regarding the successful integration of ACP into common everyday practice and conversation. This study allows us to see what is present and subsequently lacking in ACP conversations. In turn, the findings can aid in structuring interventions to help better promote NHDD and help practitioners and patients alike reap the benefits of ACP. Ultimately, the findings can provide more opportunities for conversations about ACP and hopefully encourage open communication about EOL decision-making and planning as a foundation for future presence through the EOL process.

Abstract

Background: The unique features of smartphones have extended their use in different fields, especially in the health care domain. These features offer new opportunities to support patients with chronic conditions by providing them with information, education, and self-management skills. We developed a digital self-management system to support children with cancer and their caregivers in Iran (low- and middle-income country).

Objective: This study is aimed at the development and preliminary evaluation of a cancer self-management system (CanSelfMan) tailored to the needs of children with cancer and their parents or caregivers.

Methods: This study was conducted in collaboration with a multidisciplinary team between January and February 2020 at MAHAK's Pediatric Cancer Treatment and Research Center. We developed a self-management system in six stages: requirement analysis, conformity assessment, preparation of educational content, app prototyping, preliminary evaluation, and developing the final version.

Results: A total of 35 people (n=24, 69% parents and n=11, 31% children) volunteered to participate in the study. However, only 63% (15/24) of parents and 73% (8/11) of children were eligible to participate. By adopting a user-centered design approach, we developed a mobile app, CanSelfMan, that includes five main modules (knowledge base, self-management tips, self-assessment report, ask a question, and reminders) that provide access to reliable information about acute lymphocytic leukemia and the self-management skills required for side effect measurement and reporting. A web-based dashboard was also developed for oncologists and included a dashboard to monitor users' symptoms and answer their questions.

Conclusions: The CanSelfMan app can support these groups by providing access to reliable information about cancer, facilitating communication between children or parents and health care providers, and helping promote medication adherence through a reminder function. The active participation of the target group can help identify their needs. Therefore, through the involvement of stakeholders such as patients, caregivers, and oncologists in the design process, we improved usability and ensured that the final product was useful. This app is now ready to proceed with feasibility studies.

Introduction

Background

More than 90% of children worldwide live in low- and middle-income countries (LMICs) where accessing high-quality health care is difficult or expensive [1]. On the basis of the Global Cancer Inventory reports, by 2025, the number of new cancer cases will be higher in LMICs than in other regions [2]. Although the incidence of cancer is very low in children compared with adults, it is still the second leading cause of mortality among children, even in high-income countries [3]. It is predicted that, by 2030, approximately 60 million children will die worldwide because of cancer before the age of 5 years [4]. Iran is a developing country with a population of approximately 84 million. Similar to most LMICs, there are no precise statistics on childhood cancer in Iran [1]. The results of a systematic review showed that the incidence rate of pediatric cancer in Iran is 16.5 per 100,000, which is slightly higher than that in other countries [5]. Moreover, reports related to provincial registries indicate that leukemia (with a prevalence of 30%) is the most prevalent type of cancer among children in Iran, similar to other countries [6-8].

Approximately 80% of all the cases of leukemia in children are of the acute lymphoblastic type [9]. The common treatment for this disease is chemotherapy, which causes severe side effects [10-12]. The intensity of the symptoms and their effects on the child are sometimes so high that without the ability to control and manage these symptoms, they may lead to hospitalization or even withdrawal from the treatment plan by the patients and their families [13,14]. Furthermore, patient management at home is highly challenging for patients, families, and caregivers [15]. These challenges include the ability to manage complex therapeutic protocols (eg, diagnosis and measures to control the symptoms), proper nutrition diets, coping with psychological side effects, and interacting with the health care system during the treatment plan [16]. These challenges are especially complicated in children and adolescents with chronic conditions, and adherence to therapeutic protocols in this group is <50% [17]. Therefore, empowering patients by providing information and self-management skills is a key factor in reducing side effects and improving their quality of life [18], especially for the parents who usually do not have sufficient knowledge of the disease, treatment, and symptom management [19].

The results of studies specifically examining the role of educational interventions among children with acute lymphocytic leukemia (ALL) and their parents indicated that information provision and increasing parents' knowledge about the disease greatly supported the family, enhanced parents' ability to take care of their children, and considerably improved the family's quality of life [20-23]. Consequently, patient education and the provision of information are major responsibilities of health care providers during the treatment period [24]. However, factors such as the multiplicity of tasks and limited time for education are the primary barriers to the full exercise of this responsibility [25,26]. As a result, they cannot spend enough time on patient education [27], and most of this instruction is provided by nurses via educational pamphlets or in-person sessions [20,28], which alone does not greatly affect health-related behaviors and outcomes [29]. For instance, approximately 40% to 80% of the information provided orally to patients is immediately forgotten, and half of the information is probably recalled incompletely or erroneously [30]. Using pamphlets does not seem to be a good method because it eliminates interactions and provides the same level of information for people with different levels of literacy and needs [31]. Therefore, there is a need for new methods to empower and enhance the knowledge of this group [32].

One such method is self-management, which is currently one of the best methods for cancer management [33]. Self-management emphasizes the role of education in preventive and therapeutic care activities [16]; highlights the role of the patient or caregiver in symptom identification, assessment, and reporting to health care providers; and helps the adoption of suitable measures for symptom prevention or control [34,35]. Usually, self-management interventions are implemented with the participation of health care specialists [16]; therefore, with the participation of clinical specialists, patients, and families, they can enhance patients' knowledge and empower them to achieve therapeutic goals in different stages of treatment [33,35]. Studies show that even short periods of self-management education provided by health care specialists have positive effects on clinical outcomes [25] and increase the patient's ability to control their chronic condition, thereby improving their quality of life [33,36]. An important feature of self-management interventions compared with conventional patient education programs is the customization feature that makes it suitable for use by every person [37].

This feature is made possible using information and communication technology tools such as smartphones [38]. The unique features of smartphones, such as accessibility, internet connectivity, and supported third-party apps, have extended their use in different fields, especially in the health care domain [39,40]. These features offer new opportunities to support patients with chronic conditions and provide them with information, education, and self-management skills. The World Health Organization introduces mobile health (mHealth) as a "domain of digital health aiming to provide or receive health-related information and services by using mobile communication and portable devices, e.g., cell phones, patient monitoring devices, personal digital assistants, and other wireless devices" [41,42]. The use of mHealth provides an opportunity for children and their families to receive information and education without visiting health care centers and specialists, control their condition through self-management, and enhance their quality of life [43,44].

Although the successful implementation of self-management programs requires the participation of all 3 groups, the results of a scoping review conducted in the requirement analysis stage revealed that numerous studies have been conducted in different countries, which developed mHealth interventions to support children with cancer and their families [45]. However, only a few studies engaged all stakeholders and developed self-management systems specifically to support children with ALL and their parents, which is the most prevalent type of pediatric cancer.

For instance, Wang et al [46] designed the Care Assistant app that provides access to clinical information and economic and social support for parents of children with ALL. In fact, the main users and audience of the app were caregivers. Heneghan et al [47] also developed a smartphone app to enhance medication adherence in adolescents with ALL. This app includes a list of relevant drugs and reminders for taking drugs.

Objectives

There is no comprehensive solution that can garner the cooperation and participation of all three groups (children, parents, and oncologists) and address their different needs. Therefore, in line with the World Health Organization's strategy in terms of performing interventions to increase the survival rate of children with cancer in LMICs by 2030 [48], we intend to develop and test a self-management system that provides information about ALL and self-management skills and facilitates interaction with oncologists for children and their parents.

Methods

Setting

This study was conducted between January and February 2020 at MAHAK's Pediatric Cancer Treatment and Research Center. MAHAK is a highly specialized pediatric cancer hospital in Iran. This center has 100 hospital beds and covers >25,000 children with cancer from all over the country (Iran) and neighborhood countries. According to the latest official reports, >6000 children with cancer receive chemotherapy at this center annually [49].

Participants and Recruiting Method

All participants were recruited from MAHAK's Pediatric Cancer Treatment and Research Center in the north of Tehran (Iran). We used a banner that provided information about the study (in the MAHAK outpatient chemotherapy clinic) to recruit interested individuals in this study. A total of 35 individuals (n=24, 69% parents and n=11, 31% children) volunteered to participate in the study. However, only 63% (15/24) of parents and 73% (8/11) of children were eligible to participate. The inclusion criteria for children were having ALL, being diagnosed, being aged at least 7 years old (able to express the disease and the associated problems), and being under treatment for more than a year. The inclusion criteria for the parents were being literate in Persian and having at least one child with a diagnosis of ALL who was receiving treatment for 1 year. These purposive samples of children with ALL and their parents allowed for the aggregation of data related to the development and primary evaluation of this study. Health care providers (oncologists) were also recruited from this center. The inclusion criterion for this group was having at least 10 years of clinical experience in the oncology department. Children were excluded if they were illiterate, were patients with end-stage cancer, experienced mental health problems, and were unable to use a smartphone. Parents were excluded if they did not have the ability to work with a smartphone, did not have reading and writing literacy, or were unwilling to provide informed consent.

Ethical Considerations

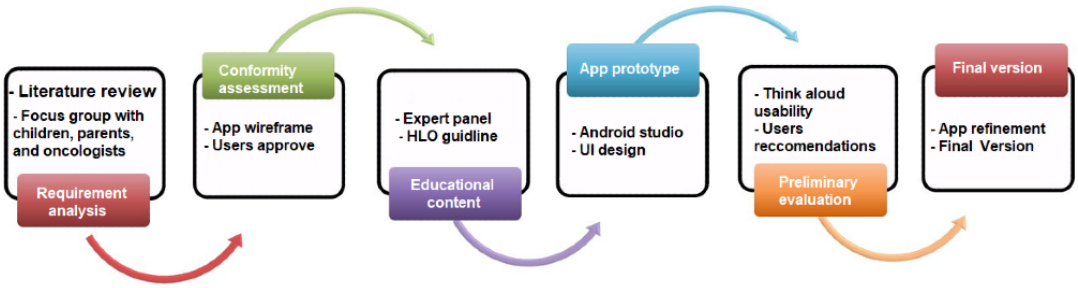
This research received ethical review approval from Shahid Beheshti University of Medical Sciences (IR.SBMU.RETECH.REC.1396.1316). All focus group (FG) meetings took place at the MAHAK hospital and were led by a team member (AM) with experience in conducting FGs. To avoid the dominance of professional feedback and blend the knowledge and expectations of other stakeholders, the identification of user needs was examined separately from 3 perspectives. For each FG, approximately 5 participants were invited. To attend the FG sessions, these children came to a meeting place with their parents. The children and their parents signed informed consent forms before each FG. For children, appropriate written and verbal information about the study and FG was provided, and informed consent was obtained from their parents to participate in the study. They also completed brief demographic questionnaires that provided information about age and sex, as well as their disease-related information.

Study Design

Overview

We adopted the user-centered design approach (Figure 1), in which all the stages of design, development, and evaluation were performed with the participation of the end users [50,51]. On the basis of this approach, the system was designed with the participation of children with ALL, their parents, and a multidisciplinary team (software engineers, medical informatics specialists, oncologists, pediatricians, and psychologists) in the following stages. Moreover, a qualitative methodology (FGs) was applied to identify the most relevant requirements from the users' perspective.

Figure 1. User-centered design process in this study [16]. HLO: Health Literacy Online; UI: user interface.



Requirement Analysis

There was no standard regarding the components and content of a self-management system for cancer; thus, we conducted a review to identify the common features and components of such apps for children and adolescents with cancer and their families. The FG method was then adopted to identify user requirements. A total of 3 separate meetings (1 session per group) were held for children with ALL, their parents, and specialists. These meetings were held in the conference hall located on the fourth floor of the MAHAK. The sessions lasted 40 minutes for children (based on the FG guidelines for children) [52,53] and 90 minutes for adults and specialists. All sessions were recorded, and qualitative data were analyzed using thematic analysis. Descriptive statistics were used to characterize the study participants.

Conformity Assessment

Conformity assessment was a team effort with the collaboration of end user representatives and design team members. On the basis of a series of high-level requirements identified in the previous step, we developed wireframe prototypes (the app's user interface [UI] version, which is not executable and made by sketcher software). Wireframes were examined by 38% (3/8) of children with ALL (aged 7-14 years) and 20% (3/15) of parents. The aim of this session was to ensure the adaptation of the initial design to the users' identified needs.

Preparing Educational Content

To prepare the educational content, we used guidelines provided by the Cancer Council [54], American Cancer Society [55], Cancer Care Ontario [56], and Children's Cancer and Leukemia Group [57], which are reputable organizations and institutions active in the pediatric cancer field. After being reviewed by 3 oncologists, a pediatrician, and a pediatric psychologist, the selected content was translated (to Persian) and organized based on the Health Literacy Online guidelines. This guideline assists in the development of educational content that is understandable by people with different health literacy levels [58,59].

App Prototyping

The prototype was developed after requirement analysis, conformity assessment, and preparation of educational content. This version almost resembled the final version, and users were able to experience the app and communicate with a UI.

Preliminary Evaluation

In the next stage, to ensure the accurate performance of the app, a preliminary evaluation was performed using think-aloud (TA) usability testing. An important advantage of using TA in the preliminary stage of design is the identification and correction of UI problems before developing the final version [60].

This evaluation was performed with 33% (5/15) of parents and 63% (5/8) of children with ALL, and 33% (5/15) of parents who were willing to participate in the study and had an Android smartphone. In this meeting, the researcher explained how the app works and is used. Each user then performed a number of predetermined tasks on the app while orally expressing their thoughts about functionality, problems, ideas, and exceptions. The researcher then recorded these ideas.

App Development

A final version was developed based on the results obtained from the preliminary evaluation. To ensure that the final version of the CanSelfMan app (a cancer self-management app) meets user expectations, an appropriate evaluation must be undertaken.

Results

Stage 1: Requirement Analysis

First, a review study was conducted as there were no guidelines or standards on the features and components of self-management apps for children with ALL. On the basis of the results, the modules of symptom evaluation, disease information, communication with specialists, and reminders had the highest frequency [45]. For requirement analysis, the results were then discussed in FG sessions with parents and children with ALL. Approximately 21% (5/24) of parents were excluded as only 2 months had passed since their child was diagnosed, 13% (3/24) as their child was in the end stages of cancer, and 4% (1/24) as they did not have a smartphone. Additionally, 27% (3/11) of children were excluded from the study as they were in the end stage of cancer. The first FG session involved volunteering parents (10/15, 67%; 6/10, 60% women). The parents' mean age was 35 (range 28-43) years, with an education level above high school diploma. The second FG session involved 63% (5/8) of children with ALL (Table 1). The third FG session was held with 6 specialists (n=3, 50% pediatric oncologists; n=1, 17% radiotherapy oncology specialist; n=1, 17% pediatrician; and n=1, 17% pediatric psychologist), and their ideas about the self-management system feature were collected.

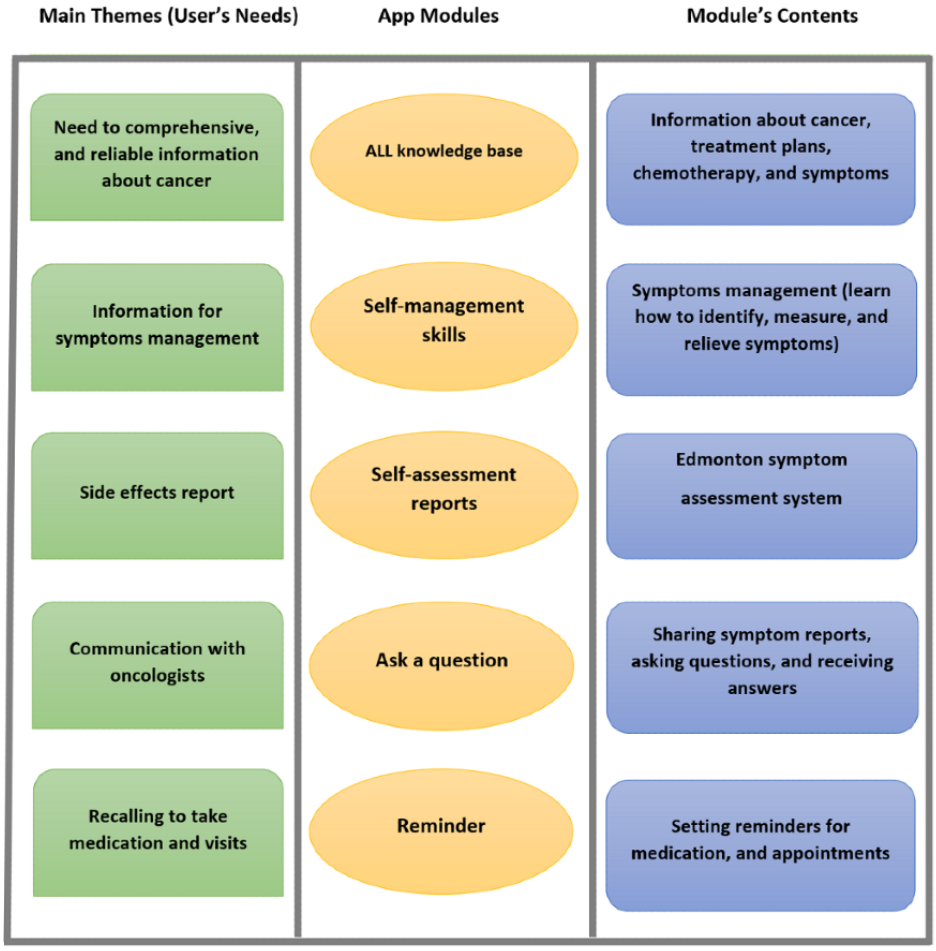
To identify the main themes, all sessions were recorded, transcribed, and thematically analyzed independently using HM and AM. Interestingly, the main themes obtained through thematic analysis were almost the same as those obtained from a review study conducted in the initial stage. Based on the themes identified from the FG sessions, the app modules were determined (Figure 2).

Table 1. Demographic characteristics for children and parents.

Study phases	Focus group sessions		Think-aloud session	
	Children (n=5)	Parents (n=10)	Children (n=5)	Parents (n=5)
Age (years), mean (SD; range)	9 (1.9; 7-14)	35 (2.9; 28-43)	11 (1.1; 7-14)	32 (2.8; 25-46)
Gender, n (%)				
Female	3 (60)	6 (60)	2 (40)	3 (60)
Male	2 (40)	4 (40)	3 (60)	2 (40)
Marital status, n (%)				
Married parent	N/A[a]	4 (80)	N/A	5 (100)
Single parent	N/A	0 (20)	N/A	0 (0)
Education level, n (%)				
Secondary school	N/A	1 (10)	N/A	1 (20)
Diploma	N/A	5 (50)	N/A	2 (40)
Bachelor's degree and above	N/A	4 (40)	N/A	2 (40)

[a]N/A: not applicable.

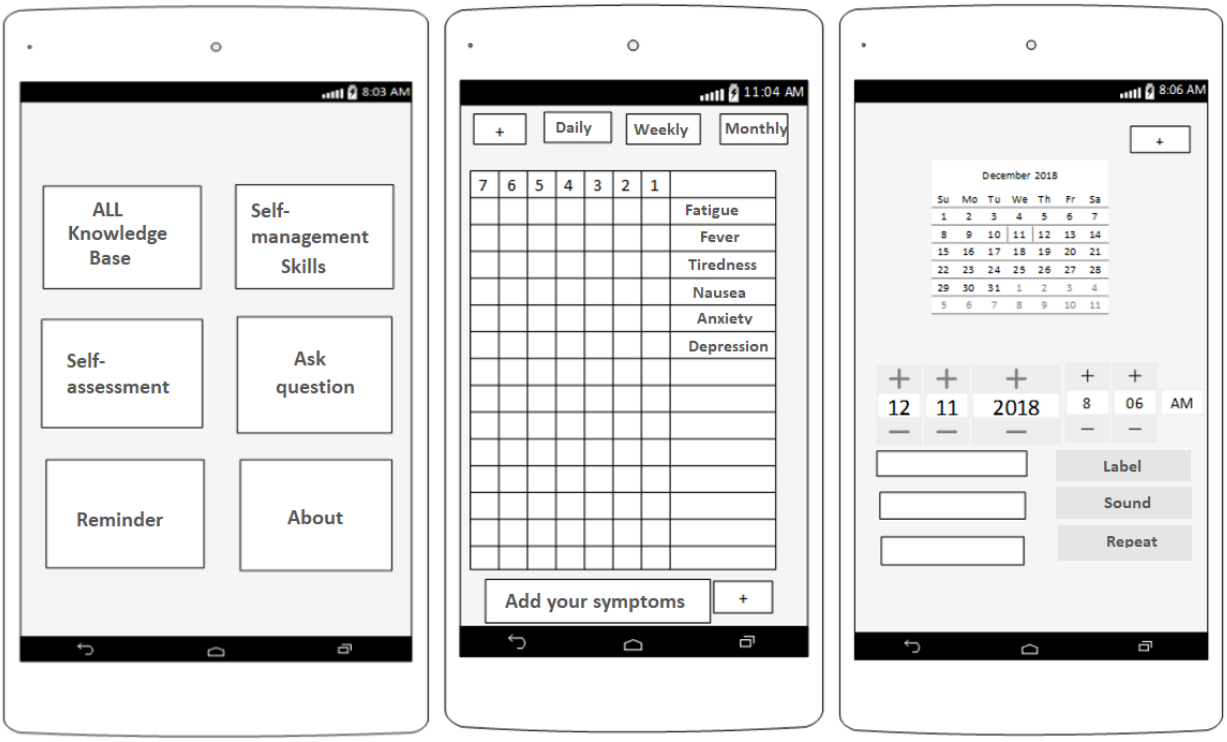
Figure 2. Focus groups extracted main themes, app module, and their content [61]. ALL: acute lymphocytic leukemia.



Stage 2: Conformity Assessment

These requirements were subsequently used to develop wireframe prototypes and technical requirements for the development phase. A total of 3 children with ALL (n=2, 67% girls; mean age 10, SD 1.4 years) and 3 parents (n=2, 67% men; mean age 39, SD 1.8 years) as representatives of the end users (selected from FG participants) were selected and took part in this session. In this session, two members of the design team (a software engineer and a medical informatics specialist) attended as well. The aim of this session was to confirm the initial design based on the users' views and modify it if necessary. In this 45-minute session, a list of the app's functionalities was first provided. Finally, for a better understanding of the user requirements, the wireframe was presented to the participants (Figure 3). At the end of the session, all the participants mentioned that the prototype was based on the requirements identified in the FG sessions.

Figure 3. Example of app wireframe for conformity assessment sessions. ALL: acute lymphocytic leukemia.



Stage 3: Preparing Educational Content

In the next step, a 90-minute expert panel was held with oncologists (4 oncologists with 15 years of experience, a radiotherapy oncology subspecialty with 14 years of experience, and a pediatric subspecialty with 11 years of experience) and a medical informatics specialist to determine the educational content. After review by this group, 4 main guidelines were selected (the Cancer Council and the American Cancer Society's guidelines for providing information and the Cancer Care Ontario and Children's Cancer and Leukemia Group guidelines for preparing self-management content). Selected content was then translated (to Persian) and organized based on the Health Literacy Online guidelines. This guideline assists in the development of educational content that is understandable by people with different health literacy levels [58,59].

Sage 4: App Prototyping

In stage 4, a prototype was implemented using the Java programming language and SQLite database in Android Studio. For the web-based version, we used the PHP programming language and MySQL database. The first prototype had five modules: information about ALL, self-management tips, self-assessment form, ask questions, and reminder function. This version was fully executable.

Stage 5: Preliminary Usability Evaluation

The first prototype was evaluated using the TA method with 10 representatives of the user groups (n=5, 50% children, with n=2, 40% girls; n=5, 50% parents, with n=3, 60% women). This method was performed individually. Before starting the test, in 5 minutes, some explanations about the app and TA evaluation were provided by HM. The app was then installed on the user's smartphone, and some predetermined tasks were performed. At the same time, the user orally provided comments on the problems, ideas, functionality, and expectations. The researcher recorded each user's comments. Some suggestions and problems expressed by children and parents at this stage are provided in Textbox 1.

Textbox 1. Think-aloud primary evaluation results.

Think-aloud comments

- "I wish we could select a profile picture."
- "I worked with a game app before; it had a cartoon character. I wish this app had a cartoon character that I could see on every page. It would look more attractive."
- "In the symptom evaluation part, score smileys can't be seen for symptoms of the last row. You have to scroll up every time to see them. I wish they were fixed so that it'd be easier to fill out the questionnaire, and you wouldn't have to scroll up."
- "In the evaluation part, it'd be more practical if you could view the results in the form of charts and send them to a specific Oncologist."
- "The font is too small and illegible in the information about the disease part; I wish we could change the font size."
- "In my favorites part you can't remove an item from the list. When I added a topic to the list, I couldn't remove it later."
- "In the reminder part, you can't choose all days of the week. You can select the minutes only in quarters. You can't exit the app."

Stage 6: Develop Final Version

Immediately after the preliminary evaluation, modifications were made, and the final version of the CanSelfMan app was developed. The app had 2 different versions for children and parents and a web-based dashboard for oncologists (Multimedia Appendixes 1 and 2). The CanSelfMan UI was specifically designed using gamification elements to provide a better user experience. On the basis of the user's suggestion, an owl character was selected as the app symbol (Figure 4). This character was selected based on the Dove, Owl, Peacock, and Eagle Psychological Test that divides people based on their characteristics into four groups: dove (symbolizing peace and kindness), peacock (extroverted and showy), owl (logical and smart), and eagle (courageous and decisive) [62]. The final version had five modules: ALL knowledge base, self-management tips, self-assessment report, ask questions, and reminders. The module provides explanations about the app and how to use it.

The ALL knowledge base provides information on the definition, etiology, diagnostic methods, medications, and common treatment protocols for ALL. The self-management module included information on identification of symptoms, evaluation, and control via pharmaceutical and nonpharmaceutical methods, physical exercise, and nutritional information. A standard Edmonton Symptom Assessment System–Revised questionnaire was used in the self-assessment report module. This questionnaire (on a 10-point scale) is commonly used in cancer care centers as a tool for the self-evaluation and reporting of symptoms by patients. After consulting with oncologists for legibility and to facilitate the completion of the form by children, a visual equivalent was used for the options for easier use and response [63,64]. In this part, the user could complete the evaluation form and view the results via graphic charts, send them to the oncologists, or present them to oncologists during in-person visits. The next module was *ask a question*, which enabled direct communication between children or parents and the oncologist (Figure 5). The users could ask their questions by completing and sending the form and choosing the oncologist's name. The important point in this module is the response time to the questions; this time was set at a maximum of 24 hours, as agreed by the oncologists. Moreover, medical recommendations based on the reported symptoms could be sent. The next module was the *reminder* module. Users could create reminders for different topics (taking medications and oncologist's appointments). The app notified the user at specified times.

The web-based version of the app provided a dashboard to view the reports and presented questions and answers to the patients and parents. This version was designed for oncologists. Its main page displayed the questions and reports received from the patients. The oncologist could select a question and answer it. In self-report management, the oncologist could view the reports sent by the users and, if necessary, make suggestions or send messages.

Discussion

Principal Findings

Most new technologies are not popular among users as they do not participate in them or consider their needs [65]. On the basis of studies, the main reason for the lack of use of mHealth apps is that they are developed without the participation of end users; therefore, in most cases, the outcomes are not compatible with user requirements and will probably not be used by them [47,66]. To resolve this problem, a user-centered design approach was adopted, which is an evidence-based approach based on the understanding of users' needs by involving their participation in all stages of the design and development process [66,67]. This method plays a key role in user interest and acceptance and increases the chances of intervention effectiveness [68]. Therefore, we used this method to develop the CanSelfMan app. All three user groups (children, parents, and oncologists) participated in the stages. Similarly, Ben-Zeev et al [69] developed a self-management system by collaborating with a multidisciplinary team of oncologists, nurses, software engineers, and end users.

In this study, we used a qualitative approach (FG) to identify system requirements and primary evaluations by collecting narrative information, including people's experiences and

feelings. This approach typically uses small sample sizes to investigate users' expectations and beliefs regarding the natural environment rather than looking for generalizable outcomes for larger samples [70]. There is no clear standard for the number of children in an FG; however, generally, between 4 and 5 participants seems enough to acquire sufficient data [53,61].

For example, to design Sisom (an app for symptom reporting by children with cancer and direct communication with health care specialists), Arvidsson et al [51] involved children aged 6 to 12 years. Similarly, to design the Care Assistant app, Wang et al [46] used FG sessions to identify parents' needs and provide access to clinical information and economic support. In the preliminary stages of designing the CanSelfMan app, to ensure that the final version meets user needs, we used wireframes before the final UI design to confirm the user requirements. Presenting a preliminary UI design provides users with an overall view of the final product, which may minimally differ from what the users had seen through the wireframe. Therefore, users' participation in confirming/providing suggestions about the preliminary design garnered their trust and reduced the risk in accepting the final product [71]. After confirming the preliminary design, a prototype was developed that contained all the specified modules and had a full UI. The TA usability test was performed at this stage. It is one of the most important evaluation methods in the preliminary stages that identifies possible defects in the UI design and program logic (product) before developing the final version [60,72].

In this study, we used the TA method to evaluate the CanSelfMan app prototype with the participation of two user groups (5 children and 5 parents). On the basis of the TA results, we developed the final version of the CanSelfMan app. Similarly, Baau and Markopoulos [73] compared the use of TA and poststudy interviews with children and found that the TA method identified more usability issues than the interviews. Owing to the labor-intensive nature of the TA approach, the sample size was typically small. However, small numbers do not indicate a small data set, and small sample sizes can still yield valid information [74]. Nielson [75] suggested that samples as large as 5 participants would provide adequate information using this method.

To develop an app for pain control and evaluation in adolescents with cancer, Jib et al [76] used this method for the preliminary evaluation of the app and collection of users' feedback. To attract users and motivate them to use the app, we used warm colors and cartoon characters. Using visual and gamification elements can lead to increased user motivation and reduce the sense of boredom, especially in children and adolescents [32]. The use of an owl cartoon character in different parts of the UI and the creation of avatars followed the same goal. In a similar study to develop an app for pain management in children and adolescents with cancer, Stinson et al [77] used graphic elements and warm colors to increase children's cooperation. This technique increased the use of the app and completion of the pain reporting forms [77].

The goal of designing this app was to support children with ALL and their parents in dealing with cancer and enable their communication with health care specialists. The end users of this app are classified into three general groups: (1) children aged >7 years who can use the app independently, (2) children aged between 5 and 7 years who cannot use the app independently and need the help of parents, and (3) parents who can use the app and its features independently or act as a proxy for using this app for their children aged <5 years. A web-based version was also developed for oncologists, which provided interactions with children and parents. This interaction included questions and answers about the disease and treatment or requests for changing the in-person appointment dates. Self-assessment, symptom reporting to the oncologist, and receiving feedback create an information flow that increases the interaction between patients or parents and oncologists [78]. This is more important when interacting with children because of the difficulty in communicating with them and their lack of verbal cooperation about the symptoms they experience [79]. Symptom reporting and evaluation are a common part of cancer self-management apps. Parents' reports are a proper source for the symptom evaluation and reporting of children aged <5 years, children with cognitive problems who have developmentally lower levels of understanding of the disease and symptoms, or children who cannot perform self-reporting because of their conditions [62]. Even when children cannot report their condition, parents' reports can offer a complementary view about the child's condition as parents have accurate knowledge about the child's health and are closely involved in the process of medical decision-making; however, their reports should not lead to the ignorance of children's views [80,81]. Therefore, based on the important role of the parents in taking care of children, and because of the limited abilities of children, especially when they are aged <8 years, any intervention whose target group is children should also involve parents in the intervention design as an inseparable part.

Strengths, Limitations, and Suggestions

In this study, we developed the CanSelfMan app in 2 different versions for children aged >7 years, and another version for their parents can be used for children aged <7 years. One of the highlights of our study was the participatory design approach to developing the app. All stages of app development and evaluation were performed with the participation of end users. This approach, owing to the focus on users and their needs, can increase user acceptance and user satisfaction with the final product. Another key strength of our study was the presence of people from different academic disciplines or professional specializations in the design team (software engineers, medical informatics specialists, oncologists, pediatricians, and psychologists). This variety of expertise and differing views benefited the study and helped us cover different aspects of the system and respond to users' needs from a broader and more diverse perspective. In addition, most of the mHealth interventions focused on children aged >8 years, and few studies targeted those aged <8 years. A reason for this might be the uncertainty about children aged ≤7 years regarding their ability to understand information about cancer and symptom assessment. However, evidence has shown that most children, aged as young as 5 years, can fill in symptom assessment questionnaires alone or with their parents' help [81].

The main limitation of this study was related to the small number of participants in the requirement analysis and evaluation phases. On the other hand, the CanSelfMan app was developed based on the requirement analysis of children with ALL and their parents in only 1 cancer treatment center. Therefore, the generalization of the study findings is limited because of the fact that the data were gathered from a single facility with a limited age group of patients. We accepted that this may have increased the risk of bias. It is likely that the participants' views in this study are not necessarily those of all children with ALL or their parents. Therefore, additional research is needed to examine more children's and parents' perspectives before wider implementation. However, as the purpose of this study was to develop a self-management system and not to investigate the effect of this app, the small number of participants in this process was not an obstacle to achieving this goal. We conducted only a primary usability evaluation; thus, future studies should include a larger sample size with a wider age range of participants and allocate more time for participants to test the UI and evaluate usability, which will be the focus of our future study. In addition, the clinical findings of this intervention have not yet been studied; thus, further clinical trials are required to demonstrate the efficacy of this product in relation to routine care.

Conclusions

The use of mHealth can facilitate access to accurate information about cancer in patients and their families. To access these services, users should only have a smartphone and little knowledge about the use of these tools. Despite these confirmed advantages, most mHealth studies have been conducted in developed and high-income countries, and the share of underdeveloped or developing countries in these studies is minimal. Meanwhile, a rise in the incidence rate of childhood cancer is predicted in future years (which will mainly occur in LMICs). Therefore, we developed a CanSelfMan system (smartphone app + web-based dashboard) to enhance self-management skills in children with ALL and their parents or caregivers. The CanSelfMan app can support these groups by providing access to reliable information and symptom management skills and facilitating communication between child/parents and oncologists. It can also be used in specialized cancer centers, especially LMICs, to increase access to these services. Future evaluation studies need to investigate the program's effectiveness and cost-effectiveness.

Abstract

Background: The prevalence of anxiety, depression, and general distress has risen in recent years. Mobile mental health programs have been found to provide support to nonclinical populations and may overcome some of the barriers associated with traditional in-person treatment; however, researchers have voiced concerns that many publicly available mobile mental health programs lack evidence-based theoretical foundations, peer-reviewed research, and sufficient engagement from the public.

Objective: This study aimed to evaluate the feasibility, acceptability, and preliminary outcomes of Noom Mood, a commercial mobile cognitive behavioral therapy– and mindfulness-based program.

Methods: In this single-arm prospective cohort study, individuals who joined Noom Mood between August and October 2021 completed surveys at baseline and 4-week follow-up. Per-protocol analyses included those who completed both surveys (n=113), and intention-to-treat analyses included all participants (N=185).

Results: A majority of the sample reported that the program is easy to use, they felt confident recommending the program to a friend, and they perceived the program to be effective at improving stress and anxiety. There were significant improvements in anxiety symptoms, perceived stress, depressive feelings, emotion regulation, and optimism in both the per-protocol and intention-to-treat analyses (all $P<.001$). Participants reported benefiting most from learning skills (eg, breathing and cognitive reframing techniques), interacting with the program features, and gaining awareness of their emotions and thought patterns. Participants also made a number of suggestions to improve product functionality and usability.

Conclusions: Results suggest that Noom Mood is feasible and acceptable to participants, with promising preliminary outcomes. Future studies should build on these results to evaluate the effects of Noom Mood using more rigorous designs.

Introduction

The World Health Organization stresses the importance of mental health, which they broadly define as a state of "well-being in which an individual realizes his or her own abilities and can cope with the normal stresses of life" [1]. Many individuals are affected by difficulties with mental health [2]; for example, anxiety disorders are highly prevalent worldwide

and are estimated to affect 18% of individuals in the United States alone [3,4]. Lifetime prevalence for depression is approximately 17% [2]. Furthermore, it is increasingly recognized that the general population can benefit from mental health support, regardless of whether clinical thresholds for mental illness are met [5,6]: as many as 57% to 84% of US adults have reported subclinical but substantial amounts of stress or worry in recent years [7,8]. Estimates suggest that anxiety, depression, and stress are associated with greater risk of mortality and hundreds of billions of dollars in economic burden per year [9,10].

Although a number of empirically supported treatments for mental health difficulties are available, myriad barriers exist that make it difficult for many people to access traditional in-person support, including cost, long waiting times to see providers, and limited provider availability, especially for individuals living in remote areas [11-15]. The COVID-19 pandemic has also increased barriers to accessing in-person support, potentially increasing willingness to seek digital support [16,17]. In addition, many individuals avoid seeking treatment due to stigma or to mistrust of the mental health system more generally [11,13].

In recent years, there has been a proliferation of interest in and development of mobile mental health programs. Use of these programs has tripled in recent years [18], and multiple reviews suggest that mobile mental health apps have the capacity to improve mental health and emotion regulation in the general population [19,20]. Mobile mental health has the potential to address many of the aforementioned barriers to treatment [21,22]; perhaps most importantly, mobile mental health allows for support or psychoeducation that is not restricted by time, location, or provider availability. In addition, digital (ie, via smartphone) delivery increases accessibility and autonomy in allowing for largely self-directed care [5,23]. Such programs facilitate self-monitoring of mood or activity, a well-known strategy to change undesired behaviors [5]. Lastly, mobile platforms allow for objective measurement of behavioral indicators, such as the number of articles read, and, therefore, allow individuals to track which strategies are most effective in helping them achieve behavioral change.

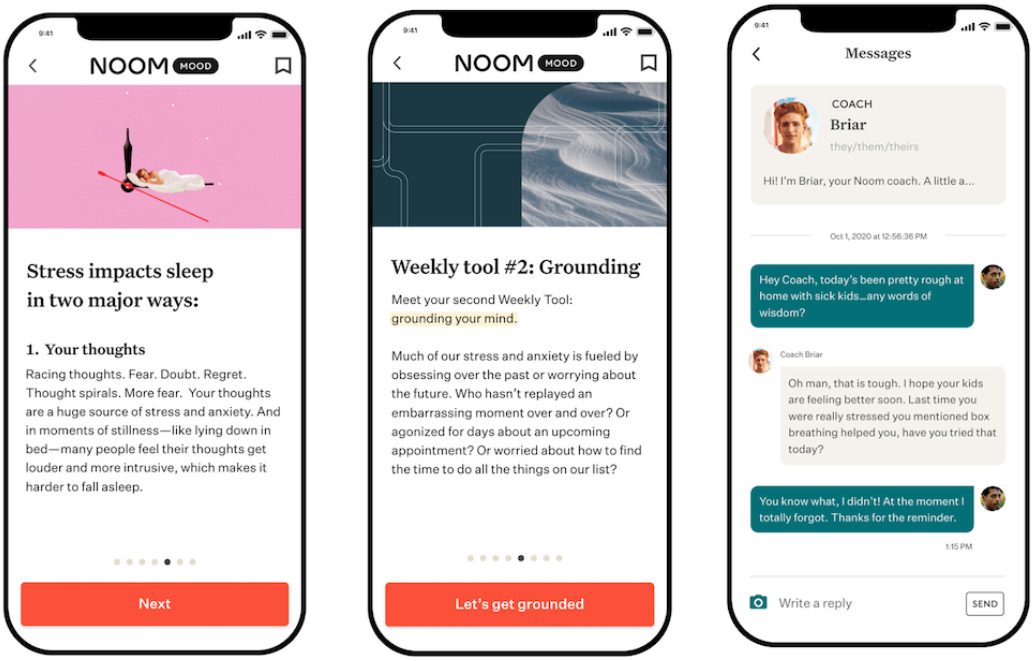
Despite this proliferation of readily accessible mobile mental health programs, researchers have raised several concerns that merit attention and that can be viewed through the lens of implementation science (see Proctor et al [24] for an in-depth discussion of implementation science variables as they apply to outcome studies). First, many mobile health (mHealth) programs available to the public are not based on evidence-based theoretical frameworks [25]. Moreover, users are self-selected, meaning that the problems they are experiencing may or may not map onto the content including the mobile app (ie, problems with appropriateness) [25]. Second, whether evidence based or not, many programs are used briefly and then discarded (ie, problems with adoption) or do not reach a broad enough segment of the population to be useful (ie, problems with penetration) [18,26]. Research has found that thousands of programs have been released on app stores that retain a very limited number of active users over time; for example, studies have shown that 97% of users do not use these mental health apps at day 15 [26,27]. This represents an obvious challenge for mental health programs, as intervention engagement has been associated with better outcomes in a multitude of studies [28-30]. Lastly, few of these mobile mental health programs include a research component to evaluate feasibility, acceptability, or outcomes of any sort; of programs based on theoretical frameworks, only approximately 6.2% have associated peer-reviewed research [25,31,32].

As such, this study was designed to address these gaps in the literature by examining the feasibility, acceptability, and preliminary outcomes of Noom Mood, a widely available commercial mHealth program that incorporates evidence-based recommendations for mobile mental health programs [5]. In particular, this study aims to contribute to the substantial gap in the evidence base, identified by implementation science researchers and review papers on mobile mental health, in data from commercial programs [25,31,33,34]. Another contribution of this study stems from Noom Mood's inclusion of personal coaching for guidance and implementation of cognitive behavioral therapy (CBT) techniques, but not clinical therapy. Few studies have examined widely available mental health programs guided by personal coaching; many existing studies examine mental health programs that are entirely self-guided (ie, without individualized coaching support), are designed to provide clinical therapy or serve as an adjunct to therapy, or provide personalized coaching in other contexts (eg, employer-provided coaching or for specific conditions) [35-38].

Noom Mood is a structured, skills-based approach to stress and anxiety management. Noom Mood uses strategies from empirically supported treatments that have been shown to improve mental health outcomes, such as anxiety, depression, and stress (eg, CBT, dialectical behavior therapy [DBT], acceptance and commitment therapy [ACT], and mindfulness-based stress reduction [MBSR]) [39-43]. Importantly, preliminary evidence has shown that CBT and MBSR can be deployed on a mobile platform and that these programs are associated with improvements in mental well-being in nonclinical and clinical populations [23,44]; however, as described previously, more empirical evaluation is needed of evidence-based, commercial programs. Program components include the following: (1) a daily curriculum consisting of psychoeducational articles for users to read, (2) individualized coaching offered through in-app messaging, (3) weekly skills-based activities, and (4) a mood-logging feature. All four components are expected to improve mental well-being (eg, reduce perceived anxiety and depressive symptoms and perceived stress). The curriculum, activities, and coaching were derived from evidence-based frameworks (ie, CBT, DBT, ACT, and MBSR) that have been shown to be effective in improving these outcomes, so these three components would be expected to be most directly related to outcomes. The fourth component of mood logging is based on behavior change techniques of self-monitoring, helping users to build self-awareness of their mood and associated behaviors [45]. More specifically, the daily curriculum was developed in collaboration with clinical psychologists and was designed to translate evidence-based treatments and psychoeducation into a format that is useful for individuals within a self-help framework. For example, each

day, participants are presented with a short article that explains conceptual terms and principles (eg, cognitive defusion from ACT), provides practical tips and quizzes to build knowledge, and guides users through a relevant practical activity (eg, how to practice cognitive defusion over the next week; Figure 1). Because of the utility of skills-training activities that help to apply evidence-based principles into daily life [5,46,47], Noom Mood introduces individuals to a short 10- to 15-minute practical activity based on evidence-based frameworks, such as breathing techniques and cognitive reframing at the beginning of each week. The activity is implemented for 1 week, with a practice on day 7 in which individuals reflect on the skill learned and how well it worked for them (Figure 1). Lastly, Noom Mood includes a messaging feature that allows participants to communicate directly with health coaches (Figure 1). Coaches help users to understand and engage in activities, encourage reflection and awareness of patterns, and provide validation for emotional experiences based on CBT techniques. Coaching protocols were adapted to this mental well-being context from the Noom weight management program, for which coaching has been refined and tested and shown to provide guidance on activities, emotional self-awareness, and emotional validation [48]. Noom Mood coaches are trained in CBT techniques but are not licensed clinicians, as Noom Mood does not provide clinical assessment, diagnoses, or treatment and is not a replacement for therapy. The coaching feature was included to address concerns that have been cited in previous studies of evidence-based programs [48-50]. Specifically, human contact from remote coaches within otherwise self-guided digital programs may encourage engagement and improve outcomes [48,51,52]. One randomized controlled trial (RCT) found that engagement check-ins from coaches improved engagement in a web-based depression program [53].

Figure 1. Screenshots of the Noom Mood program.



The first step in evaluating any new mHealth platform is to investigate stakeholders' views on the feasibility and acceptability of the proposed product [24,50]. Feasibility is defined as the extent to which end users feel that they could and would use the product in their lives for the purposes for which it was designed [54]. Acceptability is defined as the extent to which stakeholders find the product satisfactory with regard to its content and perceived credibility [54]. Results from feasibility and acceptability testing are then used to refine and update the platform to align with stakeholders' suggestions more closely.

The primary goal of this study was to evaluate the feasibility and acceptability of Noom Mood, as well as to gather preliminary data on whether the program might be associated with improved well-being. We hypothesized that users would find the platform to be feasible and acceptable. Furthermore, we hypothesized that participants who used the program would report some benefit in terms of improved anxiety symptoms, stress, depressive feelings, emotion regulation, and optimism by the end of the 4-week study.

Methods

A single-arm prospective cohort design was used to test feasibility and acceptability of Noom Mood, as well as initial symptom and well-being outcomes.

Ethics Approval

The study was approved by the Advarra Institutional Review Board (protocol No. 00055306).

Procedure and Participants

Participants were recruited from the pool of individuals who had voluntarily signed up for the Noom Mood program. A randomly selected subset of adults who voluntarily enrolled in the Noom Mood program between August and October 2021

were invited to participate. All participants provided informed consent prior to participation. Inclusion criteria for participants were as follows: located within the United States, English speaking, and aged 18 years or older. Participants were invited to complete the baseline questionnaire within 1 business day of signing up for the Noom Mood program. Those who completed the baseline questionnaire were invited to complete the follow-up survey 4 weeks later. Study completers were compensated with a US $20 gift card for their participation. Participants did not receive the program for free during or after the study. The entire study occurred remotely, including online administration of surveys via email.

Noom Mood Program

The Noom Mood program was deployed as described above. At the time of this study, approximately 15 psychoeducational articles were presented to participants each week. In addition to the curriculum, participants had access to mood-logging features, and they were encouraged by coaches to engage in the curriculum and to log their mood once per day.

Measures

Feasibility

Feasibility was assessed at 4-week follow-up.

System Usability Scale

The System Usability Scale (SUS) [55] is a 10-item scale assessing stakeholders' views of ease of use. Items were modified to substitute "program" for "system." Participants were asked to rate their agreement with each usability statement (eg, "I thought the program was easy to use") on a scale of 1 ("strongly disagree") to 5 ("strongly agree"). After reverse-scoring relevant items, sum scores were multiplied by 2.5 to create a final score ranging from 0 to 100. Research indicates that SUS scores above 68 are considered above average and scores below 68 are below average. Internal reliability for the SUS was excellent (α=.90).

Program Engagement Data

As in past work [56], feasibility was also evaluated via the amount of time participants spent engaging with the program. Engagement data consisted of usage and self-report data recorded by the program for 4 weeks. Self-report and usage data were collected by the mobile program and stored on a secured cloud server from Amazon Web Services [57]. Data were deidentified prior to extraction from the database. Engagement measures included the frequency with which participants completed mood logs, number of times the app was opened, number of articles read, number of messages sent to the coach, and number of activities completed. Data were also extracted to evaluate the number of days the user was active, which was defined as the number of days with at least one in-app action. In order to measure real-world engagement, participants were not given specific minimum engagement requirements to remain in the study.

Acceptability

Acceptability was assessed at 4-week follow-up.

Credibility and Expectancy Questionnaire

The Credibility and Expectancy Questionnaire (CEQ) [58] is a 6-item scale that was originally designed to assess perceptions of treatment credibility and expectancy for improvement in psychotherapy. To render the scale more appropriate for use in this study, questionnaire items were modified slightly (ie, "program" was substituted for "therapy" and "stress and anxiety" was substituted for "symptoms"). Items in the CEQ range either from 1 to 9 or from 0 to 100, depending on the item. In line with the CEQ's factor structure and following previous work [59], we computed average credibility and expectancy scores reflected by the first three and last three items of the scale, respectively. Internal reliability was excellent (credibility subscale: α=.90; expectancy subscale: α=.93).

Program Satisfaction Questionnaire

We asked the following open-ended questions: (1) What is the main benefit you received from Noom's stress and anxiety management program? (2) How can we improve Noom's stress and anxiety management program for you? (3) What was the most helpful part of the program? and (4) What was the least helpful part of the program? Because of the variety of answers possible, content analysis was used to code each response into categories and calculate the percentage of responses allocated to each category. The categories were created using latent Dirichlet allocation (LDA), a machine learning approach for automatic clustering of text data [60]. LDA is an unsupervised approach that automatically identifies latent clusters of words (ie, categories) that cluster within unclassified data. Each word cluster was assigned a label, or category name, by a master coder with experience with the program. For each question, each participant response was given a score (0 or 1) for each category since one response could apply to multiple categories. Interrater reliability between the master coder and another coder blind to the study's hypotheses and design ranged from 0.72 to 1.0 for all categories, suggesting good to excellent reliability [61].

Symptom and Well-being Outcomes

Symptom and well-being outcomes were assessed at baseline and 4-week follow-up.

7-Item Generalized Anxiety Disorder Scale

The 7-item Generalized Anxiety Disorder scale (GAD-7) [62] is a 7-item scale that assesses the extent to which individuals experience symptoms of anxiety (eg, "Feeling nervous, anxious, or on edge") on a scale of 0 ("not at all") to 3 ("nearly every day"). Internal reliability for the GAD-7 was good (α=.82 and α=.87 for baseline and follow-up, respectively).

4-Item Perceived Stress Scale

The 4-item Perceived Stress Scale (PSS-4) [63] is a 4-item scale assessing the frequency with which individuals experience various symptoms of stress (eg, "How often have you felt that you were unable to control the important things in your life?") on a scale of 0 ("never") to 4 ("very often"). Internal reliability for the PSS-4 was adequate (α=.68 and α=.69 for baseline and follow-up, respectively).

8-Item Patient Health Questionnaire Depression Scale

The 8-item Patient Health Questionnaire depression scale (PHQ-8) [64] is an 8-item scale that assesses the extent to which participants experience feelings of depression (eg, "feeling down, depressed, or hopeless" or "little interest or pleasure in doing things") on a scale of 0 ("not at all") to 3 ("nearly every day"). Internal reliability for the PHQ-8 was good (α=.84 and α=.85 for baseline and follow-up, respectively).

Difficulties in Emotion Regulation Scale–Short Form

The Difficulties in Emotion Regulation Scale–Short Form (DERS-SF) [65,66] is an 18-item scale assessing emotion dysregulation. It comprises six subscales: emotional awareness, clarity about the nature of one's emotions, acceptance of one's emotions, access to effective emotion regulation strategies, ability to engage in goal-directed activities while experiencing negative emotions, and ability to manage one's impulses during negative emotions. These subscales (α=.74-.91 and α=.76-.91) and the DERS-SF total score (α=.89 at both time points) demonstrated good internal consistency at baseline and follow-up, respectively.

Life Orientation Test–Revised

The Life Orientation Test–Revised (LOT-R) [67] is a 10-item scale that assesses trait optimism. Individuals are asked to rate their agreement with each statement (eg, "In uncertain times, I usually expect the best.") on a scale of 0 ("strongly disagree") to 4 ("strongly agree"). Internal reliability for the LOT-R was good (α=.86 and α=.85 at baseline and follow-up, respectively).

Statistical Analysis

Analyses were conducted in SPSS software (version 27; IBM Corp). For acceptability and feasibility, survey responses were descriptively analyzed with mean scores and percentages of participants that chose each response. For open-ended acceptability responses, content-analyzed categories are presented descriptively with the percentage of responses that fall into each category. Descriptive statistics were also conducted for engagement measures to evaluate feasibility. For preliminary outcomes, paired 2-tailed *t* tests were conducted to evaluate changes on all quantitative variables from baseline to week 4. Both per-protocol and intention-to-treat analyses were conducted. The per-protocol sample consisted of participants who completed both assessments (n=113) and included those who started the program but stopped using it. Intention-to-treat analyses included data from all participants who began the study (N=185); baseline scores were carried forward for participants who did not complete the week-4 assessment. Effect sizes were calculated using Cohen *d* [68].

Results

Participant Characteristics

Participants' demographic characteristics are presented in Table 1. A total of 185 unique Noom Mood users enrolled in the study and completed the baseline survey. Of these, 113 (62.1%) participants completed the follow-up survey. Participants who completed both baseline and follow-up surveys did not differ significantly from those who completed only the baseline survey in terms of any demographic variables or baseline survey values.

Table 1. Participant characteristics.

Demographics	Per-protocol sample (n=113)	Intention-to-treat sample (N=185)
Age (years), mean (SD)	36.8 (9.8)	37.3 (10.4)
Gender, n (%)		
Male	15 (13.3)	32 (17.3)
Female	94 (83.2)	141 (76.2)
Other	2 (1.8)	3 (1.6)
Prefer not to say or N/A[a]	2 (1.8)	9 (4.9)
Ethnicity, n (%)		
Hispanic	13 (11.5)	20 (10.8)
Not Hispanic	97 (85.8)	153 (82.7)
Prefer not to say or N/A	3 (2.7)	12 (6.5)
Race, n (%)		
White	99 (87.6)	153 (82.7)
Black or African American	5 (4.4)	7 (3.8)
Asian or Pacific Islander	3 (2.7)	11 (5.9)
Other	0 (0)	1 (0.5)
Prefer not to say or N/A	6 (5.3)	13 (7.0)
Employment status, n (%)		
Employed	88 (77.8)	144 (77.8)
Not employed	12 (10.6)	18 (9.7)
Retired	1 (0.9)	2 (1.1)
Disabled	5 (4.4)	6 (3.2)
Student	5 (4.4)	6 (3.2)
Prefer not to say or N/A	2 (1.8)	9 (4.9)
Education, n (%)		
High school, GED[b], or less education	7 (6.2)	10 (5.4)
Some college or associate degree	24 (21.2)	37 (20.0)
College graduate	45 (39.8)	67 (36.2)
Graduate degree	35 (31.0)	62 (33.5)
Prefer not to say or N/A	2 (1.8)	9 (4.9)

[a]N/A: not applicable.

[b]GED: General Education Development.

Feasibility

Responses to the SUS are presented in Table 2. As noted above, scores of 68 or higher on the SUS indicate above-average ratings of system usability. A majority (79/109, 72.5%) of participants had overall system usability scores of 68 or higher (mean 77.40, SD 19.45), which is considered an indication of good usability [59]. Most participants reported that the program was easy to use (85/110, 77.3%), and they thought that other people would be able to learn to use the program very quickly (93/109, 85.3%).

Program engagement data are presented in Table 3. Engagement data are presented as weekly averages (ie, the number of times the participant engaged in the behavior over the course of the study divided by the total number of weeks). Participants engaged within the app several times per week on average. Over 4 weeks, the per-protocol sample averaged 14.1 (SD 9.02) app opens, with 2 mean app opens per week. They had an average of 12.1 days with an in-app action, amounting to 1.7 active days per week. The intention-to-treat sample opened the app, on average, 13.7 (SD 8.6) times over 4 weeks, with an average of 1.96 app opens per week. They completed at least one in-app action on an average of 11.2 (SD 8.7) days, which amounted to 1.6 active days per week.

Table 2. Participants reporting good feasibility and acceptability.

Survey measure[a]	Value
System Usability Scale item, n (%)	
I would like to use this program frequently. (n=109)	62 (56.9)
I found the program unnecessarily complex.[b] (n=110)	81 (73.6)
I thought the program was easy to use. (n=110)	85 (77.3)
I would need the support of a technical person to be able to use this program.[b] (n=108)	95 (88.0)
I found the various functions in this program were well integrated. (n=109)	76 (69.7)
I thought there was too much inconsistency in the program.[b] (n=109)	87 (79.8)
I would imagine that most people would learn to use this program very quickly. (n=109)	93 (85.3)
I found the program very cumbersome to use.[b] (n=109)	77 (70.6)
I felt very confident using the program. (n=108)	78 (72.2)
I needed to learn a lot of things before I could get going with the program.[b] (n=107)	89 (83.2)
System Usability Scale score of 68 or higher (n=109), n (%)	79 (72.5)
System Usability Scale overall score, mean (SD)	77.4 (19.4)
Credibility and Expectancy Questionnaire item, n (%)	
At this point, how logical does the program seem to you? (n=110)	101 (91.8)
How successful do you think this program was in reducing stress and anxiety? (n=109)	83 (76.1)
How confident would you be in recommending this program to a friend who experiences stress and anxiety? (n=108)	87 (80.6)
By the end of the program, how much improvement in stress and anxiety do you think will occur?[c] (n=108)	63 (58.3)
At this point, how much do you really feel that the program will help to reduce stress and anxiety? (n=108)	85 (78.7)
By the end of this program, how much improvement in stress and anxiety do you feel will occur?[c] (n=107)	62 (57.9)

[a]The table includes participants who chose 4 or greater (out of 5) on the System Usability Scale or 5 or greater (out of 9) on the Credibility and Expectancy Questionnaire, except where indicated.

[b]These participants chose 2 or less (out of 5) on the System Usability Scale.

[c]These participants chose at least 50% out of 100%.

Table 3. Average total engagement over 4 weeks.

Type of engagement	Per-protocol sample (n=110)[a], mean (SD)	Intention-to-treat sample (n=181)[a], mean (SD)
App opens	14.11 (9.02)	13.72 (8.60)
Articles read	37.12 (28.87)	34.39 (27.44)
Mood logs	10.59 (9.54)	10.00 (10.79)
Days with one in-app action	12.14 (9.03)	11.24 (8.68)
Messages sent to coach	9.71 (10.33)	8.24 (9.09)
Activities[b]	1.33 (2.68)	1.30 (2.54)

[a]Sample sizes represent all participants for whom matching data from the database could be identified.

[b]Activities were calculated over 3 weeks because one offline activity was not tracked by the program.

Acceptability

Responses to the CEQ are presented in Table 2. Of note, the table displays the frequency and percentage of participants who chose at least a 5 (“somewhat”) out of 9 (“very much”) on the CEQ. The vast majority of participants (101/110, 91.8%) rated the program as at least somewhat logical (mean 7.1, SD 1.9, range 1-9). Most (83/109, 76.1%) thought the program was at least somewhat successful at reducing stress and anxiety (mean 5.6, SD 2.2, range 1-9). Many participants (87/108, 80.6%) also felt at least somewhat confident in recommending the program to a friend (mean 6.1, SD 2.3, range 1-9). Most participants (85/108, 78.7%) felt the program would help to reduce stress and anxiety at least somewhat (mean 5.7, SD 2.3), with more than half (63/108, 58.3%) expecting it to reduce their stress or

anxiety by 50% or more (mean 4.9, SD 2.5, with 0 referring to 0% and 10 referring to 100%).

Responses to the Program Satisfaction Questionnaire are presented in Table 4. Participants reported benefiting most from the skills and techniques they learned or practiced (eg, breathing techniques and thought reframing; 38/106, 35.8%). Participants also reported benefiting from the program's features or capabilities (eg, mood tracking and articles; 31/106, 29.2%) and greater awareness (eg, learning and reflection) encouraged by the program (30/106, 28.3%). Specifically, participants found the articles (18/106, 17.0%), coaching (18/106, 17.0%), and qualities of the program (eg, manageable, convenient, and "great" attitude; 16/106, 15.1%) to be the most helpful parts of Noom Mood.

For potential areas of improvement, most participants did not provide a response or indicated that they had no suggested improvements (37/106, 34.9%). The next most common response was "other" (21/106, 19.8%), or participants requested a new feature or program idea (19/106, 17.9%). "Other" responses included increasing the frequency of reminders, expanding areas of content (eg, support for procrastination), and slowing the pace of tasks. Participants also preferred a lower cost (16/106, 15.1%), with some mentioning the potential to be reimbursed, as well as a more personalized experience (9/106, 8.5%) and greater flexibility (9/106, 8.5%), such as the ability to progress while skipping articles, accessing future articles, or repeating an activity for another week.

When asked to describe the least helpful parts of Noom Mood, most participants did not provide a response (40/106, 37.7%). The next most common response was "other" (21/106, 19.8%); responses noted that the program contained too much repetition and that the pacing of the program needed improvement. Lastly, some participants (17/106, 16.0%) described coaching as the least helpful aspect of the program, noting that they would prefer to interact with a coach with specialized expertise or to receive more personalized responses.

Table 4. Response frequencies in each category for the Program Satisfaction Questionnaire.
