Abstract

Background: Mobile apps have shown considerable promise for reducing alcohol consumption among problem drinkers, but like many mobile health apps, they frequently report low utilization, which is an important limitation, as research suggests that effectiveness is related to higher utilization. Interactive chatbots have the ability to provide a conversational interface with users and may be more engaging and result in higher utilization and effectiveness, but there is limited research into this possibility.

Objective: This study aimed to develop a chatbot alcohol intervention based on an empirically supported app (Step Away) for reducing drinking and to conduct a pilot trial of the 2 interventions. Included participants met the criteria for hazardous drinking and were interested in reducing alcohol consumption. The study assessed utilization patterns and alcohol outcomes across the 2 technology conditions, and a waitlist control group.

Methods: Participants were recruited using Facebook advertisements. Those who met the criteria for hazardous consumption and expressed an interest in changing their drinking habits were randomly assigned to three conditions: the Step Away app, Step Away chatbot, and waitlist control condition. Participants were assessed on the web using the Alcohol Use Disorders Identification Test, Adapted for Use in the United States, Readiness to Change Questionnaire, Short Inventory of Problems-Revised, and Timeline Followback at baseline and at 12 weeks follow-up.

Results: A total of 150 participants who completed the baseline and follow-up assessments were included in the final analysis. ANOVA results indicated that participants in the 3 conditions changed their drinking from baseline to follow-up, with large effect sizes noted (ie, $\eta^2=0.34$ for change in drinks per day across conditions). However, the differences between groups were not significant across the alcohol outcome variables. The only significant difference between conditions was in the readiness to change variable, with the bot group showing the greatest improvement in readiness ($F_{2,147}=5.6$; $P=.004$; $\eta^2=0.07$). The results suggested that the app group used the app for a longer duration (mean 50.71, SD 49.02 days) than the bot group (mean 27.16, SD 30.54 days; $P=.02$). Use of the interventions was shown to predict reduced drinking in a multiple regression analysis ($\beta=.25$, 95% CI 0.00-0.01; $P=.04$).

Conclusions: Results indicated that all groups in this study reduced their drinking considerably from baseline to the 12-week follow-up, but no differences were found in the alcohol outcome variables between the groups, possibly because of a combination of small sample size and methodological issues. The app group reported greater use and slightly higher usability scores than the bot group, but the bot group demonstrated improved readiness to change scores over the app group. The strengths and limitations of the app and bot interventions as well as directions for future research are discussed.

Introduction

Background

Access to evidence-based treatment and support for addressing excessive alcohol use is a public health priority given that alcohol continues to be the third leading preventable cause of death in the United States, and its excessive use is responsible for >95,000 deaths each year [1,2]. A recent review of death certificates found that the annual number of deaths from alcohol-related causes doubled between 1999 and 2017 for individuals aged ≥ 16 years [3]. Although the effectiveness of behavioral interventions for alcohol addiction is well established [4,5], the National Epidemiological Survey on Alcohol and Related Conditions found that treatment utilization is very low; in 2019, among the 14.5 million people aged ≥ 12 years reporting a past year alcohol use disorder, only 7.6% received treatment for alcohol use at any location [6].

Technology-Delivered Alcohol Interventions and Health Equity

Technology-based interventions, including mobile apps, have great potential to meaningfully expand access to treatment and have been shown to be acceptable among alcohol and other substance users [7-9]. Over the past 15 years, numerous behavior-change interventions have been created to capitalize on the potential of the internet, including several alcohol interventions with demonstrated effectiveness in reducing alcohol consumption without the guidance of a counselor [10-13]. For example, the Drinker's Checkup, a web-based brief motivational intervention that provides alcohol-use assessment, individualized feedback, and an intervention to develop a plan of behavior change, reduced alcohol consumption among problem drinkers by 50%, with reductions maintained at the 12-month follow-up [14]. A meta-analysis found that effect sizes from technology-based interventions were "as effective or nearly as effective as face-to-face therapy" [15], with clinical benefits found in other reviews [16,17]. In addition to their effectiveness, technology-based interventions have great potential to reduce health disparities in hidden populations [18,19], including homeless individuals [20]. Whether technology is used to deliver direct treatment services [19], or to provide behavioral support for reducing alcohol use or preventing relapse [21], technology-based alcohol interventions overcome several personal and access-related barriers to in-person alcohol treatment, including poor or inadequate availability of services; cost and inadequate insurance; convenience in the face of childcare, work, and transportation challenges; and beliefs about help-seeking as shameful or a sign of weakness [22,23]—barriers to treatment that are particularly salient for women, minorities, and those in rural locations [23-25]. Relatedly, technology-based interventions have the potential to address concerns about privacy and stigma that may be associated with attending alcohol treatment facilities [25,26].

Mobile Devices and Contextual Relevance

One important advantage of technology-based alcohol interventions is that they can be accessed from home and the intervention is situated within daily contexts [27-29]. Much of what leads to continued alcohol use or relapse occurs in an individual's everyday environment, where, unlike a traditional treatment context, exposure to alcohol-related cues, stress, and negative affect are uncontrolled [30,31]. These contextual and situational cues may overwhelm an individual's coping resources and other skills that were discussed during treatment sessions with the hope that they would be used when facing cravings for alcohol triggered by internal and external factors encountered in daily life [31,32]. The increased use of smartphones to access the internet is especially promising, as these mobile devices provide a way to support behavior-change goals whenever and wherever needed. While digital divide issues persist with regard to high-speed internet access, it is estimated that 81% of all American adults, 79% aged 50 to 64 years and 53% aged ≥ 65 years, own smartphones [33]. These data also indicate that minority groups are at least as likely as White individuals to own a smartphone, and recent trends show a preference for smartphone use over desktop access to the internet [33], suggesting an opportunity to improve treatment access for historically underserved groups.

Similar to other internet-based interventions, smartphone-based interventions help bridge the gap between those in need of treatment and those receiving it by addressing stigma concerns associated with treatment program attendance, leveraging the desire to independently manage an alcohol problem, and eliminating the need for physical travel to a treatment facility. In addition, as smartphones are carried at almost all times by their owners, they have greater potential to provide timely interventions in the actual environment in which drinking occurs, and given that most mobile health apps are free or sell for <US \$5, they are much more affordable than traditional treatment. That being said, the growing volume of publicly available apps varies in quality and effectiveness, and even those developed using theories of behavior change and evidence-based content may lack rigorous evaluation. In a recent systematic review of health behavior change apps, including diet, physical activity, and alcohol use, many reported improvements in targeted outcomes, but few demonstrated significant treatment effects over comparison groups in randomized trials [34]. The reported limitations included study design issues (eg, nonrepresentative samples and inadequate comparison groups), intervention design issues (eg, features offered are not based on theory or existing evidence), and limited or short-lived engagement with the app [30,34].

Treatment Effectiveness and Effective Management

Maintained engagement with behavior change apps has been associated with app effectiveness in a number of studies and may depend on specific design features that improve adherence

and efficacy. Engagement-enhancing features include visually appealing and easily navigated content; features based on behavior-change principles including feedback, self-monitoring, and data-driven adaptation; and features that promote therapeutic alliance including acceptance and support, relatability, and positive expectations [35]. For example, conversational agents that use artificial intelligence to proactively guide, prompt, and check in with participants and encourage general use of the app have been found to improve the therapeutic alliance between the participant and the intervention, resulting in more engagement [36]. In other studies, the ability to set goals, self-monitor progress, and receive feedback increased engagement across a variety of health behaviors, including alcohol use [37]. An advantage of apps is their ability to generate utilization data, which are commonly used as a proxy for quantifying engagement. Utilization metrics typically include the number of log-ins, proportion of features accessed, and frequency and duration of use [30]. However, interpreting the relative importance of these metrics to determine the amount and type of engagement that is *sufficient* to achieve the desired behavioral and health outcomes (ie, effective engagement) has not been established [37]. Given the lack of practical measures to comprehensively assess effective engagement, researchers continue to rely on utilization data with the assumption that more engagement is better [38].

Step Away: A Behavior Change App for Reducing Excessive Alcohol Use

Step Away is a smartphone app designed to deliver empirically based alcohol assessment and intervention for individuals who drink at hazardous levels that may present health risks. Step Away is the next generation of an earlier app that we tested (the Location-Based Monitoring and Intervention System-Alcohol) with individuals with an alcohol use disorder, which demonstrated significant 6-week reductions in alcohol consumption, along with ratings by participants as being very helpful in changing their drinking habits [39]. This study also indicated that the amount of use of Location-Based Monitoring and Intervention System-Alcohol features was related to changes in alcohol consumption. The design of Step Away is informed by three theoretical constructs that are considered the key *active ingredients* for person-centered, behavioral-based intervention and the treatment of addictions: motivational enhancement [40], relapse prevention [41], and community reinforcement [42]. The app offers eight modules in addition to daily alcohol consumption and craving tracking: (1) *assessment and feedback* on alcohol consumption relative to age-specific norms, drinking-related problems, and monetary costs of drinking, including daily prompting to complete a brief questionnaire on drinking behavior and cravings during the prior 24 hours, and weekly feedback highlighting progress toward goals; (2) *goal setting*, which asks participants to select abstinence or moderation as a goal; (3) *rewards*, which prompts them to set up a reward for meeting their goal and reminds them to reward themselves when their goal is met (eg, 30 days of no drinking); (4) *cravings*, which offers 6 in-the-moment interventions for coping with cravings; (5) *moderation or abstinence strategies*, which consists of simple behavioral strategies tailored to the participant's goal; (6) *supportive persons*, which provides tools

for connecting with participant-identified friends or family when additional support is needed; (7) *reminders*, which encourages the creation of visual reminders of their reasons for changing their drinking habits, including the ability to upload inspirational photos to make a change; and (8) *new activities*, which recommends healthy behaviors and the ability to schedule selected activities within the smartphone calendar. Step Away also provides real-time intervention options; that is, when a participant clicks on the "Get Help" icon, they are provided with strategies for managing cravings or negative emotions and contacting a national treatment finder service to receive help finding in-person treatment in their area.

Although engagement with Step Away has been shown to be relatively high with a recent study of the app in a veteran sample showing that approximately 40% of participants were still engaged with the app at 6 months [43], use of the treatment *steps* or other modules was found to be relatively low [43]. In an attempt to increase intervention engagement, we developed a chatbot version of Step Away that incorporates the app modules into a chat-delivered intervention, which we postulated could result in higher use and engagement over the Step Away app. A chatbot is a computer program that simulates human conversation powered by pre-established rules and artificial intelligence. They have become common in e-commerce, call centers, and internet gaming. They serve as digital assistants that communicate with a user through texting to help a user with numerous tasks, such as planning air travel or helping with a bank transaction. In the smartphone context, they are being used in texting interfaces, in such a way that it appears to the user that they are having an actual conversation with the service. An important distinction between apps and bots is that a bot user has the perception of talking with the service. Bots are emerging as promising tools in contemporary health care [44]. An example of a health care chatbot is Melody, which has a text conversation with a patient about their symptoms and provides potential diagnoses that a health care practitioner can then use to develop a treatment plan [45].

A key difference between the app and bot is that the app relies on the user to launch a new feature on their own, whereas the bot guides the user through a conversational interface and essentially serves as an alcohol reduction personal assistant. The bot is also designed to perform a daily check-in regarding ongoing drinking and cravings and offers a menu of in-the-moment tools that can be used to manage the situation or experience.

Objective

This paper presents results from a 3-month pilot study that compared effectiveness and participant engagement differences among individuals randomly assigned to one of three groups: (1) Step Away app, (2) Step Away bot, and (3) assessment-only delayed condition (control). Our study builds on the existing literature by indicating whether a chatbot-delivered version of a smartphone-delivered intervention has superior engagement and alcohol outcomes compared with an app with similar intervention features over a 12-week duration, and whether these interventions produce superior outcomes over a waitlist control condition.

Methods

Study Design

The study used a randomized controlled study design and a mixed methods approach (ClinicalTrials.gov NCT04447794). Participants were enrolled and randomly assigned to one of three groups: Step Away app (for iPhone and Android smartphones), Step Away chatbot, and assessment-only delay (control). Participants were assessed for their alcohol consumption and related behaviors when they enrolled in the study (baseline) and again 12 weeks later (follow-up). Age and gender stratification were used to ensure a relatively even distribution across each intervention or control group.

Recruitment

Participant recruitment was conducted through Facebook advertisements, which provided a link to the study website and the web-based prescreening survey. Recruitment began in early June 2021 and was completed in early September 2021 when the target sample size was reached. Advertisements were targeted to all Facebook users who may meet the following criteria: age ≥ 18 years; have either an iPhone or an Android phone; reside in the United States; not in another form of alcohol treatment or using another mobile health alcohol intervention, be an active drinker, and have proficiency in English language.

The prescreening survey asked potential study participants about these criteria as well as all 10 questions from the Alcohol Use Disorders Identification Test, Adapted for Use in the United States (USAUDIT). Those who met these criteria, and who had a USAUDIT score between 8 and 24 inclusive for males aged ≤ 65 years and a score between 7 and 24 inclusive for females as well as males aged ≥ 65 years, were invited to complete the consent form and the baseline survey. The target audience for Step Away is those whose drinking patterns fall in the at-risk or high-risk USAUDIT zones. Therefore, those with USAUDIT scores of ≥ 8 for males and ≥ 7 for females met the criteria for risky drinking; those with scores of ≥ 25 were not eligible to participate. A US \$25 Amazon e-gift card was provided to each participant when they completed the baseline survey, and another US \$25 Amazon e-gift card was emailed after the completion of the follow-up survey.

Measures

The following measures were assessed at baseline and follow-up. The USAUDIT was assessed at the time of screening for eligibility and again at baseline for comparison. Demographic characteristics such as age, sex, education, and ethnicity were collected.

Alcohol Use Disorder Identification Test, Adapted for Use in the United States

The USAUDIT [46] is a 10-item measure used to identify hazardous drinking. The scale response is scored from the least frequent, 0 (*never*) to the most frequent, 6 (*daily*). Scores of ≥ 8 have been shown to detect hazardous drinking, and a cutoff point < 8 has been suggested as a cutoff with higher sensitivity for women [46,47]. The Alcohol Use Disorders Identification

Test was found to have a median Cronbach α of .83 and a test-retest reliability of 0.92 [47].

Short Inventory of Problems-Revised

The Short Inventory of Problems-Revised (SIP-R) [48] assesses alcohol-related problems through 15 questions scored on a 4-point Likert scale from 1 (*never*) to 4 (*daily or almost daily*). Higher scores indicate more life problems related to alcohol use [49]. Among problem drinkers, the SIP-R demonstrated good concurrent validity and internal consistency [49-51].

Timeline Followback

The Timeline Followback (TLFB) [52] assesses the quantity and frequency of alcohol consumption. Participants reported the number of drinks they had consumed each day for the past 30 days [52]. When compared with daily interviews using a smartphone, the TLFB showed concurrent validity; however, this diminished over time as participants were less likely to remember the number of drinks they had per day [53].

Readiness to Change Questionnaire

The Readiness to Change Questionnaire (RTCQ) [54] is a 12-item questionnaire that measures the stage of change. The scores were calculated to categorize a participant in the “precontemplation,” “contemplation,” or “action” stage of change regarding changing their drinking behavior [54]. The RTCQ demonstrated a test-retest reliability of about 0.80 per scale and a Cronbach α of about .80 per scale [54].

System Usability Scale

The 10-item System Usability Scale (SUS) [55] measures a user’s experience of a product’s usability. The SUS was found to be reliable, with a Cronbach α of .91 [56]. Participants in the app and chatbot groups completed the SUS to assess the usability of both tools.

Data Collection

Screening and administering consent forms and baseline and follow-up surveys were all done using the web-based survey platform *Qualtrics*. Data were downloaded from *Qualtrics* in CSV format for review and analysis.

Screening and Consent

Completed screenings, including the USAUDIT, were automatically scored using *Qualtrics* to determine eligibility. Scores of ≤ 8 indicated that they did not answer all 9 of the demographic criteria questions required for eligibility (eg, age and residency in the United States); scores of ≥ 9 were considered eligible. Individuals meeting the demographic criteria were eligible if their USAUDIT score fell between 7 and 24 for females or between 8 and 24 for males. The cutoff criteria were set to reflect the minimum cutoff score for detecting hazardous drinking [57]. Those who scored > 24 were not eligible owing to safety concerns; USAUDIT scores of > 25 indicate a moderate to severe alcohol use disorder or dependence [57]. These individuals instead received an automated message providing treatment options and mental health resources, including the SAMHSA treatment locator and the national suicide prevention hotline. If they met the eligibility criteria, *Qualtrics* was used to automatically link them to the web-based consent form.

Baseline

Baseline survey links were emailed to participants once they were manually reviewed by the study team to confirm their eligibility. Up to 3 reminder emails were sent to complete the baseline survey, if necessary.

12-Week Follow-up

Follow-up surveys were matched to the baseline surveys for each participant. An email with a link to the follow-up survey was manually sent to each participant as they became eligible (ie, after they had used the app or chatbot for 12 weeks, or 12 weeks after their study enrollment for the control group). To encourage a high follow-up response rate, up to 3 reminder emails were sent and up to 3 phone reminder calls were made.

Participant Validation

To ensure that the study did not enroll participants who were only seeking remuneration (“phishers”), further participant validation checks were conducted before emailing the baseline survey link, including reviewing the collected data for identical email addresses, multiple duplicate IP addresses, and geolocation data. At follow-up, additional validation checks were conducted. We compared the participants’ demographic responses from baseline to follow-up. In this step, 13 participants reported significant inconsistencies in demographics from baseline to

follow-up (eg, they reported inconsistent answers to questions about their ethnicity and gender between baseline and follow-up). We were unable to verify these participants through a telephone call, and they were thus removed from the analyses to ensure valid responses.

Sample

We recruited 1417 participants in total, including those who completed the prescreen. Of these, 417 patients were eligible and consented to participate. After examining participant responses regarding study eligibility, additional participants were removed because of having numerous prescreen submissions under the same IP address which represented *phishing*, or the automatic scoring through the prescreen allowing ineligible participants into the study (eg, they indicated being currently in alcohol treatment which was an exclusion criteria). Subsequently, the baseline surveys were sent to 197 participants. A few participants (n=6) were further found to be ineligible after examining their prescreening surveys, leaving 191 eligible baseline surveys. At follow-up, 163 participants completed the survey. After removing 13 participants owing to failing our validation checks, we analyzed data from 150 participants, 55 (36.7%) app users, 50 (33.3%) bot users, and 45 (30%) participants in the delay group. **Figure 1** shows the flow of this study. All analyses were conducted using SPSS (version 27; IBM Corp).

Figure 1. Participant flow.

Ethics Approval

The study was reviewed and approved by the University of Alaska Anchorage institutional review board (1521800).

Results

Sample Characteristics

Table 1 shows demographics from each intervention group.

Table 1. Sociodemographic characteristics by intervention group.

Characteristics	App (n=55)	Bot (n=50)	Delay (n=45)
Age (years), mean (SD)	42.58 (13.49)	40.82 (12.54)	41.51 (13.07)

Other	1 (2)	1 (2)	0 (0)

Change in Drinking Measure From Baseline to Follow-up

Missing data were imputed using multiple imputation. TLFB data correlated with age, gender, and SIP-R data. Multiple imputation was performed using age, gender, SIP-R, and TLFB data as predictor variables for missing TLFB data with 5 data sets imputed. A total of 36 respondents were excluded from the TLFB analyses owing to insufficient TLFB data, resulting in a total of 114 participants from the app (n=42, 36.8%), bot (n=39, 34.2%), and delay (n=33, 29%) groups for the TLFB analyses.

These participants did not complete any of the 30-day TLFB survey questions at either baseline or follow-up; therefore, multiple imputation was not possible with these participants. We calculated drinks per day (DPD), percent days abstinent (PDA), and heavy drinking days (HDD). Table 2 shows the descriptive data for each intervention group regarding drinking variables at baseline and follow-up. Figure 2 shows the percentage of days spent drinking hazardously (our primary outcome variable) from baseline to follow-up among the 3 groups.

Table 2. Means and SDs of measures by intervention group.

Measure	App		Bot		Delay	
	Baseline	Follow-up	Baseline	Follow-up	Baseline	Follow-up
Timeline followback measures (N=114), n (%)						
DPD, ^a mean (SD)	2.69 (1.72)	1.51 (1.04)	2.64 (1.26)	1.75 (1.17)	2.50 (1.14)	1.88 (1.41)
PDA ^b (%), mean (SD)	24 (28)	44 (31)	22 (22)	36 (29)	21 (24)	39 (32)
HDD, ^c mean (SD)	7.69 (8.33)	3.29 (5.50)	7.49 (7.98)	3.54 (6.76)	6.30 (5.65)	4.94 (6.92)
Drinking outcome measures (N=150), n (%)						
AUDIT, ^d mean (SD)	15.25 (4.35)	12.62 (7.24)	16.28 (3.49)	14.76 (7.01)	15.60 (4.42)	14.62 (7.50)
RTCQ, ^e mean (SD)	2.35 (0.55)	2.40 (0.68)	2.14 (0.50)	2.62 (0.57)	2.35 (0.57)	2.35 (0.65)
SIP-R, ^f mean (SD)	11.69 (7.25)	8.16 (6.80)	12.68 (10.28)	9.86 (7.95)	13.51 (9.46)	9.53 (8.45)

^aDPD: drinks per day.

^bPDA: percent days abstinent.

^cHDD: heavy drinking days (as defined by ≥ 4 DPD for females and ≥ 5 DPD for males).

^dAUDIT: Alcohol Use Disorder Identification Test, Adapted for Use in the United States.

^eRTCQ: Readiness to Change Questionnaire.

^fSIP-R: Short Inventory of Problems-Revised.

Figure 2. Percentage of days with hazardous drinking from baseline to follow-up.

Alcohol Consumption Results by Group

Repeated measures ANOVA were conducted on the 3 dependent drinking variables calculated from the TLFB, DPD, PDA, and HDD. The within-subjects variable was time (baseline to follow-up), and the between-subjects variable was the intervention group (app, bot, or delay). There was a significant effect of time on DPD ($F_{2,111}=55.93$; $P<.001$; $\eta^2=0.34$), PDA ($F_{2,111}=42.00$; $P<.001$; $\eta^2=0.27$), and HDD ($F_{2,111}=28.18$; $P<.001$; $\eta^2=0.20$), and all were large effect sizes. There was no significant interaction between time and group for both DPD ($F_{2,111}=1.74$; $P=.18$; $\eta^2=0.03$) and HDD ($F_{2,111}=2.27$; $P=.11$; $\eta^2=0.04$). These results indicate that all participants reduced their drinking significantly between baseline and follow-up, and there was no significant difference in the reduction in drinking based on the group they were randomized to.

Repeated measures ANOVA were conducted on three dependent drinking-related variables: AUDIT, RTCQ, and SIP-R. The within-subjects variable was time (baseline to follow-up), and the between-subjects variable was the intervention group (app, bot, or delay). There was a significant effect of time on the SIP ($F_{2,147}=24.76$; $P<.001$; $\eta^2=0.14$), with a large effect size. There was a significant effect of time with a medium effect size on AUDIT ($F_{2,147}=10.97$; $P=.001$; $\eta^2=0.07$) and RTCQ ($F_{2,147}=7.79$; $P=.006$; $\eta^2=0.05$). Between- and within-subjects ANOVAs were conducted to compare the intervention groups for the 3 dependent drinking-related variables. There was no significant interaction between time and group for AUDIT or SIP-R scores, indicating that all 3 intervention groups significantly improved on these drinking measures between baseline and follow-up but did not differ from one another. There was a significant interaction between time and group for the RTCQ ($F_{2,147}=5.62$; $P=.004$; $\eta^2=0.07$) with a medium effect size, indicating that readiness to change scores varied by intervention group, with those in the bot group improving significantly more between baseline and follow-up than those in the app or delay group. The intervention group did not effect change in SIP or AUDIT scores for participants.

App Versus Bot Utilization Results

Three different variables were calculated to measure utilization. We calculated from the Step Away database that the app and the bot collected, the number of times users clicked on a function of the app as the total number of visits they made to each of the interventions. Duration of use was calculated as the time between the date the user downloaded the app and their date of last use. Active days used was calculated as the number of days

that a user was actively using the app, which was defined as having entered the app and clicked on at least one feature. Utilization data from 18 bot users were missing, indicating that these participants either did not use the bot at all or did not enter their personal identification number at the start of the study, which was required to match their utilization data to their study ID. Therefore, the results must be interpreted with caution and the means for the bot utilization variables are likely lower than those presented here. Independent sample 2-tailed *t* tests were conducted between the means of each variable to determine whether there were significant differences between app and bot users. Duration of use significantly differed between app users and bot users ($F_{85}=12.23$; $t_{85}=2.45$; $P=.02$), with duration of use being higher among app users (mean 50.71, SD 49.02) than among bot users (mean 27.16, SD 30.54). Total visits were higher for app users (mean 33.96, SD 38.16) than for bot users (mean 24.56, SD 28.68; $F_{85}=1.53$; $t_{85}=1.21$; $P=.22$), and the average active days used was higher for app users (mean 22.62, SD 29.08) than bot users (mean 19.63, SD 26.30; $F_{85}=.02$; $t_{85}=.48$; $P=.88$), although neither of these differences were statistically significant.

Effect of Utilization of the Intervention on Change in Drinking Variables

Significant direct effects were shown for the duration of use of the app or bot on the change in average DPD and PDA. Increased duration of use predicted a greater decrease in DPD ($\beta=.01$, SE 0.00; $\beta=.25$, 95% CI 0.00-0.01; $P=.04$), and increased duration of use predicted a greater change in the increase of PDA ($\beta=-.18$, SE 0.07; $\beta=-.29$, 95% CI -0.32 to -0.03 ; $P=.02$). There were trends of utilization increasing change in drinking that were not significant, including an effect of total visits on the change in PDA ($\beta=-.16$, SE 0.10; $\beta=-.20$, 95% CI -0.35 to 0.03; $P=.10$), of active days of use on the change in PDA ($\beta=-.21$, SE 0.12; $\beta=-.21$, 95% CI -0.45 to 0.03; $P=.08$), and of duration of use on the change in HDD ($\beta=.03$, SE 0.02; $\beta=.23$, 95% CI -0.00 to 0.07; $P=.06$). These trends indicated that increased use of the app or bot led to greater decreases in drinking and increases in abstinence.

Usability Ratings for the App Versus Bot

Means from the overall SUS score were compared between app and bot users using independent sample 2-tailed *t* tests. App users rated a higher mean SUS score (mean 66.35, SD 19.68) than bot users (mean 61.70, SD 25.40), but this difference was not statistically significant. A typical acceptable SUS score is approximately 70, and scores <50 are considered unacceptable [56]. Table 3 presents the mean (SD) for the app and bot participants for each SUS question.

Table 3. System Usability Scale by intervention group.

Items	App (n=52), mean (SD)	Bot (n=48), mean (SD)
1. I think I would use the Step Away app/chatbot frequently.	3.33 (1.31)	3.15 (1.41)
2. I found the Step Away app/chatbot unnecessarily complex.	2.46 (1.21)	2.65 (1.44)
3. I thought the Step Away app/chatbot was easy to use.	3.83 (1.20)	3.56 (1.41)
4. I think that I would need assistance to be able to use the Step Away app/chatbot.	1.92 (1.25)	2.19 (1.35)
5. I found the various functions in the Step Away app/chatbot well-integrated.	3.42 (1.18)	3.35 (1.42)
6. I thought there was too much inconsistency in the Step Away app/chatbot.	2.35 (1.06)	2.85 (1.38)
7. I would imagine that most people would learn to use the Step Away app/chatbot very quickly.	3.94 (0.94)	3.88 (1.20)
8. I found the Step Away app/chatbot very cumbersome to use.	2.67 (1.31)	2.94 (1.48)
9. I felt very confident using the Step Away app/chatbot.	3.75 (1.05)	3.75 (1.25)
Total score	66.35 (19.68)	61.70 (25.40)

Discussion

Principal Findings

This study sought to develop a chatbot version of the empirically supported app, Step Away, and conduct a pilot trial to determine if a chatbot version could provide enhanced use and outcome effectiveness over the app version. We also sought to pilot trial a methodology that included randomly assigning participants who were hazardously consuming alcohol and interested in making a change to their drinking to one of three conditions: the Step Away app, the Step Away bot, and a waitlist control condition.

Results from this pilot study indicated that self-reported alcohol consumption from baseline to the 12-week follow-up decreased substantially in all groups. Effect sizes suggested that changes in alcohol consumption and drinking-related problems were within the large effect range. However, the results also suggested that there were no statistically significant differences in alcohol consumption variables between the 3 groups, suggesting that the waitlist control condition changed their drinking at a similar level to the intervention groups. The lack of statistical significance could potentially be related to an inadequate sample size (the purpose of the study was not to provide a robust test of effectiveness and power calculations were not performed). It is also likely that the waitlist control condition, owing to their expressed desire to change their drinking, had a strong (and positive) reaction to being assessed at baseline for their alcohol consumption and drinking-related variables, such as life problems stemming from alcohol consumption [58]. A delayed assessment of the control group (until the intervention groups are assessed at follow-up) is a highly recommended strategy for managing this possibility.

Another focus of this study, which is perhaps equally important for alcohol outcome analysis, is the utilization assessment of the 2 interventions. In contrast to our expectations, our results suggested that the app was used more frequently and for a longer time than the bot. There are 2 possible explanations for this observation. The Step Away app was originally developed in 2013 and has undergone 4 major revisions based on user input and recommendations. A finding that has emerged frequently

from research on Step Away is that the app's ability to provide self-monitoring and tailored feedback to the user is a key driver of utilization [43,59,60], which has resulted in the feedback feature being prominent and well-developed. This was the first version of the bot, and, like many first versions, it had some unforeseen limitations. First, similar to all Facebook Messenger bots, it provided a daily SMS text message prompting the user to check in with the bot; however, if they did not respond, the bot did not continue to provide prompts. It relied on the user to return to it on subsequent days to re-engage with it. We heard from some users that they thought the bot disengaged from them as it stopped providing reminders to complete their daily interviews. This notification problem did not exist with the app and app users were notified daily regardless of their response to the prompts.

Another factor related to the feedback is that although an app can provide sophisticated graphs and other pictographic representations of progress, bots are much more limited in this regard (a limitation that existed when we developed the bot). The bot's feedback, although similar in content to the app, was more simplistic and perhaps not captivating. Finally, on 2 occasions the bot *crashed* (ie, ceased to function) during the study, possibly owing to complications related to its dependence on Facebook Messenger, and making it difficult for our developers to resolve promptly. The app also crashed once during the study, but the problem was immediately corrected.

Although this study indicated numerous benefits of the app over the bot, one finding favored the bot. Bot participants were found to have a greater change in motivation to change their drinking compared with the app. It is possible that the conversational tone and the feeling that the bot was more like talking to a person could have enhanced users' motivation to change their drinking habits. Future research should explore this possibility.

Limitations and Future Directions

This study had numerous limitations, many because of its pilot nature, which are related to recommendations for future research. First, the sample was insufficient for detecting small to medium effect sizes, and our findings reflected this limitation. We estimated that a *sample size* of 195 would provide enough power to detect between-group effect sizes, as shown in this

study. Second, the methodology for assessing the waitlist control condition likely resulted in reactivity to assessment phenomena, which made detecting differences between the interventions and the control condition challenging. Future studies in this area would be wise, if using a waitlist control condition, to delay assessment, a method that has been used successfully in other studies [14]. We also had limited time to undertake this study and our 12-week follow-up period may have been insufficient for differences between interventions to emerge. Previous research with Step Away showed that participants continued to reduce their alcohol intake at 6 months [43] and that 45% of participants were still actively engaged at the 6-month follow-up. A 12-month follow-up would provide a more detailed picture of how users remain engaged with the interventions over time and how this engagement is related to improvement. Finally, although this study set out to contrast the 2 interventions and determine which had higher use and effectiveness, this contrast is perhaps not ideal. A more beneficial strategy may involve combining these technologies. Throughout the development of the bot, we realized that both bots and apps each have their unique strengths. Apps can provide highly captivating images and graphs depicting progress, while bots provide the feeling that the user is interacting with someone or something, which has the potential to increase motivation and overall engagement.

Apps are also more self-guided than bots and allow the user to interact in a more self-directed, timely manner than a bot, which guides the user by suggesting modules and responding in a conversational manner. It is possible to merge these 2 technologies into 1 system by placing a bot within an app. Thus, it may be that the *best in class* smartphone-based system for reducing drinking is a hybrid of a bot and an app, a promising direction for future interventions.

Conclusions

Research on smartphone-based interventions for alcohol problems has been promising, but more research into factors related to use and long-term effectiveness is urgently needed. This study indicated that the app and bot interventions were related to substantial improvements in drinking, as was the waitlist control condition, which resulted in inconclusive results. We found that the app was more highly used, which may have been related to some bot limitations that are easily addressable, such as improved prompting over time and greater system stability, which has undoubtedly improved since the development of the Step Away bot. Future research should use longer follow-ups, more sophisticated methodology regarding the timing of the assessment for the control condition, and perhaps leveraging the 2 technologies to develop a hybrid system that has the beneficial elements of an app and a bot.

Abstract

Background: Individuals' social networks and social support are fundamental determinants of self-management and self-efficacy. In chronic respiratory conditions, social support can be promoted and optimized to facilitate the self-management of breathlessness.

Objective: This study aimed to identify how online and offline social networks play a role in the health management of older patients with chronic respiratory conditions, explore the role of support from online peers in patients' self-management, and understand the barriers to and potential benefits of digital social interventions.

Methods: We recruited participants from a hospital-run singing group to a workshop in London, the United Kingdom, and adapted PERSNET, a quantitative social network assessment tool. The second workshop was replaced by telephone interviews because of the COVID-19 lockdown. The transcripts were analyzed using thematic analysis.

Results: A total of 7 participants (2/7, 29%, men and 5/7, 71%, women), with an age range of 64 to 81 years, produced network maps that comprised between 5 and 10 individuals, including family members, health care professionals, colleagues, activity groups, offline and online friends, and peers. The visual maps facilitated reflections and enhanced participants' understanding of the role of offline and online social networks in the management of chronic respiratory conditions. It also highlighted the work undertaken by the networks themselves in the self-management support. Participants with small, close-knit networks received physical, health, and emotional support, whereas those with more diverse and large networks benefited from accessing alternative and complementary sources of information. Participants in the latter type of network tended to communicate more openly and comfortably about their illness, shared the impact of their illness on their day-to-day life, and demonstrated distinct traits in terms of identity and perception of chronic disease. Participants described the potential benefits of expanding their networks to include online peers as sources of novel information, motivation, and access to supportive environments. Lack of technological skills, fear of being scammed, or preference for keeping illness-related problems for themselves and immediate family were reported by some as barriers to engaging with online peer support.

Conclusions: In this small-scale study, the social network assessment tool proved feasible and acceptable. These data show the value of using a social network tool as a research tool that can help assess and understand network structure and engagement in the self-management support and could be developed into an intervention to support self-management. Patients' preferences to share illness experiences with their online peers, as well as the contexts in which this can be acceptable, should be considered

when developing and offering digital social interventions. Future studies can explore the evolution of the social networks of older people with chronic illnesses to understand whether their willingness to engage with online peers can change over time.

Introduction

Background

Asthma and chronic obstructive pulmonary disease (COPD) are debilitating chronic illnesses that affect not only individuals but also have a huge impact on society as a whole [1-3]. Promoting self-management and improving self-efficacy in COPD and asthma is an effective method of tackling their burden [1,2], as it can lead to better use of health care professionals' time and enhanced self-care [2]. Similarly, a Cochrane review conducted by Gibson et al [3] showed that self-management education for adults with asthma could lead to an overall improvement in their quality of life, with a reduction in days lost from work, hospitalizations, accident and emergency department visits and unscheduled physician visits for asthma, and episodes of exacerbation of asthma at night [4].

Corbin and Strauss [5] described *self-management* as a three-step process: (1) medical management, (2) creation of new meaningful behaviors, and (3) dealing with the emotional aspects of a chronic condition. Self-management involves different types of work performed by people with long-term conditions (LTCs) and members of their networks [6]: illness related (ie, the tasks necessary to manage or treat a chronic illness and its sequelae), emotional, biographical (ie, the task of defining and maintaining an identity over the life course), and relational (ie, the tasks that are required to develop and sustain interpersonal relationships) [7]. Doing this work requires negotiating changes at the individual and network levels, which is a process shaped by individual self-efficacy, the collective efficacy of the networks of people with LTCs, and the support and resources available to individuals and within their networks [8-10]. The concept of *self-efficacy* was first described by Bandura [11] in 1977 as a person's belief regarding whether they feel they can successfully execute particular behaviors to produce certain outcomes. Bandura [12] portrayed self-efficacy as a dynamic concept that changes over time, with expectations of personal efficacy derived from performance accomplishments, vicarious experiences, verbal persuasion, and physiological states. Patients who can withstand failures associated with acquiring the skills of a more intricate task are more likely to persevere and continue with that task [13].

As the effectiveness of self-management can be directly affected by the patient's self-efficacy, health care providers can improve the confidence of patients in self-management by increasing their self-efficacy. A study conducted by Simpson and Jones showed that patients with COPD who are more confident in understanding and treating an exacerbation and controlling their breathlessness showed less anxiety and depression levels [14].

The fundamental determinants of self-management and self-efficacy are an individual's social network and social support [15]. An individual's *personal social network* comprises interpersonal connections among the individual's family members, friends, and acquaintances and can have broad effects on health outcomes and quality of life [15]. *Social support* is defined as the relative presence or absence of psychosocial support from significant others to meet a person's basic social needs [16] and typically comes in 4 forms: informational, emotional, instrumental, and appraisal [17]. Social support is further subdivided into two categories: *perceived social support* (ie, the belief that support is available when and if needed) and *received support* (ie, the exchange of support-related resources) [18]. Approximately 30 years ago, a causal link between social relationships and mortality was proposed [19]. Since then, numerous reviews have documented how perceived social support can influence physical health outcomes [17,20-22]. Some of the most compelling results were provided by a meta-analysis conducted by Holt-Lunstad et al [22], who concluded that perceived support was related to a significantly lower risk of all-cause mortality.

Previous literature has demonstrated that behavioral change and overall health and well-being are shaped by relationships within networks. These include weight gain [23], smoking cessation [24], happiness [25], and adherence to preventative medication [26]. One of the ways of studying the effects of social networks on behavioral and health-related properties is through the assessment of individuals' social capital. Granovetter [27] proposed a seminal account of the structural foundations of social capital through the "strength of weak ties." Granovetter [27] suggested that strong ties, although they foster a sense of belonging and sustain emotional support, can lead to overall fragmentation (fragmentation is defined as the proportion of mutually reachable nodes as each node is removed from the network, in other words, an inverse measure of the amount of connection redundancy in a network), whereas weaker ties amplify an individual's access to novel information and opportunities, as they introduce the individual to nonredundant and unique knowledge pools provided by disconnected neighbors. The idea of informational nonredundancy was further reinforced by Burt [28] in his theory of structural holes (ie, the absence of direct links between individuals who share a common neighbor) and their beneficial impact on the focal node. The focal node can access complementary and nonredundant sources of information through their direct links to otherwise disconnected others [21]. In the context of LTCs, weak ties have been demonstrated to offer access to a wide range of support that deburdens strong, intimate ties and is also easy to accept and reciprocate. Compared with strong ties, weak ties in the networks of people with LTCs require less relational work to

sustain them over time. Weak ties are also less threatening to an individual's sense of self and the valued roles and responsibilities they have to others. Weak ties play a key role in navigating and negotiating relationships within networks and thus increase the collective efficacy of networks as they allow individuals to access support that is acceptable to them and to members of their networks [7,10,29].

The rapid growth of social media and web-based social platforms in recent years has allowed for new approaches to social networks and support. In addition to social platforms aimed at the general population, health-related social platforms have seen a recent upsurge in popularity [30]. Integrating social media and web-based communities in the health sector opens up new potential applications [31,32], including their use as public health surveillance tools [33-35] and health-related information sources [36,37]. A meta-analysis conducted by Laranjo et al [38] showed a positive effect of social networking site interventions on health behavior-related outcomes, encouraging future research in this area [38-40]. Moreover, there is evidence that social media interventions are effective in promoting health equity (health equity means that everyone receives individualized care to bring them to the same level of health, despite health disparities between population groups) [40-42]. Forming new social connections with individuals with similar lived experiences (such as in social media interventions) has been reported to facilitate the emergence of a sense of community and strengthen engagement with social prescriptions [43]. Taking the concept of social support a step further, Panzarasa et al [44] have proposed the concept of social-medical capital, defined as "the advantages that any user can gain from participation in the social networks provided by online health communities" (online health communities [OHCs]). In particular, these advantages include improvement in patients' self-care and health in resource-constrained systems.

Objectives

Web-based personal network surveys have been developed to evaluate an individual's social network in a structured manner, translating the complexity and burdensome features of this type of questionnaire into a more usable and scalable form. Interventions aimed at modulating network composition in a social network hold the promise of a novel complementary approach to the self-management of chronic respiratory conditions. Here, we used a data collection tool that can be completed by older patients without an interviewer [45]. The objectives of this study were to adapt this previously validated social mapping network assessment tool to include online contacts to (1) understand the feasibility of using this tool to map the social networks of individuals with chronic respiratory conditions within a workshop or telephone interview; (2) identify how online and offline social networks play a role in health management for patients with chronic respiratory conditions, specifically COPD and asthma; (3) explore the role of any existing online peers in patients' self-management; and (4) shed light on the barriers and potential benefits of digital social interventions.

Methods

This was a mixed methods study that used quantitative social network assessment and qualitative analysis.

Participants and Setting

Between March and July 2020, we ran a public engagement activity titled *Promoting Research in Social Media and Health* with participants attending *Singing for Breathing* sessions at the Royal London Hospital in Whitechapel, London, to inform a grant application for developing and testing a digital social intervention. Recruitment was opportunistic, targeting a group more likely to be socially engaged, as our focus was to understand online and offline social engagement in LTCs rather than socially versus not socially engaged patients. The inclusion criterion comprised adults aged >60 years with a chronic respiratory condition. Participants provided written informed consent to take part in the study and for their anonymized quotes to be reported in the publications.

A total of 2 workshops were initially planned. The first workshop took place immediately before the singing activity. Owing to the COVID-19 lockdown, the second workshop was replaced by individual telephone interviews. The workshop activity was piloted with 2 patient and public involvement (PPI) members. Through the PPI piloting, it became clear that a 1-hour workshop would not provide enough time to guide participants to fill in the web-based survey at the same time. The survey questions were instead printed on A4 sheets, presented, and read aloud to participants during the workshop so that participants could draw simultaneously. The participants drew their networks using pencils of different colors. Red markers were used to link individuals who supported participants or one another most often (strong ties), and blue markers were used for all other contacts (weak ties). Data were subsequently transferred from paper to the web-based survey of the social network assessment tool. During the COVID-19 lockdown, participants were emailed written instructions (previously piloted by the PPIs) to complete the web-based questionnaire. According to their preferences, they could fill out the web-based survey on their own time or with the researcher's guidance by phone. They were subsequently emailed their social network maps and interviewed by phone while looking at them.

Data Collection

We collected data by adapting PERSNET, a publicly available social network assessment tool, on a secure open-source web platform (REDCap [Research Electronic Data Capture; Vanderbilt University]) [45], which generated social network maps. We focused on individuals involved in managing their illness, whether offline or on the web (ie, social contacts not involved in the management of their respiratory condition were not collected). Maps were generated in RStudio using the data collected from the REDCap survey [46]. Participants were prompted to answer the *name generator* question ("Think about people who encourage you to stay healthy by giving you motivation, advice, or direct help. Who provides this kind of support for your health?") thinking of whoever was involved in any aspect of the management of their respiratory conditions (eg, providing medical, practical, or emotional support during

exacerbations or practical help in the long-term management of the condition, eg, with ordering and collecting medications and prompting medication taking). We asked the participants to include any important individuals: clinicians, close family members (first-degree relatives and partners), and friends (both offline and on the web). Other collected information included the description of relationships with each individual (*especially close or not especially close*); the relationships between each pair of people in the network (*stranger, in between or especially close*); those who were supporting the participant *most often*; gender, ethnicity, approximate age, and higher degree of each individual, if known; how often they communicated with each person (*daily, weekly, monthly, less often, or don't know*); how many years they had known each other for (*<3 years, 3-6 years, >6 years, or don't know*); the way in which the participant was connected with each individual (*spouse, family, friend, adviser, coworker, or other*); and how far they lived from each person (*same house, 1-5 miles, 6-15 miles, 16-50 miles, or ≥50 miles*).

Once the maps were created, participants had the opportunity to reflect on how their offline or online social networks played a role in managing their respiratory condition based on the visual representation of their social maps. They were also prompted to reflect on whether they were in contact with any online peers and, if not, what would be the barriers and potential benefits of doing so be.

Analysis

We performed network and qualitative analyses of the workshop and interview transcripts and triangulated the results [47].

Network Analysis

We visualized the social networks and analyzed them using different network metrics. The network size represents the number of individuals in the network without including the focal participant (*ego*). Strong ties are represented by red lines, denoting contacts who are more familiar with the participant and provide support *most often*, whereas weak ties are represented by blue lines (all other individuals). The mean degree is the average number of connections (ties) incident upon a member of the network. Effective size is the number of the focal node's nonredundant neighbors, which is a function of the number of the focal node's neighbors (*alters*) and the extent to which these neighbors are not directly connected to each other. The effective size varies from 1 (a network that provides only a single nonredundant contact) to the total number of ego neighbors (ie, each contact is nonredundant) [45]. Effective size represents the total value ego can extract from all its alters: the higher the effective size, the larger the number of nonredundant contacts, and the higher the benefit for the ego. The node representing ego in each network was associated with node

strength, calculated as the sum of the weights of the ties connected to the node (no tie value=0, weak tie value=1, and strong tie value=2). The average tie weight was then calculated for each ego in the various networks by dividing the ego's node strength by its degree. For each ego-centered network, the correlation coefficient between the ego's average tie weight and the effective size was calculated using Microsoft Excel.

Qualitative Analysis

The workshops and interviews were audio-recorded, transcribed verbatim, and analyzed using thematic analysis. There were 2 parts to each transcript. The first covered the running of the social network assessment survey, and the second covered the participants' answers to the following semistructured questions:

1. "How does your social network play a role in managing your health?"
2. "Do you ever read on internet what peers online say about living with your medical condition/s? Are you in contact with any peers online, e.g., on Facebook or the Asthma UK or BLF online communities?"
3. "If not, what would be the barriers and potential benefits?"

Transcripts were qualitatively analyzed using thematic analysis [48] to identify and define the emerging common themes. AA read all posts to familiarize with the data and the participants. ADS independently coded 20% of the data. Disagreements were identified between the coders. Following coding, the main themes and subthemes were identified, iteratively reviewed, and refined throughout the analysis. The results were triangulated with those from the quantitative analysis by comparing and combining them, contributing to one another. Emerging themes from participants' comments during the social network assessment survey have been reported in the *Social Network Maps* section.

Ethics Approval

The Queen Mary Ethics of Research Committee granted ethical approval before the start of the study (QMREC2388a). After the COVID-19 lockdown, an ethics amendment was sought to replace the second workshop with telephone interviews.

Results

Participant Characteristics

We recruited 7 participants aged between 64 and 81 years, of whom 5 (71%) were women, and 2 (29%) were men, with a mean age of 73 (SD 5.28) years. Of the 7 patients, 5 (71%) had COPD, and 3 (29%) had asthma (one of them had comorbid asthma and COPD). The baseline characteristics, including gender, age, and comorbidities, are presented in [Table 1](#).

Table 1. Participants' baseline characteristics.

Participant number	Gender	Age (years)	Married	Live alone	Condition
N1	Male	70-75	Yes	No	COPD ^a and hypertension
N2	Female	60-65	No	Yes	COPD, asthma, and tachy-brady syndrome
N3	Female	75-80	Yes	Yes	Asthma, thyroid disease, and obstructive sleep apnea
N4	Female	65-70	Yes	No	Asthma
N5	Male	65-70	Not stated	Yes	COPD and ulcerative colitis
N6	Female	80-85	No	Yes	COPD and heart failure
N7	Female	75-80	No	Yes	COPD, interstitial lung disease, and hypothyroidism

^aCOPD: chronic obstructive pulmonary disease.

Social Network Maps

The use of the tool was feasible within the workshop and interview times and settings and acceptable to the 7 participants' networks. Participants created network maps comprising between 5 and 10 individuals and individual groups, as shown in Figure 1, with network characteristics reported in Table 2 (a complete version of Table 2 is reported in the Multimedia Appendix 1). Of the 7 participants, 5 (71%) included close family members, considering them a major source of emotional support (strong ties, indicated by red lines in Figure 1). Family members can be recognized in the maps as mutually connected with strong ties. Participants who had close family members in London also reported that they were an important source of practical support, especially during exacerbations of their disease:

My son, well he lives in London and when I did have my exacerbation a couple of years ago, he went and did all my shopping and that sort of things because I couldn't... [N3]

Some participants belonged to multiple groups (eg, choirs, exercise groups, the singing groups) and found it easier to name the whole group than single individuals within them as playing a role in the management of their chronic diseases.

Participant N4 had the highest effective size (8.9) and thus a high number of structural holes (ie, the absence of direct links between contacts) in her network, which was, therefore, likely to provide access to novel nonredundant information more easily. Participant N5 had the most close-knit network with the lowest effective size (3.4) and the highest average tie weight, with most of his social contacts being connected to all others.

Figure 1. Social networks of participants arranged according to the ego's effective size (y-axis) and average tie weight (x-axis). Line color indicates tie strength: red lines refer to strong ties and blue lines to weak ties. The gray line refers to the fitted regression line illustrating the relationship between effective size and average tie weight.

Table 2. Characteristics of social networks involved in the management of participants' long-term respiratory condition.

Participant number	Network size ^a	Density ^b	Effect size ^c	Degree, mean (SD) ^d	Maximum degree ^e	Kin proportion ^f	Average tie weight ^g	Named health care professionals	Any contacts on the web?
N1	8	39	5.7	2.7 (5)	5	37	1.50	GP ^h and COPD ⁱ nurse	No
N2	7	0	7	0 ^j	0	14	1.57	Out-of-hours GP	Yes
N3	7	23	5.73	1.4 (2)	2	42	1.85	GP and practice chest nurse	No
N4	10	13	8.9	1.2	4	20	1.7	GP and nurses, pharmacists, and consultant	Yes
N5	5	50	3.4	2	3	60	2	None	Yes
N6	7	23	5.5	1.4 (2)	4	42	1.14	GP and respiratory care staff	No
N7	6	33	4.45	1.6 (6)	2	0	1.66	GP	No

^aTotal number of unique social contacts.

^bRatio of the number of ties to maximum possible number of ties.

^cEffective size is the number of the ego's nonredundant contacts based on the Burt measure.

^dAverage degree of a network member excluding the ego.

^eMaximum degree of network member (most popular) excluding the ego.

^fProportion of network members who are kin.

^gNode strength or degree.

^hGP: general practitioner.

ⁱCOPD: chronic obstructive pulmonary disease.

^jFor some participants the tool could not calculate the SD and therefore only the mean is reported.

All participants had at least one friend in their social network who identified as a strong tie on the map. However, at least 50% of the members of the social networks of participants N2, N3, N4, and N7 were friends. These participants mentioned that in addition to emotional support, their friends offered them other forms of support, including life advice, practical and health tips, and financial support. Approximately 57% (4/7) of participants (N2, N3, N4, and N5) named their peers (ie, people with a chronic respiratory condition) among the network members. They stated that they felt part of a community when talking to peers about their disease and sharing information on how they were coping:

...the first was very much also finding out information, reading up, recommending exercises, so that's one person...[with another friend] it's good to have conversations where you're talking about how you get online, you do things and how you are limited by whatever your condition is... [N4]

The networks were plotted in terms of the ego's effective size and average tie weight. The lower the ego's effective size and the higher the average tie weight, the more close-knit and restricted the network. The correlation coefficient between effective size and average tie weight was -0.21 . The negative correlation is consistent with the Granovetter [27] theory, according to which stronger triplets (ie, high average tie weight) tend to close up into triangles (ie, low effective size).

Of the 7 participants, 6 (86%) included health care professionals in their maps. Of these, only 14% (1/7) of them mentioned a respiratory consultant, whereas the rest mentioned their general practitioners (6/7, 86%) and respiratory nurses (4/7, 57%). These participants felt particularly close to their community clinicians and could rely on them for the management of their conditions, particularly during exacerbations or infections. In addition, most participants' first line of contact with medical advice was with their community clinicians:

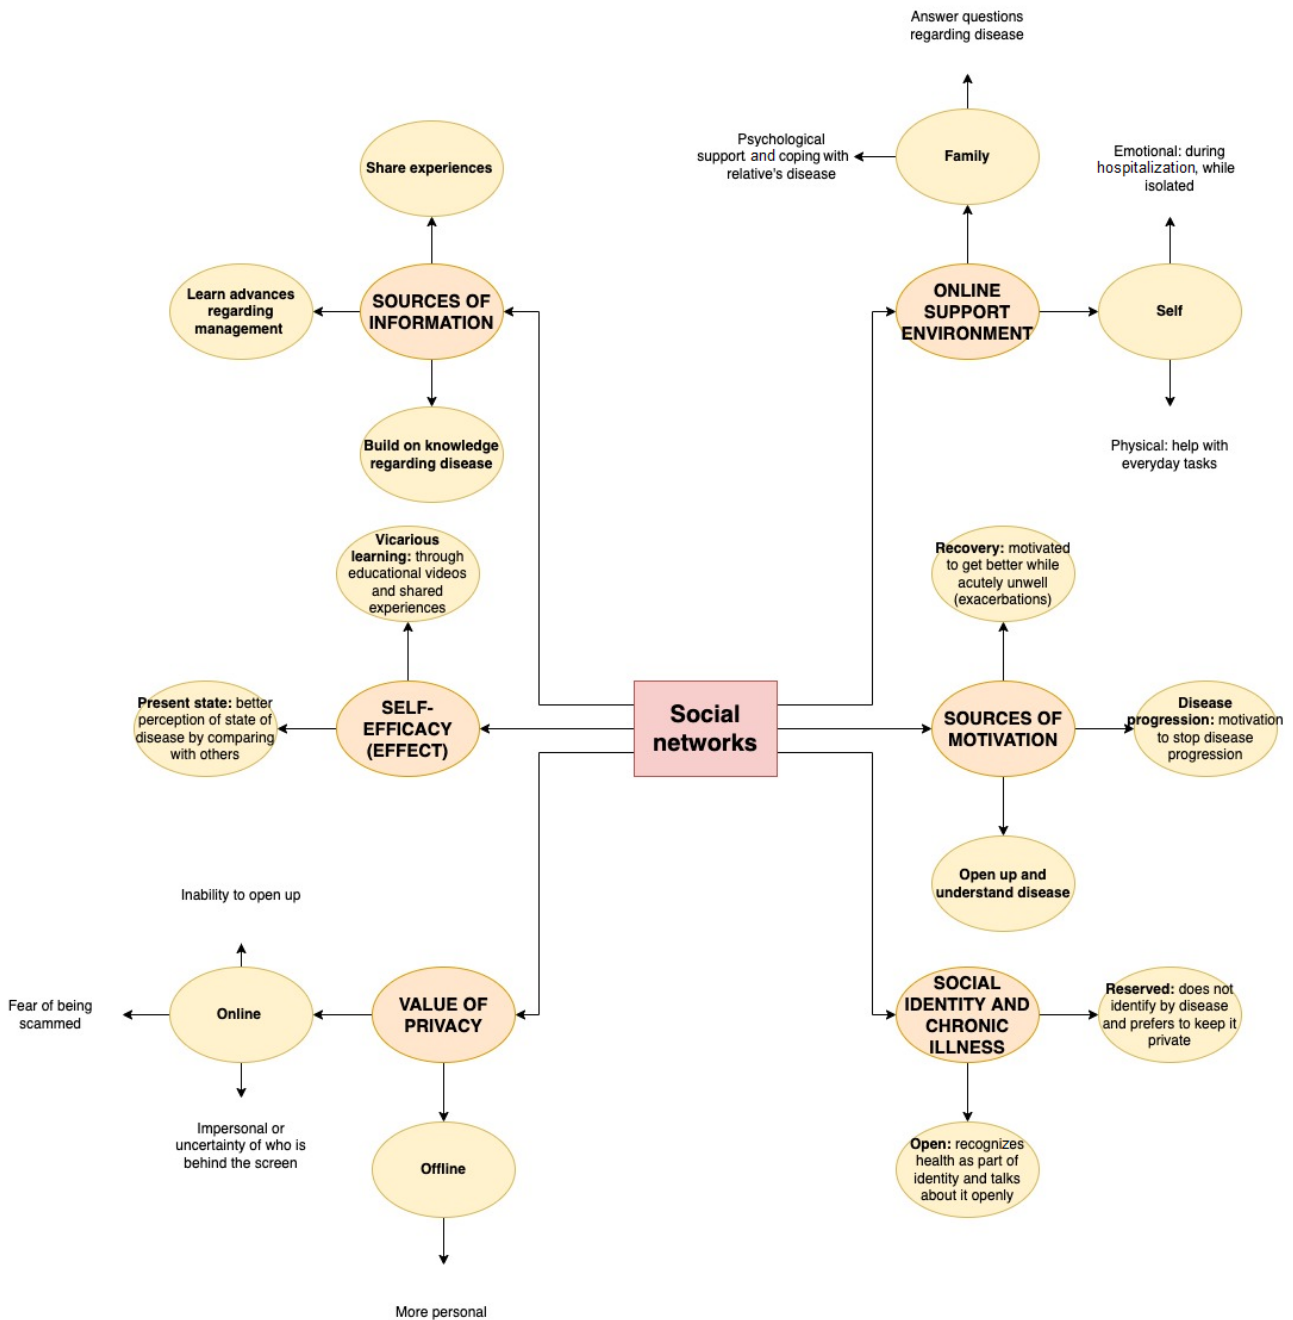

[The GP] is very supportive. I'm not on her doorstep every day, but she's a very genuine person. She's not what I call plastic. She's very genuine. She's very, very genuine and very caring...I would say [my GP provides] emotional, physical, health support [N7]

The social maps of participants N2, N4, and N5 included contacts on the web. Only participant N2 was active on web-based social platforms before the lockdown restrictions because of the COVID-19 pandemic. N4 and N5 transitioned their offline contacts to the web because of lockdown restrictions. Participant N2's online peers, in particular, provided emotional support (eg, during hospital admission for asthma exacerbation).

Themes

Several themes emerged regarding the role of both online and offline social networks in the management of chronic respiratory conditions, as illustrated in Figure 2.

Figure 2. Main themes emerging from participants’ reflections on their social networks.

Family and Chronic Illness

Most participants (5/7, 71%) included some close family members in their social networks. They highlighted the importance of family as a source of emotional support, as these are the people who know and understand them better, especially during exacerbations or when they face difficulties in their illness management. During the COVID-19 lockdown, participants reported that their close family members were still able to remotely provide the necessary support.

Social Networks and Self-efficacy

Wider social networks seemed to be markers of self-efficacy. Participants were able to better understand and manage their disease by accessing a broad social network that introduced them to novel information about self-management:

She’s a life coach and a, does energy healing and reiki and that, so that’s fantastic having her support, working on breathing and relaxation and that sort of thing...And another person is someone who I knew through work...they’re great because they’ve also got a network and they can recommend one, recommending a speech therapist or things like that [N4]

Social Networks as Motivators and a Source of Perseverance

A major theme was concerned with social networks acting as motivators for improving one’s health. Participants were encouraged to open up and discuss their disease, improving their understanding and knowledge. They could make downward comparisons and monitor their disease trajectories with those

of their peers, prompting healthier lifestyle choices that slow disease progression. In addition, participants noted that a strong and supportive social network encouraged them to recover swiftly during periods of being acutely unwell (ie, during exacerbations) and kept them engaged within their community:

...Some have had it longer than others, some are in a worse way than others. Obviously, there's different stages so, and you can get an idea if you're at a different stage. And you don't want to go any further so you try your best to follow anything which could help your condition. [N5]

Chronic Conditions and Social Identity

Some participants stated that, if possible, they preferred not to share their chronic health condition in their social networks and kept it restricted to their closest family and friends and health care professionals. Different traits regarding participants' perceptions of disease and identity seemed to emerge through their reflections. Some participants were open to sharing their experiences and chronic illness, whereas others were more reserved, considering their illness somehow part of a more private sphere they would not easily talk about with others. This was because they avoided, if possible, talking about their health

with others or *not to bother others*. This might suggest that the illness was not part of their identity, that they did not want the illness to dominate their life, or that they tried to reduce the emotional burden that living with the illness had on themselves and members of their social network:

I'm not a very..., my health is my health and I know what's wrong with me and I just want to get on with it...I just have to get on with my own life, basically. [N6]

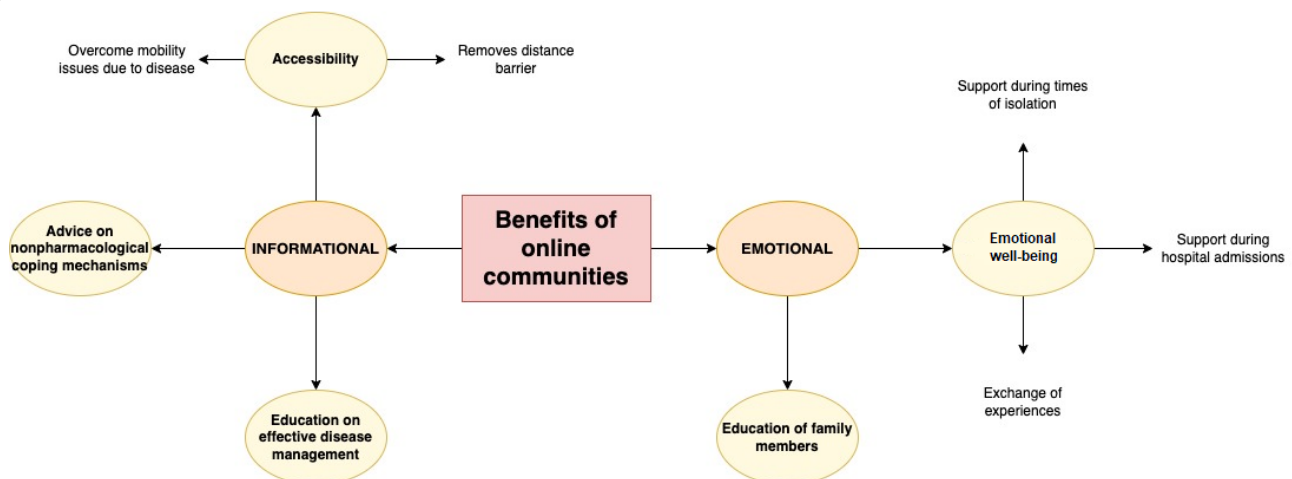

Other participants were more open about their health and shared their illness experiences with others, including their peers. This allowed them to accept the support available to them from their network members in relation to emotional and practical work:

Friends at the church in general, yes. They really are wonderful. I was very ill with my lungs a couple of years ago and I used to get texts, phone calls, hi, how are you, do you need any help? It's the same with this lockdown. [N7]

Benefits of Engagement With Online Peer Support

The benefits identified by participants of OHCs were grouped into informational and emotional support. These are illustrated in Figure 3.

Figure 3. Benefits of online communities.

Approximately 43% (3/7) of participants reported their experiences related to searching the web on breathing exercises, diet, meditation, and other calming techniques:

...people would be able to exchange more of those ideas and not feel embarrassed about saying, well actually, yeah, meditation really does help me to manage my breathing and to calm down and do that sort of, and lower anxiety levels, and if anxiety is a success, then it's quite useful to get, keep your anxiety levels lower than. [N4]

Participants described the potential of OHCs as a source of emotional support, fostering a sense of belonging and understanding. This benefit could be crucial when no other sources of support are available, such as during hospital admission, or when individuals are isolated or unable to attend face-to-face support groups and therefore are not able to benefit from sharing experiences or receiving the support of peers:

Immediately postop...I had the worst asthma attack I've had in years...But when I was in hospital, I was on Facebook then, I, all my friends, my friends were really supportive, I'd post updates and they came to see me...I was able to say, I'm getting better, or it's going well or it's not going well, so I got a lot of support. [N2]

Online peer support can be readily accessible from the comfort of someone's house, overcoming mobility constraints and eliminating the barriers of physical distance [49,50]. OHCs can be particularly useful at times of isolation, such as during the COVID-19 pandemic, and bring patients closer to their carers, peers, and family members:

...for whom making a journey was quite an effort, so it's obviously, it's the right sort of group for this group of people. [N4]

Well with my group of friends, I couldn't meet them because we're located all over the country. With my family, yes I would only, I only use the Zoom because we can't physically meet... [N6]

Participants recognized the value of OHCs as informational or educational platforms in which people with chronic conditions can use peer support passively by either watching YouTube videos made by peers about self-management tips or reading what peers say. By accessing novel information, they could build on their knowledge regarding their disease management, undertake downward comparisons, and discover new methods of coping that would not otherwise be available:

Oh yeah, it's definitely, I found it on YouTube, I don't think I would get that information from any of the people in their [inaudible] as such. [N5]

...I've actually seen videos of people who are in bad way with their oxygen and people like that who are trying to give you some, any information about how to cope if you get to that degree...I think to myself, I

don't want to end up like that, so I try and do everything I can possible until I'm [inaudible] getting worse. [N5]

...I get too much mucus produced which sort of clogs me up a bit so I normally try and find out if I can, on YouTube, what sort of recipes they've got. And if I can, if they tell me, like ginger, garlic, rosemary, things like that which help with your breathing... [N5]

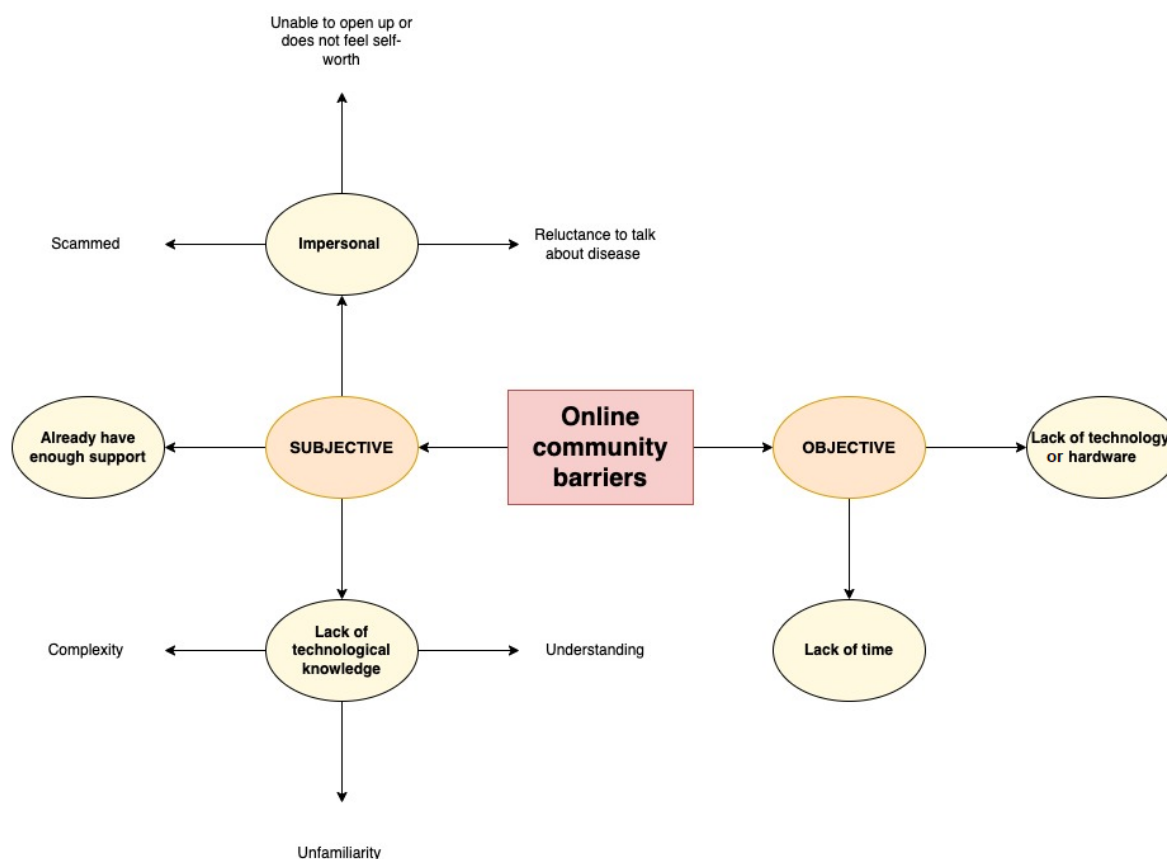

Trust and practical everyday work around food and cooking were also reported:

Obviously, it's quite a lot of good advice on there [online], in some areas it's, some, you can take it with a pinch of salt...But most of it is pretty good information. [N5]

Barriers to Engagement With Online Peer Support

Barriers identified by the participants regarding engagement with OHCs in the context of illness self-management were grouped into subjective and objective. These are illustrated in Figure 4.

Figure 4. Barriers to online communities.

Subjective Barriers to Online Peer Support

Some participants felt worried that because of the remote nature of OHCs, relationships might not become as personal as during in-person interactions. Emerging themes included a lack of value added in relationships on the web, *interference of technology*, and a preference for not-web-based interactions. Participants might occasionally use the internet to search for information or clarify issues regarding their disease

management, using it as quick and easy access to information not available via their existing network members. Their use of web-based resources could be seen as integrating access to existing offline relationships:

I don't like, I don't want to sit in front of my computer and read pages and pages and pages of stuff. I very, very rarely do that. I might look on Google for particular, something or other, and I might look at

the information and think, good. But I'm not one to, I don't watch... [N6]

No, I never have. If there's something I want to know I might Google to find out but other than that I will talk to people face to face if necessary. [N7]

Similarly, a small number of participants were concerned about their ability to provide advice regarding health management because of lack of knowledge and expertise. This makes this group of participants even less likely to be involved in online peer groups:

No, I'm not prepared to help people as far as their health is concerned...there's nothing that could compare to peoples' health...It's not my job. I don't know enough about it to advise other people on what to do. [N6]

One of the participants also expressed concerns about other risks on the web, not only as it is often difficult to understand people's true motives behind a screen but also because of her lack of technological knowledge:

No, I'm not on Facebook. I'm not on Twitter. I'm not, I've never really been interested in all that actually. I've always been a bit scared I might get scammed in some way. [N7]

The same participant explained that having an already well-established support network could be another limiting factor affecting engagement with OHCs:

But if I've got something wrong then I will book an appointment with the GP and I'm not on her doorstep every day fortunately enough. I've got too much respect for her, bless her. [N7]

I'm quite happy with the support that I've got. If I had a problem, you see I mentioned I've got sleep apnoea as well. I have check-ups on that and Telly, the physio that I see sometimes...I can discuss it with her, and she'd give me advice on it because she's so closely knit with all of them in respiratory medicine [N7]

Some participants were cagey about the idea of making technology a feature of their lives, especially if they had been able to perform their everyday tasks without it previously. They mentioned how complicated technology could be for the older population or for anyone who had not used it regularly beforehand:

...if you have up till now been able to do something without the interference of technology and now you have to learn to do the same things that you've got to mediate with the technology, sometimes you think, oh I can't be bothered with that... [N4]

I actually had this conversation with someone before this morning, who was saying that when she... presses a button and things don't happen as she expects them to do, she says, "oh, then I give up." So, I think that people may have a certain level but can be quite easily discouraged and depending on how important it is... [N4]

Objective Barriers to OHCs

Participants felt that not only did they lack the time required to familiarize themselves with the skills required to participate in OHCs, but they also did not have enough time to engage with them, even if they were able to navigate the web-based system:

My concern would be the about actually having the time to do it... [N4]

Finally, some felt that the people who would truly benefit from OHCs are older patients who seem to experience more debilitating symptoms. However, these patients are least likely to be adequately equipped with the required technology, such as tablets, computers, and smartphones:

The only trouble with that is there's a lot of people, like myself who have not really got any iPads or laptop, I've only had this one now for a year I think and I, it's still pretty new to me... [N5]

Participants highlighting barriers to engagement with OHCs tended to be those with low effective size, high tie weight, and a high percentage of network members being kin (ie, N7, N5, and N6), whereas benefits and openness to online peer support were indicated mainly by people with high effect size, low average tie weight, and low percentage of network members being kin (ie, N2 and N4).

Discussion

Principal Findings

This study shows the application of a web-based social network assessment tool in a population of patients with chronic respiratory conditions, extending it to include contacts both offline and on the web who were involved in their disease self-management. Participants were able to identify and visualize other people involved in the management of their chronic disease and describe the role of social networks in managing their health and illness, with the tool itself acting as a facilitator of this process, as previously shown [51]. With facilitation, using a web-based social network assessment tool was feasible and acceptable for this patient population in workshops and remote interview settings. The visualization of the social network through the tool enhanced participants' understanding of the role of their engagement with online and offline social contacts in their disease self-management and the work undertaken by the network itself for people with asthma or COPD.

Our qualitative analysis showed that most respondents received emotional support from close family members and friends. A small minority of participants reported using peer support through OHCs, either when no other sources of support were available or passively through watching videos.

Participants with a higher effective size welcomed various forms of informational support and openly discussed their health with their friends and family. In addition, they belonged to different communities, with each group contributing informational support in a unique way and to a different extent. This suggests that the higher the effect size and the lower the node's average tie weight, the more likely patients are to take advantage of the novel, nonredundant sources of information and support [28]

and seek advice and help from others outside their close family network. This could directly affect, as well as improve, their illness self-management and self-efficacy [11,12]. These data highlight the value of using the social network assessment tool as an intervention that can support self-management when facilitated and as a research tool that can help assess and understand network structure and network engagement in the self-management support of people with chronic respiratory diseases.

Interpretation in Light of Existing Evidence

Previous studies on social networks have shown that they can have broad effects on physical health outcomes and quality of life and even lower the risk of all-cause mortality [17,20-22]. There is also evidence to suggest that involvement in multiple support groups can foster an individual's ability to self-manage and improve their well-being and ability to cope practically and emotionally [52]. In agreement with these reports, we found that the participants' social contacts facilitated disease self-management and that networks were involved with different types of work (emotional and informational or behavioral), how the work was done, and by whom. In addition, our results are in line with the literature demonstrating a contagion effect of networks on behavioral change [23,24,26], as participants reported being encouraged by their social networks to take part in activities to keep them active and in better health conditions.

Several studies have explored the potential benefits of OHCs as health-related information sources [36,37] and how they can have a positive impact on health behavior-related outcomes [38]. It has been theorized that the extent of input by different members and OHCs of a network might change according to people's current circumstances and relationships [6]. Participants welcomed the idea of OHCs as a source of information and readily accessible psychological aid, which removed the barriers of physical distance and isolation. However, some saw OHCs as impersonal, especially if they already had a strong offline network, and would not engage out of *fear of the unknown*. Similarly, some felt underequipped to engage in such communities because of their lack of technology and expertise.

Clinical and Research Implications

The facilitated use of the social network tool [45] acted as an intervention that prompted reflections on offline and online social networks in the management of chronic respiratory conditions. This process of visualization and reflection has been referred to previously as a *positive disruption* [53]. Previous work has shown how network visualization and reflection lead to improved network engagement and can improve outcomes [54-56]. Future studies should investigate whether encouraging people with LTCs who are willing to engage in OHCs to expand their social networks to include online peers could enhance their access to novel information and potentially improve their self-management. In addition, given the direct impact that

self-efficacy can have on self-management, OHCs could focus on connecting like-minded individuals and creating new relationships. Such interactions could also bolster conversations regarding health management and motivate individuals to achieve successful disease management. Our results showed that the COVID-19 pandemic created the need for social interactions on the web and equipped some participants with the skills to overcome technological barriers.

People's perceptions and willingness to engage with OHCs are influenced by individual traits regarding willingness to discuss health and illness with others. Being able to identify patients' preferences in terms of sharing illness self-management with peers could allow health care professionals to signpost them accordingly. Research programs informed by these activities can enhance patient-centered research on social media and health, with new significance in light of the social isolation caused by the COVID-19 pandemic. A longitudinal study of patient networks over time could help to understand how exogenous factors (such as pandemics) are associated with changes in people's attitudes toward engagement with OHCs.

Strengths and Limitations

The strengths of this study include testing the feasibility and acceptability of using a social network assessment tool [45] to visualize people involved in the management of chronic respiratory conditions in the United Kingdom. However, the small number of participants is a limitation that makes it difficult to extend and generalize the findings. Some participants named whole groups (eg, choirs and exercise groups) rather than single individuals as playing a role in the management of their chronic diseases, which may have introduced a bias in the quantitative assessment of the social network. Selection bias may have been introduced by recruiting participants who were already engaged in a health community through a singing group. Furthermore, the social maps were based on participants' self-reported data; this raises the possibility of bias because of different cultural and personal beliefs on what individuals consider to be a *social network*. Finally, because of the COVID-19 pandemic and the more impersonal nature of the telephone interviews, participants' responses might not reflect how they would have answered in a workshop.

Conclusions

Online social networks are becoming increasingly important components of people's everyday lives. Their appeal in the health care domain is not only attributable to their low cost but also to their potential for changing health behavior-related outcomes [38]. Our study opens new avenues for future research, including the investigation of the evolution of social networks overtime in people with chronic illnesses and, in particular, the association between the dynamics of engagement on the web in OHCs and illness self-management.

Abstract

Background: COVID-19 has had a catastrophic impact in terms of human lives lost. Medical education has also been impacted as appropriately stringent infection control policies precluded medical trainees from attending clinical teaching. Lecture-based education has been easily transferred to a digital platform, but bedside teaching has not.

Objective: This study aims to assess the feasibility of using a mixed reality (MR) headset to deliver remote bedside teaching.

Methods: Two MR sessions were led by senior doctors wearing the HoloLens headset. The trainers selected patients requiring their specialist input. The headset allowed bidirectional audiovisual communication between the trainer and trainee doctors. Trainee doctor conceptions of bedside teaching, impact of the COVID-19 pandemic on bedside teaching, and the MR sessions were evaluated using pre- and postround questionnaires, using Likert scales. Data related to clinician exposure to at-risk patients and use of personal protective equipment (PPE) were collected.

Results: Prequestionnaire respondents (n=24) strongly agreed that bedside teaching is key to educating clinicians (median 7, IQR 6-7). Postsession questionnaires showed that, overall, users subjectively agreed the MR session was helpful to their learning (median 6, IQR 5.25-7) and that it was worthwhile (median 6, IQR 5.25-7). Mixed reality versus in-person teaching led to a 79.5% reduction in cumulative clinician exposure time and 83.3% reduction in PPE use.

Conclusions: This study is proof of principle that HoloLens can be used effectively to deliver clinical bedside teaching. This novel format confers significant advantages in terms of minimizing exposure of trainees to COVID-19, reducing PPE use, enabling larger attendance, and delivering convenient and accessible real-time clinical training.

Introduction

The initial outbreak of SARS-CoV-2 in Wuhan, China, in December 2019 developed into a global pandemic with an unavoidable collateral impact on postgraduate medical education. As of March 6, 2022, almost 446 million confirmed cases of COVID-19 and over 6 million deaths have been reported in 226 countries [1]. Further to this catastrophic impact measured in human lives, the pandemic has engendered major organizational change in health care systems and had significant economic impacts [2].

Bedside teaching plays an important role in medical education for postgraduate doctors with evidence of benefit to trainees, patients, and clinicians [3]. Despite increasingly sophisticated and capable diagnostic investigations, good history taking and clinical examination remain a core part of the diagnostic process [4].

Stringent infection control policies were introduced in hospital settings with the aim of preventing nosocomial spread of infection and protecting health care workers. These involved use of personal protective equipment (PPE), minimizing clinician contact, and social distancing. These necessary precautions had an impact on traditional forms of medical education. Social distancing has precluded students and junior trainees from gathering for teaching and clinical rotations have been cancelled.

The clinical environment in which students would usually acquire practical skills and form their professional identity was severely restricted by infection control policies during COVID-19 [5]. In a survey of 152 junior doctors in May 2020 at a UK teaching hospital, only 21.1% of participants felt that their educational needs were being met during the COVID-19 period. Learning opportunities have become fewer as operations have been cancelled and clinics transitioned to telemedical modalities. Despite this, bedside teaching has not undergone the same degree of digital transformation. However, novel telemedicine technologies may provide a solution to this challenge.

Augmented reality (AR) merges the virtual world and real world—the “display of an otherwise real environment is augmented by means of virtual (computer graphic) objects” [6]. Mixed reality (MR) is a subtype of AR where these digital objects can be manipulated and interacted with in real time as if part of the real world.

HoloLens 2 is an MR head-mounted device developed and marketed by Microsoft Corp. The headset combines several types of sensors to provide a true “heads-up display” with the ability to place virtual “hologram” objects within the user’s visual field. It also permits live bidirectional communication via video, MR composites, and voice with multiple remote users.

In a clinical setting, this allows the wearer of the device to share their clinical interaction remotely with multiple connected users as well as display and manipulate “holographic” images (within the real environment) that can also be collaboratively interacted with by the remote users.

In simple terms, this allows the patient interaction to be observed remotely by multiple trainees; in addition, participants can display and collaboratively interact with a multitude of clinically relevant “holograms” such as blood results, radiological images, or educational figures [7]. This remote yet intrasituational learning confers specific benefits in the context of the COVID-19 pandemic in terms of reducing risk of contagion and economizing PPE, especially for “nonessential” tasks.

HoloLens and similar MR devices have already been trialed in medical education, specifically for teaching anatomy [8,9]. A recent pilot study at this center demonstrated that the use of HoloLens during the COVID-19 pandemic for direct clinical care reduced time exposure of staff caring for patients with COVID-19 by 51.5%, with an 83.1% reduction in PPE use [10].

The aim of this study was to assess the feasibility of using a HoloLens device and the MR environment to deliver remote bedside teaching to trainee doctors to support the delivery of higher-quality care during the COVID-19 pandemic.

Methods

Overview

The MR sessions were led by senior specialty registrars (the clinical trainers). The clinical trainers were senior specialty trainees who regularly delivered bedside teaching prior to the introduction of social distancing rules.

Patients with demonstrable pathology or interesting histories, who would normally have been recruited for in-person bedside teaching, were selected. Patients were required to have the capacity to consent to use of the HoloLens headset and be able to communicate with the clinician. Social distancing would normally preclude junior doctors from observing these educational consultations. HoloLens was therefore used opportunistically to allow trainees to virtually attend while adhering to infection control rules.

Trainers received a briefing and had 10 minutes of practice time using the HoloLens device. The practice time included completion of the inbuilt training program by the trainers. Following this, a simulated call was set up to allow the trainer to familiarize themselves with the device.

The HoloLens headset, in collaboration with the local infection prevention and control team, was incorporated as personal protective eye protection (Figure 1) with a decontamination protocol [10].

Figure 1. HoloLens used as part of personal protective equipment (simulated using staff for patient confidentiality, presented with consent by Jabed Ahmed and authors AS and AG).

Ethical Considerations

Local institutional registration and approval was obtained, and data governance, infection prevention, and control procedures were agreed upon prior to the commencement of the project. No additional ethical approval was required as the project was conducted as a technology-led quality improvement project under the supervision of the institutional quality improvement team. No patient identifying images are provided (situations were simulated by authors and consent for the publication of the images was given). Informed consent was received from the patients by the clinical trainer to allow trainee remote observation prior to the remote session.

Remote Bedside Teaching Sessions

Approximately 4-6 trainee doctors participated via a secure, two-factor authentication video link system (Microsoft Teams) and connected to the session on a trusted computer with webcam enabled.

On entering the patient's room, the trainer placed a fixed "hologram" of the trainee doctors "attending" adjacent to the

patient, allowing bidirectional video and audio communication between the trainer and trainee doctors during the consultation (Figure 2). This was also supported by a chat function beside the "hologram." This allowed the trainees to communicate in two ways: by voice or by typing via the chat function, which appeared on the screen of the trainer, where the trainee doctors could type questions and responses. The trainee doctors were also able to select radiological images and educational figures to superimpose on the real view at the trainer's request, which would be visible for all attendees.

Two sessions were carried out. The first session reviewed a 28-year-old male presenting with bloody diarrhea and a likely flare of ulcerative colitis; this session was led by a gastroenterology specialist trainee. The second session reviewed a 62-year-old presenting with double vision and a likely third nerve palsy; this session was led by a neurology specialist trainee. Both trainers were due to clinically review the patient. Thus, these reviewers were used opportunistically for teaching so as not to increase exposure risk.

Figure 2. First-person view from the trainer wearing the HoloLens and the same view seen by remote attendee. Video and audio bidirectional communication with trainees occurs through the right screen. Relevant clinical images are shared on the left screen. Both "holograms" can be manipulated by hand gestures (simulated using staff for patient confidentiality, presented with consent by Javed Ahmed and authors AS and AG).

Ward Round Format

Gagné's [11] principles of instruction, Ker et al's [12] six questions for planning teaching ward rounds, and Abdool and Bradley's [13] work on improving medical teaching rounds were used to design the format for the HoloLens teaching ward round. Key parts of both papers were used to inform the structure of the session.

Prior to entering the patient's room, aims for the session were established by the group. The trainer then presented the initial vignette of the case, moving on to an open discussion of potential history questions and relevant clinical examination. This allowed the initial principles Gagne described to be fulfilled (ie, "gain attention of students, stimulate recall of prior learning, and provide learning guidance" [11]).

The instructor then entered the room. A history and clinical examination was taken, with participants encouraged to ask questions verbally or using the Teams chat function to most closely simulate an in-person bedside teaching session. Discussion of the case was aided by superimposition of relevant images as additional "holograms," such as endoscopy images demonstrating the patient's inflamed mucosa and diagrams showing the anatomy of the colon.

The session was then concluded away from the bedside. Questions were "scaled up the hierarchy," as described by Abdool and Bradley [12], where simpler questions were asked to more junior members of the team and harder questions to more senior members to allow for the broad spread of attendees. Key learning points were discussed and documented collaboratively using the chat function during the reflection phase.

Outcomes

Trainee doctor conceptions of bedside teaching, impact of the COVID-19 pandemic on bedside teaching, and technical success of the session were evaluated anonymously using pre- and postround questionnaires using Likert scales (from 1-7) and open questions.

Cumulative data regarding exposure to at-risk patients and use of PPE were calculated for the virtual sessions against the projected exposure and PPE use for in-person teaching.

Results

A total of 24 participants answered the pre-session questionnaire, of which 19 were junior doctors and 4 were specialist trainees. Table 1 summarizes their responses. Participants strongly agreed that bedside teaching is key to educating clinicians (median 7, IQR 6-7). It was also apparent that bedside teaching had been severely affected by the COVID-19 pandemic, becoming a rarity (median 2, IQR 2-4).

Session 1 had 6 participants and session 2 had 4 participants, all of whom had answered the prequestionnaire. There were 3 interim foundation doctors, 5 foundation year 1 doctors, and 1 registrar. Table 2 summarizes their responses to the postteaching questionnaire. The first session was affected by a loose microphone connection and this was reflected by participants strongly disagreeing (median 2.5, IQR 1.25-3) that they were able to see and hear the patient-clinician interaction as if they had been present in person. In the second session, with the issue rectified, the quality of video and audio allowed respondents to appreciate subtle clinical signs and most strongly agreed that they felt like they were physically present (median 7, IQR

6.75-7). Feedback regarding session engagement, usefulness, and quality was positive across both sessions.

Both teaching sessions were undertaken with at-risk patients with COVID-19 in the rooms. Session 1 and 2 lasted 26 and 33 minutes, respectively. Cumulative clinician exposure to at-risk patients was 59 minutes versus 288 minutes had bedside

teaching occurred in person. This was equivalent to a 79.5% reduction in exposure. Furthermore, 10 pieces of disposable PPE (gown, apron, gloves, and mask) alongside the HoloLens were used to facilitate teaching versus 60 pieces of disposable PPE had bedside teaching occurred in person. This was equivalent to an 83.3% reduction in PPE use.

Table 1. Respondents' scores to the pre-session questionnaire.

Prequestionnaire questions	Respondents' scores (n=24), median (IQR)
In my past experience, teaching occurs on ward rounds	4 (3-4) ^a
In my recent experience, during the COVID-19 period, teaching occurs on ward rounds	3 (2-3.25) ^a
Bedside teaching is key to educating clinicians	7 (6-7) ^b
I have had bedside teaching during the COVID-19 period	2 (2-4) ^a
I feel able to ask the senior clinician educational questions during ward rounds	4.5 (3-5.25) ^b

^aDenotes Likert scale scores ranging from 1=never to 7=every day.

^bDenotes Likert scale scores ranging from 1=strongly disagree to 7=strongly agree.

Table 2. Respondents' scores to the post-session questionnaire.

Postquestionnaire questions	Respondents' scores, median (IQR) ^a		
	First session (n=6)	Second session (n=4)	Pooled (n=10)
I was able to see and hear the patient-clinician interaction like I was in the room	2.5 (1.25-3)	7 (6.75-7)	4.5 (2.25-6.75)
The teaching was relevant to me	6.5 (6-7)	6.5 (5.75-7)	6.5 (6-7)
I found the clinician leading the ward round engaging as a teacher	7 (6.25-7)	7 (7-7)	7 (7-7)
I felt able to ask the clinician leading the ward round educational questions	7 (6.25-7)	6.5 (5.75-7)	7 (6-7)
I felt like my questions were answered	7 (6.25-7)	6.5 (6-7)	7 (6-7)
The session was helpful to my learning	5.5 (3.5-6.75)	6.5 (6-7)	6 (5.25-7)
In my opinion, the use of HoloLens in this context is worthwhile	5.5 (3.5-6.75)	6.5 (6-7)	6 (5.25-7)

^aAll answers presented as Likert scale scores ranging from 1=strongly disagree to 7=strongly agree.

Discussion

Principal Findings

This study is proof of principle that MR headsets can be used to deliver clinical bedside teaching with at-risk patients while reducing exposure risk and PPE use.

Objectively, there was a reduction in exposure and PPE use by clinicians. Subjectively, trainees agreed that they were able to ask questions, had their questions answered, and found the session helpful to their learning. Overall, all trainees agreed that the use of HoloLens was worthwhile in this context.

In the first session, the microphone was not plugged in correctly, which likely explains why trainees disagreed with the statement that they could hear the patient-clinician interaction as if in the room. This improved in the second session, when the microphone was appropriately plugged in and all trainees agreed with the statement.

A steep learning curve was observed, with trainers able to use the headset confidently after 1-2 practice sessions. This novel format may confer significant advantages in terms of minimizing

exposure of trainees and medical students to SARS-CoV-2, saving PPE, enabling much larger attendance than possible at traditional bedside teaching, creating an environment that is less intimidating for the patient, and enabling real-time application of learning to a clinical context (eg, by augmenting the headset view with educational figures).

A potential limitation of remote bedside teaching is the inability of the trainee to clinically examine the patient or appreciate signs themselves. The pandemic has necessitated such an approach as remote teaching was the best available surrogate to in-person teaching. It is unclear, however, if there is a difference in the educational impact of MR remote versus in-person bedside teaching. Similarly, the clinical cases chosen had signs that were appreciable remotely but some clinical signs require tactile feedback (eg, examining limb tone during a neurological examination, or auscultation for cardiac murmurs). On this latter point, we note that there exist digital stethoscopes that would allow sharing of auscultation findings and these are potentially compatible with a HoloLens.

This study itself was purely a feasibility trial and therefore it is difficult to comment on much beyond the technical feasibility to deliver a remote MR bedside teaching session.

Further research would be useful to ascertain the educational effectiveness of such an intervention using measures beyond subjective feedback. It is important to note that telemedicine is available in simpler and more accessible formats and the additional potential of the MR component, specifically to share educational figures and radiological images at the bedside, needs to be further investigated.

The pandemic has fostered innovation, with remote teaching becoming a normal part of medical postgraduate training. Remote training has demonstrated several potential benefits independent of the pandemic and social distancing. Reduction in travel is time-saving for trainees and has a positive impact on the carbon footprint. The digital nature of remote teaching allows for recording and increases accessibility, so trainees can watch at their own convenience and not miss out due to clinical commitments. Remote bedside teaching itself allows opportunistic examination of rare clinical signs normally limited

to physical attendees. Remote bedside teaching allows greater access to these rare and valuable learning opportunities.

The ability to create a virtual classroom at the bedside where learners can remotely attend a bedside clinical teaching session and relevant results images can be shared, interacted with, and discussed is a novel evolution of the traditional bedside teaching format. Its benefits in a pandemic situation are clear but its applicability outside of this context has potential and will need further investigation.

Conclusions

MR bedside teaching is technologically feasible and acceptable using the HoloLens platform. This confers significant benefit, allowing bedside teaching to continue while complying with stringent and necessary infection prevention strategies during the COVID-19 pandemic. Beyond the pandemic, there may indeed be additional benefits including the convenience of remote attendance and the introduction of educational “holograms” to the bedside. Further research into this exciting educational platform is warranted.

Abstract

Background: Empirical studies and systematic reviews have demonstrated the role of biological, cognitive, behavioral, and emotional factors in fatigue, pain, and urgency in inflammatory bowel disease (IBD). Behavioral management that addresses the cognitive, behavioral, and emotional factors offered alongside medical treatment is seldom available to people with IBD. Digital interventions provide a potentially scalable and cost-effective way of providing behavioral support to patients.

Objective: This paper aimed to describe the process of developing a supported digital self-management intervention for fatigue, pain, and urgency in IBD using theory and evidence-based approaches and stakeholder input.

Methods: The Medical Research Council framework for complex health interventions and a person-based approach were used to guide intervention development, consulting with 87 patients with IBD and 60 nurses. These frameworks informed the selection and use of a theoretical model that subsequently guided cognitive behaviorally based intervention content. They also guided the design of tailored digital intervention pathways for individuals with IBD that matched the predominant symptoms.

Results: A transsymptomatic cognitive behavioral framework of symptom perpetuation was developed for the symptoms of fatigue, pain, and urgency in IBD. A logic model was used to define the intervention techniques. Patient feedback and qualitative interviews refined the website content and functionalities, including the use of visual aids, email reminders, and graphical tracking of symptoms. Nurse focus groups informed the volume and delivery model of the therapist *facilitator* support. Ratings of acceptability out of 10 following feasibility testing (31/87, 36%) demonstrated accessibility (scoring 9.43, SD 1.040), ease (scoring 8.07, SD 3.205), clarity, and the relevant tone of the intervention. The final intervention comprised 12 web-based sessions (8 core and 4 symptom-specific), with one 30-minute facilitator phone call following session 1 and subsequent on-site messaging.

Conclusions: The use of theory and integration of stakeholders' views throughout informed the development of an evidence-based digital intervention for fatigue, pain, and urgency in IBD. This is the first web-based self-management intervention designed to address these multiple symptoms with the aim of improving the quality of life and reducing the symptom burden of IBD. The intervention is being tested in a large multicenter randomized controlled trial.

Introduction

Background

Inflammatory bowel disease (IBD) refers to both Crohn disease and ulcerative colitis, which are chronic relapsing–remitting inflammatory disorders of the digestive tract. IBD has a growing prevalence [1], with an estimated 5 million people worldwide and between 2.5 and 3 million people in Europe alone diagnosed with IBD [1,2]. Periods of severe disease flare-ups can involve hospitalization and surgery [3,4]. During remission, it is common for people with IBD to continue to experience symptoms. The most commonly reported symptoms include fatigue, urgency and/or incontinence, and pain [5]. Fatigue is widely reported to have a disruptive impact on everyday functioning and quality of life (QoL) in IBD [6,7]. Similarly, urgency of defecation with or without frank fecal incontinence [8] and pain [9] are consistently cited as particularly burdensome symptoms. In a research priority setting exercise, both patients and clinicians have highlighted a better understanding and management of these symptoms [10].

Currently, the medical management of IBD alone does not always adequately treat these symptoms [11]. There is an observable disconnect between symptoms and the degree of gut inflammation in IBD, with evidence showing that even when disease activity is low, people can experience ongoing fatigue, pain, and urgency [12–14]. Research has demonstrated the complex, multidimensional, and multifactorial pathogenesis of these symptoms. Extensive evidence demonstrates the interactive role of specific cognitive, behavioral, and emotional factors in the experience of fatigue, pain, and urgency/incontinence in IBD [7,15,16]. These factors also affect the QoL of patients with IBD.

Cognitive Behavioral Therapy for Gastrointestinal Conditions

There is substantial symptom overlap among irritable bowel syndrome (IBS), another gastrointestinal condition, and IBD [17]. Individuals with IBS experience bowel-related abdominal pain and, often, urgency and fatigue. Cognitive behavioral therapy (CBT) is the most extensively researched psychological treatment approach, demonstrating efficacy in reducing symptom severity and enhancing QoL in patients with IBS [18–20]. CBT targets IBS-related concerns and introduces other psychological techniques such as relaxation and mindfulness to interrupt the vicious cycles of symptoms and psychological processes that perpetuate symptoms [18]. Preliminary research has demonstrated the feasibility of improving fatigue and pain using CBT in IBD [21,22]. This provides a rationale for the use of CBT in targeting fatigue, pain, and urgency in patients with IBD in remission. To date, most psychological interventions for IBD have been designed to reduce affective outcomes (ie, anxiety or depression) rather than targeting other symptoms that are burdensome for patients [23,24].

Engaging patients in their health-related decisions can result in better disease and QoL-related outcomes [24,25]. Web-based self-management resources provide a means for patients to be more involved with their care, with greater scope for accessing

information and engaging with their care pathways [26]. However, attrition is recognized as a significant issue in IBD web-based intervention studies, with several contributing factors, including a lack of direct contact with a health care professional [27]. A European consensus statement [28] indicated that IBD nurses might be well placed to facilitate self-management and psychological support for patients experiencing fatigue, pain, and incontinence. As such, combining web-based programs with IBD nurses acting as intervention *facilitators* may empower patients while reducing attrition rates and increasing the effectiveness and cost-effectiveness of an intervention [29].

Theory-Driven Intervention Development

To develop a theory-driven and evidence-based intervention with maximum opportunity for wider implementation, it is necessary to draw upon intervention development frameworks. A recently published taxonomy of approaches to developing interventions to improve health suggests that there are 2 key ways of designing and creating an intervention, one of which prioritizes working with the target population and the other which focuses on theory [30]. The 2008 Medical Research Council (MRC) guidance on the development of complex interventions is a framework guiding the use of theory to inform intervention development [31]. This process is iterative, including the identification of the evidence base, systematic development of theory, modeling processes and outcomes, and feasibility and pilot testing in the development stage. The *person-based approach* is an intervention development framework that prioritizes input and guidance from the target population [32]. This uses in-depth qualitative approaches to understand the behavioral aspects of user engagement with interventions. It addresses user-centered design and feedback as an integral aspect of intervention development. This enables developers to summarize design features that are likely to be important, appealing, and persuasive for intended users to guide principles for intervention development.

Currently, there is no guidance on how to integrate both theory-based and target population–driven approaches. Normalization process theory (NPT) is an approach that focuses on factors that are likely to facilitate and inhibit the implementation of complex interventions into practice [33,34]. It recommends consulting with the target population and key stakeholders to ensure the acceptability and ease of implementation of the intervention. For example, a lack of adequate consultation with health care professionals can result in design flaws that reduce health care professionals' readiness to support the intervention and its applicability and feasibility within health care settings [35]. The involvement of end users in the development of web-based interventions in IBD outpatient settings can reduce resistance and other barriers to adoption [25,36]. Methods available for gathering input from the target population within a person-based approach include (1) using stakeholders as research participants, where data (quantitative and/or qualitative) are drawn from participants and inductively analyzed by researchers, and (2) involving stakeholders as research partners in patient and public involvement (PPI) activity, where they actively direct and inform the research processes [37].

Aims of the Paper

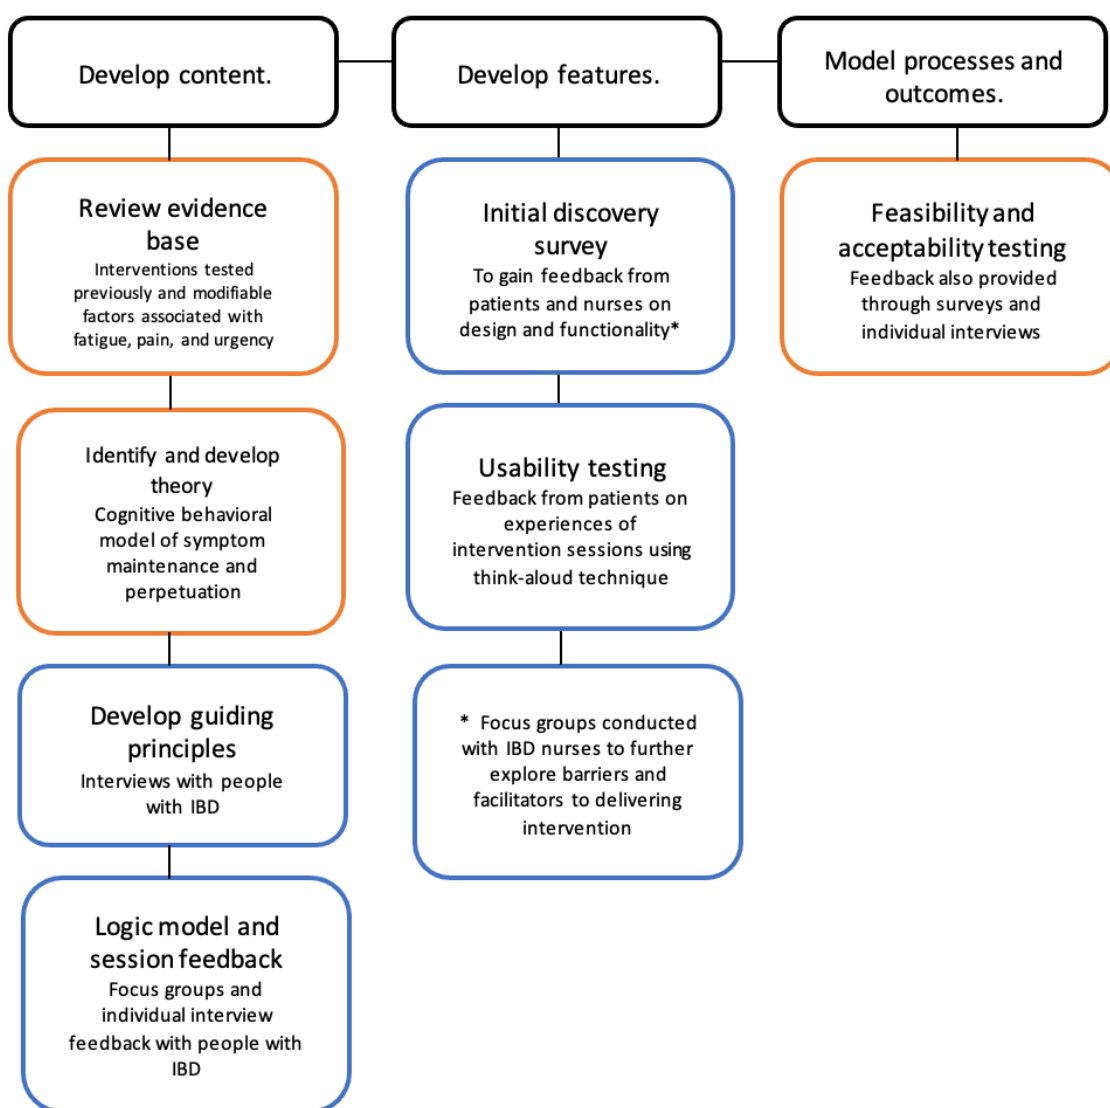

The aim of this paper is to describe the use of the MRC complex intervention framework alongside an NPT-guided person-centered approach to develop a theory and empirically driven facilitator-supported, tailored, digital cognitive behavioral intervention for fatigue, pain, and urgency/incontinence in IBD called IBD-BOOST.

Methods

Overview

The 2008 MRC guidance (the most recent, available guidance at the time we began the project) [31] and the person-based approach to intervention development [32] were combined into 3 areas to inform the intervention development sequence, as depicted in Figure 1. These areas of development were not sequential but iterative, allowing for amendments and updates throughout the intervention development process.

Figure 1. Intervention development stages as recommended by the Medical Research Council guidance (orange) and person-based approach (blue). IBD: inflammatory bowel disease.

Stakeholder Engagement

We consulted key stakeholders (patients and nurses) during the qualitative interviews and PPI activities. Qualitative interviews were conducted in 5 focus groups and in individual interviews with people with IBD to explore experiences of the 3 symptoms and the thoughts of people with IBD on a web-based

intervention for fatigue, pain, and urgency/incontinence. These qualitative findings have been reported in full elsewhere [38,39].

PPI activity included consultations with 87 people with IBD and 60 IBD nurses participating in PPI. Some members of the PPI bank were approached multiple times for feedback and testing purposes. A summary of the participants in each type of PPI activity across each development phase is depicted in Table 1.

Table 1. Summary of stakeholder involvement at each intervention development stage^a.

Intervention development stage	People with IBD ^b (n=87), n (%)	Nurses (n=60), n (%)
Patient survey to gather initial insight on functionality and design of the intervention	56 (64)	— ^c
Patient survey on intervention name options	20 (23)	—
Patient surveys (thrice) on the web-based intervention logo	20 (23)	—
Patient survey on illustrations and character names	14 (16)	—
Initial discovery interviews to gather key characteristics of the target users	5 (6)	—
Focus groups (twice) on the intervention logic model and session overview	4 (4)	—
Intervention paper session content feedback questionnaires		
Sessions 1-3	5 (6)	—
Sessions 4-6	4 (4)	—
Symptom-specific or summary session	3 (3)	—
Session 1 usability testing think-aloud interviews	10 (11)	—
8-week patient feasibility testing of the entire program	31 (36)	—
My Tasks page usability testing think-aloud interview	4 (4)	—
IBD nurse survey on training and resource needs to support the intervention	—	45 (75)
IBD nurse focus groups to gather views on intervention support and training needs	—	60 (100)

Developing Content

Identifying the Evidence Base for Potentially Modifiable Cognitive Behavioral Factors

The MRC framework [31] recommends identifying the relevant evidence base for an intervention. Systematic reviews of nonpharmacological interventions for fatigue, pain, and urgency/incontinence in IBD were completed by members of the team before developing the intervention. These informed the nature of the problem (symptoms of fatigue, pain, and urgency/incontinence), their causes, and the key modifiable factors with the greatest scope for change. Papers identifying cognitive, behavioral, and emotional factors related to symptoms were collected to inform the development of a CBT-based intervention. Gaps in the literature were also identified and addressed in subsequent empirical studies designed to explore and develop a conceptual understanding of the symptoms individually.

Identifying Theory and Components of the Intervention

Theoretical models used in interventions for fatigue, pain, and urgency/incontinence in related long-term conditions were identified. An overarching cognitive behavioral model was created transsymptomatically (for fatigue, pain, and urgency). This entailed (1) theoretical development to incorporate distinct and overlapping cognitive, behavioral, and emotional factors associated with symptoms; (2) development of an intervention logic model to identify treatment targets; and (3) consulting treatment protocols previously shown to be effective for symptom management in other long-term conditions.

Developing Guiding Principles

Interviews were conducted with PPI members (people with IBD) to inform initial intervention planning and gather views on the intervention content elements. A total of 5 interviews were conducted with people with IBD to develop *guiding principles* for the intervention. This informed us of what needs were being addressed and what contextual factors the intervention should take into account (illness experience and access to care).

Developing a Logic Model and Session Feedback

An outline for the intervention was created by combining the findings from theory and user consultation, as described in the 2 previous sections. The PPI groups then provided feedback on the logic model for the intervention and session plans. Of the 87 patients, 5 (6%) people gave feedback on sessions 1 to 3, and 4 (5%) gave feedback on sessions 4 to 6, whereas 3 (4%) gave feedback on the symptom-specific and summary sessions. Individuals were provided with a paper or electronic document version of their assigned sessions and asked to read through the content and exercises and provide feedback through a feedback form before returning to the study team. The feedback was used to inform adaptations of the intervention structure and content.

Developing Features

The person-based approach [32] was also used to inform the development and refinement of the features of the web-based intervention to aid uptake and meet the needs of the patients. Approximately 64% (56/87) of people with IBD and 75% (45/60) of IBD nurses responded to an initial survey to inform intervention functionality and design elements, such as the

program name and logo, as well as the intervention format. Items included “how much time per week would you be able to spend on the programme?” and “if you were to give a name [label] to the tasks to complete between sessions, what would it be?” Focus groups were conducted with nurses to better understand contextual factors, such as barriers and facilitators related to supporting patients in the intervention, to optimize the implementation of the intervention as recommended by the NPT.

Once the draft intervention sessions had been developed, usability testing think-aloud interviews were conducted to collect feedback on usability, function, and perceptions of intervention content. This is where verbalized thoughts from users were provided while they interacted with an interface and its features [40]. A total of 10 think-aloud usability testing interviews were conducted to understand the experience of using session 1 for people with IBD.

Modeling Processes and Outcomes: Testing the Feasibility and Acceptability of the Intervention

The MRC guidance identifies *modeling processes and outcomes* as a key part of intervention development. This involves testing the feasibility and acceptability of the intervention. Guidelines on how to model processes and outcomes are limited [41]. This step was aimed at assessing whether and how the intervention functions to deliver the desired outcomes. As this intervention was developed as part of a program grant, the substantive part of the assessment of processes and outcomes came after the intervention was developed and is being assessed in multiple stages [22,42]. However, initial assessments of the feasibility of the intervention were included in the preliminary intervention development process. This included people with IBD (31/87, 36%) who were given access to the entire intervention for a period of 8 weeks and who provided feedback through web-based surveys or telephone calls after 1 week (30/31, 97%), 4 weeks (24/31, 77%), and 8 weeks (21/31, 68%; decrease because of dropout at follow-up). People were asked to give feedback after using the intervention alone so that their experience would not be influenced by the presence of a researcher [43].

Ethics Approval

The study was carried out in accordance with the 18th World Assembly, Helsinki 1964, including later revisions and other relevant ethical guidance, which provide recommendations for physicians involved in human subjects research. IBD-BOOST obtained ethical approval (19/LO/0750) from a recognized National Research Ethics Service Committee and Health Research Authority.

Results

Stakeholder Engagement

Stakeholder input was used iteratively at multiple stages during intervention development. Therefore, it is detailed in the subsequent sections.

Developing Content

Review of Nonpharmacological Interventions

A review of the literature on nonpharmacological interventions for fatigue, pain, and urgency in IBD demonstrated a lack of theoretically grounded interventions with demonstrable efficacy for improving these outcomes. A Cochrane review included only 5 nonpharmacological interventions for IBD fatigue [44], including electroacupuncture, CBT, solution-focused therapy, and advice on physical activity. The studies were rated as low quality. There was a similarly limited and heterogeneous pool of studies with small sample sizes for IBD pain [45]. For fecal incontinence, no studies have directly tested a psychological intervention in IBD; however, the limited evidence available suggests that once active disease and differential diagnoses have been ruled out, individualized management for each patient targeted at improving QoL is recommended [46].

Relevant Theory and Associated Empirical Evidence

A cognitive behavioral model of symptom perpetuation was identified as a framework from which to understand and create changes across fatigue, pain, and urgency. The cognitive behavioral model postulates that the way individuals think about and perceive their experiences (symptoms) affects how they feel and consequently respond to them [47]. Interventions that target unhelpful thoughts about symptoms and unhelpful behavioral responses have the potential to improve distress arising from symptoms and improve the symptoms themselves [48]. Although physiological triggers may differ, similar affective, cognitive, and behavioral responses to symptoms appear to exacerbate and maintain symptoms across long-term conditions [49]. A number of systematic reviews have identified specific cognitive, behavioral, and emotional factors associated with fatigue, pain, and urgency, along with other psychological factors [7,15,16,50,51]. Anxiety and depression were found to be associated with each symptom independent of disease activity.

Common cognitive factors associated with fatigue, pain, and urgency include negative perceptions of symptoms and catastrophizing [52-54]. Behavioral factors shared across the 3 symptoms included avoidance of activity, generally because of anxiety about outcomes specific to the symptoms [53,55-57]. Boom-bust patterns of behavior, which are common in other long-term conditions, including IBS [58,59], were also identified in studies exploring IBD pain and fatigue [52,53,55,56,60]. In IBD, pain, acceptance, pain self-efficacy, and mental well-being are associated with lower pain severity and pain-related disability [53,56]. A range of safety-seeking and avoidance behaviors designed to avert the possibility of incontinence was identified as often having a significant cognitive and affective burden [8,16,61,62].

Developing a Logic Model and Session Feedback

Overview

The overlapping and distinct psychological factors associated with symptoms of fatigue, pain, and urgency in IBD were summarized and informed a draft of an intervention logic model (Figure 2) and a protocol of intervention sessions. Intervention

techniques used in cognitive behavioral interventions were mapped onto the identified psychosocial factors (Figure 3). For example, graded activity and goal-setting techniques were used to target avoidant and all-or-nothing behaviors. Stress management techniques and identifying or challenging thoughts through diary monitoring were applied to reduce distress and unhelpful thoughts (catastrophizing and fear avoidance), respectively. A cognitive behavioral model of symptom perpetuation has been applied in interventions for chronic symptom management in other long-term conditions [63-65]. Consequently, protocols and manuals used for these prior interventions were consulted (with the authors' permission) to provide preliminary guidance on the session structure and format.

Although cognitive behavioral techniques were applied to target psychosocial factors relevant across symptoms, it was critical to understand the key distinctions and influential factors for specific symptoms. For example, the likelihood of incontinence is higher than that in other gastrointestinal conditions such as IBS *because of* factors such as internal and external sphincter defects, surgery (eg, anal fistula), and loose stool [8,16,66,67]. Therefore, targeting *safety behaviors* and avoidance in IBD, as is commonly done in CBT for IBS [19], required a tailored approach appropriate for the degree of incontinence experienced in IBD. Furthermore, behavioral strategies to improve incontinence may include exercises such as pelvic floor and sphincter exercises designed to improve muscle function and increase bowel control [68]. This further supports the rationale for symptom-specific content and general content applicable across symptoms.

Figure 2. Example of overlap and symptom-specific modifiable factors in inflammatory bowel disease identified from the evidence base (systematic reviews and empirical evidence).

Patient-Identified Intervention Development Needs

From the 5 interviews conducted to develop *guiding principles*, newly diagnosed people reported inconsistent access to clear and reliable sources of information on IBD and barriers to finding guidance that matched their unique experience of symptoms. People with a longer time since diagnosis expressed the need to better track their symptoms over time to identify patterns and better understand the impact of psychological factors on symptoms. All interviewees voiced the need to confront their experience with others' experience of IBD and find ways in which to feel more socially supported and validated in relation to their symptoms. Dibley et al [39] further explored intervention needs for people with IBD in qualitative research focus groups, and the findings are described elsewhere

Logic Model and Feedback on Content in Paper Format

PPI participants (4/87, 4%) found the model (Figure 2) clear and comprehensive and could relate to the behaviors, thoughts, and emotions represented. They thought that all topics covered were valuable; however, unsurprisingly, people differed in which topics they perceived as more or less salient. Diet was identified as a missing topic and was therefore added to session 2. Participants expressed contrasting opinions on whether to make all sessions compulsory or allow the choice of which sessions to do. It was decided to make the core sessions compulsory to ensure an equal level of knowledge of the key topics for everyone in the program, with a choice of symptom-specific sessions.

Individuals reported the sessions as very helpful. They found the information accessible and concise but also comprehensive and informative. Interactive activities, patient stories, and quotes were identified as the most useful. The language was described as friendly, positive, and encouraging. However, participants suggested the need to reduce medical terms and simplify the language used in specific sections, such as those about the central nervous system and pain transmission.

Developing Features

Surveys on Design and Functionality

The results from the survey (n=101) indicated several desirable functionalities (summarized in [Textbox 1](#)), such as a preference

for completing the program on a mobile phone compared with a computer or tablet. People reported wanting the ability to complete the intervention in bite-sized chunks of time rather than in long sessions. Similarly, most suggested that they would be able to spend ≤ 60 minutes per week on the program. Key findings were the preferences of people with IBD to receive facilitator support via email or web-based messages over telephone and to conduct support sessions in the evening rather than in the daytime. By contrast, IBD nurses preferred to conduct support sessions during the day. These discrepancies further supported the use of focus groups with nurses to understand barriers and facilitators in supporting patients in the intervention ([Textbox 1](#)).

Textbox 1. Desirable content and functionalities incorporated and not incorporated in intervention and reasons why if not included.

Content and functionality incorporated into intervention

- Interactive diagrams and aids
- Reminders to log in and complete tasks
- Bookmark pages
- Videos
- Links to external resources
- Notepad
- Personal calendar
- Graphical symptom tracker
- Content around diet in irritable bowel syndrome (a small section on diet included in the activity or exercise session but did not lead to separate sessions, given the complexity of diet in irritable bowel syndrome and inconclusive evidence)

Content and functionality desired but not incorporated

- Mobile app (however, there is an ability to access BOOST website via mobile or tablet through a browser). Reason: The program was mobile phone optimized (ie, easy to few and for use on a mobile phone), but the cost of a mobile app was out of budget
- Discussion forum with other users. Reason: Time required to moderate discussion and confidentiality

BOOST was the most popular name for the program as people found it positive, optimistic, and supportive. The preference for the logo with an arrow pointing forward was because of its association with gradually becoming better and the lack of medical reference, which people found anxiety provoking. From the illustrations presented for the characters in the program, participants selected the most gender- and age-neutral ones. When given a choice of names, participants chose *Sam* and *Alex*. To ensure inclusivity and diversity, the name *Ali* was also chosen. An explanatory note about being inclusive and avoiding bias toward a particular gender was included at the beginning of the program.

Usability Testing Think-Aloud Interviews

People with IBD (10/87, 11%) liked the ability to take a break during the sessions, the short paragraphs of text on each page, and the video summary of the session content. By contrast, people struggled to see links on the pages, found it difficult to go back to the home page, and wanted the quotes to stand out more from the rest of the text. People also reported that some sessions were too text heavy. As a result, the color of the links was changed, a home button was added, and quotes were formatted with a yellow background. Optional text sections

were added to allow people to minimize or expand the amount of text to read.

Nurse Focus Groups

A total of 5 focus groups with 75% (45/60) of the nurses were conducted to understand the contextual factors that may influence the long-term implementation of the intervention. The use of *facilitator* was chosen over *therapist* as nurses were seen as taking a supportive rather than central role in the individual's participation in the program. The focus groups revealed the limited time and resources available to nurses for multiple phone calls and concerns regarding lack of training. Consequently, the intensity of facilitator support was modified from four to one 30-minute phone call, and a comprehensive facilitator training plan was developed. The results of these focus groups were analyzed using thematic analysis and are presented elsewhere [69].

Finalized Intervention

Following the stages of developing content and features, a complete intervention was finalized to be tested for feasibility and acceptability.

Program Content

The BOOST content comprises education and behavioral, cognitive, and emotional techniques. The individual is supported in developing a multifactorial understanding of the symptoms of pain, fatigue, and urgency that considers the triggers and maintenance factors. Participants would complete interactive assessments to create their own model of symptoms (vicious cycle) to identify possible behavioral, cognitive, and emotional factors that perpetuate their most distressing symptoms. The participants' vicious cycle was used as a rationale to implement behavioral, cognitive, and lifestyle changes targeted at reducing the impact of precipitating and maintaining factors. These include identifying unhelpful patterns and making changes to activity and exercise patterns, sleep hygiene, thinking strategies, management of stress and emotions, and approaches to relationships and communication with others. BOOST aims to equip participants with a variety of appropriate cognitive, behavioral, and problem-solving skills so that they can continue to make further progress after the program is completed.

Content and Structure

The program comprises of 12 web-based sessions (8 core sessions and 4 symptom-specific sessions). An overview of the content covered in each session and the associated tasks is presented in [Multimedia Appendix 1](#). Participants are advised to work through sessions, 1 at a time, at regular weekly intervals. The sessions are designed for participants to work through at their own pace, generally taking between 30 and 60 minutes to complete.

The order of the core sessions was drawn from the principles used in 2 of our previous successful digital CBT interventions for symptom management [19,65]. The first session focuses on education about contributing factors to IBD symptoms alongside self-assessment to provide patients with a coherent understanding of how cognitive behavioral approaches can help reduce symptom severity and impact. The next 2 sessions focus on behavioral strategies in the context of balancing activity patterns (eg, avoidance or all-or-nothing behavior) and sleep focus. These tasks are more concrete and easier for most patients to engage in at the start. Sessions 3 and 4 use cognitive techniques to identify challenging, unhelpful thoughts about symptoms and personal expectations. Cognitive techniques can be more challenging as they require meta-cognitive abilities. Our previous work indicated that it is helpful to include these once people are well-engaged in the program. The final core sessions on managing stress and social support incorporated both behavioral and cognitive methods drawing from the methods or techniques addressed in the previous 5 sessions. All sessions were tailored to IBD, including patient vignettes and IBD-specific examples. Symptom-specific sessions revisited the *vicious cycle* in relation to the symptoms and provided specific psychoeducation and techniques (eg, physiological factors related to fatigue, acute vs chronic pain, and bowel retraining exercises for urgency).

Features

The sessions are designed to be interactive, with personalized pathways tailored to a participant's needs. Several features are

included to facilitate participants' completion of the intervention. These include a calendar where participants can input goals they are working toward, a virtual notepad where participants can write reflections on their progress, a goals section where they can review their weekly goals, a graphical representation of the impact of their symptoms on their daily activities over time, and personalized automated emails or SMS text messages reminding participants to log into the program. A paper copy of the intervention is also available, should participants request a PDF version.

Facilitator Support

The participants have access to a facilitator who supports them in their progress. Facilitators can manage their caseloads and see relevant patient information through the BOOST facilitator platform. All participants conduct a 30-minute phone call with their facilitator after completing the first session. In this initial call, the facilitator reviews the participant's vicious cycle of symptoms with the participant to help them reflect on and clarify the factors they have identified as potentially contributing to their symptoms and guide the participant to set goals for the program. Facilitators follow a checklist to structure phone calls with participants ([Multimedia Appendix 2](#)) and send weekly SMS text messages to provide support and encouragement. For example, facilitators may help participants identify goals or prompt reflection following a session. The participants are reminded at the end of each session to seek extra support in progressing through the program by sending a web-based message to the facilitator.

Facilitator Training

Facilitators are required to complete training for BOOST, which entails attending training sessions from the research team, developing basic cognitive behavioral skills through role-plays, and practicing the telephone session with a *practice patient* (a volunteer with IBD; [Multimedia Appendix 3](#)). Facilitators are provided with a facilitator training manual and receive individual and group supervision to discuss patient cases and reflections with a BOOST supervisor (health psychologist).

Modeling Processes and Outcomes: Feasibility and Acceptability Testing

Once the initial version of the web-based intervention was developed, 31 people with IBD (aged 18-65 years, female, 16/31, 52%, and with Crohn disease, 17/31, 55%) were given access to the full program for a period of 8 weeks and provided feedback on the program through web-based surveys or telephone calls after 1 (30/31, 97%), 4 (24/31, 77%), and 8 (21/31, 68%) weeks. First impressions from feasibility testing were positive, with participants commenting on the clean, bright, professional, and easy-to-use design and functionality of the website. Overall, sessions were rated as understandable, relevant, and having an appropriate tone and length and were recognized as helpful. Feedback was provided by participants following each session on how helpful, relevant, easy to navigate, and motivating they rated sessions ([Multimedia Appendix 4](#)). Setting and reviewing goals related to the content covered in the session were rated as easy to complete and useful. Participants often tracked the impact of their symptoms using the program's

symptom graph, which was rated as a useful tool for monitoring their symptoms over time. Although the tasks were rated as useful, the functionality and layout of the task page were identified as the areas that needed the most change. Therefore, additional usability testing was conducted with 13% (4/31) of the participants to obtain more detailed feedback on how to improve the page.

In addition, it was clear that certain features of the program were not used. Therefore, the visibility and accessibility of the vicious cycle, bookmarks, and notification settings were improved. There was no facilitator support during this testing phase; however, two-thirds felt that being able to contact a facilitator while working through the sessions would have been useful, and they would have been likely to contact them for reassurance, validation, and queries relating to the content. Overall, throughout the program, users were motivated to continue and were highly likely to recommend to a friend with IBD.

Discussion

Summary of Process

This paper describes the systematic application of theory, evidence, and stakeholder involvement in the development of BOOST, the first digital cognitive behavioral intervention, with the primary aim of lessening the impact of fatigue, pain, and urgency to improve the QoL of people with IBD. A review of the evidence suggests that the cognitive behavioral model of symptom perpetuation provides a valid framework for the intervention. A mapping of findings across empirical studies looking at cognitive behavioral correlates of pain, fatigue, or urgency in IBD identified core transsymptom factors to be targeted in the intervention, including creating consistent daily routines or activity patterns, regulating sleep, and identifying and challenging unhelpful thoughts about symptoms. Symptom-specific factors such as the role of practical exercises for managing urgency [16], acceptance of chronic pain [56], and fatigue-specific beliefs [60], were also identified. Content and therapeutic techniques were mapped to create an intervention logic model. A 12-session (8 transsymptom- and 4 symptom-specific) tailored, interactive web program was then built with patient and nurse facilitator dashboards. Stakeholder input from 87 people with IBD and 60 nurses informed the build throughout, including the content and features of the website. A feasibility study with 31 people with IBD confirmed that the acceptability of the program was high and suggested further modifications of some features and language, which were made.

The intervention's theory-based logic model provides a rigorous and transparent summary of the intervention processes and mechanisms, where identified modifiable psychosocial factors were mapped onto cognitive behavioral techniques to influence intervention outcomes. Logic models provided a sophisticated way of communicating program theory to both stakeholders and the research team, facilitated process and outcome evaluation in a randomized controlled trial (RCT) [70,71], and are recommended in the 2019 MRC guidelines. Although this guidance was published after the intervention development started, the actions recommended by O'Cathain et al [71] were

each addressed because of the complementary nature of the intervention approaches used (Multimedia Appendix 5).

The development of the intervention with stakeholders allowed the design team to ensure that an acceptable, personalized, and interactive intervention was developed. These features are recognized as essential components of self-guided web-based interventions to improve user experience and clinical outcomes in the context of chronic physical health conditions [72]. Feedback on sessions and tasks was positive, with individuals describing the content as relevant, understandable, and helpful. Suggestions for improvement led to key modifications to the intervention, such as the use of a graphical symptom tracker and a personal calendar to log goals. Feasibility testing of the intervention provided an opportunity to understand how relevant and user-friendly the content and intervention features were, respectively, and identify any limitations apparent to users. This subsequently led to further changes to improve the visibility and accessibility of website functions, reinforcing the iterative nature of development and evaluation.

Understanding users' needs (referring to both recipients and deliverers of the intervention), as recommended by the person-based approach and NPT, provided an opportunity to learn about the crucial contextual factors influencing intervention delivery. Focus groups revealed the limited time available to nurses to support the intervention, their preference for predominantly SMS text messaging or email communication, and the need for comprehensive training and supervision. They subsequently informed the intensity and modality of the facilitator support and training program. Understanding the day-to-day practices of IBD nurses was fundamental to optimizing sustainability and the likelihood of the intervention being adopted [73]. The provision of adequate training to support health care professionals in integrating web-based interventions into day-to-day practice has been emphasized elsewhere [74].

Conclusions

The development of complex health interventions evaluated in RCTs has often lacked transparent reporting of the development process. This paper describes the development of a digital, tailored, facilitator-supported self-management intervention based on a cognitive behavioral model of symptom perpetuation for patients with IBD and symptoms of fatigue, pain, and urgency/incontinence. It presents the integration of intervention development frameworks and how these were used to inform the use of theory, empirical evidence, and stakeholder input to develop a transsymptomatic intervention, with the aim of improving QoL and reducing symptom burden.

The lack of RCTs describing how their interventions were developed has been highlighted previously [75]. This paper provides a robust and transparent description of the development of a web-based intervention for symptoms of fatigue, pain, and urgency in IBD, with the aim of improving QoL and reducing symptom burden. This demonstrates the compatibility of combining the MRC framework and person-based approach, where evidence was identified, the theory was developed, mechanisms and processes were outlined, and user-centered feedback informed the intervention content and functionality.

This comprehensive and iterative approach to intervention development is argued to facilitate the effectiveness and efficacy of a complex health intervention and its long-term implementation [76]. BOOST is now being tested in a National Institute for Health Research-funded large-scale RCT [42].

Acknowledgments

This paper presents independent research funded by the National Institute for Health Research (NIHR) under its Program Grants for Applied Research Program (grant reference number RP-PG-0216-20001). The views expressed are those of the authors and not necessarily those of the NIHR or the Department of Health and Social Care. It also represents independent research, with RMM and LS partly funded by the NIHR Biomedical Research Center in South London, the Maudsley National Health Service Foundation Trust, and the King's College London.

Authors' Contributions

Intervention development was conducted by a team of health psychologists (MA, LS, and SW) under the guidance of RMM, a Professor of Psychology as Applied to Medicine, who has developed a number of evidence-based interactive cognitive behavioral therapy-based digital interventions for people with long-term conditions. CN, a Professor of Clinical Nursing Research and inflammatory bowel disease specialist, provided input and feedback throughout the intervention. The sections on managing urgency were based on her earlier work in this area. CN led the patient and public involvement or stakeholder work. People with a lived experience of inflammatory bowel disease provided input throughout, as described in the manuscript. LS and SW led the writing of the paper, and all authors contributed. RMM completed the final draft.

Conflicts of Interest

There is no specific conflict of interest with the product described in this paper. Outside of this submitted work, RMM is a beneficiary of a licence agreement signed between King's College London and Mahana Therapeutics for a digital cognitive behavioral therapy for an irritable bowel syndrome product. She receives personal fees from Mahana Therapeutics for scientific advisory work and from other universities and hospital trusts for cognitive behavioral therapy training in irritable bowel syndrome.

Abstract

Background: Due to scientific and technical advancements in the field, published hypertension research has developed substantially during the last decade. Given the amount of scientific material published in this field, identifying the relevant information is difficult. We used topic modeling, which is a strong approach for extracting useful information from enormous amounts of unstructured text.

Objective: This study aims to use a machine learning algorithm to uncover hidden topics and subtopics from 100 years of peer-reviewed hypertension publications and identify temporal trends.

Methods: The titles and abstracts of hypertension papers indexed in PubMed were examined. We used the latent Dirichlet allocation model to select 20 primary subjects and then ran a trend analysis to see how popular they were over time.

Results: We gathered 581,750 hypertension-related research articles from 1900 to 2018 and divided them into 20 topics. These topics were broadly categorized as preclinical, epidemiology, complications, and therapy studies. Topic 2 (*evidence review*) and topic 19 (*major cardiovascular events*) are the key (*hot topics*). Most of the cardiopulmonary disease subtopics show little variation over time, and only make a small contribution in terms of proportions. The majority of the articles (414,206/581,750; 71.2%) had a negative valency, followed by positive (119, 841/581,750; 20.6%) and neutral valency (47,704/581,750; 8.2%). Between 1980 and 2000, negative sentiment articles fell somewhat, while positive and neutral sentiment articles climbed substantially.

Conclusions: The number of publications has been increasing exponentially over the period. Most of the uncovered topics can be grouped into four categories (ie, preclinical, epidemiology, complications, and treatment-related studies).

KEYWORDS

hypertension; high blood pressure; machine learning; topic modeling; latent Dirichlet allocation; LDA; cardiovascular; research trends

Introduction

Hypertension, together with its repercussions, has been identified as a substantial public health concern. In recent years, there has been major growth in global hypertension research activities

[1,2]. Growing worries about the global epidemic of hypertension as well as the need to offer information to policy makers and decision makers on better prevention, treatment, and control have contributed to this growth [3]. Hypertension is a global health problem, according to the World Health

Organization, with an estimated one billion people having hypertension [4]. Hypertension-related diseases such as stroke and ischemic heart disease are among the leading causes of death worldwide. As a result, putting in place evidence-based prevention, early detection, and long-term control methods that reduce mortality and improve quality of life is unquestionably necessary.

There are a lot of studies on hypertension that have been published [1]. Reading and interpreting all of these publications using typical information retrieval and review methods would be time-consuming and labor-intensive, if not impossible. Finding more delicate themes and comprehending the complicated links between such publications is considerably more difficult, but it is necessary to determine whether or not studies are consistent. Machine learning-based literature mining enables the analysis of large collections of documents in a highly automated manner [5,6]. Model topic algorithms can uncover hidden or latent subjects from large document collections automatically [7]. Documents may speak for themselves by the unattended nature of latent Dirichlet allocation, and subjects emerge without human intervention [8]. The study aims to generate evidence on the evolution of hypertension research that could ultimately inform prioritization of research, financial investments, and health policy. The aim of the study was to use natural language processing techniques to provide overview of hypertension research topics over 100 years.

Methods

Methods Overview

We searched PubMed to obtain the records of all hypertension articles published in the last 100 years using the following search strategy: “(“hypertension”[MeSH Terms] OR “hypertension”[All Fields] OR (“high”[All Fields] AND “blood”[All Fields] AND “pressure”[All Fields]) OR “high blood pressure”[All Fields]). The title and abstract of each article were extracted and combined into a single string.

Phase 1: Preprocessing

To create a document-term matrix, each article was tokenized (divided) into a list of terms (words). Text was filtered to exclude common keywords with no analytical significance (prepositions, articles, pronouns), punctuations, and digits. Following that, stemming was done, which is the process of deleting frequent word ends (eg, “compression,” “compressed,” and “compressing” are converted to “compress”). The frequency of each word was normalized using the frequency of the most common word used in all articles that year, and a scale of 1 to 100 was produced (1 being most frequently used, 100 being least frequently used). The goal of normalization techniques like stemming and lemmatization is to reduce inflectional forms and sometimes derivationally related forms of a word to a common base form.

Phase 2: Topic Extraction

The preprocessed document-term matrix was then subjected to latent Dirichlet allocation. Latent Dirichlet allocation is a hierarchical Bayesian algorithm and one of the most common topic modeling approaches. Latent Dirichlet allocation identifies

theme subjects by looking for keywords that frequently appear together in a document. The model then uses the associations between terms to define two things: (1) themes that are each characterized by a distribution of words and (2) documents as a distribution of topics. As a result, latent Dirichlet allocation is well suited to assessing articles that cover a wide range of topics. Using a collapsed Gibbs sampler set to run for 5000 iterations, model parameters were provided to uncover 50 themes with high interpretability (Dirichlet hyperparameters: $\alpha=0.02$, $\eta=0.02$). After the model fitting was complete, topic numbers were allocated.

The probability distribution of words in each topic was then visualized and used to create word clouds. The top 15 most likely terms in each topic were then put into a word cloud, with greater font size and darker color indicating higher probability.

Topic popularity and dynamics were determined by dividing the total number of abstracts in each year by the cumulative sum of articles belonging to each topic, yielding a percentage of subjects in each year. The most popular themes in each article were also determined by assessing subject popularity by article. Using simple linear regression and Cochran-Armitage trend testing, a trend analysis was performed to identify themes with growing (“hot”) or decreasing (“cold”) popularity over time.

Phase 3: Topic-Based Sentiment Analysis

The first step in the sentiment analysis was to align the preprocessed text with the valence classification (eg, positive, or negative). The Emotion Lexicon [9] is a database that indexes the valence and emotion of over 4000 regularly used English lemmas. Most words in the vocabulary are classified as positive or negative. By summing the counts of positive and negative terms, the overall positive and negative valence for each item was computed. The ratios were calculated by dividing the number of positive words in each article by the number of nonstop words, and vice versa for negative words (scores ranging from 0 neutral to 1 highest). The final score was expressed as a percentage of positive or negative words compared to other important words in the article.

This study was based on an analysis of existing data collected from PubMed.

Results

Trends in Hypertension Research

A total of 581,750 articles on hypertension research were indexed between 1900 and 2018 in PubMed. As shown in [Figure 1](#), the number of publications has been increasing exponentially over the period. The studied period was divided into the following three stages: the first stage ran from 1900 to 1940 (average publication: 7 per year), the second stage ran from 1941 to 1990 (3000 per year), and the third stage ran from 1991 to 2018 (15,000 per year). The period from 1991 to 2018 was a rapid development period, accounting for almost 75% of all hypertension research (434,487/581,750, 74.7%). [Table 1](#) provides an overview of the 20 topics, the top 15 words of the

topics with their probabilities, and the manually attached label that best captures the semantics of the words.

Most of the uncovered topics can be grouped into four categories (ie, preclinical, epidemiology, complications, and treatment-related studies). Topic 12, *animal model*, is most prevalent in the *preclinical studies* category. It contains salient words like *rat*, *inhibit*, *mice*, and *cell*. Topic 2, *evidence review* is most prevalent in the *risk factors studies* category. It contains salient words like *disease*, *review*, and *prevent*. Topic 19, *major cardiovascular events* is most prevalent in the *complications studies* category. It contains salient words like *stroke*, *coronary*, and *mortal*. Topic 10, *antihypertensive*, and topic 18, *heart surgery* are both about pharmacotherapy and interventional cardiology.

The clustering topics are shown in Figure 2, connected topics based on the similarity of topic probability distributions over the documents. The topics that were more likely included in the same articles had a high level of similarity in distribution of topics over the documents and thus were paired or clustered

together. Several interesting clusters can be seen. Topics 5 (*human proteome*), topic 9 (*physiology*), and topic 20 (*genetic*) are paired, which means these articles are focusing on the pathophysiology of hypertension. Another example is topic 11 (*plasma renin activity*), topic 7 (*chronic kidney disease*), and topic 18 (*heart surgery*) was often discussed in the same articles. It is important to note that topic 15 (*maternal heart disease*) is the only topic not connected to other topics (ie, not usually discussed in the same article with other topics).

Figure 3 shows the temporal dynamics of the distributions of all topics. It demonstrates how the popularity of each topic has changed relative to other topics over time. The interpretation of these trends is speculative, but three categories of interest were identified: increasingly *hot* (topics 1, 2, 12, and 19), decreasingly *cold* (topics 3, 7, 10, 11, 17, and 18), and infrequently published topics (topics 4, 5, 6, 8, 9, 13, 14, 15, 16, and 20). Topic 2, *evidence review* and topic 19 *major cardiovascular events* are the key *hot topics*. Most of the cardiopulmonary disease subtopics show little variation over time, and only make a small contribution in terms of proportions.

Figure 1. Trends in the number of hypertension research indexed in PubMed, 1900 to 2018.

Table 1. Topic classification and keywords on hypertension.

Classification and topic name	Keywords	Articles, n (%)
Preclinical studies		
Topic 5: human proteome	cell, protein, human, activ, tissu, express, use, studi, factor, show, membran, model, peptid, antibodi, tumor	23,270 (4.0)
Topic 9: biochemical	plasma, method, use, concentr, sampl, determin, liquid, detect, extract, chromatographi, acid, human, metabolit, pharmacokinet, serum	32,578 (5.6)

Topic 15: maternal heart disease	women, pregnanc, hypertens, matern, gestat, infant, birth, fetal, preeclampsia, deliveri, neonat, studi, pregnant, outcom, group	14,544 (2.5)
Topic 19: major cardiovascular events	patient, risk, diseas, factor, associ, diabet, studi, stroke, age, year, mortal, coronari, cardiovascular, incid, use	40,723 (7.0)
Treatment		
Topic 10: antihypertensive	patient, treatment, hypertens, effect, therapi, drug, group, blood, pressur, studi, antihypertens, trial, control, combin, signific	45,958 (7.9)
Topic 18: heart surgery	patient, case, hypertens, surgeri, present, complic, report, surgic, portal, clinic, year, postop, vein, one, intracrani	49,449 (8.5)

Figure 2. The clustering topics.

Figure 3. Dynamics and trends of the topics.

Article Sentiment Analysis

Most of the articles were framed with a negative valency (414,206/581,750; 71.2%), followed by positive (119,841/581,750; 20.6%) and neutral valences (47,704/581,750; 8.2%). Yearly sentiment trends with hypertension articles are shown in Figure 4.

Negative sentiments articles decreased slightly between 1980 and 2000. While both positive and neutral sentiments articles

Figure 4. Dynamics and trends of the article valency.

Discussion

Principal Findings

In this study found that more than half a million articles have been published on hypertension worldwide between 1900 and 2018. We identified 20 distinct topics, which can be categorized broadly into preclinical, epidemiology, complications, and therapy studies. We used an unsupervised text mining methodology to find hypertension research topics and their dynamics in this study, which looked at publications indexed in PubMed during the last century. This study adds to our understanding of hypertension research focuses and their evolutionary patterns, and it may aid researchers, journal editors, and funders in identifying new or ignored trends from established themes, as well as freshly developing trends that can be evaluated in a structured way.

Our findings revealed that the majority of the topics discovered may be divided into four categories (ie, preclinical, risk factors, complications, and treatment-related studies). The important *hot* topics include topic 2 *evidence review* and topic 19 *major cardiovascular events*. The majority of the cardiopulmonary disease subtopics show little fluctuation over time and contribute a modest share of the total. In the eyes of the researcher, commonly published topics may represent a large body of knowledge, a common disorder, or a low-cost easy-to-study subject. On the other hand, less often published topics may represent the study of less common hypertension-related

disorders and subject matter that is difficult or expensive to research. Some pathophysiological research, for example, necessitates a substantial investment of time and resources as well as collaboration among physicians, biochemists, and physiologists. Similarly, some genetic disorders may be highly rare and have a high unmet demand, posing substantial therapy and research obstacles.

Risk, chronic, syndrome, failure, and severe were the more common negative sentiments words, whereas *healthy, effective, positive, survive, and improved* were the more common positive sentiments words.

disorders and subject matter that is difficult or expensive to research. Some pathophysiological research, for example, necessitates a substantial investment of time and resources as well as collaboration among physicians, biochemists, and physiologists. Similarly, some genetic disorders may be highly rare and have a high unmet demand, posing substantial therapy and research obstacles.

In the themes, we saw some intriguing clumping. Topics 5 (*human proteome*), 9 (*physiology*), and 20 (*genetic*) were paired, indicating that these papers were all on hypertension pathophysiology. Topics 11 (*plasma renin activity*), 7 (*chronic kidney illness*), and 18 (*heart surgery*), for example, were frequently mentioned in the same articles. It is worth noting that topic 15, *maternal heart disease*, is the only one that is not linked to the others because it is not mentioned in the same article.

Comparison to Prior Work

Although more than half a million hypertension research articles have been published in the past 100 years, only a few bibliometric articles have summarized the development and application of hypertension [10-12]. To better understand the development status, research hot spots and future development trends of hypertension, it is necessary to conduct a comprehensive retrospective analysis. In recent years, hypertension research has developed rapidly, and the amount of publications has increased exponentially. This may be due to the attention paid to the burgeoning burden of high blood

pressure in various countries to promote the widespread use of prevention and prompt treatment. Bibliometric analysis is an extremely useful tool despite its focus on international peer-reviewed journals; therefore, together with our theoretical and methodological approaches taken to identify relevant global publications and the data analysis used, we have a strong base on which to state that our study presents a comprehensive systematization of global hypertension research.

Implications for Practice and Further Research

This bibliometric analysis provides insight into the historical development of hypertension research. Scientific publications play an important role in the scientific process providing a key linkage between knowledge production and use. These data reveal a solid mass of research activities on hypertension. This study provides useful information to researchers and funding societies concerned in the implementation of research strategies to improve hypertension research. Additionally, the results of this study delineate a framework for better understanding the situations of current hypertension research and prospective directions of the research in this field that could be applied for managing and prioritizing future research efforts in hypertension research. Our study provides some novel insights useful for policy makers, researchers, and funders interested in advancing hypertension research agenda. International research collaborations and research networks should be encouraged to help prioritize hypertension research particularly in women. Our findings provide baseline data for scholars and policy makers to recognize the bibliometric indicators in this study as measures of research performance in hypertension for future policies and funding decisions. Finally, our study showed that bibliometric analysis is a good methodological tool to map published literature in a particular subject and to pinpoint research gaps in that subject.

Although topic modeling has previously been used to analyze medication safety research trends [13], we believe this is the first study to apply unsupervised machine learning to assess hypertension research subjects and patterns over the past century. The procedure of data analysis was rather objective. However, the majority of the papers included in the database were written in English, which means that relevant studies published in other languages may have been overlooked.

Strengths and Limitations

Our study had various advantages, including a thorough examination of hypertension research from a variety of medical specialties. Our study has a lot of limitations. For starters, we only looked at articles, reviews, and editorials published in academic journals indexed in PubMed as part of the study design. As a result, this research does not claim to represent all of the work done on this issue, some of which may have been published in other formats (eg, books, reports, and national journals). We also do not pretend to give exact numbers in terms of country contributions to global scientific production because we did not hand-search all of the retrieved papers to ensure their

relevance, though we believe our findings reflect broad trends in the hypertension research environment.

Furthermore, the primary source of this bibliometric analysis was international academic journals indexed in PubMed, and international journals are known to contain an English language bias, which may skew our results in favor of Anglo-Saxon countries or countries where the national research system encourages publishing primarily in these types of journals [14,15]; some non-Anglo-Saxon countries have national research systems that encourage and prioritize national publications. Despite bibliometric databases expanding their journal coverage, this may diminish the international awareness of the study and obscure the true volume of research undertaken in these countries. Scholars have speculated whether *editorial racism* exists in the evaluation and selection of manuscripts for publication in international journals, with prejudice against authors from the Global South, and Harris et al [16] showed (and measured) bias by health professionals and researchers against low-income countries' research compared to high-income countries' research [17,18]. Nonetheless, rising investment in research in the Global South that includes a greater emphasis on good methodology, research infrastructure, and high-quality presentation in terms of both writing and (English) language skills could potentially offset such peer prejudice [17].

While our findings are based solely on publications in international academic journals, they are important to consider because of the importance placed on publishing in international academic journals in academia, and how it is frequently used to inform decisions about international development, policy, and research agendas. Furthermore, our findings are likely to allude to the global dynamic within this field of study. Quantitative bibliometric results say nothing about the quality of research conducted in countries worldwide; more research is needed to contextualize our findings and provide in-depth insights into the types of theoretical and methodological approaches being used and where, as well as national research priorities, and to enrich the current understanding of the historical and structural determinants of global bibliometric trends and inequity. Finally, it is important to note that common lexicons for sentiment analysis have many limitations when applied to health literature. For example, "negative" terms in the used lexicon likely are not negative in scientific literature (eg, symptoms or inhibition), and some "positive" labels (eg, survival, advanced, and progressive) are more likely to have negative sentiment in hypertension-based literature.

In this publication, we report an empirical analysis that used latent Dirichlet allocation modeling to identify key research themes based on research published in hypertension publications. We also looked at the themes' dynamics and intellectual structure. The findings gave a complete overview of hypertension-related research subjects and highlighted how these issues have evolved over time. The findings of this study could help us better understand hypertension research trends and propose areas for further study.

Abstract

Background: Social media platforms that are based on the creation of visual media, such as TikTok, are increasingly popular with adolescents. Online social media networks provide valuable opportunities to connect with each other to share experiences and strategies for health and wellness.

Objective: The aim of this study was to describe the content of the hashtag #mentalhealth on TikTok.

Methods: This cross-sectional, descriptive content analysis study included 100 videos with the hashtag #mentalhealth on TikTok. All videos that included the hashtag #mentalhealth were analyzed and coded for the presence of content categories. Additionally, the comments to each video were viewed and coded for content in the following themes: offering support or validation; mentioning experience with suicide or suicidal ideation; mentioning experience with self-harm; describing an experience with hospitalization for mental health issues; describing other mental health issues; and sharing coping strategies, experiences of healing, or ways to feel better.

Results: Collectively, the 100 videos studied received 1,354,100,000 views; 266,900,000 likes; and 2,515,954 comments. On average, each video received 13,406,930.69 (SD 8,728,095.52) views; 2,657,425.74 (SD 1,449,920.45) likes; and 24,910.44 (SD 21,035.06) comments. The only content category observed in most (51/100, 51%) of the videos included in the sample was “general mental health.” The remaining content categories appeared in less than 50% of the sample. In total, 32% (32/100) of the videos sampled received more than the overall average number of likes (ie, more than 2.67 million likes). Among these 32 videos, 23 (72%) included comments offering support or validation and 20 (62%) included comments that described other mental health issues or struggles.

Conclusions: With over 1 billion cumulative views, almost half of the assessed TikTok videos included in this study reported or expressed symptoms of mental distress. Future research should focus on the potential role of intervention by health care professionals on social media.

KEYWORDS

TikTok; mental health; adolescent; social media; short video apps; content analysis; digital health; online health; visual media; descriptive content analysis; mental distress; health professional; health care professional

Introduction

Access to accurate and accessible health information, support, and services are required for effective health care

decision-making. This applies across the health care continuum and is inclusive of self-health promotion and participation in shared decision-making with health care provider teams [1-6]. Individuals rely on family, friends, and health care professionals

for support, yet seek health-related information online at the same time [7,8]. In general, adolescents live in a hybrid reality—a mix of offline and online worlds [9]. They are increasingly seeking information about healthy lifestyles (fitness, diet), gender identity, sexual health, and mental health issues from online websites, social media platforms, wearable self-tracking apps, and other adolescents within online communities [10,11]. However, adolescents are less accepting of online or wearable apps that require them to input information [7]. Overall, online media and social media apps are seen as simple to use, unidentifiable, and impartial sources of health information by adolescents [7,12]. Health-related stories from peers are particularly valued among adolescents [7,13]. Influencers on social media, adolescents who create content, and microcelebrities are increasingly important resources for health-related information and social support [7,14-16]. However, adolescents may find the sheer volume of online information challenging and are not always confident in their ability to discern accurate information from misinformation or disinformation [7].

Social media platforms that are based on the creation of visual media, such as TikTok, are popular with adolescents. TikTok, a video-based social media platform, has been leveraged as a way to disseminate health-related information, and this has been especially visible during the COVID-19 pandemic [17]. The vast reach of TikTok worldwide offers a unique approach for disseminating information to the millions of users ranging from children to adults. As a social media platform, TikTok creators combine music and dance attached to personal messages that are widely disseminated [17].

Several studies have been conducted on the health-related content on TikTok. These studies indicate that a wide range of issues have been examined, including health promoting and compromising issues. Examples include, but are not limited to, studies related to COVID-19 mitigation, eating disorders, vaping, climate change, and equity issues [12,18-26].

Specific to mental health information and social support, researchers determined that youth and young adults appreciated shared experiences within online discussion forums, citing accessibility, anonymity, inclusivity, sense of control, and mitigation of stigma as valued resource characteristics [12]. Preference for seeking health information online or through peer-to-peer sharing can reflect individuals' concerns or experiences with nonaffirming or discriminatory health care providers [12]. Furthermore, peer-to-peer health information sharing may fill the gaps in social support from health systems, health-specific information, and insight into "how to live" with chronic diseases including mental health. In particular, select TikTok videos may serve as relevant educational resources for health care professionals' education and training [12]. However, research exploring mental health content on TikTok is essentially absent from published research literature.

Online social media networks provide valuable opportunities to connect with each other to share experiences and strategies for health and wellness, such as meditation, mindfulness, stress relief, and those specific to mental health conditions [13]. Mental health issues are highly prevalent in adolescents. According to

the World Health Organization, "globally, one in seven 10-19-year-olds experiences a mental disorder, accounting for 13% of the global burden of disease in this age group" [27]. Given these statistics, combined with the popularity of TikTok use in this age group [28], the aim of this study was to describe the content of the hashtag #mentalhealth on TikTok.

Methods

Data Collection and Analysis

This cross-sectional, descriptive content analysis study included videos with the hashtag #mentalhealth on TikTok. The methods were based on prior research and established methodology [24,29,30]. By using the "discover" function on the TikTok platform and a hashtag search of #mentalhealth, a sample of the first 100 videos was collected. At the time of the study, the hashtag had 25.3 billion views. This was the most viewed hashtag in this area at the time of the study (January 2022). Only English-language videos were considered for this sample. For each video, the date of posting and the number of views, comments, and likes were documented. All videos that included the hashtag #mentalhealth were analyzed and coded for the presence of additional content categories. The content categories included general mental health (nonspecific disorder), anxiety or fear, depression, stress, suicide, self-harm, interpersonal relationships, physical health conditions or variables, child or adolescent mental health, mental health stigma, statistics and the prevalence of mental health disorders or issues, biological and neurological influences of mental health, missing other people or connections due to COVID-19, personal experience, and coping techniques or treatment.

Additionally, the comments associated with each video were viewed and coded inductively for content in the following themes: offering support or validation; mentioning experience with suicide or suicidal ideation; mentioning experience with self-harm; describing an experience with hospitalization for mental health issues; describing other mental health issues or struggles; and sharing coping strategies, experiences of healing, or ways to feel better. All data were collected, categorized, and organized by a single reviewer (CJ), and a random number generator was used to identify a subset of (10%) the videos to be analyzed by a second reviewer (CB) to determine interrater reliability. The interrater reliability score ($\kappa=0.97$) indicated a high level of consensus. Microsoft Excel was used to record, organize, and analyze the data collected.

Ethical Considerations

This study was excluded from institutional ethics board review, as the William Paterson University Institutional Review Board does not review studies that do not involve human participants.

Results

Overall, the 100 videos studied received 1,354,100,000 views; 266,900,000 likes; and 2,515,954 comments. On average, each video received 13,406,930.69 (SD 8,728,095.52) views; 2,657,425.74 (SD 1,449,920.45) likes; and 24,910.44 (SD 21,035.06) comments. Of the 100 videos, a majority ($n=84$, 84%) were classified as consumer-generated; only 13 (13%)

were classified as influencer- or verified-user-generated, with the remaining classified as health care professional-generated ($n=1$, 1%), television- or internet-based news ($n=1$, 1%), and television-based entertainment ($n=1$, 1%).

In [Table 1](#), the first column lists the 14 different content categories of the video data and the second column details how many of the 100 videos sampled included this content. The table also includes the number of views, likes, and comments that the videos with these particular features garnered. Relative percentages from the total are included as well. The content category “statistics and prevalence of mental health disorders or issues” was omitted from the table since it was not featured in any of the sampled videos.

The only content category observed in a majority (51/100, 51%) of the videos sampled was “general mental health.” The remaining content categories appeared in less than 50% of the sample. “Personal experience” was the next most prevalent category observed in the videos and it appeared in 40% (40/100) of the sample. The remaining content categories appeared in less than 20% of the sample, with the following 5 content categories appearing in less than 5% of the sample: anxiety or fear, physical health conditions or variables, stress, mental health stigma, and missing other people or connections due to COVID-19.

[Table 2](#) provides information about the themes noted in the videos’ comments. This table shows 6 different themes, the number of videos with comments that reflected these themes, and the associated number of views, likes, and comments of

these videos. The most common themes observed in the videos’ comments sections were “offering support or validation” (61/100, 61%) and “describing other mental health issues or struggles” (49/100, 49%).

In total, 32% (32/100) of the videos sampled received more than the overall average number of likes (ie, more than 2.67 million likes). Among these 32 videos, 23 (72%) included comments offering support or validation and 20 (62%) included comments describing other mental health issues or struggles. The remaining themes were included in ≥ 10 videos: shared coping strategies, experiences of healing, or ways to feel better (10/32, 31%); describing an experience with hospitalization for mental health issues (7/32, 22%); mentioning experiences with suicide or suicide ideation (6/32, 19%); and mentioning experience with self-harm (2/32, 6%).

The frequently used words excerpted from the comments section of the TikTok platform are shown in [Multimedia Appendices 1-2](#). [Multimedia Appendix 1](#) shows the negative sentiments portrayed in the comments that reflect serious mental health concerns, which were expressed in response to participant-posted TikTok videos depicting issues of depression, grief, sadness, anger, loneliness, and trauma. In contrast, [Multimedia Appendix 2](#) shows social support and collective optimism in the comments about the posted TikTok videos. These comments were caring and reflected encouragement, praise, and acceptance. It is important to note that these comments were generally presented in the context of support from those who allegedly have shared experiences or trauma.

Table 1. Observed content, views, likes, and comments of 100 TikTok videos on mental health.

Content categories	Videos (N=100), n (%)	Views (N=1,354,100,000), n (%)	Likes (N=266,900,000), n (%)	Comments (N=2,515,954), n (%)
General mental health	51 (51)	703,700,000 (51.97)	149,000,000 (55.83)	1,331,622 (52.93)
Personal experience	40 (40)	638,900,000 (47.18)	128,400,000 (48.11)	1,093,179 (43.45)
Interpersonal relationships	18 (18)	366,200,000 (27.04)	75,100,000 (28.14)	440,502 (17.51)
Depression	13 (13)	213,700,000 (15.78)	39,000,000 (14.61)	294,830 (11.72)
Suicide	13 (13)	151,600,000 (11.20)	31,000,000 (11.61)	414,316 (16.47)
Coping techniques or treatment	9 (9)	53,700,000 (3.97)	12,400,000 (4.65)	144,074 (5.73)
Child or adolescent mental health	8 (8)	142,700,000 (10.54)	28,700,000 (10.75)	200,305 (7.96)
Biological and neurological influences of mental health	8 (8)	91,600,000 (6.76)	15,700,000 (5.88)	238,355 (9.47)
Self-harm	5 (5)	62,600,000 (4.62)	15,000,000 (5.62)	181,375 (7.21)
Anxiety or fear	4 (4)	58,600,000 (4.33)	10,600,000 (3.97)	42,000 (1.67)
Physical health conditions or variables	4 (4)	100,300,000 (7.41)	15,900,000 (5.96)	184,800 (7.35)
Stress	3 (3)	50,900,000 (3.76)	8,300,000 (3.11)	25,100 (1.00)
Mental health stigma	1 (1)	11,500,000 (0.85)	2,200,000 (0.82)	6,405 (0.25)
Missing other people or connections due to COVID-19	1 (1)	49,200,000 (3.63)	10,200,000 (3.82)	68,300 (2.71)

Table 2. Themes noted in the videos' comments and the associated number of views, likes, and comments.

Theme	Videos (N=100), n (%)	Views (N=1,354,100,000), n (%)	Likes (N=266,900,000), n (%)	Comments (N=2,515,954), n (%)
Offering support or validation	61 (61)	884,300,000 (65.31)	178,500,000 (66.88)	1,663,433 (66.12)
Describing other mental health issues or struggles	49 (49)	677,500,000 (50.03)	145,300,000 (54.44)	1,419,131 (56.41)
Sharing coping strategies, experiences of healing, or ways to feel better	16 (16)	301,500,000 (22.27)	64,200,000 (24.05)	448,510 (17.83)
Mentioning experience with suicide or suicidal ideation	14 (14)	171,400,000 (12.66)	37,700,000 (14.13)	369,724 (14.7)
Describing an experience with hospitalization for mental health issues	11 (11)	210,000,000 (15.51)	41,500,000 (15.55)	262,565 (10.44)
Mentioning experience with self-harm	7 (7)	87,000,000 (6.42)	17,100,000 (6.41)	187,339 (7.45)

Discussion

Principal Findings

It is important to note the reach of the videos included in this study. With over 1 billion cumulative views, almost half of the assessed TikTok videos included in this study reported or expressed symptoms of mental distress. Other studies have observed the expression of mental ill-health within online social media platforms [31] and expressed concern about potentially traumatic and “triggering” TikTok videos as being detrimental to some viewers [32]. This is especially concerning given the frequency of screen time among adolescents. Many adolescents are predominant TikTok participants, and there is a potential for contribution to poor mental health outcomes from repetitious and prolonged viewing, especially if traumatic events are featured in the videos [32]. Recently, TikTok has acknowledged the substantial impact of their platform on users' mental health and have provided additional resources in support of user safety, health, and mental wellness [33]. Specific to the issues of mental health, TikTok has produced well-being guides in partnership with the several international mental health organizations to support and uptake optimal messaging on the TikTok platform [34]. However, there is limited insight into the impact of traumatic or “triggering” events posted within the online platform [35], the use and impact of the TikTok mental health resources, or conversely, the health enhancing impact of positive and supportive messaging among youth who engage with social media [36,37].

Over 60% of the videos in this study had associated comments that were supportive and validating; this can signify the importance of the TikTok platform and the hashtag #mentalhealth as a possible “just-in-time” source of social support and personal validation that is made available without the need for planning, scheduling, and financial remuneration. Notably, comments that depict coping strategies were not overly common; they were apparent in about 10% of the videos with high numbers of collective views. Given the seriousness of the topics, these findings point to the fact that videos alone only tell part of the story. Health care professionals are active on

social media and, specifically, TikTok [17,38]. Comp et al [17] noted that *TikTok therapists*, some with millions of followers, are actively providing corrective information to mental health misinformation and combatting mental health stigma on TikTok.

However, it is important to note that the videos in this sample were largely posted by consumers and not by health care professionals. Hence, further research is needed on the extent to which corrective mental health information is prevalent on popular mental health hashtags. Further, our findings indicate that health care professionals, particularly those who aim to provide corrective information, should be aware of and attend to both the video content and its related commentary.

Future Implications

Future research should focus on the potential role of intervention by health care professionals on social media. This would create changes for clinician practice, including raising issues related to the ethics of following patients online, concerns related to fake accounts, the user performance factor assumed as part of the TikTok platform, and mental health assessment of social media consumption [31]. As partnerships between health care professionals and social media platforms emerge, evaluation on effectiveness and best practices will be essential. Interestingly, the call for research related to greater understanding of TikTok health content creators, the integrity of the content, and user reaction and uptake to promote evidence-based information [35] to TikTok users may be contrary to the current appeal and need for accessible health-related resources that are different from mainstream medicine [12].

Limitations

The findings of this study offer insight into the use of TikTok to discuss mental health issues. However, this study is limited by the cross-sectional design. Further, the inclusion of English-only TikTok posts is limiting; videos posted in other languages may contribute to a more comprehensive understanding of the mental health conversations posted using the hashtag #mentalhealth. Other hashtags that specify a mental health illness or experience (suicide, anxiety, or depression)

may have captured different videos than those captured by the generic use of hashtag #mentalhealth. Nonetheless, this study can serve as a foundation for further research to assess both the video content and its associated discussions, which are both important components to consider in studying mental health content on TikTok.

Conflicts of Interest

CHB serves as an Editorial Board Member for JMIR; she did not have a role in the review or editorial process for this article. All other authors declare no conflicts of interest.

Abstract

Background: This survey study investigates surgical patients' use and perception of digital health technologies in Germany in the pre–COVID-19 era.

Objective: The objective of this study was to relate surgical patients' characteristics to the use and perception of several digital health technologies.

Methods: In this single-center, cross-sectional survey study in the outpatient department of a university hospital in Germany, 406 patients completed a questionnaire with the following three domains: general information and use of the internet, smartphones, and general digital health aspects. Analyses were stratified by age group and highest education level achieved.

Results: We found significant age-based differences in most of the evaluated aspects. Younger patients were more open to using new technologies in private and medical settings but had more security concerns. Although searching for information on illnesses on the web was common, the overall acceptance of and trust in web-based consultations were rather low, with <50% of patients in each age group reporting acceptance and trust. More people with academic qualifications than without academic qualifications searched for information on the web before visiting physicians (73/121, 60.3% and 100/240, 41.7%, respectively). Patients with academic degrees were also more engaged in health-related information and communication technology use.

Conclusions: These results support the need for eHealth literacy, health literacy, and available digital devices and internet access to support the active, meaningful use of information and communication technologies in health care. Uncertainties and a lack of knowledge exist, especially regarding telemedicine and the use of medical and health apps. This is especially pronounced among older patients and patients with a low education status.

Introduction

Background

Information and communication technologies (ICTs) have changed our private and professional lives and are also increasingly being used in the health care sector [1,2]. ICTs cover a wide range of technologies that are often also subsumed under the term *eHealth*. da Fonseca et al [3] conducted a systematic literature review to clarify the content of the term *eHealth*. They formed 4 categories by classifying 446 publications with possible overlaps in content (mobile health [mHealth], telemedicine and telehealth, technology, and other), which we will adopt as the basic structure in this paper.

According to da Fonseca et al [3], mHealth includes the use of smartphone apps to identify, treat, and support disease. The scheduling of health examinations, use of wireless sensors to monitor patients, and transfer of these data between settings also fall under this category.

Under telehealth, the authors include interactions between providers and patients via digital means. Although the use of telehealth is highly dependent on the supply of health care professionals, it is difficult to assess the acceptance and engagement of patients receiving care in different settings. Therefore, we did not focus on this in the survey.

The technology category by da Fonseca et al [3] covers the encryption of patient medical data to protect them when they are accessed on the web. Data protection in health care facilities, the creation of system support, and the development of devices to implement digital applications also fall under this category. According to da Fonseca et al [3], the use of the Internet of Things, cloud storage, and big data can also be assigned to this category. This area is also very complex on the one hand and controlled by institutions on the other and, therefore, is not the focus of the survey.

The authors use the category *Other* to describe a combination of previous practices in new areas and a focus on costs.

To focus especially on technologies that patients can use independently and intrinsically, our survey focuses on the category mHealth, covering fitness devices and mobile apps as well as internet use and general digital health aspects. Fitness devices are defined as fitness bracelets or fitness watches.

Patients are one of the main target groups for ICTs related to health care. The use of ICTs can increase patients' enlightened participation by enabling them to take more active control of their own health [4]. ICTs can enable better self-assessment of health status and increase patient safety and involvement [5].

However, competencies and skills are necessary for patients to use ICTs to improve their own health. In this context, health literacy (HL) is important [6]. In the context of the COVID-19 pandemic and the associated spread of health-related misinformation and widespread implementation of digital health services such as video consults, the concept of HL has become increasingly important [7,8]. Particularly in the context of the increasing significance of ICTs in general and mobile apps in particular, eHealth literacy (eHL) has become an even more

important concept than HL [9]. Incorporated into this concept are the ability to navigate information on the internet and the ability to self-manage ICT use. In addition, eHL includes analytical competencies [10-12]. Another concept that is closely related to eHL is digital health equity. This describes the differences in the access to and use of ICTs between different populations and groups. This concept is of greatest interest regarding the increasing provision of digital health care as it describes the possible exclusion of people who lack access to and the ability to use ICTs [2,13].

The increased use of ICTs in various areas of life that occurred during the pandemic in the context of social distancing [14] has had significant implications for the issues considered in this paper.

Objectives

During the COVID-19 pandemic, there has been a tremendous increase in the use of eHealth technologies, such as video consultations [15]. However, this trial was conducted in the pre-COVID-19 era and provides an overview of the perception of these new technologies in a representative cohort of surgical patients. The aim of this pilot study was to illustrate the patient-centered aspects of digital health technologies and their use, dissemination, and acceptance depending on basic patient-related sociodemographic data. Acceptance is defined as the intention to use and, in some cases, as the actual use of health technologies [16,17]. Therefore, we investigated how surgical patients access and use digital health technologies and how their use behavior differs among different population subgroups.

Methods

Study Design

This single-center, cross-sectional survey study (Medical Information and Communication Technology Use of Patients) was conducted at the University Hospital Dresden, Germany, in the Department of Visceral, Thoracic, and Vascular Surgery between September 2019 and March 2020. A self-administered questionnaire was developed in consultation with a statistician and an expert in data management (Multimedia Appendix 1). The questionnaire was pretested and validated in a group of 10 persons working at the surgical trial unit in the Department of Surgery, University Hospital Dresden. The questionnaire was provided as a paper-based survey to ensure the participation of all patients. As the main aim of this pilot trial was to obtain a status quo of the use and perception of eHealth and mHealth technologies in a representative cohort of surgical patients rather than a thorough investigation of a general technology acceptance model, we chose to design a short, nonvalidated questionnaire ourselves. Questions were partly taken from existing instruments and partly added after obtaining results from structured qualitative interviews with patients and surgeons before this trial [9,18-20].

Ethics Approval

This study was conducted in line with the principles of the Declaration of Helsinki. The trial was approved by the ethics committee (Institutional Review Board) of the Technical

University Dresden (file 313062019, June 7, 2019). The American Association for Public Opinion Research guidelines were followed as applicable.

Measurements

The questionnaire contained four categories: (1) questions on general information, (2) questions on the use of the internet, (3) questions on mobile phones (cell phones) and smartphones, and (4) general questions on the use of ICTs ([Multimedia Appendix 1](#)). Participant-related and demographic data were collected in the questionnaire. The survey was anonymous, and a pooled analysis of the questionnaire responses was conducted so that no conclusions could be drawn about individual participants.

Sampling and Recruitment

Questionnaires were distributed to randomly selected nonemergency patients at the receptionist's office during the first patient contact at the Department of Surgery at the Dresden University Hospital, Germany.

The inclusion criteria to participate in the study were (1) admission to the clinic of the Department of Visceral, Thoracic, and Vascular Surgery of the University Hospital Dresden; (2) being aged ≥ 18 years; (3) provision of verbal consent; and (4) understanding of the German language owing to the presentation of the questionnaire in German.

The exclusion criteria were (1) admission to the hospital because of an emergency, (2) language problems, and (3) an impaired mental state or lack of compliance.

Data Collection

After oral information was provided and individuals were asked to participate in the study and complete the questionnaire, the participants were presented with the questionnaire. The participants were informed that their refusal to participate would not result in any disadvantages. The time needed to complete the questionnaire was approximately 15 minutes. No compensation was offered.

Data Analysis

Data from the questionnaires were pooled into a table using Microsoft Excel (Microsoft Office 2016). Demographic data analyses and statistical analyses were performed using R (version 4.0.2; R Foundation for Statistical Computing) in RStudio (version 1.2.1335; RStudio, Inc). A chi-square test was performed to show any relationship between the age group and the variables under consideration ($P < .05$).

Results

Overview

In total, 650 questionnaires were distributed to randomly selected nonemergency patients at the receptionist's office during the first patient contact. Of these, 406 questionnaires were returned, yielding a response rate of 62.5% (406/650). However, not all participants answered all questions, as can be seen in the results tables, which provide the absolute numbers for each question.

Participant Characteristics

[Table 1](#) shows the participants' demographic data and general information. The participants were divided into 3 age groups (young adults: 18-40 years; middle-aged adults: 41-70 years; and older adults: >71 years) to investigate differences according to age. In total, 56.1% (226/403) were men and 43.9% (177/403) were women; 15.1% (61/405) were young adults, 63% (255/405) were middle-aged adults, and 22% (89/405) were older adults. Only 26.8% (102/381) of the participants lived in cities with $>100,000$ inhabitants. Of the 406 participants, 353 (86.9%) visited their general practitioner on a regular basis, whereas only 22 (5.4%) did not regularly visit any physician. A total of 14% (55/394) reported >10 outpatient and hospital visits per year. In the sample population, 32% (123/384) had obtained an academic degree as the highest form of education, 56.8% (218/384) had completed vocational training, and 4.7% (18/384) had a school-leaving degree (see [Table S1](#) in [Multimedia Appendix 2](#) for the patients' demographic data by level of education). In total, 58.9% (229/389) of the participants had a chronic disease.

Table 1. Participants' demographic data sorted by age group (N=406).

^bMultiple answers were possible, and the percentage refers to the respective total.

Participant Internet Use by Age Group

Table 2 shows the internet use of the participants by age group. In total, 67% (266/397) of the participants reported having searched the internet for information about diseases at any time in the past. There was a statistically significant difference ($P=.004$) by age group, with 34% (29/85) of the older adults, 71.8% (181/252) of the middle-aged adults, and 93% (56/60) of the young adults using the internet to search for information about diseases (266/397, 67%). Almost half of the participants (180/390, 46.2%) had searched the internet for information about their current illness before their hospital visit. This was

done by more young adults than middle-aged adults and older adults, resulting in a strong relationship with the respective age groups ($P<.001$). Most participants (249/406, 61.3%) indicated that they had taught themselves how to use computers and smartphones, whereas some of the middle-aged adults and older adults (5/255, 2% and 4/89, 5%) had visited adult education centers for this purpose. A total of 24.6% (96/390) of the participants did not have access to broadband internet at home. The proportion of older adults who did not have access to broadband internet (37/81, 46%) was significantly higher than that of young and middle-aged adults ($P<.001$).

Table 2. Participant internet use sorted by age group (N=406).

Characteristic	Age 18 to 40 years (n=61), n (%)	Age 41 to 70 years (n=255), n (%)	Age ≥71 years (n=89), n (%)	Total ^a , n (%)

^bMultiple answers were possible, and the percentage refers to the respective total.

^cDSL: digital subscriber line.

Use of Mobile Phones and Smartphones

Table 3 summarizes the use of mobile phones and smartphones by age group. In total, 7.9% (31/393) of the study population did not own a cell phone. The percentage of participants who did not own a mobile phone was significantly higher in the group of older adults (20/89, 24%; $P<.001$), whereas all young adults owned a mobile phone. A total of 78.9% (296/375) of the respondents reported that their mobile phones were smartphones, and the proportion of older adults who did not own a smartphone was significantly higher (35/72, 49%;

$P<.001$). The Android operating system was used by most participants (192/330, 58.2%) followed by the Apple iOS system (77/330, 23.3%). Of the 49 older adults, 19 (39%) did not know which operating system was installed on their mobile phones. Most participants (299/364, 82.1%) did not own a fitness device. Significantly more young adults than older adults owned such a device ($P<.001$). Table 3 shows the participants' typical use of their smartphones in the different age groups: 12.2% (45/369) of the participants already used medical and health apps, whereas 20% (12/60) of the young adults and 4% (3/75) of the older adults used medical and health apps ($P=.005$).

Table 3. Participants' use of mobile phones, cell phones, or smartphones sorted by age group (N=406).

^aIncludes questionnaire responses without information on the age group provided, which are therefore only counted in the *Total* column.

^bMultiple answers were possible, and the percentage refers to the respective total.

Use of ICTs by the Participants

Table 4 summarizes the participants' use of and attitudes toward ICTs used in medicine, sorted by age group. Merely 30% (112/373) of the participants thought it was useful to introduce web-based or video consultations. Almost as many participants (100/373, 26.8%) indicated that they did not know. Again, there were significant differences by age group, as shown in Table 4 ($P < .001$): 74.2% (276/372) of the participants considered electronic health records to be useful, with a statistically significant difference by age group ($P = .001$). Only 1.7% (6/350) of the participants would mostly trust an app to make a correct decision, 48.3% (169/350) would trust a physician, 22.6% (79/350) would trust none of the options, and 27.4% (96/350)

did not know. The main disadvantages identified for video consultations were the lack of personal contact (225/406, 55.4%) and the absence of physical examination (264/406, 65%). Many participants stated that they would never take advantage of a video consultation (130/342, 38%). Only 5% (17/342) stated that they would use a video consultation as often as possible. A statistically significant difference by age group ($P = .01$), with older adults least wanting to take advantage of video consultations, was also observed for this aspect. Many participants (176/355, 49.6%) did not believe that the use of a fitness device could improve or enhance their health, whereas 26.8% (95/355) did not know. A significant difference among the age groups was found, with $P < .001$.

Table 4. Participants' use of information and communication technologies sorted by age group (N=406).

Question	Age 18 to 40 years (n=61), n (%)	Age 41 to 70 years (n=255), n (%)	Age ≥71 years (n=89), n (%)	Total ^a , n (%)
Do you think it would be useful to introduce web-based consultations?

^aIncludes questionnaire responses without information on the age group provided, which are therefore only counted in the *Total* column.

^bMultiple answers were possible, and the percentage refers to the respective total.

Use and Perceived Usefulness of Medical and Health Apps

Table 5 shows the assessment of use behavior and the perceived usefulness of medical and health apps. Only between 46.1% (187/406) and 49% (199/406) of the participants answered the questions in this section. Approximately half of all respondents rated the usefulness of various apps positively, including apps

for medication (110/195, 56.4%), monitoring of vital signs (97/199, 48.7%), web-based appointments (111/189, 58.7%), exchanges with health insurance companies (91/187, 48.7%), and fitness (77/196, 39.3%). However, 19.4% (38/196) of the participants were already using such an app. Again, there were differences among the age groups. Very few participants in the older adult age group were able to answer the questions in this section.

Table 5. Use and usefulness of medical apps for participants by age group (N=406).

Characteristic	Age 18 to 40 years (n=61), n (%)	Age 41 to 70 years (n=255), n (%)	Age ≥71 years (n=89), n (%)	Total, n (%)
Medication app (eg, reminders or insulin scheme)				
Finding it useful	34 (82.9)	67 (52.8)	9 (33.3)	110 (56.4)
Using it	2 (4.9)	17 (13.4)	4 (14.8)	23 (11.8)
Not useful	5 (12.2)	43 (33.9)	14 (51.9)	62 (31.8)
Total	41 (100)	127 (100)	27 (100)	195 (100)
App for monitoring of vital signs (eg, pulse or blood sugar)

Analysis by Education Status Obtained

We analyzed differences in results according to academic degree (Tables S2-S5 in [Multimedia Appendix 2](#)). There was a significant difference by academic degree in the percentage of patients searching on the web for information about their current illness (Table S2 in [Multimedia Appendix 2](#)). Although 60.3% (73/121) of the patients with an academic degree had searched for information regarding their illness before the hospital visit, only 41.7% (100/240) of the patients with another degree or no degree had done so ($P=.001$). There were also significant

differences in the perception of electronic health records as useful ($P=.01$) and in trust in an app, a physician, or none of the options to make a correct diagnosis ($P=.01$). A total of 65% (47/72) of the participants with an academic degree perceived a web-based appointment allocation tool to be useful (compared with 63/110, 57.3% of the participants with no degree), and 21% (15/72) were already using such an app (compared with only 14/110, 12.7% of the participants with another degree or no degree; $P=.03$; Table S5 in [Multimedia Appendix 2](#)).

Discussion

Principal Findings

In a cohort of 406 patients from the outpatient department of a tertiary academic referral center in Germany, we found significant differences in the use and perception of digital health technologies depending on the age and educational status of the patients. Older patients and patients with a lower education status lack access to broadband internet and knowledge of and access to smartphone use; these populations have a lower level of eHL.

The aim of this trial was not an in-depth analysis of use and acceptance models of modern ICTs but rather to obtain a status quo of the actual use and perception of modern eHealth and mHealth technologies in a representative cohort of surgical patients in Germany in the pre-COVID-19 era.

Overall, the older the participants were, the more frequently they had regular contact with physicians and were hospitalized. Unfortunately, fewer people of older age answered the questions. We suspect that many of these people did not understand the specific topic or could not answer the questions. However, the older the patients were, the less frequently they searched for information on the internet about illness in general or their own illnesses specifically and the less ready they were to use ICTs with regard to their health [21-24]. This finding is in line with previous data reporting that information technology (IT) use and IT use for health are more common and better accepted by younger people [25]. This indicates a clear difficulty faced by older people with regard to their involvement in health decisions if up-to-date health information on the internet is accessible [26]. Six access points for seeking health information have been classified: (1) interpersonal sources, (2) traditional mass media, (3) traditional and modern internet sources, (4) Web 2.0 sources, (5) libraries, and (6) government agencies or social services [27]. Which of these access points people use depends not only on the design and accessibility of the source itself but also on the users [27].

The older the participants in our study were, the less likely they were to have learned how to use smartphones and computers themselves and the more they relied on external help. This is closely related to the digital literacy paradox described in the literature: competencies for using ICTs can be learned only by using ICTs. However, older people often do not have full access to ICTs and continue to have poor digital literacy skills [28]. This is consistent with the results of our study, which revealed that only a minority of the older adults reported owning smartphones and <50% of them (38/81, 47%) had access to broadband connections at home. However, it was not only older people who showed a limited understanding of ICTs in our study. For example, 12.4% (41/330) of the participants said they did not know which operating system their smartphones had. In 2020, the European Union Memorandum on Lifelong Learning explicitly included IT skills among the new basic skills that all individuals need [29]. This underscores the danger of people being excluded from a large area of (social) life owing to a lower level of competence in this area [30].

A recent trial found that low HL was related to limited functional HL, low socioeconomic status, and frequent visits to physicians [31]. These findings indicate a strong need for HL education services across all age groups.

Other findings of this study were that the participants were partially unaware of the possibility of ICTs and the participants' confidence in the usefulness of medical and health apps was low. It is also noticeable that not all participants answered these questions. This indicates that this technology is rarely used. Presumably, this also has an impact on trust in it. However, many of the participants also stated that they were unable to make a statement in this regard, and only 48.3% (169/350) of all respondents believed that a physician could make a correct diagnosis on the web. Certainly, occasions exist in which a face-to-face consultation is essential. However, many of the drawbacks cited by the participants were unfounded [22-24,32]. These findings have been further reinforced in the context of the increase in telemedicine during the COVID-19 pandemic [33].

Considering that 58.9% (229/389) of the participants had a chronic illness, the low number of people using medical and health apps is surprising. Current data show positive results when medical and health apps are used by patients with chronic diseases. However, for some apps, no evidence of a benefit exists [34]. Regardless of whether they are used for chronic disease management, medical and health apps can confer benefits [35]. The literature shows that the use of medical and health apps can have positive consequences but that their use must always be critically questioned. There are 4 factors playing a significant role as direct determinants of user acceptance and use behavior: performance expectancy, effort expectancy, social influence, and facilitating conditions.

Relatedly, it is important to consider that the use of ICTs also poses dangers that users should be aware of to protect themselves. Younger participants used new technologies in private and health care settings more often and evaluated the benefits more positively than older participants. In general, younger people are more positive about health information from the internet than older people [36]. Nevertheless, many young adults in our study reported concerns about data security when using ICTs. These concerns are entirely justified. The ICT market for health care is currently opaque. ICTs often use sensitive data for other purposes [37]. Therefore, it is more worrying that the participants in the other age groups indicated significantly lower concerns in this regard. The study also showed that, in general, people with a higher education status were more informed, were more open, and used modern ICTs more frequently than people with a lower education status. This finding highlights the fact that the digital divide is related not only to the age group to which patients belong but also to other socioeconomic aspects such as educational status [38].

However, educating patients regarding eHL alone is not sufficient to improve the quality of care. Health care professionals must also be trained to provide meaningful information and guidance to patients. Currently, eHL among physicians is limited [39]. Therefore, it is necessary to pursue an approach that enables education for the entirety of society

[40]. It is of utmost importance to focus on the digital divide among different age and socioeconomic groups in the design and implementation of new digital technologies [41].

Limitations

In some ways, this paper is anachronistic, reflecting results regularly reported 10 to 20 years ago for other countries or for industries other than health care. The reason for this is that remote medical consultations were not permitted in Germany until 2018. Another limitation of this study from the current perspective is the timing of the survey before the COVID-19 pandemic. The pandemic has led to considerable changes in health care, especially regarding the use of telemedicine [42] as well as the use of apps for contact tracing [43] and self-reported symptom tracking [44]. The COVID-19 pandemic has changed people's views; in a recent study of patients of urology in Germany, 85% wanted a videoconference teleconsultation rather than a face-to-face consultation [45]. However, the potential impact on eHL requires further investigation. The pandemic may also have had an impact on the digital divide as many individuals have experienced pay cuts or job losses because of the pandemic [46].

However, the pandemic has also highlighted the critical importance of the study described in this paper. For the routine care of patients, ICTs have been widely used and implemented during the COVID-19 crisis [47]. Good HL is the foundation for understanding the risk factors and consequences of contagion during the COVID-19 pandemic [48]. Thus, the pandemic can hopefully become the driving force for much-needed improvements in eHL that can support digital equity.

In our opinion, nonresponse bias does not threaten the validity of the findings of this study. It is likely that the results would be even more pronounced as people with limited eHL mostly refused to participate and did not answer the questions. This

was randomly confirmed by routinely questioning patients who decided not to participate about their reasons.

We did not use validated instruments or methods for user technology acceptance in this work, such as the unified theory of acceptance and use of technology model, as our focus was not on a thorough technology acceptance investigation but rather on obtaining a general status quo of use, attitudes, and behavior of surgical patients in terms of new digital health technologies. However, recently, much work has been done regarding digitization and digital health technology in Germany, which we will use to design future trials [49-51]. For further studies, it would be recommended to use additional validated instruments.

Conclusions

The data from our study indicate that there is a need for education across all age groups regarding the opportunities and risks of using ICTs in health care. Regarding eHL, it is important that educational programs build participants' knowledge in the areas of computers and smartphones, health, and science. The increase in the importance of ICTs can promote participative decisions in health care, enabling patients to influence their illnesses and drive prevention via active self-management. However, critical to the provision of such health care is the training and equipping of all patients, especially older patients, to enable them to safely use ICTs.

With respect to medical and health apps focused on the self-management of chronic conditions, app developers should be mandated to use data-based evidence to increase the safety and usefulness of the apps. Further research should address patient needs that must be met for patients to be able to actively use health-related ICTs. In addition, it is crucial to investigate how trust in the use of ICTs in the health care setting can be increased [52,53].

Abstract

Background: Mobile health apps can support the self-management of pediatric asthma. Previous studies on mobile apps for children aged >7 years with asthma are limited, and most reports on asthma apps do not consider interactions between the children and their caregivers. Therefore, we developed an asthma app for children aged 0-12 years and their caregivers based on the results of our previous study regarding user needs.

Objective: The aim of this study was to evaluate the feasibility of a developed mobile app for children with asthma and their caregivers and to modify and complete the app according to the feasibility results.

Methods: We recruited children diagnosed with persistent asthma by an allergy specialist at 2 children's hospitals, 1 university hospital, 2 general hospitals, and 1 pediatric clinic. Thereafter, the app usage was assessed, and questionnaires were administered. This study used convergent mixed methods, including providing user feedback about the pediatric asthma app, completing questionnaire surveys regarding preferences, and obtaining quantitative data about app usage. Quantitative data were analyzed based on the ratings provided for the app features used by the participants, and the usage of the app features was analyzed using descriptive statistics. Qualitative data were analyzed via a descriptive qualitative research analysis and were used to identify codes from the content-characteristic words.

Results: In total, 30 pairs of children aged 2-12 years and their caregivers responded to the 3-month survey, and 20 pairs of children aged 4-12 years and their caregivers responded to the 6-month survey. In the 3- and 6-month surveys, "record" was the most commonly used feature by both caregivers and children. The average access logs per month among the 20 pairs ranged from 50 to 79 in the 6-month survey. The number of access logs decreased over time. In the qualitative results, app utilization difficulties were identified for 6 categories: record, preparing, alert settings, change settings, mobile phone owner, and display and motivation. Regarding app feasibility, 60% (12/20) of the caregivers strongly agreed or agreed for all evaluation items, while 63% (7/11) of the children strongly agreed or agreed for 6 items, excluding satisfaction. In the qualitative results, feasibility evaluation of the app was classified into 3 categories: high feasibility of the app, improvement points for the app, and personal factors preventing app utilization. Based on the results of the feasibility analysis, the final version of the app was modified and completed.

Conclusions: The app feasibility among children with asthma and their caregivers was generally good. Children aged 7-12 years used elements such as record, quiz, and manga. This app can support the continuous self-management of pediatric asthma. However, efforts must be taken to maintain and improve the app quality.

Introduction

Background

Mobile health (mHealth) apps can support the self-management of chronic diseases, including medication use. Based on a previous review of digital health interventions for children with asthma, the implementation of such interventions may provide opportunity to improve treatment adherence and asthma control [1,2]. Digital health interventions for children with asthma include technologies that are useful for tracking asthma symptoms and medications, setting drug reminders, improving inhaler use techniques, providing asthma education, and using electronic monitoring devices, speech recognition calls, text messaging, mobile apps, and interactive websites [1].

mHealth apps for asthma generally target adult patients, and only few consider pediatric patients. Several mHealth asthma apps for children are intended for caregivers or adolescents who have their own smartphones. A systematic review of digital asthma self-management interventions was performed in the 2000s, and the interventions were commonly implemented among children aged 7-17 years [2,3] and their caregivers [4]. Since children aged >12 years usually have their own smartphones, previous studies on pediatric asthma apps usually included this age group [5,6]. Although digital self-management programs are available for children with asthma and their caregivers, only few studies have investigated the efficacy of these mobile apps.

Given the promising evidence of digital interventions for pediatric asthma, practitioners should support the use of evidence-based behavioral strategies to improve asthma management and health outcomes by recommending digital technologies and providing asthma education [2]. The features of asthma apps include asthma education material, symptom forecast, asthma action plan, telemedicine, local specialist connection, management during an emergency, symptom monitoring, airborne trigger identification, and clinic notifications [7]. The features of mHealth asthma apps are classified into 7 categories, that is, inform, instruct, record, display, guide, remind/alert, and communicate [8]. The most commonly used behavioral change techniques in asthma management apps are instruction, behavior-health association, self-monitoring, feedback, teach to use prompts/cues, consequences, and others' approval [9]. An app can determine the asthma phenotype in children using the asthma control test

by monitoring activity, sleep, peak expiratory flow, and indoor air quality [10,11].

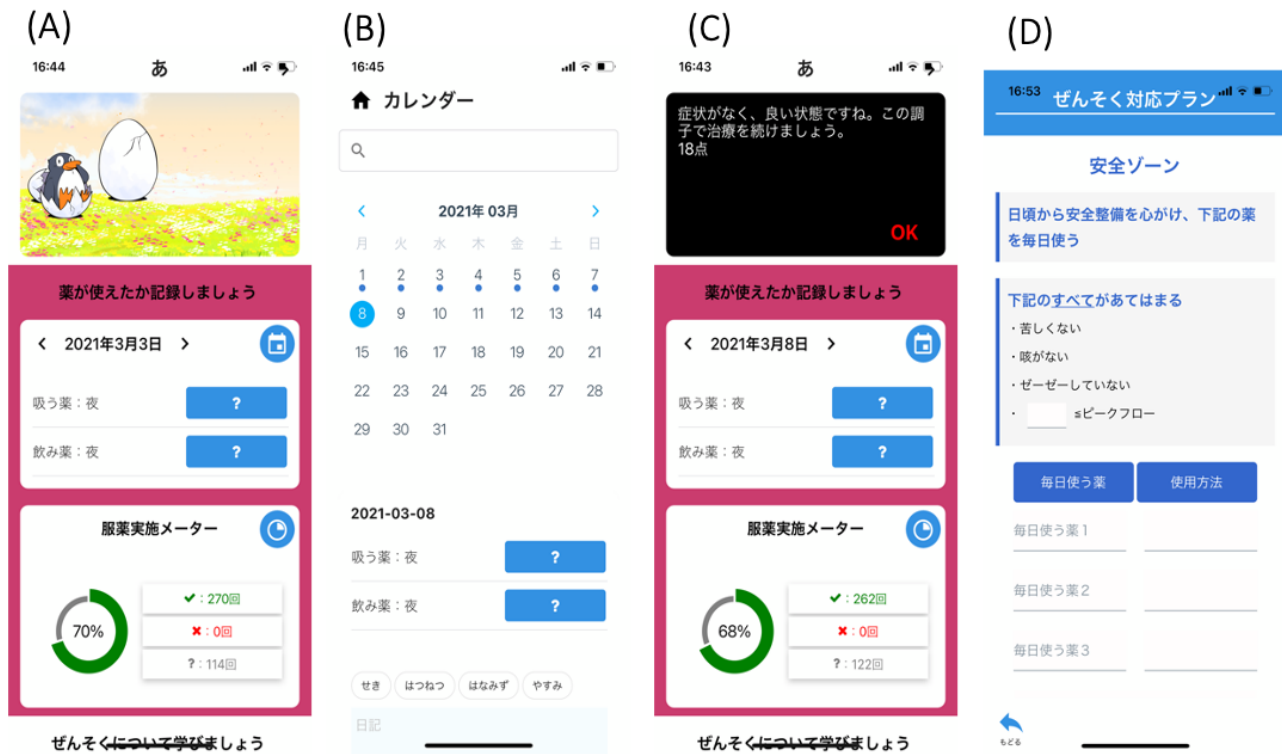

Overall, there are only few apps that can be independently used for self-management by both children with asthma who are aged 7-12 years and 4-6 years and their caregivers. Most studies on asthma apps did not consider interactions between children and caregivers. Furthermore, previous studies on mobile apps associated with asthma self-management among children aged 7-12 years are limited. Therefore, we developed and improved a mobile asthma app for children and their caregivers based on the results of our previous survey [12], which assessed interactions between children and their caregivers. The proposed beneficial features of our app were identified under 6 themes: asthma knowledge, elements for continuous use, universal design, notification, monitoring, and functions [12].

Development of a Mobile Asthma App for Children and Caregivers

We developed the prototype of a mobile asthma app for children and caregivers based on an individualized program using a touch-screen computer that we had developed [13]. The social cognitive theory [14] and tailoring [15] were used to develop a new mobile pediatric asthma app, which comprised a combination of asthma knowledge, behavioral change, and target behaviors and theory applications. The 3 main goals of this app are to (1) increase caregivers' feelings of self-efficacy in asthma management, (2) improve asthma knowledge, and (3) facilitate continuous self-management behavior of controlling asthma symptoms.

We improved and remade the prototype mobile asthma app for children and their caregivers based on the results of our previous survey [12]. In particular, the screen design of the app was changed to make it more user-friendly. The contents of self-monitoring of medication and symptoms were modified to separately classify medications and symptoms. In addition, a screen was added on the top page to motivate children to continue recording their medication behavior, that is, one can see an egg growing after the continuous use of medications, and animals are born after breaking out from the eggs. By maintaining a record of the medications, the egg cracks in 10 days, the animal inside it becomes slightly visible in 45 days, and finally, the egg hatches in 3 months. After the egg hatches, a new egg appears (Figure 1). Each egg has 6 animal characters, regardless of the gender of the child. Each time an egg hatches a character, a new egg appears.

Figure 1. Examples of the different screens in the developed mobile asthma app for children and their caregivers. Examples of the screens commonly used by children aged <7 years and 7-12 years: (A) motivation screen and self-monitoring input of medications; the egg on the top panel grows after the continuous use of medications, and animals are born by breaking out from the eggs, (B) detailed calendar for self-monitoring, (C) tailored message display, and (D) asthma action plan for asthma exacerbation and disaster.

This app was established for infants and toddlers (aged 0-6 years) and school-age children (aged 7-9 years and 10-12 years) according to their developmental stages. The common contents of the pediatric asthma app for children aged 0-12 years and their caregivers were self-monitoring of the medications and symptoms, preparing for asthma exacerbation and disasters, asthma action plan, and tailored feedback according to the Japanese pediatric asthma control test. Not only caregivers but

also children could use the app based on their developmental stages. The common functions of the app for children aged 0-12 years and their caregivers were medication alert, app input alert, and notification of the results in the pediatric asthma control test (Figure 2). The individualized feedback messages based on the medication usage status were regularly displayed for the caregivers.

Figure 2. Examples of the different screens in the developed mobile child asthma app for children and their caregivers. Examples of the screens used by children aged <7 years and 7-12 years: (A) settings on the screen showing medication alert function, (B) screen for asthma knowledge and notification of the results in the pediatric asthma control test, (C) screen for asthma knowledge for children aged <7 years and caregivers, and (D) manga, a Japanese-style comic, for asthma knowledge for children aged 7-12 years and their caregivers.

The contents of the asthma app for children aged 0-6 years and their caregivers focused on asthma knowledge (via a pictorial book about asthma clinical condition, causal factors, and complicating factors; quiz). These contents were mainly for caregivers, but the pictorial book could be completed by the child and the caregiver together (Figure 2). The pictorial book not only provides asthma knowledge but also promotes interaction between the child and the caregiver.

The contents of this app for children aged 7-12 years and their caregivers consisted of asthma knowledge (via manga, a Japanese-style comic, regarding asthma, medication, exercise-induced asthma, and stress management; quiz) and individualized feedback according to the status of medication usage. The difference in the app contents between children aged 7-9 years and 10-12 years was the use of “kanji,” a Japanese writing system that uses Chinese characters. Further, the app contents used manga, making the process of learning about asthma knowledge and management fun for children (Figure 2). Additionally, individualized feedback messages based on the medication usage status were regularly displayed for children and caregivers.

Aim of This Study

Developing an evidence-based smartphone app requires conceptualization (understanding users’ needs and making decisions according to a theoretical basis) and pretesting feasibility and usability before efficacy evaluation [16,17]. To improve feasibility, we need to evaluate the performance of an app by allowing target populations to regularly use it. Therefore, this study aimed to evaluate the feasibility of a developed mobile

app for children with asthma and their caregivers and to modify and complete the app according to the evaluation results. Evaluating the app’s feasibility can help improve the usage of mobile asthma apps among children and their caregivers. In addition, the mobile asthma app development must be completed by meeting the needs of the children and their caregivers.

Methods

Study Design

We used the convergent mixed methods design that included providing user feedbacks in a corrected pediatric asthma app, completing questionnaire surveys about preferences, and obtaining quantitative data about app usage. This study collected both qualitative and quantitative data, integrated both data, and derived interpretation from the combined strengths of both data. Compared with the use of 1 type of data, the integration of qualitative and quantitative data can provide a better understanding of the research subject. Therefore, this study design was selected because it was useful in evaluating the feasibility of the app.

Recruitment

We recruited children aged 0-12 years who were diagnosed with persistent asthma by an allergy specialist at 2 children’s hospitals, 1 university hospital, 2 general hospitals, and 1 pediatric clinic. The details of persistent asthma, such as severity and treatment regimen and duration, were not considered. Considering the emphasis on the continuous use of the app for long-term medicine management, this study participants

included children with persistent asthma, regardless of its severity. In Japan, children with asthma regularly visit hospitals or clinics based on the disease severity and complications of other allergic diseases. The target populations of this app are children with asthma and their caregivers, regardless of the hospital type they visit or the disease severity. Therefore, by recruiting children who visit various hospital types, the practicality of the app could be evaluated in a wide range of participants. Participants who were not eligible for this study owing to their mental and physical conditions based on the physician's discretion were excluded. Purposive sampling, which can gather information-rich cases that manifest the phenomenon under investigation, was performed. Participants who met the inclusion criteria were selected based on data from the electronic medical records.

In this mixed methods study, we needed to consider the sample size options in both the quantitative and qualitative study stages. Our sample size options weighted the qualitative data to be equal to those of the quantitative data. The sample size was guided in line with consensus guidance [18]. For trade-offs between the breadth and depth of qualitative research, at least 30-60 participants is needed [19], given that less depth from a large number of people can be especially helpful in exploring a phenomenon and documenting diversity or understanding variation [18]. Therefore, researchers approached the caregivers of children with asthma who regularly visited the outpatient clinics. In total, 36 caregivers who met the inclusion criteria were contacted. The caregivers and children with asthma provided consent during the outpatient visit.

Data Collection

We contacted 36 pairs of children with asthma and caregivers, of whom 34 agreed to participate in this study. Of the 36 caregivers who contacted us, only 1 caregiver of a child in the age group of 6-12 years did not participate because consent was not obtained. The other caregiver of a child in the age group of 0-6 years had difficulties in visiting the hospital regularly owing to moving to a different residence. The participants downloaded and used the pediatric asthma app for 6 months at home after providing consent. All participants answered the web-based questionnaire survey at 3 and 6 months from study registration. For children aged 0-6 years, only the caregivers answered the questionnaire, while both children aged 7-12 years and their caregivers answered the questionnaire. This study period was from June 2020 to March 2021. Data about the demographic characteristics of the participants, such as age, sex, age at asthma onset, and relationship with caregivers, were collected.

Quantitative Data

Caregivers and children aged 7-12 years responded to the 3- and 6-month web-based survey questionnaires. After 3 and 6 months since app download, the app displayed an access link to the web-based questionnaire. After 6 months, we collected data about the number of access logs and the usage frequency of each feature (diary, asthma symptom control test, asthma knowledge: manga and quiz, preparing for asthma exacerbation, including asthma action plan, preparing for disaster, medication alert, and app input alert). The 3-month survey aimed to identify the usage frequency of the app features (diary, asthma symptom

control test, asthma knowledge: manga and quiz, preparing for asthma exacerbation including asthma action plan, preparing for disaster, medication alert, and app input alert). Meanwhile, the 6-month survey collected data about the usage frequency of the app features, most commonly used app features, and app features that have never been used. To evaluate the specific elements of the app, we created a 7-item questionnaire according to the feasibility assessment using the 10-statement System Usability Scale by Brooke [20]. The participants rated feasibility on a 5-point scale for usability, benefit, satisfaction, continuous availability, intention of behavior, universal design, and view of tailored messages (1 [very bad] to 5 [very good]).

Qualitative Data

After 3 months, the caregivers and children aged 7-12 years described the following 2 viewpoints in the web-based survey questionnaires: (1) barriers for the continuous use of the app and (2) facilitators for promoting the continuous use of the app. Additional demographic information such as age at asthma onset and treatment duration was collected. After 6 months, the caregivers and children aged 7-12 years provided their views about their impressions of the app. The 3- and 6-month web-based surveys were mainly used to identify the portion of the app that required final modifications and the proposed beneficial features of the app.

Data Analysis

Quantitative Analysis

The questionnaire on the feasibility rating of the app features used and the usage frequency of the app features were analyzed using descriptive statistics. The number of access logs was summarized as the number of logs for each feature. Equivalence of demographic and medical information was compared using Fisher exact test at 3-month and 6-month time points. All statistical data were analyzed using the R software, version 3.6.1 (R Foundation).

Qualitative Analysis

Qualitative data were transcribed verbatim in Japanese. A descriptive qualitative research analysis was performed to identify codes, subcategories, and categories from the qualitative data. Moreover, these data were analyzed in 2 phases: (1) becoming familiar with the collected data and (2) generating the codes and collating similar data for each code. Research members included 2 pediatric nurses (MI and MN) and 3 pediatricians who specialize in allergies (YM, KY, and MN). After the initial coding of each transcript, the researchers discussed and identified the categories and subcategories.

Integration

Quantitative and qualitative data were integrated, and a joint display was created.

Ethics Consideration

This study was approved by the ethics committee for the Research of Social Medicine in the National Center for Child Health and Development (2019-103), the university ethics committee for studies involving human subjects, and the ethics committees for research involving human subjects in the 2

general hospitals. Participants who met the inclusion criteria and their caregivers were provided verbal and written information about the aim, significance, and methods of this study. Moreover, they were informed about their rights as voluntary participants, including study withdrawal, data anonymity, protection of confidential information, handling and disposal of data, and possibility of study publication. Participants aged 7-12 years provided written informed assent, and the caregivers of all the participants gave written consent.

Results

Characteristics of the Participants

Table 1 shows the characteristics of the participants. Of the 34 pairs enrolled in this study, 30 responded to the 3-month survey. Of those who responded to the 3-month survey, the average age of the children (16 boys and 14 girls) was 7.2 years and that of

the parents was 42.4 years (27 mothers and 3 fathers). The average age of the infants and toddlers was 4.8 years and that of the school-age children was 8.9 years.

In total, 20 pairs responded to the 6-month survey; the average age of the children (12 boys and 8 girls) was 7.2 years and that of the parents was 41.9 years (17 mothers and 3 fathers). The average age of the infants and toddlers was 5 years and that of the school-age children was 9 years.

Of the 10 pairs that were lost during follow-up, 7 children were in the developmental stage of 7-12 years; these 10 pairs consisted of 6 girls and 4 boys, and all the caregivers were the children's mothers. In the therapeutic regimen, 3 children used inhaled corticosteroids, 3 used leukotriene receptor antagonists, and 4 used inhaled corticosteroids+leukotriene receptor antagonists. Developmental stage, sex, therapeutic regimen, and caregivers' relationship were not significantly different between the populations at the time points of 3 and 6 months.

Table 1. Characteristics of the participants who responded to the 3-month and 6-month surveys.

Demographic characteristics	3-month survey: 30 pairs (n)	6-month survey: 20 pairs (n)

App Usage Status and the Main Codes in the 3-Month Survey

Table 2 shows the children and caregivers' app usage status and the main codes in the 3-month survey. The most commonly used app features by the caregivers and children were "record," that is, calendar/diary and asthma control check; the children most frequently utilized record. The total number of record access logs was 5153. The average access logs per month by the 30 pairs ranged from 45 to 69. About 61% (11/18) of the children used asthma manga. The usage rate of the asthma picture book among toddlers (n=12) and their caregivers was 25% (6/30). The app usage rate of preparing for asthma exacerbation and disaster was 27% (8/30) and 23% (7/30), respectively, and the lowest usage rate among children was 6% (1/18).

In the qualitative analysis results, difficulty in using the app contents was identified in 6 categories and 9 subcategories from 27 codes. These 6 categories were *record*, *preparing*, *alert settings*, *change settings*, *mobile phone owner*, and *display and motivation*. The coding and classifying phases revealed 3 subcategories in the category of *record*. According to the caregivers, "It can only enter about asthma" and "It takes time." Both the caregivers and children reported that "It cannot record my daily physical condition, climate, and events." The coding and classifying phases revealed 1 subcategory in the categories of *preparing*, and children claimed, "It does not know how to use preparing." The coding and classifying phases revealed 1 subcategory in the categories of *alert setting*, and children mentioned, "It cannot display alert." Another subcategory in the categories of *change setting* was noted to be difficult, and 1 child stated, "It does not know how to use the change settings."

The children answered “My mother was typing everything” and “The eggs do not grow, and the contents cannot be seen.”

Further, the coding and classifying phases revealed 1 subcategory in the categories of *mobile phone owner*. The

caregiver and children reported “Not a child’s mobile phone.” Finally, another subcategory in the categories of *display and motivation* was revealed, and the caregivers and children responded, “The eggs do not grow and the contents cannot be seen.”

Table 2. Summary of the app usage status and categories of difficulties in using the app by children and caregivers in the 3-month survey.

App contents	Access logs (n)	Usage status of caregivers (n=30), n (%)	Usage status of school children (n=18), n (%)	Qualitative data Categories and subcategories of difficulties in using the app (number of codes)
Record: medication and diary	5153	24 (80)	11 (61)	Record
Average in the 1st month	69	— ^a	—	It can only enter asthma. (Caregiver: 2 codes)
Average in the 2nd month	53	—	—	It takes time. (Caregiver: 1 code)
Average in the 3rd month	45	—	—	It cannot record my daily physical condition, climate, and events. (Caregiver and children: 9 codes)
Asthma control check	84	24 (80)	8 (44)	N/A ^b
Asthma picture book	20	6 (25)	—	N/A
Asthma manga	83	12 (40)	11 (61)	N/A
Asthma quiz	88	14 (47)	9 (50)	N/A

App Usage Status and App Difficulty Categories in the 6-Month Survey

Table 3 depicts the children and caregivers’ app usage status in the 6-month survey. Record was the most commonly used featured among both caregivers and children. The total number of record access logs was 7628. The average access logs per

month among the 20 pairs ranged from 50 to 79. Asthma control check was used by about 50% of both caregivers (9/20) and children (6/11). About 50% (6/11) of the children used the asthma manga and asthma quiz, and the rate was higher than that of caregivers. About 80% (24/30) of the participants used asthma control check, and the total number of access logs was 130.

Table 3. Summary of the app usage status of children and caregivers in the 6-month survey.

App contents	Access logs (n)	Frequently used app contents, n (%)		Most commonly used app content, n (%)		App content not used at all, n (%)	
		Caregivers (n=20)	Children (n=11)	Caregivers (n=20)	Children (n=11)	Caregivers (n=20)	Children (n=11)

App Feasibility Evaluation

Figure 3 and Tables 4 and 5 show the good- or low-feasibility evaluation results of the app among children and caregivers in the 6-month survey, that is, 70% (22/31) of the caregivers and children found the app usability to be very good or good. Several caregivers and children reported that “it was easy to use.” However, a caregiver reported that “entering the data took longer than I expected,” and another caregiver reported that “I was reluctant to let my child touch my smartphone.” About 80% (16/20) and 46% (5/11) of the caregivers and children were satisfied with the app, respectively. A caregiver stated that “I did not forget to take the medicine.” Meanwhile, both children and caregivers reported that “It was different from what I wanted to use.”

In the qualitative analysis results, good- or low-feasibility evaluation of the app was observed in 3 categories and 23 subcategories from 129 codes. By grouping the categories of good feasibility, a category called as *high feasibility of the app* was identified. This category comprised 11 subcategories: *simple, easy to use, convenience of alert, convenience of app, keeping records, opportunity to talk about asthma with a child, confirmation of asthma knowledge, action of management, user-friendly design, game elements, and existence value of app.*

In addition, by grouping the categories of low feasibility, 2 categories, namely, *improvement points for app* and *personal factors in preventing to use of app* were identified. The category of *improvement points for app* comprised 9 subcategories: *not aware of contents of app, it takes time to input, hard to know how to use, understanding of child’s developmental stage, eggs do not break, design improvements, addition of motivational elements, gap with participants’ needs, and request for app.* The category of *personal factors in preventing to use of app* comprised 3 subcategories: *no time, can be managed without using app, and difficulty of children to use their caregivers’ mobile phone.*

About 60% (12/20) of the caregivers and 73% (8/11) of the children showed a positive intention of behavior in app usage. Caregivers reported “it was easy to manage because you always see your smartphone with the app” and “aiming for self-management by the child.” About 70% (14/20) of the caregivers and children read the tailored messages in the top page of the app. However, a caregiver reported that “I was too busy to read,” and a child answered “I did not know where the message was.” Overall, in terms of app feasibility, 60% (12/20) of the caregivers reported “strongly agree” or “agree” for all evaluation items, and 63% (7/11) of children reported “strongly agree” or “agree” for 6 items, excluding satisfaction.

Figure 3. Evaluation of app feasibility. This graph shows the percentage of respondents who answered strongly agree and agree for the evaluation items.

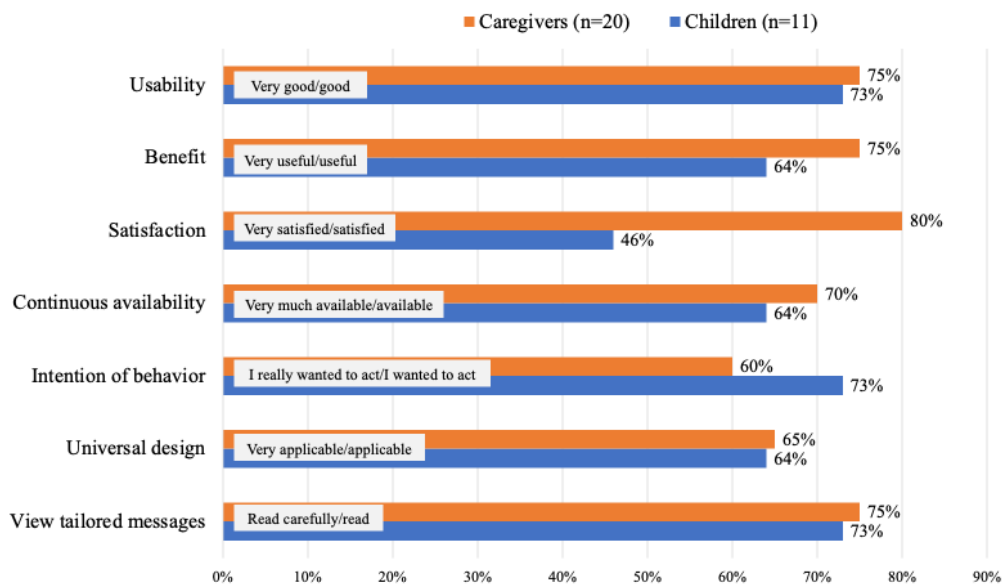

Table 4. Good-feasibility evaluation of the app by caregivers and children.

Final Version of the App

The final version of the app was modified and completed according to the access log, feasibility, usability, and qualitative feedback. We added tabs for easy operation, provided

supplementary explanation of medication alerts, and added explanations to make the prepared version easily noticeable (Figure 4). By shortening the duration of egg breaking, the egg cracked in 5 days, the animal inside it became slightly visible in 20 days, and the egg finally hatched in 40 days.

Figure 4. Modified contents of the mobile asthma app for children and their caregivers. The red frames indicate the commonly used options among children aged <7 years and 7-12 years, and added the tabs at the bottom of the top page. (A) Motivation screen and the self-monitoring input of medications, (B) detailed calendar for self-monitoring, (C) settings on the screen for medication alert function, and (D) asthma action plan in preparing for asthma exacerbation and disaster.

Discussion

Principal Results

In this pediatric asthma app, the most commonly used feature of *records* by caregivers and children aged 7-12 years were medication and diary. The asthma manga and quiz features were more frequently used by school-age children than by caregivers. However, the app feature of preparing for asthma exacerbation and disaster was rarely used. About 50-70 access logs were observed per month among the 20 pairs of the participants. Regarding app feasibility, 60% (12/20) of the caregivers agreed in all the evaluation items, whereas 63% (7/11) of the children agreed in 6 items, excluding satisfaction. In the qualitative results, difficulties in using the app were identified under 6 categories: *record*, *preparing*, *alert settings*, *change settings*, *mobile phone owner*, and *display and motivation*. Additionally, app feasibility was analyzed under 3 categories: *high feasibility of the app*, *improvement points for app*, and *personal factors in preventing the use of the app*.

Feasibility of the Asthma App for Children

This study aimed to complete the development of the pediatric asthma app according to the evaluation results of the app's feasibility. The feasibility of the app was regarded as generally good by children with asthma and their caregivers. Elements such as record, quiz, and manga were utilized by children aged 7-12 years. Based on our previous study, children enjoy quiz and manga [12]. This study revealed that the access logs for manga were higher among children aged 7-12 years than in caregivers, indicating that manga was highly acclaimed by children with asthma in this age group. Meanwhile, these

children and their caregivers reported that they used and accessed *record*, but children could not input their medication status because they did not have their own mobile phones. School-age children who did not have their own mobile phones found the app less feasible and useful than what their caregivers reported. Thus, the feasibility of the app according to children was influenced by mobile phone ownership.

For the continuous use of the app, we need to incorporate elements that capture children's interest. Adolescents aged 11-18 years with asthma used the inhaler sensors of the mobile app with game features and reminders [21]. Moreover, they reported interest in the continuous use of the management system and would recommend this app to friends [21]. Although there is a difference that adolescents have their own mobile phone, elements such as games and comics that allow children to continue self-management with fun are important. However, in some cases, parents and children fight over the use of apps. This app intends to promote caregiver-child interaction. However, caregivers and children may have trouble using this app. Hence, it is necessary for them to discuss in advance how to use the app. In addition, the evaluation of app satisfaction showed that 80% (16/20) of the caregivers were satisfied or very satisfied. Meanwhile, only 46% (5/11) of the children aged 7-12 years felt the same. The satisfaction rating was also affected because children used the mobile phones of their caregivers instead of their own.

Asthma control check was the second most frequently used feature among children aged 7-12 years with asthma and their caregivers. In this study, we delivered tailored messages based on the results of the monthly asthma control test. However, we

did not investigate the actual asthma control status for 6 months. Regarding technical feasibility, the usability score of the app was 78 based on the System Usability Scale, and approximately 75% (18/24) of the children with moderate-to-severe asthma indicated that eHealth helped them to control their asthma during the program [22]. A previous study [22] showed that eHealth care led to an 8.6% increase in asthma control, 25% in the self-management level, and 20.4% in therapy adherence. Therefore, the regular control tests and delivery of tailored messages may be effective in maintaining and improving asthma control.

Over time, the number of access logs decreased. A previous study has shown that the number of asthma app users decreases over time [23]. In this study, we instructed the participants to use the app only once a week or more on a regular basis. Thus, they could use the app freely. Of the 59 young adults with asthma who completed this study, 49 (83%) used the app ≥ 1 day per week [24]. Qualitative user experiences can be grouped under 2 themes: (1) learning how to use the app to suit the individual and (2) benefits and relevance of using the app [23]. When using the app, the content of the app must be used according to personal preference.

Adolescents identified various features such as ease of use and minimal effort as desirable criteria of an electronic monitoring device [24]. In terms of the usability evaluation in this study, 70% (22/31) of the caregivers and children reported good or very good. The results of the qualitative data indicated the high feasibility of the app, such as simple and easy to use. This app was generally easy to use. Hence, it is practical. The caregivers of the participants in this study emphasized the ease of using the app, good relationships with children, and support for self-management independence. In addition, caregivers captured the desire of children to use the app to understand asthma accurately and the mutual understanding of asthma with their children. In a previous study on a management system involving health care professionals, patients, and family members, family members supported patients in 269 (97.8%) of 275 coaching sessions [25]. That study showed that conversational agents, designed as mediating social actors involving health care professionals, patients, and family members, play not only the role of a “team player” but are also capable of improving health-relevant outcomes in chronic disease management [25]. The successful management of chronic diseases requires a trustful collaboration between health care professionals, patients, and family members. Asthma in children can be managed with the support of caregivers through the app.

As for the benefits of this app, 75% (15/20) of the caregivers reported the app to be useful or very useful. Children and adolescents aged 8-17 years and their caregivers preferred the use of technology to facilitate medication and disease management, and children had a strong willingness and ability to actively engage in their care [26]. A previous study [27] revealed that 14 children and adolescents aged 8-17 years and their caregivers reported the acceptability of using smartphones for real-time asthma monitoring. The app was easy and practical for caregivers and children. The app wireframe for adolescents based on the self-regulation theory was generally well-received, and suggestions on how to improve the app included further

customization of charts and notifications, reminders, and alerts [28]. The participants believed that the app was generally useful for managing their asthma. This feasibility study revealed areas for improvement for the asthma app for children aged 0-12 years and their caregivers. Specific improvements based on the subcategories shown in the qualitative analysis results were indicated. Addressing these areas is important in developing an engaging and effective pediatric asthma app.

An interactive digital solution study showed the feasibility and benefits of deploying user-centric design methods that engage real patients and caregivers throughout the health technology design process [29]. Another study proposed a paradigm shift—from providing features that are easy to implement technologically to using an approach in which apps are designed to deliver theoretically grounded preferred components [30]. This app was developed and modified based on theoretically grounded preferred components of our previous studies [12,13]. Moreover, it reflected the opinions of health care professionals, pediatric patients with asthma, and caregivers during the app development process. Based on a previous review about the potential of publicly available and well-adopted mHealth apps for improving asthma self-management, the apps can be consistent across review frameworks [31]. However, several apps had low quality [32]. This app can support continuous self-management of pediatric asthma. However, efforts must be taken to maintain and improve the app quality.

Limitations

This study had several limitations. The 3-month survey findings of the 30 pairs of participants and the 6-month survey findings of the 20 pairs of participants were used to identify the feasibility of the app among children with asthma and their caregivers. However, although we recruited 34 pairs of participants in this study, 14 pairs dropped out. The web-based survey showed a survey link in the app at 3 and 6 months after the app was installed. As a factor of dropout, the participants had to answer on the spot, and once the participants close the survey form, the questionnaire could not be accessed again; therefore, we could not consider the 14 pairs who dropped out. However, the evaluation of the 14 pairs with regard to app feasibility would have provided potentially more information.

The caregivers were usually mothers. Although the number of double-income families is increasing in Japan, mothers still attend the outpatient visits of children. Further, children with persistent asthma were recruited in different types of hospitals such as children’s hospital, university hospital, general hospital, and clinics, but this was not considered as a potential selection bias.

The severity of persistent asthma was not taken into consideration during participant selection. The app could be used by any child with asthma anytime and anywhere in Japan. Therefore, the results were useful in evaluating the app feasibility in the target population: children aged <7 years and 7-12 years with asthma and their caregivers. In addition, this study validated the caregiver-reported feasibility of the app among children aged <7 years. However, children aged <7 years had difficulties in answering the questions accurately, given the limited language function and cognitive development. Therefore,

caregivers were instructed to provide information regarding their needs.

The feasibility of the app was evaluated using a quantitative questionnaire that was developed by us, according to the computer system usability scale [20]. This questionnaire is not yet validated and adopted by other studies, thereby lacking external validity.

The mobile phones of the caregivers of children aged 7-12 years were used, as they do not have their own phones. This study showed inconveniences in the children's inability to use the phones freely and in their efforts toward self-care independence. However, using a caregiver's mobile phone can lead to communication and interaction between children and their caregivers.

Strengths and Future Research

The strengths of this study are as follows. This study included preschool children aged 0-6 years and 7-12 years who were not previously targeted by app developers. The data collected from children aged 2-12 years, such as usage of data app features and their comments regarding the app, could help evaluate its

feasibility and operability. In addition, it incorporated eggs that grow with the continuous use of medications and typing, which could have motivated the children with asthma and their caregivers.

The efficacy evaluation of the app will help practice effective patient education among preschool and school-age children (0-12 years) with asthma and their caregivers. In the future, the efficacy of the contents of the final version of the app must be evaluated. In addition, the behavior associated with the app usage should be considered.

Conclusions

The pediatric asthma app feasibility among children with asthma and their caregivers was generally good. Children aged 7-12 years had used elements such as record, quiz, and manga. Based on the usage data of the app features and the comments regarding the app among children aged 2-12 years with asthma and their caregivers, the app generally had good feasibility and operability. Hence, this app can support the continuous self-management of pediatric asthma. Nevertheless, efforts must be taken to maintain and improve the app quality.

Acknowledgments

We thank the children with asthma and their caregivers who participated in this study. We also wish to thank Naoki Kajita, Shoko Yokoyama, and Shinichiro Inagaki for assisting in recruitment. This study was supported by JSPS KAKENHI Grant Number JP18H03101.

Authors' Contributions

MI conducted the research idea, planning, and app development process; data collection and analysis; and wrote the overall manuscript. MS and MN recruited patients, developed the app content, discussed data analysis, and provided comments on the paper. TO, TK, AK, and RN recruited patients, managed participants' personal information, and provided comments on the paper. KY, MN, and YO helped develop the app content, discussed data analysis, and provided comments on the paper.

Conflicts of Interest

None declared.

Abstract

Background: Tanzania introduced District Health Information Software (version 2; DHIS2) in 2013 to support existing health management information systems and to improve data quality and use. However, to achieve these objectives, it is imperative to build human resource capabilities to address the challenges of new technologies, especially in resource-constrained countries.

Objective: This study aimed to determine the perceived usefulness, competency, and associated factors in using DHIS2 data among district health managers (DHMs) in Tanzania.

Methods: This descriptive cross-sectional study used a quantitative approach, which involved using a self-administered web-based questionnaire. This study was conducted between April and September 2019. We included all core and co-opted members of the council or district health management teams (DHMTs) from all 186 districts in the country. Frequency and bivariate analyses were conducted, and the differences among categories were measured by using a chi-square test. *P* values of <.05 were considered significant.

Results: A total of 2667 (77.96%) of the expected 3421 DHMs responded, of which 2598 (97.41%) consented and completed the questionnaires. Overall, the DHMs were satisfied with DHIS2 (2074/2596, 79.83%) because of workload reduction (2123/2598, 81.72%), the ease of learning (1953/2598, 75.17%), and enhanced data use (2239/2598, 86.18%). Although only half of the managers had user accounts (1380/2598, 53.12%) and were trained on DHIS2 data analysis (1237/2598, 47.61%), most claimed to have average to advanced skills in data validation (1774/2598, 68.28%), data visualization (1563/2598, 60.16%), and DHIS2 data use (1321/2598, 50.85%). The biggest challenges facing DHMs included the use of a paper-based system as the primary data source (1890/2598, 72.75%) and slow internet speed (1552/2598, 59.74%). Core members were more confident in using DHIS2 compared with other members (*P*=.004), whereas program coordinators were found to receive more training on data analysis and use (*P*=.001) and were more confident in using DHIS2 data compared with other DHMT members (*P*=.001).

Conclusions: This study showed that DHMs have appreciable competencies in using the DHIS2 and its data. However, their skill levels have not been commensurate with the duration of DHIS2 use. This study recommends improvements in the access to and use of DHIS2 data. More training on data use is required and should involve using cost-effective approaches to include both the core and noncore members of the DHMTs. Moreover, enhancing the culture and capacity of data use will ensure the better management and accountability of health system performance.

KEYWORDS

DHIS2; Tanzania; health information system; health management information system; perception; competency; usefulness

Introduction

Background

Health information systems (HISs) are 1 of the 6 building blocks of the health system [1] and are crucial in addressing health challenges and improving health service delivery in resource-limited countries [2]. However, many resource-limited countries face challenges in improving their HISs using information and communication technology (ICT) [3]. The advent of a free and open-source web-based District Health Information Software (version 2; DHIS2) signaled a new era by providing a solution for addressing one of the major challenges in HISs [4], that is, the availability of quality and timely data for planning and evaluating health sector performance [5].

DHIS2 is a tool for the collection, validation, analysis, and presentation of aggregate data, tailored to facilitate integrated health information management activities and inform decision-making [3,6]. The software is based at the district level and derives primary data from paper-based monthly reports of health facilities. As a web-based system in a centralized server, DHIS2 presents a more stable solution compared with the previous HIS solutions [7]. With DHIS2, anyone with a computing device connected to the internet, a system username, and a password can view data anywhere as soon as it is entered [8].

The DHIS2 is a simplified generic tool based on an open metadata model and a flexible user interface that does not require a preconfigured database application [9]. Users can customize the software package according to their information needs without the need to have advanced programming skills or learn complex programming language [8-10]. The ultimate aim of DHIS2 is to establish a centralized database that connects service delivery with other health systems [11].

DHIS2 has several modules and features that make it superior to the previous HIS software used in sub-Saharan African countries [9]. Its features include customizable data entry forms with indicators; data visualizers, such as graphs, web-based pivot tables, and dashboards; an integrated geographic information system module; import and export metadata; customizable data quality checks; user access control; and messaging and mobile solutions. Other modules include a patient tracker and mobile app and are interoperable with other systems [12].

The DHIS2 in Tanzania

Over the past decade, the Tanzanian health sector has seen an increasing focus on strengthening its national HIS. This followed a wind of change that swept across other African countries south of the Sahara because of accelerated disease control initiatives, specifically HIV, tuberculosis, and malaria, which created

additional demand by partners for timely measurement of results [11].

Since then, several reviews have been conducted to identify bottlenecks and address them to improve HISs. The review conducted before the introduction of the DHIS2 showed that reporting systems were weak, both in terms of completeness and timeliness [13].

Consequently, the Ministry of Health, in collaboration with implementing and development partners who support various health service activities, including the DHIS2 implementation, created the Monitoring and Evaluation Strengthening Initiative in 2010, whose vision was to have a comprehensive platform for health information, evidence-based decision-making, and accountability for results [14]. The key strategic objective was the introduction of the DHIS2. Tanzania adopted the DHIS2 as a national health management information system (HMIS) platform in 2010, and by December 2013, all districts in the country were using the system. The system was customized to capture and process all routine aggregate data collected monthly from all health facilities, including public and nonpublic facilities [15,16].

ICT has an impact when people have the necessary competencies to develop and use it; otherwise, the system becomes a waste of resources [17]. Although ICT has been introduced to help manage resources and increase efficiency, many resource-limited countries face a severe shortage of appropriate human resources, both in terms of quantity (numbers) and quality (skills) [6,15,18]. The implementation of the DHIS2 in Tanzania, as in other resource-constrained countries that have adopted the system, is likely to suffer from poor and unevenly developed infrastructure, inadequate competencies among the workforce to support the system, and the use of information for decision-making [11]. To maximize return on investment, implementers of the DHIS2 need to address the major challenges, including skill deficiencies in the workforce [18]. Other factors affecting the successful implementation of an electronic HISs include positive attitudes toward the HISs, confidence in using computers and the HISs, and fast and reliable internet connectivity. These factors need to be regularly monitored, and challenges affecting the effective use of an electronic HISs must be addressed to promote a data culture for evidence-informed decision-making [19]. However, there is limited information on district health managers' (DHMs) perceptions and competencies in using the DHIS2 and its data for informed decision-making in Tanzania.

Methods

Aim of This Study

This study aimed to determine the perceived usefulness of DHIS2 and its competency in using generated data among DHMs, who are the primary target beneficiaries of the system.

Study Design

This is a descriptive cross-sectional analytic study that used a quantitative approach to gather information on the perceived usefulness of the DHIS2, the competencies of DHMs, and factors associated with the use of DHIS2 data to improve health services. Factors associated with DHIS2 use, according to the Performance of Routine Information System Management framework, were categorized as technical, organizational, and behavioral issues [20]. Respondents were not only given an opportunity to select from predefined factors but also given the freedom to specify other issues affecting the use of the DHIS2 and its data.

Study Setting

Tanzania is an East African country made up of the mainland and islands of Zanzibar and is the largest country in the East African Community. It spreads over 947,300 km² of land, is multiethnic, and has wide cultural diversity. At the time of this study, Tanzania was a low-income country, with a gross domestic product per capita of 957 and a growth rate of 6.8%. The Tanzania Mainland alone is estimated to have a population of 55 million, distributed in 26 regions and 186 districts. The country has >8000 health facilities, offering a wide range of health care services [21].

The health system in Tanzania is well organized in a hierarchical structure from the community to the national level. It is a decentralized system, whereby local government authorities are responsible for the planning and management of primary health service delivery. At the primary level, there are district hospitals, health centers, and dispensaries. The DHMs are responsible for district health planning, resource allocation, implementation of health interventions, and supervision of health service provision in primary health care settings. Thus, it is paramount to assess the perception and competencies of DHMs regarding the use of the DHIS2 and its data in accomplishing their core functions.

We defined the use of DHIS2 to include the entire process from data entry, navigation through the DHIS2 application, data validation, data analysis, and production of visualizations. We defined data use as the reported use of DHIS2 data for the planning and implementation of activities, for example, for planning, staff deployment, allocation of funds, procurement of medicine and supplies, and production of league tables.

Study Population

All core and co-opted members of the district health management teams (DHMTs) were included. Core members were recruited based on their professional cadre. These included the district medical officer, who is a medical doctor, and the district health officer, who is an environmental health scientist by profession. Co-opted members are program coordinators who are invited to the DHMT from time to time when issues pertaining to their programs are discussed. These include the reproductive and child health, HIV, tuberculosis, and malaria programs.

Sampling Strategy and Sample Size

Data were collected to represent the entire country; hence, 186 districts in all 26 regions in the country were included. In each

district, both core and co-opted members of the DHMTs (approximately 15) were interviewed.

At the beginning of this study, the researchers (DS, FS, and CK) collected the names, email addresses, and phone numbers of all DHMs from among the regional HMIS focal persons. Data managers linked DHMs to the web-based questionnaire through their email addresses, and phone numbers were used to follow up on nonresponders and to communicate data discrepancies. The email addresses were collected on a separate sheet and used only by the data managers for follow-up during data collection. No identifiable personal information was included in this questionnaire.

Data Collection Approaches

This study was conducted between April and September 2019. We developed a questionnaire containing different aspects of the DHIS2, data management and use. The questionnaire had several sections, including sociodemographic information, respondents' self-rated skill levels on basic computer applications and the DHIS2, and skills on data use for various purposes. The questionnaire also had a section that assessed perceived usefulness, ease of use, and user satisfaction with the DHIS2 [22]. The perception statements were rated on a 5-point Likert scale, ranging from 1 (strongly disagree) to 5 (strongly agree), covering managers' experience and perception of the application of the DHIS2 in their work, its perceived benefits, and their willingness and ability to use the DHIS2 and data from the system for various decision-making processes. The availability of ICT support from the councils as well as challenges hindering the implementation and use of DHIS2 were also included in the questionnaire.

The questionnaires, translated into Kiswahili, were formatted using Google Forms to ease the filling and submission by respondents via an internet-enabled device with an internet browser. Furthermore, the questionnaires had mandatory quality checks to ensure that all relevant fields had been filled in before submission of the data into a database.

A total of 26 field staff members, 1 from each of the 26 regions, were recruited to facilitate data collection. The field staff comprised regional HMIS focal persons, who are government officials assigned with the responsibility to oversee HMIS activities in their respective regions. The regional HMIS focal persons received a half-day orientation on the study objectives and data collection procedures during the 2019 annual regional HMIS focal persons meeting. They were also tasked to provide the names and addresses of members of all DHMTs in their respective regions. Data managers later used these to send questionnaires to the respondents, who had to provide consent, fill in the questionnaire, and submit their responses on the web to a server located at the Muhimbili University of Health and Allied Sciences (MUHAS) offices. Field staff made follow-up visits to the respective districts to ensure the completion of the questionnaires.

Data managers and researchers (DS and FS) scrutinized the submitted data daily for duplicate submissions, incomplete questionnaires, and discrepancies. When duplicate forms were dropped, incomplete questionnaires and discrepancies were

communicated to the respondents before making the necessary corrections in the database. In addition, the types of errors observed were communicated to the field staff, who used this information to guide respondents on proper filling in of the questionnaires during on-site follow-up visits. This helped to avoid the recurrence of similar mistakes.

The questionnaire was pretested with staff at Muhimbili National Hospital and MUHAS in Dar es Salaam to ascertain the ease of filling in the questionnaires and to ensure that the questions were clearly understood. The findings from the pretest were used to improve on the tools before distributing them to the respondents.

Data Analysis

Data analysis was performed using SPSS (version 20; IBM Corporation) software. Frequency tables were prepared to assist in data cleaning. Data were presented using tables and charts with comparisons of different categories. Bivariate analyses were conducted to determine the relationships among the selected variables. Differences among categories were measured using the chi-square test. $P < .05$ were considered significant.

Ethical Clearance

Ethical clearance was obtained from the institutional review board of MUHAS, Tanzania (reference number DA.282/298/01.C). Permission to implement this research was obtained from the Ministry of Health, Community Development, Gender, Elderly, and Children and the President Office Regional Administration and Local Government. Written informed consent was obtained from all participants. No identifiable personal information regarding the respondents was collected. The research data were kept secure and confidential by 2 researchers (DS and FS) and 2 data managers.

Results

General Characteristics

Responses from DHMs were received from all 186 district councils in the 26 regions in Tanzania Mainland. A total of 2667 (77.96%) of the expected 3421 DHMs responded, of which 2598 (97.41%) consented and completed the questionnaires. More than half (1466/2598, 56.43%) of the respondents were male, and approximately half (1291/2598, 49.69%) were aged between 35 and 48 years. Most participants (2038/2598, 78.44%) had a medical professional background (Table 1).

Table 1. Sociodemographics of participants (N=2598).

Perceived Usefulness of the DHIS2

DHMs were asked for their opinions on the usefulness of DHIS2. Most responses indicated that DHIS2 contributed to improved data quality (2239/2598, 86.18%) and reduced workload (2123/2598, 81.72%). Furthermore, 86.64% (2251/2598) of the respondents indicated that DHIS2 use has improved data availability ([Multimedia Appendix 1](#)).

Opinions of Respondents on the Use of the DHIS2

As indicated in [Table 2](#), DHMs were asked about their opinions on several issues pertaining to the usefulness of DHIS2 and the ease of use of the system. Overall, most DHMs expressed satisfaction with the system, explaining that the system was good for their work (2288/2598, 88.07%) and enabled them to be more effective (2187/2598, 84.18%). When asked if the system was confusing and difficult to learn and understand, most DHMs disagreed, as 66.05% (1716/2598) said it was not confusing and 75.17% (1953/2598) said it was not difficult to learn and understand.

Table 2. Opinions of respondents on the use of District Health Information Software (version 2; DHIS2; N=2598).

Opinion statements based on perception	Not sure, n (%)	Disagree, n (%)	Agree, n (%)
The DHIS2 enhances data use	233 (8.97)	126 (4.85)	2239 (86.18)
The DHIS2 enables effective completion of work	283 (10.89)	128 (4.93)	2187 (84.18)
The DHIS2 is good for my work	225 (8.66)	85 (3.27)	2288 (88.07)
The DHIS2 is confusing	527 (20.28)	1716 (66.05)	355 (13.66)
The DHIS2 is difficult to learn and understand	410 (15.78)	1953 (75.17)	226 (8.7)
Generally, I am satisfied with the DHIS2	321 (12.36)	203 (7.81)	2074 (79.83)

Levels of Basic Computer Skills

For the DHMs to be able to use the DHIS2 as a tool, they ought to have skills in basic computer operations and applications and use of the DHIS2 software. Respondents were assessed using self-rated questions to establish their skill levels regarding various ICT issues. As indicated in [Multimedia Appendix 1](#), slightly more than half (1377/2598, 53%) of the DHMs reported having advanced skills in basic computer operations, file management (1439/2598, 55.39%), Microsoft Word (1404/2598, 54.04%), and internet use (1298/2598, 49.96%). Almost all

(2390/2598, 91.99%) members of the DHMT reported having either average or advanced skills in DHIS2 use.

A bivariate analysis was performed on some of the factors likely to be associated with respondents' skills in DHIS2 use. [Table 3](#) provides the association between respondents' ability to use the DHIS2 and their sex, profession, title, and level of English proficiency. Male respondents, medical professionals, core members of the DHMT, and those with very high levels of proficiency in English were more likely to have higher skills in the use of the DHIS2 compared with their counterparts. The differences were statistically significant.

Table 3. Bivariate analysis of factors associated with respondents' self-rated skill levels in District Health Information Software (version 2) use (N=2598).

Access to the DHIS2 and Training in Data Analyses

For DHMs to use DHIS2 data, they must have access to the DHIS2 and training on how to use it. Approximately half (1380/2598, 53.12%) of them reported having a user account and password to access the DHIS2. Slightly less than half (1237/2598, 47.61%) of the DHMs received training on data analysis using the DHIS2.

A bivariate analysis was performed on factors likely to be associated with receiving training in DHIS2 data analysis. [Table 4](#) provides the association between training in DHIS2 data analysis and respondents' sex, age, profession, experience at work, title, level of education, and level of proficiency in English. More male respondents, medical professionals, respondents with long experience at work, respondents who are program coordinators, nondegree holders, and respondents with a very high level of proficiency in English received training in DHIS2 data analysis.

Ability of DHMs to Use DHIS2 Data

DHMs were asked to rate their skill levels based on their ability to enter data into the DHIS2 and use the data for decision-making. The ability to prepare league tables to rank the level of health facility performance was used as a proxy for data use. Approximately half (1287/2598, 49.54%) of the DHMs reported having an advanced level of skill for data entry, and approximately half (1321/2598, 50.85%) reported having average or advanced skills to prepare and use league tables. The proportion of team members with no skills to enter data or prepare and use league tables was very small (34/2598, 1.31% and 59/2598, 2.27%, respectively).

Ability of DHMs to Use DHIS2 Modules and Data

DHMs were asked about their confidence in using the DHIS2 system and its data. Approximately two-thirds of the respondents had an average or high level of confidence in conducting data validation (1774/2598, 68.28%) and analyzing DHIS2 data to produce visualizations (1563/2598, 60.16%). Slightly less than

three-quarters (1865/2598, 71.79%) of the team members had an average or high level of confidence in using DHIS2 data for planning. Of these team members, less than half were highly confident in conducting data validation (1151/2598, 44.3%) and using DHIS2 data for planning (1237/2598, 47.61%). Only one-third (937/2598, 36.07%) of them were highly confident in analyzing DHIS2 data and producing visualizations. Other areas in which data from DHIS2 are used included staff deployment and allocation of funds, medicine, and supplies.

Table 5 shows that the ability to use DHIS2 data (which was measured using ability to produce league tables as a proxy) was also associated with the respondent's sex, age, profession, title, and level of proficiency in English. Male respondents, medical professionals, and those with a very high level of proficiency in English were more confident in using DHIS2 data compared with their counterparts, and the difference was statistically significant. However, unlike for DHIS2 use, most (1075/2598, 41.38%) of the core members of DHMTs who have skills in using both the DHIS2 software and data were program coordinators.

Table 5. Factors associated with the ability of district health managers to use District Health Information Software (version 2) data (N=2598).

^aThe ability to produce league tables was used as a proxy to measure the ability to use District Health Information Software (version 2) data.

Existence of a Supporting Environment for the Use of the DHIS2

In general, approximately 59.85% (1555/2598) of the respondents indicated the need for more resources to support the effective use of DHIS2. More than half of the respondents did not agree that their councils had an adequate number of computers (1504/2598, 57.89%) and reliable internet connection to support DHIS2 functions (1485/2598, 57.16%). Slightly less than half (1227/2598, 47.23%) of the team members disagreed that their councils had an adequate budget to run the DHIS2.

Perceived Challenges Hindering the Implementation and Use of the DHIS2

Respondents were asked to indicate the challenges affecting the implementation and effective use of the DHIS2. Table 6 shows that most of the respondents (1890/2598, 72.75%) felt that overwhelming paperwork was the main constraint affecting the implementation of the DHIS2. Approximately two-thirds (1670/2598, 64.28%) of the respondents felt there was inadequate connectivity and ICT support (1734/2598, 66.74%), approximately 59.74% (1552/2598) felt that slow internet speed was a serious problem, and approximately half (1307/2598, 50.31%) thought data quality was a challenge.

Table 6. Perceived challenges hindering the implementation and use of the District Health Information Software (version 2; N=2598).

Challenges affecting the use of District Health Information Software (version 2)	Participants, n (%)
There is a lot of paperwork	1890 (72.75)
Inadequate technical support	1566 (60.28)
Inadequate information and communication technology officers	1734 (66.74)
Unreliable internet connectivity	1670 (64.28)
Slow internet speed	1552 (59.74)
Data quality compromised during data processing	1307 (50.31)
Lack of guidelines for filling out the main data sources and reporting forms	1190 (45.8)
Data collection and reporting forms are not standardized; some groups have their own formats	1028 (39.57)
Lack of feedback	986 (37.95)
Electrical power interruption or unreliable electricity	895 (34.45)
Parallel data systems collecting the same indicators	814 (31.33)
Data collection and reporting forms are not standardized; some groups have their own formats	733 (28.21)
Data overload: data management operational processes are not documented	675 (25.98)
Personnel are not trained in the use of data sources and reporting forms	596 (22.94)

Discussion

Principal Findings

In this study, most (2074/2598, 79.83%) DHMs reported satisfaction with the DHIS2, stating that it improved their quality of work and made their daily work effective. This study shows that DHMs have appreciable competencies in using the DHIS2 and its data. Some challenges have been identified, and recommendations have been made for the improvement of access to and use of DHIS2 data. Similar findings have been reported in other countries that implemented the DHIS2, where health workers were reported to be satisfied with the ease of data processing [11,23,24]. In addition, the perception of health workers regarding the use of health information technology, such as DHIS2, is influenced by user-friendliness and the perceived benefits of the system [25]. Although in these studies the reported satisfaction was limited to the use of the application (in data processing), our study went further to reveal satisfaction with the outcomes of using the application. Furthermore, in this study, >80% of the DHMs in Tanzania indicated a high level of commitment to using the DHIS2, as they perceived the system to have improved data quality, reduced workload, and improved data use and decision-making (Table 2). This is above the commitment levels reported in other studies in Ethiopia, Ghana, Nigeria, and Iran [26].

The high rate of satisfaction reported in our study was attributed to the improved availability and quality of routine data and the reduction in workload burden for DHMs. Before the introduction of the DHIS2, availability and quality of routine data were unsatisfactory [13,27]. Reporting systems were weak, and user satisfaction with usability was low. The situation changed after the introduction of the DHIS2, where completeness and timeliness of reporting were maintained at a very high rate [28]. Improved data availability can be attributed to the web-based feature of DHIS2 with a centralized server that simplifies data entry and access and enables anyone with access rights to view

the data from anywhere [8,11]. In Tanzania, the DHIS2 has integrated >15 intervention programs and several digital HISs, including human resources for HISs and health facility registries [16]. The creation of a central data warehouse on a central web-based server integrated with other digital HISs makes the DHIS2 a robust source of information and ensures better access to data and information by users [11,24,29-31].

The DHMs' satisfaction with data quality emanates from the DHIS2 data validation tools that simplify consistency checks compared with when the exercise was performed on a paper-based system [9]. As the DHIS2 brings together data from various programs, data triangulation can be performed easily and discrepancies, identified [15]. Moreover, the ease in accessing DHIS2 data has exposed more people to it, which has facilitated feedback and self-assessment, making it easier for DHMs to identify errors for prompt correction [4,24].

DHMs' satisfaction with reduced workload burden can be explained by the ability of the DHIS2 modules to produce standardized tables and allow tailor-made reports to be prepared by users using pivot tables [9].

The high level of satisfaction with the software reflects the readiness of DHMs to develop further, which can be taken as an opportunity for the DHIS2 implementers or Ministry of Health to strengthen the strategy for increasing data demand and use, which is currently a major challenge [32].

Almost all (2390/2598, 91.99%) DHMs reported having at least basic-level skills on the DHIS2, whereas half of them (664/2598, 25.56%) reported having advanced skills. To our knowledge, this is the first study to quantify and report the competencies of health managers in using the DHIS2 and data generated from it.

One of the major factors that might have contributed to such a level of competency is the introduction of the DHIS2 on an existing paper-based HISs, which was relatively well developed

with functioning structures and materials for data collection, reporting, and analysis [33]. In addition, the training of DHMs was based on hands-on practice for data analysis using actual data, the provision of technical support and supportive supervision, and the distribution of computers and accessories to all districts immediately after the training. Furthermore, the high level of competencies is likely to be because of the decentralization of governance in the districts, which has provided them authority for decision-making in the planning and implementation of interventions [34]. The extensive use of data from the DHIS2 during the preparation of Comprehensive Council Health Plans through the Planning and Reporting system (PlanRep) [35] may also explain why more DHMs reported a higher level of competency in the use of DHIS2 data for planning compared with other purposes.

Program coordinators received more training in data analysis compared with other members of the DHMT. This can be explained by the fact that training for continuing education in many districts is supported by implementing and development partners through their respective intervention programs. In such training, program managers are given priority, whereas other members are often left out because of limited funding.

In this study, only half (1380/2598, 53.12%) of the DHMs reported having access rights to the DHIS2 application. Similar findings were reported in a study conducted in Kenya, where approximately half of the health workers in the studied health facilities reported having no access rights, and as a result, they did not use the DHIS2 data [4]. Challenges in having access rights undermine the strength of the DHIS2 in ensuring that DHMs have prompt access to information for decision-making [8,11]. Nevertheless, we report a higher proportion of DHMs using the DHIS2 than those reporting to have DHIS2 user accounts. In addition to sharing accounts among DHIS2 users, this may also indicate peer or self-learning, a phenomenon that is uncommon in the country's health sector [18].

Finally, we report challenges in the provision of a supporting environment that is likely to have undermined the competency of DHMs in using the DHIS2 application and the generated data. These include inadequate support for ICT, including computers and internet connections and insufficient funds at the district level. Interestingly, the level of achievement attained with only half of the expected resources is appreciably high. This indicates that there is a high potential for improvement if more resources are available to DHMs.

Implications of the Study Findings

Training in DHIS2 use has been cited in the literature as one of the challenges affecting the establishment and effective use of the system [10]. The fact that almost all (2390/2598, 91.99%) DHMs reported having at least basic computer and DHIS2 application skills provides a favorable environment for upgrading to the advanced level. As the proportion of DHMs who reported having advanced skills in the use of DHIS2 data was dismal, it is still adequate to form a critical mass that can be used to prepare data use champions. These can then be deployed to provide on-the-job peer education; supportive supervision; and mentoring to all members of the DHMT, irrespective of their cadre; with the aim of strengthening the

organizational culture of data demand and use for decision-making [36].

DHMs play a central role in the planning and implementation of primary health care services in a decentralized country such as Tanzania [34]. The reported competency in using DHIS2 data found in this study is likely to have a multiplier effect at the health facility level, where decisions made by DHMs have a profound effect, and at the national level, where DHMs are held accountable for resources invested in district health services.

Methodological Considerations of This Study

The findings of this study are self-reported; hence, they are likely to be overestimated for respondents who want to exaggerate their capacity in the hope of being applauded or may underestimate their capacity in the hope of receiving more support. Studies have indicated that respondents prefer to attend training or meetings because of the allowances paid—the *per diem syndrome* [37-39]. In this case, some respondents may prefer to underestimate their level of knowledge so that they can get opportunities to attend training for the sake of receiving allowances. Therefore, it is difficult to predict the direction of bias likely to result from the reported data.

The web-based administration of questionnaires enables access to large and different populations, and it is an inexpensive, quick, and convenient approach to collecting data [40-42]. However, this approach has the disadvantage of having relatively lower response rates compared with face-to-face administration [40]. Nevertheless, in this study, the response rate was higher (75.9%) than the mean response rate for web-based data collection approaches reported by Blumenberg and Barros [40].

Furthermore, the scope of this study was limited to determining DHMs' perceived competency in using DHIS2 and the generated data. The quantitative nature of this study prevented us from answering some pertinent practical questions. Questions such as "What is behind the reported success in Tanzania?" will require qualitative studies to answer them.

Strengths of Our Study

This is the first study to report the competencies of DHMs in using the DHIS2 application and the generated data. This study gathered primary data from the DHMs in 186 districts in the country. In this study, we quantified the level of satisfaction with the DHIS2 application among DHMs, its usefulness, and their competencies in using the application and generated data.

Conclusions

DHIS2 modules have enhanced availability and quality of data and reduced workload burden compared with the situation that existed before its commencement. This has led to satisfaction with the application by most (2187/2598, 84.18%) DHMs because of improved quality of work and their effectiveness. Although almost all (2564/2598, 98.69%) DHMs reported to have at least basic skills on DHIS2, approximately one-fourth of them (746/2598, 28.71%) reported having high-level skills. The Ministry of Health needs to seize this opportunity to train the few DHMs with high-level skills to enable them to support the majority who have basic-level skills in data use for

decision-making. Further research is needed to determine the factors that influence the reported DHMs' competency and the extent to which the competencies are translated into data use for decision-making to improve health care services.

Acknowledgments

The authors are grateful to the management of the Ministry of Health, Community Development, Gender, Elderly and Children and the President Office Regional Administration and Local Government for allowing them to carry out this research at their sites. The authors also thank the members of the Regional Health Management Teams and district health management teams for providing valuable support during this study. This study was funded by the Global Fund to fight HIV, tuberculosis, and malaria. The funder did not have any role in the study design, data collection and analysis, decision to publish, or manuscript preparation. The manuscript writing was not supported financially.

Conflicts of Interest

None declared.

Abstract

Background: There is increasing interest in the potential uses of mobile health (mHealth) technologies, such as wearable biosensors, as supplements for the care of people with neurological conditions. However, adherence is low, especially over long periods. If people are to benefit from these resources, we need a better long-term understanding of what influences patient engagement. Previous research suggests that engagement is moderated by several barriers and facilitators, but their relative importance is unknown.

Objective: To determine preferences and the relative importance of user-generated factors influencing engagement with mHealth technologies for 2 common neurological conditions with a relapsing-remitting course: multiple sclerosis (MS) and epilepsy.

Methods: In a discrete choice experiment, people with a diagnosis of MS (n=141) or epilepsy (n=175) were asked to select their preferred technology from a series of 8 vignettes with 4 characteristics: privacy, clinical support, established benefit, and device accuracy; each of these characteristics was greater or lower in each vignette. These characteristics had previously been emphasized by people with MS and or epilepsy as influencing engagement with technology. Mixed multinomial logistic regression models were used to establish which characteristics were most likely to affect engagement. Subgroup analyses explored the effects of demographic factors (such as age, gender, and education), acceptance of and familiarity with mobile technology, neurological diagnosis (MS or epilepsy), and symptoms that could influence motivation (such as depression).

Results: Analysis of the responses to the discrete choice experiment validated previous qualitative findings that a higher level of privacy, greater clinical support, increased perceived benefit, and better device accuracy are important to people with a

neurological condition. Accuracy was perceived as the most important factor, followed by privacy. Clinical support was the least valued of the attributes. People were prepared to trade a modest amount of accuracy to achieve an improvement in privacy, but less likely to make this compromise for other factors. The type of neurological condition (epilepsy or MS) did not influence these preferences, nor did the age, gender, or mental health status of the participants. Those who were less accepting of technology were the most concerned about privacy and those with a lower level of education were prepared to trade accuracy for more clinical support.

Conclusions: For people with neurological conditions such as epilepsy and MS, accuracy (ie, the ability to detect symptoms) is of the greatest interest. However, there are individual differences, and people who are less accepting of technology may need far greater reassurance about data privacy. People with lower levels of education value greater clinician involvement. These patient preferences should be considered when designing mHealth technologies.

KEYWORDS

mobile technology; neurological conditions; multiple sclerosis; epilepsy; discrete choice experiment; digital health; mHealth; wearable technology; wearable biosensors; health economics; health data

Introduction

Mobile health (mHealth) technologies such as wearable biosensors could supplement the care of people with neurological conditions, as symptoms of disability can evolve over time and are generally hard to capture through single measurements. mHealth technologies can help to detect variations in movement and physiological signals that indicate changes in the underlying disease state, thereby allowing earlier intervention or tailored therapy. While there is emerging evidence to suggest that mHealth technologies are acceptable to people with neurological conditions, such as epilepsy, stroke, multiple sclerosis, dementia, and Parkinson's disease [1-6], adherence, especially over long periods, can be low. In a recent systematic review of engagement with remote measurement technology (RMT) for health care support, we found that despite studies being short (the longest study was 13 months) they had variable, and in some cases relatively high, dropout rates (0%-44%) [7]. If people with neurological conditions are to benefit from these resources over the long term, we need a better understanding of what influences their engagement.

Theories of technology engagement emphasize the role of beliefs and perceptions [8]. In general, when there is motivation to use mHealth technologies, and these tools are perceived to be useful, accessible, and convenient, user engagement may be high [7,9]. Specifically, factors such as performance expectancy (how much technology will help to achieve something); effort expectancy (how easy technology is to use); and how well resourced and supported the technology is, account for differences in behavioral intentions and affect mHealth technology use (with a medium effect size) [10]. However, there are additional factors that are correlated with variability in mHealth technology use, including demographic variables, such as gender and age [11,12], prior experience with technology [13], and social influence (how important the technology is to others) [8]. People with different diagnoses also have different views of what might attract or deter them from RMT use. In this study, we have chosen to focus on 2 specific neurological conditions in which people experience a relapsing-remitting course and for which there is already some evidence that technology may be an acceptable method for long-term symptom management:

multiple sclerosis (MS) and epilepsy. In our earlier work, we identified barriers, facilitators, and moderators specific to people with MS or epilepsy [4-6]. For both conditions, we highlighted the need to balance costs against rewards when deciding on the use of mHealth technologies. Better understanding these trade-offs would provide a more sophisticated understanding of which factors most influence engagement in these two populations. This would enable us to develop technology that is more acceptable to people with neurological conditions such as MS and epilepsy, encouraging long-term adherence.

One approach emerging from health care economics is the use of discrete choice experiment (DCE) surveys [14,15]. DCEs have been used to break down health care interventions or services into characteristics, known as attributes, and then to quantify their relative value by asking individuals to choose between services described according to varying attribute levels. Analysis of these choices allows the identification of the most important and preferred attributes [14,15]. Previous DCEs have explored preferences for health care choices among people with epilepsy or MS, and have investigated factors such as the design of interventions, (eg, whether people with MS prefer oral treatment versus intravenous infusions) [16-19], methods of diagnosis (eg, if people with epilepsy prefer long-term 24-hour electroencephalography or sleep-deprived electroencephalography) [20], the best targets for treatment (eg, whether patients prefer to delay the progression of their disability or improve their quality of life) [21,22], and the acceptability of different medications (such as by comparing different side effects) [23-27]. Meta-analyses have shown that DCEs can produce reasonable predictions of real-world health-related behaviors [28]. Ryan et al [29] argue that the strength of this approach lies in the integration of patients' values concerning all aspects of care into a single measure; this could inform the efficient allocation of resources in a health care system, particularly in relation to the introduction of new technologies.

Research on relative preferences for sharing health data, which is integral to digital technology use, has discovered that information on mental health is more sensitive than information on physical health, and that privacy-utility trade-offs are important [30]. The present study extends these findings, to

explore the relative importance of several other dimensions that have been shown to affect mHealth technology engagement in people with MS or epilepsy, and determined whether any of these dimensions varied by subgroup. We chose to investigate potential moderators identified in previous research on the general public and specific patient populations: demographic factors (such as age, gender, and education), acceptance of and familiarity with mobile technologies, and symptoms that could affect motivation (such as depression).

Methods

Study Design

This was an observational study of participants with MS or epilepsy. The participants were asked to choose between alternative mobile technologies that were described according to a set of characteristics in a DCE survey. The survey was administered online and was given ethical approval by the National Research Ethics Service Committee London—Social Care (19/IEC08/0013).

Development and Implementation of the DCE

Service Users' Identification of Key Barriers and Facilitators for mHealth Technology Engagement and Assignment of Levels

A systematic review was used to generate 8 potential attributes that could vary continuously [7]. This list of attributes was checked against data from a qualitative analysis of 9 focus groups, including 44 people who had received a diagnosis of either MS [6] or epilepsy [5], and an analysis of a further 5 focus groups, including 25 people who reported symptoms of depression (which are commonly comorbid with neurological conditions) [31]. After this review, 7 more attributes were added, for a total of 15. The final list of 15 attributes and levels was sent to a patient advisory group, which included 5 people with epilepsy, 3 people with MS, and 6 people with depression. This group independently ranked the list in order of importance. Average ranked scores were used to generate the top 4 barriers and facilitators for inclusion in the survey, so as not to overburden participants. This group further advised on the wording of the final set of items (see [Textbox 1](#)).

Textbox 1. Final attributes and their levels used in the discrete choice experiment.

1. Accuracy of detection
 - High: detects symptoms correctly 75% of the time.
 - Moderate: detects symptoms correctly 50% of the time.
 - Low: detects symptoms correctly 25% of the time.
2. Privacy
 - High: all information is stored on the device; no information leaves the device unless authorized by the user.
 - Moderate: information that is hard to use to identify the user is automatically shared with the organization that makes the device or software.
 - Low: information that can identify the user (eg, through digital identifiers or location) is automatically shared with the organization that makes the device or software.
3. Benefit to user
 - High: clear, proven, practical benefit (ie, the device currently contributes to health management).
 - Low: possible but unknown benefit (ie, the system is being tested as part of research and may contribute to health management now or in the future).
4. Scope for support
 - High: personal use only (eg, self-management of a health condition).
 - Low: personal use and ability to share identifiable information with a clinician (eg, clinician-assisted management of a health condition).

Survey Format and Scenario Development

The final 4 attributes and levels selected provide $2^2 \times 3^2 = 36$ unique combinations. We used NLOGIT software (NLOGIT) to generate an 8-task fractional-factorial main effects design, aiming to obtain near orthogonality, conducted in 1 block. We

asked participants to choose between 2 different unlabeled mobile technology descriptions and an opt-out option (“I don’t know”). The scenarios were balanced in terms of the number of times that each level of the attribute appeared; [Figure 1](#) shows an example. The survey was created using the software Qualtrics (Qualtrics Experience Management).

Figure 1. Questionnaire example.

You have been asked to use one of two mobile technologies that could help in the management of your health. They collect the same information and are used in the same way but differ on a number of features detailed below.

Mobile technology 1		
Accuracy	75%	Detects symptoms correctly 75% of the time
Privacy	High	All information is stored on the device, no information leaves the device, unless authorised by the user
Benefit	Possible	Possible but unknown benefit (system being tested as part of research, may contribute to health management now or in the future)
Support	Clinician assisted	Personal use and ability to share identifiable information with a clinician (e.g., clinician assisted management of a health condition)
Mobile technology 2		
Accuracy	25%	Detects symptoms correctly 25% of the time
Privacy	Medium	Information where it is hard to identify the user is automatically shared with an organisation that makes the device or software
Benefit	Clear	Clear, proven, practical benefit (currently contributes to health management)
Support	Personal use	Personal use only (e.g., self-management of a health condition)

If you were offered one of these technologies, which would you prefer?

Mobile technology 1

Mobile technology 2

I don't know

Additional Data Collected

The use and acceptance of mobile technology (eg, smartphones and wearable devices) were assessed, the latter with a modified version of the Unified Theory of Acceptance and Use of Technology 2 (UTAUT2) questionnaire, which provides a score from 0 to 28 [32] (details are described in [Multimedia Appendix 1](#)). Information on age, gender, level of education, self-reported diagnosis, and whether people had experienced an episode of a depressive disorder within the past 2 years were also collected.

Survey Administration and Data Collection

Participants were recruited from two sources to increase participant variation and overcome the digital divide: (1) through charities such as the MS Society and Epilepsy Action, who circulated an online link to the survey and promoted it on social media, and (2) through outpatient hospital clinics for people with epilepsy and MS, with the researchers facilitating survey access. No incentives were offered.

Sample Size and Data Analysis

Formal sample size calculations are challenging for DCEs, but their level of precision increases rapidly up to 150 participants, [33] so we adopted this as our sample size guide for each group (ie, MS and epilepsy). Analysis was undertaken using a mixed multinomial logit model which allows for unobserved heterogeneity of preferences across respondents. This modeling approach also accommodates multiple observations per respondent and relaxes the assumption of independence of irrelevant alternatives required in the commonly applied multinomial logit model. Responses of “I don’t know” were treated as missing data rather than rejection of the device. It was hypothesized that higher levels of privacy, greater levels of support, increased accuracy of detection, and clearer benefit to the user would influence respondents’ decisions. Coefficient signs and significance were explored to investigate whether the data supported these hypotheses. The attribute accuracy of

detection was specified as a categorical variable with 3 levels to allow for a nonlinear relationship with utility. All categorical variables were effects coded to aid interpretation [34]. Marginal rates of substitution were calculated to express the degree to which respondents would trade off attribute levels and accuracy. It was assumed that the change in accuracy was linearly related to the change in utility for changes in accuracy within the levels modeled.

The effects of 7 prespecified patient characteristics on response data were investigated. The characteristics were health condition (ie, MS or epilepsy), age, gender, education (categorized as low, medium, or high), depression within the past 2 years (categorized as yes or no), current user of wearable technology (categorized as yes or no), and score for acceptance of technology. Each patient characteristic was investigated separately by inclusion of interaction effects. Improvement in the Akaike information criterion was used as a criterion for a significant difference in preferences by subgroup. Interaction terms for all subgroups identified as having a significant impact on preferences were included in a single model. Backwards elimination was undertaken to assess whether the identified characteristics were capturing different underlying distributions of preferences across respondents. Characteristics were retained when inclusion of their interaction terms minimized the Akaike information criterion. The impact of these characteristics on preferences was quantified by recalculating the marginal rates of substitution by patient subgroup, utilizing a mixed logit model including interaction terms for that patient characteristic.

Results

Respondent Characteristics

A total of 318 respondents completed the survey. Of these, 141 (44%) of the respondents had MS, 175 (55%) had epilepsy, and 2 (0.6%) had both MS and epilepsy. All respondents answered

at least one question. [Table 1](#) reports the demographic and other characteristics of these respondents.

The coefficients from the mixed logit model excluding interactions with patient characteristics are shown in [Table 2](#). Improved accuracy, higher privacy, increased level of benefit to the user, and the availability of clinical support were all associated with an increased likelihood of selecting a mobile technology device. Accuracy was the most important attribute, with a nonlinear effect; a move from low to moderate accuracy was valued higher than a move from moderate to high accuracy. The next most important attribute was privacy. Again, there was a modest nonlinear effect, with a stronger preference for moving from low to moderate privacy. Clinical support was the

least valued of the attributes. The SDs reflect the impact of unobserved heterogeneity of preferences. There was evidence of unobserved heterogeneity in preferences for low versus moderate accuracy and for clinical support.

[Table 3](#) reports the marginal rates of substitution for each attribute compared to accuracy. This is the percentage of accuracy that respondents were prepared to trade to achieve an improvement in the remaining attributes. Respondents were prepared to trade a modest amount of accuracy to achieve an improvement in privacy. Clinical support, in contrast, was not valued; respondents were only prepared to accept small reductions in accuracy in exchange for a high level of clinical support.

Table 1. Characteristics of the respondents (N=318) divided by the 7 variables included in the model.

Characteristics	Recruited through charities and social media	Recruited through hospital clinics	Total
Health condition			
Epilepsy, n (%)	159 (89.8)	18 (10.2)	177 (55.7)
MS, n (%)	24 (16.8)	119 (83.2)	143 (45.0)
Age, median (range)	46 (17-77)	40 (18-76)	44 (17-77)
Female, n (%)	128 (69.9)	96 (65.2)	217 (67.9)
Education			
“A” level ^a or equivalent, n (%)	50 (27.3)	37 (27.4)	87 (27.4)
Degree level, n (%)	81 (44.4)	66 (48.9)	147 (46.3)
Positive for symptoms of depression within the past 2 years, n (%)	63 (34.4)	44 (32.6)	107 (33.6)
Current user of wearable technology, n (%)	62 (33.9)	36 (26.7)	98 (30.8)
Acceptance of technology, median (range)	0.8 (0.15-1)	0.7 (0.16-1)	0.7 (0.15-1)

^aA-Levels are qualifications usually undertaken in the 12th and 13th year of school (up to age 18).

Table 2. The mixed logit model (no interactions with respondent characteristics).

Attribute	Coefficient (SE)	P value	95% CI
High accuracy	1.04 (0.06)	<.001	0.92 to 1.17
Low accuracy	-1.27 (0.07)	<.001	-1.41 to -1.13
High privacy	0.53 (0.05)	<.001	0.42 to 0.63
Low privacy	-0.66 (0.06)	<.001	-0.78 to -0.54
Benefit	0.37 (0.04)	<.001	0.30 to 0.44
Clinical support	0.18 (0.03)	<.001	0.11 to 0.24

Table 3. Percentage of accuracy respondents were willing to trade (mixed multinomial logit model, N=318).

Attribute	Acceptable change in accuracy from high to moderate	Acceptable change in accuracy from moderate to low
For high privacy	13%	10%
For moderate privacy	16%	13%
For high benefit	9%	7%
For high clinical support	4%	4%

Subgroup Analyses

The coefficients from the mixed logit model including interactions with patient characteristics can be found in Table 4 and Table 5. Regression analyses indicated that health condition (ie, MS or epilepsy), age, gender, and depression had no significant effect on preferences. Current use of wearable technology had a marginal impact on preferences. Technology acceptance did have an impact, as did education level. After a multivariate analysis that included wearable technology use, education level, and technology acceptance score, wearable technology use was no longer significant. Preferences varied significantly for patients in the low education group but not between those in the average or high education groups. Table 6 reports the marginal rates of substitution for each attribute compared with accuracy for respondents with education beyond age 18 compared to those without, and for patients with a high

technology acceptance score (in the 75th percentile) compared to those with a low score (in the 25th percentile).

Respondents with lower technology acceptance scores were prepared to trade far more accuracy for an improvement in privacy. The impact of technology acceptance on preferences for clinical benefit and clinical support was more modest. Respondents with high technology acceptance were prepared to trade slightly more in terms of loss of accuracy to improve clinical benefit or clinical support. These data suggest privacy is a far greater concern for respondents with a low technology acceptance score. The impact of education was more modest. Respondents with low education appeared less inclined to trade accuracy for improvements in clinical benefit and privacy but were more prepared to trade accuracy for improvements in clinical support.

Table 4. Mixed logit model including interactions with technology acceptance.

Attribute	Coefficient (SE)	P value	95% CI
High accuracy	1.10 (0.26)	<.001	0.64 to 1.56
Low accuracy	-1.71 (0.26)	<.001	-2.22 to -1.20
High privacy	1.52 (0.22)	<.001	1.08 to 1.95
Low privacy	-1.45 (0.24)	<.001	-1.91 to -0.99
Benefit	0.37 (0.14)	.007	0.10 to 0.63
Clinical support	0.19 (0.13)	.13	-0.05 to 0.44
Tech acceptance*high accuracy	0.01 (0.32)	.98	-0.61 to 0.62
Tech acceptance*low accuracy	0.52 (0.34)	.13	-0.15 to 1.19
Tech acceptance*high privacy	-1.32 (0.28)	<.001	-1.88 to -0.76
Tech acceptance*low privacy	1.07 (0.31)	.001	0.46 to 1.68
Tech acceptance*benefit	0.03 (0.18)	.88	-0.33 to 0.38
Tech acceptance*clinical support	0.00 (0.17)	.99	-0.34 to 0.34

Table 5. Mixed logit model including interactions with technology acceptance.

Attribute	Coefficient (SE)	P value	95% CI
High accuracy	1.10 (0.07)	<.001	0.96 to 1.25
Low accuracy	-1.37 (0.08)	<.001	-1.53 to -1.20
High privacy	0.58 (0.07)	<.001	0.45 to 0.71
Low privacy	-0.70 (0.07)	<.001	-0.85 to -0.56
Benefit	0.41 (0.04)	<.001	0.33 to 0.50
Clinical support	0.18 (0.04)	<.001	0.11 to 0.26
Low education*high accuracy	-0.21 (0.13)	.01	-0.47 to 0.04
Low education*low accuracy	0.30 (0.14)	.04	0.02 to 0.59
High education*high privacy	-0.15 (0.11)	.19	-0.37 to 0.07
Low education*low privacy	0.13 (0.13)	.32	-0.13 to 0.39
Low education*benefit	-0.16 (0.08)	.05	-0.31 to 0.00
Low education*clinical support	-0.02 (0.08)	.82	-0.17 to 0.13

^aThe IQR was used to define high and low technology acceptance scores.

Table 6. Percentage of accuracy respondents were willing to trade, divided by education level and technology acceptance.

Attribute	Education beyond age 18		No education beyond age 18		Low technology acceptance score (0.554) ^a		High technology acceptance score (0.875) ^b	
	Acceptable change in accuracy from high to moderate	Acceptable change in accuracy from moderate to low	Acceptable change in accuracy from high to moderate	Acceptable change in accuracy from moderate to low	Acceptable change in accuracy from high to moderate	Acceptable change in accuracy from moderate to low	Acceptable change in accuracy from high to moderate	Acceptable change in accuracy from moderate to low
For high privacy	13%	11%	12%	10%	18%	14%	8%	7%
For moderate privacy	16%	13%	16%	13%	19%	15%	11%	10%
For high benefit	9%	8%	7%	6%	9%	7%	9%	8%
For high clinical support	4%	3%	5%	4%	4%	3%	4%	4%

^aThe value for low technology acceptance represents the 25th percentile.

^bThis value for high technology acceptance represents the 75th percentile.

Sensitivity Analysis

Including missing data as an active decision to reject both technologies for the respective question (ie, an “opt-out”) had a minimal impact on the magnitude of the model coefficients, and their significance and direction were unchanged. These results are available on request.

Discussion

Principal Findings

Our analyses revealed that people with epilepsy or MS value higher levels of privacy, greater levels of support, increased accuracy, and a clearer benefit to the user when selecting mHealth technology devices. This is a key finding that is in line with our hypotheses and validates feedback received from people with epilepsy and MS in other studies [1,5,6]. Of all these factors, people preferred a higher degree of accuracy, regardless of their diagnosis. When asked to make compromises between levels of privacy, clinical support, accuracy, and benefit to the user, people were willing to trade some accuracy for greater privacy but were less influenced by the other factors. This analysis reveals a hierarchy in the importance of factors influencing engagement with mobile technologies (Figure 2).

We wanted to explore individual variability in how people traded off these attributes, because this should lead to a more tailored or personalized approach to RMT development. We found no

evidence that age, gender, or experience of depression affected preferences. This is in contrast to other studies, such as one that found that age influences technology use in a different patient population [11]. We did, however, discover the following: (1) the people who were less accepting of technology placed greater value on privacy and were willing to give up some degree of accuracy for privacy, and (2) people with no qualifications beyond those that might have been obtained before the age of 18 were willing to compromise some degree of accuracy to receive greater clinical support. These moderating factors are shown in Figure 2.

This model will help those designing mobile technologies to prioritize features for development that can maximize engagement. Accuracy is the key feature; individuals were willing to make compromises on accuracy, but the reduction in accuracy they were prepared to accept for improvements in other characteristics was relatively small (<20%). We did not find that people with MS and people with epilepsy had different preferences; however, accuracy may have a different meaning for devices that detect seizures in epilepsy and devices that measure symptom recurrence or deterioration in MS. Issues to do with privacy and the willingness to share information with a clinician were more transdiagnostic, with subgroup differences relating more to trust and familiarity with technology and educational level. This indicates that some level of personalization may be required in the design of devices.

Figure 2. A hierarchy of factors to consider in the design of mobile technologies to influence engagement for people with a neurological condition, with the size of each segment indicating the weight of the preference. The arrows indicate potential moderating factors: preferences for privacy and clinical support increased for individuals with lower technology acceptance and lower education, respectively.

Strengths and Limitations

This study is the first of its kind to try to understand the relative value and influences of factors affecting engagement with mobile technologies for people with neurological conditions. It used a quantitative approach, which is novel in this area of research, adopted from the field of health economics. The study size was large enough to explore some subgroups, selected for their hypothesized relationship with technology use, but future researchers may wish to focus on a greater number of health-related variables, such as illness severity, which we were unable to discuss in this paper. Basing our study on the completion of an online survey, albeit one that was supervised for participants who were recruited from clinics, may have led to a sampling bias toward respondents who were more familiar

with technology. However, there were few differences in the patterns of the data and in the makeup of the samples. An additional limitation is that we did not design the DCE in a way to allow validity checks on choice data, such as by including repeated tasks or dominant alternatives.

Conclusions

We have shown that people with epilepsy and MS are influenced by factors such as the accuracy, privacy, benefit of the technology, and the amount of clinical support received, but that in some instances they are willing to make compromises. These preferences should be factored into the design of mHealth technologies, alongside the views of other stakeholders, in the future.

Acknowledgments

This paper was written as part of the development of useful mHealth and remote measurement technology systems in the Remote Assessment of Disease and Relapse in Central Nervous System Disorders (RADAR-CNS) project. The RADAR-CNS project has received funding from the Innovative Medicines Initiative 2 Joint Undertaking (grant 115902). This Joint Undertaking receives support from the European Union's Horizon 2020 research and innovation program and the European Federation of Pharmaceutical Industries and Associations [35]. A single pharmaceutical company supported the preparation of this manuscript as part of this precompetitive public and private partnership. This communication reflects the views of the RADAR-CNS consortium; neither the Innovative Medicines Initiative, the European Union, nor European Federation of Pharmaceutical Industries and Associations are liable for any use that may be made of the information contained herein. This paper also represents independent research funded in part by the National Institute for Health Research Biomedical Research Centre at South London, the Maudsley National Health Service Foundation Trust, and King's College London. The views expressed are those of the authors and not necessarily those of the National Health Service, the National Institute for Health Research, or the Department of Health and Social Care. Author TW would specifically like to acknowledge support from the National Institute for Health Research for their Senior Investigator Awards. Further acknowledgments go to the following charitable organizations: the MS Society, Epilepsy Action, and the International Bureau of Epilepsy, as well as all the health care professionals at King's College Hospital who supported data collection through their epilepsy and MS clinics.

Abstract

Background: Indoor air quality is an important environmental factor that triggers and exacerbates asthma, the most common chronic disease in children. A mobile app to monitor indoor air quality could help occupants keep their indoor air quality clean. However, no app is available that allows children to monitor and improve their indoor air quality.

Objective: Previously, we conducted a series of user-centered design studies to identify user needs and design requirements toward creating a mobile app that helps children with asthma to engage in monitoring and improving indoor air quality as part of their asthma management. Based on the findings from these studies, we created AirBuddy, a child-friendly app that visualizes air quality indoors and outdoors.

Methods: This paper reports on the findings from a field deployment with 7 pediatric asthma patients, where we evaluated AirBuddy's usability and usefulness in real-world settings by conducting weekly semistructured interviews for 8 weeks.

Results: All participants positively responded to the usefulness and usability of AirBuddy, which we believe is thanks to the iterative, user-centered design approach that allowed us to identify and address potential usability issues early on and throughout the design process.

Conclusions: This project contributes to the field of mHealth app design for children by demonstrating how a user-centered design process can lead to the development of digital devices that are more acceptable and relevant to target users' needs.

KEYWORDS

asthma; children; indoor air quality; mobile app; smartphone; mHealth

Introduction

Asthma is recognized as the most common chronic disease in children, affecting approximately 12% of children worldwide [1,2]. Its common symptoms include coughing, wheezing, chest tightness or pain, and difficulty breathing. Childhood asthma is especially concerning because it creates a substantial burden on the affected children and their families by requiring regular medical encounters, restricting the child's physical activities, and increasing the chance of school absences [3-6].

Asthma cannot be cured currently, but good management can control the disease and enable people with asthma to sustain a normal, active life. One important aspect of asthma management is avoiding or reducing environmental asthma triggers. Among

the various triggers that contribute to excessive asthma morbidity, exposure to air pollutants is a significant environmental trigger that worsens symptoms and causes asthma attacks [7-10]. Since children spend most of their time indoors, the condition of the indoor air quality (IAQ) determines their exposures to many air pollutants [11,12]. Thus, it is crucial to keep IAQ clean and healthy for asthma management [13-15]. However, it is challenging to detect air pollutants with human perception because many air pollutants are invisible and thus impossible to detect with human senses. Furthermore, childhood asthma management is complex because pediatric patients with asthma rely on caregivers to manage asthma, and caregivers cannot fully keep track of the environmental triggers to which a child might be exposed [16]. A tool that allows children to monitor IAQ easily might help mitigate these problems by

enabling them to reduce their exposure to air pollutants and make healthy choices themselves.

Mobile apps are increasingly available and used to facilitate various aspects of asthma management [17-20]. However, few apps are available for IAQ monitoring, and even fewer apps are designed for children’s use. Thus, this project aimed to create a mobile app for children with asthma to engage in monitoring and improving IAQ. Specifically, we aimed to adopt an iterative, user-centered design approach by involving potential users throughout the design process to employ their perspectives in design. Previously, we investigated children’s perspectives and design requirements through a review of existing applications and 2 sets of semistructured interviews with 12 children with asthma [21]. Based on the findings from these previous studies, we developed AirBuddy, a mobile app that visualizes air quality indoors and outdoors in a child-friendly manner. As the last stage of this project, this paper reports on the outcomes of a 2-month field deployment where we evaluated the usability of AirBuddy in real-world settings.

Methods

System Development

For IAQ sensing, we used an off-the-shelf sensor that continuously measures the levels of 5 air pollutants: fine particulate matter (PM_{2.5}), carbon monoxide (CO), carbon dioxide (CO₂), total volatile organic compounds (TVOC), and nitrogen dioxide (NO₂) (see Figure 1). This sensor transmits the measurements of these air pollutants to the server every 15 seconds. Then, the system determines the current IAQ level based on the level of the air pollutant that has the lowest Air Quality Index (AQI) rating [22] among the five air pollutants. For instance, if the 5-minute average of PM_{2.5} is 20 µg/m³, and its AQI category is the lowest among the air pollutants (see Figure 2), the system determines the current IAQ level as “moderate.” The server sends the determined IAQ level to AirBuddy every 5 minutes, and the AirBuddy app displays IAQ as “moderate.” In addition, outdoor air quality data are retrieved from an AirNow API (application programming interface) [22] that provides current air quality data by zip code.

Figure 1. Atlasen Pico, an Air Quality Index monitoring station.

Figure 2. The Air Quality Index (AQI) category for fine particulate matter (PM_{2.5}) [22]. USG: Unhealthy for Sensitive Group.

AQI Category	AQI Value	Average PM _{2.5} Concentration (µg/m ³)
Good	0 - 50	0 - 15.4
Moderate	51 - 100	15.5 - 40.4
USG	101 - 150	40.5 - 65.4
Unhealthy	151 - 200	65.5 - 150.4
Very Unhealthy	201 - 300	150.5 - 250.4
Hazardous	301 - 500	250.5 - 500.4

The AirBuddy app consists of a home page and three sub menus. At the top of the home page is the IAQ information pane with a house icon, an IAQ label with a numerical AQI value, and a horizontal AQI color strip to indicate the current IAQ level (see Figure 3). The color of a house icon and its location on a color strip change according to the current IAQ level based on an AQI color code [22] (eg, green for good IAQ, yellow for moderate IAQ, and red for unhealthy IAQ, see Figure 2). Below that is an outdoor information pane with a cloud icon for outdoor

air quality and a weather icon. We juxtaposed these two icons to convey outdoor air quality information as part of outdoor weather information. When a user clicks anywhere in the IAQ information pane, the app moves to an IAQ detail page where a chart of recent IAQ trends is displayed (see Figure 4A).

Further below in this screen, we presented more details about color codes with legend labels and a spider web for five air pollutants (see Figure 4B). Next, clicking the house icon at the bottom left corner of a navigation bar brings up a chatting page

where a user can interact both verbally and via typing with Airic, a chatbot, to ask any question relating to IAQ and asthma management (see Figure 4C). In addition, we provided a list of recommended actions that the user can take to improve the IAQ

(see Figure 4D). Lastly, we implemented a push notification to notify a user when IAQ gets worse than the “good” range (see Figure 4E).

Figure 3. A final design of AirBuddy: home screen indicating different indoor air quality levels.

Figure 4. A final design of AirBuddy: (A) a bar graph for indoor air quality (IAQ) history; (B) a spider web for five air pollutants; (C) Airic, a chatbot; (d) a list of actions to improve IAQ; and (E) a push notification.

Participant Recruitment

Children aged 8 to 12 years with asthma, as determined by the Guidelines for the Diagnosis and Management of Asthma [23], were eligible to participate in this study. We determined this age range for the participants because a child at the age of 8 years starts to understand abstract terms and complex sentences, develops the ability to read and critically analyze what they read, and shifts from learning to read to reading to learn [24]. Thus, children in this age range can use digital devices with complex and abstract languages for autonomous tasks [24]. Children were not eligible if they could not read or speak English, did not own a smartphone or other equivalent devices,

or their involvement was deemed inappropriate by the pediatrician concerning their mental and physical conditions.

We recruited all participants from the pediatric pulmonology department of a tertiary hospital in an urban area. We first described the purpose of the study to a pediatrician, and the pediatrician shared us with a list of eligible patients upon their caregivers’ approval. Then, we approached by telephone caregivers of the patients to ask for their interest in participating in the study. A total of 7 participants were recruited (5 females and 2 males; mean age 10, SD 1.9 years; see Table 1). All caregivers and their children provided consent electronically prior to participating in the study.

Table 1. Participant demographics.

Participant ID	Age (years)	Gender	Asthma severity
P1	12	Female	Moderate
P2	8	Male	Moderate
P3	9	Female	Intermittent
P4	10	Female	Moderate
P5	10	Female	Intermittent
P6	8	Female	Intermittent
P7	12	Male	Mild

Data Collection

We conducted a field deployment for 8 weeks. During the study, we conducted weekly interviews with each participant (8 interviews per participant in total) to investigate pediatric patients' use of AirBuddy in their everyday lives over time.

Before initiating the study, we visited each participant's home to set up an IAQ sensor in the room of their preference (eg, a child's bedroom or living room; see [Figure 5](#)) and install AirBuddy on their smartphone. After setup, we described how the IAQ sensor works to the participants and their parents and

gave basic instructions on how to use AirBuddy, which we introduced as "a mobile app that allows you to monitor air quality in your home and outside and find information about actions to take for asthma management." Then, we conducted the first interview. Additionally, parents filled out a survey to inform us of the participants' basic demographic information, including age, gender, and asthma severity. Lastly, participants were told to freely use AirBuddy as much as they wanted throughout the study period. They were given the contact information of the research team if they needed technical support.

Figure 5. The location of an indoor air quality sensing unit for a deployment study: a vanity in a child's bedroom (left) and a bookshelf in a living room (right).

The interviews focused on the following four topics: (1) how children initially perceive and respond to AirBuddy, (2) how they use it in their daily lives, (3) what motivates or prevents their use of the device, and (4) how their engagement in IAQ changes over time. Accordingly, we constructed three sets of open-ended interview questions to explore these topics in three phases. The first phase focused on understanding the general perspectives about IAQ and initial impressions of AirBuddy in the first interview. The second phase focused on exploring the user experience in-depth, including patterns of AirBuddy use,

engagement in IAQ, and factors contributing to or preventing children's engagement in monitoring IAQ throughout the deployment duration, except for the last interview. Finally, the third phase focused on exploring suggestions for improving AirBuddy and reviewing the overall reflection on the app in the last interview. Each interview lasted up to 60 minutes. After the study was complete, the research team visited the participants' homes to pick up the IAQ sensor. All participants were compensated with a US \$80 e-gift card.

All interviews except the first interview were conducted virtually using videoconferencing software of the participants' choice (eg, Skype, Zoom, Google Duo). While all interview questions were asked to the children, we encouraged their parents to join the interview and share their thoughts if they wanted.

Ethics Approval

This study was reviewed and approved by the Rutgers University institutional review board (reference #:Pro2019000875) prior to the conduct of the research.

Data Analysis

We analyzed all interview data using thematic analysis to have significant patterns and themes emerge across data sets through the Grounded Theory process of open coding, axial coding, and selective coding [25]. First, we conducted open coding to identify and code concepts significant in the data as abstract representations of events, objects, happenings, actions, etc. Then, we grouped the related concepts created by open coding into a category to demonstrate conceptual phenomena using axial coding. Phenomena refer to repeated patterns of events, happenings, actions, and interactions that represent people's responses to problems and situations. Finally, we followed the selective coding process to integrate all conceptual phenomena extracted from axial coding into a single storyline through building relationships across phenomena.

Results

Responses to the Graphical Interface

Initial impressions of AirBuddy's graphical interface were positive across all participants. In the first couple of interviews, all participants expressed overall contentment with the aesthetics of the interface and positively mentioned its graphical components, including the vivid colors, color-coded icons, and child-friendly emojis.

The little characters are really cute. I like the house with the question marks and frowny faces or confused faces. What I like to do mostly with the app is that I can check the air numbers, good or bad. I like to do that because most people can't. [Participant P3, week 1]

I like the colors that are bright and popped. And it's easy to understand the color of the house and air quality. Red means bad, yellow means okay, and green means good. The house is green now. It says that the air is good inside. [Participant P5, week 2]

As the usage continued, the interfaces presenting detailed information about IAQ (see Figure 4A,B) were perceived differently by different participants. Even though the age range of our participants was not wide (school-age children 8-12 years old), participants in different age groups expressed different reactions. Most of the older participants (aged 10 years and older) were content with and easily comprehended the detailed information on IAQ early in the study. However, younger participants (aged 9 years and under) expressed difficulty interpreting the presented information and complained about its complexity, especially that of the bar graph and a spider web. This suggests the need for more tailored considerations of

effectively conveying information to children in different developmental stages.

I think everything is pretty self-explanatory. Something that I like is the graphs and how it tells you what you need to know. It doesn't go into all these like super technical things that not every kid will understand. It just gets to the point. [Participant P1 W1]

I am a little confused about the spider graph thing because I'm not good with those. I don't have a clue what it means. I'm fine with the bar graphs though. [Participant P6, week 2]

Nevertheless, even younger participants gradually learned to interpret IAQ information presented in AirBuddy as they continued using it over time. We provided instructions on how to interpret IAQ information whenever needed to those who had difficulty understanding it, but support needs significantly decreased after several weeks of app use. In all, we confirmed that AirBuddy is easy for children to use.

AirBuddy is a very good and informational app that teaches you about air quality around you and how to deal with it. It gives me good resources. At first, it was a little confusing because there were so many stuff. But now it is easy to navigate. [Participant P6, week 4]

Motivations for App Use

One of the key questions we sought to investigate was what motivates or prevents children's use of AirBuddy. To explore this, we asked when or why they opened AirBuddy to check air quality in every interview. Two prevalent answers emerged as triggers for app use. The most prevalent motivation to use AirBuddy was to inquire into the cause of their asthma worsening. Throughout the study, we had numerous statements about participants using AirBuddy to check the air quality indoors and outdoors whenever they had difficulty breathing. In most cases, participants found the air quality in the surrounding area worsened when they checked upon the occurrence of an asthma symptom. Consequently, participants learned that worsening air quality significantly contributes to asthma exacerbation. This demonstrates that AirBuddy is an effective tool for pediatric patients to check and confirm the source of an environmental asthma trigger.

I check the app when I'm not feeling too good or when I'm wheezing. Last week when I couldn't breathe well, I opened AirBuddy to check if the air quality was okay, bad, or unhealthy. It was yellow. I think a person that has asthma would love it as it tells you how the air around you is. [Participant P4, week 4]

On Sunday, I felt my throat was itchy and I was struggling for air, and that's when I quickly checked AirBuddy. It said air quality is unhealthy and I told my mom. And she turned on the AC and opened the windows. [Participant P5, week 5]

An equally prevalent trigger was the app's push notification to notify a user when the IAQ worsens. Once participants learned a significant relationship between air pollution and asthma worsening, they considered IAQ worsening seriously and took prompt action as soon as they received a push notification.

I've gotten notifications from the app when my air quality was bad. It's like telling me "Hi [username], the air quality outside is bad you better stay inside." A reminder helps a lot. [Participant P6, week 2]

Apart from these two triggers, participants frequently checked IAQ out of curiosity in the first couple of weeks. As their app use continued, however, this use pattern significantly decreased, which we believe was due to the novelty effect, and the participants relied solely on the two aforementioned triggers for their AirBuddy use. Only a few participants developed a routine to check IAQ over time.

Yesterday, we were looking at the graph. And it was funny because we noticed the graph was yellow at 6 AM and then went back to green at 8 AM. So, mom and I were trying to figure out what caused that. I think it's heat. [Participant P1, week 2]

I only think about air quality when I'm having trouble breathing. So, if I'm fine, then it doesn't really faze me. [Participant P5, week 6]

Consequently, many participants reported that the frequency of app use gradually decreased as the study proceeded. They pointed out the lack of interactivity and fun aspects in AirBuddy as the main reason for their decreased app use. Accordingly, most participants suggested ideas to improve the app, related to adding more interactivity and fun features.

I'm completely comfortable using it. But I forget to use it because it is a little boring without much interaction. In fact, looking at air quality's not that fun. My favorite is watching a streaming site or FaceTime. [Participant P2, week 7]

"It would be cool if I could compare my data to other people's air quality. If people could see that you had bad air quality, they might want to go over to your house to fix your air quality. Or you could have a setting where you would talk to each other about low-quality air day or how you felt that day. [Participant P7, week 8]

Engagement in Indoor Air Quality

Regardless of the app use frequency, we found that the participants' overall experiences with AirBuddy remained positive from start to finish. All participants confirmed that AirBuddy helped promote their engagement with IAQ and increase their awareness and understanding of the effect of air quality on asthma. We received commending statements about the usefulness of AirBuddy in managing asthma and improving IAQ from every participant in the final interview. In particular, they found it helpful to acquire IAQ information whenever needed that was critically related to their asthma conditions but could not be obtained otherwise. In all, the study confirmed that AirBuddy is beneficial for children with asthma to effectively engage in and monitor IAQ information to manage their asthma conditions.

The app made me think about air quality a little more and more aware of my asthma. I never really put any thought into it before. Now, when I got the notifications of bad air quality, even if I am not at home, I think about how my breathing is... The other day when I was at play practice, I got a notification saying that my house had bad air quality. So, I texted and asked mom what

she was doing and then thought about my breathing. [Participant P2, week 8]

It's awesome that I get to see how the air is around me, like whether I should turn on the AC or do anything to help my breathing. Before I was introduced to the app, I never thought about air quality. I've been doing the daily medicine a good three months, but it's just daily thing and I didn't think about it. But now I got AirBuddy, and it makes me think about air quality a lot more and makes me more aware of keeping air clean and healthy. [Participant P7, week 8]

Discussion

Principal Findings and Study Strengths

This project aimed to create AirBuddy, a mobile app for children with asthma to monitor IAQ. To achieve the goal, we employed a user-centered design process whereby designers focus on the users and their needs in each phase of the design process by putting users at the center of product design and development [26]. Previously, we conducted a series of design studies, including reviewing existing systems, brainstorming ideas, wireframing, and high-fidelity prototyping, through which we iteratively revised and improved the app to assure that children can use it efficiently, effectively, and reliably [21]. Building on the previous work, this paper reports on a system development and its 2-month field deployment, the last step of a user-centered design process, in which we investigated how potential users would use AirBuddy in real-world settings. Overall, all participants positively responded to the usefulness and usability of AirBuddy, which we believe is thanks to the iterative, user-centered design approach that allowed us to identify and address potential usability issues early on and throughout the design process.

Supporting Timely Access to Needed Information for Sustained Engagement

Technologies are considered successful not only when they are usable but also engage users [27], as the increased engagement has proven to be positively associated with solving problems [28]. In the past few decades, the health-informatics and human-computer interaction communities have recognized the importance of understanding and designing to promote engaging experiences with mHealth tools for effective health management [29-31]. Sustained engagement with mHealth tools has been proven to motivate patients to better adhere to health interventions and positively impact health behaviors and clinical outcomes [32,33]. Therefore, researchers have sought to determine elements for promoting effective and sustained engagement with mHealth tools [34,35]. Widely used design elements to boost sustained engagement include reminders, reward systems, and gamification [36,37].

One of our key design considerations was to ensure children's sustained engagement with AirBuddy and thus sustain them to monitor IAQ over time. To serve this goal, we first considered implementing gamification features in the app design in the previous work [21], which has been widely employed to keep users, particularly children, hooked to the system [38,39]. However, we eventually discarded the idea for the following

reasons. First, the IAQ in modern buildings in urban areas mostly stays healthy, except when indoor activities that negatively affect IAQ occur (eg, cooking, cleaning, increased humidity and temperature, or inadequate ventilation [40]) or when outdoor air pollutants penetrate indoors [41]. Thus, we concluded that it is more important for occupants to catch the moment of IAQ worsening and take prompt action to remove air pollutants rather than constantly checking the state of the IAQ. Second, we were concerned about providing children with yet another game app among the plethora of online games. While educational games have proven to be great tools for children to learn and drill specific skills [42,43], there is also a growing concern about increased screen time in children and its potentially adverse effects on health [44]. In the end, the crux of IAQ monitoring is on identifying the right moment to take proper action rather than the practice of monitoring itself. Thus, instead of aiming to keep a user's attention constant in monitoring IAQ, we focused on drawing the user's attention only at the point of interest—IAQ worsening. To that end, we implemented a push notification feature to alert users when IAQ worsens.

Participants expressed a feeling of boredom as their app use continued and pointed out the lack of fun features in AirBuddy as its primary area for improvement. Despite this drawback, all participants positively valued AirBuddy. While AirBuddy did not provide any entertaining features to keep users attached to the app, the participants concurred with its utility, in that the app promoted them to be more aware of managing their asthma condition and keep the IAQ clean and healthy. In the end, the ideal situation is one in which IAQ always stays good, so occupants do not need to pay attention to it. Thus, the onset of users' asthma symptoms and push notification when IAQ worsens were sufficient in sustaining users' engagement with the app without increasing their screen time. This finding implies

that designing for children's engagement can be realized not only by keeping them attached to the system—gamification—but also by enabling timely access to needed information. The next step is to explore ways to make available needed information for the users in a timely and relevant yet entertaining manner to boost sustained engagement with mHealth apps.

Limitations

Our findings must be evaluated under the consideration of limitations. First, our sample size was small (N=7), and thus our participant pool may not represent a general children population. We initially planned to recruit more participants but were unable to due to the COVID-19 pandemic. Because people with asthma are particularly vulnerable to viral respiratory tract infections, most parents of pediatric patients with asthma were reluctant to participate in this study, which included 2 home visits. After recruiting participants for over 9 months, we decided to stop recruiting and proceed with the study with 7 participants. Second, we used convenience sampling for recruitment by recruiting participants from a children's hospital in an urban area, which also runs the risk of compromising generalizability. Selection bias or unmeasured factors (eg, the homogeneity of participant characteristics and socioeconomic status) might have influenced the responses.

Conclusion

This project designed, developed, and evaluated AirBuddy, a mobile app for children with asthma to monitor IAQ through a user-centered design process. This paper contributes to the field of mHealth app design for children by demonstrating how a user-centered design process can lead to the development of digital devices that are more acceptable and relevant to target users' needs. A similar user-centered design approach can be effectively applied when designing mHealth apps for children to address self-management needs for other pediatric conditions.

Acknowledgments

We are thankful to all the families who participated in our study. We appreciate Dr Maya Ramagopal at the Robert Wood Johnson University Hospital for the support in participant recruitment. This research was funded by the Busch Biomedical Research Grant from Rutgers University.

Authors' Contributions

SK conceived of the idea, acquired funding, designed the study, performed the data analysis, drafted and revised the manuscript, and supervised the entire project. KS undertook the data collection. YP contributed to creating and revising design artifacts and prototypes. ST contributed to developing the app.

Conflicts of Interest

None declared.

Abstract

Background: Digital applications are commonly used to support mental health and well-being. However, successfully retaining and engaging users to complete digital interventions is challenging, and comorbidities such as chronic pain further reduce user engagement. Digital conversational agents (CAs) may improve user engagement by applying engagement principles that have been implemented within in-person care settings.

Objective: To evaluate user retention and engagement with an artificial intelligence–led digital mental health app (Wysa for Chronic Pain) that is customized for individuals managing mental health symptoms and coexisting chronic pain.

Methods: In this ancillary survival analysis of a clinical trial, participants included 51 adults who presented to a tertiary care center for chronic musculoskeletal pain, who endorsed coexisting symptoms of depression or anxiety (Patient-Reported Outcomes Measurement Information System score of ≥ 55 for depression or anxiety), and initiated onboarding to an 8-week subscription of Wysa for Chronic Pain. The study outcomes were user retention, defined as revisiting the app each week and on the last day of engagement, and user engagement, defined by the number of sessions the user completed.

Results: Users engaged in a cumulative mean of 33.3 sessions during the 8-week study period. The survival analysis depicted a median user retention period (i.e., time to complete disengagement) of 51 days, with the usage of a morning check-in feature having a significant relationship with a longer retention period ($P=.001$).

Conclusions: Our findings suggest that user retention and engagement with a CBT-based CA built for users with chronic pain is higher than standard industry metrics. These results have clear implications for addressing issues of suboptimal engagement of digital health interventions and improving access to care for chronic pain. Future work should use these findings to inform the design of evidence-based interventions for individuals with chronic pain and to enhance user retention and engagement of digital health interventions more broadly.

Introduction

Digital health interventions offer an opportunity to reduce health care barriers for individuals with chronic pain by increasing accessibility and decreasing cost- and time-related barriers to care [1,2]. They offer the ability for patients to engage in care at the convenience of their own space and time, outside the resource constraints of specialized care [3]. There are several digital intervention delivery vehicles (e.g., internet-based interventions and health-related mobile apps), and most are based on a self-guided approach. Research supports the efficacy of self-guided digital psychosocial interventions such as cognitive behavior therapy (CBT) in improving impairment from chronic pain in adults [4-6]. However, the effectiveness of self-guided digital interventions still suffers from low retention and engagement rates [7,8].

Engagement refers to the extent of usage and the perceived desire to use the digital intervention over a prolonged time period [9]. Retention with a digital intervention refers to the proportion of users who remain active with the intervention during a specified time frame [10,11]. Top-performing health apps have an average 30-day retention rate of only 15% [12]. Furthermore, people with chronic illness such as chronic pain are almost twice as likely to drop out from self-guided digital interventions when compared to traditional, guided interventions [6]. Lack of engagement is associated with low adherence to interventions and high dropout rates [13,14]. Understanding and achieving high levels of retention and engagement with digital interventions for people with chronic illness, such as chronic pain, may lead to improved intervention effectiveness.

Key factors that support engagement and retention within in-person clinical care settings include patient-clinician agreement, patients' perception of listening and empathy by clinicians, collaborative learning mechanisms for patients, and reminder systems [15]. Artificial intelligence (AI)-led conversational agents (CAs) apply these principles to deliver therapeutic content through interactive media such as conversations and stories.

The purpose of this study was to examine user retention and engagement with Wysa for Chronic Pain—a digital CA based on CBT principles—that is designed to improve general well-being among people with chronic pain.

Methods

Study Design and Participant Recruitment

This is an ancillary analysis of a pilot clinical trial that examined the feasibility of delivering a digital mental health intervention within the setting of an outpatient clinic visit for the management of chronic pain. As such, participant recruitment and eligibility criteria have previously been described in the pilot study [16].

In brief, participants were recruited between December 2020 and July 2021 from a US tertiary care orthopedic clinic that specializes in the management of chronic musculoskeletal pain. To be eligible, patients had to be 18 years or older and screen positively for symptoms of depression or anxiety by scoring 55

or greater on the Patient-Reported Outcomes Measurement Information System measures for depression or anxiety. Patients who were actively planning to start in-person mental health treatment and those without access to a mobile device were excluded from the study.

Participants were recruited in person by a study coordinator and were offered 8 weeks of complimentary access to the digital intervention (Wysa for Chronic Pain). After providing informed consent, they were given a unique code to access Wysa for Chronic Pain on any Android or iOS phone. Once the code was redeemed, an in-app consent screen appeared before app onboarding began. Throughout the study, no email or phone reminders were sent by the study team outside the app environment for the purposes of app retention or engagement.

Ethical Considerations

The pilot feasibility study received approval from the Washington University institutional review board prior to participant recruitment (202005219), and the study was registered on ClinicalTrials.gov (NCT04640090).

Intervention: Wysa for Chronic Pain

The Wysa for Chronic Pain digital health app is a novel intervention that was specifically developed for people with mental health concerns and coexisting chronic pain. It uses an AI-based digital conversational agent that acts as a supportive companion for users, and it also includes human “coaches” with master's degrees in counseling, who support users in identifying appropriate therapeutic interventions.

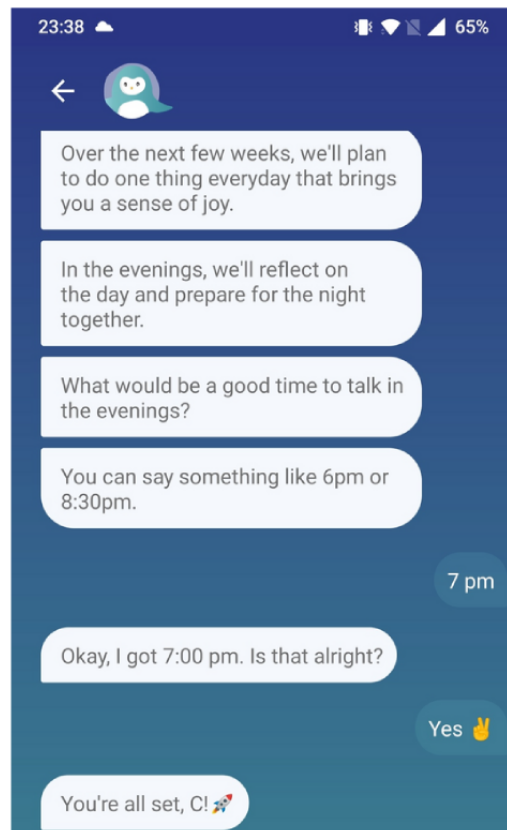

Wysa for Chronic Pain uses CBT principles in the app design and within digital and human conversations. A recurring and key feature of the app is morning and evening conversations (“check-ins”) with the CA (Figure 1), which occur at times chosen by the user. These conversations use behavioral activation principles.

During the morning check-ins, users report their mood on a visual analog scale and commit to engaging in an activity that day that brings them joy. Based on users' responses, the CA suggests interventions within the app to facilitate pain acceptance and cognitive restructuring. The evening check-ins consist of mood monitoring, and a check on the completion of the planned activity. Based on users' responses, the CA suggests additional interventions as appropriate and completes the check-in with offering users a bedtime meditation to assist with falling asleep.

The app's engagement framework primarily rested upon notifications. The timing for the notifications would be chosen by the users, and the app would send these twice a day for the morning and evening check-ins. These would be displayed in the phone notification window, and would bring the user back to the app. Once within the app, the check-in would begin the designed structured intervention. Each week's efforts would also be encouraged with a weekly report that offered insights and a new tool pack and further guided with a visual roadmap that would outline the path ahead.

It was hypothesized that a consistent and reliable structure that offered scheduled rewards would lead to greater app engagement and retention, along with efficacy.

Figure 1. The conversational agent asks the user for a check-in time.

Measures

All engagement and retention data were collected automatically via the app's usage log. To maintain user anonymity and be consistent with Wysa for Chronic Pain's confidentiality protocols, demographic data and personally identifiable information were not collected within the app. App sessions were only counted toward engagement and retention if a user completed a conversation with the CA, conversation with the human coach, or an intervention exercise within the app. Passive events, such as opening the app or an element within the app, were not counted.

Engagement metrics included the number of sessions a user completed within (1) each week and (2) during the entire 8-week study period. Retention metrics included the following: (1) retention duration (i.e., users' last day of engagement with the app during the 8-week study period) and (2) weekly app usage (i.e., interaction with the app at least once each week).

Analysis

Continuous data were summarized as mean (SD) values and categorical data as n (%) values.

Previous studies have shown that quantifying user retention of an app using survival analysis is feasible. For survival analysis in this trial, the event of interest was defined as complete disengagement (i.e., the day after which a user did not return to the app within the study period). Users whose last day of

engagement was after the last day of the study period were right-censored. To minimize blinding to the extent of full engagement in the study period, the Spearman and Kendall rank correlation coefficients were calculated between the total days of engagement and the last day of retention.

Kaplan-Meier nonparametric estimators for computing retention over time and the Cox proportional hazards model were used to understand the impact of morning and evening check-in notifications on user retention over the study period. All analyses included only the prespecified 8-week study period even though users could continue engaging with the app after the conclusion of the study. Data cleaning was performed using Python (version 3.6; Python Software Foundation), and all statistical analyses were performed using R (version 4.1.2; The R Foundation).

Results

Of the 51 study participants who redeemed an app code for the trial, 49 (96%) onboarded successfully to the app.

App Engagement

Users engaged in a mean of 4.0 (SD 0.9) sessions per week and a mean of 33.3 (SD 42) total sessions during the 8-week study period. When categorized by the type of intervention each tool delivers, the most frequently used interventions were the following: Thought Recording (19.7%), Pain Acceptance (16%), and Sleep Meditations (14.9%) (Table 1).

Table 1. The most frequently used interventions in Wysa for Chronic Pain.

Intervention	Usage, %
Thought Recording	19.7
Pain Acceptance	16.0
Sleep Meditation	14.9
Mindfulness	10.4
Anxiety Management	9.8
Gratitude	8.1
Motivational Stories	7.3
Calming Exercises	6.5
Social Support	2.0
Grounding	1.4

App Retention

The median user (N=49) retention period (i.e., time to complete disengagement) was 51 days (95% CI 33-53 days) (Figure 2). The retention rate at 30 days (1 month) was 70%, and 20% of users were right-censored, indicating they were still engaging

with the app after completion of the prespecified 8-week study period. A strong correlation was found between users' total number of days engaged with the app and their last day of retention (Spearman $\rho=0.82, P<.001$; Kendall $\tau=0.68, P<.001$). Usage of the morning check-in was associated with a longer retention period (hazard ratio=0.89, $P=.001$) (Table 2).

Figure 2. Kaplan-Meier survival curve modeling user retention in the Wysa for Chronic Pain app during the 8-week study period. Dashed lines represent 95% CIs of the survival curve. Model concordance=0.829 (SE 0.045, $P=.001$ on the Wald test).

Table 2. Cox proportional hazards model to explore the impact of engaging with morning and evening check-ins on user retention.

Variable	Hazard ratio	SE	P value
Morning check-in	0.894	0.035	.001 ^a
Evening check-in	0.987	0.024	.59

^aStatistically significant.

Discussion

Principal Findings

This study aimed to examine levels of app retention and engagement with Wysa for Chronic Pain, when used by participants managing chronic pain. The app evaluated was an AI-led mental health app (Wysa for Chronic Pain), which used proven in-person health care techniques to improve app engagement. The pilot study that used this intervention has also examined the app's clinical efficacy while sustaining this engagement [16]. In previous studies on digital health interventions, most participants disengaged within the first week of the study, with average retention periods between 4 and 16 days [17,18]. In comparison, over 50% of users in this study continued returning to the app each week, and the median user retention period was 51 days.

These high rates of engagement and retention suggest that the participants found the app features and interventions helpful and meaningful to their everyday challenges [8]. There is a large body of research examining predictors of user engagement with digital health interventions. The literature indicates that the inclusion of behavior change techniques (e.g., self-monitoring and goal setting) [19,20] and coping strategies (e.g., mindfulness and meditation) [12] is important for the uptake and engagement with digital health interventions. Consistent with this work, our intervention included behavioral activation principles and meditation to support users. Another review based on experiential and behavioral perspectives identified content (e.g., behavior change techniques, social support, and reminders) and content delivery (e.g., professional support, personalization, and aesthetic features) as key factors that may affect engagement with digital health interventions [9]. In line with these findings, our intervention included morning and evening check-ins and personalization of content. Users received customizable notification-type reminders—a feature that has been identified as useful for engagement with digital health interventions [21,22].

Additionally, a recent study found that relational factors predict user engagement with mobile health interventions [23]. The CA in our study used machine learning and AI methods to simulate human-like behaviors and support [10,24]. Considering this, users may have developed a relational connection or a therapeutic alliance with the CA. For example, a recent study demonstrated that Wysa for Chronic Pain users' therapeutic alliance scores were comparable to ratings from previous studies on alliance in human-delivered face-to-face psychotherapy with clinical populations [25].

Our achievement of high user retention and engagement with a CA-based, pain-customized, digital mental health intervention has clear implications for addressing issues of suboptimal engagement with digital health interventions and of improving access to care for chronic pain. Research indicates that people with chronic pain are almost twice as likely to drop out from self-guided digital interventions when compared to traditional, guided interventions [21]. Despite this, the present trial achieved high levels of retention and engagement among a sample of individuals with chronic pain. Based on the literature highlighting practical strategies and recommendations to tackle issues related to user attrition in digital health interventions, we incorporated behavior change techniques, coping strategies, and morning and evening check-ins. From our results, it is clear this combination of engagement strategies and therapeutic content has the potential to retain and engage users, which may be related to the enhanced effectiveness of the intervention. Future work should use these findings to inform the design of evidence-based interventions for individuals with chronic pain and to enhance user retention and engagement of digital health interventions more broadly.

Limitations

The key limitations of this study are its small sample size, the lack of demographic analysis (which reduces information about the retained users), and the limited generalizability. The event of interest within the survival analysis (i.e., defined as complete disengagement) partially blinded the data to the number of breaks until the last day of engagement. With a larger sample size, a more granular analysis could evaluate each streak within the data set, leading up to the last day of engagement. Additionally, there was no comparison group, which reduced the ability to establish causality for the possible factors responsible for engagement and retention.

Given the promising results, future research should be undertaken with a larger sample size and comparative groups. It should also be determined if these results can be replicated with populations managing other health conditions and for users who were not initially introduced to the app through a medical clinic setting.

Conclusions

This study highlights the ability to attain high retention and engagement with a mental health app that uses a digital CA and established behavioral paradigms that improve engagement with in-person therapy, specifically to deliver CBT to people with mental health concerns and coexisting chronic pain.

Authors' Contributions

CS conceptualized the ancillary analysis and contributed to the writing of the manuscript. ALC reviewed the data and contributed to the final manuscript. MK contributed to the statistical methods and analysis of the study.

Conflicts of Interest

CS and MK are reported as being employees of Wysa Inc and owning equity in the company. ALC declares no conflicts of interest related to the study and is funded by the National Institutes of Health and the National Institute of Arthritis and Musculoskeletal

and Skin Diseases (K23AR074520) and the Doris Duke Charitable Foundation. The pilot clinical trial was funded by a Washington University/BJC HealthCare Big Ideas innovation grant. Of note, the pilot clinical trial was conducted by ALC, and prespecified results were reported independent of input from Wysa Inc. This manuscript describes an ancillary analysis of data that were collected during the conduct of the pilot clinical trial.

Abstract

Background: Enrollment in pregnancy registries is challenging despite substantial awareness-raising activities, generally resulting in low recruitment owing to limited safety data. Understanding patient and physician awareness of and attitudes toward pregnancy registries is needed to facilitate enrollment. Crowdsourcing, in which services, ideas, or content are obtained by soliciting contributions from a large group of people using web-based platforms, has shown promise for improving patient engagement and obtaining patient insights.

Objective: This study aimed to use web-based crowdsourcing platforms to evaluate Belimumab Pregnancy Registry (BPR) awareness among patients and physicians and to identify potential barriers to pregnancy registry enrollment with the BPR as a case study.

Methods: We conducted 2 surveys using separate web-based crowdsourcing platforms: Amazon Mechanical Turk (a 14-question patient survey) and Sermo RealTime (a 11-question rheumatologist survey). Eligible patients were women, aged 18-55 years; diagnosed with systemic lupus erythematosus (SLE); and pregnant, recently pregnant (within 2 years), or planning pregnancy. Eligible rheumatologists had prescribed belimumab and treated pregnant women. Responses were descriptively analyzed.

Results: Of 151 patient respondents over a 3-month period (n=88, 58.3% aged 26-35 years; n=149, 98.7% with mild or moderate SLE; and n=148, 98% from the United States), 51% (77/151) were currently or recently pregnant. Overall, 169 rheumatologists completed the survey within 48 hours, and 59.2% (100/169) were based in the United States. Belimumab exposure was reported by 41.7% (63/151) patients, whereas 51.7% (75/145) rheumatologists had prescribed belimumab to <5 patients, 25.5% (37/145) had prescribed to 5-10 patients, and 22.8% (33/145) had prescribed to >10 patients who were pregnant or trying to conceive. Of the patients exposed to belimumab, 51% (32/63) were BPR-aware, and 45.5% (77/169) of the rheumatologists were BPR-aware. Overall, 60% (38/63) of patients reported belimumab discontinuation because of pregnancy or planned pregnancy. Among the 77 BPR-aware rheumatologists, 70 (91%) referred patients to the registry. Concerns among rheumatologists who did not prescribe belimumab during pregnancy included unknown pregnancy safety profile (119/169, 70.4%), and 61.5% (104/169) reported their patients' concerns about the unknown pregnancy safety profile. Belimumab exposure during or recently after pregnancy or while trying to conceive was reported in patients with mild (6/64, 9%), moderate (22/85, 26%), or severe (1/2, 50%) SLE. Rheumatologists more commonly recommended belimumab for moderate (84/169, 49.7%) and severe (123/169, 72.8%) SLE than for mild SLE (36/169, 21.3%) for patients trying to conceive recently or currently pregnant. Overall, 81.6% (138/169) of the rheumatologists suggested a belimumab washout period before pregnancy of 0-30 days (44/138, 31.9%), 30-60 days (64/138, 46.4%), or >60 days (30/138, 21.7%).

Conclusions: In this case, crowdsourcing efficiently obtained patient and rheumatologist input, with some patients with SLE continuing to use belimumab during or while planning a pregnancy. There was moderate awareness of the BPR among patients and physicians.

belimumab; crowdsourcing; systemic lupus erythematosus; pregnancy; registry

Introduction

Background

Data on the safety profile of novel therapies before, during, and soon after pregnancy are of paramount importance to patients and their treating physicians. However, clinical trials before regulatory approval generally exclude pregnant women, require the use of a highly effective contraception method, and require withdrawal of treatment if a pregnancy is identified during the relevant period of exposure. Basic pregnancy outcome information is actively sought when pregnancy occurs while in a clinical trial [1]. As a result, physicians may be reluctant to prescribe novel treatments to pregnant women owing to a lack of human pregnancy data to allow an informed benefit-to-risk balance decision. To generate additional safety data in pregnant women, postapproval studies using data collected from pregnancy registries can be undertaken [1]. Voluntary pregnancy registries enroll pregnant patients who have received a therapy of interest into a cohort, with nonexposed pregnant women being an ideal comparator group, although this is not always feasible [1]. Registries can generate timely and comprehensive data on the maternal and fetal safety profile of a specific drug, including postnatal outcomes [1].

Recruitment of patients to pregnancy registries is often challenging [1-5]. Enrollment during the early years of a pregnancy registry can be very low, with reasons including the drug of interest being new to the market, the voluntary enrollment process often used, and the therapy of interest being rarely prescribed to pregnant women [1-5]. Registries may use a variety of approaches to maximize enrollment, such as designating a single coordinating center to handle recruitment, or using automated alerts of pregnancy registrations [1,3]; however, recruitment challenges remain.

Systemic lupus erythematosus (SLE) is a chronic multisystem autoimmune disease that predominantly affects women, many of whom are of childbearing age [6-8]. Patients with SLE with a history of active lupus nephritis or antiphospholipid antibodies during pregnancy are susceptible to premature birth and/or hypertension, highlighting the need for prepregnancy counseling [9]. Patients with autoantibody-positive active SLE may be prescribed belimumab, a B-lymphocyte stimulator inhibitor [10,11]. The Belimumab Pregnancy Registry (BPR; GlaxoSmithKline study 114256; NCT01532310) is a multinational, prospective, voluntary registry [12] established to document belimumab exposure in pregnant women. The BPR was initiated in 2012 with the aim of recruiting 500 pregnant women treated with belimumab; however, the number of patients enrolled has been low (69 evaluable patients as of July 10, 2020) despite considerable awareness-raising activities.

Objectives

Crowdsourcing, in which a large group of people is tasked either competitively or noncompetitively to solve a problem or complete a task on web, has shown promise across several areas of health [13,14]. Several studies have used crowdsourcing to improve patient engagement and obtain patient insights to help inform future research directions [14,15]. Crowdsourcing platforms such as Amazon Mechanical Turk (MTurk) [16] allow researchers to easily identify platform members who meet specific requirements, such as those with a specific disease or receiving particular treatments [17]. This study used 2 web-based crowdsourcing platforms to evaluate awareness of the BPR among patients and physicians and identify potential barriers to enrollment in pregnancy registries by using the BPR as a case study example.

Methods

Project Design

Two surveys were designed and conducted using 2 separate web-based crowdsourcing platforms: MTurk [16] and Sermo RealTime [18].

Patient surveys were conducted via MTurk [16], which enables the delivery of tasks (human information tasks) to a globally distributed, quality-managed workforce (Turkers) who self-select their participation in the survey. Turkers were remunerated as per Amazon guidelines [19] for completion of the questionnaires, with remuneration amounts set in line with the GlaxoSmithKline policy to ensure that payment rates are similar to national minimum wage standards. Surveys were anonymous and quick, but it was not possible to verify the self-reported disease status and demographics of Turkers, and follow-up questions after the initial response were not possible. Self-imposed best practices were used to maximize the quality of results. This included the rejection of incomplete surveys and surveys from respondents who had previously reported inconsistent demographics, such as gender. Survey submission time was also inspected and surveys that took <30 seconds to complete were rejected. Respondents were not financially compensated if their survey was rejected, and these responses were removed from the data set. Rheumatologist surveys were conducted via Sermo RealTime [18], a medical crowdsourcing site that has >800,000 verified, licensed physician members worldwide. Sermo is a commercially available fee-for-service platform on which surveys are anonymous and quick. Follow-up questions were made possible after the initial response.

Patient and rheumatologist survey questions were in the English language only and were designed to assess belimumab exposure during pregnancy, patient and rheumatologist awareness of the

BPR, rheumatologist willingness to refer patients to the BPR, perceived BPR enrollment barriers for physicians and patients, and SLE treatment during pregnancy. The patient survey consisted of 14 questions and the rheumatologist survey consisted of 11 questions (2 screening questions, followed by 9 questions). Responses were collected from patients and rheumatologists in eight (Austria, Belgium, Canada, France, Germany, Spain, Sweden, and United States) of the countries the BPR was active in, which were deemed to have sufficient MTurk and Sermo populations to provide a useful number of responses. The patient and rheumatologist survey questions are available in [Multimedia Appendix 1](#).

Patient Population

Eligibility was assessed using a short set of screening questions in which patients could self-report their demographic and clinical characteristics. In addition, the Amazon Turk selection criteria were used to request access to the survey only for women from the 8 countries where the BPR was active. Patients who reported that they were women; aged 18-55 years; had a diagnosis of SLE; and were pregnant, had recently been pregnant (within 2 years), or were planning a pregnancy were eligible for inclusion. Patients completed their web-based MTurk questionnaire regarding SLE medication use and BPR awareness. The survey was conducted for 3 months, from June to September 2018.

Rheumatologist Population

The rheumatologist survey targeted rheumatologists (in the 8 countries where the survey was active) based on the Sermo specialty classifications, who had a history of prescribing belimumab in pregnancy. A target of 200 rheumatologist respondents was set, with the availability of the questionnaire determined by the number of responses received. Rheumatologists completed a web-based questionnaire on prescription patterns and factors related to BPR awareness and enrollment. Responses were obtained within a 48-hour period in September 2018.

Analysis

As there was no direct way to validate whether Turkers had SLE, the similarity between rheumatologist-recommended and patient self-reported treatment options according to SLE severity were compared in patients who were pregnant or trying to conceive using a set of questions regarding medication use. Chi-square statistics were computed for each individual drug per SLE severity level, as well as an overall chi-square statistic to determine how well the 2 groups aligned and to help determine the reliability of the patient responses received on MTurk. The null hypothesis was that the proportion of medication use across the 6 treatment options reported by patients was at the same rate as that recommended by rheumatologists. All other responses were descriptively analyzed.

Ethics Approval

According to UK Health Research Authority criteria [20], this project did not require ethical approval. The project was conducted under GlaxoSmithKline plc.'s Scientific Engagement Policy [21] which enables the non-promotional interaction and exchange of scientific information between GlaxoSmithKline plc. and external communities to advance scientific and medical understanding and improve patient care. Patients, general practitioners and practice managers all provided consent to take part in the two crowdsourcing platforms via signed consultancy contracts and were reimbursed for their time at Fair Market Value.

Results

Participant Demographics and Clinical Characteristics

Patients

A total of 151 patients, primarily from the United States (n=148, 98%), responded with a steady submission response rate over a 3-month period (Figure S1 in [Multimedia Appendix 2](#)). The average time to complete the survey was 9 minutes. Most patients were aged between 26 and 35 years and reported mild or moderate SLE. Half of the patients (77/151, 51%) were either currently or recently pregnant ([Table 1](#)).

Table 1. Patient and rheumatologist demographics and characteristics.

Demographics	Respondents
Patients (N=151)	
Age (years), n (%)	
18-25	26 (17.2)
26-35	88 (58.3)
36-45	32 (21.2)

^aSLE: systemic lupus erythematosus.

Rheumatologists

A total of 169 rheumatologists completed the survey. Responses were obtained within a 48-hour period from rheumatologists, with most being US-based (100/169, 59.2%; [Table 1](#)).

Respondents from the United States were geographically well distributed.

Barriers to Study Enrollment

Overall, 85.2% (144/169) rheumatologists (84/100, 84% in the United States) explained why they would not prescribe

belimumab during pregnancy. Concerns among rheumatologists included an unknown pregnancy safety profile (119/169, 70.4% overall; 75/100, 75% in the United States), preference for other treatment options (63/169, 37.2% overall; 39/100, 39% in the United States), the disease being mild or symptoms being tolerable (50/169, 29.6% overall; 27/100, 27% in the United States), and *other* (2/169, 1.2% overall; 0/100, 0% in the United States). In addition, 23.7% (40/169) rheumatologists (28/100, 28% in the United States) reported that their patients had no concerns about belimumab exposure during pregnancy, whereas 16% (27/169; 12/100, 12% in the United States) reported that their patients preferred other treatments, 23.1% (39/169; 21/100, 21% in the United States) reported that their patients had a desire to reduce medication, and 61.5% (104/169; 66/100, 66% in the United States) reported that their patients were concerned about the unknown safety profile of belimumab during pregnancy.

BPR Awareness

Patients

Awareness of the BPR was greater in patients who had been previously exposed to belimumab (32/63, 51%) than in those

who had never been exposed to belimumab (5/88, 6%; **Figure 1A**). Among 37 women who reported the source of their awareness of the BPR, the most commonly reported sources of knowledge about the study were rheumatologists (21/37, 57%), followed by a friend or family member (8/37, 22%), internet (4/37, 11%), or brochure (4/37, 11%). Overall, 60% (38/63) patients reported that they discontinued belimumab because of pregnancy or planned pregnancy, whereas 40% (25/63) patients continued treatment during pregnancy or while trying to become pregnant (**Figure 2A**). For patients who discontinued belimumab, BPR awareness did not appear to affect the decision to continue or discontinue, with approximately equal numbers in the continued and discontinued groups aware or not aware of the BPR; 52% (13/25) patients who continued treatment were aware of the BPR, whereas 48% (12/25) were unaware of the BPR; 50% (19/38) patients who discontinued treatment were aware of the BPR, whereas the other 50% (19/38) patients were unaware of the BPR (**Figure 2A**).

Figure 1. (A) Patient-reported previous belimumab exposure and Belimumab Pregnancy Registry (BPR) awareness and (B) rheumatologist-reported belimumab prescriptions for patients who were pregnant or planning a pregnancy.

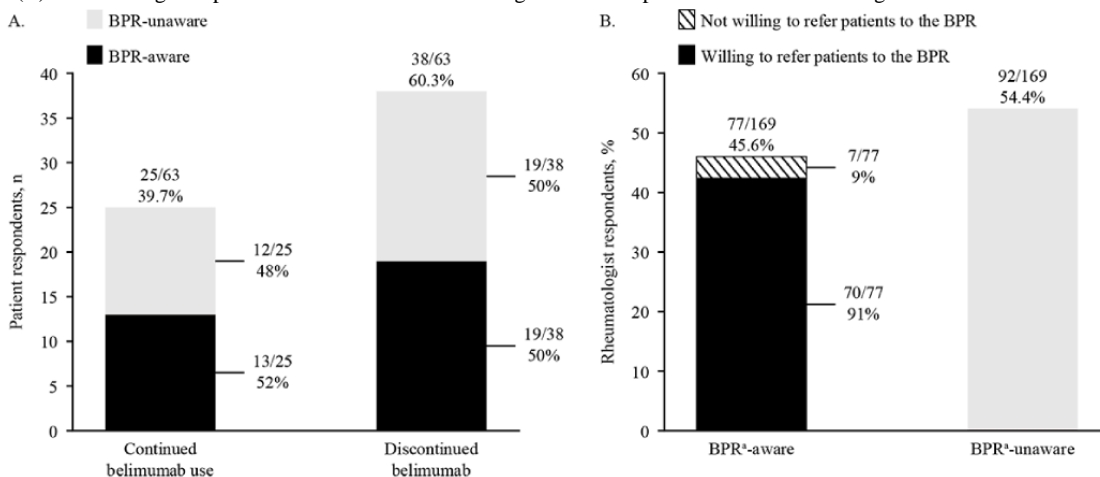

Figure 2. (A) Patient-reported belimumab discontinuation because of pregnancy or planned pregnancy and Belimumab Pregnancy Registry (BPR) awareness and (B) rheumatologist-reported BPR awareness and willingness to refer patients to the BPR among those who were BPR-aware.

Rheumatologists

Overall, 45.6% (77/169) rheumatologists were aware of the BPR, with most BPR-aware rheumatologists (70/77, 91%) referring patients to the registry (Figure 2B, Multimedia Appendix 3). Among US rheumatologists, 43% (43/100) were aware of the BPR, and most referred patients for BPR enrollment (40/43, 93%).

Belimumab Exposure

Patients

Previous belimumab exposure was reported by 41.7% (63/151) patients (Figure 1A). Belimumab exposure differed slightly among patients who were pregnant or recently pregnant (39/77, 51%) and those planning a pregnancy (24/74, 32%). Among all patients who had been exposed to belimumab, 54% (34/63) reported <1 year of use, 36% (23/63) reported 1-2 years of use, and 10% (6/63) reported >2 years of use.

Rheumatologists

Overall, 145 rheumatologists (86 from the United States) provided the number of patients with SLE (who were pregnant or trying to become pregnant) who they had treated with belimumab over the course of their careers; of these, 75 (51.7%) had prescribed belimumab to <5 patients who were either pregnant or trying to become pregnant, 37 (25.5%) had prescribed belimumab to 5-10 patients in this category, and 33 (22.7%) had prescribed belimumab to >10 patients in this category (Figure 1B). Using the minimum and maximum estimates, this approximately equated to a minimum of 600 patients who had been exposed to belimumab during pregnancy, with the upper estimate being at least 1108. The results were similar in the group of rheumatologists from the United States; 58% (50/86) rheumatologists had prescribed belimumab to <5 patients who were either pregnant or trying to become pregnant, 21% (18/86) had prescribed belimumab to 5-10 patients in this category, and 21% (18/86) had prescribed belimumab to >10 patients in this category.

A total of 8 rheumatologists who completed the survey were screened out; 7 (88%) because they did not prescribe belimumab and 1 (13%) because they did not treat pregnant patients or those trying to become pregnant.

Treatment Patterns

Belimumab exposure was reported by patients with mild (6/64, 9%), moderate (22/85, 26%), and severe (1/2, 50%) SLE during pregnancy, recently after pregnancy, or while they were trying to conceive (Figure 3A). Rheumatologists more commonly recommended belimumab for patients who were potentially pregnant, recently pregnant, or trying to conceive with moderate (84/169, 49.7% overall; 50/100, 50% in the United States) and severe (123/169, 72.8% overall; 69/100, 69% in the United States) SLE than with mild SLE (36/169, 21.3% overall; 27/100, 27% in the United States; Figure 3B).

Use of immunosuppressive agents during pregnancy, recently after pregnancy, or while trying to conceive was reported by patients with mild (19/64, 30%) or moderate (29/85, 34%), but not severe (1/2, 50%), SLE (Figure 3A). Rheumatologists most commonly recommended immunosuppressive agents for severe disease (149/169, 88.2% overall; 91/100, 91% in the United States), followed by moderate (91/169, 53.8% overall; 56/100, 56% in the United States), and mild (25/169, 14.8% overall; 14/100, 14% in the United States) disease in this group of patients (Figure 3B).

Overall, patient-reported drug exposure by disease severity in patients who were pregnant, recently pregnant, or trying to conceive was statistically different from rheumatologist-recommended treatment options ($P<.001$; Table 2). As only 2 patients self-reported having severe SLE, we further restricted our comparison to only include mild and moderate SLE and found that the null hypothesis must still be rejected ($P<.001$). However, when individual disease severity and treatment options were compared, most of the patient responses (10/18, 56%) agreed with rheumatologists' recommendations ($P>.05$; Table 2).

In total, 82% (138/169) of rheumatologists (80/100, 80% in the United States) reported that they would suggest a washout period from belimumab before pregnancy; 31.9% (44/138; 26/100, 26% in the United States) would suggest a period of 0-30 days, 46.4% (64/138; 38/100, 38% in the United States) would suggest a period of 30-60 days, and 21.7% (30/138; 16/100, 16% in the United States) would suggest a period of more than 60 days (Figure 4).

Discussion

Principal Findings

Pregnancy registries can provide valuable maternal and fetal safety data for newly available therapies; however, recruitment of patients into these registries can be challenging [1,3,5,22]. In the current project, crowdsourcing was used as a novel method to obtain insights from patients and health care professionals on pregnancy registries, specifically the BPR, a multinational, prospective, voluntary registry, established in 2012 to document belimumab exposure in pregnant women.

Web-based crowdsourcing surveys were completed by a considerable number of patients (N=151) and rheumatologists (N=169), demonstrating that crowdsourcing is an effective data collection method to obtain relevant patient and health care professional inputs into ongoing studies. Crowdsourcing was chosen over traditional surveys as it is cost-effective, rapid, targeted, and provides geographically diverse physician and patient feedback. The crowdsourcing approach allowed for cost-effective specific targeting of women with SLE via the MTurk platform; however, as the Turker population is dynamic, it is important to ensure that an adequate period is provided to reach target response levels. Similarly, Sermo allowed for rapid response rates from physicians, which were typically received within 48 hours in the current project. This analysis adds to the growing body of literature that demonstrates the value of crowdsourcing in health research, with previous studies using crowdsourcing across a range of diagnostic, surveillance, and public health applications, among others [13]. However, drawbacks of a crowdsourcing approach are well known, including potential bias in the sample that reduces the generalizability to a wider population [14,15].

Assessment of the safety of pharmaceutical therapies during pregnancy is necessary to gather data that can be used by health care professionals when treating and counseling patients who are pregnant or who wish to become pregnant [3]. This is of particular importance in patients with diseases such as SLE that predominantly affect women, many of whom are of childbearing age, and can be associated with adverse pregnancy outcomes such as premature birth [23]. The overarching principles of the European League Against Rheumatism to guide the use of SLE medication during pregnancy and lactation include aiming to prevent or suppress maternal disease activity without harm to the fetus or child and balancing the risk of medication for the fetus or child against the risks of untreated maternal disease [24]. The US Food and Drug Administration guidelines on the assessment of the outcomes of pregnancies in women exposed to pharmaceutical products state that pharmacovigilance, pregnancy registries, and complementary data sources can be used to evaluate drug safety during pregnancy [1]. However, pregnant patients are generally a population that is difficult to reach, and the feasibility of there being sufficient treatment exposure and recruitment within the patient population to allow enough reliable pregnancy and infant outcome information to be obtained is a critical consideration in the design of pregnancy registries to ensure a sufficient sample size [1,25]. The European League Against Rheumatism has published recommendations

for a core data set that pregnancy registries should aim to collect; by gathering data more uniformly, data from different registry sources could be analyzed together, helping to address the issue of low recruitment [26].

The responses received from patients and rheumatologists in the current project are consistent with previous reports of low recruitment into pregnancy registries despite considerable treatment exposure [2,22]. The results suggest that although some women report belimumab exposure during pregnancy (39/77, 51% of pregnant patient respondents in the current project), very few have entered the BPR to date. This may be because of a lack of awareness, with only approximately 51% (32/63) of patients who had been exposed to belimumab during pregnancy or while planning a pregnancy and 45.6% (77/169) of participating rheumatologists reporting that they were aware of the BPR. These data suggest that pregnancy registries could generally focus on improving engagement levels with both pregnant patients and physicians to help increase awareness and recruitment rates. However, as most patients (21/37, 57%) stated that the source of their BPR awareness was a physician, increasing registry awareness among health care professionals may be a particularly effective method to improve recruitment. This is consistent with previous studies on pregnancy registry recruitment, which also identified physicians as the major target for increasing awareness [2,22].

Interestingly, most rheumatologists (70/77, 91%) who were aware of the BPR reported that they were willing to refer patients to the registry, and almost half of them (70/145, 48.3%) reported that they had prescribed belimumab to >5 pregnant (or soon-to-be pregnant) patients during their career. The relatively high number of rheumatologists who were aware of BPR and willing to prescribe belimumab during pregnancy contrasts with the low recruitment numbers to date. This suggests that there may be additional obstacles that prevent physicians from enrolling patients in pregnancy registries in routine practice. Possibilities include administrative barriers, the voluntary nature of enrollment, the lack of compensation for time and resources, and no immediate benefit to the participating patients. Therefore, recruitment into voluntary patient registries is likely to be reliant on the participation of patient subgroups who may generally be more motivated and health conscious [27].

As expected, low recruitment into pregnancy registries can also be attributed to the current lack of pregnancy safety data for the drug of interest. In this study, only small proportions of rheumatologists and patients reported no concerns about belimumab exposure during pregnancy, and more than half of the rheumatologists (119/169, 70%) and patients (104/169, 62%) reported the unknown pregnancy safety profile of belimumab as a concern. This is consistent with the Food and Drug Administration belimumab prescribing information, which highlights the limited pregnancy data available [11]. Many rheumatologists have also indicated a preference for alternative treatments or a desire to eliminate all treatments during pregnancy. Therefore, further information on the safety profile of belimumab during pregnancy will be of great value to support patient and physician decisions regarding SLE treatment during pregnancy. This can be facilitated by further awareness-raising activities and recruitment of the target population into pregnancy

registries or by alternative methods of collecting pregnancy surveillance data.

Survey responses indicated that belimumab treatment is more commonly recommended by rheumatologists as a treatment for patients with SLE who were recently pregnant, potentially pregnant, or trying to conceive with moderate or severe rather than mild disease. In patients who self-reported mild severity, the major drug classes (nonsteroidal anti-inflammatory drugs, corticosteroids, immunosuppressive agents, and belimumab) were all within the expected range of rheumatologist recommendations.

Strengths and Limitations

The strengths of this project include the size of the sample of patients with SLE and rheumatologists with a history of treating patients with SLE, along with the use of a real-world SLE population with varied self-reported disease severities. Limitations of this analysis include geographic representation being predominantly US-based; thus, country-specific differences in participation rates may influence interpretability or generalizability to other countries outside the United States. Respondents had to have internet access, and there was a bias toward patients with an understanding of the English language given that the survey questions were only available in English. These requirements could have introduced bias regarding the socioeconomic and educational status of the patients, which was not available or requested. Participants were also required to have Amazon MTurk or Sermo accounts and be willing to participate in the survey. Verification that MTurk respondents were female patients with SLE who were pregnant or planning a pregnancy was not possible, and it is possible that some participants completed the survey imposing as patients for financial gain. To mitigate this concern, we implemented screening procedures, such as rejection of incomplete or inconsistent surveys and surveys completed in <30 seconds, to safeguard the validity of the data collected. A review of the strengths and weaknesses of MTurk research found similarities

between MTurk participants and traditional samples and concluded that MTurk has many benefits that make it suitable for assessing a variety of behavioral research, with evidence showing that Turkers produce reliable results consistent with standard decision-making biases [28]. In addition, patients had unverified disease severity; reporting mild, moderate, and severe SLE was made at the discretion of MTurk respondents, and although these are likely to be more standardized among rheumatologists, patient perceptions of mild, moderate, and severe disease may differ. We assessed the similarity between rheumatologist-recommended and patient self-reported treatment options according to SLE severity using a set of questions regarding medication use to verify patients' responses; however, this proxy approach is not without its own limitations given the disproportionate participation between countries. Moreover, rheumatologists' views on prepregnancy washout were collected for belimumab and not for other treatments. Finally, all data including belimumab exposure were reported by the patients and rheumatologists themselves and could not be verified.

Conclusions

Web-based crowdsourcing is a viable approach for obtaining patient and physician input and enables insights to be gathered from difficult-to-recruit populations. Using our case example, crowdsourcing responses from patients and rheumatologists suggest that there exists a population of patients with SLE who continue to use belimumab during pregnancy. There was moderate awareness of the BPR among patients and physicians. In contrast, enrollment in the BPR is low despite considerable time and resources being devoted to raising awareness among patients and rheumatologists, as well as a willingness among rheumatologists to refer patients to the registry. Barriers to enrollment in pregnancy registries such as the BPR may include a lack of awareness, preference for alternative or no treatment during pregnancy, lack of data on the benefit/risk profile associated with treatment during pregnancy, and the voluntary nature of the study. Alternative approaches to enrolling patients in pregnancy registries should be explored.

Acknowledgments

The authors would like to thank the patient and rheumatologist respondents for their participation in the surveys. This project was funded by GlaxoSmithKline. Medical writing support was provided by Liam Campbell, PhD, of Fishawack Indicia Ltd, part of Fishawack Health, and was funded by GlaxoSmithKline.

Data Availability

GlaxoSmithKline (GSK) is committed to publicly disclosing the results of the GSK-sponsored clinical research that evaluates GSK medicines, and as such was involved in the decision to submit. Researchers can inquire about the availability of data from GSK clinical studies that are not listed on the site before they submit a research proposal from ClinicalStudyDataRequest.com.

Authors' Contributions

JMP, JLP, KG, and GP contributed to the study design. JLP acquired the study data. JMP, JLP, KG, RAL, MP, PM, and GP analyzed the data.

Conflicts of Interest

At the time of the project, JMP, KG, GP, RAL, MP, and PM were employees of GlaxoSmithKline and held stocks and shares in the company. At the time of the project, JLP was the sole proprietor of Jivecast Consulting, which conducted the analyses funded by GlaxoSmithKline.

Abstract

Background: Recruiting young people for health and intervention studies by traditional methods has become increasingly challenging. The widespread access to the internet may offer new strategies for online recruitment.

Objective: This study aims to assess the feasibility of online recruitment for a randomized controlled trial evaluating the effectiveness of Mindhelper, an online national youth mental health promotion service. The target group was young Danes aged 15-25 in need of mental health promotion.

Methods: Advertisements for recruitment were set up on Facebook and Instagram. Browser history was collected for a subsample of participants. We compared basic characteristics of participants who completed the baseline survey and those who did not, as well as of participants who completed the follow-up survey and those who were lost to follow-up. The significance of these differences was tested with the Pearson chi-square test.

Results: A total of 560 Danes aged 15-25 were recruited within 1 month (ie, had completed the baseline survey). Among these participants, 356 (63.6%) were at risk of developing depression or stress. The average advertisement price per participant completing the baseline questionnaire was 31 DKK (approximately €4 [US \$4.2]). The follow-up survey was sent to 545 participants, of whom 318 (58.3%) completed the survey. No statistically significant differences were observed in baseline characteristics of participants who completed the follow-up and those who were lost to follow-up in terms of gender ($P=.45$), age ($P=.35$), occupation ($P=.17$), cohabitation ($P=.90$), mental well-being ($P=.26$), mental illness ($P=.44$; impact of the illness, $P=.05$), or use of the internet when having a hard time ($P=.92$).

Conclusions: We conclude that it is feasible to recruit young Danes online for a large-scale randomized controlled trial assessing the effectiveness of Mindhelper.

KEYWORDS

recruitment; web based; online; mental health; young people; well-being

Introduction

Recruiting participants for intervention studies is increasingly difficult, and participation rates in research projects are generally declining, which may hamper data quality, statistical power, and validity of research findings. Recruitment and retainment

of young people with mental health problems, for health and intervention studies, are shown to be especially challenging [1-4].

Most young people are active on social networking sites, being online multiple times a day, which may offer an alternative

strategy to recruit young participants. In 2020, 93% of 16- to 24-year olds used the internet on a daily basis in Denmark [5], and 96% of all Danes aged 16-39 were social media users [6], of which Facebook had the largest market share [7].

In recent years, an increasing number of studies have applied online recruitment methods, advertising on, for example, social media platforms, through Google search engine, and by website campaigns. Studies have assessed the feasibility of online recruitment among the general population [8,9], and in specific groups, especially among adolescents, and groups that are considered difficult to recruit by traditional means, for example, men who have sex with men [10-18]. Generally, the results show that the cost per participant recruited online is lower compared with offline recruitment methods [13,18-22], and that it is possible to reach populations who are otherwise challenging to enroll [15,19,23]. Studies find that participants recruited online are younger, more highly educated, have poorer self-rated health, and are more likely to be White and female than representative samples [8,18,20,24-26]. However, a systematic review of studies recruiting for health, medical, or psychosocial research using Facebook showed that the majority (86%) of the studies that examined the representativeness concluded that samples recruited through Facebook had similar representation to those recruited through traditional methods [23]. Further, another systematic review examining studies using Facebook for recruiting participants for health research concluded that recruitment through Facebook was more likely than traditional recruitment methods to result in better representation and improved participant selection among adolescents [18].

The widespread access to and use of the internet further opens opportunities for online interventions. Mental health problems are prevalent among young people both in Denmark and abroad [27,28]. Although young people experience the highest rates of mental health problems of any age group, less than half of young people with mental health problems seek professional help [29-32]. Concerns about stigma and confidentiality, low mental health literacy, and difficulties navigating existing mental health services are among the many barriers to help-seeking among young people [33,34]. Online services may overcome some of the obstacles of help-seeking; however, only few studies have examined the effectiveness of unstructured digital mental health solutions [35-40]. Mindhelper [41] is an online, open-access, self-directed youth mental health promotion service that provides information, self-help tools, and guidance to young people in Denmark. Since January 2019, the service has been freely available and disseminated to young people and youth mental health professionals across the country.

The aim of the study was to assess the feasibility of online recruitment for a randomized controlled trial assessing the effectiveness of a website (Mindhelper) targeting young people aged 15-25 years in need of mental health promotion.

Methods

The Intervention: Mindhelper

Mindhelper is a highly scalable, unstructured, multicomponent online mental health promotion service that offers young people

information, tools, and support for life problems and mental health difficulties. The site was co-developed (from 2014 to 2017) by the Centre for Telepsychiatry in the Mental Health Services in the Region of Southern Denmark in partnership with young people and 4 Danish municipalities. Mindhelper does not provide psychological or therapeutic treatment. It is designed to provide practical help strategies and tools to support well-being and help-seeking from everyday stressors to more complex mental health issues. The issues range from dealing with family difficulties, depression, and substance use/dependence. Tools and information are derived mainly from the cognitive field, including mindfulness exercises and general strategies to good mental well-being. Mindhelper also offers a supportive outreach service in the form of responding to letters sent by young people. The letters exchanged are published in an anonymized form, so that other young people with similar concerns or worries may benefit from the supportive advice. The website also serves as a national directory to local youth mental health services for further support and help.

The service has been freely available and disseminated across the country since January 2019. In 2020 Mindhelper had more than 1.2 million visits.

Evaluating the Effectiveness of Mindhelper in a Large-Scale Study

In a large-scale study, we aim to evaluate the effectiveness of Mindhelper, contributing to the much needed evidence base for interventions promoting mental health that target young people [42,43]. This feasibility study was undertaken to investigate whether it is possible to recruit young people with mental health problems via social media platforms, to randomize them to use or not to use Mindhelper, and to keep the intervention and control group separate, although the site is open and freely available online. Further, we aimed to explore whether it is possible to retain the participants in the study over time and to assess the validity of self-reported use of Mindhelper.

Browser History

To assess whether self-reported questions on online behavior is a valid measure for actual behavior, a subsample of participants, who had given informed consent to access their browser history, was contacted and invited to the National Institute of Public Health (NIPH). Here they met a project employee, who coded the participants' browser history (in all available browsers) related to the use of Mindhelper for the intervention period from the devices they bought (usually their laptop and mobile phone). All coding was done manually, and thus nothing was downloaded from the participants' devices. The participants were present during the coding and had full insight into the process.

Because of COVID-19 restrictions, participants were not allowed to enter the NIPH by the end of the recruitment period, and therefore they were guided through the coding process online, meaning that the coding was partly self-reported. Participants who offered access to their browser history were given a gift card for cinema (200 DKK \approx €27 [US \$28.4]) in appreciation for their participation in the study. The financial compensation for participants was given irrespective of their

survey responses and browser history. Hence, there was no reason to believe that the gifts impacted the study in any other way than to promote participation in the study.

The Advertisement Setup

Facebook and Instagram were chosen over other platforms, as the advertisement tools on these platforms enable a more detailed targeting of advertisements than other social media platforms, and because Facebook/Instagram had the lowest cost per eligible contact to participants in a study with a similar aged target group [15]. Advertisements targeted Danish speakers aged 15-25. To allow an easier access to the NIPH, all advertisements further targeted young people living within a 20 km radius from the center of Copenhagen (where the NIPH is located). Age was based on the information listed in the user's Facebook/Instagram profile, while location was based on the internet protocol address or the address listed on the user's profile [44].

The advertisements contained a short title (eg, "Help us improve mental well-being among young people"), an image (a photo or drawing of a young male or female looking sad or troublesome), and a main text (eg, "Are you 15-25 years? Help us improve mental well-being among young people. It only requires 2 times 15 minutes of your time"). Examples of the advertisements are displayed in [Multimedia Appendix 1](#). All advertisements were Dynamic Creative Ads, where Facebook's/Instagram's algorithms automatically combine title, images, and main text to run based on advertisement performance and the cost per click. In this process advertisements are placed within *advertisement sets*. For this study, 4 sets of advertisements were constructed with a total of 6 advertisements.

Advertisers can choose to be charged per click on the advertisement, or each time the advertisement is displayed a certain number of times [44]. We chose the cost-per-click option, as we were interested in people clicking through to our website at the lowest possible cost. The cost per click depends on the current competition between advertisers within the target group, and thus may fluctuate over the recruitment period.

The first advertisement was released on Facebook and Instagram on November 2, 2020. Participants were led from the advertisements to a webpage for the study, where information about the study and data collection was provided. From this webpage, participants could click their way further to the baseline questionnaire, if they had given informed consent to participate in the study. We used the online survey tool SurveyXact [45], which allowed secure collection and data protection.

Randomization and Surveys

An automatic randomization was set up allocating everyone opening the baseline questionnaire to either the intervention group or the control group.

Questions on participants' demographics and use of the internet when they were having a hard time were included. Further, multiple scales were included to assess a broad spectrum of mental health. Well-being was assessed by the Well-Being Index

[46,47], psychological distress and daily functioning were assessed by the Short Warwick-Edinburgh Mental Wellbeing Scale (SWEMWBS) [48], while intentions to seek help were assessed by the General Help-Seeking Questionnaire—vignette version (GHSQ-V) [49]. As no Danish version of GHSQ-V exists, the scale was translated by the authors: one in the research group translated the questionnaire from English to Danish, while another translated the Danish version back to English (SHH and DLS). In the few instances where there were inconsistencies between the 2 translations, the best translation was discussed until agreed upon by the researchers.

The survey was pilot tested among 5 young informants within the target group through cognitive interviews, to assess how the posted questions were interpreted and to identify potential challenges in responding to the survey [50]. Special attention was paid to (1) GHSQ-V, as no validated Danish version exists; and (2) new questions formulated by the research group to, for example, measure use of Mindhelper. Based on the informants' comments, wording was changed to ease the reading, categories corrected to better grasp expected answers, and questions left out due to misinterpretations. However, as no major changes were needed to the questions or structure, it was unnecessary to repeat the pilot testing of the revised questionnaire.

Participants were informed of the follow-up survey, asked to provide their contact details (email or phone number), and informed that they would take part in a lottery of gift cards for the cinema (200 DKK \approx €27 [US \$28.4]) when responding to both surveys. All participants who had completed the baseline survey were invited to answer the follow-up survey 1 week after their completion of the baseline survey. They received the invitation via SMS text message and/or email, depending on the information they had provided in the baseline survey. If they did not respond to the survey within 3 days after the invitation, they received reminders via SMS text message or email. The follow-up survey included questions on the usage of Mindhelper in addition to measures of mental well-being.

Participants were all shown the same questions until the end of the baseline survey. The intervention group was provided with information on Mindhelper and an active link to the website, whereas the control group was informed about the follow-up survey by the end of the baseline survey and received information about Mindhelper only when completing the follow-up survey. On December 2, 2020, the baseline survey was closed; thus, all recruitment was completed within 1 month.

Statistical Methods

We compared basic characteristics of participants who completed the baseline survey and those who did not and used the Pearson chi-square test to assess if differences were statistically significant. Similarly, we compared characteristics of participants who completed the follow-up survey and those who were lost to follow-up and tested the significance of these differences using the Pearson chi-square test.

Ethical Considerations

The design of this study was guided by the CONSORT (Consolidated Standards of Reporting Trials) statement for pilot and feasibility trials [51], and conducted in accordance with the

Danish Council for Independent Research's ethical guidelines. All participants received comprehensive information about the purpose of the project and terms of participation and provided informed consent to participate before responding to the baseline questionnaire. The study was registered at ClinicalTrials.gov (NCT04650906), legally approved by the Region of Southern Denmark (journal number: 20/55262), and ethically approved by The Research Ethics Committee of the University of Southern Denmark (case number: 20/68029).

Consent to Participate

It was clearly stated that participation in the study was voluntary, and participants gave consent that their data could be used for research purposes.

Results

The flow of participants in the study population is presented in [Figure 1](#). A total of 1284 participants opened the baseline questionnaire. There were 48 participants who could not be categorized as within the target group, either because they had missing information on age or residency (which were the only mandatory questions within the questionnaire), or because they were younger than 15 or older than 25 years, or not living in Denmark. There were 671 participants who did not complete the questionnaire. Further, 5 participants completed the baseline questionnaire, but did not provide valid contact information, and therefore could not receive the follow-up questionnaire. Thus, a total of 560 participants within the target group completed the baseline questionnaire. All participants completing the baseline questionnaire should receive the follow-up questionnaire; however, 15 participants were mistakenly never invited due to technical errors. A total of 227 participants who received the follow-up questionnaire did not respond, while 318 respondents completed the follow-up questionnaire, and thus a retention probability of 58.3% (318/545) was achieved.

In total, we were able to track 1009 unique clicks to the baseline questionnaire from the landing page. However, the baseline questionnaire had been started 1284 times, thus several clicks to the questionnaire were not tracked. This may occur if participants shared the link to the questionnaire or because of technical issues related to JavaScript. It was predominantly females who interacted with all sets of ads. The average advertisement price per participant completing the baseline questionnaire was 31 DKK (approximately € [US \$4.2]).

Baseline characteristics of young people who did and did not complete the baseline and follow-up surveys are presented in [Table 1](#). Most of the participants were females, undergoing postsecondary or higher educations, and living together with both parents. More than half of the participants were at risk of developing depression or stress according to the Well-Being

Index. Every second participant had at some point been told by a general practitioner or psychologist that they had a mental illness, of whom nearly half (29/52, 56%) were daily affected by the illness during the past 12 months. More than half of the participants used the internet often or sometimes if they were having a hard time.

Participants completing the baseline survey were older, more likely to attend a higher education, and to live apart from their parents than those not completing the baseline survey. However, there was no statistically significant differences between participants completing and not completing the baseline questionnaire regarding gender ($P=.51$), mental well-being ($P=.39$), mental illness ($P=.17$; impact of the illness, $P=.17$), or use of the internet when having a hard time ($P=.31$).

The 560 participants who completed the baseline survey were equally randomized to the control ($n=280$) and intervention group ($n=280$), and no baseline differences were observed between the 2 groups (data not shown).

The follow-up survey was sent to 545 young people, and 318 (58.3%) completed the survey. No statistically significant differences were observed in baseline characteristics of participants completing the follow-up and those who were lost to follow-up regarding gender ($P=.45$), age ($P=.35$), occupation ($P=.17$), cohabitation ($P=.90$), mental well-being ($P=.26$), mental illness ($P=.44$; impact of the illness, $P=.05$), or use of the internet when having a hard time ($P=.92$). However, participants who did complete the follow-up survey were slightly older and more likely to be in the risk zone of depression or stress according to the Well-Being Index, compared with those not completing the survey. Furthermore, participants completing the follow-up survey were more likely to have a mental illness and to have been daily impacted by the illness during the past 12 months than those not completing the survey.

During the follow-up period, 21.9% (34/155) of the participants in the intervention group and 3.1% (5/163) of the participants in the control group used Mindhelper (data not shown). The difference in usage between the intervention and control group was statistically significant ($P<.01$).

In total, 49 participants got their browser history coded. However, 3 participants were subsequently excluded as they could not be identified in the survey data, resulting in 46 usable browser histories linked with survey response ([Table 2](#)). Overall, when participants in the survey reported that they had not visited Mindhelper, it was consistent with data from the browser history (an agreement between their survey response and their browser history of 94% [31/33]). When participants reported that they had visited Mindhelper, results were less clear (an agreement between their survey response and their browser history of only 64% [7/11]).

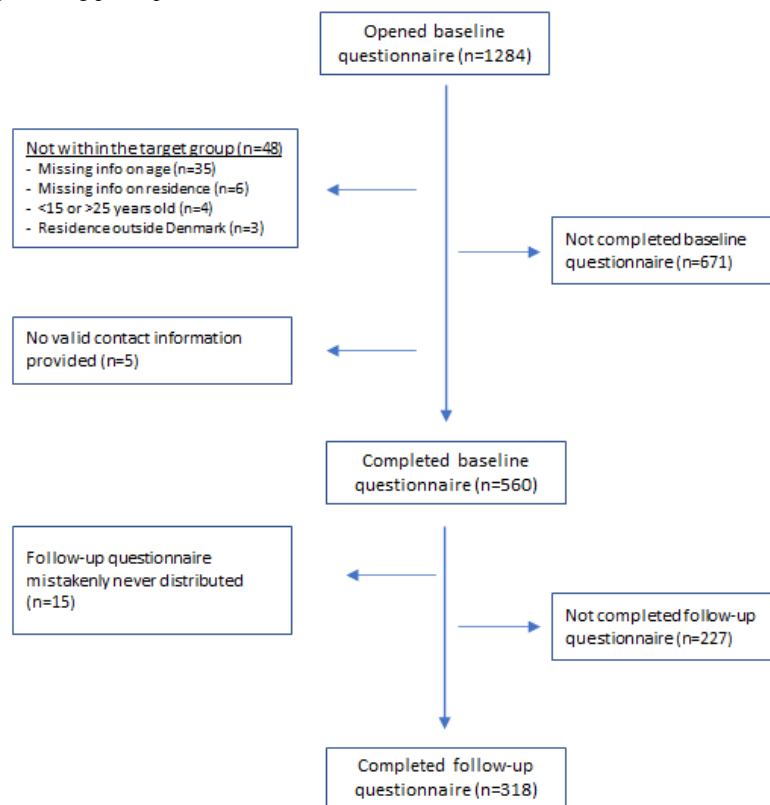

Figure 1. Study flowchart presenting participant recruitment.

Table 1. Baseline characteristics of young people who did and did not complete the baseline and follow-up surveys, respectively.

Characteristics	Baseline not completed (n=671)	Baseline completed (n=560)	P value	Follow-up not completed (n=227)	Follow-up completed (n=318)	P value

Discussion

Principal Findings

In 1 month, 560 participants within the target group and in need of mental health promotion were recruited. Participants completing the baseline survey were generally older than those not completing the survey, and in line with this, a larger proportion attended a higher education and lived apart from their parents. However, no statistically significant differences regarding mental health and well-being were observed between young people with completed and noncompleted baseline surveys.

A retention probability of 58.3% (318/545) was achieved, which is lower than the average probability of 79% observed in a systematic review of engagement of children and young people

in digital mental health interventions (ranging from 16% to 100% in the included studies) [52]. However, the average probability covers a wide variety of target groups and interventions, and thus may not be comparable to ours. The study included in the review most like ours targeted Australians aged 16-25 years and assessed the efficacy of an online self-guided app recommendation service aiming to improve well-being [39]. In that study, a retention probability of 50% (4 weeks after baseline) was achieved. Compared with this, a retention probability of 58.3% (318/545) may be acceptable after 1 week. The 318/545 (58.3%) participants who completed the follow-up survey did not differ significantly from those lost to follow-up in demographic characteristics, mental health, and well-being, thus decreasing the risk of selection bias. However, participants who completed the follow-up survey were more likely to be at risk of developing depression or stress, to have

a mental illness, and to be daily impacted by the illness than those not completing the survey. This may indicate that we were able to retain participants in need of mental health promotion, and thus to reach the target group of the intervention. The risk of attrition at follow-up will be accounted for in the sample size calculation in the large-scale randomized controlled trial.

We targeted males and females equally; however, we mainly recruited females (488/560, 87.1%). This tendency is in line with other studies recruiting using Facebook, where the majority of the participants recruited have also been females [23]. The advertisement algorithm favors subparts of the target group who have previously interacted with the advertisement, and thus the advertisements were increasingly shown to females during the recruitment process. This may be corrected for in the large-scale effectiveness study of Mindhelper by re-designing the advertisements, oversampling specific groups, or narrowing down the target group for some advertisements (eg, by only including males). The ability to create multiple advertisements targeting different populations, to closely monitor their real-time performance, and to continuously adjust make online advertising a powerful tool for recruiting according to specific demographic requirements. This will help to ensure a broader representation in the study, but will probably also result in a slightly increased price per recruited participant. With an average advertisement price per participant completing the baseline questionnaire of 31 DKK (approximately €4 [US \$4.2]), online recruitment proves economically favorable compared with traditional methods. However, one should be aware of the dynamic nature of advertisement algorithms, and the fact that price per click depends on the current competition between advertisers within the target group. Hence, the achieved advertisement price per participant may fluctuate. Further, the advertisement success of future studies may be affected by changing Facebook algorithms and policies.

According to the follow-up survey, 21.9% (34/155) of the participants in the intervention group and 3.1% (5/163) of the participants in the control group had used Mindhelper during the intervention period. Survey-reported online activity was consistent with browser history when participants reported not to have visited Mindhelper, but results were less clear among participants reporting to have visited Mindhelper, due to the relatively few observations and low overall usage of Mindhelper. However, our results indicated that it was possible to ensure that very few participants in the control group used the website, although the website is open and freely available.

A more active and persistent encouragement of participants in the intervention group is needed to increase the usage of Mindhelper. Currently, the most frequent user flow of Mindhelper is people entering the site from diagnostic and research search phrases in search engines (ie, pull marketing). Recruiting through online advertisement flips the user flow (push marketing). Hence, different measures will be applied in the large-scale effectiveness study of Mindhelper to improve the motivation for interaction with the site. Throughout the intervention period, automated series of emails/SMS text

messages introducing participants to learn more about the site, and specific series offering advice on improving mental health (eg, evidence-based advice on self-care) will be applied to remind the intervention group of the site's possibilities.

Strengths and Limitations

In 1 month, 560 eligible participants within the target group were recruited and thus, we succeeded in recruiting a large study population within a short timeframe. The large study population decreases the impact of nonsystematic errors and improves statistical power. The short recruitment period decreases the risk of other things occurring simultaneously that potentially impact recruited participants and the explored associations.

Some limitations of the study need to be considered. Exposure to the advertisements depended on having a profile on Facebook/Instagram, and the users supplying their correct age in their profile, other users' interaction with the advertisement (as the advertisement algorithm favors subparts of the target group who have previously interacted with the advertisement), and time spent on Facebook and Instagram. If systematic differences exist between those who were exposed to the advertisements and those who were not, this may give rise to selection bias. Further, there may be considerable differences between those who click on advertisements in Facebook/Instagram and those who do not. Similarly, if young people volunteering to participate in the study vary systematically from those who did not open the survey, self-selection bias may be an issue. As no information was gathered about participants who did not begin the baseline questionnaire, this bias cannot be excluded.

Since recruitment was completed within 1 month, no information was retrieved on longer-term trends in recruitment rates, which may diminish over time. This could be an area for future research.

Young people may access the internet daily from several devices, and they may not have brought all these devices to the NPHI for coding. Additionally, the participants may occasionally browse in incognito mode, and if they did while visiting Mindhelper, this will not show up in the browser history. Therefore, a participant might have actually visited Mindhelper, but it will not show up in his/her coded browser history. This inaccuracy is likely to be highest in the intervention group, as the control group was not provided with information about Mindhelper, and thus the use of Mindhelper may be underestimated in the intervention group.

We were also unable to track all activities from the study website to the questionnaire due to technical issues. In the large-scale effectiveness study of Mindhelper, we will seek to implement the survey directly on the website, which will give us more precise usage data.

Based on the results from this feasibility study, we conclude that it is possible to assess the effectiveness of Mindhelper in a randomized controlled trial and to recruit participants online via social networking sites.

Abstract

Background: Video consultation (VC) is increasingly seen as a cost-effective way of providing outpatient care in the face of dwindling resources and growing demand for health care worldwide. Therefore, the sustainable implementation of VC is a phenomenon of interest to medical practitioners, researchers, and citizens alike. Studies are often criticized for not being sufficiently robust because the research settings are mostly small-scale pilot projects and are unable to reflect long-term implementation. The COVID-19 pandemic has compelled clinicians worldwide to conduct remote consultation, creating a favorable context to study large-scale remote consultation implementation.

Objective: The aim of this study was to thoroughly investigate how clinicians reason their choice of different consultation modes in the routine of consultation and what the underlying reasons are for their choices. We posited that a deeper understanding of clinicians' perceptions of remote consultation is essential to deduce whether and how remote consultation will be adopted on a large scale and sustained as a regular service.

Methods: A qualitative approach was taken, in which the unit of analysis was clinicians in one of the largest university hospitals in Norway. In total, 29 interviews were conducted and transcribed, which were used as the primary data source. Using the performative model of routine as the theoretical framework, data were analyzed using deductive content analysis.

Results: Clinicians have mixed opinions on the merits and demerits of VC and its position between in-person and telephone consultation. Totally, 6 different planning criteria were identified, and individual clinicians used different combinations of these criteria when choosing a mode of consultation. The ideals that clinicians hold for conducting consultation can be divided into three aspects: clinical, interpersonal, and managerial. VC engenders a new ideal and endangers the existing ideals. VC causes minor changes in the tasks the clinicians perform during a consultation; thus, these changes do not play a significant role in their choice of consultation. Clinicians could not identify any changes in the outcome of consultation as a result of incorporating a remote mode of consultation.

Conclusions: Clinicians feel that there is a lack of scientific evidence on the long-term effect of remote consultation on clinical efficacy and interpersonal and managerial aspects, which are crucial for consultation service. The absence of sufficient scientific evidence and a clear understanding of the merits and demerits of VC and standard practices and shared norms among clinicians regarding the use of video for consultation both create a void in the consultation practice. This void leads clinicians to use their personal judgments and preferences to justify their choices regarding the consultation mode. Thus, diverse opinions emerge, including some paradoxical ones, resulting in an uncertain future for sustainable large-scale implementation, which can reduce the quality of consultation service.

KEYWORDS

video consultation; work routine; outpatient care; telemedicine; clinician; professional work

Introduction

Background

Video consultation (VC) is increasingly seen as a cost-effective way of providing outpatient care in the face of dwindling resources and growing demand for health care worldwide [1,2]. Several pilot studies have reported VC to be beneficial while providing health care access to patients in rural areas with insufficient care providers [3,4], thus making the consultation time-efficient [5], reducing the need for travel for patients [6,7], and providing the ability to add care providers from different locations and family members as needed to provide coordinated care [4]. Therefore, the sustainable implementation and adoption of VC is a phenomenon of interest to medical practitioners, academic researchers, and citizens alike. Studies on VC have taken several trajectories, such as measuring efficacy, diagnosis-specific outcomes, and safety. However, these studies are often criticized for not being sufficiently robust because the research settings are often small-scale pilot projects or interventions and, therefore, are unable to reflect long-term implementation [2,8]. To address this gap, we focused on a hospital where VC is no longer a trial project but is gradually becoming a regular service. We aimed to understand how, in their regular work routine, clinicians choose a particular mode of consultation when three alternative modes—in person, video, and telephone—are available to conduct a consultation. Clinicians are the ultimate decision makers in adopting or abandoning technology in hospitals [9]; therefore, they are the focus of this study. The pandemic has compelled clinicians worldwide to use remote consultations through telephone and video. Therefore, clinicians have gained substantial experience in conducting remote consultations. Thus, the pandemic has created a favorable context to study how clinicians choose the consultation mode. In contrast, as pandemic restrictions are being lifted, it is crucial to investigate how clinicians are making sense of the situation and how this may impact remote consultation implementation. Henceforth, we have used the term *remote consultation* to imply both video and telephone consultation and the abbreviations *PC*, *VC*, and *TC* to imply in-person, video, and telephone consultation, respectively.

Previous Studies

Although there is a lack of in-depth studies considering the intricacies of remote consultation implementation, recent studies have focused on the process of implementation. The nonadoption, abandonment, scale-up, spread, and sustainability framework aims to assist and evaluate the success of technology-enabled health care programs through pragmatic questions focusing on seven domains: condition or illness, technology, value proposition, adopter system, organizations, wider (institutional and societal) context, and interaction and mutual adaptation among all these domains over time [10]. An extension of this framework—the planning and evaluating remote consultation services method—has been developed for VC. This framework evaluates the following domains: reason

for consulting, patient, clinical relationship, home and family, technologies, staff, health care organization, and wider system [11]. These frameworks offer a comprehensive method for planning and evaluating implementation. However, the mechanisms that drive or limit the implementation process are not the focus of these frameworks.

Nonetheless, studies on how VCs have expanded during the pandemic has discussed these mechanisms, positing that the reasons for successful expansion include the national-level groundwork conducted before the pandemic, a strong strategic vision, a well-resourced quality improvement model, dependable technology, and multiple opportunities for staff to try the video option [8]. However, these results are only from the pandemic period. As this is a special situation and does not reflect normal conditions, it does not shed light on the future of VC when the pandemic no longer limits citizens' movements. A prepandemic study by Greenhalgh et al [12] investigated the real-world implementation of VCs and concluded that (1) although clinicians consider VC to be safe, effective, and convenient for some patients in certain situations, those situations are rare compared with the overall number of outpatient consultations and (2) it is challenging to embed VC into the routine practice of consultation when clinicians are hesitant to change.

A recent literature review indicated that empirical studies focusing on VC implementation did not identify the distinct processes essential for achieving large-scale adoption of VC [13]. We argue that how clinicians choose different modes of consultation is an essential process in the long-term adoption of VC. Clinicians are empowered with expert knowledge that is inaccessible to people outside the clinical profession; thus, clinicians decide both the definition of the goals (eg, what is quality of care) and the means to reach the goals (eg, how the quality of care can be attained) [14]. On the one hand, clinicians have codified knowledge and standard practices based on scientific evidence. However, on the other hand, they have shared values and norms that are seemingly flexible, yet uniformly shared and strongly held [15]. Therefore, clinicians play a crucial role in the implementation of any technology in hospitals, and their role may even be more significant for VC adoption because, mostly, a consultation is a one-to-one service between the clinician and patient. We posit that a deeper understanding of clinicians' perceptions of remote consultation is essential to deduce whether and how VC will be adopted on a large scale and sustained as a regular service. Hence, this study focused on how clinicians decide on the mode of consultation in their regular work routines. We used the performative model of routine as the theoretical framework, as explained in the following section.

Theoretical Framework: Performative Model of Routines

Studying information technology (IT) implementation from a professional's routine perspective can provide a better understanding of the long-term applications of IT [16]. The tasks within an organization are accomplished through temporal

structures known as routines [17], standard operating procedures [18], and habits [19]. “An organizational routine is not a single pattern but, rather, a set of possible patterns—enabled and constrained by a variety of organizational, social, physical and cognitive structures—from which organizational members enact particular performances” [20]. Routines work as both stabilizing force and apparatus to evolve with changing environmental demands in an organization [16]. We used the performative model of routine [21] to identify how the implementation of VC impacts the routine of consultation. Figure 1 shows how the equilibrium of the state of routines can change and follow a new pattern in organizations; this model has been used in different studies as a theoretical lens for studying human-technology interaction [22], along with how people make sense of the changing organizational goals [23].

According to the performative model of routine, routines are not fixed actions performed by the people in an organization; rather, they are dynamic patterns stemming from ongoing exchanges between ideals, plans, actions, and outcomes. Ideals represent normative influences including values, goals, missions, and expectations. Plans are thoughts and intentions that cause the actions. Plans and actions generate the outcome. The outcomes are then compared with the ideals to set the next

course of plans and actions. None of these 4 aspects are immune to change. Even ideals can be altered if the generated outcomes—whether intended or unintended—reveal new possibilities. The people in an organization change the routine when they see that the outcomes of the ongoing routines are either falling short of the ideals or showing the possibility of new ideals. When the outcomes fall short of the existing ideals, the actors strive to change their plans and actions to attain the ideals. When the outcomes show the possibilities of new ideals, the actors expand their plans and actions to fulfill the new ideals. We used this model to frame how clinicians make sense of the implementation and continuation of the large-scale application of VC, along with TC and PC, in hospitals.

This study aimed to thoroughly investigate how clinicians reason their choice of different consultation modes, namely, PC, TC, and VC. The performative model of routine provided us with a systematic structure to analyze clinicians’ choices regarding different consultation modes. On the basis of the findings, this paper also explained the underlying reasons for the clinicians’ choice. The following was the guiding research question: How do clinicians choose the consultation type from among PCs, VCs, and TCs?

Figure 1. Performative model of routine [21].

Methods

Overview

A qualitative approach was taken, in which the unit of analysis was the clinicians in one of the largest university hospitals in Norway, which is anonymized as the Pioneer Hospital in this paper. We purposefully chose this hospital because it provides a rich ground to investigate our research question. As the name suggests, the hospital is a pioneer in promoting and deploying cutting-edge digital tools to provide and manage health care services in the region. An active research and development center works closely with the hospital management to maintain a progressive approach regarding the use of technologies in health care, and the hospital has a substantial financial budget for the innovation and implementation of new technologies. As the Pioneer Hospital has a long tradition of innovating and

designing IT-enabled services, it can be presumed that there are fewer managerial and organizational challenges to the implementation of VC when compared with a hospital that has little or no experience with the implementation of new technology. A hospital that seemingly has few managerial and economic challenges in implementing VC can provide us with the opportunity to look beyond the financial and organizational challenges mentioned in previous studies [12] and focus on how clinicians choose between different modes of consultation. In the following sections, we have discussed the context of the study and explained the data collection and analysis process.

Research Setting

Amid resource constraints and an increasing demand for health care, the health authority in Norway has decided to implement VC as an alternative to PC in hospitals countrywide. The goals of implementing VC are to (1) reduce the cost incurred from a

patient traveling to and from the hospital for PC and (2) reduce the travel-induced stress and other activities that a patient may need to consider (eg, taking leave from work and managing childcare) [24]. Following the mandate of the health authority, the Pioneer Hospital started to prepare to implement VC and decided to use Skype for Business (Microsoft Corporation). This was a strategic decision because this software had been in use in the Pioneer Hospital previously for long-distance meetings. Therefore, the people working in the hospital, including clinicians, were familiar with the technology and video calling options. After buying adequate accessories (eg, headphones and video cameras), the hospital started to implement VC in 2019. The clinicians were not involved in planning or designing the VC implementation. They were also not forced to adopt VC. Initially, the advisers reached 3 of the department heads to ask their clinicians to conduct VC as a pilot project. The plan for the pilot project was made by the advisers and department heads, who were also clinicians and conducted consultations. The clinicians were given the freedom to decide whether and when VC is suitable. No particular goal (eg, minimum number of VCs) or time frame was given for the project. Before the introduction of VC, the hospital had two modes of consultation: PC and TC. However, TC was used as an impromptu way of contacting the patient, specifically when a quick call to the patient seemed to be more practical than waiting for weeks—or even months—for a scheduled consultation. The hospital was not paid for these TCs, and no records of the number of TCs made by the outpatient clinics were maintained.

At the beginning of 2020, the hospital asked all the departments to start conducting VCs. Similar to the pilot project, the clinicians were given the freedom to decide on the mode of consultation. However, this time, an annual goal was set for the departments, not for the individual clinician. As mentioned by both advisers and clinicians, there was no penalty or consequence for not being able to meet the goal. Currently, a plan is made to provide additional budgets to the departments that meet the goal in the future. At the beginning of VC implementation, the health authority changed the reimbursement plan for how the clinics were paid (by the government) for the consultations. According to the new plan, VC and TC were reimbursed with 75% and 67% of that received for PC, respectively. Despite the request to use VC and this change in the reimbursement plan, the clinicians were sluggish in using VCs until the COVID-19 pandemic hit the country and a nationwide lockdown was announced in March 2020. The restraint on movement stopped the patients from visiting the clinics for consultations, and the hospital was only allowed to admit patients with emergency issues. Therefore, clinicians were compelled to conduct VCs more frequently than before the lockdown. As the lockdown continued, the health authority revised the reimbursement plan again, this time, providing equal pay for all modes of consultation. This plan has remained active so far, irrespective of the changes in the strictness of the lockdown. [Textbox 1](#) provides an overview of the time line of VC implementation in the hospital since 2019.

Textbox 1. Implementation of video consultation (VC) at the Pioneer Hospital (2019-2021).

2019

- Identified VC to be a solution (1) for reducing the cost of public health care service by reducing the need for patients to travel to hospital for consultations and (2) by reducing travel-induced stress and other activities for patients.
- Planned and arranged the necessary software and hardware for VC.
- Conducted pilot projects for VC.

2020 (before the pandemic and lockdown)

- Set a goal for the number of VCs for each department after discussion with the department heads.
- Started to receive incentives for telephone consultation and VC, at rates of 67% and 75% of an in-person consultation, respectively.

2020 (from the beginning of the pandemic and lockdown)

- Changed the incentive to be equal for all modes of consultation.
- Revised and scaled up the goals for VC.
- Total number of VCs increased from 200 (in 2019) to 2000.

Present (October 2021)

- Planned to give an additional budget to the departments that reach the annual target of VC by the end of the year.
- Planning to establish VC as a regular alternative to in-person consultation in standard patient pathways.
- Saved NOK 52,000,000 (US \$5,362,318) in traveling costs.

Ethics Approval

This study was approved by the Norwegian Center for Research Data (NSD; reference number 800636). The committee assessed

the application and decided that “the processing of personal data in this project will comply with data protection legislation, presupposing that it is carried out in accordance with the information given in the Notification Form and attachments,

dated 08.10.2019. Everything is in place for the processing to begin.” We also sought permission (reference number 58059) from the Regional Committee for Medical and Health Research Ethics (REK) for interviewing patients. However, the committee assessed that the project falls outside the scope of the Health Research Act (ACT 2008-06-20 number 44); thus, it could be conducted without the REK’s approval. Following the NSD guidelines, written consent was obtained for each interview, and data were anonymized and stored on the researcher’s server at the university where the project was conducted.

Data Collection and Analysis

A semistructured interview technique was used to collect data. Following the checklist provided by the consolidated criteria for reporting qualitative research [25] and the case study protocol guidelines provided by Yin [26], we developed an interview guide (Multimedia Appendix 1). The guide includes three sets of questions to be asked to the clinicians, patients, and advisers, respectively. The interview guide aimed to include all questions that could capture the complexities and dynamic character of the clinicians’ routines of consultation and VC implementation process. The questions were open ended, and the focus was to gather information on (1) the VC implementation process, (2) how the implementation of VC changes the consultation process, and (3) the perceptions of VC. To create a broad array of questions, we did not follow any particular framework at this stage, but instead, outlined the questions following different studies, including the performative model of routine [21], technology acceptance models [27,28], and structural model of technology [29]. The interview guide was submitted to the hospital authority, NSD, and REK before data collection began. The questions were approved without changes. However, we added question number 8 for the clinicians after the first interview because that interview revealed that the duration of consultation may vary and that the documentation of patient records requires substantial amount of time.

We studied VC implementation in the Pioneer Hospital since the fall of 2019 and interviewed a group of clinicians (n=16), advisers of the research and development center responsible for facilitating VC implementation (n=7), and patients (n=16). We selected these 3 groups because they have the best knowledge of implementing, conducting, and receiving VC service, which is an essential criterion for selecting the sample [30]. All the advisers involved in VC implementation in the hospital were interviewed. To recruit clinicians and patients, we sent invitation letters to them, asking them to participate. The inclusion criterion was that they had experienced at least one mode of remote consultation, that is, TC or VC, at least once in the past 6 months. The hospital’s communication channel was used to send invitation letters via email. To determine the number of clinicians and patients in the respective sample group, we relied on data saturation—the point of time when information from the informants becomes repetitive and no further information can be gained from further data collection [30]. Therefore, to recruit enough informants, the invitation letter was sent twice to clinicians and thrice to patients, leaving an interval of 2 months in between. The interviews were a mix of face-to-face and video calls, following the pandemic guidelines in the region.

The face-to-face interviews were audio-recorded, and video calls were video-recorded. Documents and nonparticipatory observation methods [31] were used to gather contextual information. A wide range of reports on the digitalization of the hospital, published between August 2019 and August 2021, was scrutinized. These reports can be divided into two categories: (1) public reports published by the government and (2) internal reports published by the hospital. The first group of reports provides the macrocontext of VC implementation, presenting how the government is planning and strategizing different digital health services, including VC [24,32,33]. The second group of reports provides the ongoing status of VC implementation in the hospital, including the numbers of PC, VC, and TC, along with the future goals for these consultation modes. To maintain confidentiality, these reports are not cited. Furthermore, the first author (AE) participated and took notes in a workshop in which clinicians shared presentations of their experience of using VC with the top management. Subsequently, the author gained access to those presentations.

In this study, the primary data source was interviews with clinicians, whereas the other interviews, documents, and observation notes were used for contextual understanding and data triangulation [34]. Data triangulation was performed to enhance the quality of the data used and strengthen the findings of the study [26]. We interviewed the clinicians twice: once in the middle of the pandemic (2020) and once when the pandemic-induced restrictions were lifted in Norway (2021). Of the 16 clinicians, 3 (19%) clinicians could not participate in the second round of interviews for different reasons, resulting in a total of 29 interviews. The first round of interviews lasted between 60 and 75 minutes, and the second round lasted approximately 45 minutes. All the interviews were recorded and transcribed. We contacted 19% (3/16) of the clinician-informants via email after the transcribing process to obtain some clarification on certain issues mentioned in the interview.

To keep data analysis transparent and easy to understand, we followed the criteria from the consolidated criteria for reporting qualitative research framework, which suggests reporting on the number and roles of data analysts and the derivation of themes and performing participant checking [25]. Initially, all the recordings of the interviews were transcribed verbatim by the first author (AE) to minimize interviewer bias. The interview transcripts were then read several times to gain familiarity with the content, and a comprehensive narration of the case was written and shared with the other 2 authors (HCD and LdB). A narrative strategy is often used in qualitative studies to organize data and increase contextual understanding [35]. The remaining data analysis can be divided into two parts: (1) mapping the VC implementation process and (2) mapping the clinicians’ routines for conducting consultation services. To map the VC implementation process, we used a visual mapping strategy that is beneficial to arrange data from different sources sequentially and against the time line [35]. Therefore, we plotted the events that occurred regarding the implementation of VC. We plotted these events as narrated by our informants and as described in public and internal documents. We used pen and paper to map

the process. [Textbox 1](#) presents a schematic version of the implementation process.

For the second part of data analysis, we used the deductive content analysis method, which “...aims to test existing categories, concepts, models, theories, or hypotheses...in a new context” [36]. The performative model of routine was applied as the theoretical framework to guide our analysis. The four aspects of the model (ie, ideals, plans, actions, and outcomes) were used to color-code the quotes in the clinician’s interview, and then, those quotes were grouped under these 4 aspects in an Excel spreadsheet. This process was conducted separately for the first and second rounds of the interviews to assess whether their perceptions and routine have changed over time. During this process, the coauthors investigated different quotes obtained from the clinicians and discussed their meaning to ensure that the researchers’ personal biases were minimized. Moreover, no change in routine or perception was identified between the two rounds of interview. The notes made from the documents and experience-sharing webinar were then cross-matched with the data content in the Excel sheet. Finally, the narrations of advisers and patients were thoroughly read and compared with the clinicians’ data content to identify discrepancies among the clinicians, advisers, and patients. For

example, we asked both clinicians and patients how they decided on the mode of their next consultation. Therefore, we compared the answers provided by patients with those provided by clinicians to identify any discrepancies. Similarly, we compared the advisers’ responses to whether a guideline is provided to the clinicians on when to use which mode of consultation with the response of clinicians. Subsequently, our analysis was presented to the study participants in two meetings at the hospital and two digital meetings with the advisers and clinicians, to ensure that the researchers were not misinterpreting the data or misusing the quotes. The feedback received from these meetings was considered for further refinement by changing a few words in the findings, so that they were easier to understand.

Results

Overview

In this section, using the performative model of routine, we identified how the clinicians chose different modes of consultation. First, we have provided a list of ideals, plans, actions, and outcomes ([Textbox 2](#)), and then, we have explained and analyzed them with exemplar quotes.

Textbox 2. List of ideals, plans, actions, and outcomes in the routine of consultation, as described by the clinicians.

<p>Ideals</p> <ul style="list-style-type: none"> • Right diagnosis. • Right course of action for treatment (ie, laboratory test and medicine). • Good communication and conversation with the patient. • Making patients feel safe and comfortable about the diagnosis and the treatment. • Reducing patients' stress or need to adjust the daily schedule for traveling to the hospital. <p>Plan</p> <ul style="list-style-type: none"> • Whether physical examination is needed in the next consultation. • Whether telephone consultation (TC) is more efficient than video consultation (VC) for this consultation because it has low need for technical ability and the consultation room does not need to be equipped with microphone, speaker, and camera. • Whether VC is more efficient because the patient can be seen to an extent. • Where the patient lives. • Whether the patient will be able to use the technology for VC and understand and respond to the instructions over a video call. • Whether making a telephone call instead of a video call can add any benefit for the clinician, for example, by taking the call from home or after clinic hours. <p>Action</p> <ul style="list-style-type: none"> • Checking the patient's history and referral immediately before inviting the patient into the consultation room or a day before, depending on the time available to the clinician and complexity of the case. • Bringing the patient into the room (for in-person consultation [PC]), calling the patient using a telephone (for TC), or logging in for the VC and admitting the patient from the web-based waiting room to the web-based consultation room. • Troubleshooting technical issues both at the clinician's and patient's end. If the technical issue (most often at least one party cannot see or hear the other) persists, either calling the patient by phone immediately or rescheduling the consultation (for VC). • Opening up the conversation and conducting clinical triage. • Conducting a physical examination (only for PC). • Taking notes on paper or computer. • Prescribing medication and ordering tests. • Discussing the time of the next consultation (this step is irregular). • Filling the reimbursement form and giving it to the patient (for PC) or the health administrator at the end of the day (for VC and TC). • Filling the details of the consultation in the patient's electronic health record. • Submitting the completed form to the system. <p>Outcome</p> <ul style="list-style-type: none"> • Patients are diagnosed correctly and appropriate treatment is started. • Laboratory tests are ordered to further investigate the patient's health status. • The laboratory report is discussed with the patient, and suitable treatment is started. • The effects of treatment are checked, and the course of future treatment is set.
--

Clinicians' Choice of Consultation Type: PC, VC, and TC

Ideals and Outcomes

Outcomes and ideals are closely related because ideals are the desired outcomes. Therefore, we have discussed these 2 aspects together. In the Pioneer Hospital, the clinicians did not feel the need for a change in consultation routine before VC was introduced. Therefore, VC was an agenda placed on clinicians from an external source (ie, the government), rather than a

change initiative taken up internally by the clinicians. Among the five groups of ideals presented in [Textbox 2](#), a new ideal is emerging because of the implementation of remote consultations. Previously, it was taken for granted that a patient must visit the clinician in person for consultations. However, with opportunities for remote consultation burgeoning, clinicians are becoming aware that making the consultation easily accessible to patients should also be a desired outcome. However, two different patterns in clinicians' opinions of how VC implementation is affecting the ideals have been identified:

(1) endangering the existing ideals of consultation and (2) creating new ideals. Regarding the first pattern, we identified that the aspects can be divided into two parts: clinical aspects, for example, assessing the symptoms and identifying the diagnoses, and interpersonal aspects, which are more subjective and include human interaction, communication, and the importance of small talk. Clinicians have shown certain reservations about VC, as it can reduce the ideal or expected quality of care if conducted regularly in place of PCs. This is illustrated by the following quote:

The fact that the video calls are brief and to the point may sound very positive, there is a negative aspect to that as well. We are actually, very dependent on knowing on who this person is, what kind of patient do we have in front of us, what is their societal context, who do they live with and what do they work with, how is their lifestyles and how would they present their symptoms, and how any disorder they might have that influences the daily life—so a lot of things around those we need to understand. So, if we have to depend on solely on screen for this kind of knowledge that would be limited and that's a type of quality loss. And that can be harmful in the long run. [clinician 9, during the first round of interviews]

Regarding the interpersonal aspects of the consultation, the clinicians had diverse opinions. Some thought that VC can significantly reduce the quality of these aspects, thus affecting the quality of care:

I actually see a great value in that small talk part, and I feel it is important as a doctor to connect with your patient and it increases their will to use the medication that you prescribe, and it enhances the doctor-patient relation. That's very important for the patient to trust the doctor and I think that part of consults disappears a bit when we are doing it over the phone or video. I think that's why a lot of my patients have said that they look forward to coming here. [clinician 11, during the first round of interviews]

Others agreed that these aspects are important for the treatment, at least to an extent, but felt that VC does not reduce the quality of these aspects:

I would say, they [small talk] contribute, they are kind of an ice breaker, but everybody there really understands why we are here. They are not really here to chat with me, they are there for the treatment. With VC, I manage to have that much chit chat. [clinician 4, during the second round of interviews]

Although these opinions are primarily about whether and how VC can endanger the overall quality of care in the consultation service, another stream of thought focuses on whether and how VC can improve the quality of care. Some clinicians emphasized how VC makes the consultation service easily accessible to patients and their family members by reducing the need to travel to the hospital, thereby minimizing travel-induced stress and tiredness, as illustrated by the following explanation by a clinician:

We do not want the children to miss their school and parents to miss their job a lot. Because then disease becomes a big part of their daily life. So, making the treatment as less intrusive as possible is our goal, which can be attained using video consultation under specific circumstance[s]. [clinician 1, during the first round of interviews]

Thus, VC opens up the possibility for clinicians to minimize patients' travel-related challenges, which results in the emergence of a new ideal in the consultation service. These two patterns of ideals—potentially harming the care quality and potentially improving the care quality—create opposing effects on clinicians' decisions about VC. Those who perceive that the potential loss of care quality outweighs the reduction of travel-induced predicaments are more likely to prefer PC over VC when other aspects, which will be discussed later, remain the same. Similarly, those who perceive that the reduction of travel-induced predicaments outweighs the potential loss in care quality will prefer VC over PC. However, the clinicians did not identify any changes in the outcome of the consultation, positing that it was very early to detect whether VC will change the outcome of the consultation:

It will take time to see how really VC affects the consultation in the long run. [clinician 2, during the second round of interviews]

The other aspects can be grouped as managerial ones that include dimensions such as waiting time and facility use. Some clinicians thought that the durations of TC and VC are shorter than that of PC. Thus, according to them, using VC and TC, where appropriate, can reduce a patient's waiting time:

Think about it. A person enters your room, hangs the overcoat, and settles down on the chair. By that time, she is quite relaxed and up for more like a conversation. So, we open up the conversation with how is the weather, how was the travel to the hospital, and then, we start talking about treatment, health, and so on. We don't do that on video or telephone consultation. So, they [TC and VC] take a shorter time. [clinician 16, during the first round of interviews]

In contrast, some clinicians thought that the duration of the consultation is not dependent on the mode of consultation (ie, the duration does not vary depending on whether it is PC, VC, or TC):

Usually, I plan video consultation for 30 minutes, physical for 30 to 60 minutes. But you know, on a given day, telephone consultation can also take 60 minutes. So you cannot generalize. Sometimes, video consultation can take even longer [than physical]. Either the patient or I can have a technical problem, so it takes more time to connect with the patient and keep the talk going. [clinician 12, during the first round of interviews]

Finally, the clinicians thought that VC can affect facility use in the hospital. The consultations conducted over the telephone and video do not need a traditional consultation room equipped for physical examination; thus, they can be conducted in either

the clinicians' private office or smaller rooms that are equipped for telephone and video calls without beds and other clinical apparatus:

In our outpatient clinic, we are at the border of the capacity, so if we are to continue to expand the way we have in the last 10 years with 5–7% the number of patients, it would not work. We have to do something. So to us, the prospect of increasing our activity with telephone and video is a necessity. [clinician 1, during the second round of interviews]

However, this outcome cannot be realized until the number of VC and TC reaches a certain level:

But we need a certain volume in order to change the use of a room or to relieve ourselves from hiring rooms from the internal system for that. So, we have not saved anything as of today, it must be in the future. [clinician 15, during the first round of interviews]

To summarize, the clinicians shared diverse thoughts on how VC and TC can affect the ideals and outcomes of the consultation. These opinions can be grouped into clinical, interpersonal, and managerial aspects. Depending on a clinician's perceptions of (1) how different modes of consultation affect each of these aspects and (2) how these aspects affect the overall quality of consultation service, the clinician will make plans for the consultations. In the following section, we have elaborated on how clinicians plan and conduct different consultations.

Plans and Actions

Textbox 2 lists 6 different planning criteria that clinicians use to choose the consultation mode. However, not all clinicians consider all these criteria, and their opinions about these criteria are varied. Some clinicians considered patients' living location as a criterion for choosing VC or TC, whereas others thought this can result in discrimination because patients living closer to the hospital would receive more PC than those living farther away. In this section, we analyzed how the clinicians reasoned for their planning criteria. Here, it is noteworthy that even amid the restrictions of the pandemic, the number of TC was much higher than that of VC, and it continues to be so. Clinicians who were used to TC before VC was introduced often thought that if a physical examination is not required in a consultation, the flexibility and ease that TC offers outweighs the benefit of seeing the patient's face, as can be seen from the following quote:

We feel that the telephone is sufficient; it works well. Everyone has a telephone, it is easy, everyone knows how to use it, and to start this video consultation, you need to collect email addresses from the patients beforehand, make a call appointment, you have to log on to the tech [the video platform], the patient has to log on to the tech—all that seems like new obstacles without gaining any clinical advantage for them. [clinician 7, during the first round of interviews]

In contrast, some clinicians emphasized the importance of seeing patients, thus considering VC to be superior to TC:

To be honest it is very interesting to see patients in their own home, the background. Sometimes I feel like to go to their home and see how they live, if it is tidy or they living in the mess. This is very valuable for the doctors. When you see the patients on video or they come to you, you see a lot of that life that is missed in audio. Most importantly you need to see the face of the patients, this is very important. All that you miss in a telephone consultation. [clinician 5, during the second round of interviews]

We identified some changes in the steps of consultation activities (**Textbox 2**) when a clinician conducts VC or TC instead of PC. The changes in actions were limited to making a video or telephone call instead of taking the patient into the consultation room, communicating with the patient through a device (ie, computer or telephone instead of direct communication), and occasional troubleshooting of technical issues. Although these activities are new to the routine of consultation, they are not unfamiliar to clinicians or something that clinicians need to learn or be trained for. The software used by clinicians to make video calls has been in use at the Pioneer Hospital for long-distance videoconferences for some time. This makes VC easier for clinicians. However, the clinicians sometimes faced technical difficulties in making video calls. An easy work-around for such instances was switching to telephone calls, and the clinicians did not report troubleshooting the issues after the consultation:

As long as I have made the consultation, talked to the patient, I do not go back on thinking why Skype did not work this time. [clinician 4, during the first round of interviews]

Besides these changes in some of the steps of consultation activities, we did not identify any changes in terms of the role that clinicians have in the consultation. **Textbox 3** provides an overview of how the clinicians navigated through these 4 aspects of the consultation routine in PC, VC, and TC.

Textbox 3. A summary of the routine of consultation incorporating in-person consultation (PC), video consultation (VC), and telephone consultation (TC).

Ideals

- The ideals that clinicians held for consultation can be divided into three aspects: clinical, interpersonal, and managerial, and all the three aspects affect the quality of care.
 - Clinical aspects include diagnoses and treatments.
 - Interpersonal aspects include human interaction, communication, trust, safety, and comfort.
 - Managerial aspects include waiting time and facility use.
- Introduction of VC prompts clinicians to consider (1) a new ideal of improving a patient's accessibility to the consultation service by reducing travel-induced stresses and time spent for the consultation and (2) whether VC can potentially reduce the quality of human interaction and communication and weaken the patient's experience regarding safety and level of comfort in consultation.

Plans

- Clinicians had mixed opinions on the potential merits and demerits of VC and its position between the two other modes of consultation (ie, TC and PC) that existed before the introduction of VC.
- Totally, 6 different planning criteria have been identified in [Textbox 2](#), and the individual clinicians used a different combination of these criteria when choosing a mode of consultation.

Actions

- According to the clinicians, conducting VC does not require rigorous training and does not add to or omit any existing role. The minor changes in the actions in a consultation do not seem to play a significant role in clinicians' choice of consultation mode.

Outcomes

- The clinicians could not identify any changes in the outcome of consultation because of the introduction of VC. Cost reduction was an evident outcome of remote consultation in hospitals. Although clinicians were aware of the importance of cost efficiency to run the hospital, they did not consider this as a desired outcome of consultation service.

Discussion

Principal Findings

This study found that clinicians' choice of consultation mode depends on clinical, interpersonal, and managerial aspects and the changes identified in their daily consultation-related tasks are simple to manage. However, when they were faced with technical difficulties in conducting VC, they preferred to switch to TC instead of spending time in fixing the technical issue. Although the health authority and hospital management have emphasized the cost efficiency of VCs, the clinicians did not consider it to be a deciding factor for consultation mode. Before the introduction of VC in the hospital, the clinicians did not find it necessary to change the ongoing consultation service that included only PC and TC, and they could not identify any change in the outcome of the service after the introduction of VC. We identified that the clinicians neither rejected VC nor embraced it, but rather accepted it with caution and a reluctant attitude. They reasoned their attitude toward VC in various ways that were not entirely consistent. The way the clinicians reasoned their use of different modes of consultation appears to be paradoxical. On the one hand, while choosing PC over VC, they posited that VC could harm the quality of care in the long run. They argued that not being able to meet the patient in person could mean that the communication and interaction between the patient and clinicians become less rich and informative. In contrast, they justified using TC over VC, positing that telephones are easier and more flexible to use, which implies

that they did not value the ability to see the person on screen in VC. It seems that the clinicians were caught between the importance of seeing and meeting the patients during the consultation and the ease and flexibility of using a particular mode. Consequently, the clinicians have developed their personal favorites and preferences, which they justified using different reasonings.

Explanation of Choices Made by Clinicians

In this section, we provide a plausible explanation for the clinicians' diverse and inconsistent choices regarding consultation modes. When compared with health care technology, such as a minimally invasive cardiac surgery technique [37], the technology for VC requires only simple changes in clinicians' routines. Studies have shown that technology that causes disruptive changes in routine actions or limits professional autonomy is harder to implement and often ends up being abandoned or used in a limited manner, as opposed to finding large-scale application [10,37,38]. In the case of adopting VC, the clinicians did not feel that their roles or professional autonomy had been altered in any way, and they did not feel the need for formal learning or training to conduct VC. Therefore, VC was not dismissed by clinicians because of disruptive change in routines. Although VC implementation does not provide any strong reason to dismiss it, it does not provide any explicit benefit for the clinicians to adopt it immediately. We cannot ignore the growing number of randomized controlled trial studies that show how VC impacts diagnosis-specific clinical efficacy and safety [39,40]. However,

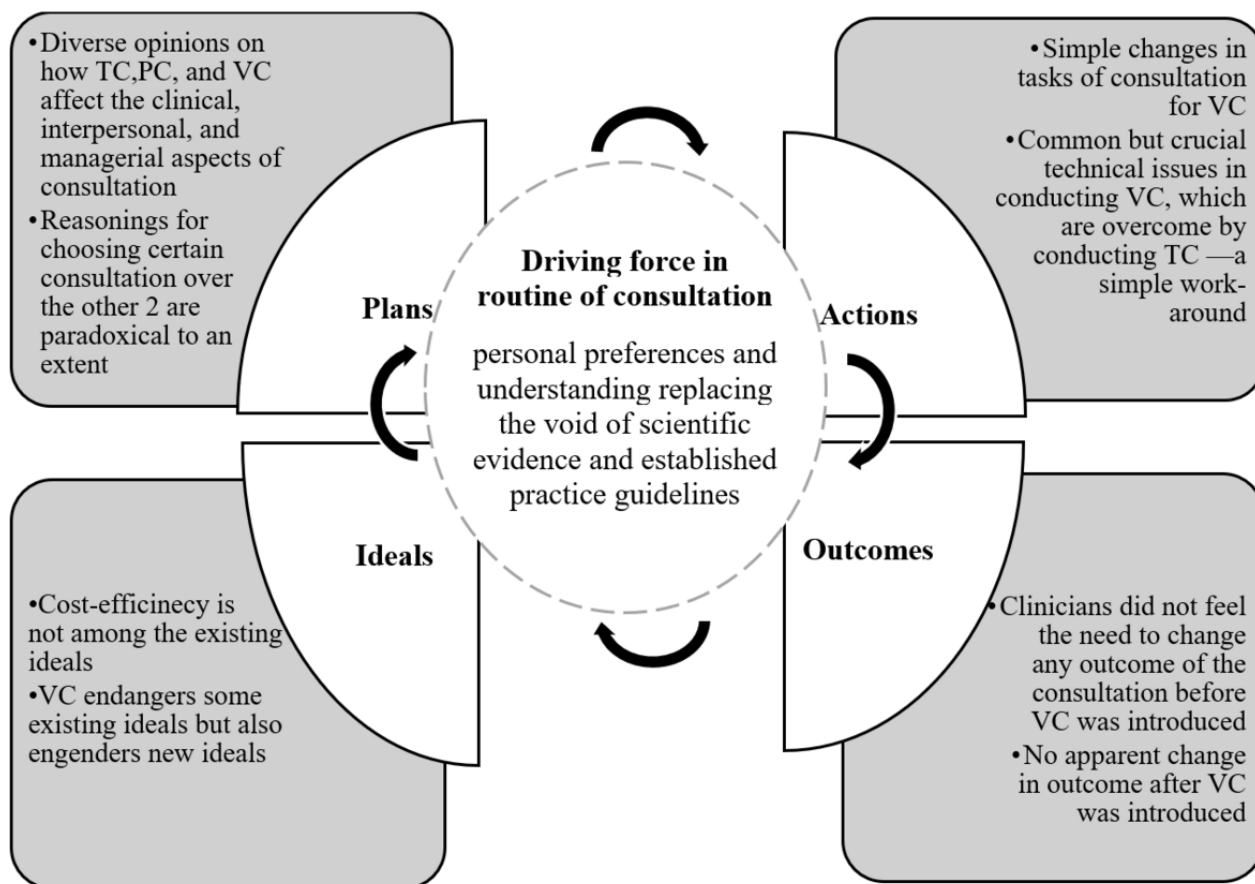

there is an increasing discrepancy between experimental trials and the experience of remote consultation as a regular service [12,41,42]. The clinicians in our study wondered about the long-term effects of VC on the quality of care. Moreover, we identified that it is not only how VC impacts the clinical aspect that needs to be considered but also how it impacts the interpersonal and managerial aspects. Scientific evidence on the long-term effect of VC on all the three aspects is inadequate according to clinicians in our study, and this is consistent with previous studies [41,42].

Another important issue to consider is that the objective of VC implementation in the hospital was primarily economic, a factor that the clinicians did not feel strongly or care about in terms of treating patients. Other interventions, such as computed tomography scanners [43] or minimally invasive surgery techniques [37], have demonstrated clear improvements in the level of clinical care from the beginning of their implementation. Previous studies have shown that when medical professionals realize that an intervention can improve their clinical practices, they are less dismissive of the changes and eager to incorporate the new practice while trying to minimize the changes in their routine [15]. VC does not offer any such explicit incentive to clinicians. Therefore, the clinicians have not embraced this new mode of consultation with much enthusiasm, which explains

why the clinicians were not using VC to a great extent before lockdowns were imposed in March 2020.

We posit that the absence of sufficient scientific evidence, clear understanding of the merits and demerits of VC, and standard practices and shared norms for conducting VCs have created a void in the consultation practice. This void leads clinicians to use their personal judgments and preferences to justify their choices regarding PC, VC, and TC. Thus, a wide variety of moderately paradoxical reasons can be identified from the clinicians' accounts of how they choose the mode of consultation. This void—created by lack of evidence and standard practice and shared norms—is a unique phenomenon for clinical practice. These factors are the pillars of the medical profession, and they drive the medical practitioners' decision-making [14,44]. In the absence of these pillars, each clinician uses their professional autonomy and agency to interpret the effects of VC and decide how and when to use each consultation method [45]. This explains the variety and paradoxes seen in their reasoning regarding the choice of consultation. Figure 2 shows an updated framework for the routine of consultation (ie, findings in plans, actions, outcomes, and ideals) and the driving force behind the current routine that incorporates all three modes of consultation.

Figure 2. Performative model of routine for services using in-person consultation (PC), telephone consultation (TC), and video consultation (VC).

Comparison With Previous Studies

The literature relevant to VC has been discussed previously; therefore, in this section, we compare this study with previous

studies focusing on clinicians. One of these studies [2] examined how clinicians perceive the limitations of VC and how the relationship between clinicians and patients may change when VC replaces PC. The primary finding was the set of disturbances

and limitations experienced by clinicians who have experienced VC. The study provided in-depth analysis of the disturbances and limitations of VC and revealed the consequences of the consultation if such disturbances persist. Moreover, the study also identified that the responsibility of creating a suitable ambiance for consultation is shared by both the clinician and patient in VCs, proposing that if clinicians do not consider the patient's ability to create a suitable environment, the consultation may have reduced quality. A second study conducted by the same group of researchers focused specifically on the selection criteria clinicians used to choose patients for VC [46]. Our findings confirm the selection criteria used by the clinicians in their study when choosing patients. However, our study further generates new insights by examining how clinicians navigate through a consultation service when they have three alternative modes to provide the service.

First, we examined clinicians' choices, not only regarding VC but also regarding the total service (ie, PC, TC, and VC), showing that the availability of TC along with PC adds paradoxes in clinicians' choice of consultation. By using a performative model of routine as the theoretical lens, we then identified how clinicians compare the goal of VC with their ideals and expected outcomes of consultations and, consequently, plan and conduct the consultations. Thus, in addition to the barriers and patient selection criteria, our analysis identified other criteria for choosing the consultation mode, including interpersonal and managerial ones and a clinician's personal preferences and previous experience with TC. Our analysis of an individual clinician's routine of consultation also reveals the wide variations that exists in clinicians' sense-making processes regarding the different modes of consultation and their opinions on the potential benefits and harms these modes can cause. Finally, we provide a plausible explanation for the varied and moderately paradoxical opinions of clinicians by using the literature on the medical profession and professional organizations.

Strengths and Limitations of the Study

This study contributes to the eHealth literature by generating deeper insights into clinicians' decision-making processes regarding remote and PC, which has significant effect on the sustainability of the large-scale implementation of remote consultations. Once the variety in clinicians' opinions about the different consultations can be minimized, the uncertainty of how and when to use each mode of consultation can be reduced, making it more likely that all modes of consultation will become routine (ie, the flow of actions without a less active comparison between outcomes and ideals and adjustments in plans) [47], hence, making it become sustainable. We argue that to minimize the variety in opinion, clinicians require the scientific, long-term evidence on the effect of VC and TC not only on clinical but also on interpersonal and managerial aspects of the consultation, which have not been in focus in the literature.

Moreover, our findings are useful for health care IT implementation in general. To advance IT implementation practice and research, it is essential to identify the theoretical mechanisms and contingencies of IT implementation [27]. This is not addressed by most of the current health care IT literature

[48,49]. We provide an explanation for the low number of large-scale IT adoption and sustainable implementation projects in health care organizations: when the objective of an IT implementation program is not directly aligned with the ideals that clinicians hold for a certain health care service, clinicians do not immediately welcome the implementation, even if the IT does not threaten their professional autonomy or complicate their existing routines. Instead, they seek reasons to dismiss or adopt it. In these situations, if enough evidence or uniform understanding of the benefit and harm caused by the IT is nonexistent, the professionals can rely on their individual judgment and personal preferences to decide how and to what extent they adopt the IT. Consequently, diverse opinions emerge, including some paradoxical ones, resulting in an uncertain future for sustainable large-scale implementation.

The limitation of this study is that it focuses on a single health care organization. Although the chosen organization is one of the largest and most prominent hospitals in Norway, one can question the extent to which our findings and explanations are valid for other hospitals worldwide. To minimize this limitation and enhance the usability of the study, we provided a detailed description [50] of the national and local contexts of the hospital. We aimed to provide readers with good understanding of the context and demonstrate that the findings and explanations are embedded within the context. Thus, the findings of this study can be compared and contrasted with those of future studies from similar or different contexts.

Directions for Future Studies

We posit that it is crucial to investigate and identify the efficacy of remote consultations in their entirety so that the potential benefits can be realized and exploited to the maximum and the potential harms can be minimized. Our findings emphasize the need for future studies on VC in several directions: (1) the long-term clinical effect of remote consultation (eg, VC and TC), (2) the effect on the interpersonal aspects of consultations and how these aspects affect the quality of care in consultation, and (3) the effect on managerial aspects and how remote consultation can improve the management and organization of consultation services. Studies conducted in these directions can help provide scientific evidence for a different mode of consultation and a strong base to generate, share, and help to develop the values and norms about how clinicians practice consultations using multiple modes.

Our study also reveals that besides conducting studies in these areas, a strong focus is needed on how to disseminate these findings among clinicians. If clinicians are not aware of the scientific evidence, their process of choosing the consultation mode will remain the same. On the one hand, a separate stream of research on how to disseminate scientific evidence and good practices for different consultation modes would be beneficial. In contrast, as a crucial step in implementing VC, the management of the hospital needs to consider facilitating learning, sharing of experiences (good or bad), and dissemination of research.

Conclusions

The research and practitioner communities worldwide are deeply engaged in anticipating how VC will be adopted in hospitals as a regular service and how it will change the consultation service. This study contributes to this ongoing conversation by including new insights into how, on a daily basis, clinicians make sense of the availability of the three modes of consultation (ie, PC, TC, and VC) and how they reason their choice of a mode over others. We conclude that as a digital intervention, VC does not drastically change the routine of consultation for clinicians. However, it also does not provide an immediate clinical benefit. Thus, clinicians neither dismiss the option of VC nor feel an urgency to adopt it. The study also revealed the absence of sufficient scientific evidence on the long-term merits and demerits of VC, standard practice, and shared norms regarding

when to use (and not to use) VC. Under this circumstance, clinicians tend to rely on their personal assessment and preferences to decide the mode of consultation, which leads to wide variety in clinicians' choice of consultation mode. This variety risks the quality of the consultation service and patient satisfaction because patients with similar diagnoses may receive different forms of health care, depending on the clinicians they are consulting. Therefore, this study calls for future studies on the long-term effect of VC, not only regarding clinical attributes but also interpersonal and managerial attributes. We also emphasize that the dissemination of these studies among clinicians is equally important because these results can answer the questions they ask about the long-term effect of VCs, and consequently, develop best practices and share the norms for this digital service.

Acknowledgments

The authors would like to thank all the advisers, clinicians, and patients at the Pioneer Hospital who agreed to participate in the study. The authors would also like to thank the administrators of the hospital who helped us to send the invitation letters to our informants.

Conflicts of Interest

None declared.

Abstract

Background: The successful rehabilitation of musculoskeletal pain requires more than medical input alone. Conservative treatment, including physiotherapy and exercise therapy, can be an effective way of decreasing pain associated with musculoskeletal pain. However, face-to-face appointments are currently not feasible. New mobile technologies, such as mobile health technologies in the form of an app for smartphones, can be a solution to this problem. In many cases, these apps are not backed by scientific literature. Therefore, it is important that they are reviewed and quality assessed.

Objective: The aim is to evaluate and measure the quality of apps related to shoulder pain by using the Mobile App Rating Scale.

Methods: This study included 25 free and paid apps—8 from the Apple Store and 17 from the Google Play Store. A total of 5 reviewers were involved in the evaluation process. A descriptive analysis of the Mobile App Rating Scale results provided a general overview of the quality of the apps.

Results: Overall, app quality was generally low, with an average star rating of 1.97 out of 5. The best scores were in the “Functionality” and “Aesthetics” sections, and apps were scored poorer in the “Engagement” and “Information” sections. The apps were also rated poorly in the “Subjective Quality” section.

Conclusions: In general, the apps were well built technically and were aesthetically pleasing. However, the apps failed to provide quality information to users, which resulted in a lack of engagement. Most of the apps were not backed by scientific literature (24/25, 96%), and those that contained scientific references were vastly out-of-date. Future apps would need to address these concerns while taking simple measures to ensure quality control.

KEYWORDS

mobile app; shoulder pain; mHealth; Mobile App Rating Scale; mobile phone

Introduction

Shoulder pain is one of the most common musculoskeletal complaints [1], with prevalence rates ranging from 1% to 67%

among varying populations [2]. As the shoulder helps to stabilize the upper arm for many activities, ongoing shoulder pain can have a significant negative effect on daily activities, such as getting dressed, and can potentially result in poor psychological

factors, such as anxiety around pain [3]. These altered beliefs around pain can lead to poorer treatment outcomes in the long term, increasing the risk of shoulder pain becoming chronic [4]. Surgical input (eg, decompression surgery) and the use of nonsteroidal anti-inflammatory drugs were previously seen as the gold standard of shoulder pain management [5]. However, there is evidence suggesting that the use of conservative treatments, such as exercise therapy and musculoskeletal physiotherapy, can be as effective as surgery and has fewer associated risks, such as the risk of infection [6]. These conservative interventions can include measures such as exercise therapy and physiotherapy techniques, including electrotherapy (eg, ultrasound), and manual therapies such as spinal and peripheral joint mobilizations, soft tissue release, muscle energy techniques, and taping [7]. However, obtaining sufficient levels of support via face-to-face appointments is not feasible due to a lack of time, demand constraints, and the recent COVID-19 global pandemic [8]. Therefore, the importance of prescribing exercise therapy for shoulder pain has increased to provide better outcomes for patients [9]. However, the evidence for the benefits of exercise for shoulder pain is still inconclusive [10]. To achieve the best long-term outcomes, it is important to encourage self-management, as this is an important predictor of successful rehabilitation [11].

Technology-based interventions for pain management, such as mobile health interventions, are an effective way of providing such self-management skills and education to both patients and health care providers [12,13]. This branch of health care is becoming increasingly popular due to the high availability of smartphone devices [14]. Mobile health has helped to increase the accessibility and affordability of health care for those living in rural locations or on low incomes [15]. This is especially important due to the previously mentioned COVID-19 pandemic, as many patients still require ongoing treatment despite the lack of face-to-face appointment availability [16]. Clear guidelines are given to app developers via The Developer Program Policies, alongside the Developer Distribution Agreement [17], to ensure the inclusion of appropriate content and the fair use of users' data. However, the poor enforcement of these guidelines leads to the market saturation of poor-quality apps with no scientific backing [18]. As a result, despite the availability of thousands of commercially available apps related to pain management, there is no published guidance for health care professionals on how to identify a user-friendly, evidence-based app for patients [19].

The aim of this work is to provide an overview of apps related to shoulder pain that have been reviewed by using the Mobile

App Rating Scale (MARS) [20]. The focus of this study is to provide new information on the quality of the content and aesthetics of currently available apps related to shoulder pain and to identify the most engaging and appealing aspects of these apps. Our findings will help guide the development of future bespoke and motivating rehabilitation apps.

Methods

This study included shoulder pain-related apps (free and paid apps) that are available on the official stores for Apple (App Store) and Android (Google Play Store). These are the two major app stores that are currently available, accounting for a large sample of the top grossing apps [21]. The search was carried out in English.

The disease of interest was defined by using the following generic term: *shoulder pain*. The apps that focused on shoulder pain specifically were included in this study. Those that were related to another condition or had technical issues were excluded.

A total of 5 reviewers evaluated these apps by using the MARS. These five reviewers (JMRA, DPK, CEH, CN, EM) were chosen to avoid the potential subjectivity of a single reviewer. Two of these reviewers (CN and EM) had no previous medical background. As such, they were able to provide a layperson's perspective on the information being provided in the apps. All apps were reviewed by each author during a consensus meeting to limit the introduction of heterogeneity in the decision-making process. This also allowed each app to be reviewed 5 times before a final decision was reached. The web-based platform Microsoft Forms was used to help complete the MARS. The MARS consists of 23 items, and each item is grouped into different sections related to apps—"Engagement," "Functionality," "Aesthetics," "Information Quality," and "Subjective Quality." The MARS also contains an initial section for collecting general information on apps. There are 6 final items that can be adapted to specifically include information related to the topic of interest. Each item is scored from 1 (inadequate) to 5 (excellent). A final "Subjective Quality" section allows reviewers to give their personal opinions and recommendations for each app. This is used to give a measurement of overall app quality [22].

A descriptive analysis of the MARS scores was performed to provide an overview of the general quality of the available apps. Information for comparing the quality of content in free apps to that in paid apps was provided in the MARS. The layout of the MARS can be seen in [Textbox 1](#).

Textbox 1. Mobile App Rating Scale structure.**Sections and definitions**

- Section A: *Engagement*
 - App is fun, interesting, customizable, and interactive and is targeted to audience
- Section B: *Functionality*
 - App functioning, app is easy to learn, navigation, flow logic, and gestural design
- Section C: *Aesthetics*
 - Graphic design, visual appeal, color scheme, and style consistency
- Section D: *Information*
 - Contains high-quality information from a credible source
- Section E: *App subjective quality*
 - Personal interest in the app
- Section F: *App specific*
 - Perceived impact of the app on the knowledge, attitudes, and intentions to change of the users, as well as the likelihood of actual change in the target health behavior

Results

Overview of Apps

Initially, 27 apps were chosen to be included in the final analysis. In the time between the initial search and the evaluation of the apps via the MARS, 2 apps were no longer available for access on the Google Play Store and were excluded from the final analysis. A total of 25 apps were included in the final analysis (8 from the App Store and 17 from the Google Play Store).

An overview of the main characteristics of each app included in this study is shown in [Table 1](#). A star rating scale ranging

from 1 to 5 was used, and the consensus among the reviewers resulted in an average star rating of 1.97, with no preferences for paid or free apps. The affiliations of most of the apps were commercial (22/25, 88%), except for one that was endorsed by a legitimate health care professional (Frozen Shoulder Protocols by Dr. Isaac's Holistic Wellness). The apps mainly focused on physical exercises, with some providing further information related to shoulder pain conditions. Overall, there was no difference in app quality between the App Store and Google Play Store, suggesting that there were no preferences for one platform among the app developers. The results of the MARS can be seen in the following descriptive analysis sections.

Table 1. Mobile app characteristics.

App name	Platform	Developer	Price ^a
Clinical Pattern Recognition: Shoulder Pain	Android	PhysioU	£16.99
Frozen Shoulder Exercises	Android	abayapps	£0
Frozen Shoulder Exercises	Android	FeedTheGraph	£0
Frozen Shoulder Protocols	Android	Dr.Isaac's Holistic Wellness	£0
Healure: Physiotherapy Exercise Plans	Android	Healure Technology	£0
Home Remedies for Shoulder Pain	Android	Ocean Digital Store	£0
Home Remedies for Shoulder Pain	Android	mikeg3590	£0
Neck & Shoulder Pain relief exercises, stretches	Android	OHealthApps Studio	£0

Engagement

Overall, the reviewers concluded that most apps lacked a lot of engaging features (21/25, 83%; [Figure 1](#), [Multimedia Appendices 1-4](#)). In terms of the apps being fun to use, 22% (14/65) of apps were dull to use and not fun at all. Further, 34% (22/65) of the apps were boring and only slightly better, while 29% (19/65) were rated as being okay at best. With regard to the interest in the apps' information presentation, 26% (17/65) of the apps were rated as not at all interesting, and 32% (21/65) were rated as mostly uninteresting. Additionally, 26% (17/65) were rated as okay.

With regard to the customization of the apps, a large majority of the apps (40/65, 62%) had no customization features; 15% (10/65) had very little features; and 17% (11/65) had very basic

features, including a basic option for setting a list of exercises without a reminder option. Closely related to this is that 58% (38/65) of the apps were reported as having no interactivity features; 25% (16/65) had very few interactivity features; and 14% (9/65) had basic interactivity features, such as a calendar feature.

The final aspect of determining if an app was engaging was its appropriateness for its target audience. The majority of apps (34/65, 52%) were deemed to be acceptable but were not specific enough that they may be difficult for a layperson to engage with, and 22% (14/65) were reported as being acceptable enough that someone may be able to continue using the app without assistance. Further, 6% (4/65) were rated as not being appropriate at all, and 9% (6/65) were deemed to be perfectly suited to its intended audience.

Figure 1. App entertainment.

Functionality

The reviewers rated the same apps much higher in this section, as they were generally well built and easy to use (Figure 2, Multimedia Appendices 5-7). Overall, the performance of the apps was rated very highly, with 29% (19/65) of the apps having perfect performance and 43% (28/65) being rated as very good,

with only minor issues such as slow loading speeds. Most of the apps were rated as being very easy to use with minimal guidance (27/65, 42%). Additionally, 26% (17/65) of the apps were rated perfectly in this section, as they could be used immediately with no effort, while 25% (16/65) required some time and effort.

Figure 2. App performance.

Closely linked with an app’s ease of use is the navigation through each section of an app; 54% (35/65) of the apps were rated as easy to understand, with 17% (11/65) being perfect in terms of navigation, and 22% (14/65) were rated as good, only requiring minimal time to understand. The gestural design of the apps, such as the ability to zoom into pictures via pinching, was another functional aspect that most of the apps contained, with 23% (15/65) being rated as perfect. The majority (30/65, 46%) were mostly good, and 29% (19/65) were just okay, generally lacking the ability to zoom via pinching.

Aesthetics

The general aesthetics of the apps were rated as average (Figure 3, Multimedia Appendices 8 and 9). The layouts of the apps, such as the arrangement of the buttons and content on the screen, were rated as either satisfactory (22/65, 34%) or mostly clear (14/65, 22%). However, a large proportion (17/65, 26%) of the apps were rated as having a bad and unclear design that was difficult to navigate and understand. The quality of the graphics in the apps, which included pictures and videos, was mostly rated as moderate (26/65, 40%). The graphics in 20% (13/65) of the apps were high quality, and those in another 20% (13/65)

were low quality, with pictures being either too small or too big to fit the screen correctly. The overall visual appeal was rated as average (26/65, 40%), with 25% (16/65) of the apps being very pleasant to look at and having an appropriate color scheme.

However, 17% (11/65) were rated as ugly, and 15% (10/65) were rated as bad, having very poor designs such as oversized buttons and a loud, inappropriate color scheme.

Figure 3. App layout.

Information

The quality of the information provided by most of the apps (24/65, 37%) was rated as moderately relevant with potential for more concise information (Figure 4, Multimedia Appendices 10-12). Moreover, 25% (16/65) were rated as poor and inappropriate, with 9% (6/65) reported as having no available information. Among the apps that did provide information, the quantity was generally insufficient (21/65, 32%) or minimal

(15/65, 23%). Additionally, 23% (15/65) of the apps provided a basic quantity of information, which was not comprehensive, and 6% (4/65) of the apps provided comprehensive and concise information. Further, 49% (32/65) of the apps provided a mostly clear and logical visual representation of information in the form pictures or videos, with 8% (5/65) providing perfectly clear graphs and pictures; 22% (14/65) provided visual information that was often unclear and not always logical; and 5% (3/65) provided no visual information at all.

Figure 4. Quality of information.

Overall, the credibility of the sources of the information provided was rated as low, with the information in 29% (19/65) of the apps lacking any credibility at all, and the information in 6% (4/65) was believed to be from a suspicious source, as defined by the MARS scale. For 38% (25/65) of the apps, the legitimacy of their sources were questioned, but the apps were not believed to be suspicious, and 12% (8/65) provided no information regarding the credibility of their sources.

Subjective Quality

This section provided information on the reviewers’ personal opinions on the apps being rated (Figure 5, Multimedia Appendices 13 and 14). When asked if they would recommend an app to someone who might benefit from it, the majority (36/65, 55%) responded with “not at all.” Additionally, 25% (16/65) of the apps would be recommended to very few people,

and only 8% (5/65) of the apps would be definitely recommended.

This trend continued when the reviewers were asked how many times they would use the apps in the next 12 months if the apps were relevant to them; 66% (43/65) of responses were “none,”

9% (6/65) were “1-2” and “3-10,” and only 2% (1/65) were “more than 50 times.”

When the reviewers were asked if they would pay for an app, 89% (58/65) responded with “no,” with only 11% (7/65) responding “yes.”

Figure 5. App recommendation.

Discussion

Principal Findings

This study presents a search and evaluation of smartphone apps related to shoulder pain that are available on the App Store and Google Play Store. An important point to note is that the mobile app market is very volatile and is constantly changing [23]. As this change is unpredictable, it is highly likely that the situation of the market at the time of the publication of this study will not be the same as the one presented herein. Throughout the duration of this study, changes in the market were detected. Principally, 2 apps were removed from this study, as they were no longer available on the Google Play Store and were unable to be evaluated by using the MARS. Despite this, the results presented in this study are the most accurate with regard to shoulder pain apps that were available at the time of writing and were evaluated using a validated assessment tool, such as the MARS.

Overall, the quality of the apps evaluated in this study was regarded as generally low, with the apps scoring an average star rating of 1.97 out of 5. The worst scores were related to what was offered to the users (“Engagement” and “Information” sections), and the best scores were related to the overall usability of the apps (“Functionality” and “Aesthetics” sections). This suggests that the apps are generally well built, with a few exceptions, but fail to interest the users. This statement is further reinforced with the apps’ subjective quality; over half of the reviewers would not recommend the apps (36/65, 55%) or use them again within the next 12 months (43/65, 66%). An overwhelming majority would also not pay for the apps (58/65, 89%), with some of the paid apps providing less information than their free counterparts and, in some instances, providing dangerous advice, such as recommending overhead exercises as the first stage of the rehabilitation of shoulder instability to

a layperson with no previous medical knowledge, thereby putting them at risk of dislocation [24]. Within another paid app, links to videos caused the app to crash. In general, it was agreed among the reviewers that none of the apps would help to increase their knowledge or awareness of shoulder pain conditions or change their intentions to seek help and begin a rehabilitation program. Some of the apps contained too much information for the average user, and guidance would be advised before continuing their use. These apps also contained out-of-date references for their information, with some references being 30 years old.

The positive aspects of the apps that were outlined in the MARS included useful, working links to YouTube videos that provided further information on an appropriate exercise program for shoulder pain. Related to this is that some apps contained built-in video clips demonstrating the exercises being performed and provided a short written information section to allow the users to easily understand the exercises that they were being asked to perform. The general consensus was that a simple layout—one with clearly labeled buttons on the screen providing easier navigation throughout the app—was better. The most functional apps provided the option to sync the users’ exercises to their calendar, thereby providing a daily reminder notification to improve their adherence to an exercise program. The ability to increase the difficulty of the exercises was another useful functionality that was available in some of the apps to keep the users engaged for longer periods. The best apps generally had a larger range of exercises available, including body weight and weighted exercises for strength and stretching exercises.

Limitations

This study has the usual limitations of these types of studies due to the nature of the products being studied (namely mobile apps). There is the possibility that some apps may have been missed that did not contain *shoulder pain* in their titles. Another

limitation is the exclusion of the growing number of other mobile app stores outside of the main two, such as the Huawei App Store in China [25]. This in turn resulted in potentially relevant apps that are in a foreign language and are available in only specific regions being excluded from this study. The inclusion of paid apps, which may have access to additional customization options, could potentially lead to bias in favor of these apps when compared to their free counterparts. A reliance on the product summaries and subjective rating tools used in app stores leads to another risk of bias with regard to the quality of the product due to a lack of validation [26].

Conclusion

The shoulder pain-related apps that are currently available are generally well built technically but fail to offer an appropriate

quantity and quality of information to the users. Therefore, they fail to have an engaging impact. The vast majority of such apps are not based on scientific evidence, with the few exceptions being vastly outdated. They are unlikely to have been rigorously tested, putting into question the safety and confidentiality of the information being collected from users. There is also a low level of health care professional involvement in the development process, which could result in potential safety issues for users if the information provided by an app is not legitimate. Future apps that are being developed should aim to improve on these aspects while taking advantage of the constant innovation of mobile technology, such as integration with wearable devices to track activity levels and increase exercise adherence [27,28]. Simple measures, such as recognized quality assurance standards and external reviews, should also be proposed [29].

Abstract

Background: Digitalization affects almost every aspect of modern daily life, including a growing number of health care services along with telemedicine applications. Fifth-generation (5G) mobile communication technology has the potential to meet the requirements for this digitalized future with high bandwidths (10 GB/s), low latency (<1 ms), and high quality of service, enabling wireless real-time data transmission in telemedical emergency health care applications.

Objective: The aim of this study is the development and clinical evaluation of a 5G usability test framework enabling preclinical diagnostics with mobile ultrasound using 5G network technology.

Methods: A bidirectional audio-video data transmission between the ambulance car and hospital was established, combining both 5G-radio and -core network parts. Besides technical performance evaluations, a medical assessment of transferred ultrasound image quality and transmission latency was examined.

Results: Telemedical and clinical application properties of the ultrasound probe were rated 1 (very good) to 2 (good; on a 6-point Likert scale rated by 20 survey participants). The 5G field test revealed an average end-to-end round trip latency of 10 milliseconds. The measured average throughput for the ultrasound image traffic was 4 Mbps and for the video stream 12 Mbps. Traffic saturation revealed a lower video quality and a slower video stream. Without core slicing, the throughput for the video application was reduced to 8 Mbps. The deployment of core network slicing facilitated quality and latency recovery.

Conclusions: Bidirectional data transmission between ambulance car and remote hospital site was successfully established through the 5G network, facilitating sending/receiving data and measurements from both applications (ultrasound unit and video streaming). Core slicing was implemented for a better user experience. Clinical evaluation of the telemedical transmission and applicability of the ultrasound probe was consistently positive.

Introduction

Digitalization affects almost every aspect of modern daily life including a constantly growing number of health care services

along with telemedicine applications. Telemedicine, or telehealth in general, describes the distribution of health-related services and information via electronic information and telecommunication technologies [1]. It allows transmission of

medical data or diagnostic information from the patient or a health care provider without the need for the patient and, for example, a medical expert to be present together in the same physical location [2].

With its beginnings in the 1980s, the driving forces of telemedicine have been space travel, expeditions, and military operations. Since then, telemedicine applications have been applied to many different clinical disciplines with three levels to be distinguished: teleconsultation, telepresence, and telemanipulation (telesurgery) [3].

Teleconsultation refers to a video- or audio-based consultation in which the consulting physician represents only a passive (advising) role in the treatment management. In telepresence, the practitioner (eg, a medical expert) actively intervenes in the treatment of the patient over a spatial distance. This can be done, for example, by controlling a diagnostic or therapeutic tool that is used on site during the intervention. The third pillar of telemedicine, telemanipulation (telesurgery), is a further development of telepresence, whereby the active performance of the operation is carried out entirely via a mechatronic system (robot-guided surgery). Teleconsultation thus becomes teleoperation.

Emergency health care is a newer but applicable field for telemedicine [4]. Preclinical point-of-care (POC) information (eg, from an injured patient can be sent from the ambulance car

to a remote medical expert in a hospital in real time (and vice versa), regardless of the actual location of the patient prior to arrival [5]. This bidirectional data transmission may consist of physiological data, as well as voice, audio, and video data [6]. Thanks to the constant developments and improvements of broadband wireless communication technologies in recent years, telemedicine applications are nowadays expanding their use range from traditional desktop systems to wireless mobile solutions and thus are a part of smart health care services.

In smart health care systems, Bluetooth, ZigBee, and Wi-Fi are the most noticeable short-range wireless technologies, whereas body area networks, LTE, and WiMAX are long-range technologies used for wireless data transmission [7], enabling various Internet of Things (IoT) applications. For broad IoT adoption, fifth-generation (5G) mobile communication technologies are going to play a major role [8] with significant challenges in terms of interoperability, performance, and security needing to be considered [9].

Compared to the current mobile transmission standard 4G/LTE, 5G facilitates a 100 times higher data transmission rate (up to 10 Gbit/s), an extremely low latency (1 ms), and a 1000 times higher capacity [10]. The following types of scenarios (Figure 1) [11] for 5G networks can be classified [12]: enhanced mobile broadband (eMBB), massive machine-type communications, ultrareliable low-latency communications (URLLCs), and wireless regional area networks.

Figure 1. Specifications of 5G new radio providing a set of specifications for the 5G core network as defined in 3GPP Release 15 [11]. CT: computed tomography; MRI: magnetic resonance imaging.

As medical data is considered highly sensitive and requires high security levels, (very) low latency, stable, and ultrareliable data transmission rates, telemedicine applications are linked with strict requirements [12,13]. Since 5G networks include the eMBB and URLLC application profiles, these networks have the potential to fill the gap in mobile (smart) health care [14].

Medical diagnostic ultrasound is a widespread and (compared to other image modalities such as magnetic resonance imaging or computed tomography) inexpensive imaging modality that has become commercially available in portable and mobile configurations in recent years [15]. Thus, mobile ultrasound is the imaging modality best suited for emergency telemedicine applications. In recent years, different mobile ultrasound systems

have been developed (eg, for the paramedic care of patients with trauma), allowing the performance of required POC emergency diagnostics prior to hospital arrival [16].

Establishing a wireless connection between an ambulance car (emergency site: paramedics, inexperienced doctors) and a hospital (remote site: medical experts) enables the following medical achievements: increased patient safety due to supervised medical care, improved patient allocation or avoidance of treatment delays by patients' data analysis and diagnostics prior to arrival, and reduction of (unnecessary) hospitalization rates through preclinical identification of injury severity.

The 5G network has the potential to meet these demands; however, appropriate connectivity setups are needed that take

into account optimized bidirectional audio-video streaming according to different parameters such as acceptable image quality and resolution, bandwidth, network slicing, and latency constraints.

In this study, we demonstrate a real field test of a 5G framework enabling preclinical diagnostics with mobile ultrasound for emergency patients using 5G network slicing technology. A bidirectional audio-video data transmission between the ambulance car and the hospital was established, combining both 5G-radio and -core network parts to render an end-to-end (E2E) test (Figure 2). Besides technical performance evaluations (key performance indicators [KPIs]) of the 5G network, the medical assessment of transferred ultrasound image quality and transmission latency was examined.

Figure 2. Framework for the 5G field test. Ambulance car (left) equipped with mobile ultrasound and pan, tilt, zoom camera connected to a UE modem. The latter is connected to an RF unit, which is connected to UE antennas on the top roof of the ambulance car. Methods

Ethics Approval

This study was conducted in line with the principles of the Declaration of Helsinki. The experimental protocols of the study were approved by the ethics committee (Institutional Review Board) of the Technical University Munich (file AZ 8/16S) and met the guidelines of our responsible governmental agency [17]. All human subjects gave their written informed consent before participating in the study.

Statistics

Statistical analysis was performed using Excel 2016 XLSTAT (Microsoft Corporation). Descriptive analyses were obtained when applicable. Mann-Whitney *U* tests were calculated for nonparametric distribution. Statistical significance was determined by $P < .05$.

Prior to the performance of the 5G field test, a clinical evaluation of the mobile ultrasound probe (Clarius C3 HD [2-6 MHz], Clarius Mobile Health Corp, Vancouver, BC) was conducted.

Clinical Evaluation of Mobile Ultrasound Probe

A panel of 20 medical doctors recruited from the departments of surgery and radiology at Klinikum Rechts der Isar, TU Munich experienced in abdominal sonography took part in the clinical evaluation.

They were provided with a questionnaire compiled by the authors consisting of 17 topic-specific theses/questions assessing the ultrasound probe in relation to its application feature "telemedicine" (n=6 theses/questions), technical features (n=6 theses/questions), and suitability for clinical use (n=4 theses/questions).

To achieve the highest possible face and content validity of the survey, satisfactory scores of these main three clinical aspects were assessed through a specific 6-point Likert scale, ranging from 1 (very good/strongly agree) to 6 (insufficient/strongly disagree), which has been used previously in similar studies [18].

Performance of at least 5 objective structured clinical examinations with the ultrasound probe according to the Focused Assessment with Sonography for Trauma (FAST) criteria were required per examiner.

The 5G Field Test

The field test was conducted in Munich, Germany and consisted of a 2-part setup located at the Huawei Munich research center facility: the ambulance car and the remote hospital site. Both were connected through the 5G network using the radio access network (RAN) part of an experimental 5G user equipment (UE) modem and the gNodeB (gNB). The RAN part connects to the core network part located in a cloud data center at the remote hospital site. In the core architecture, a set of network functions, specifically session management functions, user plane functions, and network slicing management functions, whose main features are aligned with the current 3GPP standards, were implemented. The ambulance car was parked in a position of line of sight with the gNB antenna with small buildings located in between as well as cars and pedestrians passing by during the test.

The main target of the field test (Figure 2) was to provide a 5G-based data transfer facilitating bidirectional data transmission for the ultrasound and video source between (1) the ambulance car, equipped with the 5G experimental UE, high-resolution camera (pan, tilt, zoom camera, Hikvision DS-2DE2A404IW-DE3/W, Hangzhou, China) and the ultrasound system, and (2) the remote hospital site (medical expert), equipped with display monitor, camera, and laptop computer.

The field test scenario consists of the parallel transmission of two different applications (ultrasound unit and camera video streaming) with low latency through the 5G network. The carrier frequency was 3.41 GHz, the bandwidth was 40 Hz, and the Modulation Coding Scheme was set to Quadrature Phase Shift Keying. Transmission Time Interval length was 0.5 milliseconds, the intercarrier spacing was 30 KHz, and the antenna gain was 5 dB for UE and 15.5 dB for gNB.

In addition, a traffic saturation to both data channels was simulated by injecting iPerf data with higher throughput. Methods of network slicing were introduced to prove the benefit to network functionality and quality of service (QoS) by

prioritizing data traffic and preserving low latency and high-reliability features.

Clinical Evaluation of the Bidirectional Data Transmission

To assess the medical application of the network KPIs, we performed a qualitative clinical evaluation of the data transmission parameters image quality and latency between ambulance and hospital.

Therefore, the same panel of 20 medical doctors was provided with a structured evaluation form compiled by the authors to assess both image quality and latency of the mobile ultrasound, remote ultrasound, and video stream subject to data traffic with/without uplink traffic and use of slicing technology by a specific 6-point Likert scale, ranging from 1 (very good/strongly agree) to 6 (insufficient/strongly disagree). Therefore, the transmitted ultrasound image was recorded (mpeg-4 file) during the field test and made available to the rating participants as was the video recording from the ambulance.

Results

Clinical Evaluation of Mobile Ultrasound Probe

A total of 20 medical doctors experienced in ultrasound examinations participated in the clinical evaluation study of the ultrasound probe, which was carried out prior to the 5G field test. All questionnaires were returned for analysis. The application feature “telemedicine” (6 thesis/questions) was generally rated “good”; the aspect of time saving was rated “very good.” Assessment of the ultrasound probe (6 thesis/questions) revealed the overall rating “good”; usability and transmission stability (between ultrasound probe and handheld device; eg, tablet or smartphone by Wi-Fi) were considered to be “very good.” Participants evaluated the clinical application properties (4 thesis/questions) to be “very good” to “good”; in 25% (5/15) of ultrasound examinations a FAST recheck with a second (conventional ultrasound system) was necessary. Table 1 gives a detailed overview of the evaluation results.

Table 1. Clinical evaluation of the mobile ultrasound probe with its telemedical and clinical application properties: survey results (N=20 participants).

Application properties	Scores ^a , mean (SD)
Application feature “telemedicine”	
...is helpful	1.9 (0.6)
...is user-friendly	2.0 (0.7)
...saves time	1.4 (0.5)
...provides feedback opportunity	2.3 (0.8)
...conveys confidence	1.5 (0.5)
...increases examination quality	1.7 (0.7)
Technical features ultrasound probe	
Haptics	1.7 (0.8)
Usability	1.3 (0.5)
Menu navigation	2.0 (0.8)
Display size	2.0 (0.6)
Image quality/resolution	2.7 (0.7)
Transmission stability	1.3 (0.4)
Suitability for clinical use	
Facilitates diagnostics	1.8 (0.7)
Increases patient convenience	1.6 (0.7)
Increases physician convenience	1.5 (0.6)
“Meets the purpose”	1.4 (0.5)

^aSatisfactory scores were graded on a 6-point Likert scale: 1 to 1.5 (very good/strongly agree), 1.6 to 2.5 (good/agree), 2.6 to 3.5 (satisfying/neutral), 3.6 to 4.9 (sufficient/disagree), and 5 to 6 (insufficient/strongly disagree).

The 5G Field Test

Bidirectional data transmission between the ambulance car and the remote hospital site was successfully established through the 5G network, facilitating sending/receiving data and measurements from both applications (ultrasound unit and camera video streaming).

The measured average E2E round trip latency, including RAN and core for the data traffic of the two applications is approximately 10 milliseconds (Figure 3). The measured average throughput for the ultrasound image traffic is approximately 4 Mbps and for the video stream 12 Mbps.

Traffic saturation (additional uplink traffic) to compete with both data channels was simulated by injecting iPerf data with higher throughput. For the ultrasound application, a lower video quality and a slower video stream was observed, leading to a heavily interrupted ultrasound image. Additionally, the latency increased up to 400 milliseconds (Figures 3 and 4).

Without core slicing, the throughput for the video application was reduced to 8 Mbps after the additional uplink traffic was added. This was also noted for the ultrasound throughput, however, with less influence. By implementing core network slicing, the two applications were prioritized with 2 individual network slices, leading to an immediate quality and latency recovery fulfilling the predefined system requirements (Figure 5).

Figure 3. Average end-to-end round trip delay of the two applications: latency and time (seconds). Additional uplink traffic (traffic saturation) marked with *.

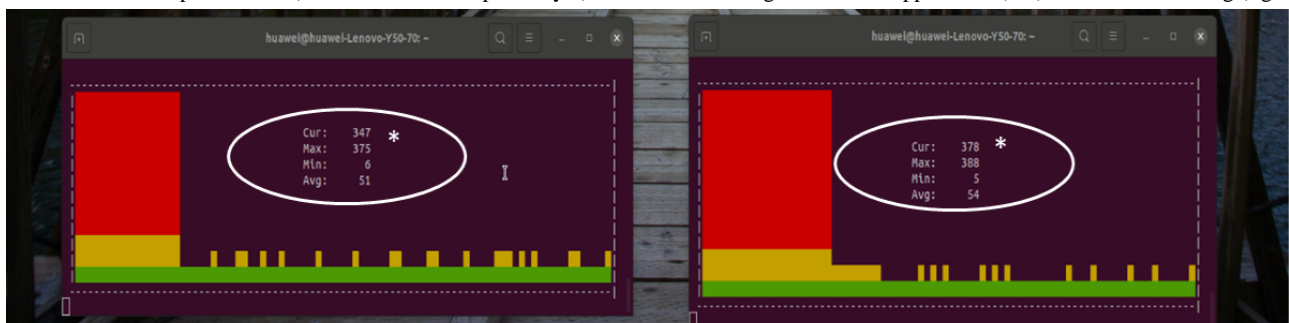

Figure 4. Additional uplink traffic (end-to-end round trip latency *) without core slicing. Ultrasound application (left) and video streaming (right).

without core slicing

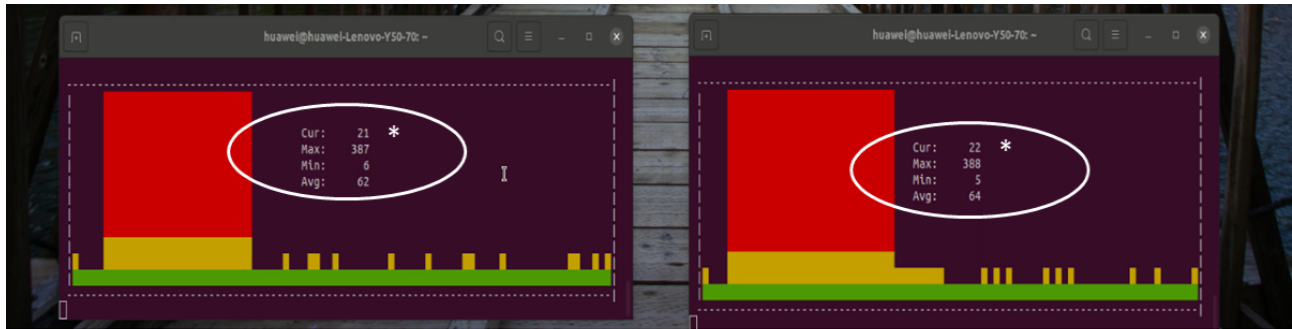

Figure 5. Additional uplink traffic (end-to-end round trip latency *) with core slicing. Ultrasound application (left) and video streaming (right).

with core slicing

Clinical Evaluation of the Bidirectional Data Transmission

Table 2 reveals the survey results of the medical assessment of the bidirectional data transmission characteristics (image quality, latency) between ambulance car and hospital depending on data traffic with/without uplink traffic and use of slicing technology. Whereas the remote ultrasound image quality (hospital site) was not affected by additional uplink traffic, the latency of the

displayed image was significantly increased. The same was noted for the video stream transmission. However, using core slicing technology, applicable results for both image quality ($P=.07$) and latency ($P<.001$) were obtained, enabling potentially routine application of the experimental setup. Suitability of image quality and latency for routine clinical application was considered good without uplink traffic (mean 2.2, SD 0.4) and with core slicing (mean 2.2, SD 0.7), respectively.

Table 2. Clinical evaluation (N=20 participants) of bidirectional data transmission depending on data traffic with/without uplink traffic and use of slicing technology: survey results.

Data source or characteristics	Uplink traffic			Slicing	
	Without, mean (SD) ^a	With, mean (SD) ^a	P value ^b	Score, mean (SD) ^a	P value ^b
Mobile ultrasound (ambulance)					
Image quality	1.7 (0.7)	N/A ^c	N/A	N/A	N/A
Remote ultrasound (hospital)					
Image quality	2.0 (0.7)	2.0 (0.5)	.79	2.2 (0.4)	.28
Latency	1.6 (0.7)	3.8 (0.6)	<.001	2.2 (0.6)	<.001
Video stream					
Image quality	1.9 (0.6)	2.3 (0.4)	.07	2.3 (0.5)	<.001
Latency	2.0 (0.4)	3.6 (1.0)	<.001	2.2 (0.4)	<.001

^aSatisfactory scores were graded on a 6-point Likert scale: 1 to 1.5 (very good/strongly agree), 1.6 to 2.5 (good/agree), 2.6 to 3.5 (satisfying/neutral), 3.6 to 4.9 (sufficient/disagree), and 5 to 6 (insufficient/strongly disagree).

Discussion

Principal Findings

This usability study of a 5G-enabled emergency setting ensures mobile health care by establishing a bidirectional data transfer (mobile ultrasound imaging, video streaming) between ambulance car (first responder) and remote hospital site (medical expert). Besides technical performance evaluations (KPIs) of the 5G network, a medical assessment of transferred ultrasound image quality and transmission latency was examined. Compared to 4G networks, higher data rates and very low latencies were achieved.

In this study, a real-world 5G field test for a medical application (mobile ultrasound) was performed, examining the benefits of ultralow latency and high reliability (URLLC), which have been proven to be important criteria for providing sensitive and time critical mobile health care applications [12] and slicing. This use case of a 5G-enabled emergency telemedicine application mobile ultrasound consisted of the parallel transmission of 2 different data traffic applications with low latency through a 5G network: first, a mobile ultrasound application providing imaging of the patient with average uplink required service throughput of 5 Mbps, and second, a camera video stream application showing the inside of the ambulance car (patient and doctor) as well as the remote hospital site with average uplink of 10 Mbps and downlink required service throughput of 5 Mbps.

KPIs of the 5G network are consistent to other comparable studies [14]; however, the methods of network slicing that were introduced in our study proves the benefit to network functionality and QOS by prioritizing data traffic and preserving low latency and high-reliability features have not yet been otherwise reported.

Without slicing, the throughput for the video application was reduced to 8 Mbps after the additional uplink traffic was added. This was also noted for the ultrasound throughput, however, with less influence. By implementing network slicing, the two applications were prioritized, leading to an immediate quality and latency recovery and fulfilling the predefined system requirements.

Comparison With Prior Work

Since its introduction into the industry about 4 years ago, 5G has now begun to show substantial potential and advantages in the health care sector (eg, facilitating intelligent hospital services by real-time patient and asset monitoring [19]). However, there are still certain limitations such as data confidentiality issues, security aspects, and lack of network deployment and support that need to be adequately addressed. For example, from the regulatory point of view, there is currently no bandwidth allocated to emergency services in general [20]. A private band similar to the campus networks in the 3.7 to 3.8 GHz range, which are now available in Germany, would be ideal.

Additionally, 5G technology not only opens new IoT applications for the medical sector [7] but also enhances existing fields such as telemedicine by evolution of cellular networks [21]. Mobile emergency health care apps involving remote assistance by medical experts have stringent connectivity criteria that can be fulfilled by 5G's promising potential [14]. These include high data rates, massive connectivity, and URLLCs, enabling for example, wireless transmission of mobile ultrasound imaging in real time [2,22] in an emergency. Currently available technologies for data transmission in telemedicine (ethernet/LAN, Wi-Fi, Bluetooth) are limited in terms of transmission rate, latency, and signal stability [10].

To estimate and prove how 5G will restructure the health care system, for example, in the fields of virtual reality and telemedicine [21], representative use cases according to specific, measurable, attainable, relevant, and time-bound objectives [23] are the current worldwide focus of research in this area. An objective of the EU-funded program 5G-VINNI [24] is, for example, boosting the deployment of 5G in Europe by providing E2E facilities, simplifying the vertical industries to pilot use cases and supporting them with evolving infrastructure.

It has been shown that modern telecommunication technologies have the potential to enable the development of sophisticated assistance systems [25] not only for industry 4.0 but also to shape the future of a digitalized health care system. However, to ensure both routine deployment in medical practice and the acceptance of the potential users, systems must meet the prevalent requirements. For instance, we should endeavor to create a noncommercialized band in the range of 3.7 to 3.8 GHz [20].

Limitations

In this usability study, the 5G system was not exposed by maximum data rates, and the field test was only carried out once without repetition. In addition, clinical evaluation was performed by only 20 participants. Validity and reliability are essential components in the critique of every research and may have an impact on the quantitative and qualitative results of the clinical evaluation.

Conclusion

Bidirectional data transmission between ambulance car and remote hospital site was successfully established through the 5G network, facilitating sending/receiving data from both applications (ultrasound unit and video streaming). The average E2E round trip latency was 10 milliseconds. The measured average throughput for the ultrasound image traffic was 4 Mbps and for the video stream 12 Mbps. Core slicing facilitated the recovery of quality and latency in case of traffic saturation. The clinical evaluation of the telemedical transmission and applicability of the ultrasound probe was consistently positive (satisfactory score of 1-2 on a 6-point Likert scale; $P < .001$).

Abstract

Background: Consumer-based activity trackers are increasingly used in research, as they have the potential to promote increased physical activity and can be used for estimating physical activity among participants. However, the accuracy of newer consumer-based devices is mostly unknown, and validation studies are needed.

Objective: The objective of this study was to compare the Polar Vantage watch (Polar Electro Oy) and Oura ring (generation 2; Oura Health Oy) activity trackers to research-based instruments for measuring physical activity, total energy expenditure, resting heart rate, and sleep duration in free-living adults.

Methods: A total of 21 participants wore 2 consumer-based activity trackers (Polar watch and Oura ring), an ActiGraph accelerometer (ActiGraph LLC), and an Actiheart accelerometer and heart rate monitor (CamNtech Ltd) and completed a sleep diary for up to 7 days. We assessed Polar watch and Oura ring validity and comparability for measuring physical activity, total energy expenditure, resting heart rate (Oura), and sleep duration. We analyzed repeated measures correlations, Bland-Altman plots, and mean absolute percentage errors.

Results: The Polar watch and Oura ring values strongly correlated ($P < .001$) with the ActiGraph values for steps (Polar: $r = 0.75$, 95% CI 0.54-0.92; Oura: $r = 0.77$, 95% CI 0.62-0.87), moderate-to-vigorous physical activity (Polar: $r = 0.76$, 95% CI 0.62-0.88; Oura: $r = 0.70$, 95% CI 0.49-0.82), and total energy expenditure (Polar: $r = 0.69$, 95% CI 0.48-0.88; Oura: $r = 0.70$, 95% CI 0.51-0.83) and strongly or very strongly correlated ($P < .001$) with the sleep diary-derived sleep durations (Polar: $r = 0.74$, 95% CI 0.56-0.88; Oura: $r = 0.82$, 95% CI 0.68-0.91). Oura ring-derived resting heart rates had a very strong correlation ($P < .001$) with the Actiheart-derived resting heart rates ($r = 0.9$, 95% CI 0.85-0.96). However, the mean absolute percentage error was high for all variables except Oura ring-derived sleep duration (10%) and resting heart rate (3%), which the Oura ring underreported on average by 1 beat per minute.

Conclusions: The Oura ring can potentially be used as an alternative to the Actiheart to measure resting heart rate. As for sleep duration, the Polar watch and Oura ring can potentially be used as replacements for a manual sleep diary, depending on the acceptable error. Neither the Polar watch nor the Oura ring can replace the ActiGraph when it comes to measuring steps, moderate-to-vigorous physical activity, and total energy expenditure, but they may be used as additional sources of physical activity measures in some settings. On average, the Polar Vantage watch reported higher outputs compared to those reported by the Oura ring for steps, moderate-to-vigorous physical activity, and total energy expenditure.

actigraphy; fitness trackers; motor activity; energy expenditure; steps; activity tracker

Introduction

In a research setting, accelerometers are often used to objectively measure movement behavior (eg, sleep, physical activity, and sedentary behavior). Device outputs are converted into various estimates for physical activity, energy expenditure, sleep, and heart rate (for devices with a heart rate sensor). A wide range of devices exist for both research [1] and the consumer market [2].

Consumer-based activity trackers are increasingly used in research, as they have the potential to increase activity participation [3] and can be used for estimating physical activity and related variables [2,4,5]. Compared to research-based accelerometers and heart rate sensors, consumer-based activity trackers are often cheaper and less intrusive and have increased battery and storage capacity. They are also associated with less participant burden than that associated with self-report instruments, such as physical activity and sleep diaries. Sleep diaries [6] are less resource demanding than polysomnography, but compliance can be challenging [7]. Consumer-based activity trackers that measure sleep duration can therefore be a potential replacement for sleep diaries.

The accuracy of newer consumer-based devices is mostly unknown, and validation studies are needed. The validity of consumer-based activity trackers can be studied via comparisons against research-based accelerometers (eg, ActiGraph [ActiGraph LLC]) that, in turn, have been validated against gold standard methods. The Polar Vantage watch (Polar Electro Oy) and the Oura ring (Ōura Health Oy) are 2 new consumer-based activity trackers that can potentially replace, or be used in addition to, existing research-based accelerometers or self-report tools. However, before using these trackers, there is a need to test their accuracy.

A previous lab-based validation study of Polar Vantage devices found that the devices estimated energy expenditure within 20% of the actual value (commonly deemed “acceptable” in the literature) in 59.5% of all cases; however, this error rate varied depending on the activity type (ranging from 27% to 93%) [8]. No validation or comparison study on physical activity or sleep has been conducted on the Polar Vantage watch to date, and no study on this activity tracker has been done with free-living populations. Similarly, de Zambotti et al [9] compared the Oura ring to polysomnography and found that although further validation studies are needed, the Oura ring has the potential to be used as a tool for detecting the time spent in different sleep phases in studies conducted with free-living populations. However, there are no previous validation studies that have tested the validity of the physical activity or energy expenditure measures of the Oura ring.

The aim of this study on free-living adults was therefore to test the validity and comparability of the physical activity and energy expenditure measures of the Polar Vantage watch and Oura ring by comparing them to those of the ActiGraph. We also compared the resting heart rates (RHRs) measured by the Oura ring to

those measured by Actiheart electrocardiograms (CamNtech Ltd). In addition, we compared sleep durations from a sleep diary and outputs from the Polar Vantage watch and Oura ring.

Methods

Instruments

The Polar Vantage activity tracker (Polar Electro Oy) was released in 2018, and it is equipped with a 50-Hz (ie, 50 measurements per second) triaxial accelerometer for physical activity tracking. It weighs 45 to 66 g, has 1 week of battery life, and comes in multiple strap and metal casing colors. The Polar Vantage watch is a multisport watch that is to be worn on the wrist.

We used Polar Flow (Polar Electro Oy) to download daily Polar Vantage variables for steps, moderate-to-vigorous physical activity (MVPA), total energy expenditure (TEE), and sleep duration (sleep time).

The Oura activity and sleep ring (Ōura Health Oy) was released in 2018, and it is equipped with a 50-Hz triaxial accelerometer for physical activity tracking and a photoplethysmograph with 2 infrared light-emitting diodes for optical pulse measurements. It comes in sizes US 6 to US 13, weighs 4 to 6 g, has 6 days of battery life, and comes in different shapes and colors. The Oura ring is a smart ring that is to be worn on the finger and focuses on sleep and well-being by combining physical activity and heart rate parameters.

The Oura Generation 2 cloud dashboard was used to download daily Oura variables for steps, MVPA, TEE, sleep duration (total sleep), and RHR.

The ActiGraph wGT3X-BT (ActiGraph LLC) is a triaxial accelerometer. The sample rate can be set to 30 to 100 Hz. It weighs 19 g and has up to 25 days of battery life. It is extensively used to estimate activity in free-living research, as it provides reasonable estimates for physical activity intensity [10], steps [11], and energy expenditure [12].

We used ActiLife (ActiGraph LLC) to download ActiGraph accelerometer data and generate variables. We used triaxial activity (ie, vector magnitude [VM]) counts to generate physical activity and energy expenditure variables in addition to step counts, which were reported directly. We calculated minutes of MVPA by using the cut points defined by Sasaki et al [10] (ie, >2690 VMs). Activity energy expenditure was calculated by using the “Freedson VM3 combination 2011 + Williams work-energy equation” [10] and was converted to TEE by using the Schofield equation [13] for resting energy expenditure and subtracting 10% of the original energy expenditure value to account for diet-induced thermogenesis. Although the ActiGraph is an objective instrument, researchers must make subjective choices (eg, cut points, sample rate, and wear location) that can influence output variables and thus affect conclusions.

The Actiheart 4 (CamNtech Ltd) records heart rate by using a 1-lead electrocardiogram with a 128-Hz sampling rate. It weighs

less than 10 g and is attached to the chest by using 2 standard electrocardiogram electrodes. Actiheart is valid and reliable for heart rate detection [14].

The Actiheart software was used to download sleeping (ie, resting) heart rate data from the Actiheart (CamNtech Ltd). Sleep duration (time in bed) was calculated based on manually recorded times (ie, time getting out of bed minus time getting into bed) from the sleep diary. We did not analyze sleep duration by using the Actiheart software, as this feature is considered experimental.

We only included valid days in the analysis, which were defined as days with at least 10 hours of wear time [15]. Wear time for the ActiGraph was analyzed by using the ActiLife default settings for the Troiano [16] wear time algorithm. The wear time algorithms for Polar Vantage and Oura are unknown.

The sleep diary contained a subset of questions from the Consensus Sleep Diary [17] that were relevant to sleep duration, which was measured as the time in bed. Specifically, it contained question 1 (“What time did you get into bed?”) and question 7 (“What time did you get out of bed for the day?”).

Participants and Procedure

We used convenience sampling to recruit 21 participants. Participants were eligible for inclusion if they were above 18

years of age, had normal physical function, and were willing to wear all 4 devices and keep a sleep diary for 5 days. Participants were recruited among university students and staff and people who were close to these participants.

We initialized devices with self-reported information on height, weight, age, sex, and dominant hand. Participants wore the Polar Vantage watch and Oura ring on their nondominant hand. The ActiGraph was set up for 100-Hz recording and placed on the right hip (attached via an elastic band). The Actiheart was placed at the level of the fifth intercostal space on the sternum (medial part) and to the left (lateral part) and was attached via two 3M Red Dot 2238 electrodes (3M Company). Participants were asked to wear all 4 devices simultaneously and complete the sleep diary for 5 days. They were instructed to complete the sleep diary (time getting into bed and time getting out of bed) upon waking every morning. Since the devices were placed on participants on day 1 and removed on day 5, the expected number of valid days per person was up to 3. Data were collected from May to June 2019. Figure 1 shows the device placements.

An overview of instrument details and the software used for instrument setup, data download, and variable generation is given in Table 1.

Figure 1. Illustration of instrument placements for the Actiheart, Polar Vantage watch, ActiGraph, and Oura ring.

Table 1. Overview of the instrument suppliers, models, firmware versions, and software versions used to set up instruments, download data, and generate output variables.

Characteristic	Instrument			
	Actiheart	Polar Vantage watch	ActiGraph	Oura ring
Supplier	CamNtech	Polar Electro	ActiGraph	Oura
Model	4	V/M	wGT3X-BT	2P
Firmware version	H90.65	3.2.10	1.9.2	1.91.1
Software for instrument setup, data download, and variable generation	Actiheart 5.1.10	Polar Flow [18]	ActiLife 6.13.3	Oura app [19]

Statistics

The ActiGraph was used as a reference monitor for steps, MVPA, and TEE. The Actiheart was used as a criterion measure for RHR. The sleep diary (time in bed) was used to compare sleep durations (Polar: sleep time; Oura: total sleep). Normality was tested by using the Shapiro-Wilkins test, and bootstrapping was used on all variables. Correlations were calculated by using repeated measures correlations [20-22] with the correlation cutoffs suggested by Evans [23] (ie, very weak: <0.2; weak: 0.2-0.4; moderate: 0.4-0.6; strong: 0.6-0.8; very strong: >0.8). Mean absolute percentage error (MAPE) was calculated across person-day cases to assess measurement errors between each instrument and the reference monitor. Although there is no universally accepted threshold for MAPE, a common practice that was established in prior validation studies conducted with free-living populations is to use 10% as a cutoff to indicate low error [24,25]. We therefore used a below-10% cutoff to indicate low or acceptable error and an above-10% cutoff to indicate high error. Some participants had a high level of MVPA based on the Polar Vantage watch but a low level of MVPA based on the ActiGraph. We conducted a subanalysis in which we excluded these outlier participants and recalculated MAPEs.

Bland-Altman plots for multiple measurements were created to determine the agreement between each instrument and the reference monitor, as well as the agreement between instruments (Polar watch and Oura ring) [26]. This is, according to Bland and Altman [26], an appropriate approach for assessing the

agreement between methods when there is an unequal number of observations per participant.

Ethics Approval

The Norwegian Regional Committees for Medical and Health Research Ethics North reviewed this study (approval number: 2019/557/REK nord). Participants received written and oral instructions and gave informed consent. This study was conducted in accordance with the 1964 Declaration of Helsinki and its later amendments.

Results

Participant Characteristics

Summary statistics for participants' age, sex, height, weight, and BMI, are given in Table 2.

Each participant had 2 to 6 valid days of physical activity recorded, totaling 57 and 68 valid person-days of simultaneous ActiGraph and activity tracker usage for the Polar Vantage watch and Oura ring, respectively. On average, each participant simultaneously wore the ActiGraph and Polar Vantage watch for 2.7 days and the ActiGraph and Oura ring for 3.2 days. Participants manually recorded 0 to 5 days of sleep, totaling 48 and 44 person-days of sleep diary and activity tracker recordings for the Polar Vantage watch and Oura ring, respectively. On average each participant kept a sleep diary for 2.3 days. There were 39 person-days of Oura and Actiheart RHR recordings, averaging 1.8 person-days of recordings per participant.

Table 2. Participants' age, sex, height, weight, and BMI (N=21).

Variable	Value
Age (years), mean (SD; range)	33 (14; 22-71)
Men, n (%)	57 (12)
Height (cm), mean (SD; range)	176 (9; 160-190)
Weight (kg), mean (SD; range)	79 (13; 57-103)
BMI (kg/m ²), mean (SD; range)	26 (4; 18-35)

Correlation, Error, and Agreement

Table 3 presents valid person-days, correlations, MAPEs, and mean differences (with limits of agreement) for the step, MVPA, TEE, sleep duration, and RHR (Oura) measures of the Polar Vantage watch and the Oura ring, which were compared to the criterion measure. Table 4 presents the same variables (except RHR), which were used to compare the Polar Vantage watch with the Oura ring directly.

The mean differences are illustrated in Figure 2 by using Bland-Altman plots. Each participant is represented by a different color. Similarly, Figure 3 further illustrates how the Polar Vantage watch directly compares to the Oura ring by using Bland-Altman plots. In Figure 3, a mean difference above the line of equivalence indicates that the Polar Vantage watch reports higher numbers on average compared to those reported by the Oura ring.

Step counts were strongly correlated between the reference monitor and both the Polar Vantage watch and the Oura ring.

Bland-Altman plots showed that both the Polar Vantage watch and the Oura ring overreported steps. The MAPE was high for both activity trackers. The correlation between the Polar Vantage watch and Oura ring was very strong for steps. On average, the Polar Vantage watch reported 305 additional steps per day when compared to those reported by the Oura ring.

MVPA values were strongly correlated between the reference monitor and both activity trackers. The Polar Vantage watch overreported MVPA values, while the Oura ring underreported MVPA values. For the Polar Vantage watch, overreporting was higher for higher values of MVPA. The limit of agreement ranges in the Bland-Altman plots were also wider for the Polar Vantage watch. MAPEs were high, but the Oura ring had lower mean errors compared to those of the Polar Vantage watch. We identified 3 participants for whom the Polar Vantage watch reported a high MVPA value and the ActiGraph reported a low MVPA value. The MAPE subanalysis, in which these three participants were excluded, showed a MAPE of 49%—a decrease from 143%. The correlation between the Polar Vantage

watch and Oura ring was very strong for MVPA. On average the Polar Vantage watch reported 81 additional minutes of MVPA per day when compared to those reported by the Oura ring.

TEE values were strongly correlated between the reference monitor and both activity trackers. Both activity trackers overreported TEE, but the Polar Vantage watch overreported TEE at a higher rate. Both MAPEs were higher than the 10% cutoff for acceptable error. The correlation between the Polar Vantage watch and Oura ring was very strong for TEE. On average, the Polar Vantage watch reported 349 additional kcal per day when compared to those reported by the Oura ring.

Sleep durations were strongly correlated between the diary and the Polar Vantage watch and were underreported by a mean of 30 minutes by the Polar Vantage. The Oura ring-derived sleep durations very strongly correlated with the diary-derived sleep durations but were overreported on average by 6 minutes. Both activity trackers had a borderline acceptable MAPE. The correlation between the Polar Vantage watch and Oura ring was strong for sleep duration. On average, the Polar Vantage watch reported 38 fewer minutes of sleep per day when compared to those reported by the Oura ring.

RHRs were very strongly correlated between the criterion measure and the Oura ring. The MAPE was low (3%), and on average, the Oura ring underreported RHR by 1 beat per minute.

Table 3. Repeated measures correlation (RMC), mean absolute percentage error (MAPE), and mean difference for each Polar Vantage watch and Oura ring variable.

Measure	Person-days, n	RMC ^a (95% CI)	MAPE	Mean difference (lower LoA ^b , upper LoA)
Polar Vantage watch				
Steps	57	0.75 (0.54-0.92)	72	4091 (−2693, 10 876)
MVPA ^c	57	0.76 (0.62-0.88)	143	59 (−148, 266)
Total energy expenditure	57	0.69 (0.48-0.88)	19	430 (−267, 1127)
Sleep duration	48	0.74 (0.56-0.88)	11	−30 (−183, 123)
Oura Generation 2 ring				
Steps	68	0.77 (0.62-0.87)	69	3779 (−3361, 10 919)
MVPA	68	0.70 (0.49-0.82)	49	−18 (−96, 61)
Total energy expenditure	68	0.70 (0.51-0.83)	13	148 (−624, 920)
Sleep duration	44	0.82 (0.68-0.91)	11	6 (−152, 164)
Resting heart rate	39	0.90 (0.85-0.96)	3	−1 (−4, 1)

^aAll RMC *P* values are <.001.

^bLoA: limit of agreement.

^cMVPA: moderate-to-vigorous physical activity.

Table 4. Repeated measures correlations (RMCs) and mean differences between Polar Vantage watch and Oura watch variables.

Measure	Person-days, n	RMC ^a (95% CI)	Mean difference (lower LoA ^b , upper LoA)
Steps	44	0.89 (0.77-0.97)	305 (−5832, 6441)
MVPA ^c	44	0.82 (0.69-0.91)	81 (−133, 296)
Total energy expenditure	44	0.85 (0.75-0.93)	349 (−411, 1109)
Sleep duration	51	0.74 (0.49-0.93)	−38 (−157, 82)

^aAll RMC *P* values are <.001.

^bLoA: limit of agreement.

^cMVPA: moderate-to-vigorous physical activity.

Figure 2. Bland-Altman plots for comparing the Polar Vantage watch and Oura ring to the ActiGraph. Participants are represented by different colors. Black solid lines represent the mean difference, black dashed lines represent the limits of agreement, and grey dashed lines represent the line of equivalence. bpm: beats per minute; MVPA: moderate-to-vigorous physical activity; TEE: total energy expenditure.

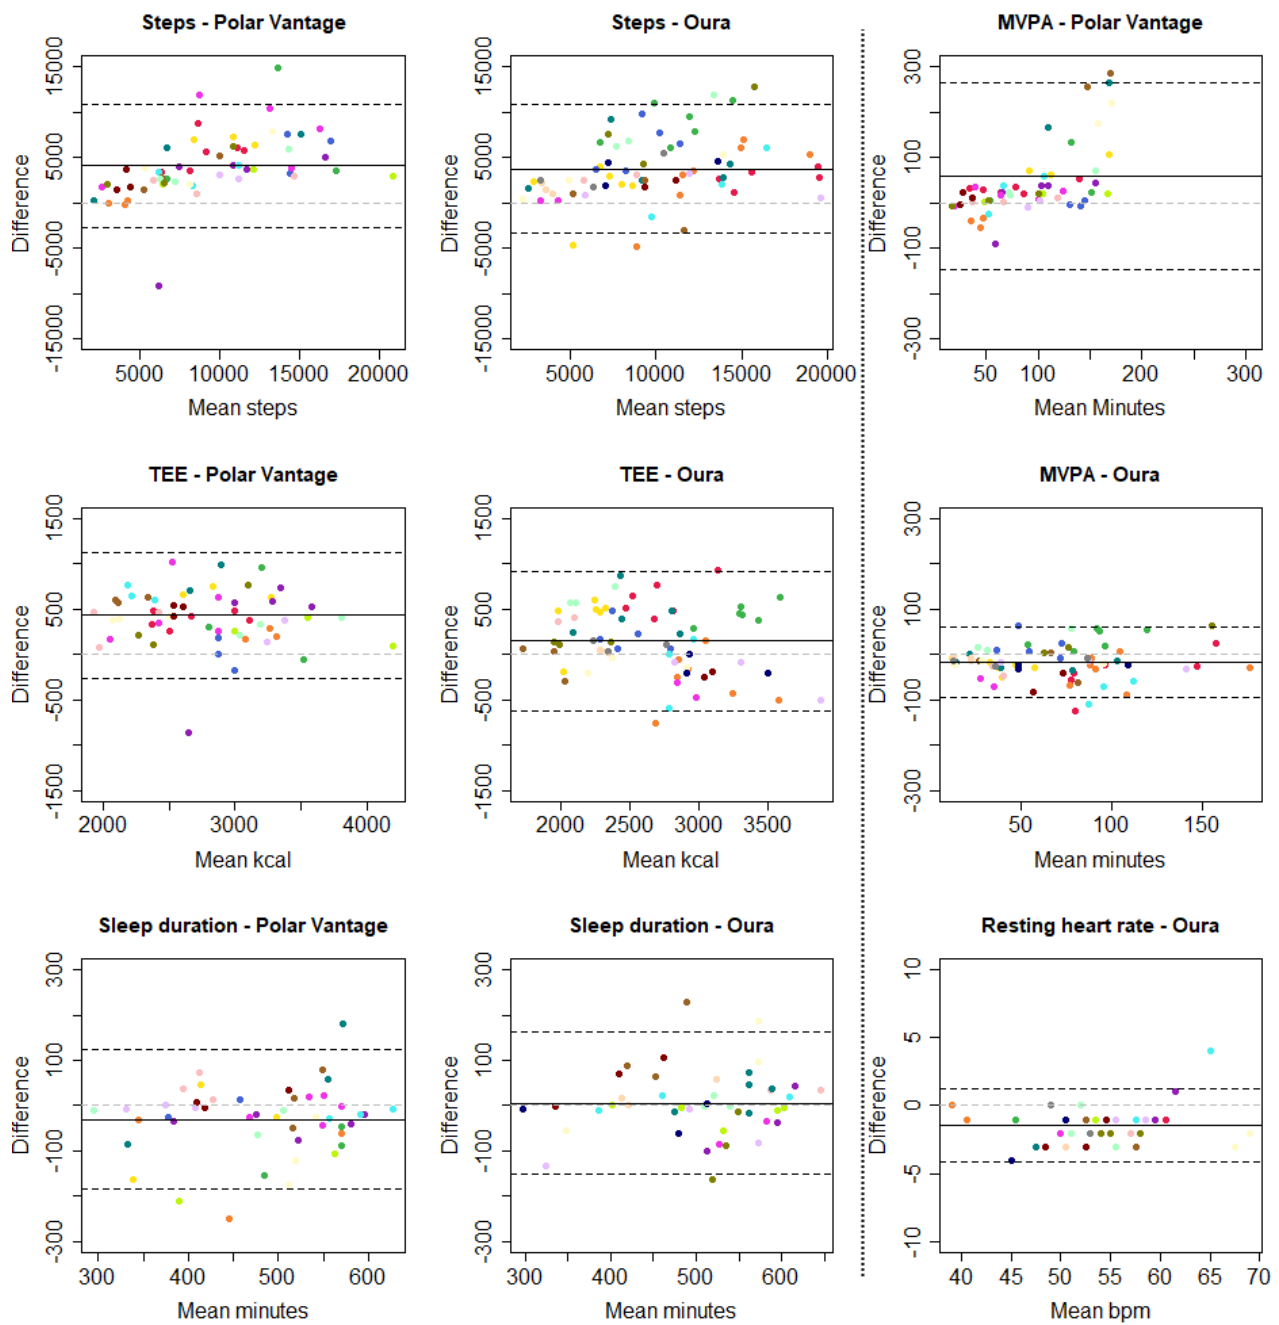

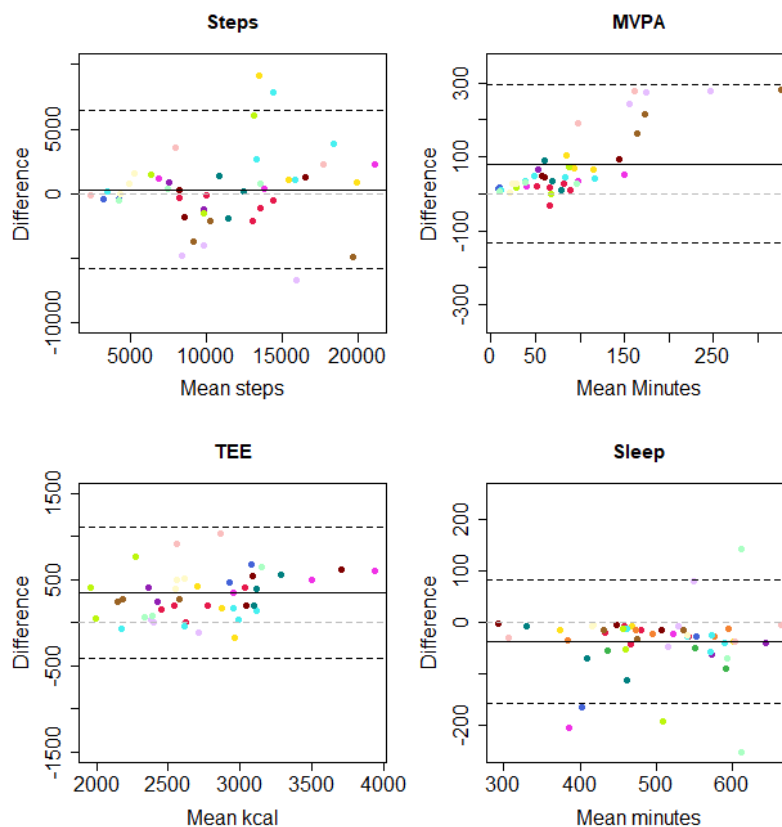

Figure 3. Bland-Altman plots for comparing the Polar Vantage watch and Oura ring measures for steps, moderate-to-vigorous physical activity (MVPA), total energy expenditure (TEE), and sleep duration. Participants are represented by different colors. Black solid lines represent the mean difference, black dashed lines represent the limits of agreement, and grey dashed lines represent the line of equivalence.

Discussion

Principal Findings

Step, MVPA, and TEE outputs from the activity trackers all strongly correlated with those of the ActiGraph. The MAPEs were high for these variables, with lower errors recorded for the Oura ring compared to those recorded for the Polar Vantage watch. Sleep durations were strongly to very strongly correlated between the sleep diary and both the Polar Vantage watch and the Oura ring. In addition, RHRs recorded by the Oura ring very strongly correlated with those recorded by the Actiheart. The MAPEs for the sleep diary were borderline acceptable, while the MAPEs for RHR were acceptable. The correlations between the Polar Vantage watch and Oura ring were very strong for steps, MVPA, and TEE and were strong for sleep duration.

The CI range was wide for all correlations and was borderline acceptable for Oura ring-derived RHR. The wide ranges are not surprising, given the low sample size. The MAPEs were very high for some comparisons, especially for MVPA and the Polar Vantage watch. In the MAPE subanalysis for the Polar Vantage watch and the ActiGraph, the MAPE dropped from 143% to 49%. This is well above the 10% threshold.

Strength and Limitations

The major strength of this study is the inclusion of multiple days of recordings for each participant instead of 1 mean measure per participant. Using multiple measurements per participant increases the width of the limits of agreement and

thus provides a more accurate representation of the actual agreement between methods [26]. A further strength is the gender balance and the wide range of ages, heights, weights, and BMIs among the participants. This is also the first study to assess the accuracy of physical activity estimates from the Oura ring. The major weakness of this study is the use of non-gold standard methods for comparing step, MVPA, and energy expenditure values. However, there is no gold-standard for estimating physical activity in free-living populations. The ActiGraph has been previously validated using gold standard methods [10-12] and is an appropriate reference monitor for studies conducted in free-living settings. The gold standards for estimating energy expenditure and sleep duration are the doubly labeled method and polysomnography, respectively. We did not have access to these two methods.

Comparison With Prior Work

Although the correlation for Polar Vantage watch-derived energy expenditure in this study ($r=0.69$) is stronger than those in most previous studies on Polar Vantage devices (only discontinued devices) [27], it is weaker compared to those in a 2019 lab-setting study on a Polar Vantage device ($r=0.89$) [8] and a 2018 free-living study on the Polar M430 ($r=0.91$) [28]. The correlations for MVPA values in previous Polar device validation studies vary, but our findings ($r=0.76$) are as strong as the findings from a study on the Polar M430 ($r=0.75$) [28]. Similarly, the strong correlation ($r=0.75$) for step counts is in accordance with those in previous studies on the Polar M430 ($r=0.85$) [28] and the Polar V800 ($r=0.89-0.92$) [29].

For the Oura ring, we could not find any previous studies on steps, MVPA, or TEE. Even though the correlations were strong in this study, most results showed that the measurement error was high, and most variables were overreported when compared to those reported by the reference monitor. Thus, we cannot recommend replacing existing research-based accelerometers with the activity trackers investigated in this study. However, as additional instruments for long-term physical activity recording, these consumer-based activity trackers can potentially provide additional value to studies examining changes in physical activity over time. TEE may be especially interesting to measure over time, since it had close to acceptable errors (range: 13%-19% mean error).

We could not find any previous validation studies on sleep duration for the Polar Vantage watch. However, the strong correlation ($r=0.74$) in this study is in accordance with the findings for an earlier Polar watch model (Polar A370); its sensitivity for correctly detecting sleep duration was >0.91 [4]. Sleep duration was underreported in both studies, which is expected since sleep onset and sleep offset are generally greater than 0 minutes. The Oura ring overreported sleep duration but only by an average of 6 minutes per night. This is in accordance with the findings of de Zambotti et al [9], who concluded that the Oura ring shows “promising results” for sleep detection (ie, a 96% sensitivity for detecting sleep) in their study involving polysomnography. Both the Polar Vantage watch and Oura ring can provide reasonably close estimates for sleep duration with a 10% to 13% average error, which is close to the acceptable cutoff. This is especially interesting for long-term sleep monitoring, as keeping a manual sleep diary is prone to low compliance [7], and objective wrist-worn devices can provide more accurate results [30].

The strong correlation and low average error found for the Oura ring-derived RHR is in accordance with heart rate measurements from some wrist-worn activity trackers [5,31]. A recent validation study on Oura ring-derived sleeping heart rate also reported high agreement (Spearman correlation: 0.996) between the Oura ring and an electrocardiogram [32]. Compared to the Actiheart and other similar research instruments, the Oura ring

is a low-burden device that is capable of collecting various heart rate measures over several months. This makes it an interesting instrument for future research, when long-term heart rate measuring is of interest.

Several systematic reviews on consumer-based activity tracker validity have been published in the last few years, and they reported similar conclusions [27,31,33-38]. Fuller et al [31] published a large systematic review in 2020 that assessed the validity of step, energy expenditure, and heart rate estimates for devices from Apple, Fitbit, Garmin, Mio, Misfit, Polar, Samsung, Withings, and Xiaomi. Based on the 148 included validation studies, they concluded that although there is variation, consumer-based activity trackers can accurately measure steps and heart rates in lab settings. The most recent systematic review on Garmin activity trackers by Evenson et al [38] reported high validity for step counts (good to excellent correlation coefficients and acceptable MAPEs) but low validity (large variations in correlation coefficients and high MAPEs) for energy expenditure values and heart rates. A systematic review and meta-analysis on energy expenditure by O’Driscoll et al [37] further showed that accuracy is dependent on the type of activity performed and that trackers with heart rate monitors have lower measurement errors. The Polar Vantage watch reported on average higher numbers compared to those reported by the Oura ring.

Although several systematic reviews have been published [27,31,37,38], these reviewed activity trackers that are now discontinued. This highlights the need for continuous validation studies on new devices, as suggested by Fuller et al [31].

Conclusions

The Oura ring can be used as an alternative to the Actiheart to measure RHR unless very high accuracy is required. Similarly, the Polar Vantage watch and Oura ring can potentially be used as replacements for a manual sleep diary for sleep duration measurements. Neither the Polar Vantage watch nor the Oura ring can replace the ActiGraph when it comes to measuring steps, MVPA, and TEE, but they may be used as additional sources of physical activity measures in some settings.

Acknowledgments

AH, FS, and LAH conceived this study and designed the study protocol. AH collected the data with support from Celina Jakobsen and Jørgen Halvorsen. AH performed the data analysis, and AH, LAH, SG, GH, and FS contributed to the interpretations of the results. AH drafted the initial manuscript, and a critical review was performed by LAH, SG, FS, and GH. All authors read and approved the final manuscript. The authors would like to thank Celine Jakobsen and Jørgen Halvorsen for their contributions to data collection.

This work was supported by UiT The Arctic University of Norway’s thematic priority grant Personalized Medicine for Public Health (grant Series-1). The publication charges for this article were funded by a grant from the publication fund of UiT The Arctic University of Norway.

Abstract

Background: Unhealthy alcohol use is associated with increased morbidity and mortality among persons with HIV and tuberculosis (TB). Computer-based interventions (CBIs) can reduce unhealthy alcohol use, are scalable, and may improve outcomes among patients with HIV or TB.

Objective: We assessed the acceptability, adaptability, and feasibility of a novel CBI for alcohol reduction in HIV and TB clinical settings in Pune, India.

Methods: We conducted 10 in-depth interviews with persons with alcohol use disorder (AUD): TB (6/10), HIV (2/10), or HIV-TB co-infected (1/10) selected using convenience sampling method, no HIV or TB disease (1/10), 1 focus group with members of Alcoholics Anonymous (AA; n=12), and 2 focus groups with health care providers (HCPs) from a tertiary care hospital (n=22). All participants reviewed and provided feedback on a CBI for AUD delivered by a 3D virtual counselor. Qualitative data were analyzed using structured framework analysis.

Results: The majority (9/10) of in-depth interview respondents were male, with median age 42 (IQR 38-45) years. AA focus group participants were all male (12/12), and HCP focus group participants were predominantly female (n=15). Feedback was organized into 3 domains: (1) virtual counselor acceptability, (2) intervention adaptability, and (3) feasibility of the CBI intervention in clinic settings. Overall, in-depth interview participants found the virtual counselor to be acceptable and felt comfortable honestly answering alcohol-related questions. All focus group participants preferred a human virtual counselor to an animal virtual counselor so as to potentially increase CBI engagement. Additionally, interaction with a live human counselor would further enhance the program's effectiveness by providing more flexible interaction. HCP focus group participants noted the importance of adding information on the effects of alcohol on HIV and TB outcomes because patients were not viewed as appreciating these linkages. For local adaptation, more information on types of alcoholic drinks, additional drinking triggers, motivators, and activities to substitute for drinking alcohol were suggested by all focus group participants. Intervention duration (about 20 minutes) and pace were deemed appropriate. HCPs reported that the CBI provides systematic, standardized counseling. All focus group and in-depth interview participants reported that the CBI could be implemented in Indian clinical settings with assistance from HIV or TB program staff.

Conclusions: With cultural tailoring to patients with HIV and TB in Indian clinical care settings, a virtual counselor–delivered alcohol intervention is acceptable and appears feasible to implement, particularly if coupled with person-delivered counseling.

KEYWORDS

computer-based-intervention; HIV/TB clinical setting; alcohol use disorder (AUD); alcohol; India; HIV; TB; feasibility; acceptability

Introduction

It is well known that unhealthy alcohol use, encompassing heavy/hazardous use, binge drinking, and alcohol use disorders (AUDs) [1] is associated with increased HIV transmission, decreased use of and adherence to antiretroviral therapy (ART), lower viral suppression, decreased engagement and retention in care [2,3], more rapid HIV disease progression, and mortality [4-6]. Similarly, a recent systematic review and meta-analysis indicated that there is a nearly 3-fold increase in the risk of incident tuberculosis (TB) among people with AUDs [7,8]. Additionally, many studies show a strong association between unhealthy alcohol use and unfavorable TB outcomes, including treatment default, TB relapse, and death [7,9-11].

India accounts for about a quarter of the world's TB burden [12] and is ranked third in absolute HIV burden [13], with 23.4 lakhs people living with HIV [14]. Unhealthy alcohol use is rapidly increasing in India with more than 50% of those who drink alcohol at unhealthy levels [15]. In India, the prevalence of AUDs among people with HIV and TB has been reported as 12.3% [16] and 24% [17], respectively. Further, although Indian HIV and TB programs mandate alcohol assessments at intake prior to initiation of HIV and TB treatment, effective evidence-based alcohol treatment programs are not routinely implemented in TB and HIV care settings [10].

Brief alcohol interventions (BAIs; 1-4 sessions) are based on cognitive behavioral therapy, the transtheoretical model, or the information, motivation, behavioral skills (IMB) model with motivational interviewing typically used as the style to deliver the intervention [18]. BAIs can reduce alcohol consumption, improve medication adherence, and reduce viral load among people with HIV [19-24]. Despite demonstrated efficacy, however, numerous patient and provider barriers prevent widespread access to and uptake of these interventions [25,26]. These include patient concerns about stigma and confidentiality and the reluctance or inability to access care, as well as lack of provider time or training [26,27]. Computer-based interventions (CBIs) may overcome some of these barriers. They are cost-effective, can reach a large number of people with unhealthy alcohol use, can be delivered with fidelity, and provide confidentiality and convenience [28,29]. Importantly, CBIs appear as effective as person-delivered interventions at short-term (<4 month) follow-up [30].

To date, CBIs have been largely developed and tested in developed countries but not in resource-limited settings [31]. For CBI interventions to be relevant, scalable, and have community-wide impact in resource-limited settings like India, cultural adaptation is required. This includes incorporating the target population's values, beliefs, language, concepts, and

metaphors or key characteristics, while preserving the intervention's core theoretical components [32,33]. Cultural adaptation also includes the integration of specific contextual factors including feasibility, organizational capacity for adoption, and acceptability to enhance effective implementation [34,35].

In this study, we reviewed a US-developed, evidence-based CBI delivered by a virtual counselor for the reduction of unhealthy alcohol use among people with HIV [36]. Through interviews with adult patients with HIV or TB and focus group discussions with health care providers (HCPs) in government clinical settings in India, we investigated the specific key characteristics of the existing intervention that would need modification for cultural adaptation to yield an acceptable and relevant CBI and the feasibility of CBI implementation.

Methods

Study Design

We conducted a qualitative study in Pune, India, consisting of focus group discussions and in-depth interviews with patients, providers, and stakeholders to evaluate the acceptability, adaptability, and feasibility of a CBI for alcohol reduction. Our semistructured interview guide was developed based on our previous work culturally adapting evidence-based interventions [37]. It was designed to assess and make recommendations regarding (1) virtual counselor acceptability, (2) intervention adaptability, and (3) feasibility. We followed the Consolidated Criteria for Reporting Qualitative Research (COREQ) guidelines [38] to report the study.

Ethics Approval

The Johns Hopkins School of Medicine institutional review board in Baltimore, Maryland, United States (IRB00174744 / CR00026582), and the Byramjee Jeejeebhoy Government Medical College ethics committee in Pune, India, approved this study.

Computer-Based Brief Alcohol Intervention Delivered by a Virtual Counselor

On one occasion, participants viewed a single session of a US-developed evidence-based CBI designed for people with HIV who consumed alcohol at unhealthy levels [36]. Our CBI used well-established, evidence-based cognitive behavioral techniques, including personalized feedback, pros and cons of drinking, problem solving high-risk situations, and goal setting for reduction or cessation of alcohol use. The software platform was derived from Computer Intervention Authoring Software, an authoring tool to create and enter intervention script into electronic packages featuring a synthetic text-to-speech engine that reads all questions and speaks aloud to the participant (via

headphones); synchronous interactivity; natural language reflections; branching logic; and the ability to incorporate specific images, graphs, figures, text, or videos. The flexible and modular platform allows for efficient content modification for a variety of populations [39,40]. Using a motivational interviewing style, a virtual counselor interacts with participants to provide IMB skills that foster alcohol use reduction or abstinence [41,42]. The virtual counselor is a 3D character named Peedy the Parrot that has over 50 specific actions that can be selected to display interest and empathy and increase participant engagement and motivation with the intervention. Although Peedy is an avian character, it appears anthropomorphic through its animations (eye gaze, facial expressions, and body movements) and script (eg, expressive reflections to user answers).

Recruitment

Study participants were selected using convenience sampling and provided informed consent prior to enrolling. For the in-depth interviews, adults aged 18 years and older with AUD were eligible and were referred to us through ongoing clinic research studies at a government tertiary care hospital in Pune. AUD was defined for males as having an Alcohol Use Disorders Identification Test–Concise (AUDIT-C) score of 4 or more and for females having a score of 3 or more on the AUDIT-C [43]. Between June and November 2018, we approached 15 eligible individuals, and 10 agreed to participate. Those who refused (n=5) were all males and were unable to participate for the required hour to complete the interview. We also conducted 3 focus group discussions: 1 with members of an Alcoholics Anonymous (AA) group (n=12) and 2 with HCPs from a tertiary care hospital (n=21), including counselors, nurses, and clinicians. All HCPs who participated in the study work in same hospital where the study was conducted. Focus groups were conducted in the afternoon when their outpatient department work was over. All in-depth interviews and focus groups were conducted in an easily accessible, private conference room at a hospital in Pune, India.

Data Collection Procedures and Analysis

Focus groups were moderated by a study co-investigator (NS), who is an Indian female medical anthropologist, and assisted by the study coordinator (GD), who is also an Indian female medical anthropologist, using an interview guide based on topics reviewed in the CBI and adaptation procedures. Focus groups and in-depth interview participants viewed the intervention, which was displayed screen by screen on a white board using a projector. Both the virtual counselor's speech and the information on each screen was interpreted from English to the local language, Marathi, by GD and NS. After watching each screen, NS and GD obtained participant feedback using the

semistructured field guide. On CBI screens where the virtual counselor asked questions with multiple choice answers, participants of HCP focus groups chose the most common option they encountered in their clinical practice, while AA focus group and in-depth interview participants chose the options applicable or suitable to them. We then discussed the feedback provided by the virtual counselor, Peedy, and reviewed the other answer options and feedback. We sought further suggestions and recommendations from the participants.

The main areas of inquiry expected were as follows:

- Participants were asked “How acceptable is this virtual computer-based counselor to reduce drinking?” HCPs were asked “What are the factors in the acceptance or nonacceptance of this computer-based virtual counselor–delivered counseling tool in a clinical setting?”
- Participants were asked about intervention content acceptability and areas of needed adaptation: “What do you like most about this app? Why? What that you did not like? Why?”
- HCPs were asked about the feasibility of implementation factors: “What barriers and facilitators do you expect to uptake and use with HIV/TB patients in clinical settings?”

All in-depth interviews and focus groups were audiorecorded and notes were taken by GD. In-depth interview and focus group texts were then transcribed in the local language and translated into English. A coding guide was prepared based on inductive and deductive codes. All transcripts were coded by GD and reviewed by NS, and data were analyzed in MAXQDA 12 (VERBI GmbH) software using the framework approach [44].

Results

Overview

The majority (9/10) of in-depth interview respondents were males with a median age of 41 (IQR 30-56) years. In-depth interview participants included people with TB (6/10), HIV (2/10), HIV/TB co-infection (1/10) and no HIV/TB (1/10; [Table 1](#)). Of our 2 HCP focus groups, 1 was conducted with counselors working in HIV and TB research studies who were predominantly female (female to male ratio 12:1). The other focus group was conducted with HIV clinic HCPs and was majority male (female to male ratio 3:6), including 2 counselors, 3 nurses, 2 doctors, 1 pharmacist, and 1 psychologist. Participants of the AA group were all male (12/12) and did not have a TB or HIV diagnosis. Results were organized into 3 domains reflecting the aims of the study: (1) virtual counselor acceptability, (2) intervention adaptability, and (3) feasibility of CBI in clinic settings. Results are illustrated using direct quotations from the respondents.

Table 1. Characteristics of the study participants.

Characteristics	In-depth interviews	Focus group discussions		
		Health care providers from HIV clinic	Research counselors	Alcohol Anonymous group members
Participants	10	9	13	12
Age (years), median (IQR)	41 (30-56)	36 (25-64)	38 (24-43)	53 (30-63)
Gender				
Male	9	6	1	12
Female	1	3	12	0

Domain 1: Virtual Counselor Acceptability

First, the majority (8/10) of in-depth interview participants found the Peedy the Parrot virtual counselor to be acceptable and felt comfortable honestly answering alcohol-related questions.

Yes, liked it very much. I have not seen anything like this before and nobody explains things to you so well. Nobody makes you sit and speak like this. (female, in-depth interview participant)

Moreover, some respondents stated a preference for a virtual character over a human counselor.

It is better with the bird than [a person such as a] counselor as you can openly discuss with the bird. (male in-depth interview participant)

HCP focus group participants also found the virtual counselor to be acceptable and reported that they would expect patients to trust the information from the virtual counselor, noting the advantage of confidentiality of a virtual counselor-guided discussion.

App is good and patients will be more confident to share information with the app as it doesn't ask them their name, and they will feel that information will remain confidential. The patient may also trust the information given by Peedy. (female HCP focus group participant)

The predominantly male HCP and AA focus group participants felt that a male virtual counselor with a loud, confident voice would be more effective in facilitating disclosure of alcohol use and alcohol use-related consequences.

So, maybe a male voice or male person to hear them out might help them understand that it's more nonjudgmental, it's more, you know, unbiased in a way. (male HCP focus group participant)

If we look at it statistically, then substance use is more prominent among the male gender... So, when they are talking and a female is guiding them it might make them uncomfortable...like you know, make it difficult for them to address certain things. (male AA focus group participant)

By contrast, the predominantly female HCP focus group participants preferred a female virtual counselor because a female in the role of caregiver is more acceptable and patients

would feel more connected to a human character than to a bird character.

...a human face especially female instead of a bird as a virtual counselor because patients would feel more connected to a human than a bird. People better link it to female 'caregiver' of family and may feel more comfortable. (female research counselor focus group participant)

In-depth interview participants had no gender preference; although they liked the bird as counselor, few preferred a human virtual counselor over an animal/avian virtual counselor.

It is better with both (male/female [virtual] counselor), nothing different. Both are good. (male in-depth interview participant)

Finally, nearly all respondents agreed that it would be important for a live human counselor to be present in the session. Virtual counselors (whether avian/animal or human characters) were noted to have limitations in communication whereas a human counselor could ensure that the information was more persuasive and compelling.

Virtual counselor is less likely to have convincing power. This is because while talking it may not know which point should be stressed upon, it will speak in the same frequency, in the same tone. It will not have feelings and emotions based on the respondent's responses. (male HCP focus group participant)

Only thing is [virtual counselor] will not have that human feel that they can have with counselor. However, it is good to use it in combination with [a human] counselor. (female research counselor HCP focus group participant)

Domain 2: Intervention Content Acceptability and Areas of Needed Adaptation

In-depth interview and focus group participants made several recommendations for adaptations to the CBI key characteristics in the areas of drinking triggers, standard drink definition, and IMB skills needed to reduce alcohol consumption. Table 2 shows these recommendations and associated quotations. For local adaptation, participants advised incorporating triggers such as locality and family background, relief from physical pain and stress from family, and type of work. More information was deemed necessary on types of local alcoholic drinks.

Notably, there was a mixed response to the virtual counselor's discussion of the effect of alcohol on HIV/TB and on gradual versus immediate cessation of drinking. The in-depth interview participants, although diagnosed with HIV or TB, tended not to see the connection between alcohol use and poor health outcomes, whereas AA and HCP focus group participants agreed with the effects and suggested adding more information. HCP and AA focus group participants were concerned that patients tend to have a limited understanding of the impact of alcohol use on HIV and TB drug interactions and on health outcomes such as sexual dysfunction and liver and kidney function. They observed that this knowledge potentially could motivate reduced consumption. Additionally, both in-depth interview and AA focus group participants tended to advocate for abstinence rather than reduction in use of alcohol. Finally, respondents suggested

adding behavioral skills to engage participants in (1) religious and spiritual events, (2) learning to refuse alcohol offered by peers, and (3) the willpower to stop drinking alcohol.

Finally, it was suggested that the CBI will be more acceptable if it contains illustrations, especially to aid nonliterate users. Twenty focus group participants suggested that adding more images of major CBI points in addition to the oral presentation by the virtual counselor could improve comprehension and effectiveness.

If [CBI] shows "under what good things can happen if you quit alcohol" that a man after quitting, enjoying with family and having fun with children," it would have a good impact. (male HCP and AA focus group participant)

Table 2. Qualitative data presentation using the information, motivation, and behavioral skills model.

Computer-based intervention domain	Agreement with current content	Data source	Suggestions for adaptation	Quotations
Information				
Reasons for drinking; triggers	All participants agreed with the list of triggers with few adaptations	IDI ^a	Type of occupation or work could be added as the reason for drinking	“I work in a morgue and it is not possible for me not to drink. I daily deal with dead bodies so I used to drink every day. My work is like that.” (male participant)
		FG ^b : AA ^c and HCP ^d	Include the influence of the surrounding environment, family background, and locality as major contributions to unhealthy alcohol use, including: Indian culture, drinking alcohol gives confidence, depression due to sexual relationships in HIV discordant couples, alcohol as a pain reliever, feeling of inferiority complex, unemployment, and sometimes to avoid family responsibilities	“Ninety percent of alcoholics are children of alcoholics only. That’s my experience. Dysfunctional family, environmental reasons...environmental reasons mean suppose if a person born in a settlement that has all drunkards around him; so, he inherits that. So, he finds it very common and engage in drinking habit.” (male AA participant) “I used to drink so that no one would ask me to do any work as I am ‘drunk.’ This was an easy excuse to run away from my household responsibilities.” (male AA participant) “If you drink you feel on top of the world and gain confidence to talk and do things you would not otherwise do.” (male HCP participant)
Definition of standard drink; safer and risky levels of alcohol use	Very useful information	FG: AA and HCP	Participants suggested the addition of the term Tadi, which is a popular local alcohol drink; its measuring unit is a balloon (1 balloon=250 mL) Linguistic adaptation advised such as use of local terminologies for alcohol like Tadi and daru Participants mentioned that the information about standard drinks mentioned by Peedy is correct in the western context; however, in an Indian context, people may not be aware of the term ‘standard drink’ and the alcohol content in one standard drink	“If they know how much [drink] they take usually and know how much [alcohol/standard drink] there is in one peg [unit], it will benefit them in terms of reducing the quantity of drink.” (female HCP participant)
Association with disease	Agreed	IDI	In IDIs, participants were not able to link their disease condition with alcohol use; they reported that alcohol is not related to their disease condition	“...not because of drinking alcohol but because of sharing used glasses [of alcohol], disease [TB ^e] spreads.” (male participant)
		FG: AA and HCP	All participants mentioned that TB disease is related to alcohol.	“Alcohol leads to TB for sure...” (male AA participant) “Alcohol use will impact their [patients’] adherence to medicines and their visits to the clinic.” (female HCP participant)
Motivation				
Negative consequences of drinking	Agreed with consequences reported by Peedy	FG: AA	Some negative consequences of alcohol drinking such as health issues and absence at the workplace Some additional consequences reported by them are sexual dysfunction, effect on family relationship, and the loss of confidence	“Absenteeism (absence) from the job or unable to perform well at their job.” (male AA participant) “Sexual inability to perform 90% inability to perform [sexual activity]... Work area; going late, leaving early, taking leaves, again in financial area, taking loans, taking loan from society. And important consequence is, we commonly see that.” (male AA participant)

Computer-based intervention domain	Agreement with current content	Data source	Suggestions for adaptation	Quotations
		IDI	Effect on kidneys, sadness, fighting, weakness, and lack of concentration One of the IDI participants reported that alcohol drinking has more disadvantages	“There were no benefits [of alcohol use]. Disadvantages were more. Even in the tension, after drinking I used to get more tensed.” (male participant)
Reasons for drinking	Agreed with consequences reported by Peedy	IDI	Participant mentioned that he felt relaxed after drinking alcohol	“After drinking alcohol at least for some time, you feel comfortable. You feel relaxed from the stress, like this.” (male participant)
Behavioral skills				
Cognitive behavioral techniques to reduce/ quit drinking (delay, discuss, and do something else)	All participants agreed with behavioral techniques suggested by Peedy (delay, discuss, and do something else)	FG: AA and IDI	All except one suggested immediate cessation of alcohol Include religious and spiritual therapy FG participants also highlighted that the patient’s willpower along with peer guidance is very important for quitting Some participants also mentioned that the first sip itself is dangerous so it is important to avoid that craving for first sip and try to keep your stomach full of food. As narrated by one of the AA FG participants	“It is like this if a person drinks two times in a day and drink one bottle at one time then he should have half a bottle, If one drinks three or two times then he should drink only once in a day if he wants to stop drinking. I have stopped drinking like this only [gradually and not suddenly].” (male AA participant) “Not to drink at all is the only answer for that. Even if I start drinking, I drink 3 to 4 bottles [at a time]. I think it is appropriate to stop [instead of reducing it gradually].” (male IDI participant) “You can also tell patient that even after so much of drinking you are alive that means God want you to live and live a better life. He is giving you another chance to live good life. Patient will start believing. Belief in spiritual power is very important.” (male AA participant) “If we become engaged in something else then thoughts about drinking doesn’t come to mind.” (male AA participant) “One suggestion was sharing your drinking limit with friends before drinking. It could help. Your friend should stop you once you complete your drinking limit.” (male AA participant) “I told you that alcohol is nothing but sugar [level in blood]. So, if I was drinking till yesterday and suddenly stopped taking it from today, then my people [peers from AA group] tell me that you should drink electrolyte powder [salt and sugar powder to be mixed in water and taken for treatment of dehydration], eat sweets, as much as you can, so that your glucose level will be maintained [and you do not crave for alcohol] slowly you [alcoholic person] become okay, not only psychologically but also physically. We have seen this.” (male AA participant)

^aIDI: in-depth interview.

^bFG: focus group.

^cAA: Alcoholics Anonymous.

^dHCP: health care provider.

^eTB: tuberculosis.

Domain 3: Feasibility in Clinic Settings

All participants noted several features of the CBI that would make it feasible for administration in a clinic setting. They reported that intervention duration (about 20 minutes) and amount of information provided were appropriate for use in medical settings. Most in-depth interview participants (8/xx) found the CBI easy to operate. Some in-depth interview

participants (2/10) reported that if they were required to use a cellphone instead of the tablet for the intervention, this would be a barrier as some people did not have an Android phone and were not familiar with its operations.

Yes, will help if it is on mobile because even after drinking, everyone is on the mobile. (male in-depth interview participant)

I mean, I cannot operate touch screen mobile. (male in-depth interview participant)

AA focus group participants noted an advantage to the CBI was its capacity for standardized administration, which may not necessarily occur with a person-delivered intervention.

From this [app], the information will be provided systematically and uniformly and the patient doesn't feel that these people [counselors] are telling their thoughts. Means this is standard and content will be there. (male AA focus group participant)

HCP focus group participants also identified challenges to intervention implementation. Currently with no alcohol treatment services in their clinics, a CBI could result in increased provider workload if providers needed to be physically present to assist while patients are using the software program.

We will give them an appointment. It may affect their work. They cannot take leave to visit the clinic. Our time is 9 AM to 5 PM and they have the same working hours. Sometimes on these lines, [a patient] may drop out. (female HCP focus group participant)

In addition, they noted that patients have limited time in the clinics and often limited reading literacy.

They [the patients] should be able to read options at least [the patient should be literate enough to read the options presented in the CBI]. (female HCP focus group participant)

Finally, other challenges highlighted were availability of internet access in clinics, confidential space for counseling during outpatient hours, and troubleshooting technical problems. However, they also mentioned that such patients may be handled by appointment in the afternoon time in the clinic.

Discussion

Principal Findings

Computerized interventions delivered by a virtual counselor can reduce unhealthy alcohol use among people with HIV in the United States [36] and with adaptation may show promise in India among patients with HIV or TB, where unhealthy alcohol use is also prevalent. Using 10 in-depth interviews and 3 focus groups, we analyzed the components of a US-developed CBI. Our study findings suggest that HIV and TB patients found Peedy the Parrot to be acceptable as a virtual counselor. Using a virtual counselor rather than a person was seen as an advantage to foster disclosure of alcohol use and provide confidentiality, a demonstrated advantage of CBIs [45]. Virtual counselors are accepted as counselors if they are sufficiently anthropomorphic [46] and empathic, which Peedy was programmed to be. AA and HCP focus group participants specifically suggested that a human virtual counselor (versus animal/avian counselor) could improve acceptability and efficacy of the intervention. This observation reflects an active question in the human-computer interaction literature as to the relative significance of anthropomorphism and realism of virtual agents in fostering connection between users and content [47]. A related feature of virtual counselor evaluation was its optimal gender. In this

study, all participants of the AA group believed that a male virtual counselor could facilitate greater disclosure and comfort because unhealthy alcohol use is predominantly reported among men in India. By contrast, the mostly female HCP focus group participants had a preference for the female gender for the virtual counselor.

Comparison With Prior Work

Such differing evaluations between the HCP and AA focus groups align with findings of numerous studies showing that people tend to prefer congruence with their virtual counselors [48,49]. Our findings underscore the importance of providing choice in a virtual counselor to increase engagement, interest, and comfort in interacting with intervention content and the importance of examining choice in improving alcohol use outcomes [50,51].

The CBI content was rated highly, showing the generalizability of evidence-based, core behavior change components; however, additional key content was identified for inclusion. All study participants suggested adding drinking triggers (influence of surrounding and locality, type of occupation, avoidance of responsibilities) and adding motivators (peer counseling and willpower). Study participants also recommended that the CBI define a standard drink of alcohol for the local setting. As there is much variation in beverage-specific drink size and types of alcoholic drinks across regions in India, local standardization for alcohol interventions is imperative for this CBI [52].

Importantly, there were areas of discrepancy between the HIV/TB patient, HCP, and AA focus groups. The focus groups wanted more information provided on the well-established link between harmful effects of alcohol on HIV and TB health outcomes, whereas HIV/TB patients rejected the link between alcohol and poor HIV/TB health outcomes.

In cessation versus reduction of alcohol use, HIV/TB patients and AA focus groups argued for immediate cessation for all patients, although it is well established that gradual cessation is the medically recommended approach if there are concerns about alcohol withdrawal [1]. Such discrepancies reflect the larger challenge to present credible and persuasive but often unwelcome health information. Many CBI nuances such as visual design and personalization, unrelated to the quality of the health information, are being explored to influence credibility judgments that subsequently influence acceptance of health information [53,54]. This suggests that further refinement of our CBI may be needed to incorporate this emerging evidence base.

While our study found that CBI delivery in government HIV and TB clinical settings is feasible, most respondents believed that it should be delivered in the presence of a counselor or therapist and not as a stand-alone therapy. This qualitative finding corroborates a recent meta-analysis [30] showing that human-supported interventions were more effective than fully automated interventions in reducing mean weekly alcohol consumption among adults with unhealthy alcohol use. In virtual counselor-based care for mental health, both clinicians and participants preferred digital technology as a complement to, rather than a replacement of, face-to-face treatments [30,54].

CBIs seem to offer advantages over person-delivered care; however, future investigation will explore these advantages. High fidelity, for example, is presumed; however, it can be attenuated by user inattention to or misinterpretation of intervention content [55]. Incorporating standardized evaluation of human-computer interaction measures will be essential to ensuring fidelity. A second area of future investigation will be to routinely identify the active mechanisms of behavior change. So far, CBIs have varied in their incorporation of evidence-based theory, which limits ability to identify effective components of interventions [56]. Finally, as the accuracy of transdermal alcohol sensors develops, CBIs can be paired via mobile phone to provide needed on-demand delivery of alcohol treatment [57].

Limitations

A limitation of the study is that currently the CBI is available only in the English language. This necessitated interpretation of the virtual counselor dialog by the authors in the in-depth interview and focus groups. This may have fostered the perception of many respondents that the CBI (apart from

technical concerns) could not be effectively delivered without the physical presence of a live counselor. Another limitation of the CBI is that provisions must be made for limited reading and technical literacy. In the hospital setting, this would mean that a minority of patients would attend CBI on an appointment basis for assistance from staff. This could potentially limit administration, especially during busy clinic hours. It may be that future iterations of this CBI include more visually based intervention material that is even simpler to operate.

Conclusions

In summary, CBI appears to be acceptable to HCPs and people with HIV and TB and adaptable to an Indian clinical setting. This promising approach to alcohol counseling based on the IMB model is uniform, structured, organized, and provides intervention fidelity. If effective, CBI would result in not only increased access to evidence-based AUD interventions [58], which are currently not available in Indian HIV/TB clinical settings, but also to improved clinical outcomes and quality of life among people with HIV and TB with unhealthy alcohol use.

Acknowledgments

We thank the study participants for their immense contribution. This study was supported by a Johns Hopkins Center for AIDS Research Award to NS.

Authors' Contributions

The authors NS, AD, SRC, AG, GC, and HH conceived the study. NS, GD, MS, and SS prepared data collection tools and implemented the study. NS, GD, GC, and HH contributed to data analysis and data interpretation. AG, SRC, GC, HH, MS, SS, and AD critically reviewed the manuscript and provided feedback. All authors approved the manuscript. Abstract

Background: Digital technologies and mobile interventions are possible tools for prevention initiatives to target the substantial social and economic impacts that anxiety, mood, and substance use disorders have on young people.

Objective: This paper described the design and development of the *Mind your Mate* program, a smartphone app and introductory classroom lesson enhancing peer support around the topics of anxiety, depression, and substance use for adolescents.

Methods: The development of *Mind your Mate* was an iterative process conducted in collaboration with adolescents (n=23), experts, school staff, and software developers. The development process consisted of 3 stages: scoping; end-user consultations, including a web-based survey and 2 focus groups with 23 adolescents (mean age 15.9, SD 0.6 years); and app development and beta-testing.

Results: This process resulted in a smartphone peer support app and introductory classroom lesson aimed at empowering adolescents to access evidence-based information and tools to better support peers regarding mental health and substance use-related issues. The program contains links to external support services and encourages adolescents to reach out for help if they are concerned about themselves or a friend.

Conclusions: The *Mind your Mate* program was developed in collaboration with a number of key stakeholders in youth mental health, including adolescents. The resulting program has the potential to be taken to scale to aid prevention efforts for youth mental health and substance use. The next step is to conduct a randomized controlled trial testing the feasibility, acceptability, and efficacy of the program.

Introduction

Background

Mental health and substance use problems are common in the general population and increase across childhood and adolescence [1]. They are the leading cause of disability among young people worldwide [2], causing substantial impairment

both during adolescence and later in life. Recent evidence indicates that mental health problems among youths are worsening, with data worldwide showing a historic rise in rates of depression and emotional problems among recent cohorts of youths, even before the COVID-19 pandemic [3-5]. Alongside access to treatment, effective and novel prevention efforts are needed to avert the costs and rising tide of poor mental health among youths. The use of web-based technologies and mobile

health (mHealth) interventions provides a possible avenue for large-scale prevention initiatives.

Despite the impact and early onset of mental health and substance use problems, most young people do not seek professional help [6,7]. Two key barriers to help-seeking are stigma around accessing mental health care and an attitude of self-reliance [8,9]. When asking where they would turn for help, a large annual survey of Australian young people consistently found peers to be the number 1 reported source of support for young people in the previous 4 years [10-13]. Young people with mental health problems are also most likely to seek help from peers and family ahead of health professionals [14]. Peers play an important role during adolescence, helping shape identity as young people develop increasing independence from their family unit [15]. Peers are also uniquely positioned to notice behavioral or emotional changes in their friends, although many are unequipped to approach or support a friend showing early symptoms of mental health difficulties [16]. Therefore, it is important that young people are given the appropriate skills and knowledge to support peers regarding mental health and substance use in a format that is accessible and engaging to them. A systematic review of existing school-based peer interventions showed that, despite the widespread use of peer interventions, there is a lack of evidence demonstrating improvements in mental health and well-being [17], although 1 face-to-face adolescent peer-training mental health intervention (Teen Mental Health First Aid) demonstrated promising improvements in mental health literacy and intentions to seek help [18].

Increasingly, communication between adolescent peers is occurring on the web, and almost all adolescents in high-income countries now own or have access to a smartphone [19-21]. Adolescents report regularly using their phones to stay in touch with friends and access information [22]. Using smartphone devices and the internet to improve engagement and delivery of mental health care has been heralded as a potential avenue to take mental health prevention and early intervention programs to scale, particularly for the current generation of young people whose use of technology is ubiquitous in everyday life [23]. Over the past decade, there has been a proliferation of mobile app technologies for mental health. Most of these apps focus on self-help for the app user, such as tracking mood and using cognitive behavioral therapy or mindfulness techniques. However, the most commonly searched for mental health and substance use apps have limited evidence of effectiveness in improving mental health outcomes [24].

Although mental health apps have proliferated, there is a lack of evidence-based interventions aiming to upskill adolescents regarding supporting peers in relation to mental health and

substance use. A literature review of mHealth peer support interventions showed a lack of research evaluating the use of apps in peer support for mental health [25]. When the search was broadened to include health outcomes more generally, it was found that, although youths have pre-existing digital comfort and benefit from peer support, most of the existing commercial and research-based health apps often encounter problems with engagement, which in turn hinders intervention efficacy [25]. A peer support app named the *Companion App* was evaluated in a control group study in Sweden [26]. It aimed to reduce unemployment-related stress among adolescents while fostering peer support through discussion groups. Although the adolescents endorsed the concept of the app, it had no effect on stress levels or the perception of social support, possibly because of a lack of engagement and inconsistent use of the app by the intervention participants during the trial [26]. It is well-recognized that involving end users of technology in the design process results in higher engagement and satisfaction levels [27-29]. For this reason, it is crucial to include the voices and perspectives of adolescents themselves alongside other key stakeholders from the start of the development process for novel web-based and app mental health interventions [28].

Objective

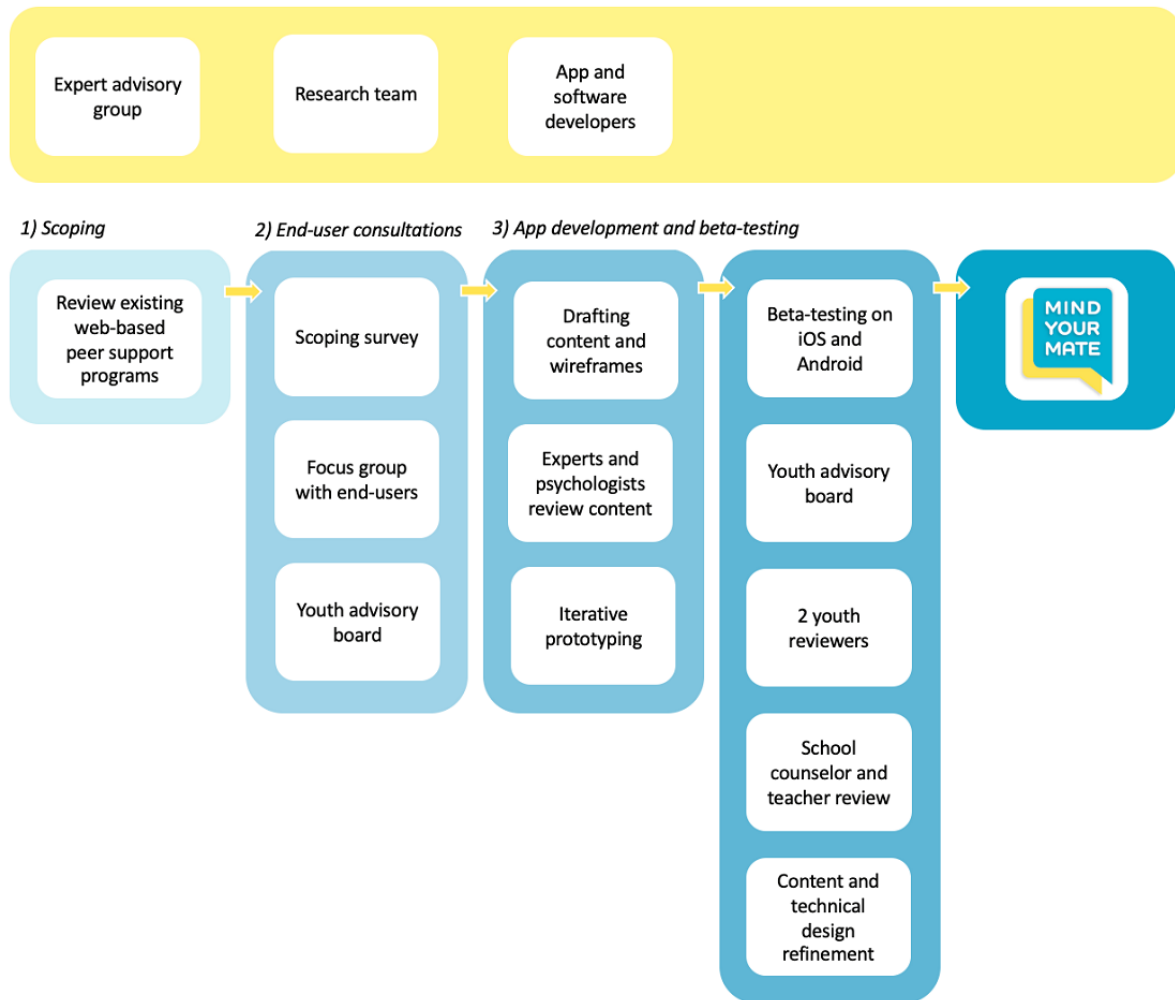

In summary, despite very high levels of web-based communication among adolescents and the fact that peers are commonly the first port of call for young people experiencing mental health problems, there are currently no effective web-based interventions to assist adolescents to better support their peers regarding mental health. To address the need for an effective, evidence-based mobile intervention to assist adolescents in better supporting friends regarding mental health and substance use, we developed the *Mind your Mate* program. This paper describes the co-design process of the program, which consists of a classroom lesson plus a companion smartphone app.

Methods

Overview

The development of *Mind your Mate* was an iterative process conducted in collaboration with adolescents, experts, and software developers. It drew on principles from the *create* phase of the accelerated creation-to-sustainment model framework [30]. As illustrated in Figure 1, the codevelopment process consisted of three stages: (1) scoping the existing app landscape, (2) end-user consultations, and (3) app development and beta-testing. The development process incorporated user-centered design principles [31].

Figure 1. Overview of the *Mind your Mate* development process.

Stage 1: Scoping

As part of the formative process, we conducted a scoping review of existing peer support mobile apps, aiming to identify common features, functionality, and gaps. We searched for evidence-based peer support programs that focused on youth mental health or substance use across both the Apple App and Google Play stores. Search terms included “peer support,” “supporting friends’ mental health,” “friends’ wellbeing,” “youth mental health,” “wellbeing chats,” “friends’ wellbeing check,”

“alcohol and drug wellbeing,” and “peer support for quitting.” Apps that fell under our search terms and were directed at youths were included in our scoping review (Table 1). The inclusion criteria were youths as the target audience and at least one of the following: mental health or alcohol and other drug education, focus on helping others, or interpersonal communication support (structured guidance for conversations with others and a forum for users). Owing to the limited number of youth peer support apps, we did not exclude self-help apps that met the criteria.

Table 1. Scoping review of existing peer support apps.

Included features	Selected apps					
	Chats for life	The Check-In	SAM: Self-help Anxiety Management	Stigma	Moodnotes	Woebot
Focus on helping others	✓	✓				
Self-help for carer						
Structured guidance for conversations with others	✓	✓				
Reminders to follow up with others		✓				
Password and privacy measures	✓		✓	✓	✓	✓
Crisis hotlines	✓	✓	✓	✓	✓	✓
Forum for users			✓	✓		
Safety plan or information for emergencies	✓		✓	✓	✓	✓
Customizable features						
Inclusion of mental health or AOD ^a education	✓		✓		✓	✓

^aAOD: alcohol and other drugs.

Stage 2: End User Consultations

To ensure that the *Mind your Mate* program was appropriate and tailored to the needs of adolescents, a web-based scoping survey and a face-to-face focus group were conducted with the target audience (adolescents aged 15-16 years).

Participants and Procedure

Following the advertisement of the study through the researchers' networks, 2 independent schools (one male-only and one female-only) in Sydney, New South Wales, Australia agreed to participate in a short web-based survey and in-person focus group. School-based recruitment was used for convenience and because of the implementation model using school delivery. Following permission from the school principal, 1 Year 10 class per school was invited to take part in a short web-based survey followed by a focus group conducted at their school facilitated by 2 experienced researchers (AFB and JD). Each focus group was conducted in a quiet classroom and lasted approximately 50 minutes. Both active parental consent and participant consent were obtained before the survey and focus groups. A semistructured format was used during the focus group sessions. The discussion guide used to structure the focus group sessions can be found in [Multimedia Appendix 1](#).

In total, 23 high school students aged 15 to 17 years (mean 15.9, SD 0.6 years; 14/23, 61% female) from 2 independent schools completed a confidential web-based survey through a secure web application, Qualtrics (Qualtrics International Inc), hosted on the server of the University of Sydney. All students then participated in a focus group (14/23, 61% in one focus group and 9/23, 39% in the other). Feedback was sought about key components, usability, and design during the focus groups, and the discussions were recorded using an audio recorder. The participants were entered into one of 2 draws to win an Aus \$50 (US \$35.49) Prezee gift card as reimbursement for their participation.

Measures

The participants completed a 20-item web-based survey that contained multiple-choice, Likert-scale, and open-ended questions (for the full survey, see [Multimedia Appendix 2](#)). The participants were asked to indicate whether they owned a smartphone; if yes, they were then surveyed on their use of web-based mobile apps (eg, *what are the top five apps your regularly use on your phone?*). They were also asked about their preferences around accessing information to support their peers when they might be feeling anxious or low or using alcohol or other drugs. Finally, the participants were asked about their likelihood of using a mobile app on this topic.

Analysis

Descriptive analyses were performed on the quantitative questions from the scoping survey using SPSS (version 25; IBM Corp). The focus group recordings were transcribed verbatim by a research assistant (SS). For both the qualitative responses from the scoping survey and qualitative responses from the focus groups, general inductive analysis [32] was conducted by 3 members of the research team (SS, AFB, and LB), who independently coded segments of text from the responses or transcripts. Common subthemes were generated from segments of the text. The coders then collectively arranged the subthemes into primary themes to create higher-order explanatory thematic groupings. The coding categories were then simplified and merged into overarching themes capturing the key themes and subthemes. The 3 coders discussed any discrepancies until all coders agreed on the major themes. This analysis method was selected for its ability to identify patterns in qualitative data without reflecting researcher bias or familiarity with the subject matter [33].

A similar inductive thematic analysis approach was used to code the open-ended responses of the Qualtrics scoping survey that the focus group participants completed. Open-ended responses were coded by 2 independent coders (SS and LB), who were blind to one another's coding. Discrepancies were resolved via consensus, and themes and subthemes were

generated to capture participant responses. The framework was finalized with the assistance of visually organizing the responses on a digital whiteboard platform, Miro (Miro Corporation), and they are displayed in [Multimedia Appendix 3](#).

Stage 3: Program Development and Beta-Testing

The design and content of the *Mind your Mate* program were informed by the aforementioned scoping review, survey, and focus groups.

Mental health content was adapted from the Mental Health module of the Climate Schools and Our Futures mental health prevention program [34]. After the initial drafting and adaptation of the content by the lead researcher (LB), each section was independently reviewed by 2 experts in either the mental health or drug and alcohol prevention field (researchers with PhD qualifications) and 2 registered psychologists. These experts were recruited from the researchers' networks. Revisions were made based on suggestions from the experts.

Throughout the development process, we twice consulted the Youth Advisory Board (YAB) of the National Health and Medical Research Council Centre of Research Excellence in Prevention and Early Intervention in Mental Illness and Substance Use. The YAB comprises a representative group of young people who provide comments and feedback on research drawing on personal experiences. During the initial consultation, the YAB provided feedback on the initial draft content and features and the program name, provided suggestions, and identified gaps in the initial program proposal. Second, they reviewed the early designs of the program app and were invited to review a beta version of the app, providing feedback and suggestions for improvements.

The first beta version of the app was scripted in both the iOS and Android operating systems. Once a working beta version of the app had been developed, it was reviewed by 2 end users (aged 16-17 years), a high school teacher and a school counselor over a period of approximately 2 weeks. The teacher and school counselor were selected from a convenience sample and provided perspectives on implementation within the school setting. These stakeholders were asked to rate what they did and did not like about the app, comment on the suitability of the app for Year 9 and 10 students, comment on what they would change, and report on any bugs or glitches. Revisions were

made in response to end-user feedback to improve the app before its public release on the iTunes and Google Play stores. A further round of testing and refinement by the research team (lasting approximately 2 months) ensured that all changes were implemented on both the iOS and Android operating systems.

Ethics Approval

This procedure was approved by the University of Sydney Human Research Ethics Committee (2019/723).

Results

Stage 1: Scoping Review Results

The most common features and content covered by existing peer support apps included information about mental health and substance use literacy, inclusion of privacy measures, crisis hotlines, safety plans, and user forums. Although the existing apps typically contained one or more of these features, most did not include all features, and none included self-help information, indicating gaps in knowledge that the *Mind your Mate* program sought to address (Table 1). Only *Chats for Life* [35] and *Check-In* [36] provided functions related to conversing with and helping others. The features of both apps included structured conversation templates, and *Check-In* also included reminders to conduct follow-up conversations. However, both apps lacked support for the app users themselves.

Stage 2: End User Consultations

Focus Group Results

The thematic analysis identified key themes summarized under the 2 broad categories of *peer support* and *app functions and features*. This distinction differentiated between students' personal experiences of peer support and their expectations of a mobile peer support tool.

Under the broad category of *peer support*, subthemes included (1) looking after yourself, (2) barriers to helping friends, and (3) helpful strategies for assisting friends.

Under the second overarching theme, *app functions and features*, seven subthemes emerged: (1) visual aspect of the app, (2) content, (3) functions of the app, (4) engagement, (5) user experience, (6) trust, and (7) dissemination (Table 2).

Table 2. Focus group transcript thematic analysis themes and subthemes.

Theme and subthemes	Examples
Peer support	
Looking after yourself	<ul style="list-style-type: none"> • Manage pressure, responsibility, and expectations for the person who is helping • Tips for dealing with the fear of making things worse or saying the “wrong thing”
Barriers to helping friends	<ul style="list-style-type: none"> • Concerns about respecting and overstepping boundaries • Worry about lingering in the negatives by talking about it
Helpful strategies for assisting friends	<ul style="list-style-type: none"> • Asking for advice. Confiding in a teacher or a close family member they trust • Checking in, recognizing that it is a continuous process with follow-up required
App functions and features	
Visual aspect of the app	<ul style="list-style-type: none"> • Visual content: videos, cartoons, media, and songs • A wall of text leads to disengagement
Content	<ul style="list-style-type: none"> • Understanding what is wrong with a friend leads to more confidence and comfort helping them • Quick access to helplines • Want suggestions on how and who to link their friend to for more support
Functions of the app	<ul style="list-style-type: none"> • Link to other apps should be simple and easy for within-app efficiency (copy and paste text or send via Messenger) • Personalize and customize the visuals (colors) • Checklist
Engagement	<ul style="list-style-type: none"> • A sense of achievement, reward, and competition from games is engaging • Too many notifications can be annoying; no hassling to come back to the app but rather something that catches your attention • Tone within the app should be engaging and empathetic
User experience	<ul style="list-style-type: none"> • Privacy is important: not showing activity to friends, not needing location, and being able to transparently see and control privacy • Participants disagreed about inclusion of a social networking component
Trust	<ul style="list-style-type: none"> • Participants trusted lived experience, influencers, celebrities, and professionals (psychologists and researchers) • Distrust in internet resources as they are nonspecific and outdated and may be wrong
Dissemination	<ul style="list-style-type: none"> • Social media is where participants learn about mental health initiatives • Reduce stigma with influencers and athletes • Participants were more likely to google a problem than search the app store; the website should link to the app

Key Implications for App Development

Looking After Yourself

Participants agreed that young people as supporting peers required specific guidance to manage pressure, responsibility, and expectations. The importance of self-care was also emphasized by participants citing the concerns they had about supporting their peers; for example, “it’s really hard not to feel like all the pressure is on you.” An entire educational module and functions of the app were dedicated to supporting the user in self-care. This included mood trackers and customizable self-care activity lists.

Barriers to Helping Friends

The participants indicated that they would try a variety of responses when concerned about a friend (such as providing distractions “to get it out of their mind,” giving their friend space, and stepping away to respect boundaries) but also cited

key barriers. The participants acknowledged feeling worried about bringing up negative topics and uncertainty around how to start conversations. These concerns were specifically addressed in the educational modules within the *Mind your Mate* app and via a structured conversation planner built into the app to assist with starting and planning conversations with friends.

Helpful Strategies for Assisting Friends

The strategies that emerged were largely related to conversing with a friend, such as tips on how not to interrupt with your own stories. Recognizing changes in mood or behavior, which context is best for a conversation, and how to reach out to an adult were also discussed. Therefore, these topics were included in the app’s educational modules. In addition, recognizing that helping a friend is a continuous process led to app features that reinforced ongoing conversations, such as reminders and scheduling check-ins as functions available in the app.

Visual Aspect of the App

There was broad consensus among the focus group participants that paragraphs of written text would lead to disengagement. It was suggested that visual content (ie, infographics and videos) should be included. In response, recorded videos and animations were created for inclusion in the app and web-based lesson. The animations are consistent with a light and bright theme to visually destigmatize the app so that “people don’t feel negative having [the app] because of the way it’s set up.”

Content

Although some participants reported that they had received some mental health or substance use education before the focus group, many indicated that they would like to know more about “why it happens...the science behind it” as well as a clear pathway or action plan about what to do if they needed to assist a friend. The tone of the app content was positioned as relatively casual and approachable to assist users in gaining confidence when reaching out to friends. Education was presented as a source of empowerment throughout the modules, including quick links to specific topics if a user felt overwhelmed by the information or needed more focused support.

Functions of the App

To guide the user through the process of checking in with and following up on a friend, the participants indicated that checklists that can be edited or interacted with and how-to instructions would be beneficial. They also discussed functions that could improve engagement, such as customizing the color theme and adjusting notification settings—both of which were implemented in the final app.

Engagement

Several key concerns emerged regarding short- and long-term engagement with educational apps. Some participants indicated that they usually deleted an app when it was no longer useful, whereas others said that they would keep an app on their phone just in case. As such, gamification to increase the sense of achievement, as well as staggered release of content, was incorporated to promote deeper engagement with the app.

User Experience

Privacy emerged as a key concern, with most participants being in favor of passwords and transparent privacy policies. However, disagreement arose around creating a social networking aspect within the app; some participants expressed interest in chatting

with peers in the app, whereas some were concerned about how these conversations might be monitored. An additional user experience concern for the participants was whether the app was straightforward to use. Disliked apps were described as follows: “The layout is confusing, everything is blue and white, it’s just hard to use.”

Therefore, iterative prototyping and beta-testing were conducted to facilitate the creation of an intuitive user experience design.

Trust

The participants indicated 2 sources of trust: professionals and public figures. They noted that “half the stuff on the internet you may not trust, it could be wrong.” Specifically, a lack of trust in many mental health apps indicates the importance of emphasizing the evidence-based nature of a program, including promoting the expertise of the developers. Public figures with lived experience were perceived as not only credible but also relevant to the user.

Dissemination

Public figures emerged again as a method of gaining young people’s attention and trust, particularly the potential use of celebrities on social media. The participants indicated that they often learned about mental health initiatives through advertisements and activism on social media. If they were unsure of an issue, they expressed that they were more likely to search for it on the web than to search in an app store, leading to the recommendation that there could be a companion *Mind your Mate* website hosting a clear call to action to download the app.

Scoping Survey Results

Scoping Survey Quantitative Results

Most participants (20/23, 87%; [Table 3](#)) indicated that having access to relevant information about going through *tough times* would be somewhat or very helpful. This agreement was similarly reflected when questioned about alcohol and drug information (18/23, 78%). Access to tips on how to help a friend was also well-supported and translated into support of participants being likely or very likely to access this information through an app (19/22, 86%). Interestingly, only 50% (11/22; [Table 4](#)) of the participants indicated that they thought it was likely that other young people their age would use the app; however, 68% (15/22; [Table 4](#)) were likely or very likely to recommend the app to a friend.

Table 3. Agreement with statements regarding the usefulness of using a peer support mobile app (N=23).

Statement	Response, n (%)				
	Very helpful	Somewhat helpful	Neither helpful nor unhelpful	Somewhat unhelpful	Very unhelpful
How helpful would it be to have access to more information about why young people sometimes go through tough times (eg, they might be feeling anxious, low, or not themselves)?	8 (35)	12 (52)	3 (13)	0 (0)	0 (0)
How helpful would it be to have access to more information about how many young people use alcohol and other drugs (including the effects this can have on them)?	7 (30)	11 (48)	4 (17)	1 (4)	0 (0)
Do you think it would be helpful to have access to tips about how to support a friend who might be feeling anxious, low, or not themselves (including examples of what to say or do)?	13 (57)	8 (35)	2 (9)	0 (0)	0 (0)
Do you think it would be helpful to have access to tips about how to support a friend who might be using or thinking about using alcohol or other drugs (including examples of what to say or do)?	8 (35)	14 (61)	0 (0)	1 (4)	0 (0)

Table 4. Agreement with statements regarding the likelihood of using a peer support mobile app (N=23).

Statement	Response, n (%)				
	Very likely	Likely	Unsure	Unlikely	Very unlikely
Would you access this kind of information via a mobile app?	3 (13)	16 (70)	2 (9)	2 (9)	0 (0)
How likely would you be to use an app like this?	1 (5)	14 (64)	2 (9)	5 (23)	0 (0)
How likely do you think it is that other people your age would use an app like this?	0 (0)	11 (50)	11 (50)	0 (0)	0 (0)
How likely are you to recommend an app like this to a friend?	4 (18)	11 (50)	5 (23)	2 (9)	0 (0)

Scoping Survey Qualitative Results

Overview

The participants wrote about both their favorite and challenging aspects of the mobile apps that they regularly used. Regarding peer support, the participants shared their needs when supporting friends and their preferences for information content and format. Each theme from these results is explained individually in the following sections, and a more detailed summary of the key themes can be found in [Multimedia Appendix 4](#).

Favorite Aspect of Apps

The participants indicated that socializing is a well-liked aspect of their most frequently used apps. This included direct socialization, such as “I can talk to my friends,” as well as indirect socialization, such as “see how [my friends] are going and what they are doing.” Being able to intuitively use these apps also contributes to their place as favorites, with intuitive apps being described as “straight forward” and “smooth.” The enjoyment found in using these favorite apps was described as both entertainment and relaxation.

Unfavorable Experiences When Using Apps

Young people reported several unfavorable app features, including (1) interruptions of use such as glitches, advertisements, and time lags; (2) when an app consumes excessive resources (the participants indicated that their “phone

battery drains very quickly when using TikTok” and that “addictive” apps can use up their data); and some participants reported (3) ambivalence about app use, including comments such as “they are a distraction sometimes” and “some apps [are]...harder to use.”

Helpful Resources When Worried About a Friend

The participants noted a variety of sources for *third party support*, such as counselors, parents, and “another person knowing what I knew about that friend.” Therefore, the content within the *Mind your Mate* program was designed to emphasize the importance of a support network as well as to encourage users to reach out to responsible adults and helplines. Another theme to emerge was *effective ways to help friends*, encompassing information about support methods and specific tips on how someone could support a friend who is struggling. In line with this theme, the need to know how to start a conversation emerged as its own specific concern. Fears of “trigger[ing] something,” uncertainties in how to approach a conversation, and wanting to “know helpful questions” indicated a broad need for assistance in talking to friends. The final *Mind your Mate* program provides scaffolds for conversations as well as checklists to prepare the user for potentially difficult discussions.

What Kind of Information

When asked what kind of information would be useful, the participants' answers fell under the theme *how to have a conversation*. Many had difficult questions that they wanted to ask their friends, such as “why do they use alcohol and drugs?” and “are they being influenced?”. Participants wanted more information about how to ask these questions, as well as how best to respond. They also indicated that they wanted information to discourage substance use, including “evidence and statistics,” as well as ways to “remind them of the consequences.” Therefore, the program content includes educational modules on these topics. *Mind your Mate* also provides extensive resources for users to reach out to a third party as the participants indicated that they wanted to know “where to go, who to tell [and] what to tell them.”

Information Formats

Most participants (19/23, 83%) indicated that they would access information about supporting friends in the form of an app, whereas almost half (11/23, 48%) reported they would also like to see this information presented via a website. A student said the following: “An app would be an ideal format, but a website would be helpful as well.”

Other suggestions included offline visual media, such as a brochure, and web-based visual media, such as YouTube and Instagram posts. In addition, verbal presentations were suggested in the form of workshops, seminars, and school talks. The participants were supportive of the idea of developing an app.

Stage 3: Program Development and Beta-Testing

Overview

Following the user-centered design process, a beta version of the *Mind your Mate* mobile app and web-based classroom lesson was created. End-user consultations and beta-testing of the app and classroom lesson were conducted, and minor updates were made to the app in response. A logic model underpinning the program can be found in [Multimedia Appendix 5](#).

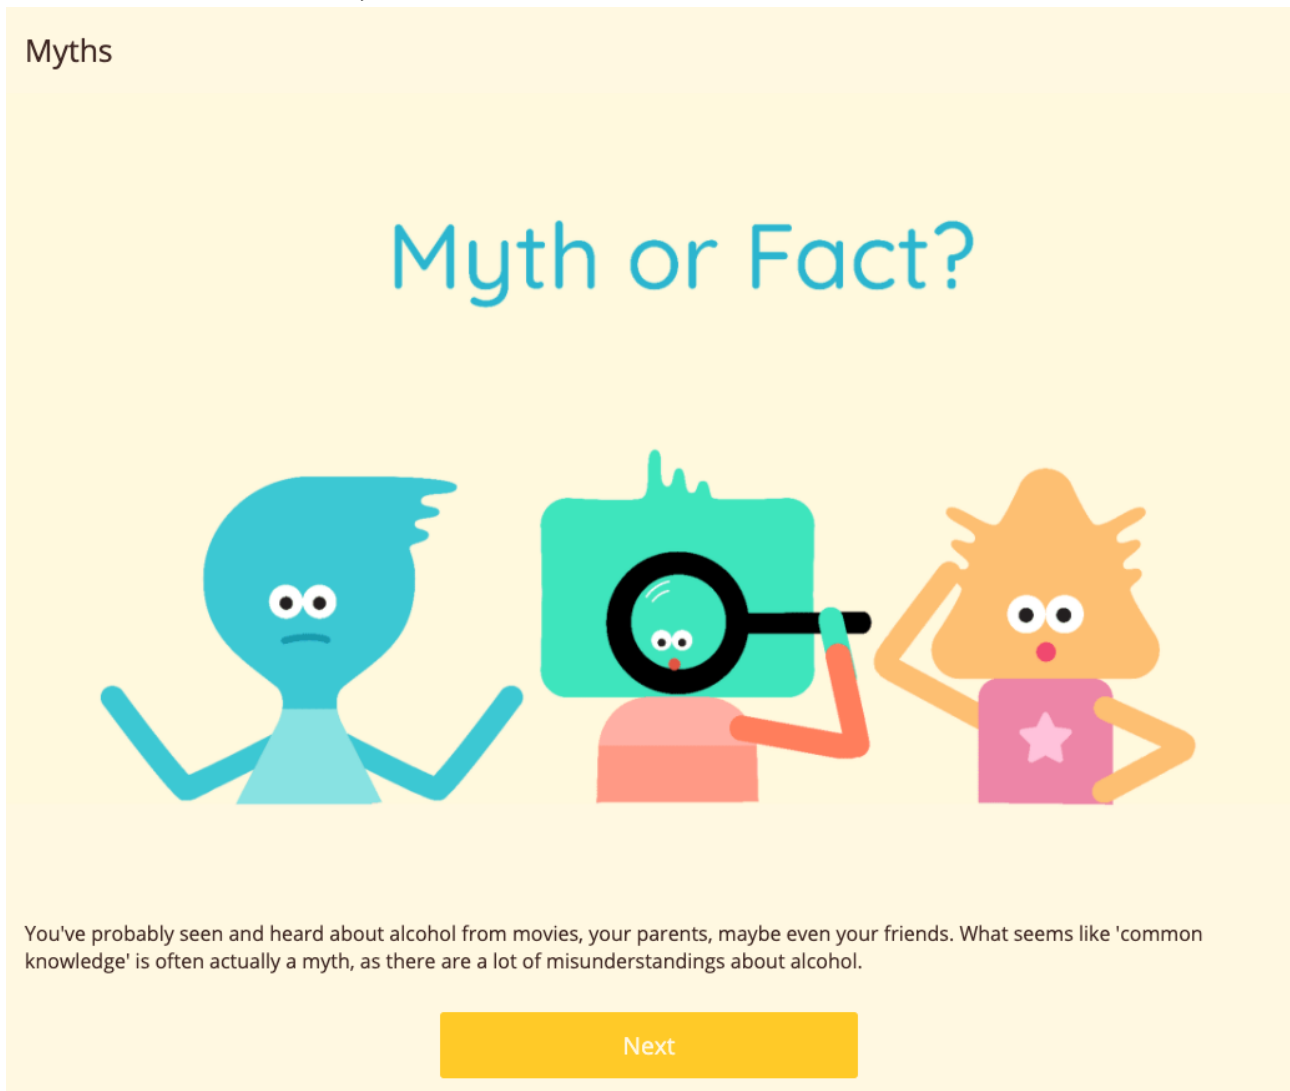

Web-Based Classroom Lesson

One of the most common barriers to mHealth programs are uptake and engagement with the intervention [37]. This is important as higher levels of engagement with digital programs are associated with improved mental health outcomes [38]. Schools represent an ideal delivery avenue to enhance uptake

and engagement with mHealth prevention programs, providing large numbers of adolescents with access to mental health content linked to existing well-being curricula. To aid in the uptake and dissemination of *Mind your Mate*, we planned an implementation model using delivery through high schools, designing a classroom lesson (introducing the concept of mental health literacy and supporting friends) with students downloading and registering on the app at the end of the lesson. This lesson was integrated into regular schooling and linked to the existing curriculum on drug and alcohol use and mental health. This model enabled *Mind your Mate* to be linked to the existing school system and delivered to whole school cohorts, thereby reaching large numbers of adolescents who may not otherwise engage with the app if it was listed on the app stores only. The implementation and sustainability of the program was thought to be enhanced if the intervention had the capability to be embedded into existing structures and systems. This approach was also seen as favorable in overcoming potential biases introduced when digital intervention recruits highly selected samples from potentially large pools of web-based participants (the denominator problem [30]). In prevention, the education and school system are the main contact points for adolescents, in contrast to treatment services and the health care system for treatment interventions. Findings from the digital treatment literature also show enhanced outcomes when human support is included alongside digital technologies [39]; hence, teachers were used to facilitate the web-based lesson and ensure the download of the app, although this lesson could be facilitated by any school staff member.

On the basis of teacher feedback (that student engagement might benefit from an introduction to the app in class) and the aforementioned rationale, we developed a short introductory lesson (approximately 40 minutes long) accessed through a web-based portal (see [Figure 2](#) for screenshots). The lesson's subject matter was derived from content prepared by the lead researcher (LB) and experts, with a focus on normative challenging and active listening techniques. During this lesson, students watch a series of explanatory and narrative short videos, take part in interactive quizzes and classroom discussions, and role-play activities. They are introduced to core concepts of mental health literacy, alcohol use, and peer support. At the end of the lesson, all students are prompted to download the smartphone app and shown a short introductory explainer video on how to use and navigate the app.

Figure 2. Selected screenshot of the *Mind your Mate* web-based lesson.

Mobile App

The mobile app included the following key sections—*Friends*, *Learning*, *Home*, *Self-care*, and *Settings*—displayed as separate tabs within the app (see Figure 3 for screenshots). Table 5 also summarizes the key components of the final app, which include conversation scaffolds and checklists to build users' confidence in discussing mental health and substance use, reminders to conduct follow-up conversations and further the support given to friends, accessible mental health and substance use literacy content, and tracking the user's own mood. The app also includes a button to access helplines, the Australian emergency number, Lifeline, and KidsHelpLine, which are always visible and accessible on every page.

In the *Friends* section, users can create custom profiles for their friends. They are prompted to plan a conversation, send a message, view scheduled conversations that are upcoming, and follow up on past conversations. The conversation planner helps the user scaffold a conversation with their friend, prepares them, and adds the conversation to their phone's calendar. A similar scaffold helps users review and follow up after a conversation has taken place. Example messages can be edited and copied and pasted from the app onto other messaging platforms, not

only helping users start conversations but also creating an optional function for socializing.

The *Learning* section contains the educational modules with quick links to specific topics for easy access. Content is provided in paragraph, dot-point, infographic, animation, and video format. The module icons track the user's progress and award a tick mark after a module has been completed.

The *Home* section features a greeting to the user with the customized avatar. It also presents quick links to educational modules, a reminder of upcoming conversations, and a mood rating function. The landing page redirects the user to various functions of the app.

The *Self-care* section relates to looking after oneself, where users can rate their mood. The most recent mood ratings are displayed, and a broader history can be accessed by viewing a calendar. This allows users to maintain an oversight of their own well-being. To aid a user if they themselves are struggling with their well-being while helping a friend, a curated list of self-care activities can be created. Users can select from a variety of suggested healthy activities as well as write their own custom activities.

In the *Settings*, users can edit their profile information and notification settings. To foster trust in the app and promote its evidence-based nature, the privacy policy and a section about *Mind your Mate* are also available for reading. Users may also customize their experience within the *Settings*. Here, users can

select their avatar's shape, color, and accessories. A name and hobbies can also be selected as well as picking between 2 color themes for the app overall. Personalization was often mentioned throughout the co-design process as an important engagement factor.

Figure 3. Selected screenshots of the *Mind your Mate* app.

Discussion

Principal Findings

This study outlines the co-design process of *Mind your Mate*, an mHealth app developed to assist young people to better support their friends regarding mental health and substance use. The iterative, user-centered design approach included peer and expert reviews at all stages of development, from initial scoping to prototyping and beta-testing. Most of the adolescents surveyed reported that they would find it helpful to have access to more information about mental health (21/23, 91%) and alcohol and drugs (22/23, 96%) and that they would access this information in the form of a mobile app (19/23, 83%). The mHealth app aims to empower young people to develop action plans, set goals, and track progress through access to comprehensive,

evidence-based information and strategies on mental health and substance use.

The initial scoping review showed that most existing peer support mHealth apps include the provision of comprehensive mental health and substance use information, access to crisis hotlines, safety plans, and strict privacy measures. The scoping review also illuminated several gaps in mHealth apps, particularly regarding the lack of evidence of effectiveness, which is consistent with a recent systematic review of mHealth apps in mental health [40] and substance use [41]. In addition, currently no peer support app provides information on self-help for the carer despite this being essential in developing adolescent self-regulation and health promotion skills [42]. The importance of self-help strategies was explored and confirmed during end-user consultations, whereby adolescents identified self-help as important in combating burnout and fear of responsibility

when supporting a friend. Indeed, other studies have found that self-care is lacking in adolescent mental health, substance use prevention, and health promotion [40]. There is evidently a large need for further self-help strategies and information to be delivered to adolescents when substance use and mental health problems begin to emerge.

A significant barrier to the impact of mHealth apps is their low initial uptake and decreasing engagement over time [43]. Consultations with key stakeholders such as teachers and a school counselor informed the innovative 2-part implementation of *Mind your Mate* whereby students are introduced to peer support and self-help via a web-based portal during class time and then prompted to download and explore the companion mobile app. This implementation strategy aims to help break down known barriers to adolescent engagement with mental health and substance use mHealth apps and ensures that the critical and key components of the intervention are delivered to all students within the classroom setting. Consultations with adolescents highlighted the role that celebrities and public figures can play to increase engagement with apps by building trust and credibility in the first instance, and this dissemination strategy has been successfully applied in health areas [44]. Several additional strategies arose to help promote sustained engagement with the app. This included practical tools and strategies such as structured conversation prompts—which few current apps include—customization through color schemes and avatars, gamification through progress levels and rewards, and the frequent release of new content updates.

During end-user consultations, privacy emerged as a key concern, with adolescents requesting passwords and transparent privacy policies. Notably, there were mixed reviews of social networking features in mHealth apps. Although many adolescents reported socializing both actively (messaging) and passively (public posts and activity status) to be a favorite element of their most used apps, focus groups revealed that students worry about breaching their friends' privacy by discussing their concerns with a parent or counselor. By extension, it was determined that students' engagement with the app's core functions may be hindered rather than supported by communication and sharing between users. Thus, because of accentuated privacy concerns around mental health and substance use and the risk of irresponsible socializing, social networking functions were not built into the *Mind your Mate* app.

Acknowledgments

The authors acknowledge Netfront Pty Ltd for programming, web, and mobile development. They would also like to acknowledge the input of project advisory board members Nicola C Newton, Cath Chapman, Louise Thornton, Jennifer Debenham, and Katrina Prior throughout the development process. This study was funded by a Brain and Mind Centre Research Development Grant. LB is supported by a Bruce Edwards Australian Rotary Health Postdoctoral Research Fellowship. The funders had no role in the study design, data collection and analysis, decision to publish, or preparation of the manuscript.

Conflicts of Interest

None declared.

Limitations

The results of this study must be interpreted within the constraints of several limitations. First, the initial scoping review of currently available apps was not a formal systematic review. Nonetheless, the app was designed with well-proven peer support and self-care strategies that help promote well-being for adolescents (goal setting, action plans, and self-monitoring). Second, although end users identified celebrities and public figures as important to increase engagement with the app, resourcing constraints during the first wave of the COVID-19 pandemic hindered this content from becoming a part of the first release of the app. However, a list of influential people to contact was collated, and these features are planned to be included in future iterations of the app. Finally, the iterative development process was informed by several key stakeholder groups whose sampling can be improved upon in future studies. For instance, both schools that participated in the focus groups were same-sex, which may have left a gap in insights on mixed-sex peer relationships. The relatively small sample size also means that the findings from the focus groups and survey should be viewed cautiously as early insights, and larger sample sizes with young people are required to pilot and evaluate the effectiveness of the app and inform future iterations. A key strength of this study is the user-centered design approach whereby end users, key stakeholders, and content area experts were involved at different stages of the development process. A critical next step in the development of the evidence base for *Mind your Mate* will be to conduct a large-scale randomized controlled trial of the effectiveness of the mHealth app in the target group of adolescents.

Conclusions

Mental health and substance use carry significant and escalating harms for young people, and the burden can fall largely on peers during adolescence. Adolescence is the typical age of onset of mental health and substance use issues, and there is a great opportunity for peers to play a key role in supporting each other. The *Mind your Mate* mHealth app was developed to address the needs of young people to better support their peers regarding substance use and mental health and uniquely includes self-care strategies, gamified continuous support, and customizable content. A larger controlled trial currently underway is the next critical step to build the evidence base in this important mental health prevention area.

Abstract

Background: The COVID-19 pandemic exacerbated existing racial/ethnic health disparities in the United States. Monitoring nationwide Twitter conversations about COVID-19 and race/ethnicity could shed light on the impact of the pandemic on racial/ethnic minorities and help address health disparities.

Objective: This paper aims to examine the association between COVID-19 tweet volume and COVID-19 cases and deaths, stratified by race/ethnicity, in the early onset of the pandemic.

Methods: This cross-sectional study used geotagged COVID-19 tweets from within the United States posted in April 2020 on Twitter to examine the association between tweet volume, COVID-19 surveillance data (total cases and deaths in April), and population size. The studied time frame was limited to April 2020 because April was the earliest month when COVID-19 surveillance data on racial/ethnic groups were collected. Racially/ethnically stratified tweets were extracted using racial/ethnic group-related keywords (Asian, Black, Latino, and White) from COVID-19 tweets. Racially/ethnically stratified tweets, COVID-19 cases, and COVID-19 deaths were mapped to reveal their spatial distribution patterns. An ordinary least squares (OLS) regression model was applied to each stratified dataset.

Results: The racially/ethnically stratified tweet volume was associated with surveillance data. Specifically, an increase of 1 Asian tweet was correlated with 288 Asian cases ($P<.001$) and 93.4 Asian deaths ($P<.001$); an increase of 1 Black tweet was linked to 47.6 Black deaths ($P<.001$); an increase of 1 Latino tweet was linked to 719 Latino deaths ($P<.001$); and an increase of 1 White tweet was linked to 60.2 White deaths ($P<.001$).

Conclusions: Using racially/ethnically stratified Twitter data as a surveillance indicator could inform epidemiologic trends to help estimate future surges of COVID-19 cases and potential future outbreaks of a pandemic among racial/ethnic groups.

KEYWORDS

racial/ethnic stratification; geo-tagged COVID-19 tweets; racial/ethnic disparity; surveillance

Introduction

As the novel SARS-CoV-2 virus, which causes COVID-19, started spreading worldwide in early 2020, people began practicing social distancing as a measure to reduce contagion [1]. The public also started using Twitter to exchange information about the pandemic, which contributed to the exponential increase in social media traffic volume [2]. According to the Centers for Disease Control and Prevention (CDC), as of March 31, 2022, the pandemic had claimed over 995,000 lives in the United States, which continues to rise [3,4]. This is the worst pandemic the United States has experienced since the 1918 flu [5].

Racial/ethnic disparities in health in the United States have been well documented. Stark racial disparities exist in health outcome measures, health care, and chronic health conditions [6,7]. In almost all health outcome measures, these disparities are precipitated by the disproportionate representation of Black Americans, Hispanic/Latino Americans, Asian Americans, and other racial/ethnic minorities [6,8] and often due to limited access these communities have to hospitals and health care facilities [9]. The COVID-19 crisis has further exacerbated those disparities because racial/ethnic minorities have higher representation in sectors most affected by the pandemic and are more likely to be employed in low-wage or precarious jobs [8,10,11].

An increasing number of public health and medical agencies are using Twitter data to monitor disease trends and detect outbreaks at the national and local levels [12,13] (ie, dental pain [14], cancer [13], as well as a syndromic surveillance system [15]). Twitter data, especially geotagged tweets, have several advantages over traditional surveillance data. Traditional surveillance systems, such as surveys or clinical data collection, are expensive and time-consuming monitoring mechanisms [16]. Tweets, on the other hand, are more timely and less costly [16,17]. In addition, the geographic extent of tweet data makes it easy to conduct multiscale studies, from a neighborhood to counties to across multiple nations [18]. Geotagged tweets can also be geocoded to match exact location information, making it possible to link to other data sources based on common geographical attributes (ie, state, county, or local address) for geospatial analysis [19]. By contrast, most publicly available traditional surveillance data have restricted geographic variables, and county level is often the finest spatial resolution as these data need to be aggregated from a privacy perspective [20-22].

In 2020, Twitter data alone was used for the national surveillance of COVID-19 hospitalizations in Belgium [1], COVID-19-related anti-Asian sentiments in the United States [23], evaluating world leaders' COVID-19 response measures [24], and tracking mental health symptoms mentioned during the COVID-19 pandemic within the United States [25]. In particular, the relation between tweet volume and surveillance was explored for various purposes [26-29]. Increased tweet volume is often assumed to correlate with increased public interest in certain topics. Subsequently, this approach was used as a measure to monitor public discourse on mask-wearing [26],

increased COVID-19 cases [27], and predicting outbreaks [28,29].

Despite these great benefits, Pobiruchin et al [27] pointed out the need and importance of investigating the potential correlation between tweet volume and infection or death rates; Nguyen et al [23] suggested future work on the geographical variation in area-level COVID-19 infection and mortality rates and their associations with demographics such as density of racial/ethnic groups. Considering the research gaps and the context of the COVID-19 pandemic's disproportionate impact on racial/ethnic minorities, our goal was to explore the association between racially/ethnically stratified tweets and COVID-19 cases and deaths. We believe this study will reveal the potential relation of public discourse about the pandemic's impact on each race/ethnicity group and COVID-19 cases and deaths. Using racially/ethnically stratified tweet volume as a surveillance indicator will provide more evidence and help address racial/ethnic health disparity in this COVID-19 crisis.

Methods

Data Collection

English tweets geotagged within the United States from April 1, 2020, to April 30, 2020, were downloaded using the Tweepy Python library—Twitter's search application programming interface (API)—and a set of predefined search terms [30]. Referencing the most searched terms from Google's Daily Search Trends summary from March 10, 2020, to April 1, 2020, we derived a list of search terms. The search terms included (1) the most widely adopted scientific name of the disease ("corona," "COVID-19," "pandemic," "coronavirus"), (2) the name of the racial/ethnic groups in which we were interested ("Asian," "Blacks," "Hispanics," and "Latino"), and (3) other related terms ("test positive," "COVID," "n95," "Flatten the curve," "Social Distancing," "Chinese Virus"; see the complete list of keywords in [Multimedia Appendix 1](#)). We only included geotagged tweets with location information (ie, geographical coordinates and city names) to filter tweets within the United States. The location information allowed us to match tweets to specific states and then link state-level surveillance data for further analysis. Each tweet's text, timestamp, coordinates, or place names were extracted and used in the detailed analysis.

COVID-19 cases were the "total number of confirmed plus probable cases of COVID-19 reported by the state or territory" for April 2020 obtained from The COVID Tracking Project [31]. COVID-19 deaths were "total fatalities with confirmed or probable COVID-19 case diagnosis" from The COVID Tracking Project, the only source with data about race across all states. These data cannot be found in neither the CDC COVID Data Tracker nor the COVID-19 Dashboard at John Hopkins University. State-level population data for each racial/ethnic group were obtained from the US Census Bureau's 2019 American Community Survey 5-year estimates [32].

Spatial and Statistical Analysis

[Figure 1](#) illustrates the organization of the tweets and COVID-19 case and death data and the analytics implemented to examine the racial/ethnic relationships. First, the tweets were cleaned

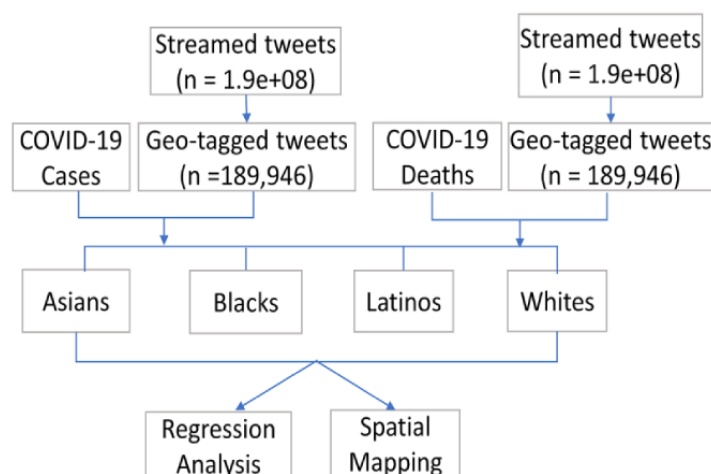

using natural language processing steps, removing punctuation, English stop words (ie, a, an, the), and special characters. Using the name of each racial/ethnic group, we extracted tweets that contained conversations about the subpopulations of interest: Asians, Blacks, Latinos, and Whites. If multiple racial/ethnic groups were mentioned in 1 tweet, the tweet was examined multiple times. “Black” and “White” can also refer to the name of colors. To exclude tweets that used “Black” and “White” but did not mean ethnic groups, the tweets were manually evaluated to identify and exclude irrelevant tweets. Next, we calculated the total number of tweets (or tweet volume) for Asians, Blacks, Latinos, and Whites in 50 states and Washington, DC, based on geotagged information.

COVID-19 case and death data were recorded twice a week, so we combined these data to yield the total cases and deaths for April 2020. To map and compare the cases and deaths across racial/ethnic groups, we used 2019 US Census population data to adjust the number of cases or deaths per 100,000

Asians/Blacks/Latinos/Whites. The population-adjusted cases and deaths were mapped using the geospatial processing tool ArcPro 2.5 (ESRI, 2020; Redland, CA) to allow comparison across racial/ethnic groups.

Using the state name as the common field, we linked tweet volume, COVID-19 cases and deaths, and population estimates for the 50 states and Washington, DC. Four ordinary least squares (OLS) regressions were implemented for Asians, Blacks, Latinos, and Whites, respectively, to examine the association of tweet volume with COVID-19 cases. In each model, tweet volume was used as the independent variable, the population was the control variable, and the number of COVID-19 cases was the outcome variable. Another 4 OLS regressions were implemented for Asians, Blacks, Latinos, and Whites, respectively, to examine the association between tweet volume and COVID-19 deaths. Tweet volume, population, and COVID-19 deaths were used as each model’s independent, control, and outcome variables, respectively.

Figure 1. Data management and workflow.

Results

The final analysis included 189,946 geotagged tweets. Of these, we extracted 141 (0.07%) tweets mentioning Asians, 869 (0.46%) tweets about Blacks, 47 (0.02%) tweets about Latinos, and 588 (0.31%) tweets about Whites. Example tweets about each racial/ethnic group are presented in [Table 1](#).

The spatial locations of tweets were mapped, and hot spots based on tweet volume were identified ([Figure 2](#)). These hot spots (gradient from red to yellow indicates increasing volume) include New York, Los Angeles, and Chicago. The non-hot spot locations (blue-gray color) represent low tweet volume.

The distributions of population-adjusted COVID-19 cases for Asians, Blacks, Latinos, and Whites in April 2020 are shown in [Figure 3](#). Alaska and Hawaii are not shown on the maps because the cases were few for Asians and close to 0 for the other 3 racial/ethnic groups in both states in April 2020. The number of COVID-19 cases ($\leq 95,345$ per 100,000) among Asians was highest in Illinois, Massachusetts, and Washington. Similarly, Latino cases were highest in Illinois, Utah, and Washington. The highest cases among Blacks were in the Midwest, Northeast, and Southern regions (eg, Illinois,

Massachusetts, Alabama, among others). Compared with Asians and Blacks, the number of COVID-19 cases among Whites was the lowest across all states.

[Figure 4](#) shows the distributions of population-adjusted COVID-19 deaths for Asians, Blacks, Latinos, and Whites in each state for April 2020. The number of deaths among Asians was highest (>220 per 100,000) in Illinois, Massachusetts, New York, and Washington. Massachusetts, New York, and Washington were the states that reported the highest numbers of death for Latinos (>220 per 100,000). Similar to the number of infected cases, the number of deaths among Blacks was also highest (>220 per 100,000) in the Midwest, Northeast, and Southern regions (ie, Alabama, Illinois, Massachusetts, Michigan, New Jersey, New York, North Carolina, South Carolina, and Texas).

[Tables 2](#) and [3](#) show the linear regression results between COVID-19 cases and tweet volume. We observed a significant relationship between Asian tweet volume and the number of COVID-19 cases. Specifically, an increase of 1 Asian tweet was linked to 288 Asian cases (Model 1, adjusted $R^2=0.72$, $P<.001$). The rise of Black, Latino, and White tweets was not correlated with COVID-19 cases. Furthermore, tweet volume

for all racial/ethnic groups was significantly associated with COVID-19 deaths: An increase of 1 Asian tweet was linked to 93.4 Asian deaths (Model 5, adjusted $R^2=0.57$, $P<.001$); an increase of 1 Black tweet was linked to 47.6 Black deaths

(Model 6, adjusted $R^2=0.23$, $P<.001$); an increase of 1 Latino tweet was linked to 719 Latino deaths (Model 7, adjusted $R^2=0.38$, $P<.001$); and an increase of 1 White tweet was linked to 60.2 White deaths (Model 8, adjusted $R^2=0.18$, $P<.001$).

Table 1. Example tweets about each racial/ethnic group.

Ethnic group	Example tweets
Asians	<ul style="list-style-type: none"> “Eating at #Italianos for the #1stTime. My #Wife told Me not to eat any #AsianFood because the #Covid19 started in Asia.” “Asian fam, stay safe out there. We 'bout to be targeted much more now than ever. This is an okay time to be paranoid. sadly.” “A terror attack in Texas due to anti-Asian hatred and bigotry. THIS is why it is appalling and abhorrent to apply a nationality and ethnicity to a f*cking virus.” “Latinos and Asians in New York City are disproportionately representing the proportion of COVID-19 cases.”
Blacks	<ul style="list-style-type: none"> “Our COUNTRY is shut down, not because of a black guy, but because of a white guy @realDonaldTrump#COVID19.” “I am disappointed in my fellow blacks for being so ignorant during this time. I just read a comment that said “they puttin the virus in the COVID tests now that Black people being tested, so they get sick.” “There is research showing that Black women and other minorities aren’t believed when they report symptoms in the E.R. Could this lead to major racial disparities in the survival rates of COVID-19 patients?#CNNTownHall”
Latinos	<ul style="list-style-type: none"> “I live in one of the epicenters of the epicenter of this damn #COVID19 crisis. Working class Black & Latino folks. When will we get tested?” “Important. Even here in Iowa, #COVID19 is disproportionately impacting Black and Latino people.” “As of April 12, a total of 31 Latinos have died from complications from COVID-19, according to data from the medical examiner’s office. But that figure is not accurate.” Via @mizamudio “Younger blacks and Latinos are dying of COVID-19 at higher rates in California.”
Whites	<ul style="list-style-type: none"> “White nationalists looking to weaponize coronavirus pandemic, both literally and figuratively.” “Striking maps of Milwaukee by overlaying COVID cases on high African American (left) or White population.” “White supremacy backfiring on Trump. He closed the border to China, but not Europe. Most covid-19 cases in USA have a Euro/British origin.” “Same people ok with a bunch of white folks parading around with guns protesting a pandemic had a problem with black folks protesting police brutality and injustice.”

Table 2. Association between COVID-19 cases and racial/ethnic group–related tweets.

Model, outcome, and measurement variable	Coefficient	<i>P</i> value	Confidence interval	Adjusted <i>R</i> ²
Model 1: Asian COVID-19 cases				
Asian tweet volume	288.192	0.00	162.3 to 414.0	0.72
Asian population	0.002	0.00	0 to 0	
Model 2: Black COVID-19 cases				
Black tweet volume	97.088	0.28	–80.3 to 274.5	0.08
Black population	0.004	0.07	0 to 0	
Model 3: Latino COVID-19 cases				
Latino tweet volume	2161.828	0.05	–24.0 to 4347.7	0.26
Latino population	0.001	0.00	0 to 0	
Model 4: White COVID-19 cases				
White tweet volume	163.938	0.07	–12.3 to 340.1	0.19
White population	0.001	0.03	0 to 0	

Table 3. Association between COVID-19 deaths and racial/ethnic group–related tweets.

Model, outcome, and measurement variable	Coefficient	<i>P</i> value	Confidence interval	Adjusted <i>R</i> ²
Model 5: Asian COVID-19 deaths				
Asian tweet volume	93.3750	0.00	68.9 to 117.7	0.57
Asian population	–0.0001	0.02	0 to 0	
Model 6: Black COVID-19 deaths				
Black tweet volume	47.6001	0.00	24.1 to 71.0	0.23
Black population	–0.0002	0.39	0 to 0	
Model 7: Latino COVID-19 deaths				
Latino tweet volume	719.2882	0.00	463.4 to 975.1	0.38
Latino population	–0.0001	0.29	0 to 0	
Model 8: White COVID-19 deaths				
White tweet volume	60.2326	0.00	26.1 to 94.3	0.18
White population	–0.0002	0.07	0 to 0	

Discussion

Principal Findings

To our knowledge, this is one of the first studies to investigate the association between racially/ethnically (Asian, Black, Latino, and White) stratified COVID-19 tweet volume and COVID-19 surveillance data (cases and deaths). Our results revealed a relationship between tweet volume and COVID-19 cases and deaths for all racial/ethnic groups in our study during April 2020 despite varying degrees of association. The key contribution of our study is the examination of the racial and ethnic bias of the pandemic using early-onset data from social media and reported cases and deaths, which was not evident early during the pandemic. This study demonstrates the importance of timely surveillance data collection to characterize the threat and spread of infectious disease among certain racial/ethnic communities, which is critical to effectively and efficiently guide a

well-coordinated and targeted public health response to reduce the spreading and adverse health impacts of a pandemic.

The concentration of high tweet volumes in several hot spot locations, including New York, Los Angeles, and other places in April, could be influenced by 2 main factors. First, the regions have a large population and densely populated urban areas and a significant number of active Twitter users. Second, the increasing number of COVID-19 cases and deaths in these regions could potentially cause the COVID-19-related tweet volume to spike. The regression analysis showed that Asian tweet volume and COVID-19 cases correlated with their population. However, this association was not observed among other racial/ethnic groups. One possible reason could be the alarming increase in discrimination and hate crimes against Asians as the pandemic surged. A similar study by Nguyen et al [23] investigating negative sentiments using tweets before and shortly after COVID-19 emergence found an abnormally higher proportion of negative tweets referencing Asians than

tweets about other racial/ethnic groups. The OLS results also revealed that the Asian tweet volume and Asian population were associated with Asian deaths, whereas the volume of Black, Latino, and White COVID-19 tweets was only associated with COVID-19 deaths. These different associations with tweet volume between COVID-19 cases and deaths could partially be because of restricted testing capacities for COVID-19 cases as opposed to deaths, which were actively reported and recorded. Thus, COVID-19 cases may be underestimated, and an association with COVID tweet volumes was not detected.

The findings also suggest that Twitter data, when stratified by racial/ethnic groups, could yield novel insights in using social media to detect trends in disease occurrence and the potential impact on specific racial/ethnic groups. A previous study investigated changes in racial sentiment before and after COVID-19 emergence using race-related tweets (Asian, Black, Latino, White) [23]. The study found a higher proportion of negative tweets mentioning Asians increased by more than 68%, while those relating to other racial/ethnic minorities and Whites remained stable. The timely use of tweet data is essential to detect area-level racial sentiment [23]. One side note about this previous study is that only the proportion of tweets about each race was compared and area-level comparisons were not explored; however, our research conducted area-level analysis and explored the association between tweet volume and surveillance data. Another study investigated the association between the volume of tweets against mask wearing and daily COVID-19 cases and found a rise in negative tweet volume was strongly correlated with the number of new cases [26]. This finding concurs with ours regarding the change in tweet volume associated with COVID-19 cases and deaths, although at varying degrees for different racial/ethnic groups. Different from our research, this study did not use geotagged tweets. Thus, no geographic attributes can be used to link population density, which is also a key factor influencing tweet volume. Cuomo et al [33] investigated subnational longitudinal and geospatial trends of COVID-19 in the United States between March 3, 2020, and April 13, 2020. The authors explored the association between change in tweet volume and population-adjusted COVID-19 case increase. They also conducted geospatial hot spot analysis and included population-adjusted results and found a high proportion of rural inhabitants in some of the hot spot regions, which partially overlaps with our results, as we also found high COVID-19 cases per 100,000 people in some rural states (ie, Alabama, Iowa) for the Black population.

Although previous studies have examined the relationship between tweets and COVID-19 cases, none included COVID-19 deaths as a measure in their investigations. COVID-19 deaths are an important measure because our statistical results show that all Asian, Black, Latino, and White COVID-19 tweets were associated with COVID-19 deaths but not with COVID-19 cases. One possible explanation for this is that the reporting of COVID-19 cases was limited by testing capacity in April 2020, but this limitation influenced the reporting of COVID-19 deaths less.

Future research could focus on exploring the use of Twitter to develop streamlined tools to automatically extract, process, and analyze COVID-19 (or other public health events) and

racially/ethnically related tweets to monitor tweet volume about racial/ethnic groups and COVID-19–related health disparities [34]. The state-level COVID-19 surveillance data that we used limited our geospatial analysis to the state level, despite the much finer spatial resolution of the geotagged tweets. Although state-level aggregation is essential from a privacy perspective, in the future, we will consider using surveillance data at a finer spatial resolution (eg, county) to explore the variability of infected cases and deaths among different demographic groups (based on factors such as race, gender, income, age). Using early-onset Twitter data, we demonstrated a pandemic's racial/ethnic disparity among the most populous racial/ethnic groups, which could be replicated in future public health events using social media data. In the future, we will expand this study by including surveillance data for other racial/ethnic groups if this information is available.

Public Health Implications

This retrospective study provides evidence for the use of racially/ethnically stratified Twitter data as a surveillance indicator. Social media data can provide insights to track epidemiological trends, especially for outbreaks, epidemics, or pandemics that are novel and spread fast. Such findings can aid public health practitioners and policy makers make public health decisions using this nontraditional near-real-time data set before traditional surveillance data sets are available. The research findings also encourage health care professionals to actively engage in public discourse to present scientific and clinical evidence to help reduce racial/ethnic health disparities [23,26] and eliminate misinformation. For instance, COVID-19–induced discrimination against Asians is mainly due to misunderstanding and politicizing COVID-19 origins; health care professionals can share scientific findings of possible COVID-19 origins that might not have been widely circulated [35].

The association between tweet volume and COVID-19 cases and deaths proved that tweet volume could be used as proxy surveillance data to estimate the spread of COVID-19 cases and deaths. This association can also evaluate potential locations for future COVID-19 cases and deaths. Identifying future areas for COVID-19 cases and deaths could be used for public health responses when official surveillance is not available and complement official surveillance data when available. Since Twitter surveillance is low-cost and efficient, it can be streamlined and implemented as a long-term disease surveillance tool to ensure prompt response to future public health crises.

Limitations

Although this study used COVID-19 cases and deaths as the 2 outcomes of this disease, we are aware of the concerns about the accuracy of cases due to limited testing capabilities (ie, lack of access to testing) and challenges in the attribution of the cause of death in the early onset of the coronavirus outbreak [36]. Considering these factors, the authors acknowledge the limitation of using the counts of COVID-19 cases and deaths as variables in our models. Similar to other studies that rely on social media data, Twitter users are not representative of the population (ie, one-third of its users are between 25 and 34 years old), thus bringing selection bias to the analysis [37,38]. The exclusion of tweets in other languages, especially Spanish, also

limits our understanding of information exchange between Latinos who speak Spanish.

Another limitation of this study is the spatial granularity at the state level because the surveillance data were obtained at the state level. If surveillance data can be obtained at a finer spatial resolution, then the analysis will yield more accurate and precise results and insights into the location of COVID-19 cases and deaths. Although this is a limitation of the study, given the bias towards specific racial/ethnic groups, and in order to protect the privacy of the users, state-level aggregation is a good starting point to demonstrate the methodology implemented herein to explore the racial/ethnic aspect of a pandemic.

We only used tweets collected in April 2020 and conducted a cross-sectional analysis. We acknowledge that this analysis could offer more insights into the temporal trends of conversations about different racial/ethnic groups if the data set had a larger temporal scale. However, several issues exist with extended time frame data. First, many states did not report or minimally reported race data, as it was not a requirement to report COVID-19 cases and deaths after several months into the pandemic [31]. Second, some states intentionally adjusted or manipulated their case and death data to obscure rising infection rates and mislead the public to achieve specific political goals, such as Florida's COVID-19 dashboard incident [39-41]. Since 2020, different states have implemented varying policies about social distancing and wearing masks, which probably contributed to asymptomatic cases that are difficult to identify and probably were never reported. Due to these issues, even the CDC COVID Data Tracker and COVID-19 Dashboard at John Hopkins University do not provide data about race in all states, limiting what can be studied about geographic and longitudinal racial health disparities during this pandemic.

Past research and this study have revealed that Twitter data can be used to correlate with the increased public interest in certain emergencies, such as predicting public health outbreaks [26,27] and using Twitter as a disaster situation awareness tool [42]. Twitter data are a good indicator to assess the racial/ethnic bias of the pandemic. However, we also observed that COVID-19 and race/ethnicity-related tweets significantly decreased with extended time frame data due to the aforementioned reasons. Thus, the effect of Twitter data as a surveillance indicator to inform epidemiologic trends may attenuate with time. Several reasons may have contributed to this change. For instance, the

lockdown after the COVID-19 outbreak in the United States naturally brought the nation's attention to the pandemic, and an unusually high number of people turned to Twitter to obtain or share COVID-19-related news. The politicization of the pandemic combined with the spreading of misinformation and cyber-racism [43] as well as the increase in vaccination probably contributed to a reduction in COVID-19-related tweets as we did not retrieve a significant number of tweets about COVID and race/ethnicity in December 2021 to replicate the study for the fifth wave. The continuation of this pandemic, combined with other extreme events and the economic situation that has impacted the country since 2020, probably has desensitized the public about the disproportionate impact of COVID-19 on certain racial/ethnic groups, thereby contributing to a reduction in tweets as well. Despite these limitations, similar to Cuomo et al [33], we used the data from the first month of the pandemic to understand the racial/ethnic biases of the pandemic. Hence, public health-related studies could replicate our study to explore the racial and ethnic aspects of public health problems to aid health officials with scientific communication and appropriate response measures.

Conclusion

This research is an effort to test the possibility of using racially/ethnically stratified Twitter data as an info surveillance indicator to estimate the impact of COVID-19 on racial/ethnic groups in the United States to inform public health crisis response efforts and racial/ethnic equity. Using COVID-19 and geotagged racial/ethnic group-related Twitter data in the United States during April 2020, we filtered conversations about racial/ethnic groups in the early onset of the COVID-19 pandemic. Using the state-level counts of COVID-19 cases and deaths stratified by racial/ethnic groups, we found a strong correlation of tweet volume with COVID-19 deaths among Asians, Blacks, Latinos, and Whites and with COVID-19 cases among Asians. These findings demonstrate that racially/ethnically stratified Twitter data, as a surveillance indicator, could inform epidemiologic trends and help estimate the future surge of COVID-19 or other public health-related cases, deaths, and potential outbreaks of mutant viruses. The observed differential impacts on racial/ethnic minorities could guide public health policies to address racial/ethnic health disparities and deploy appropriate interventions (ie, more robust COVID-19 data collection about race and tailored measures to help racial/ethnic minorities).

Abstract

Background: Telecare is a health service that involves the home installation of a number of information technology support systems for individuals with complex needs, such as people with reduced mobility or disabilities and the elderly. It involves the use of sensors in patients' homes to detect events, such as smoke in the kitchen, a front door left open, or a patient fall. In Northern Ireland (NI), outputs from these sensors are monitored remotely by the telecare team, who can provide assistance as required by telephone or through the emergency services. The facilitation of such rapid responses has the aim of promoting early intervention and therefore maintaining patient well-being.

Objective: The aims of this study were to construct a descriptive summary of the telecare program in NI and evaluate hospital-based service use by telecare patients before and after the installation of telecare equipment.

Methods: An exploratory retrospective cohort study was conducted involving more than 2000 patients. Data analysis included the evaluation of health care use before and after the telecare service was initiated for individual participants. Individuals with data for a minimum of 6 months before and after the installation of the telecare service were included in this analysis.

Results: A total of 2387 patients were enrolled in the telecare service during the observation period (February 26, 2010-February 22, 2016). The mean age was 78 years (median 81 years). More women (1623/2387, 68%) were enrolled in the service. Falls detectors were the most commonly deployed detectors in the study cohort (824/1883, 43.8% of cases). The average number of communications (calls and/or alarms) between participants and the coordinating center was the highest for patients aged ≥ 85 years (mean 86 calls per year). These contacts were similarly distributed by gender. The mortality rate over the study period was higher in men than women (98/770, 14.4% in men compared to 107/1617, 6.6% in women). The number of nonelective hospital admissions, emergency room visits, and outpatient clinic visits and the length of hospital stays per year were significantly higher ($P < .001$) after the installation of the telecare equipment than during the period before installation.

Conclusions: Despite the likely benefits of the telecare service in providing peace of mind for patients and their relatives, hospital-based health care use significantly increased after enrollment in the service. This likely reflects the increasing health care needs over time in an aging population.

telecare; Northern Ireland; assistive technology; elderly people; healthcare use

Introduction

It has been claimed that home-based telecare, particularly for the elderly, reduces the need for community care, prevents unnecessary hospital admissions, and delays or prevents admission into residential or nursing home care [1-6]. Telecare Northern Ireland is a service which provides a range of information technology support services to assist mainly elderly people who live independently in their own homes. It typically involves the use of sensors placed in patients' homes to allow for the detection of critical events, such as smoke in the kitchen, a tap left running, a front door left open, or a patient fall [7-9]. The sensors allow for the transmission of alerts to a central coordinating center, from which staff respond as appropriate. Telecare can be used by a full spectrum of patients but is mainly used by elderly people who live alone in their own homes [4,5,9].

In 2008, the Minister for Health, Social Services, and Public Safety for Northern Ireland (NI) announced £1.5 million (US \$1.97 million) funding for pilot projects to promote the development of telehealth [3]. A telecare program was introduced as part of this initiative, under the umbrella of a more extensive Telemonitoring NI initiative. At the time the cohort of users was established, there were approximately 1.7 million people in the United Kingdom (UK) using telecare services [10].

Telecare programs in NI typically involve the deployment of different equipment and/or sensors, depending on the perceived benefits to the patient. Although telecare has the potential to play an important role in enhancing the ability of elderly people to manage their activities of daily living and, if required, avail of rapid response services, there is often a misunderstanding regarding the role of the service. It should be considered an aid to improve elderly patients' independence and quality of life and not a solution to their growing need for general health care and hospital-based care [3-5,9].

A private company (TF3) won the contract to provide telecare services in NI. The UK National Health Service (NHS) operates in NI, and the telecare service, as is the case with other health care services, is free of charge to patients. Patients were enrolled in the program by their clinical team. The range of sensors and components deployed in the NI program were as follows: a pendant that the patient can activate if he or she experiences a fall, an emergency alarm button, an extreme temperature sensor, a bed or chair occupancy sensor, a home safety package (consisting of a pressure mat, bogus caller button, epilepsy sensor, and property exit sensor), a fumes detector, a flood detector, and an immobility sensor. The combination of components used with each patient was adjusted according to individual patient needs. The equipment was installed and maintained in patients' homes by TF3 and all patients across NI were connected to a call center that dealt with alarms and calls from patients receiving the service.

The aims of this exploratory study were to construct a descriptive summary of the use of the telecare program in NI and evaluate patient use of hospital-based services before and after the introduction of the telecare service.

The objectives were as follows:

- Using patient administrative data collected by the provider of telecare services in NI (TF3) as part of service provision, together with health care use data sets held at the Business Services Organisation (BSO) in NI, develop a descriptive summary of the patients enrolled in the telecare service from 2010-2016.
- Using data held by TF3 and Health and Social Care in NI (HSC), compare hospital-based service use before and after telecare service initiation in patients' homes.

Methods

Ethics Approval

Ethical approval was obtained from the National Research Ethics Service Committee (Research Ethics Committees 15/SW/0015, SET/14/68, WT/14/37; Integrated Research Application System project ID: 167795). Governance approvals and data access agreements were approved by the HSC Trusts.

Data Access and Confidentiality

Access to the health care data sets of individual NHS patients in NI is only made available to researchers in anonymized form via a confidential data repository (ie, the Honest Broker Service [HBS], established by the BSO in NI. The HBS provides a "safe haven" in which data can be accessed and analyzed within a confidential secure environment).

Patient-level data supplied by TF3 and the HSC Trusts were anonymized by the HBS and made available to the research team. To ensure confidentiality, identifiable data are not accessible to researchers and results from analyses undergo scrutiny before being released.

Data Acquisition and Inclusion in Master Data Set

Health care use data (ie, nonelective hospital admissions, periods of hospital stay, outpatient clinic visits, and emergency room [ER] visits) were obtained for all enrolled patients.

Individual patient data sets were retrieved using Health and Social Care numbers (HCNs) for the period before and after the installation date. If a patient died after installation, the date of death was inputted as the endpoint for that individual. The HCN is a unique identifier for all patients registered to receive NHS services in NI and was crucial for data linkage. The date of telecare equipment installation was used as the cut-off point to demarcate preservice and postpatientservice use. Following clearance by the data guardians at the 5 HSC Trusts, TF3 provided data sets on telecare usage to the HBS for linkage and access by the research team. Patients who had data relating to a minimum of 6 months before and after the initiation of the telecare service were included in the health care use aspect of the study.

Data Analysis

The data were analyzed in the HBS using SPSS (version 22; IBM Corp). Descriptive data analyses on patient demographic characteristics (eg, age and gender), number of calls (communications between the patient and coordinating center), telecare equipment components installed, and mortality rates

were performed. Differences in the continuous variables relating to health care use before and after telecare installation were tested for significance using the paired *t* test.

Results

Demographic Data

Data for a total of 2387 patients enrolled in the telecare service in NI indicated that more female patients than male patients received the telecare service ($n=1623$, 68% female patients compared to $n=764$, 32% male patients). The mean age of participants was 78 (SD 12) years; 1716 (1716/2387, 72%) individuals in the study population were 75 years or older. Only 295 (295/2387, 12%) were under 65 years of age.

Contact Calls by Age Group and Gender

Out of the 2387 patients enrolled to receive the telecare service, 2330 patients had records of contact with the coordinating center (eg, in a fall alarm event, both the incoming alarm and outgoing call were recorded and counted as 2 calls). There were between 1 and 7183 calls per patient per year, with a mean of 64.7 and a median of 33 calls per year.

The highest average number of annual patient contact calls was in the ≥ 85 years age group, with an average of 86 calls per year. This decreased to 59 calls per year in the 75-84 years age group and 54 calls per year in the 65-74 years age group. In addition, the lowest mean number of calls (47 calls per year) was in the ≤ 64 years age group. Finally, the average number of calls was very similar for female (65.6 calls per year) and male patients (62.8 calls per year).

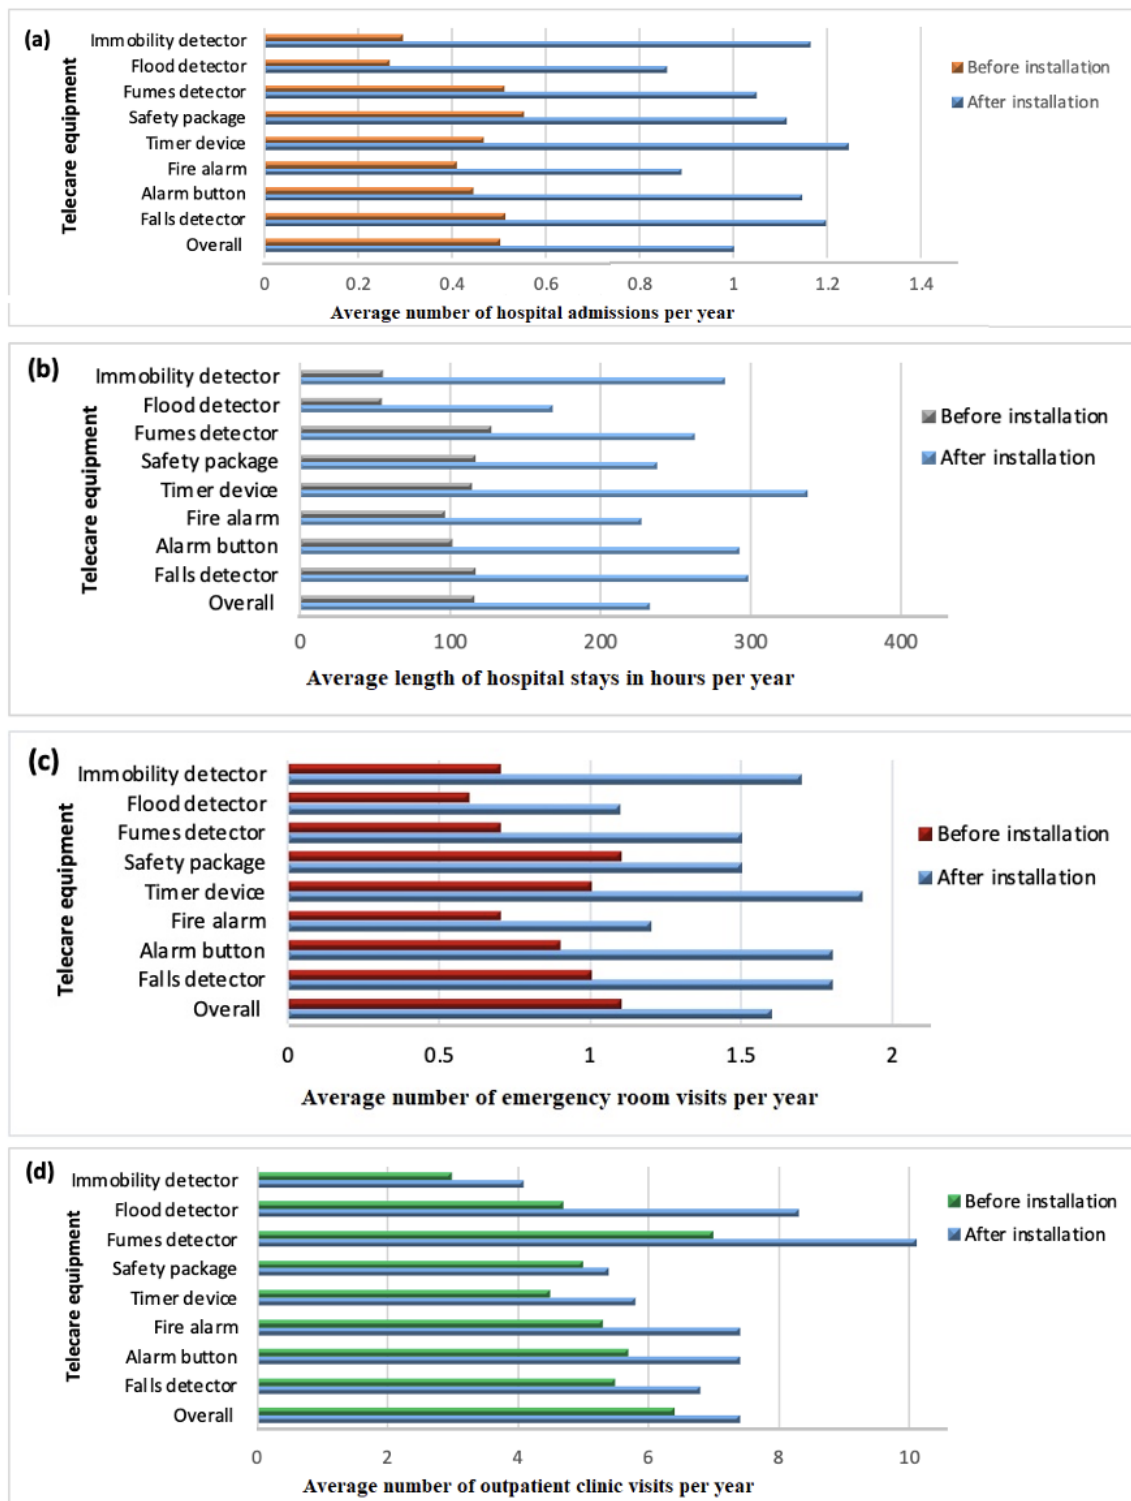

Mortality of the Enrolled Patients

A total of 205 (205/2387, 8.6%) of patients died during the observation period. As expected, the mortality rate was the highest in patients who were ≥ 85 years when they were first enrolled. Mortality during the observation period was more than 2 times higher in male participants (98/770, 12.7%) compared with female participants (107/1617, 6.6%).

Installation Frequency of Telecare Equipment Components

Out of a total population of 2387 patients, 1883 patients had data available on the individual telecare equipment components installed in their homes. Data showed that almost all (1867/1883, 99.2%) of the patients had a call advisor or home unit installed. This equipment provides an alternative to a landline telephone and allows the patient to contact the call center. A total of 824 patients had a fall detector installed (a pendant that a patient can activate if he or she has a fall). The remaining telecare equipment components or detectors (shown in [Figure 1](#)) were less commonly installed. This includes the alarm (a button that a patient can activate in case of any emergency; 441 cases), fire alarm (an extreme temperature sensor; 276 cases), timer (a bed or chair occupancy sensor that has a timer device that can be set according to each individual's routine and is placed under their mattress or chair cushion; 181 cases), safety package (consisting of a pressure mat, bogus caller button, epilepsy sensor, and property exit sensor; 96 cases), fumes detector (detects dangerous levels of carbon monoxide; 82 cases), flood detector (detects if water has overflowed onto the patient's floor; 38 cases), and immobility sensor (detects lack of movement within the patient's home, which suggests that patient has collapsed; 37 cases).

Figure 1. The mean (a) number of nonelective hospital admissions per year, (b) length of hospital stays in hours per year, (c) emergency room visits per year, and (d) outpatient clinic visits per year for patients with differing telecare equipment components pre and post installation (n=1883).

Health Care Use Pre and Post Installation of the Telecare Components

The health care use parameters increased significantly after the installation of the telecare equipment. For example, the average number of nonelective hospital admissions per year increased from 0.5 (SD 0.6) to 1.0 (SD 1.5; $P<.001$), the average length of hospital stays increased from 115.3 (SD 190.6) to 232.2 (SD

485.2) hours per year ($P=.006$), the average number of ER visits increased from 1.1 (SD 1.7) to 1.6 (SD 2.5) visits per year ($P<.001$), and the average number of outpatient visits increased from 6.4 (SD 8.4) to 7.4 (SD 8.7) visits per year ($P<.001$). The results presented in Figure 1 illustrate these data with reference to the telecare equipment installed in patients' homes.

Discussion

Study Focus

This study had a narrow focus (ie, to construct a descriptive summary of patients enrolled in and the use of the telecare program in NI and to evaluate hospital-based service use by patients before and after installation of the telecare equipment). In interpreting the results, one must consider that there is often tension within health and social care provision regarding the value versus the cost of various services since different services have different impacts on clinical, humanistic, and economic outcomes.

Patient Age and Gender

The highest proportions of telecare NI patients were in the elderly age groups, with only 12% (295/2387) of participants under the age of 65 years. A total of 12% of the total UK population of >66 million people are aged ≥ 65 years [11]. Aging statistics in NI, which had a total population of 1.9 million in February 2021, show that the total number of people aged ≥ 65 years has increased from 13% (mid-1994) to 16.6% (mid-2019) [12]. This age group is projected to grow in all Great Britain (GB) regions by mid-2028 [13] (ie, there is a growing elderly population who may avail of telecare services).

The patients who enrolled for this telecare service were predominantly aged 75 years and above (1716/2387, 72% of the study population). The profile of participant age groups in this study is similar to the patients who enrolled for telecare services in England in the telehealth whole system demonstrator (WSD) project, in which approximately 60% of participants (intervention group) were aged ≥ 75 years [7]. The mean age of the patients enrolled for the telecare service in NI was 78 (SD 12) years, while it was 75 (SD 14) years for patients in the telecare arm of the WSD project [7].

All patients enrolled in this study were still able to live in their own homes or sheltered accommodation and were deemed able to take care of themselves with the aid of telecare equipment. In GB, approximately 60% of women aged ≥ 75 years live alone in their own homes, compared with 36% of men of the same age [14]. This disparity in the female-to-male ratio was evident in the uptake of telecare services in NI (1218:499 for patients aged ≥ 75 years).

Overall data on gender showed that 68% (n=1623) of the 2387 patients enrolled in the telecare service in NI were female. This is similar to a telecare service in Scotland, where 62% of a cohort of 7487 patients was comprised of female patients [5]. A similar male-to-female ratio was reported in the WSD project in England, where 67.5% of patients in both the control (n=1236) and intervention (telecare arm) groups (n=1190) were female [7].

Patient Contact Calls

Despite the high level of activity in this study (eg, an average of 86 contacts annually between the telecare center and patients >85 years), markers of the need for hospital-based care increased over time among patients enrolled in the program.

Research by others has indicated more nuanced outcomes; for example, a systematic review [15] on the benefits of home telecare services for elderly patients involving 21 randomized trials and 12 observational studies found that regular calls between health care providers and patients reduced or delayed hospital admissions and improved discharge rates in elderly people with long-term conditions, leading to cost savings. The observational studies in the systematic review also indicated that supplementing the type of telecare service delivered in NI with daily follow-up telephone calls from nurses may further reduce costs by delaying hospital admissions and lowering the number of readmissions in elderly patients with heart disease, diabetes, and chronic obstructive pulmonary disease. However, the review found insufficient rigorous evidence about the effects of safety and security alert systems, such as fall detectors and community alarms, on either individual or system outcomes [15]. A more recent study conducted in England found that the number of requests for ambulances as a consequence of falls was reduced by the rapid response of a telecare call center [6].

Mortality

In NI, mortality rates have decreased in recent years across all age groups, but the mortality rates in men remain higher than in women. It has also been noted, however, that although women live longer, they often live the extra years in poor health [14]. These data help explain the greater use of the telecare service by women and their lower mortality in this study.

Telecare Equipment Installation and Health Care Use

In NI, as in other locations, a wide assortment of sensors and devices were used according to the perceived needs of clients [9,16-18]. After the advisor call unit, the most frequently installed was fall detection equipment (824/1883, 44%). Falls are particularly problematic in an aging population and can have serious consequences, including bone (especially hip) fractures [6,19].

Although telecare is increasingly being used across GB, there has been little definitive work on its impact on health outcomes [20,21]. The variety of equipment components makes the delivery of randomized trials complex and difficult to perform [3]. The range and combinations of telecare equipment components used in different regions and countries, coupled with differing health and social care delivery models, also make it difficult to compare data from different centers.

An increase in health care use over time is to be expected in this study population because the majority (1716/2387, 72%) who enrolled were aged 75 years or older. Because a control group of people with similar characteristics who did not receive the telecare services was not available, the impact of telecare could not be evaluated; however, a doubling of the mean number of hospitalizations (0.5 to 1.0; $P < .001$) was disappointing and clearly highlights the impact of aging on health and well-being.

These findings can be considered alongside a report which summarized details of the Scottish Telecare Development Program [22]. This telecare provision was implemented at the time of hospital discharge over a 1-year period (2007-2008). As in this NI study, there was no control group. A total of 7902 patients were provided with the telecare service (85% aged ≥ 65

years). It was estimated (by the 18 telecare service providers involved) that more than 500 delayed discharges were avoided by the use of telecare, saving an estimated >5000 bed days. It was also estimated that more than 1200 emergency admissions were avoided, saving an estimated 13,000 bed days [22].

The demographics of the NI telecare recipient population were similar to those of the participant population in the study in Scotland. Since both regions operate under the UK NHS system, it is likely that benefit was accrued from the telecare service in NI despite the increased use of hospital-based services post installation. Peace of mind (through feeling safe and secure) achieved by both patients and their families, as demonstrated by other researchers [6,9,22-24], was likely to have been achieved, but this benefit could not be assessed using the NI data.

Conclusions

Despite the likely benefit of the telecare service, including peace of mind for patients and their relatives [23,24], hospital-based health care use significantly increased after enrollment in the service. This may simply reflect the increasing health care needs due to health deterioration over time within an aging population; with no control data available, it was not possible to quantify the impact of the telecare service.

This quantification would require a new prospective study with a control group and, therefore, a randomized controlled trial is recommended to fully evaluate the potential of telecare services to improve clinical, humanistic, and economic outcomes across NI. This should be supplemented by a substantive qualitative aspect to the research, including interviews with both patients and their next of kin and the development of a number of case studies involving patients who engaged with the telecare service.

Acknowledgments

The work was funded by a grant from the Health and Social Care Research and Development Office, a division of the Northern Ireland (NI) Public Health Agency (grant COM/4943/13). We also gratefully acknowledge the assistance with data access and linkage provided by the staff of TF3 and the Health and Social Care in Northern Ireland Trusts, Honest Broker Service (HBS), and Business Services Organisation (BSO) in NI. The HBS is funded by the BSO and the Department of Health for NI.

Abstract

Background: African swine fever (ASF), a highly contagious disease affecting both domestic and wild pigs, has been having a serious impact on the swine industry worldwide. This important transboundary animal disease can be spread by animals and ticks via direct transmission and by contaminated feed and fomites via indirect transmission because of the high environmental resistance of the ASF virus. Thus, the prevention of the introduction of ASF to areas free of ASF is essential. After an outbreak was reported in China, intensive import policies and biosecurity measures were implemented to prevent the introduction of ASF to pig farms in Thailand.

Objective: Enhancing prevention and control, this study aims to identify the potential areas for ASF introduction and transmission in Thailand, develop a tool for farm assessment of ASF risk introduction focusing on smallholders, and develop a spatial analysis tool that is easily used by local officers for disease prevention and control planning.

Methods: We applied a multi-criteria decision analysis approach with spatial and farm assessment and integrated the outputs with the necessary spatial layers to develop a spatial analysis on a web-based platform.

Results: The map that referred to potential areas for ASF introduction and transmission was derived from 6 spatial risk factors; namely, the distance to the port, which had the highest relative importance, followed by the distance to the border, the number of pig farms using swill feeding, the density of small pig farms (<50 heads), the number of pigs moving in the area, and the distance to the slaughterhouse. The possible transmission areas were divided into 5 levels (very low, low, medium, high, and very high) at the subdistrict level, with 27 subdistricts in 10 provinces having very high suitability and 560 subdistricts in 34 provinces having high suitability. At the farm level, 17 biosecurity practices considered as useful and practical for smallholders were selected and developed on a mobile app platform. The outputs from the previous steps integrated with necessary geographic information system layers were added to a spatial analysis web-based platform.

Conclusions: The tools developed in this study have been complemented with other strategies to fight against the introduction of ASF to pig farms in the country. The areas showing high and very high risk for disease introduction and transmission were applied for spatial information planning, for example, intensive surveillance, strict animal movement, and public awareness. In addition, farms with low biosecurity were improved in these areas, and the risk assessment developed on a mobile app in this study helped enhance this matter. The spatial analysis on a web-based platform helped facilitate disease prevention planning for the authorities.

African swine fever; multi-criteria decision analysis; risk-based surveillance; risk assessment; spatial analysis

Introduction

Background

African swine fever (ASF) is a highly contagious disease affecting both domestic and wild pigs of all ages. It is highly contagious because the morbidity and mortality in exposed pig herds are possibly up to 100% [1]. The ASF virus (ASFV) is a large, enveloped, double-stranded DNA virus with a size of 170 to 190 kbp, and its genome includes >50 structural proteins and several nonstructural proteins [2,3]. Owing to the large size and complex structure of the virus, there is no effective vaccine producible at the moment [2]. The virus is also highly survivable, allowing the virus to spread via various sources, including infected live and dead pigs, infected pork products, contaminated feed, and contaminated fomites [3]. The ASFV can survive for up to 18 months in serum at room temperature and for several months in raw pork products such as raw ham or sausage and treated products [2]. It survives for a longer time in frozen material and resists a pH level between 4 and 13 [4]. Hence, it is a serious disease in the swine industry worldwide, causing serious economic and production losses [3].

The World Organization for Animal Health identifies ASF as an important transboundary animal disease that has spread across almost all continents and in many countries [3]. After the ASF genotype I was first detected in Kenya in 1910, it circulated in several countries in Africa [1]. The virus was then introduced to Europe, where it was first found in Portugal in 1957 and spread to many countries in Europe and also in South and Central America [3,5,6]. Besides Sardinia [7], ASF type I has been successfully eradicated in Europe and America [1,2]. Subsequently, ASF genotype II emerged in Africa and was first introduced to Europe in 2007 and spread to many countries, beginning with Georgia [8] to its neighbors [5,6] and across to the west [9]. The virus was first introduced to Asia in 2018 in China and, since then, the disease has spread to many countries in Asia and the Pacific [10]. In 2019, 11 countries encountered the ASF, including Mongolia, Vietnam, Cambodia, Hong Kong, the Democratic People's Republic of Korea, Laos, Myanmar, the Philippines, the Republic of Korea, East Timor, and Indonesia. In 2020, 2 more countries were affected by the disease: Papua New Guinea and India. The latest outbreak was detected in the north of east Malaysia in 2021 on the Borneo island, which it shares with Brunei and Indonesia [9].

The transmission cycle of ASF worldwide includes 3 main hosts: wild pigs, soft ticks, and domestic pigs. The ASFV can replicate in the soft ticks of the genus *Ornithodoros*, which are mainly found in Africa and some parts of Europe [11]. This type of tick has been identified as a biological vector of the ASFV and has spread the virus to wild and domestic pigs [1,11]. Pig-to-pig transmission occurs via direct and indirect contact. Direct contact between infected and susceptible pigs has been identified as a very effective transmission route [12]. Indirect contact shows that the ASFV is introduced to susceptible pigs

through people, contaminated feed, infected boar semen, and contaminated fomites [11,13]. Experimental studies have found that the *Stomoxys* flies can be a mechanical vector transmitting ASFV to domestic pigs for a limited time [14,15]; however, ASFV tested in flies collected on ASF-affected farms in Lithuania produced negative results [11]. Feeding pigs with contaminated pork products or fodder is considered to play a major role in the transmission of ASF across countries. Although the import of pigs and pork products from ASF-infected countries was officially banned, it was found that the first outbreak in Europe occurred in a pig farm near the Lisbon airport in Portugal in 1957 caused by feeding pigs waste from airline flights [16]. The same occurred in 2007; the ASF genotype II was first introduced to Georgia through contaminated pork carried by international ships that was then fed to pigs [8].

ASF has a high impact not only on the commercial pig industry but also on smallholders. The introduction of ASF to countries has resulted in many impacts, for example, the loss of up to 50% of the pig population, affecting food security, the cost of disease control, and the loss of status for international trade [16]. The greatest losses occur in countries where most pig farmers are smallholders or practice backyard farming [16]. This sector usually relates to low farm biosecurity, poor knowledge of disease prevention, and a lack of financial resources for farm improvement [17-20]. Europe has experience in ASF spread and successful eradication, the lessons learned including, for example, that (1) pig holders with poor biosecurity usually facilitate the first occurrence of the outbreak [16]; (2) in the areas dominated by commercial pig production, strict animal movement and implementation of culling policies successfully prevented the spread of the disease [16]; and (3) in endemic areas mostly dominated by poor biosecurity farming, apart from both aforementioned measures, the eradication program emphasized improving farm biosecurity, increased disease awareness in pig farmers, and extensive monitoring activities [16].

Objectives

Southeast Asia, where Thailand is located, has been facing the spread of ASF [10]. Immediately after ASF was reported in China in 2018 [21], Thailand has been intensively preventing the introduction of ASF to pig farms in the country by implementing the control measures learned from other countries, in particular European countries [5,6,16,22]. We conducted this study to enhance the measures for preventing the introduction of the ASFV to high-risk farms, focusing on high-risk areas in the country, as well as for assisting responsible officers in spatial information planning. Therefore, the objectives of this study were 3-fold: (1) to identify the potential areas for ASF introduction and transmission in Thailand, (2) to develop a tool for farm assessment of ASF risk introduction focusing on smallholders, and (3) to develop a spatial analysis tool that is easily used by local officers for disease control planning.

Methods

We developed tools for ASF prevention and control, including (1) a suitability map for ASF introduction and transmission in the first stage of virus introduction; (2) a mobile app for farm assessment of ASF risk introduction; and (3) a web application for spatial analysis of ASF prevention and control by combining a layer of suitability map, locations with risk level of farm assessment, and other relevant layers. The methods for each step are detailed in the following sections.

Developing a Suitability Map for ASF Introduction and Transmission

We applied a knowledge-driven model called a spatial multi-criteria decision analysis (MCDA) to determine the suitability areas for ASF introduction and transmission. The analytical hierarchy process, one of the MCDA methods, was used in this study for its power and simplicity [23]. The analysis consisted of four steps: (1) defining and standardizing risk factors, (2) assigning relative importance to the risk factors, (3) combining all layers of risk factors, and (4) assessing the sensitivity and uncertainty of the analysis.

We used a participatory approach [24] by inviting 20 experts in relevant fields, including 12 (60%) epidemiologists, 2 (10%) virologists, and 6 (30%) stakeholders in pig production, to define, standardize, and assign the relative importance of the risk factors of ASF introduction and transmission in the country, with emphasis on the first stage of virus introduction. Each expert initially assigned individual outputs, and then all experts assigned the final outputs together. The defined factors were standardized using fuzzy membership functions [25] in which the relationship between the values of each factor and the

suitability for ASF introduction and transmission ranging from 0 (unsuitable) to 1 (highly suitable) was defined. There were 4 types of relationships proposed to the experts—namely, linear, sigmoidal (s-shaped), j-shaped, and user-defined—with increasing, decreasing, or symmetrical functions [25]. The Fuzzy tool from the IDRISI software (Clark Labs) [26] was used to implement this standardization step. The Fuzzy tool requires the position along the x-axis of each risk factor of 4 parameters (*a*, *b*, *c*, and *d*) governing the shape of the fuzzy membership function [25].

A pairwise comparison technique was used to define the relative importance of each factor. The procedure consisted of comparing each pair of factors using a 9-point continuous comparison scale (Table 1). The weight value for each factor (W_i) was calculated by taking the eigenvector corresponding to the largest eigenvalue of the pairwise score matrix and then normalizing the sum of the components to a unity [27-29]. The consistency ratio (CR), which is calculated as the consistency index divided by a random index, was used to verify the consistency of the matrix. The random index, derived from the study by Saaty [30], depends on the number of analyzed factors (3 factors=0.58, 4 factors=0.90, 5 factors=1.12, 6 factors=1.24, 7 factors=1.32, 8 factors=1.41, 9 factors=1.46, 10 factors=1.49, 11 factors=1.51, 12 factors=1.54, 13 factors=1.56, 14 factors=1.57, and 15 factors=1.58). The consistency index is calculated as

$$CI = \frac{\lambda_{max} - n}{n(n-1)}$$

where λ_{max} is the maximum eigenvalue of the judgment matrix and *n* is the number of factors. If the CR is >0.10, then some pairwise values need to be reconsidered, and the process is repeated until the desired value of CR of <0.10 is reached [30].

Table 1. The 9-point scale values used in the pairwise comparison of factors.

Intensity of importance	Description
1	Equal importance
3	Moderate importance
5	Strong or essential importance
7	Very strong or demonstrated importance
9	Extreme importance
2, 4, 6, 8	Intermediate values
Reciprocals	Values for inverse comparison

The suitability map was produced by incorporating all standardized factor layers using the weighted linear combination (WLC) [31] method in the R software (R Foundation for Statistical Computing). The packages *raster*, *maptools*, and *fields* in R were used. In the WLC, each standardized factor is multiplied by its corresponding weight, these are summed, and then the sum is divided by the number of factors. Its equation is as follows:

$$S_i = \frac{\sum_{j=1}^n w_j x_j}{\sum_{j=1}^n w_j}$$

where w_j is the weight of criterion *i*, x_j is the criterion score of criterion *i* (value of the corresponding raster cell in the criterion

raster map), *n* is the number of criteria, and c_j is the criterion score (1 or 0) of constraint *j*.

With regard to the sensitivity analysis, we applied the one-at-a-time method, which works by changing 1 input factor at a time and evaluating the effect of the change on the output [32]. It was selected for its simplicity and good comparability results. The sensitivity analysis was carried out for each factor by setting 2 parameters: a step size of 1% and a range of 50% (-25% to +25%) [33]. By changing 1 factor at a time, all other factors can be fixed, at least to a great extent, to their central or baseline value. The sum of all criteria weights at any percent change (PC) level should always be equal to 1. The weight of

the main changing criterion ($W(c_m, pc)$) at a certain PC level can be calculated as follows: $W(cm, pc) = W(cm, 0) + (W(cm, 0) * pc)$, $1 \leq m \leq n$, where $W(c_m, 0)$ is the weight of the main changing criterion c_m at the base run (the original weights). The weights of the other criteria $W(c_i, pc)$ are adjusted proportionally in accordance with $W(c_m, pc)$ to maintain the sum of all criteria weights at any PC of 1 with the following equation:

$$W(c_i, pc) = \frac{W(c_i, 0) * W(c_m, pc)}{W(c_m, 0)}$$

where $W(c_i, 0)$ is the weight of the i th criterion c_i at the base run.

We evaluated this step using the mean of the absolute change rate (MACR) [34]. In each simulation, the original suitability map (the original weights) and the output map of the alternative model (changing criterion weights) were quantitatively matched through a pixel-by-pixel comparison. The MACR was calculated using the following equation:

$$MACR = \frac{\sum |W_{original} - W_{alternative}|}{N}$$

where $MARC(w_j, cr)$ is the mean absolute value of the change rate, with w_j as the change rate, and N is the number of pixels. In addition, an uncertainty surface resulting from the changes in weights was produced for the study area representing the SD of the different suitability maps [35,36].

The spatial data used in this part are listed in Table 2. The distance risk factors were processed using the cost distance tool in ArcGIS (version 10.2; Esri) [37], in which the objects from the nearest distances, including the border, the ports, and the slaughterhouses, were estimated. Pig movement data in 2018 were obtained from a web-based movement registration system [38] (e-Movement), through which the movements of pigs and other animals are required to be registered. Pig population data were obtained from the animal census data operated by the Department of Livestock Development (DLD) officers annually, in which pig farms with <50 pigs were included for analysis. Surveys of pig farms using swill feeding were conducted by local DLD officers between September 2018 and December 2018. All geographical data were converted into raster data sets with a 100-meter resolution using ArcGIS.

Table 2. Spatial risk factors, standardized methods, and relative importance of each factor.

Spatial risk factors	Fuzzy membership functions	Inflection points				Weights
		a	b	c	d	
Distance to border, m	Sigmoidal monotonically decreasing	10,000	10,000	10,000	100,000	0.2295
Distance to port, m	Sigmoidal monotonically decreasing	10,000	10,000	10,000	100,000	0.3567
Distance to slaughterhouse, m	Sigmoidal monotonically decreasing	10,000	10,000	10,000	100,000	0.0580
Pigs moving in the area, n	Sigmoidal monotonically increasing	1	5	5	5	0.0668
Density of small pig farms (<50 heads), farms/km ²	Sigmoidal monotonically increasing	0.1	1	1	1	0.1219
Pig farms using swill feeding, farms/km ²	Sigmoidal monotonically increasing	0.01	0.5	0.5	0.5	0.1670

Developing a Mobile App for Farm Assessment of ASF Risk Introduction

We also applied the analytical hierarchy process to develop a set of factors and algorithms for risk assessment, which was performed through a platform in a mobile app. Publications on ASF risk factors were reviewed and proposed to the experts, who then selected and standardized the factors. First, risk factors for ASF introduction at the farm level such as biosecurity measures and characteristics of the farms' environments were selected by the experts. The selected factors were also standardized by defining the relationship between each of the factors and suitability using a 5-point scale (1=very low, 2=low, 3=medium, 4=high, and 5=very high). The relative importance of each factor was then defined using a pairwise comparison technique.

We designed questionnaires and coded algorithms on a mobile app for both iOS and Android operating systems by applying the outputs obtained from the previous steps. The combination of all factors to produce a final weighted estimate of suitability was implemented using a mobile app. The final score of each farm was obtained from the WLC method categorized into 5 suitability levels (<1.5=very low, >1.5-2.5=low, >2.5-3.5=medium, >3.5-4.5=high, and >4.5=very high). We set the provinces that found high and very high suitability for ASF distribution areas (analyzed in the previous step) as the targeted areas for farm assessment. District livestock officers were trained on how to install and use the app and then evaluated all non-Good Agricultural Practice pig farms in their responsible areas between April 2019 and July 2019.

Developing a Spatial Analysis of ASF Prevention and Control on a Web Application

We developed a spatial analysis of ASF prevention and control on a web-based platform. The necessary geodata for prevention and control planning were provided, including a suitability map for ASF introduction and transmission (step 1), the farm locations with ASF risk level (step 2), and other relevant layers such as locations of slaughterhouses (collected by DLD staff). The buffer rings surrounding selected pig farms were also developed, which allows users to download the important data in spreadsheet files, such as the number and details of neighboring farms and the distance to selected farms.

Ethics Approval

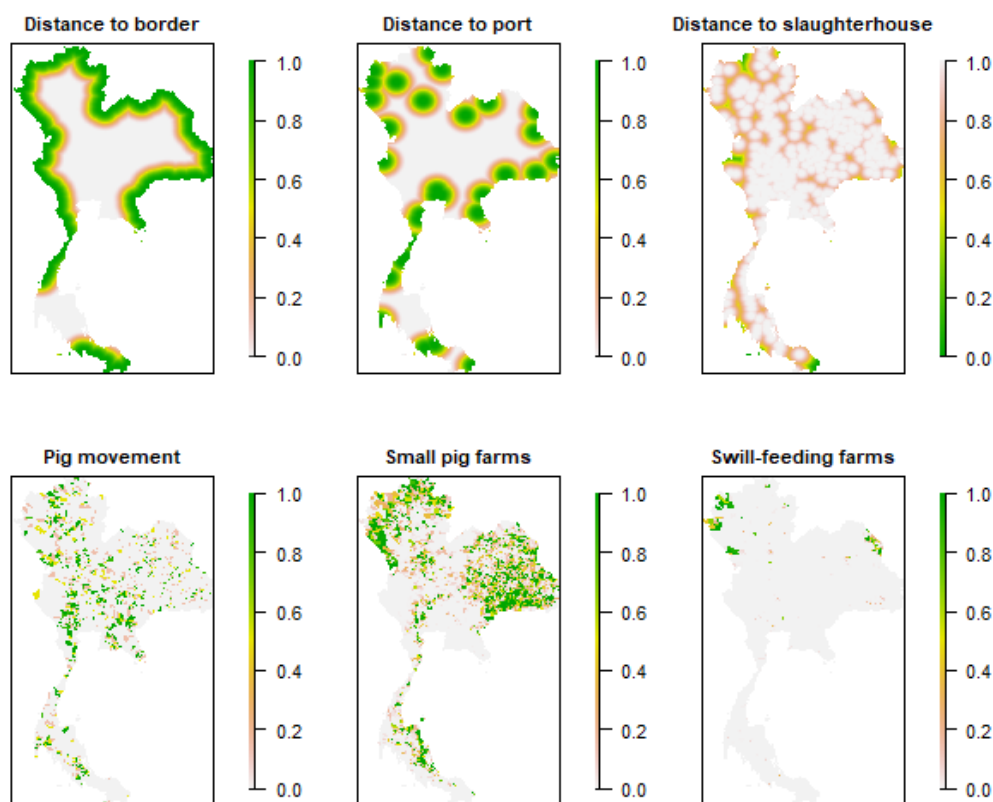

This study was approved by the Research Committee of the Bureau of Disease Control and Veterinary Services, DLD, Thailand (permit 64(2)-0105-110).

Results

A Suitability Map for ASF Introduction and Transmission

Table 2 shows the results of the defined factors, the standardized methods, and the relative importance of each factor, where

Figure 1. Maps of the standardized risk factors used to analyze the suitability for African swine fever introduction and transmission in Thailand. From top left to bottom right: the distance to the border, the distance to the port, the distance to the slaughterhouse, the number of pigs moving in the area, the density of small pig farms (<50 heads), and the number of pig farms using swill feeding.

distances are measured in meters and areas are measured in square kilometers (km²). Six spatial risk factors were identified by the experts: (1) the distance to the border, (2) the distance to the port, (3) the distance to the slaughterhouse, (4) the number of pigs moving in the area, (5) the density of small pig farms (<50 heads), and (6) the number of pig farms using swill feeding. The results showed that, according to the experts, the distance to the port had the highest weight, followed by the distance to the border, the number of pig farms using swill feeding, the density of small pig farms (<50 heads), the number of pigs moving in the area, and the distance to the slaughterhouse. Figure 1 shows the standardized risk factors used to produce the final suitability map for ASF distribution.

Figure 2 shows the suitability map for ASF introduction and transmission in Thailand if it were first introduced to the country. The resulting most potential areas were clustered near the north and northeast borders. The entire area was extracted and aggregated into 5 levels (very low to very high) at the subdistrict level, as shown in Table 3. There were 27 subdistricts in 10 provinces with very high suitability and 560 subdistricts in 34 provinces with high suitability.

Figure 2. The suitability map for African swine fever (ASF) introduction and transmission in Thailand.**Table 3.** Number of subdistricts, districts, and provinces according to African swine fever (ASF) risk levels.

ASF risk levels	Subdistricts (N=7416), n (%)	Districts (N=926), n (%)	Provinces (N=77), n (%)
Very high	27 (0.4)	17 (1.8)	10 (12.9)
High	560 (7.6)	144 (15.6)	34 (44.2)
Medium	1408 (18.9)	353 (38.1)	52 (67.5)
Low	2693 (36.3)	490 (52.9)	75 (97.4)
Very low	5833 (78.7)	478 (51.6)	55 (71.4)

Figure 3 shows the results of the one-at-a-time sensitivity analysis, in which the simulated suitability maps for ASFV transmission in pigs in Thailand were generated with the weight of each factor changed from -25% to 25% with a step size of 1% . The MACRs were used to display the sensitivity of each factor, with a high gradient indicating a greater change in the values of the output maps (high sensitivity). It appeared that the most sensitive factor was the distance to the port followed by the distance to the border, the distance to the slaughterhouse,

the number of pigs moving in the area, the density of small pig farms, and the number of pig farms using swill feeding.

The uncertainty analysis showed fairly robust results and a spatial heterogeneity. The uncertainty surface remained stable, with the maximum SD value being <0.1 (Figure 4) even though the risk factors were varied. This implies that the predicted suitability areas for ASFV transmission in pigs in Thailand according to the suitability index are fairly robust.

Figure 3. The results of the one-at-a-time sensitivity analysis. Distoborder: the distance to the border; distoport: the distance to the port; distoslaugh: the distance to the slaughterhouse; pigmovein: the number of pigs moving in the area; smfden: the density of small pig farms; swfarm: the number of pig farms using swill feeding.

Figure 4. Uncertainty map: SD of the suitability maps for African swine fever introduction and transmission in pigs in Thailand.

Farm Assessment of ASF Risk Introduction Using a Mobile App

The defined risk factors of ASF introduced to pig farms, standardized risk factors, and relative importance of risk factors (weight) are shown in Multimedia Appendix 1 [39-54]. The experts defined 17 risk factors that would be important at the farm level, which were categorized into 3 groups: farm biosecurity, farm management, and farm location. The 3 most

important identified factors were the pig feed, the farm location on an ASF risk level, and the breeding practices on the farm.

The results of the farm assessment of ASF introduction are presented in Table 4. There were 61,747 pig farms in 34 provinces evaluated using the developed app on a mobile platform. Of the 61,747 evaluated farms, 4 (0%) and 4380 (7.09%) were found to have very high and high risk of ASF introduction, respectively.

Table 4. The results of pig farms assessed using an app developed on a mobile platform.

Risk assessment level	Farms (N=61,747), n (%)	Provinces (N=34), n (%)
Very low	3919 (6.4)	32 (94.1)
Low	23,604 (38.2)	33 (97.1)
Medium	29,840 (48.3)	32 (94.1)
High	4380 (7.1)	28 (82.4)
Very high	4 (0)	4 (11.8)

A Spatial Analysis of ASF Prevention and Control on a Web Application

Figure 5 shows a spatial analysis on a web application in which the components are composed of the outputs obtained from the

previous processes, including the suitability map (step 1) and the locations of pig farms with risk-assessed level (step 2). In addition, we included other important layers useful for disease control planning, including the locations of the slaughterhouses.

Figure 5. A spatial analysis of African swine fever (ASF) prevention and control on a web application. A spatial analysis conducted by integrating all relevant layers for ASF prevention and control, such as (A) an ASF risk map, (B) farm locations with ASF risk at the farm level, and (C) the buffer zones and farms surrounding a selected farm.

Discussion

Principal Findings

The prevention of the introduction of ASF to Thailand started with the questions of how and where. As learned from the infected countries, the ASFV was introduced to the country possibly through infected live and dead pigs, infected pork products, infected boar semen, contaminated feed, and contaminated fomites [55,56]. Banning pigs, pork products, boar semen, animal feeds, and feed ingredients from affected countries; strictly checking pork products carried by travelers from affected countries; and encouraging pig farmers not to feed pigs with swill were immediately implemented by the Thai authorities [32]. However, with the increasing efficiency of virus detection and prevention, specific areas with a high possibility of virus introduction should be more focused on disease prevention activities [57,58]. Hence, a geographic information system-based MCDA was used in this study to evaluate the suitability for ASFV introduction and transmission in pigs in Thailand in the absence of actual data on ASFV occurrence in the country [59-61], where the outputs of the MCDA were required to help convert the current state of knowledge into a visualization. MCDA is a static, knowledge-driven model that ranks the best choices of a set of weighted rules based on existing publications and expert knowledge [61]. However, the quality of the predictions may be compromised by the misidentification of some unknown factors. It has been applied in many countries to predict suitability maps for ASF [59] and other animal diseases [24,36,62,63].

The 6 spatial risk factors identified and prioritized by the experts were the distance to the port, which had the highest weight; the distance to the border; the number of pig farms using swill feeding; the density of small pig farms (<50 heads); the number of pigs moving in the area; and the distance to the slaughterhouse. This consideration was based on the risk pathways of ASFV transmission by separating the factors into 3 groups in the offensive line. First, if the ASFV were introduced to the country through various sources [1,2,16], as a first line, it would officially and unofficially pass through international and border ports as well as border lines through smuggling [16,58]. Therefore, the distance to the port and to the border was initially included in the analysis. Second, if the ASFV passed through the first line to the territory by not being detected, as a second line, it would initially occur in pig farms that fed pigs with swill feed [16] or it would attack smallholders with poor farm biosecurity, as shown in Europe [16,64,65]. Finally, if the ASFV infected local pig farms, pig movement would facilitate the spread [16], and the virus would be present in slaughterhouses and adjacent areas [49,66].

Prevention of ASFV introduction to pig farms requires good farm biosecurity [16,67]. Biosecurity comprises the measures aimed at reducing the risk of introduction and spread of disease agents or, more simply, “to keep disease agents away from pigs” or “to keep pigs away from disease agents” [68]. Biosecurity practiced by large-scale commercial pig farms mostly corresponds to large investments in infrastructure and equipment

that are hardly implemented by smallholders. However, biosecurity improvements in the smallholder sector can already be achieved through very simple and low-cost precautionary measures [69]. This study was focused on selecting biosecurity that is practical for smallholders (as described in [Multimedia Appendix 1](#)) and using a simple way for local officers or farmers to be able to evaluate pig farms through a mobile app platform. Risk management [58] can also be communicated through the app, in which biosecurity practices with low scores would be suggested for improvement. Moreover, the outputs of the spatial risk analysis part were added to the farm evaluation part, allowing farmers to be more concerned with biosecurity improvement if their farms are located in high-risk areas [70].

This study developed a spatial analysis web-based platform that can facilitate disease prevention and outbreak control implemented by the responsible officers. Spatial epidemiological analysis plays an important role in planning for disease prevention and outbreak control [61] and has been used to describe and visualize the spatial distribution of hosts [71,72] and diseases [73,74], identify clusters of diseases [73,75], and predict disease risk [36,62]. The outputs of the analyses can be applied for disease prevention [16,59,76], for example, conducting intensive surveillance in high-risk areas, mitigating the risk of disease transmission in high-risk areas by strict animal movement, improving biosecurity, and minimizing the number of susceptible hosts. Spatial analysis is also applied for outbreak control. As guided by the World Organization for Animal Health [77], following the confirmation of an outbreak, control areas based on epidemiological factors may be established around the affected premises. Control measures basically include restriction of animal movement, intensive surveillance, and other specific measures applied to the affected premises. Implementation of these activities requires knowledge of the extent of these areas, the number of animals and farms within the areas, the exact locations of the farms, and the exact locations for setting checkpoints. However, working on spatial analysis is limited by things such as computers with high capacity, geographic information system software, geodata, technicians, and time-consuming processes [61].

Although MCDA is a fast and easy approach to be applied for developing tools for risk assessment at the spatial and farm levels, the limitations may be caused by the approach itself. Knowledge-driven models such as MCDA provide an interesting alternative to model the suitability for ASFV distribution in space or at the farm level as a way to prioritize surveillance and improve prevention [78], but the quality of the predictions may be compromised by the misidentification of some unknown factors. For instance, the spatial risk factors used in this study were focused on the pig-to-pig transmission cycle; therefore, the outputs may not be suitable for the sylvatic transmission cycle as analyzed in Africa [59]. Regarding farm evaluation, the accuracy of the evaluation may cause doubt and needs to be further tested.

Conclusions

This study developed tools by integrating a spatial risk assessment, a farm assessment on a mobile app, and a spatial analysis on a web-based platform aiming for the prevention of

ASFV introduction to pig farms in Thailand. The high-risk areas of ASF transmission in Thailand extracted from a risk map were used for disease prevention, such as intensive surveillance, strict movement control, biosecurity improvement if possible or not raising pigs in the farm if not possible, and public awareness. The risk assessments developed on a mobile app were used to evaluate pig farms focusing on smallholders in the most

prioritized areas based on a spatial risk assessment. A spatial analysis on a web-based platform was used by local authorities for spatial planning of disease prevention and could be used for outbreak control if an outbreak occurred. The tools developed in this study have been complemented with other strategies to fight against the introduction of the ASFV to pig farms in the country.

Acknowledgments

The authors thank the staff of the Department of Livestock Development for enhancing the tool development; the Center of Excellence for Biomedical and Public Health Informatics, Faculty of Tropical Medicine, Mahidol University, for developing the electronic platforms; and the Faculty of Veterinary Medicine, Kasetsart University, for facilitating the project. The authors would like to express their special thanks to Dr Sumeth Subchukul (Huvepharma [Thailand] Co, Ltd) and the US Agency for International Development and Food and Agriculture Organization for providing funds. Part of this work was supported by the Huvepharma Fund; the Faculty of Veterinary Medicine, Kasetsart University; and a US Agency for International Development and Food and Agriculture Organization grant (LOA/RAP/2018/04).

Data Availability

The data that support the findings of this study are available from the Department of Livestock Development, but restrictions apply to the availability of these data, which were used under license for this study and so are not publicly available. Data are available from the authors upon reasonable request and with permission from the Department of Livestock Development.

Authors' Contributions

WT conceived and designed the study. WT, VW, WS, and KT generated the raw data and performed the statistical analysis. AK developed the mobile app and web application platforms. WT drafted the paper, which KL and JK critically reviewed. SK and NR provided data and facilitated the project. All authors read and approved the final manuscript.

Conflicts of Interest

None declared.

Multimedia Appendix 1

The defined risk factors of African swine fever introduced to farms, standardized factors, and weight of each factor.

Abstract

Background: The COVID-19 pandemic, with all its virus variants, remains a serious situation. Health systems across the United States are trying their best to respond. On average, the health care workforce is relatively homogenous, even though it cares for a highly diverse array of patients. This perennial problem in the US health care workforce has only been accentuated during the COVID-19 pandemic. Medical workers should reflect on the variety of patients they care for and strive to understand their mindsets within the larger contexts of culture, gender, sexual orientation, religious beliefs, and socioeconomic realities. Along with talent and skills, diversity and inclusion (D&I) are essential for maintaining a workforce that can treat the myriad needs and populations that health systems serve. Developing hiring strategies that will help achieve greater workforce diversity remains a challenge for health system leaders.

Objective: The primary aims of this study were to: (1) explore the characteristics of US health systems and their associations with D&I practices and benefits, (2) examine the associations between D&I practices and three pathways to equip workforces, and (3) examine the associations between the three pathways to better equip workforces and business and service benefits. The three pathways are: (1) improving D&I among existing employees (IMPROVE), (2) using multiple channels to find and recruit the workforce (RECRUIT), and (3) collaborating with universities to find new talent and establish plans to train students (COLLABORATE).

Methods: During February to March 2021, 625 health systems in the United States were surveyed with the help of a consultant, 135 (21.6%) of whom responded. We assessed workforce talent- and diversity-relevant factors. We collected secondary data from the Agency for Healthcare Research and Quality Compendium of the US Health Systems, leading to a matched data set of 124 health systems for analysis. We first explored differences in diversity practices and benefits across the health systems. We then examined the relationships among diversity practices, pathways, and benefits.

Results: Health system characteristics such as size, location, ownership, teaching, and revenue have varying associations with diversity practices and outcomes. D&I and talent strategies exhibited different associations with the three workforce pathways. Regarding the mediating effects, the IMPROVE pathway seems to be more effective than the RECRUIT and COLLABORATE pathways, enabling the diversity strategy to prompt business or service benefits. Moreover, these pathway effects go hand-in-hand with a talent strategy, indicating that both talent and diversity strategies need to be aligned to achieve the best results for a health system.

Conclusions: Diversity and talent plans can be aligned to realize multiple desired benefits for health systems. However, a one-size-fits-all approach is not a viable strategy for improving D&I. Health systems need to follow a multipronged approach based on their characteristics. To get D&I right, proactive plans and genuine efforts are essential.

Introduction

Background

Health systems have been overwhelmed with COVID-19 patients [1]. Perennial shortages in the health care workforce have been exacerbated during the pandemic [2]. Stress, trauma, and burnout have tested the limits of health systems' existing workforces [3], and health systems lack workforces to treat the diversity of COVID-19 patients [4,5].

In general, the workforce in medicine is relatively homogenous, despite serving diverse populations. The health care system faces significant challenges matching patients' beliefs, attitudes, expectations, and care customization to an appropriately diverse workforce. In 2020, the US health care workforce reportedly comprised more than 50% white, approximately 20% Asian, 7% Black, and less than 1% Hispanic and Native American workers [6]. Two-thirds of physicians and surgeons are Christian, 14% are Jewish, and fewer than 15% represent other religions [7]. In addition, two-thirds are men, although this is changing as more women are admitted to medical schools [8]. In addition, dropouts among medical students in the first 2 years are high due to socioeconomic factors [9]. Assessment of sexual and gender diversity is also problematic, as disclosures risk discrimination claims [10], although schools attract unrepresented LGBTQ applicants [11]. In general, a lack of diversity in the health care workforce poses challenges for caring for diverse populations of patients, leading to variable and often detrimental access and quality issues [12]. Although the value of diversity has been well-established, unless health system leaders adopt explicit strategies to improve diversity and inclusion (D&I), they will not accomplish this goal. Moreover, it is not clear how health systems can best equip their workforces along with best practices to achieve a diverse workforce.

This study sought to assess efforts to improve D&I, as reported by chief executive officers (CEOs) of health systems across the United States. We argue that in addition to the talent and skills required for effective health care delivery, D&I needs to be part of the strategic agenda. Without this consideration, catering to the diverse needs of various populations will continue to present a challenge. This study thus explored the characteristics of US health systems and the perceived benefits of D&I. To achieve a diverse workforce in health care, health systems need to leverage different pathways. We examined factors that may shape those pathways to help balance talent and diversity. We also explored the associations between workforce pathways and both business and service benefits. Our approach will provide decision-makers with helpful practice and policy inputs [12,13].

Health Care Workforce Diversity

Health disparities are not homogeneous. Segments of populations are affected differently by different diseases. Accordingly, approaches and treatments may vary across these

segments and thus require customized care [13]. Therefore, it stands to reason that a lack of diversity in the health care system can negatively affect patients. For instance, an Indian patient with traditional ethnic or religious values or a transgender patient may have needs unique to their circumstances and worldview. A diverse workforce in health systems should respectfully and knowledgeably approach and assist all patients with an appreciation of their values and needs [12]. Professionals from different cultures and backgrounds bring unique perspectives to share with colleagues and patients alike as they strive to better understand and respond to patients' needs.

Alarming, when patients do not find providers, approaches, or treatments that echo or align with their beliefs, culture, or life circumstances, they are more prone to delay or avoid care. This problem is inherent in the current health care system. Patients from different cultures may perceive diseases and treatments differently. Greater diversity among health care workers will help reduce the barriers patients face when seeking care and contribute to better access and quality of care.

Prior research suggests that health care workforce diversity can improve creativity and decision-making while catering to multiple perspectives and contexts [14,15]. Specific to the COVID-19 context, research suggests that diversity-oriented leadership could improve employees' knowledge-sharing, promote professional collaborations, and help reach marginalized and hard-to-reach communities [16,17]. For example, immigrant and refugee professionals represent essential resources that can provide linguistic and cultural services for their communities during and after the COVID-19 pandemic [18]. Greater diversity broadens traditional boundaries to improve care and patient satisfaction, and could prove helpful in managing stressful environments [4,5].

Employee engagement is also higher in organizations with diverse workforces [19]. As the populations served by doctors are becoming increasingly diverse, doctors need to adopt a more global mindset. Ensuring a diverse student body in medical schools will help future doctors broaden their perspectives and improve their understanding of D&I. Doctors from such schools will be better equipped to provide care in diverse environments [6].

Prior Work on the Value and Benefits of D&I

Valuing D&I in the workforce goes beyond the basic requirements of skills and capabilities. Prior research suggests seven categories of diverse attitudes and perceptions: (1) diversity sensitivity, (2) integrity with a difference, (3) interaction variations, (4) valuing differences, (5) team inclusion, (6) managing conflict over differences, and (7) embedding inclusion [20]. Diversity focuses on the makeup of a population or its demographics, while inclusion encompasses involvement, engagement, and integration into organizational processes [21]. It is vital to create a supportive environment that is diverse, respectful, and inclusive [20]. Such an environment eases the

expression of dissenting opinions, is open to new problem-solving approaches, encourages innovative thinking, and more effectively avoids the dangers of groupthink, thereby opening doors for innovation and creativity-based organizational culture and business performance [22]. Diverse customers are often more loyal to diverse workforces and businesses [11]. Thus, through diversity, companies create organizational capabilities beyond their collective talents and skills, and can be more responsive to a comprehensive system of values and customers in a competitive marketplace [23]. To illustrate, a diverse and inclusive organization can potentially tap into the disposable income of African Americans in the United States, which reached US \$1.2 trillion in 2018 [24], and the buying power of Asian Americans, which topped US \$1 trillion in 2018 [25].

Although diversity has attracted substantial research attention, significant barriers and difficulties often accompany its implementation [26]. A workable approach begins with embedding inclusiveness in all aspects of an organization's culture, starting with recruiting different races, genders, sexual orientations, national origins, and religions. It also requires a conscious shift toward a culture in which policies and procedures provide opportunities for all employees to excel [27].

Diversity goes beyond the traditional "black and white" [28]. In addition to addressing observable attributes of inclusiveness such as race, invisible attributes such as religion, values, and beliefs are also important features of organizational culture to promote inclusiveness actively [29]. For instance, gender differences in the professional workforce have decreased considerably. Women now represent 47% of the US workforce and 52% of all managerial and professional positions [30]. Technology-driven, gender-fair hiring processes in many organizations have contributed to this trend [31]. In addition to hiring more women to improve diversity, there is an increasing trend of better representation among racial and ethnic minorities, immigrants, and people with disabilities in the US labor market. A 2018 study by Accenture found that the US economy could grow up to US \$25 billion if more people with disabilities were to join the labor force [32]. US regulations also require federal contractors to hire more workers with disabilities to avoid penalties [33]. There is a myth that hiring people with disabilities will cost more, which is a concern among organizations with low revenue levels. However, research has shown that more than 30% of the accommodations for workers with disabilities do not require additional expenditures, even after purchasing assistive technologies [34,35]. Nevertheless, valuing D&I must move beyond the surface or visible attributes to encompass different cultural and situational values and behaviors [36]. Ultimately, such efforts must become embedded within the organizations to be successful.

Firms outside of health care (eg, Apple, Google, IBM) recognize the benefits of diversity [37]. Research has shown that a discriminatory work environment can hinder an organization's ability to build and equip the workforce it needs, leading to decreased productivity and performance. Conversely, proactively valuing D&I can attract the best talent and create an environment of belongingness and respect [36].

Health care workforce diversity needs to improve to successfully treat a greater variety of patients, from increasing care reach to improved satisfaction for racial and ethnic minority patients. Accessibility to underserved patients through a diverse workforce will bring health care closer to African American, Hispanic, and Native American communities [38]. Patients treated by physicians of their own racial or ethnic background are more likely to report receiving higher-quality care [39]. Improving access, care, quality, and reach all have significant implications for the long-term success of the health care sector in the United States.

Pathways to Equip the Workforce: Improve, Recruit, and Collaborate

What is the starting point toward greater workforce diversity? Undoubtedly, schools and universities are the formative platforms to inculcate D&I in young minds through examples, demonstrations, and practices [6]. Diverse classrooms broaden perspectives, promote active thinking, foster intellectual engagement, develop social skills, teach empathy, and improve racial understanding, all of which are essential for embracing diversity [40]. At the same time, organizations need to put more significant pressure on the education system to drive diversity. We consider three pathways to achieve this.

First, existing employees must acquire the necessary skill sets and diversity training. Programs such as "returnships," in which experienced professionals take career breaks for training through professional and executive development programs, can help to promote and equip a more diverse workforce [41].

Second, technologies have made the recruitment process more efficient. Platforms such as LinkedIn and other social media avenues have become instrumental in finding talent. While health systems rely on traditional recruitment processes, using emerging channels to discover new talent could prove helpful.

Third, reaching out to and collaborating with universities can effectively expand the talent pool to recruit. This may start at the beginning of an education cycle, continue through projects and internships, and result in hiring from the collection of students engaged with the organization through these avenues.

For large health systems with diverse customers, a diverse base of employees is required. The revenue status of a health system can change its recognition of the direct link between diversity and performance. Major teaching health systems, as knowledge-based organizations, may have more proactive organizational cultures and reputations for openness, which will help them attract talent regardless of nationality or ethnic background. Macro factors such as increased mobility due to climate change and changing economic situations portend more women, more people of color, and more immigrant workers in the United States over the next 25 years [42]. To broaden recruitment to reflect the composition of society and the spread of business operations, organizations will need more women and people from different ethnic origins. In this context, understanding what health systems are doing to diversify their workforces remains an open question. In addition, due to social distancing policies implemented during the COVID-19 pandemic, digital transformations such as virtual teams and

telehealth pose new challenges for collaboration. Diverse backgrounds among virtual collaborators, if managed well, can promote better learning to achieve more efficient outcomes [43]. Recognizing this potential will enhance remote working both during and after the COVID-19 pandemic.

The question remains as to which one or more of the three pathways mentioned above—improve, recruit, and collaborate—can effectively meet the challenges of D&I requirements. Identifying and assessing effective pathways will help instill appropriate plans in health systems. For example, explicitly valuing D&I will motivate organizations to develop long-term career plans to retain talent [44]. Organizations can better equip existing employees by developing internal training and education programs [20]. The critical element is an individual's openness to change, which can be improved through training [45]. At the same time, it is also essential to recruit new employees, as having a diversity of work experience is a helpful way to refresh organizational culture. Finally, external collaboration with strategic partners benefits allying partners' resources, including human resources [46]. This study further explores these three pathways to equip the workforce better—improving, recruiting, and collaborating—and their relative associations with business and service-oriented benefits.

The pathway model has been used in previous studies on diversity [47]. A common framework is diversity practices—pathways—performance [48]. Following this framework, we considered business and service benefits as the performance component. We examined the associations with three pathways: improving, recruiting, and collaborating. The two types of diversity practices are D&I strategy and talent strategy.

Methods

Data Collection

The effort to study the talent strategy in health systems is part of a broad project undertaken by the Health Administration Research Consortium at the Business School of the University of Colorado Denver. The idea of monitoring health systems emerged from observations and conversations with several chief executives of health systems during the COVID-19 pandemic. This research is part of the Health Systems' Climate Study of 2021 conducted by the Health Administration Research Consortium [49]. The Climate Study aims to understand the current state of health systems in the United States following the COVID-19 pandemic. The objective was to collect and disseminate the insights of health systems' CEOs to help inform policymakers, practitioners, and academic stakeholders as they collaborate to create ongoing strategies to help the industry respond to this pandemic and prepare for the next crisis.

A questionnaire was developed in December 2020 to collect data from health systems. We drew the survey items from prior literature, and questions were reworded to fit the health systems

context. We sought input from knowledgeable researchers, consultants, and executives with the requisite expertise to design and evaluate the questions. The survey was pilot-tested, revised, and finalized in January 2021 with five top executives who are part of the Health Administration Program Advisory Board.

A contact list of CEOs was compiled from 624 health systems across the United States using multiple sources, contacts, professional connections, websites, and annual reports. The survey instrument was administered using a professional online survey platform, and was mapped to emails to the platform to create unique, trackable links for each health system. Email and phone solicitations were made in multiple rounds between January 25 and March 2, 2021. In addition, the authors called several CEOs and asked them to complete the survey instrument either online or in paper format. The researchers also requested CEOs who had participated in the survey to share the link with other CEO colleagues. A total of 148 responses were received, with a 24% response rate; however, 13 incomplete responses could not be used, leaving 135 usable responses. We address potential nonresponse bias in a later section.

The 135 health systems represented in this survey varied from 1 to 18 hospitals and from 176 to 75,000 employees. The annual revenue of the health systems in 2020 ranged from US \$0.7 million to US \$14 billion. The health systems represented US \$300 billion in revenue and 1.1 million employees across the United States.

We then matched the survey data set with secondary data collected from the Agency for Healthcare Research and Quality compendium to construct a complete picture of the health systems. Our final sample included data from 124 health systems across the United States. We analyzed this combined data set, which yielded several important insights.

Variables and Measures

Table 1 describes the variables used in this study. The two constructs of health systems' workforce strategy focus are D&I STRATEGY and TALENT STRATEGY. The two constructs of health systems' benefits are BUSINESS BENEFIT and SERVICE BENEFIT. These variables were each measured using 7-point Likert scales. We also tested the internal-consistency reliability of these multi-item variables using Cronbach α . The four α values were close to or greater than the recommended acceptable threshold of .70 for exploratory research [50].

The three variables used to measure the pathways to equip the workforce by health systems were IMPROVE (ie, improve current talent), RECRUIT (ie, recruit new talent), and COLLABORATE (ie, collaborate with universities). This study's other independent and control variables represented several categories: size, region, teaching status, revenue, and several other system characteristics. We coded these variables (see Table 1) to reflect the attributes of a health system.

Table 1. Description of variables, including survey questions and coding scheme.

Variable	Description and coding
Question: “To what extent do the following dimensions describe how you address or plan to address in your company’s workforce strategy?”^a	
D&I ^b STRATEGY	Inclusion of diversity-relevant dimensions in your organization’s workforce strategy to attract talent: gender, ethnicity and race, disability, experience (Cronbach $\alpha=.60$)
TALENT STRATEGY	Inclusion of diversity-relevant dimensions in your organization’s workforce strategy: knowledge, attitude toward career and progression, personal quality or mindset, and adaptability (Cronbach $\alpha=.67$)
Question: “What benefits, if any, have your organization obtained from its strategy to promote diversity and inclusiveness?”^a	
BUSINESS BENEFIT	Obtaining business benefits from promoting diversity and inclusiveness: enhancing business performance, strengthening brand reputation, and innovating internally or externally (Cronbach $\alpha=.70$)
SERVICE BENEFIT	Obtaining service benefits from promoting diversity and inclusiveness: enhance customer satisfaction, serve customer needs, leverage technology advancements for services, and compete in new industries (Cronbach $\alpha=.83$)
Three pathways to equip the health systems workforce: “How will you address talent needs in your organization?”^a	
IMPROVE	Returnships of existing employees to acquire new skills
RECRUIT	Use multiple channels to find and recruit workers (ie, aspirations to discover new talent for health systems through emerging digital channels and traditional recruitment channels)
COLLABORATE	Reach out and collaborate with universities to find new talent and establish plans to train students
Coding of contingent variables	
SIZE	The size variable is measured using the total beds managed by the health system across all hospitals, reported by AHRQ ^c Hospital Compendium
SIZE_B-SMALL	Health system has fewer than 100 beds
SIZE_B-MEDIUM,	Health system has 100 to 400 beds
SIZE_B-LARGE	Health system has more than 400 beds
REGION	Following the Census Bureau’s categorization, the region variable is coded based on the health system’s primary location in the United States
REGION-NE	Health system in the Northeast
REGION-MW	Health system in the Midwest
REGION-SOUTH	Health system in the South
REGION-WEST	Health system in the West
TEACHING	The teaching variable is coded based on the teaching status of a health system
TEACHING-NON	Nonteaching health system
TEACHING-MINOR	Minor teaching health system
TEACHING-MAJOR	Central teaching health system
REVENUE	The revenue variable of the health system is measured using its annual revenue across all hospitals
REVENUE-LOW	Revenue less than US \$2 billion
REVENUE-MEDIUM	Revenue US \$2-5 billion
REVENUE-HIGH	Revenue more than US \$5 billion
HIGH-DSH-HOSP	The health system includes at least one high-discharge-patient-percentage hospital: 1=yes, 0=no
HIGH-BURDEN-SYS	Health system-wide uncompensated care burden flag: 1=yes, 0=no
HIGH-BURDEN-HOSP	The health system includes at least one high uncompensated care burden hospital: 1=yes, 0=no
OWNERSHIP	Predominantly investor-owned hospitals: 1=yes, 0=no
PHYSICIANS	The number of physicians in the health system is measured by the number of physicians reported by the AHRQ Hospital Compendium
HOSPITALS	This variable is measured by the number of hospitals the health system has reported by the AHRQ Hospital Compendium

^aResponses reflect a 7-point Likert scale from 1=strongly disagree to 7=strongly agree.

^bD&I: diversity and inclusion.

^cAHRQ: Agency for Healthcare Research and Quality.

The size variable measures the number of beds in a given health system (SIZE_B-SMALL, SIZE_B-MEDIUM, SIZE_B-LARGE). The region variable reflects the location of a health system (REGION-NE, REGION-MW, REGION-SOUTH, REGION-WEST). The teaching status variable assesses how a health system operates in association with a teaching program (TEACHING-NON, TEACHING-MINOR, TEACHING-MAJOR). The revenue variable measures the annual revenue of a health system (REVENUE-LOW, REVENUE-MEDIUM, REVENUE-HIGH). Finally, we included variables to capture the high discharge levels of the health systems (HIGH-DSH-HOSP), uncompensated care burden (HIGH-BURDEN-SYS and HIGH-BURDEN-HOSP), ownership status (OWNERSHIP), number of physicians (PHYSICIANS), and number of hospitals (HOSPITALS). [Table 1](#) presents complete information about the variables in our study.

Sample Statistics

The descriptive statistics and pairwise correlations among the key variables used in this study are shown in [Table 2](#) and [Table 3](#), respectively. As shown in [Table 2](#), health systems, on average, value a talent strategy for improving employees' skills and capabilities more than a D&I strategy. The most popular pathway to equip a workforce is through collaboration with universities, followed by recruitment, and then by improving the current workforce.

In addition, to ensure there was no nonresponse bias, we compared the characteristics of responding and nonresponding health systems. As shown in [Table 4](#), the *t* test results for all comparisons indicated no significant difference between respondents and nonrespondents.

Table 2. Summary statistics of the variables (N=124).

Variables ^a	Mean (SD)	Range
D&I ^b STRATEGY	4.62 (9.4)	2.3-6.5
TALENT STRATEGY	4.87 (1.10)	2.2-6.5
BUSINESS BENEFIT	5.35 (0.94)	1.7-7.0
SERVICE BENEFIT	4.67 (1.28)	2.0-6.5
IMPROVE	4.49 (1.35)	1-7
RECRUIT	4.67 (1.51)	1-7
COLLABORATE	4.82 (1.36)	2-7
SIZE_B-SMALL	0.09 (0.28)	0-1
SIZE_B-MEDIUM	0.37 (0.49)	0-1
SIZE_B-LARGE	0.54 (0.50)	0-1
REGION-NE	0.22 (0.42)	0-1
REGION-MW	0.24 (0.43)	0-1
REGION-SOUTH	0.35 (0.48)	0-1
REGION-WEST	0.18 (0.38)	0-1
TEACHING-NON	0.30 (0.46)	0-1

^aSee Table 1 for variable descriptions.

^bValues in italics indicate a significant correlation at $P < .10$.

Table 4. Characteristics of responding and nonresponding health systems.

Characteristics ^a	Respondents (n=124), n (%)	Nonrespondents (n=511), n (%)	t value
Size			
Small (6-99 beds)	11 (8.8)	41 (8.0)	-0.19
Medium (100-399 beds)	46 (37.1)	210 (41.1)	-0.56
Large (≥400 beds)	67 (54.0)	260 (50.1)	1.41
Region			
Northeast	27 (21.8)	118 (23.1)	0.07
Midwest	30 (24.2)	132 (25.8)	0.55
South	45 (36.3)	169 (33.1)	-0.48
West	22 (17.7)	92 (18.0)	-0.12
Physicians			
Small (51-199 physicians)	50 (40.3)	189 (37.0)	-0.74
Medium (200-999 physicians)	41 (33.1)	204 (40.0)	-0.69
Large (≥1000 physicians)	33 (26.7)	118 (23.1)	1.53
Hospitals			
Small (1-3 hospitals)	83 (66.9)	338 (66.1)	-1.27
Medium (4-6 hospitals)	20 (16.1)	66 (12.9)	-0.02
Large (≥7 hospitals)	21 (16.9)	107 (20.9)	0.81
Ownership status			
Investor-owned	3 (2.4)	15 (2.9)	-0.85
Noninvestor-owned	121 (97.6)	496 (97.1)	0.85
Teaching status			
Major teaching	29 (23.4)	138 (27.0)	-0.15
Minor teaching	58 (46.8)	225 (44.0)	-0.61
Nonteaching	37 (29.8)	148 (29.0)	0.85

^aThe numbers of physicians and hospitals are presented in this table in different categories for easy comparison across respondents and nonrespondents.

Statistical Analysis

We used ordered logit regressions to estimate (1) the relationship between specific hospital characteristics and workforce-strategy focus as well as diversity benefits, (2) the relationship between workforce-strategy focus and pathways to equip the workforce, and (3) the mediating effects of workforce choices on the relationship between workforce strategy focus and diversity-driven business and service outcomes. We used ordered logit regressions because the dependent variables are ordinal. This approach does not assume equal intervals between levels of the dependent variable. The ordered logit model is as follows:

$$Y_i^* = \beta X_i + e_i,$$

where Y_i^* is the propensity of respondents to indicate higher levels of the dependent variables, X_i is a set of explanatory variables, β a vector of parameters, and e_i are disturbances (errors).

We do not observe Y_i^* ; instead, we observe the ordinal dependent variable Y_i . Depending on the values of thresholds or cut-off points τ_{m-1} and τ_m , the probability distribution of Y_i is as follows:

$$\Pr(Y_i=m|X_i) = F(\tau_m - X\beta) - F(\tau_{m-1} - X\beta)$$

Ethical Considerations

An ethics review was not applicable for this study. The data used was received through a leading professional consulting firm that anonymizes and provides secondary firm-level data for research and analysis to draw insights.

Results

Estimation Outcomes

The first two columns in [Table 5](#) display the results from the ordered logit-model estimations that describe the relationship between contingent factors and health systems' workforce strategy focus. The remaining two columns in [Table 5](#) present the results on health systems' diversity-enabled benefits.

First, the results indicate that compared to small-sized health systems, medium-sized health systems are less likely to value diversity and inclusiveness in their D&I strategies ($P < .001$). Conversely, large-sized health systems are more likely to value D&I strategies than small-sized health systems ($P = .002$). There are some differences between health systems located in the Northeast and West, insofar as those in the West tend to focus more on diversity and inclusiveness ($P = .001$).

Second, when the health system includes at least one high-discharge-patient-percentage hospital, it tends to value D&I more ($P < .001$). The results also showed that high-revenue health systems seem to value D&I less than low-revenue health systems. In addition, health systems with a system-wide high uncompensated care burden tend to value D&I less.

These results differ from the estimation results of the contingent factors on valuing a talent-acquisition strategy (Table 5). In terms of a workforce strategy focus, there seem to be no differences in health systems concerning size, ownership status, discharge, uncompensated care burden, and the number of physicians and hospitals. Region and revenue level yielded the most significant differences. The results indicate that health systems in the Northeast emphasize employees' skills and capabilities more than those located in the South and West. In addition, compared to low-revenue health systems, medium- and high-revenue health systems tend to place less emphasis on a talent-acquisition strategy ($P < .001$).

The last columns in Table 5 show the associations between health system characteristics and business and service benefits (while valuing D&I). The results of size and revenue were consistent for both types of benefits. For both business benefits ($P < .001$) and service benefits ($P < .01$), small-sized health systems tend to gain compared with medium- and large-sized health systems. Further, high-revenue health systems are more likely to gain both types of benefits than low-revenue systems ($P < .001$).

We also found some differences between these two benefits across health systems. For the business, investor-owned health systems, health systems with medium revenue (vs low revenue), health systems with at least one high-discharge-patient-

percentage hospital, and health systems with a system-wide uncompensated care burden tend to gain more benefits, whereas health systems with more hospitals are more likely to gain fewer business development benefits due to a diversity strategy. For service-oriented benefits, some differences were found according to region. Compared with health systems located in the Northeast, those in the South and in the West seem to gain fewer service-improvement benefits (Table 5).

Table 6 shows the different relationships between the three workforce pathways and the D&I and talent strategies. The results indicate a significant and negative relationship between D&I STRATEGY and COLLABORATE, but a significant and positive relationship between TALENT STRATEGY and RECRUIT. The relationship between TALENT STRATEGY and COLLABORATE was significant and positive. The relationships between the two strategies and the IMPROVE pathway as well as the relationship between D&I STRATEGY and the RECRUIT pathway were not significant.

Table 7 displays the mediating effects of the three workforce pathways (ie, IMPROVE, RECRUIT, and COLLABORATE) on the direct relationship between D&I and talent strategies and the business benefit. Analysis of the mediating models using Sobel Goodman tests, which determine whether a variable carries (or mediates) the effect of an independent variable to the dependent variable (the outcome of interest), showed that overall, IMPROVE has a higher mediating effect (44%) than COLLABORATE (4%) and RECRUIT (7%) between a D&I strategy and business benefit. Similarly, IMPROVE has a higher mediating effect (13%) than COLLABORATE (5%) and RECRUIT (1%) between a talent strategy and business benefit.

Table 8 shows the mediating effects of the three workforce pathways (ie, IMPROVE, RECRUIT, and COLLABORATE) on the direct relationship between D&I and talent strategies on service benefit. Analysis of the mediating models using Sobel Goodman tests showed that overall, IMPROVE has a higher mediating effect (27%) than COLLABORATE (2%) and RECRUIT (0.05%) between a D&I strategy and service benefit. Similarly, IMPROVE has a higher mediating effect (26%) than COLLABORATE (0.06%) and RECRUIT (0.02%) between a talent strategy and service benefit.

Discussion

Implications of Findings

Getting diversity right in the health care workforce remains a challenge, regardless of the widespread realization that D&I is critically important in this sector. Health systems lag in proactive plans, results-driven strategies, and subsequent implementations. Without these, the concept of D&I will be but a fad without any tangible results for decades to come.

This study explored the differences in D&I strategies across different health system characteristics. The findings suggest that health systems with fewer beds, those located in the western United States, with low revenues, with at least one high-discharge hospital, and a relatively low system-wide uncompensated care burden tend to value D&I more and are more likely to have a D&I strategy in place. Plausibly, these systems are driven by a focused strategy, locational alignments, and a manageable suite of complexities to instill D&I plans. Some of these differ from a talent-acquisition approach,

indicating that health systems treat these two diversity practices differently. Regarding the diversity benefits, it seems that small health systems with comparatively high revenue have been able to gain both business- and service-related benefits; however, in other aspects of the health systems, the benefits vary across categories.

The most important contribution of this study has been to compare and contrast the three workforce pathways and their associations with benefits. The findings suggest that health systems that value *only* a D&I strategy may *not* rely on collaboration with universities to equip their workforces. However, health systems that value a talent strategy will look externally to recruit new workers and seek collaboration with universities.

While examining the pathways through mediation analyses, we established that the IMPROVE pathway is more effective than the RECRUIT and COLLABORATE pathways in enabling the diversity strategy to prompt business or service benefits. Moreover, these pathway effects go hand-in-hand with a talent strategy, indicating that both talent and diversity strategies need to be aligned to achieve the best results for a health system.

Limitations and Directions for Further Research

This study has some limitations that future studies may be able to address. For example, we did not focus on the effects of internal issues (eg, management, coordination) on diversity. Furthermore, the opportunities and barriers to diversity strategies should be studied in detail. Relating diversity to well-known aspects of health care delivery, such as cost, quality, and patient-experience outcomes, is also essential. We also need to

note that the 22% response rate is not very high, although it represents the US health systems' population. Increasing response rates and covering all health systems in a study will require significant resources, and we may perform such a study in the future.

Conclusions

The challenges and uncertainties that COVID-19 presented to health systems in the United States have been unprecedented. The pandemic has propelled many issues to the forefront, including diversity. It is time for health systems to address the diversity issue, which has been a point of conversation for more than two or three decades. However, little progress has been made to date, and few proactive strategies are in place, leading to a nondiverse workforce in US health care.

This study demonstrates that D&I efforts have numerous positive business and service outcomes. Regarding the methods to address the talent shortage, it seems that health systems that value D&I are less likely to seek external collaborations. This may be because external collaboration is not an effective way to promote D&I inside the health systems. A notable point is the importance of professional and executive training programs, and further education for instilling a D&I mindset, strategy, and pathways in a health system. This improvement pathway is beneficial for outcomes; however, diversity and talent-acquisition efforts must be aligned with recruitment to yield multiple benefits for health systems. Following these findings, our recommendations will help health systems establish a more diverse health care workforce and improve outcomes for a diverse population.

Acknowledgments

Our sincere thanks to the active and candid participation of the executives from 135 health systems. The authors thank Naser Shekarian, PhD candidate in the Computer Science and Information Systems Business PhD program at the University of Colorado Denver, for help in compiling chief executive officers' addresses and for data collection in the climate study. The authors thank the Business School at the University of Colorado Denver for support for this project and, specifically, the Health Administrations and the Computer Science and Information Systems Business PhD Programs for the time and effort of the authors involved with this study.

Abstract

Background: The effect of dietary collagen on managing digestive symptoms is currently lacking in the literature.

Objective: To gain a better understanding of this issue, we conducted a 2-phase mixed methods study.

Methods: Phase 1 was a mixed methods design to explore current attitude and practice among consumers and health care practitioners. The findings were used to design an 8-week phase 2 digital study called Gutme! conducted in the United States in healthy female volunteers (BMI > 25 kg/m²). Our aim was, first, to determine the feasibility of conducting a fully digital mixed methods study; second, the study explored the effect of an 8-week daily supplementation of 20 g dietary collagen peptide (Peptan) on digestive symptoms. Phase 2 was a prospective, open-label, longitudinal, single-arm study. Participation involved 2 weeks of baseline tracking (digestive symptoms, mood, stool, and lifestyle) using an app, followed by 8 weeks of tracking and taking 20 g collagen peptide supplement split into 2 dosages per day. Participants were required to complete a web-based symptom questionnaire at baseline, week 2, and week 8, as well as participate in 2 scheduled video interviews.

Results: Phase 1 revealed that consumer awareness of collagen for digestive health is low (64/204, 31.4%). Among the dietitians prescribing collagen for their patients, the most common dosage was 20 g a day with notable effects after 6 weeks of intake. Within the phase 2 study, of the 40 recruited participants, 14 (35%) completed the full course of supplementation. The findings indicate that 93% (13/14) of those who completed the study experienced a reduction in digestive symptoms, which included bloating.

Conclusions: A mixed methods digital study design is feasible and acceptable for collecting relevant data in a real-life setting. The use of a 20 g daily collagen peptide supplement may reduce bloating and improve mild digestive symptoms in otherwise healthy female adults in the absence of any other dietary or lifestyle interventions.

Trial Registration: ClinicalTrials.gov NCT04245254; <https://clinicaltrials.gov/ct2/show/NCT04245254>

Introduction

Background

Disorders of gut-brain interaction (DGBIs), formerly known as functional gastrointestinal disorders (FGIDs), relate to an array of gastrointestinal (GI) disorders, with irritable bowel syndrome

and functional dyspepsia being the most common. Symptoms of DGBIs include bloating, stomach cramps, pain, diarrhea, constipation, flatulence, irregular bowel movements, and acid reflux. Most recently, a Rome Foundation Global Study estimated that >40% of the global population experiences at least one digestive disorder, with similar statistics in the United States alone (39.9%) [1]. Women are disproportionately

affected, with an odds ratio of 1.7 compared with men [1]. A possible explanation for this phenomenon is that women are more likely to discuss digestive symptoms with their medical doctor than men [2]. Although uncomfortable digestive symptoms commonly do not warrant a medical visit or hospitalization, they can affect quality of life [3], and the economic impact cannot be ignored, with recent findings demonstrating that the direct and indirect costs, including absenteeism and productivity, in the United States were US \$21 billion or the equivalent of US \$500 to US \$1200 per patient per annum [3].

The etiology for DGBIs is not always very clear. On the basis of the biopsychosocial model for FGIDs from the Rome IV study, potential explanations include an interplay among the following factors: genetics, psychological factors (early life trauma, psychological state, and social support), disturbance in gut-brain axis, and environmental stressors (infection, use of antibiotics, and poor dietary habits such as a low-fiber diet) [4].

Despite its high prevalence, for many decades the management of what was formerly known as FGIDs revolved around treating specific gut symptoms with over-the-counter medications, many without credible scientific data backing their efficacy [5]. The cause of digestive symptoms can be multifactorial; current practice is to use standard approaches based on the diagnosis. Examples of current approaches include cognitive behavioral therapy [6]; a diet low in fermentable oligo-, di-, and monosaccharides and polyols [7]; over-the-counter solutions such as fibers and gels; and lifestyle changes [8]. Dietary supplements and functional food products, including probiotics, vitamins, L-glutamine, and antacids, are additional approaches commonly chosen by consumers to help them manage their symptoms [9]. Most recently, dietary collagen in the form of collagen peptides or collagen hydrolysates have been added to this supplement selection. Collagen peptides are sourced from bovine, porcine, marine, or poultry sources [10]. Although there are positive reports of the use of collagen supplementation in skin hydration as well as joint, bone, and muscle health, especially in athletes to aid exercise recovery, reports of the benefits of the use of collagen in digestive health are currently lacking [11-15].

The intestinal epithelium acts as an active barrier between the external and internal environments, protecting the organism from toxins as well as regulating intestinal homeostasis and nutrient absorption [16]. Tight junctions (TJs) are an integral part of these paracellular barriers, it having become clear in recent years that they are responsible for more functions beyond simple diffusion. Their proteins have been shown to be used by viruses and pathogenic bacteria to gain access across the barrier into the cells; moreover, mutations in the genes encoding these proteins have been linked to an array of inherited diseases [17]. Dysregulation of the intestinal barriers can be multifactorial, with infection and inflammation playing a part [16]. This can lead to increased gut permeability, which has also been discovered in several GI disorders such as Crohn disease and described as a contributing factor in pathogenesis of one of the most common DGBIs, irritable bowel syndrome [18,19]. TJs are affected by inflammation and proinflammatory cytokines, in particular, elevated levels of tumor necrosis factor-alpha, and

this has been shown to disrupt the barriers, leading to increased permeability [20]. Research regarding the effect of collagen peptides on gut permeability through different mechanisms of action is limited and restricted to animal models or cells [21-23]. In the study by Chen et al [16], collagen peptides derived from the skin of the Alaska pollock significantly attenuated the tumor necrosis factor-alpha-induced dysfunction of the TJ barrier in Caco-2 cell monolayers. These interesting findings need to be explored further; however, this may be an indication that collagen peptides might be helpful in targeting gastric and bowel-related issues. The goal of this paper was to explore the potential role collagen could play in the management of common digestive symptoms such as bloating.

Despite the best intentions, traditional study designs may not sufficiently detect interindividual differences [24] and are often far removed from real-life settings [25]. New approaches and study designs as well as statistical methods are now recommended to better identify and detect interindividual differences in response to supplements, ingredients, or interventions [26]. These new study approaches leverage digital technologies, such as apps, wearables, trackers, and smartwatches, that have opened up the opportunity to reach wider groups and offer an efficient and convenient way to collect valuable data in the real-world context [27]. With common digestive symptoms in particular, apps can be useful to identify the often hidden relationship among food, mood, lifestyle, and digestive symptoms, which can then be used to personalize dietary and lifestyle advice accordingly [28]. Advanced analytics such as machine learning or artificial intelligence can then identify patterns or trends in the data shared or submitted by users [29].

Objectives

The main aim of the Gutme! study was to assess the feasibility and acceptability of a mixed methods digital study.

The secondary aims were set for each phase as follows:

- The aim of the first phase of the study was to obtain a better understanding from consumers and frontline health care practitioners on how they use collagen to manage digestive symptoms such as bloating and explore their perceptions on how collagen works.
- The aim of the second phase of the study was to determine the response to a collagen peptide supplementation to reduce digestive symptoms in otherwise healthy consumers.

The purpose of the study was to determine whether a mixed methods study design could be used to collect reliable data in a real-life setting and whether collagen peptides could be potentially used as a solution in the management of mild digestive symptoms in healthy female adults.

Our hypothesis was that an 8-week supplementation with bovine-based collagen peptides would reduce digestive symptoms in healthy female adults.

Methods

Study Design

The phase 1 consumer study, which was led by a third party based in the United Kingdom (Streetbees), included a web-based survey that used an artificial intelligence approach. Web-based

interviews were conducted by a Portugal-based consultancy (Qina) with a small group of functional and integrative nutrition registered dietitians (RDs) based in the United States who used collagen peptides for the management and treatment of digestive complaints. The phase 2 study used a prospective, open-label, single-arm, longitudinal design. The full study design flow is outlined in Figure 1.

Figure 1. Phase 2 study flowchart. Baseline relates to a 2-week preintervention phase with variable tracking: diet and lifestyle, stools, symptoms, and Medical Symptoms Questionnaire (MSQ) 1; week 0-8 relates to an 8-week-long collagen supplementation with variable tracking; MSQ 2 was administered 2 weeks after supplementation; and MSQ 3 was administered 8 weeks after supplementation. RD: registered dietitian.

Ethics Approval

The study design was approved by Advarra, an ethics advisory board (2329-ProofPilot), and was registered on ClinicalTrials.gov (NCT04245254). The Gutme! study ran between March 2020 and October 2020 during the COVID-19 pandemic.

Inclusion and Exclusion Criteria

Phase 1

The inclusion criteria were as follows: the consumer group, as determined by Streetbees, included participants actively taking collagen supplements, were based in the United States, had access to the Streetbees app, and were aged 18 to 65 years. Current or past medical history was not part of the screening. The RD group included functional and integrative nutrition RDs based in the United States who were using collagen in their practice.

Phase 2

The inclusion criteria were as follows: women aged 35 to 65 years with access to the internet and experiencing 3 out of the following 5 symptoms: bloating, flatulence, acid reflux, stomach pain, and irregular bowel movements; app or smartphone user; English speaking; based in the United States; and with no self-reported medical diagnosis and not on medication (with the exception of oral contraceptives). Age range was determined from the interviews with the RDs in phase 1 who reported that the majority of their clients with GI symptoms were aged 35 to 65 years.

The exclusion criteria were as follows: participants with <3 digestive symptoms, chronic kidney disease, scleroderma, allergy to glutamate and beef, or kidney stones. This was based on feedback from the RDs in the phase 1 study. In addition, we excluded participants who were already taking collagen, had recent antibiotic use, or experienced occurrence of DGBIs (eg, Crohn disease) or ulcerative colitis.

In terms of quality criteria, participants who did not respond to emails after 5 attempts were considered dropouts. Study completion was considered at 9 weeks. In addition, on the ProofPilot platform, no more than 2 users per physical address were allowed to participate.

Participant Recruitment

With no prior data to base the recruitment numbers on, power calculations were not performed for phase 2; to start the study, the goal was set arbitrarily at $n=40$. Participants were recruited through social media advertisements on Facebook and Instagram, web-based forums, professional networks, social media influencers, and private gut health groups, as well as the ProofPilot platform. On the basis of the statistics provided by the advertising platforms, recruitment reached >20,000 participants, and the recruitment goal was reached at 8 weeks.

Study Materials (Phase 2)

Peptan (Rousselot) was the collagen peptide brand used as the intervention. The powdered supplement mixes easily into food and beverages and is widely available on the market. The collagen peptides were supplied by the manufacturer as 10 g stick packs, each batch coded and labeled for the entire study period and delivered directly to each participant's home through a courier service. Participants were instructed to take 20 g per

day (as 2×10 g divided doses), mixed in food or beverages. Participants were aware that they were taking collagen peptides; however, they were not told which brand was being used. Maltodextrin was the only potential candidate as a control supplement; however, because of its deleterious effect on gut health [30], an alternative was to enable participants to track the effect of supplementation through a 2-week baseline assessment of their usual food intake, physical activity, and symptoms.

The Medical Symptoms Questionnaire (MSQ) is a functional medicine tool used to measure self-reported symptoms, which helps to identify potential health issues within various physiological and emotional body systems (Multimedia Appendix 1) [31]. Administering this questionnaire was the preferred method of collecting data by the RDs in their practice to track their clients' progress over time. The questionnaire consists of 71 questions, with each symptom scored on a 5-point (0 to 4) Likert scale from *Never or almost never have the symptom* to *Frequently have it, effect is severe*. The decision to use the questionnaire was based on the phase 1 study, which found that the tool was used by the majority of RDs in their clinical practice. The MSQ was administered as a web-based survey directly on the ProofPilot app to all eligible and consented participants at baseline as well as at week 2 and week 8 after supplementation. The survey took 10 to 15 minutes to complete.

The Cara Care app is a digital therapeutic app for use by individuals experiencing digestive symptoms. The app is a certified Class I medical device that has been approved as a digital therapeutic for the management and treatment of digestive disorders by Germany's Federal Institute for Drugs and Medical Devices [32]. The app consists of features for logging and tracking meals, gut symptoms, stool, mood, bowel regularity, menstruation, water consumption, and physical activity. The app has a dashboard feature that can be shared with the research team for viewing submitted data in real time. The dashboard consists of a visual chart that indicates how total scores for bloating and stool symptoms track over time. In this study, we used the free version of the app, which does not provide personalized feedback.

Bloating score on the app refers to a self-reported assessment of fluid retention based on a scale of 1 to 100 and is categorized into the following groups: none (0), mild (25), moderate (50), severe (75), and extreme (100).

Stool score on the app is based on the Bristol Stool Chart [33] and refers to the physical appearance of the feces reflecting intestinal transit time. The stool score used in this study ranges from 0 reflecting no bowel movement on a particular day through 7 different categories of stool appearance from constipation (14) to diarrhea (100): separate hard lumps (14); lumpy and sausage-like (28); sausage shape with cracks in surface (42); perfectly smooth, soft sausage (57); soft blobs with clear-cut edges (71); mushy consistency with ragged edges (85); and liquid consistency with no solid pieces (100). Stool frequency refers to the number of stools each participant reported during a 7-day period.

A recent study has demonstrated that using the Cara Care app leads to a reduction of digestive symptoms and improves quality of life [34].

ProofPilot is a digital research platform that is compliant with both the Health Insurance Portability and Accountability Act and General Data Protection Regulation. The platform has a web interface for researchers to track data in real time. Study participants used the platform as an app downloaded onto their smartphone. Participants received reminders to complete study tasks directly on their smartphone during the entire study period.

Google Meet with enhanced security was used to conduct secure video calls with participants at week 2 and week 8 after supplementation.

Study Procedure

Phase 1

The survey was completed by eligible participants directly on the Streetbees app. The questions consisted of a mixture of Likert scale and free-text questions. Participants were also asked to upload images or videos of the nutritional supplements they were taking. Out of the total cohort taking collagen supplements, those who took collagen to manage their digestive symptoms were identified. For the interviews, eligible RDs were identified and contacted through email and a mutually convenient time was set up to conduct the recorded video interviews, each of which lasted up to 60 minutes. All video interviews were transcribed and checked for quality.

Phase 2

During the recruitment phase, interested participants were directed to the Gutme! study landing page on the ProofPilot platform, which provides details of the study. If participants were interested in further information, they were required to set up an account on ProofPilot, at which point data regarding their date of birth, location, and gender were collected, as outlined in Figure 1. After registration, all participants were required to complete the eligibility questionnaire.

Immediately after taking the web-based eligibility questionnaire, participants were told about their suitability for the study. Participants then received an email message to confirm their acceptance and were served with an e-consent form at that point. Only consented participants could continue with the tasks that followed. Participants who were not eligible were informed through an email; they were offered the opportunity to scrutinize the ProofPilot study page to participate in any other available studies that were recruiting.

Consented participants were onboarded using a welcome voice message and downloadable instructions that included *How to mix the collagen* and *How to download the Cara Care app*. The first task for onboarded participants was to complete a baseline questionnaire (MSQ 1), after which participants were asked to download the Cara Care app and order their supplements, which were provided free of charge.

Participants were then given instructions to share their Cara Care app dashboards and track their symptoms to obtain baseline measures on what was considered normal for them over the first

2 weeks. Participants were asked to continue with their habitual food intake and exercise for the duration of the study. During this initial 2-week period, participants would have received their supplement delivery. They were then requested to continue tracking their symptoms daily and take the collagen peptide supplement (20 g total per day) as 10 g twice daily, mixed into either food (such as yogurt or oats) or beverages (water or coffee) for the remaining 8 weeks (corresponding to week 0 to week 8). All participants received daily encouraging and informational messages for the duration of the study as a reminder to track their symptoms and take the collagen based on best practice guidelines [35]. Participants were invited to schedule a video call with an RD at week 2 and week 8, to clarify concerns, give feedback, or ask questions. Participants did not receive any dietary or lifestyle advice either on the web or during the video calls, but they were given guidance on how to mix the supplement and log their data. Weekly email reminders were sent through the ProofPilot app to complete assigned study tasks. All participants completed a final web-based exit survey to provide feedback on their experience.

Statistical Analysis

Data are expressed as mean and 95% CI or mean and SD. As this is a pilot study and no power calculations were performed ahead of the study, the statistical analysis is exploratory, with no *P* values reported. Instead, percentage change was calculated to report changes between treatment weeks.

Treatment Effect Size

Treatment effect was calculated using the Hedges *g* formula, which comprises the Cohen *d* formula adjusting for within-group estimates of repeated measures variables from baseline and week 8 with 95% CI. The Cohen *d* formula for treatment effect gives biased estimates of the population size because it is based on sample averages (also referred to as uncorrected effect size) [36]. Hedges *g* corrects for the size of the treatment groups and is therefore better suited to repeated measures as used in the

study. On the basis of the Cohen assumption, the effect size can be interpreted as follows: 0.2, *small* effect size; 0.5, *medium* effect size; and 0.8, *large* effect size [36]. The full formulas are illustrated below:

$$\frac{M_1 - M_2}{\sqrt{\frac{SD_1^2 + SD_2^2}{2}}}$$

$$\frac{M_1 - M_2}{\sqrt{SD_1^2 + SD_2^2}}$$

where M_1 : mean of group 1; M_2 : mean of group 2; SD_1 : SD of group 1; SD_2 : SD of group 2; n_1 and n_2 : number of participants in each treatment; and r : correlation between group 1 and group 2.

Results

Results of Phase 1 Study

Consumer Survey

Of the 204 consumers who participated in the survey, 35 (17.2%) were collagen users. Collagen users tended to be educated to a higher level and were in the higher income bracket (Figures S1 and S2, respectively, in [Multimedia Appendix 1](#)) compared with the rest of the Streetbees app users. The results demonstrate that awareness of collagen for digestive health is low, with only 31.4% (64/204) answering *Yes* and 63.7% (130/204) answering *No* to the question *Before today, had you ever heard of collagen supplements being used to help with digestive health?* The most common reasons for using collagen in digestive health included better digestion, better stomach, and less bloating (Table 1).

Responding to the question *How often do you use your collagen supplement?*, 63% (22/35) indicated that they used it 1 to 2 times per day mostly in powder format and mixed into water (Table 2), which correlated well with the recommendations from practitioners (see *Practitioner Interviews* section).

Table 1. Participants’ responses regarding reasons for using collagen (N=35).

What do you think this product does for you?	Participants, n (%)
I feel better overall	9 (26)
Helps with digestion	8 (23)
Keeps me regular	6 (17)
Helps with bloating	2 (6)
Helps with bowel movements	2 (6)
Maintains gut health	2 (6)
Reduces or relieves pain	2 (6)
Helps me to sleep and relax	1 (3)
Helps with constipation	1 (3)
Helps with weight control	1 (3)
Reduces heartburn or acid reflux	1 (3)

Table 2. Participant responses to the question *How often do you take collagen?* (N=35).

Responses	Values, n (%)
Multiple times a day	1 (3)
1 to 2 times a day	22 (63)
A few times a week	9 (26)
Less often	1 (3)
I only use it when I am experiencing digestive issues	2 (6)

Practitioner Interviews

Interviews with US-based practitioners (n=15) revealed positive outcomes when starting patients and clients on collagen peptides, which included reduction in bloating, stomach cramps, flatulence, and acid reflux, as well as improvement in irregular bowel movements when used daily for a period of at least 6 to 8 weeks. The most common dosage recommended by practitioners was 20 g of collagen peptides per day in powder format, irrespective of the brand. It is important to note that

collagen peptides were used as part of a comprehensive supplementary regimen that could include micronutrients, digestive enzymes, glutamine, colostrum, prebiotics, and probiotics. It would therefore be difficult to conclude that an improvement in digestive symptoms was due to collagen alone. A summary of the phase 1 study with practitioners is presented in [Table 3](#).

The first phase provided a clear picture of how and why collagen was being used to manage digestive symptoms, which provided the basis for designing the phase 2 study.

Table 3. Main findings of the phase 1 study interviews with registered dietitians (N=15).

Theme	Findings	Quotes
Indication for starting a collagen supplementation	Most started their clients on collagen supplementation based on careful assessment of digestive problems	“So it’s everything from GI ^a symptoms, from constipation, diarrhea, bloating, [...] reflux [...]”
Recommended dosage	20 g per day as separated doses	“I definitely want people to have at least 12 grams a day. You probably have benefits right up through 25 grams a day”
Duration	6 to 8 weeks	“I would [...] say six weeks and then check in and see your response at that time”
Target group	Women aged 35 to 65 years	“[...] I would say 40s to 60s, but that’s certainly not to say that I haven’t started seeing more and more people in their early 30s”
Perceived benefits	Reduces bloating; heals gut lining; improves digestion	“It depends on the person, most people love continuing on them because not only are you getting the gut healing benefits from collagen [...]”
Monitoring progress	MSQ, ^b diary, repeat stool test	“We’re using one from the Institute of Functional Medicine and that one’s called the MSQ medical symptom questionnaire”

^aGI: gastrointestinal.

^bMSQ: Medical Symptoms Questionnaire.

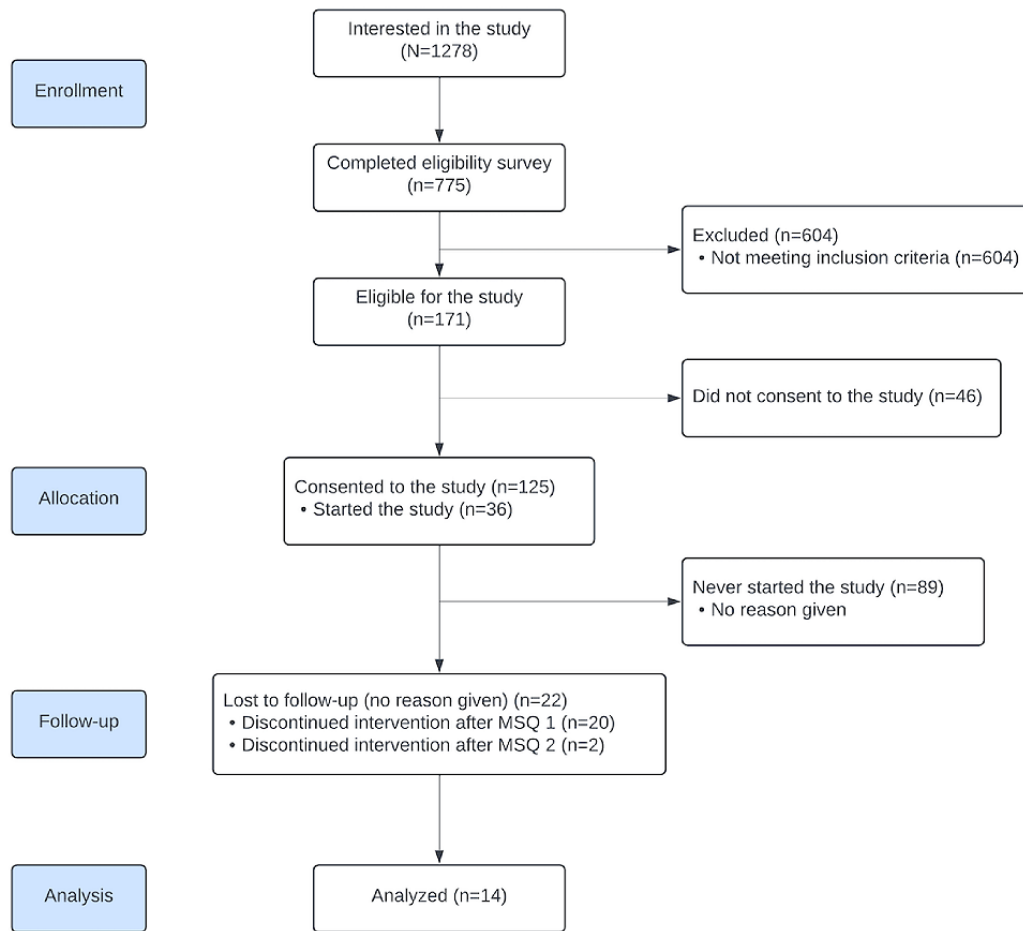

Results of Phase 2 Study Gutme!

Participant Recruitment

Of the 775 individuals who completed the eligibility survey, 604 (77.9%) were not eligible and 171 (22.1%) were eligible. Of these 171 individuals, 46 (26.9%) did not consent. Although the target for recruitment was set at n=40, the platform was left open to allow additional eligible individuals to participate to

account for attrition. In total, 125 individuals consented; however, 89 (71.2%) did not start trial participation, leaving 36 (28.8%) who started the study. Of these 36 participants, 22 (61%) were lost to follow-up (n=20, 91%, after MSQ 1 and n=2, 9%, at 2 weeks after supplementation [MSQ 2]). Reasons for not participating were not investigated. [Figure 2](#) shows the CONSORT (Consolidated Standards of Reporting Trials) diagram with study recruitment figures.

Figure 2. CONSORT (Consolidated Standards of Reporting Trials) diagram with study recruitment figures. MSQ: Medical Symptoms Questionnaire.

Study Retention

At baseline and after consenting, the participants (n=36) entered the Gutme! study. By week 4, of the 36 participants, 20 (56%) dropped out, leaving 16 (44%) participants. By week 8, of the 16 participants, 2 (13%) dropped out, leaving 14 (87%) participants after supplementation. Reasons for the high dropout rate include the disruption caused as a result of the COVID-19 pandemic; of the 36 participants, 1 (3%) was diagnosed with a medical condition; a few participants (n=3, 8%) withdrew because of unexpected medical and family emergencies related to COVID-19; however, many participants (n=18, 50%) either failed to respond to emails or withdrew for unknown reasons.

Participant Characteristics and Supplement Use

All participants who completed the study were women with an average age of 46 (SD 6.2; range 37-58) years and average BMI of 28 (SD 7.8; range 21-48) kg/m². None of the participants had any medical conditions or were on medication. Ethnicity breakdown of the 14 participants was as follows: White: 9 (64%); African American: 3 (21%); Hispanic or Latino: 1 (7%); and other: 1 (7%). None of these participants had been taking collagen supplements; 14% (2/14) took vitamin and mineral supplements, 28% (4/14) took probiotics, and 21% (3/14) took digestive enzymes.

Baseline Symptom Characteristics

Participants regularly experienced all digestive symptoms as outlined in Table 4.

Table 4. Symptom occurrence at baseline (N=14).

Symptom	Participants, n (%)
Bloating	14 (100)
Acid reflux	9 (64)
Flatulence	14 (100)
Irregular bowel habits	14 (100)
Stomach cramps	10 (71)

Change in MSQ Score

Symptom occurrence at baseline is shown in Table 4. The change in MSQ scores for total MSQ and specific symptoms is shown in Table 5. On average, participants reduced their MSQ scores by 4.8 (SD 15.2) points, which indicates a slight improvement in their overall symptoms. On subscore analysis

(Figure 3), bloating scores reduced from an average of 3.9 to 2.6 (31%) after an 8-week supplementation, with a trend for reduction in bloating after 2 weeks of supplementation; constipation dropped from 2.2 to 1.8 (19%), indicating an overall improvement. Intestinal stomach reflux reduced from 2.6 to 1.6 (39%), with a substantial reduction after 2 weeks; acid reflux reduced from 2.1 to 1.6 (21%) after 8 weeks.

Table 5. Absolute and percentage change in Medical Symptoms Questionnaire (MSQ) scores.

	Baseline score, mean (SD); 95% CI	Week 2 score, mean (SD); 95% CI	Week 8 score, mean (SD); 95% CI	Change, baseline to week 8 (%)
Total MSQ score	61.2 (11.1; 54.4-67.9)	64.6 (4.7; 61.8-67.5)	56.4 (13.5; 48.3-64.5)	-8
Bloating	3.9 (0.4; 3.7-4.1)	3.2 (1.0; 2.7-3.8)	2.6 (1.1; 2.0-3.3)	-31
Constipation	2.2 (1.0; 1.7-2.8)	2.2 (0.8; 1.8-2.7)	1.8 (1.0; 1.2-2.4)	-19
Intestinal stomach pain	2.6 (0.7; 2.2-3.0)	1.9 (0.5; 1.7-2.2)	1.6 (0.8; 1.1-2.0)	-39
Acid reflux	2.1 (1.0; 1.5-2.7)	2 (1.0; 1.5-2.6)	1.6 (1.2; 1.0-2.3)	-21

Figure 3. Absolute change in Medical Symptoms Questionnaire (MSQ) scores, n=14: (A) total MSQ score over the study period. Questionnaire administered: MSQ 1 at baseline, MSQ 2 at week 2, and MSQ 3 at week 8 after supplementation; (B) average bloating score; (C) average constipation score; and (D) average intestinal stomach pain score. Average scores in figures B, C, and D were calculated as subscore of digestive health category within the MSQ 5-point scale of symptom occurrence and its effect: 0=never or almost never; 1=occasional but not severe; 2=occasional, severe; 3=frequent, not severe; and 4=frequent, severe. Data are expressed as mean (SD).

Effect Size

Results of the effect size calculations are shown in Table 6. Total MSQ score, constipation score, and acid reflux score fall

within a *small* effect size (<0.5), whereas changes in bloating and intestinal stomach pain scores fall within a *large* effect size (>0.8) as per the Cohen assumptions.

Table 6. Effect size.

	Hedges g^a	Lower limit	Upper limit	r^b
Total MSQ ^c	0.36	-0.3	1.0	0.25
Bloating	1.1	0.7	2.3	0.64
Constipation	0.41	-0.3	1.1	0.21
Intestinal stomach pain	1.3	0.6	2.2	0.38
Acid reflux	0.37	-0.1	0.9	0.63

^aHedges g is calculated from Cohen d accounting for repeated measures. Effect size is based on the Cohen assumptions: $g=0.2$ would be considered a *small* effect size, 0.5 represents a *medium* effect size, and 0.8 a *large* effect size.

^b r : Pearson correlation.

^cMSQ: Medical Symptoms Questionnaire.

Cara Care App Data

The Cara Care app logging rate for the 10-week study period was overall very poor. This has resulted in inconsistent data and inconclusive results for a cohort analysis. Reasons for not logging regularly included a difficult interface on the app, it was time consuming to log dietary intake, and participants forgot to log in on a daily basis despite receiving reminders. When participants did provide very occasional food diary entries, they were reviewed by an RD and compared against the national healthy eating guidelines. The diaries indicated that foods selected and consumed suggested a standard American diet high in processed food, low in fiber, and high in fat [37].

Of note, individual variability in symptom scores is demonstrated for a small number of participants in Figures S3 and S4 in [Multimedia Appendix 1](#).

Self-reported Data From Interviews and Exit Survey

The exit survey indicated that participants were overall happy with participating in an entirely digital study. When asked where participants had heard about the study, 71% (10/14) indicated friends or family, 14% (2/14) indicated Twitter, 7% (1/14) indicated ProofPilot, and 7% (1/14) had heard about it from a health care professional. Motivation for joining the study included the following: keeping participants busy during COVID-19, 36% (5/14); trying a new supplement, 50% (7/14); and convenient to participate, 14% (2/14). Finally, 64% (9/14) of the participants indicated that they would have been happy to participate if the study was longer: "I found it very eye opening. It made me realize what foods were my trigger and that I needed to change my eating behavior."

The video interviews and exit surveys provided detailed insight and data into the effect of taking the collagen peptide supplement over the study period. Participants reported a difference in their gut symptoms within approximately 2 days of taking the collagen supplement. On the basis of the interviews and the exit survey data, 93% (13/14) of the participants reported a reduction in bloating and 93% (13/14) experienced an improvement in bowel habits with the most frequently reported symptom being relief from constipation:

The product, it did help with my bloating quite a bit, but even more than that, it practically resolved my chronic constipation. Prior to the study I'd have

problems with constipation on almost a daily basis, since beginning the product I've had issues maybe once or twice. I no longer have that heavy feeling, as I had in the past.

It's like day and night with my gut. Bloating is down and I now go to the toilet regularly.

Great reduction in bloating. Consistency of stools now normal, first time ever. No more diarrhea. Felt a difference almost from day 2.

Discussion

Principal Findings

Collagen peptide supplements have become increasingly popular over the last decade and are estimated to grow into a US \$7.5 billion market by 2027 [28]. Although the majority of collagen users are within the hair and beauty market [28], the use of collagen has found its way into consumer health products such as for sport recovery [15]. Technology-assisted personalized nutrition solutions such as web-based diaries and symptom trackers have grown in popularity and have enabled new ways of delivering care, providing information as well as gathering data [37]. It is this personalized nutrition approach that gives practitioners and consumers alike the opportunity to experiment with new supplements and ingredients (or a combination thereof) to track the effects on their own bodies through a range of digital tools and at-home tests [38]. In fact, the COVID-19 epidemic has spurred the update of digital health tools and supplements owing to an increased awareness and interest in health and nutrition [39].

The effect size of the intervention on digestive symptoms has shown that collagen supplementation resulted in a large effect on symptoms of bloating and intestinal stomach pain, which is consistent with feedback received from participants. Bloating is 1 of the 2 most commonly reported digestive symptoms, with distension being the other [40]. Numerous reasons have been provided, from food intolerance to delayed intestinal transit or infection; yet, the cause is individual and most often not related to the amount of gas in the bowels [40]. The Gutme! study findings indicate that collagen may be useful to reduce bloating in women who regularly experience the symptom. It is important to note that all the participants were in the overweight range, which has been associated with a lower microbiome diversity

[41] and therefore potentially poses an increased risk of bloating. Constipation is one of the most common digestive symptoms with a global prevalence of 14% [42]. Common causes include consuming a diet low in fiber, medication (such as iron supplements), a lack of physical activity, and dysbiosis of the gut microbiota [43]. Bowel frequency is often poorly characterized and highly personal [44]. Our qualitative findings indicate that of the 16 participants, 15 (94%) increased their bowel frequency and 3 (19%) reported that their bowel frequency increased from historically once per week or less to once per day since starting the collagen supplement. We would have therefore expected to see a bigger drop in the MSQ score, based on the detailed information and dramatic changes that participants reported during the video calls in terms of their bowel habits, but this was not the case. This could be because the questionnaire took time to complete [45], meaning the participants were tired and not careful in scoring or did not remember how they felt at the start. In addition, the symptoms of a participant who regularly experienced floating stools, an indication of possible malabsorption, resolved after taking the collagen supplement. The reasons for this change in bowel habit are not clear and will require further clinical investigation. Potential explanations for the change in bowel frequency could be a shift in the microbiome composition because of the increased protein load [46] or simply because of an increase in water consumption, with the lack thereof being a common reason for constipation [3]. Although we can speculate that collagen peptides act on the microbiome, the mechanism is not clear. It is unlikely that this change came about as a result of gut healing (or resolution of leaky gut), as suspected in our interviews with practitioners, because the effect would take weeks and not days [47]. Furthermore, it is important to note that we did not provide any dietary or lifestyle guidance to participants. Dietary intake data from the Cara Care app suggested that all participants were following a standard American diet high in processed foods and low in fiber [37]. Participants also had low levels of physical activity (data not shown), which could contribute to their gut symptoms. Whether the supplementation would still have the same effect if participants had an overall better baseline diet and gut microbiome requires further investigation.

Key Learnings From the Study

Digital studies offer the advantage of including volunteers in real-life settings when they are able to follow their normal routines, including diet and exercise. Especially during the pandemic, the number of digital studies conducted have increased and can offer significant advantages, in particular with remote site monitoring and recruitment [48]. Social media can be a good way to attract and recruit study participants by means of word of mouth through family and friends for common issues that are often discussed freely on the web. Cross-referencing the data of the Cara Care app, the MSQ questionnaire, and video interviews allowed us to view the data both as a cohort and individually. Furthermore, participants expressed an appreciation of being viewed as equals during the study where they also received information in exchange (an explanation of their Cara Care app dashboard) and were given the opportunity to contribute to the development of a needed

solution for women, making digital studies an attractive and convenient option.

Limitations

This study lacked a control group; hence, including a control group, which could comprise a group of participants receiving standard practice, should be considered for future studies. As it was a pilot study with only 1 arm to assess feasibility, the study was neither randomized nor blinded. These study designs could contribute greatly to obtaining more reliable data on the effect of supplementation and will be taken into account for future studies. During the recruitment process, the study suffered high dropout rates, especially after consent. As previously discussed, the pandemic played a role in the willingness of participants to commit to additional responsibilities; however, this should be considered in future studies. Moreover, the sample size was small and therefore the findings should be interpreted with caution. The study period was long, which could have affected participation and completion rates; future studies could be shorter in duration, especially considering that participants reported much perceived improvement within days of taking the supplement. Selecting participants from different locations with a variety of dietary patterns could provide better insight into the true effect of collagen supplementation for the same digestive symptoms. Our sample only included women, and therefore future studies should also include men. Menstrual cycles are known to affect fluid retention, which has an impact on body composition, with levels peaking on the first day of menstruation [49,50]. This physiological process may have an impact on the effect of supplementation on the gut in studies where bloating is one of the outcomes, such as the study reported here. Another limitation is that the study was limited to participants who were digitally literate and had access to the internet, thereby excluding individuals who were not digitally literate and did not have access to the internet [51].

The completion rate for this study was 35% (14/40), which was mostly as a result of unforeseen circumstances during the COVID-19 pandemic; yet, these could be addressed with better participant screening, monitoring, and engagement or by adopting a hybrid approach. Other digital studies have reported a completion rate between 50% and 80% [52,53]. It was cumbersome for participants to use 2 separate apps (ProofPilot and Cara Care), which led to inconsistent tracking with regard to diet and physical activity. Selecting interoperable solutions that already have popular apps integrated should be a key consideration for future studies. Finally, participants were told that the interviews would be conducted by an RD, and this could have introduced bias in terms of how big an effect collagen supplementation had [54]; however, the results in terms of effect size suggest otherwise.

Future studies should consider including microbiome, genetic, and metabolic data. They should also consider diet quality and lifestyle factors using convenient and noninvasive tracking. Research-grade image-recognition dietary assessment tools could improve the participant experience by reducing time to log meals and provide insight into the quality of their diet. In addition, increasing the ethnic diversity of participants should

be a core focus in future research, considering that digestive symptoms are so common and span across ethnicities.

Conclusions

A mixed methods digital study design is a feasible and acceptable method to explore the effect of a supplement in a

real-life setting. In this small 8-week digital study, the consumption of 20 g collagen peptide supplement (Peptan) may have resulted in a reduction in bloating and an improvement in bowel frequency in the absence of any other dietary or lifestyle intervention or advice. These findings warrant confirmation in a larger, well-controlled study with or without dietary guidance.

Acknowledgments

This research was funded by Rousselot.

Authors' Contributions

MA and JP conceived the study and were responsible for the methodology, manuscript review and editing, and project administration. MA and RO were responsible for the software used in the study. Validation was carried out by MA, JP, and RO. MA was responsible for the formal analysis, investigation, and preparing and writing the original draft. All authors have read and approved the final version of the manuscript.

Conflicts of Interest

MA received funding for consulting services from Rousselot. JP is an employee of Rousselot. The funders had no role in the design of the study; in the collection, analyses, or interpretation of data; in the writing of the manuscript; or in the decision to publish the results.

Abstract

Background: Digital tools may help to address social deficits in schizophrenia, particularly those that engage social comparison processes (ie, evaluating oneself relative to others). Yet, little is known about social comparison processes in schizophrenia or how best to capture between- versus within-person variability, which is critical to engaging comparisons in digital interventions.

Objective: The goals of this pilot study were to (1) better understand affective responses to social comparisons among individuals with schizophrenia, relative to healthy controls, using a validated global self-report measure; and (2) test a new brief, mobile assessment of affective responses to social comparison among individuals with schizophrenia, relative to the full measure. This study was conducted in 2 phases.

Methods: We first compared self-reported affective responses to social comparisons between individuals with schizophrenia (n=39) and healthy controls (n=38) using a traditional self-report measure, at 2 time points. We examined the temporal stability in responses and differences between groups. We then evaluated the performance of brief, mobile assessment of comparison responses among individuals with schizophrenia, completed over 12 weeks (n=31).

Results: Individuals with schizophrenia showed greater variability in affective responses to social comparison than controls on traditional measures and completed an average of 7.46 mobile assessments over 12 weeks. Mobile assessments captured within-person variability in affective responses in the natural environment (intraclass correlation coefficients of 0.40-0.60). Average scores for mobile assessments were positively correlated with responses to traditional measures.

Conclusions: Affective responses to social comparison vary both between and within individuals with schizophrenia and capturing this variability via smartphone surveys shows some evidence of feasibility. As affective variability is a potential indicator of poor outcomes among individuals with mental health conditions, in the future, a brief, mobile assessment of affective responses to social comparisons may be useful for screening among individuals with schizophrenia. Further research on this process is needed to identify when specific comparison messaging may be most effective in digital interventions and could suggest new therapeutic targets for illnesses such as schizophrenia.

KEYWORDS

schizophrenia; social comparison; mobile assessment; smartphone app; variability

Introduction

Schizophrenia currently affects approximately 1% of the US population [1]. Available pharmacological treatments can address positive symptoms (eg, hallucinations, delusions), but they are not as effective for negative symptoms (eg, amotivation, social deficits) [2], which are associated with greater disability and impairment [3]. While specialized therapies exist to help treat the social deficits in schizophrenia, access to them remains limited [4], and understanding ways to encourage social engagement remains a core priority for research and clinical care.

Across health care, digital technologies have the potential to increase access to and improve quality of care. Digital treatments for mental health conditions, such as those delivered via smartphone apps, are popular and over 10,000 already exist [5]. However, sustained engagement with app-based treatments is low: after 2 weeks, 96% of those who download a mental health app have stopped engaging with it [6]. Given the relapse, remitting, or chronic pattern of mental illnesses such as schizophrenia, sustained engagement is critical for digital treatments to have maximal impact. Strategies to boost engagement with these treatments include use of social networks to promote social support [7]. Evidence shows that social networks are currently the most effective means to drive sustained engagement with mental health apps, and that apps that offer social support have higher rates of engagement than those that do not [6].

In addition to processes such as social support, the efficacy of social networks to drive engagement (and consequent behavior change) rests in part on *social comparison* processes. Comparing one's opinions, skills, or behaviors to those of relevant others allows people to evaluate themselves, which reduces uncertainty in these domains [8]. Theory and evidence indicate that people make *upward comparisons* (comparing themselves to someone better off) or *downward comparisons* (comparing themselves to someone worse off), and that these comparisons can have a range of consequences for both short-term affect and longer-term behavior [9]. The effects of comparisons depend on a variety of person-level and contextual factors, including perceived similarity to the comparison target [10].

Specifically, the Identification/Contrast Model [11], which has been applied often in chronic illness populations, suggests that focusing on similarities between the self and an upward comparison target (*upward identification*) leads to positive affective responses, such as increased confidence in one's ability to achieve the target's status and motivation to engage in related behaviors. Focusing on differences between the self and an upward target (*upward contrast*) has the opposite effect, as it highlights the comparer's inferiority and may suggest that a similar status is not achievable. Conversely, focusing on similarities with a downward target (*downward identification*) leads to negative affective responses, as this confirms that the comparer's situation is or will become grave. Focusing on differences between the self and a downward target (*downward contrast*) can alleviate anxiety and boost positive affect, as the comparer is already doing better than someone else.

In addition, there is ample evidence that people with mental health conditions (eg, major depression, anxiety disorders) may use and respond to comparisons differently than people without these conditions [12,13], though the extent to which identification and contrast processes contribute to these differences is unknown. Specifically, within-person *variability* in affective response associated with identification versus contrast may help to explain these differences. Greater (vs. lesser) affect variability is associated with poorer mental health outcomes, such as lower self-esteem, worse depressive symptoms, and more neuroticism [14], as well as more frequent alcohol use [15]. A better understanding of variability in affective responses to social comparison in schizophrenia would be useful for treatment, given the disease-specific needs to improve social outcomes and general needs to improve engagement with digital treatments (eg, mobile apps) that afford the potential of scalable and accessible care. Social comparison offers a theoretical basis with real-world applicability to drive engagement with digital treatments in this population.

Although both upward and downward comparisons are common in illnesses such as cancer [10], prior research suggests that those with schizophrenia predominantly use downward comparisons [16], and that downward comparisons may propagate delusional states [17]. However, this research is limited in scope, and to date, the topic has received little attention. Further, despite the frequency with which social comparison is cited as a feature of digital health apps [18], little is known about *how* social comparison drives engagement and outcomes with apps, especially apps designed for chronic mental illness. Understanding the impact of social comparison in this context is critical, as negative uses of social comparison (eg, upward contrast or downward identification) could reduce app engagement and motivation for healthy behavior, while positive use (eg, upward identification or downward contrast) could drive sustained engagement and healthy behaviors. At present, however, it is not clear how best to assess patients' identification and contrast processes in the context of a digital environment.

Effective assessments should be ecologically valid and respond to known contextual influences on social comparison processes [19]—specifically, that they will capture variability in responses for the same person over time, as well as differences between people that are more stable over time [20]. This distinction is particularly necessary for examining affective variability and has been identified as critical to advancing clinical science in schizophrenia [21,22]. Ideally, these assessments also would be brief and conducive to integration with other app features, to allow these features to adapt to immediate or longer-term shifts in response to social comparisons. As no such assessment tool exists, the aims of this pilot study were to differentiate between- versus within-person variability in responses to a global social comparison measure among individuals with schizophrenia and healthy controls, and to examine the performance of a brief, mobile version of this measure among individuals with schizophrenia. The research questions and exploratory hypotheses that guided this study were:

1. How do self-reported responses to social comparisons among individuals with schizophrenia compare with those of healthy controls? We expected to observe stronger

- negative or weaker positive responses to comparisons among those with schizophrenia.
2. A. How much within-person variability is there in self-reported responses to social comparisons? We expected to observe meaningful within-person variability in affective responses to social comparisons.
B. Does variability differ between individuals with schizophrenia and healthy controls? We expected to observe greater within-person variability in affective responses to social comparisons among individuals with schizophrenia.
 3. Among individuals with schizophrenia, does a brief mobile assessment of self-reported responses to social comparisons show convergent validity with the full scale? We expected to observe moderate to strong correlations between scores on the full and mobile versions of this measure.

Methods

Participants and Procedure

Procedures were approved by the institutional review board at the supporting institution and all participants provided written informed consent. Adults with schizophrenia were recruited from outpatient clinics in a large city in the northeastern United States region, where diagnosis was verified through clinical records. Control participants were recruited via online social media postings targeting college students in the same city. Control participants were assessed in person and were eligible

if they did not screen positive for mental illness based on the Mini International Neuropsychiatric Interview [23]. Smartphone ownership and ability to run the study app on that smartphone, age 18 or older, and ability to participate in informed consent processes were the inclusion criteria in both samples.

Participants were 39 patients with schizophrenia (20/39, 51%, men; mean age 37.45 [SD 14.86] years) and 38 healthy controls (17/38, 45%, men; mean age 30.50 [SD 16.65] years; [Table 1](#)). As part of a larger clinical battery, all participants completed the full Identification-Contrast Scale (described below) in the clinic, both at the start of the study and at the second visit 3 months later. A total of 59 participants returned for the 3-month follow-up (n=31 patients, n=28 healthy controls); rates of attrition did not differ between samples ($\chi^2_1=0.05$; $P=.82$). All participants were compensated for in-person assessments at US \$20 per visit.

During 12 weeks of mobile assessment that occurred between clinic visits, the mobile version of the Identification-Contrast Scale developed for this study (also described below) appeared twice per week, among patients with schizophrenia only. A total of 24 patients completed mobile assessments during the 12-week window. Participants were oriented to the questions in person. When using the app between sessions, participants were free to ignore any mobile surveys and were not compensated on the basis of completion.

Table 1. Demographic information for individuals with schizophrenia and healthy controls.

Demographic	Individuals with schizophrenia (n=39)	Healthy controls (n=38) ^a
Age, mean (SD)	37.45 (14.86)	30.50 (16.65)
Gender, n (%)		
Men	20 (51)	17 (45)
Women	19 (49)	19 (50)
Race, n (%)^b		
American Indian or Alaskan native	4 (10)	0 (0)
Asian American	1 (3)	25 (66)
Black or African American	11 (28)	3 (8)
Multiracial or other	1 (3)	2 (5)
White	21 (54)	6 (16)

High-school graduate/General Educational Development	11 (28)	3 (8)
Some high school	3 (8)	0 (0)

^aTwo participants did not provide complete demographic information.

^bOne participant did not specify their race.

Full Measure (All Participants)

The Identification-Contrast Scale [24] is a 12-item measure of positive and negative responses to comparisons with upward and downward targets, allowing for inferences about

identification and contrast with each directional target. The measure has subscales for each direction and type of response (upward identification, upward contrast, downward identification, and downward contrast), with 3 items per subscale. Items such as “When I see or think about others who

are doing better than I am, I am pleased that things can get better” are rated on a scale of 1 (*not at all*) to 5 (*strongly*). Responses for the 3 items associated with each subscale are averaged to create subscale scores; higher scores on each subscale indicate stronger perceptions of identification or contrast with the relevant target (upward vs. downward). This measure has shown strong psychometric properties among individuals with chronic conditions such as cancer [25] and traumatic brain injury [26]. In this study, internal consistency estimates (Cronbach α) across all participants at baseline were high for all subscales: .84 for upward identification, .78 for upward contrast, .83 for downward identification, and .85 for downward contrast.

Mobile Assessment (Individuals With Schizophrenia Only)

The mobile version of the Identification-Contrast Scale was designed to maximize the power of the full scale while limiting the number of items to be completed in the natural environment. To achieve this balance, the item on each scale with the highest factor loadings was selected for delivery via mobile app [24]. These were *When I see or think about others who are doing better than I am, I realize that it's possible to improve* (upward identification); *When I see or think about others who are doing better than I am, I feel frustrated about my own situation* (upward contrast); *When I see others who are doing worse than I am, I feel fear that my future will be similar to them* (downward identification); and *When I see others who are doing worse than I am, I feel relieved about my own situation* (downward contrast). We retained the exact wording of these items to maintain their validity. During orientation to the measures, however, participants were instructed to respond to these items with their recent (rather than global or aggregated) experiences; specifically, they were asked to focus on their experiences since the last assessment.

Data Analysis

Descriptive statistics for each subscale of the full Identification/Contrast measure included means and SDs for each group (individuals with schizophrenia vs. healthy controls) at each time point. To address the first research question, independent *t* tests with associated Cohen *d* effect sizes were used to compare scores between groups at each time point. With respect to the second research question, 2-level multilevel models with restricted maximum likelihood estimation were used to account for assessment points (level 1) nested within

individuals (level 2). Intraclass correlation coefficients (ICCs) were calculated from empty models to determine the proportions of variance attributable to stable, between-person differences and within-person variation (plus error; research question 2A), and differences between groups were tested with model comparisons (χ^2 ; research question 2B).

The third research question was addressed in 2 ways. First, descriptive information was examined to determine how often individuals with schizophrenia completed mobile assessments of social comparison responses and how much variability in their responses was between- versus within-person. Second, bivariate correlations (*r*) were calculated between full-scale scores and the average of each participant's brief mobile assessments. Given the small sample size for this preliminary study, particularly for individuals with schizophrenia who completed mobile assessments (*n*=24), the criterion for statistical significance was set at $P < .10$, and effect size estimates were emphasized for interpretation of findings.

Ethical Approval

The Institutional review board at Beth Israel Deaconess Medical Center has approved this study (institutional review board protocol number: 2017P000359).

Results

Identification and Contrast Among Individuals With Schizophrenia Versus Healthy Controls

Descriptive statistics for each group by time point are presented in Table 2. At time 1, individuals with schizophrenia reported stronger tendencies toward upward contrast ($t_{76}=2.82$, $d=0.63$) and downward identification ($t_{76}=3.10$, $d=0.69$) than healthy controls ($P_s < .01$), and both differences were associated with medium effect sizes. At time 2, the group difference for downward identification persisted ($t_{56}=2.66$, $d=0.71$; $P=.01$), and a group difference for downward contrast emerged (ie, individuals with schizophrenia reported weaker tendencies; $t_{56}=-2.35$, $d=0.63$; $P=.02$). However, the group difference for upward contrast disappeared at time 2 ($t_{56}=1.54$; $P=.13$). Groups did not differ with respect to upward identification at either time point ($P_s > .57$). Thus, for 3 of 4 subscales, individuals with schizophrenia reported stronger tendencies toward negative-outcome comparisons, and weaker tendencies toward positive-outcome comparisons than did healthy controls.

Table 2. Descriptive statistics for traditional self-report measures and differences between individuals with schizophrenia and healthy controls.

Response to comparison	Individuals with schizophrenia, mean (SD)	Healthy controls, mean (SD)	Differences between samples
Time 1^a			
Upward identification	4.06 (1.08)	4.19 (0.99)	$t_{76}=-0.57, d=0.13$
Upward contrast	2.54 (1.35)	1.81 (0.92)	$t_{76}=2.82^b, d=0.63$
Downward identification	2.06 (1.26)	1.37 (0.55)	$t_{76}=3.10^b, d=0.69$
Downward contrast	3.36 (1.26)	3.78 (0.97)	$t_{76}=1.69, d=0.37$
Time 2^c			
Upward identification	3.92 (1.11)	4.01 (0.86)	$t_{56}=0.33, d=0.09$
Upward contrast	2.57 (1.29)	2.07 (1.18)	$t_{56}=1.54, d=0.40$
Downward identification	2.22 (1.26)	1.49 (0.71)	$t_{56}=2.66^d, d=0.71$
Downward contrast	2.88 (1.42)	3.62 (0.91)	$t_{56}=-2.35^d, d=0.63$

^a $n=39$ and 38 for columns 2 and 3, respectively.

^b $P<.01$.

^c $n=31$ and 28 for columns 2 and 3, respectively.

^d $P<.05$.

Variability in Identification and Contrast

Across time points and participant groups, ICCs for upward and downward identification were 0.40 and 0.41, respectively, indicating that approximately 40% of variability in these tendencies was due to stable, between-person differences, whereas 60% was due to within-person variation (and error). Stability estimates for upward and downward contrast were slightly higher (ICCs 0.60 and 0.57, respectively), though within-person variation components for all 4 scales were statistically significant ($P_s<.01$). Moreover, individuals with schizophrenia showed greater variability in responses to social comparison than healthy controls on 3 of 4 subscales (upward contrast: $\chi^2_1=8.20$; downward identification: $\chi^2_1=25.70$; downward contrast: $\chi^2_1=8.70$; $P_s<.03$). The exception was for upward identification ($\chi^2_1=1.50$; $P=.50$), where variability did not differ between groups.

Brief Mobile Assessment of Identification and Contrast

Among individuals with schizophrenia, there was considerable between-person variability in the number of mobile assessments of social comparison responses completed during the 12-week assessment window. These individuals completed assessments between 1 and 28 times, with an average of 7.46 times per person (SD 6.47). ICCs showed that 40%-60% of variability in response to each item was attributable to stable, between-person differences (Table 3), with the remaining 40%-60% capturing within-person variation across assessments and error. Between-person, average scores for mobile assessments of social comparison responses were positively correlated with responses to the same items when they were completed as part of the full measures (ie, at times 1 and 2). The strength of these associations ranged from $r=0.17$ to 0.72 ($P_s<.10$). Mobile assessment of downward contrast showed the most consistent positive associations, with $r=0.55$ at time 1 and $r=0.66$ at time 2 ($P_s<.02$). Moreover, scores on 1-item assessments were positively correlated with subscale scores on the full measures, with the strength of associations ranging from $r=0.24$ to 0.76 (Table 3).

Table 3. Variability estimates for mobile social comparison response measure and relations with traditional self-report measure among individuals with schizophrenia (n=24).

Response to comparison	Variability estimate (intraclass correlation coefficient)	Relation with time 1 score (<i>r</i>)	Relation with time 2 score (<i>r</i>)
Upward identification	0.40	0.38 ^a	0.24
Upward contrast	0.60	0.53 ^b	0.33
Downward identification	0.41	0.40 ^a	0.76 ^c
Downward contrast	0.57	0.50 ^b	0.74 ^c

^a*P*<.10.^b*P*<.05.^c*P*<.01.

Discussion

Individuals with schizophrenia experience meaningful deficits in social integration and perception that may be targeted with digital interventions, though patient engagement with these interventions is modest. The opportunity to make social comparisons may help to address these problems, though this concept has received little attention in schizophrenia. As an initial step, the results of this study provide necessary, if preliminary, insight into this process at multiple levels. The limited existing work on social comparisons among individuals with schizophrenia focused on the use of upward versus downward comparisons [16]. As both upward and downward comparisons can have positive and negative consequences [27], however, this study extended previous work by focusing on *responses* to upward and downward comparisons, rather than on their mere occurrence or frequency.

Specifically, this study captured reports of affective responses to upward and downward social comparisons (as indicators of identification and contrast processes), which are better longitudinal predictors of clinical outcomes among individuals with chronic medical conditions than the reported direction of comparisons [26]. Our findings show that patients with schizophrenia report experiencing negative affect from comparisons more often than healthy controls, and that this difference persists over 3 months. If these findings are confirmed in larger samples, clinical implications include (1) considering discussion of social comparisons in therapy sessions with patients as a potential trigger for their symptoms, and (2) providing guidance in digital interventions to minimize negative effects. Research implications include using comparisons to increase positive engagement with digital health interventions (eg, smartphone app notifications) and understanding whether social comparisons moderate negative symptoms in schizophrenia, depending on the environmental and social context.

Further, although most studies of social comparison focus on stable differences between people [9,10], the present findings underscore the dynamic nature of social comparison and suggest the value of repeated assessment for revealing how comparisons also vary over time and across contexts—particularly among individuals with chronic conditions such as schizophrenia. In addition to showing more frequent negative responses to

comparisons than healthy controls, patients with schizophrenia showed greater *variability* in their negative and positive affective responses to comparisons over 3 months. Given that affect variability has been linked to poor mental health outcomes [14,15], it is possible that affect variability in response to comparisons in schizophrenia contributes to the maintenance of social deficits and related negative symptoms. This hypothesis requires further investigation.

Importantly, findings from this study also provide preliminary support for the feasibility of collecting real-time data on social comparison responses through digital tools such as apps, and suggest the potential for these data to inform the tailoring of digital interventions for schizophrenia. For example, although there were considerable between-person differences in the number of social comparison smartphone assessments completed (and considerable variability in item responses), smartphone assessments showed 3 important features. These assessments were voluntarily completed throughout the assessment period; they captured both between- and within-person variability in affective responses to comparisons; and responses to mobile items correlated with those completed with traditional self-reports from the original measure. Thus, a brief, smartphone-based assessment of social comparison responses appears to perform well for its intended purpose, and additional work is needed to confirm and extend these findings.

Overall, the observed variability in affective response to comparisons among patients with schizophrenia suggests that there are times when negative (and positive) affective responses are stronger than others. In future studies of this kind, smartphone-based assessment may enable modeling of moderators of social comparison response, such as comparison dimension (ie, what about the self is being compared), mode of comparison (ie, face-to-face vs. via social media), or motivation for comparison (ie, self-selected from a range of options for a particular purpose, or in response to exposure to a single target) [19]. Such an assessment also could be paired with passive data from smartphone sensors (eg, about sleep patterns, mobility, location) to help determine when a patient is likely to respond positively or negatively to a specific type of comparison, and thus, whether a comparison might have immediate utility. Together, this approach may enable more personalized models of social comparison that are tailored to the dynamic, real-time state of each patient, thus enabling more actionable decision

points for use in just-in-time adaptive interventions [28]. Such tailoring is likely to promote engagement with digital interventions by more effectively responding to immediate needs, and thus, customizing a comparison opportunity that is most likely to be engaging or helpful to that person at the time it is deployed.

In the current era of socially connected digital health tools, where patients with schizophrenia engage at rates equal to the general population [29], there is a renewed need to understand how social comparison theory can assist in ensuring that technology-mediated social interactions are engaging and beneficial. In addition, the need to increase engagement with digital therapies is broader than the context of schizophrenia [28]. Although the results of this study offer insights into social comparison processes in schizophrenia, the methodology presented should be generalizable across many diverse use cases. Thus, the potential of social comparison processes to help drive engagement through more meaningful, relevant, and beneficial messaging that are responsive to local environmental, temporal, and social circumstance highlights the broad applicability of our novel methods.

Strengths of this study include its recruitment of both individuals with schizophrenia and healthy controls, both with equal proportions of men and women, and the use and comparison of both traditional self-report measures and brief versions modified for mobile assessment. Further, the emphasis of this study was on differentiating between- and within-person variability in a critical but understudied aspect of social comparison (ie, affective response), using appropriately sophisticated statistical methods.

As this was a formative pilot study, however, there were noteworthy limitations. Our sample sizes were modest, particularly at time 2, and participants were predominantly White or Asian American. We also did not have the opportunity

to include a clinical control group. Given that participants had flexibility in their completion of mobile assessments, compliance with these assessments was inconsistent across participants. Modest compliance with mobile assessments is common among individuals with schizophrenia and other severe and persistent mental illnesses [30-33]. To ensure that missing data do not bias conclusions, a priority for future work will be to understand patterns of missingness and best practices for reducing it in these and similar populations. For example, participants were not compensated for completing assessments and did not have access to their survey data; adding these components may increase compliance with mobile assessments among individuals with schizophrenia.

In addition, despite reviewing instructions with participants at orientation to specify the time window they should use for reference when completing the mobile version of the Identification-Contrast Scale, it is possible that participants with schizophrenia responded with more global than contextually sensitive impressions of their affective responses. The considerable within-person variability observed in their responses suggests that the measure was sensitive to context, but future studies should consider adding more specific instructions to the mobile version of the measure.

Finally, given the complexity of social comparison and the emphasis on general affective responses in this study, assessments also did not capture all of the aspects of this process that may be relevant to its role in daily life. For example, measures used in this study did not assess individual instances of social comparison, and thus, did not capture the dimension or mode [34]. Nevertheless, as an initial step in this line of work, findings from this study provide critical evidence to inform future research focused on mobile assessment of social comparison and the tailoring of comparison opportunities to promote patient engagement with digital interventions.

Abstract

Background: Contact tracing has been globally adopted in the fight to control the infection rate of COVID-19. To this aim, several mobile apps have been developed. However, there are ever-growing concerns over the working mechanism and performance of these applications. The literature already provides some interesting exploratory studies on the community's response to the applications by analyzing information from different sources, such as news and users' reviews of the applications. However, to the best of our knowledge, there is no existing solution that automatically analyzes users' reviews and extracts the evoked sentiments. We believe such solutions combined with a user-friendly interface can be used as a rapid surveillance tool to monitor how effective an application is and to make immediate changes without going through an intense participatory design method.

Objective: In this paper, we aim to analyze the efficacy of AI and NLP techniques for automatically extracting and classifying the polarity of users' sentiments by proposing a sentiment analysis framework to automatically analyze users' reviews on COVID-19 contact tracing mobile apps. We also aim to provide a large-scale annotated benchmark data set to facilitate future research in the domain. As a proof of concept, we also developed a web application based on the proposed solutions, which is expected to help the community quickly analyze the potential of an application in the domain.

Methods: We propose a pipeline starting from manual annotation via a crowd-sourcing study and concluding with the development and training of artificial intelligence (AI) models for automatic sentiment analysis of users' reviews. In detail, we collected and annotated a large-scale data set of user reviews on COVID-19 contact tracing applications. We used both classical and deep learning methods for classification experiments.

Results: We used 8 different methods on 3 different tasks, achieving up to an average F1 score of 94.8%, indicating the feasibility of the proposed solution. The crowd-sourcing activity resulted in a large-scale benchmark data set composed of 34,534 manually annotated reviews.

Conclusions: The existing literature mostly relies on the manual or exploratory analysis of users' reviews on applications, which is tedious and time-consuming. In existing studies, generally, data from fewer applications are analyzed. In this work, we showed that AI and natural language processing techniques provide good results for analyzing and classifying users' sentiments' polarity and that automatic sentiment analysis can help to analyze users' responses more accurately and quickly. We also provided a large-scale benchmark data set. We believe the presented analysis, data set, and proposed solutions combined with a user-friendly interface can be used as a rapid surveillance tool to analyze and monitor mobile apps deployed in emergency situations leading to rapid changes in the applications without going through an intense participatory design method.

Introduction

Contract Tracing in the COVID-19 Response

Since the emergence of COVID-19, public authorities are trying their best globally to slow down the infection rate of the virus. As part of their efforts, several solutions, such as closing public places, imposing full or partial lockdowns, and limiting people's contacts, have been implemented. Contact tracing has been globally recognized as one of the effective methods to slow down the infection rate of the virus [1]. To this aim, most of the initial efforts were based on manually tracing the contacts of infected persons. Manual contact tracing works only when the infected person knows who has been in physical contact with him or her, which reduces the effectiveness of the method. Moreover, manual contact tracing is a very time- and resource-consuming process [2,3].

The potential of contact tracing could be fully utilized if, ideally, the contact tracing mechanism can track the contact of an infected person on a very large scale. For instance, it would be ideally beneficial if authorities are able to track where the infected person has been and identify and notify the potential contacts of the patient. Technology, such as proximity sensors in smartphones and wearable devices, can help in such situations, allowing authorities to automatically notify potential cases more quickly and accurately [1,4]. To this aim, several mobile apps with a diversified set of features have been developed worldwide, each aligned with COVID-19-related policies, social values, and local infrastructure. However, the success of such applications is largely constrained by the number of users. According to Hinch et al [5], the potential of these mobile apps could be fully utilized if used by at least 80% of mobile users—which is 56% of the total population in the case of the United Kingdom, as reported by the authors, but generally depends on mobile penetration in the country.

To increase the number of users of these applications, different strategies and policies have been devised [6]. For instance, public authorities in several countries have made it mandatory for residents to install the contact tracing application to be able to access shopping malls, transportation, hospital, and other public places.

However, there are several concerns over these applications in terms of both effectiveness and privacy. For instance, since the applications require the tracking of individuals' movements with GPS and other sensors to track their interactions, privacy

concerns may arise [7,8]. Moreover, the literature has also identified a lack of understanding and unavailability of the technology (eg, smartphones) for a large portion of the population in limited-income countries as one of the main reasons for the lower effectiveness of such contact tracing applications [9].

Motivation for This Study

The motivation for this study originated from the observation that, despite their successes, contact tracing applications have been subjected to public criticism and scrutiny globally due to concerns over privacy and other technical issues including enhanced battery consumption. We believe an analysis of users' reviews on these applications will lead to a better understanding of the concerns over these applications. There are already some efforts in this regard [3,9,10]. However, the majority of the methods rely on exploratory and manual analysis of the users' reviews, which is a resource- and time-consuming process. Moreover, some of the work also relies on existing general sentiment analysis platforms or tools, without training or fine-tuning the tools on COVID-19 application reviews. For instance, in [10], a commercial tool, AppBot, has been used for sentiment analysis of users' reviews on only 9 mobile apps used in Europe. However, the tool relies on artificial intelligence (AI) models trained for generic sentiment analysis and returns 4 types of sentiment, namely positive, negative, neutral, and mixed. As a result, the outcome is not reliable, as the models are not trained on the task-specific data (ie, app reviews). For instance, a vast majority of the reviews are highlighting some technical issues, such as difficulties with registration, which also need to be analyzed. To address those limitations, we believe a task-specific model trained on a large-scale data set of manually annotated user reviews will help to make a better and context-specific classification of the reviews. Moreover, the existing literature relies on user reviews of fewer applications used in a specific region, which cover only a portion of the world's population.

Scope and Contributions

To facilitate an automatic sentiment analysis of users' reviews on these applications, a large-scale manually annotated data set is needed to train and evaluate machine learning (ML) models for sentiment analysis. In this work, we collected and annotated a large collection of manually annotated user reviews of 46 different applications. More specifically, we collected and

annotated a large-scale data set of Android and iOS mobile app users' reviews for COVID-19 contact tracing.

We analyzed how AI models can help to automatically extract and classify the polarity of users' sentiments and propose a sentiment analysis framework to automatically analyze users' reviews on COVID-19 contact tracing mobile apps. Several algorithms were proposed and evaluated on the data set as a proof of concept to show the efficacy of automatic sentiment analysis of users' reviews of these applications. After manually analyzing and annotating users' reviews, we employed both classical (ie, multinomial Naïve Bayes [MNB], support vector machine [SVM], random forest [RF]) and deep learning (ie, neural networks [11], fastText [12], and different transformers [13]) methods for classification experiments. This resulted in 8 different classification models. Moreover, to the best of our knowledge, this is the first attempt to develop a large-scale benchmark data set for sentiment analysis of users' reviews on COVID-19 contact tracing applications, which are from 46 distinct countries, from Google Play and Apple App Store. The proposed solutions combined with an interface can be used as a rapid surveillance tool to monitor how effective the app is and to make immediate changes without going through an intense participatory design method, which, although in normal circumstances is optimal, is not optimal in emergency situations in which a mobile device needs to be deployed immediately for the greater public good and with little-to-no user input from the beginning.

The main contributions of the work can be summarized as follows: We provide 34,534 manually labeled reviews based on the analysis of 40,000 reviews from 46 different COVID-19 contact tracing applications. The labels consist of sentiment polarities (ie, positive, neutral, and negative) and a label (technical issue). We provide an in-depth analysis of the data set that demonstrates different characteristics and insights. We share the data set and data splits with the research community for both reproducibility and further enhancements. We report benchmark results using 8 different classification experiments, which can serve as a baseline for future studies. We also propose a web application employing the proposed NLP techniques and

with a user-friendly interface allowing stakeholders to quickly analyze people's perceptions about such mobile apps.

Related Work

To fight the COVID-19 pandemic, almost all research communities, such as health, NLP, and computer vision, have been playing a significant role. As a result, several interesting solutions aimed at different aspects of the pandemic have been proposed over the last year [14]. For instance, there have been efforts for early COVID-19 outbreak detection to help in emergency response preparedness [15]. Similarly, a large portion of the efforts aimed to address automatic diagnosis, prognosis, and treatment [15,16]. Fake news detection, risk assessment, logistic planning, and understanding of social interventions, such as monitoring social distancing, are the other key aspects of the pandemic that received the attention of the community [14,17,18]. Contact tracing is also one of the aspects of the pandemic that has been widely explored in the literature. For instance, the study by Lash et al [19] analyzed the mechanism and results of contact tracing in 2 different countries. The authors reported that an accurate and efficient mechanism of contact tracing can significantly reduce the infection rate of the virus. However, several challenges are associated with timely and accurate contact tracing of a COVID-19 patient. In this regard, a joint effort from the community and the use of more advanced methods relying on different technologies, such as GPS, Wi-Fi, Bluetooth, social graph, network-based APIs, and mobile tracking data, will help to a great extent [20,21]. Handheld devices, such as mobile phones, that are already embedded with such technologies are ideal platforms for deploying contact tracing solutions. Being a feasible solution, several mobile apps have already been developed in different parts of the world. In addition to basic contact tracing capabilities, different features are also implemented based on the domestic COVID-19 policies [22]. For instance, in different countries, such as Qatar and Australia, the applications are used to access different facilities. Similarly, in Saudi Arabia, an application is used to seek permission for going out during lockdown. In Table 1, we provide a list of some of the prominent contact tracing applications used in different parts of the world.

Despite being a feasible solution for slowing down the infection rate, these applications are subject to criticism due to risks associated with them. In the literature, several issues, such as privacy, power consumption, and annoying alerts, have been reported. For instance, Bengio et al [23] analyzed and reported privacy issues associated with COVID-19 contact tracing applications. In addition to some recommendations on how to ensure users' privacy, the authors also proposed a decentralized design for contact tracing by optimizing the privacy and utility trade-offs. Reichert et al [24] also analyzed privacy concerns of applications and proposed a privacy-preserving contact tracing mechanism relying on the privacy-preserving protocol secure multi-party computation [25] to ensure individuals' privacy. Power consumption is another key challenge with contact tracing applications.

The literature also describes several interesting studies in which the feasibility of such mobile apps is assessed by analyzing people's response or feedback on these applications [22,26,27]. For instance, in [28], an online survey was conducted to analyze citizens' responses to HSE3, a contact tracing application used in Ireland. During the survey, a reasonable percentage of the participants showed their intention to use the application. However, the survey mainly aimed to analyze and identify different barriers to the use of such an application without analyzing the experience of the users with the application. To better analyze, understand, and evaluate users' experiences and feedback on COVID-19 contact tracing applications, a detailed analysis of public reviews is required, which are available in Apple and Google Play Store. There are already some efforts in this direction. For instance, Rekanar et al [3] provided a detailed analysis of users' feedback on HSE3 in terms of usability, functional effectiveness, and performance. However, the authors relied on manual analysis only, which is a time-consuming process. Another relevant work is reported in [10], in which an exploratory analysis of users' feedback on 9 COVID-19 contact tracing applications used in Europe is

provided. To this aim, the authors relied on a commercial app-review analytics tool, Appbot, to extract and mine the users' reviews on the applications. To the best of our knowledge, the literature still lacks a benchmark data set to train and evaluate ML models for automatic analysis of users' feedback on COVID-19 contact tracing applications. Moreover, the existing literature relies on user reviews of few applications used in a specific region, which covers only a portion of the population of the world. Hence, our work differs in the following ways: We (1) analyzed reviews of a large number of applications used in different parts of the world, (2) manually annotated a data set and provided it for the community, and (3) provide detailed experimental results.

Methods

Overview

In this section, we provide an overview of the methodology adopted in this paper. The complete pipeline of the proposed work is depicted in Figure 1. The work was mainly carried out in 2 different phases, including the (1) data set development phase and (2) experimental phase. In the development phase, as a first step, we scraped Google Play and App Store to obtain users' reviews on COVID-19 contact tracing applications used in different parts of the world. After obtaining user reviews, a crowd-sourcing study was conducted to annotate the reviews for the training and evaluation of ML models for automatic sentiment analysis of the reviews. The annotation and other details obtained during the crowd-sourcing study were then analyzed, as detailed in later sections. In the experimental phase, before conducting experiments, data were preprocessed to make the data more meaningful for the AI models deployed in the experiments. During the experiments, we employed several AI models, as detailed in later sections. In the remainder of this section, we provide details of our data set development process, including our methodology for collecting, annotating, and analyzing the data set.

Figure 1. Block diagram of the proposed pipeline for sentiment analysis of users' feedback on COVID-19 contact tracing mobile apps, roughly divided into 2 components, namely (1) data set development and (2) experiments.

Data Set Development

Data Collection

To obtain real-world user reviews for our analysis, we crawled reviews from 46 COVID-19 contact tracing applications used in the different parts of the world and hosted on Google Play and Apple's App Store. These applications are listed in [Table 1](#). The list of the applications to be covered in this work was obtained from online sources. During our search, we used different key words to make sure most of the applications were covered in the analysis. We note that, in this work, we considered reviews in the English language only when we made sure to analyze and annotate at least 50% of reviews of each application. However, to make sure the data set was balanced in terms of reviews from different applications, for some applications, such as Aarogya Setu, a lesser portion of the available reviews was analyzed. In addition to users' reviews, we also obtained replies to the reviews, if any were available, as well as the ratings. However, for this study, we only used the reviews for the analysis and experiments. We note that the reviews were obtained from December 20, 2020, to December 25, 2020. It is important to mention that, in this work, we mainly aimed to collect a large collection of users' reviews for training and evaluation of ML models to automatically analyze users' reviews of the applications in the future. Thus, covering all reviews on a particular application was not our interest in this work. However, we tried our best to cover enough samples from all applications. Moreover, the main idea behind covering reviews from several applications instead of a single application was to train our models on a diversified data set, which will ultimately help our model to automatically analyze reviews on any application used in any part of the world.

Data Annotation

For the annotation of sentiment, typically 3 sentiment polarities are used: positive, negative, and neutral. From our initial analysis, we realized that applications could have technical problems; hence, we used another label, technical issues, for the annotation. Hence, our annotation consists of 4 labels: (1) positive, (2) negative, (3) neutral, and (4) technical issues. We note that the neutral reviews were the reviews that neither praised nor complained about the applications.

To facilitate the annotation process, we developed a web application through which user reviews on the applications were presented to the annotators to manually label them. In [Figure 2](#), we present a screenshot of the annotation platform, which demonstrates the review and labels to be annotated (Q.1). In addition, we asked the annotators to briefly provide the reason behind their decision provided in response to Q.1. The question (Q.2) was used to evaluate the quality of the annotation (ie, whether the annotator carefully read the review). Moreover, we believe this question will provide useful information for the manual analysis of user feedback.

In total, 40,000 reviews were analyzed. To assure the quality of the annotations, each review was analyzed by at least 2 participants (graduate students from different age groups), and we considered the reviews and labels for which the majority of the annotators agreed. During the annotation process, we removed some reviews due to reasons such as (1) not being in English, (2) having a large number of emoticons or signs, and (3) irrelevancy (ie, not directly commenting on the applications). This process resulted in a total of 34,534 annotated reviews.

We made the data set publicly available for researchers to further explore the potential of NLP techniques for the automatic analysis of user feedback on contact tracing applications [29].

Figure 2. Screenshot of the annotation platform.

The Data Annotation Task for COVID-19 Contact Tracing Applications

Given Review

Sadly, this app does not solve any problem. The government thought that the privacy is far more important than people's lives. Even in the app You see that the government is trying to protect your privacy, but they don't have any announcement about how to protect people's lives in this app. It's a shame.

Questions

Q.1: Please select an appropriate label from the following list

Positive Negative Neutral Technical Issues

Q.2: Please give the reason for choosing a particular tag in Q. 1

Reason for choosing a tag

Next

Analysis

Overall, the data set covers a significant number of samples in each class. However, one of the classes, namely neutral, was composed of relatively fewer samples. In total, we had 15,587 reviews in the positive class, while the negative and technical issues classes were composed of 8178 and 9496 samples,

respectively. The minority class (ie, neutral) contained a total of only 1271.

From the analysis of the second question (Q.2), we identified the reasons and information that influenced the participants' decisions. In this section, we provide the statistics related to the second question (Q.2). In [Figure 3](#), we provide a taxonomy of

the most frequent reasons and causes for positive and negative reviews, along with the common technical issues.

In Table 2, we provide the distribution of the most common reasons and causes associated with the positive reviews, negative reviews, and technical issues, respectively.

Figure 3. Taxonomy of main reasons or causes for the positive and negative reviews, as well as technical issues.

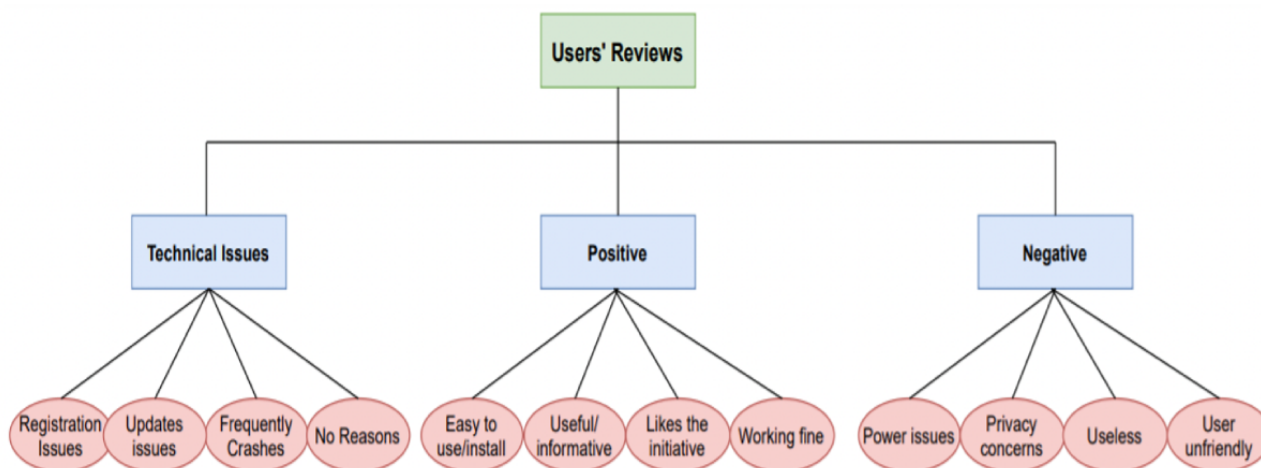

Table 2. Common reasons for the feedback provided in the reviews (n=34,534).

Type of feedback	Frequency of responses, n (%)
Positive feedback (n=15,587)	
Easy to install or use	1137 (7.3)
Useful, informative, and helpful	5673 (36.4)
Likes the idea or initiative	904 (5.8)
Working fine	3226 (20.7)
No reason or other	4645 (29.8)

In the majority of positive reviews, users found the applications useful, informative, and helpful in the battle against COVID-19. Some sample positive reviews were:

Thank you very much. it's very helpful and informative. it helps keep people away from suspicious areas.

A very good app for tracing and stopping coronavirus Always getting updated information about the virus Very useful and informative app.

A significant portion of positive reviews was also based on ease of installation, while some reviews mentioned that the

application they were using is working fine, without further details. However, the most encouraging aspect was the fact that a significant percentage of users appreciated the idea, concept, and efforts made by the authorities for contact tracing to slow down the infection rate. Some sample reviews included:

A good initiative by the government

Good initiative to prevent the spread of corona virus, I appreciate who work behind this effort.

There was also a large number of short reviews in which the users simply showed their positive response without mentioning any particular reason. In addition to these, other common reasons

for positive reviews highlighted by the users included some specific features of different applications in different parts of the world. For example, the Takkawalna app from the Saudi Government, which was used to seek permission to go out during lockdown, was praised for being a source of seeking permissions.

On the other hand, the key technical issues with these applications included registration and update issues. Moreover, a large number of reviews also highlighted that the application crashes or frequently stops working. In addition to these common issues, the reviews also hinted at certain technical issues, such as device compatibility and connectivity issues; lack of support for some languages, such as English; and not correcting QR codes from different applications. Some sample reviews highlighting technical issues in the applications included:

- The app continually crashes.*
- I have business visa i am unable to register please give a solution on this.*
- I installed but i cant register yet.*
- I can't update?*
- Install the apps, but keep showing connection error. Even restart the phone, also the same.*

The most common issues included power consumption, uselessness, and privacy (Table 2). A significant number of reviews also highlighted that the majority of the applications are not user-friendly. There were also reviews depicting other issues, such as annoying notifications, unnecessary access to

the gallery, slow response from the helpline, and unavailability of some key features, which could further improve the effectiveness of the applications. Some sample negative reviews included:

- Too much personal information collected. Privacy risk. Non-compliant to international standards.*
- Allow too many permissions please ban this application. A total waste.*
- I have concerns with their data privacy.*
- This app is a battery hog.*

We also provide statistics by country in Figure 4, where we summarize the number and percentage of samples and reviews on the applications used in different countries belonging to each category. An important observation from the figure is the variation in the distribution of number of negative, positive, neutral, and reviews highlighting technical issues in different parts of the world. The variations in the number of reviews in each class depict how different responses to the use of the applications have been observed in different parts of the world. As can be seen, in certain countries, such as Japan, Israel, Canada, and Ireland, the ratio of negative reviews is high. The ratio of positive reviews is sufficient in most countries, which shows the trust of users in the applications. On the other hand, as expected, fewer neutral reviews from the majority of the countries were obtained for the data set. The data set also covers a significant ratio of the technical issues class in the majority of the countries. For instance, the ratio of the reviews highlighting technical problems in the applications is significantly high in Denmark, Tunisia, and Cyprus.

Figure 4. Distribution of negative, positive, and neutral reviews as well as technical issues reported for the applications in our data set, by country.

To analyze the changes in the polarity of user sentiment over time, in Figure 5, we provide a preliminary temporal analysis to analyze the variation in the distribution of negative, positive, and neutral as well as technical issues over time. We note that, in this work, we provide a preliminary temporal analysis, which will be explored further in the future, and to this aim, we manually analyzed the 200 most recent reviews and the initial 200 reviews on applications having a reasonable time duration in the initial and more recent reviews. As seen in Figure 5, a higher overall variation is observed in the positive, negative, and neutral categories. As far as the individual applications are concerned, higher variation in the polarity of sentiments is

observed for the applications used in Australia, Singapore, the United Arab Emirates, and Canada.

During the data analysis, though there were some doubts about privacy, we observed that, at the beginning, the initiative or idea of contact tracing was largely appreciated by the users in different parts of the world. Moreover, we also observed that the users of these applications faced device compatibility and registration issues with the application with time. Interestingly, in the case of most of the applications, the number of negative reviews increased with time. One of the possible reasons for the increase is the applications' failure to achieve what they promised.

Figure 5. Preliminary temporal analysis reflecting the changes in the distribution of the sentiment classes over time. The data were compiled by analyzing the top 200 more recent (ie, December 25, 2020) and the initial 200 reviews from some of the applications that had a sufficient number of reviews.

Lexical Analysis

To understand the lexical content, we conducted an analysis of the number of tokens for each review. It can help to understand the characteristics of the data set. For example, for convolutional neural network and long short-term memory-based architectures, it is necessary to define the maximum sequence length. The minimum, maximum, and average numbers of tokens in the data set were 3, 198, and 18, respectively. Table 3 provides the statistics of the data set in terms of length of the different reviews in the data set.

We also analyzed the lexical content in each category to understand whether they are distinctive in terms of the lexical

content top n-grams. This analysis also demonstrates the quality of the labeled data. We compared the vocabularies of all categories using the valence score [30,31], ϑ for every token, x , using the following equation:

$$\vartheta(x) = \frac{C(x)}{TL_i} - 1$$

where $C(\cdot)$ is the frequency of the token x for a given class L_i , TL_i is the total number of tokens present in the class. In $\vartheta(x) [+1 -1]$, the value $+1$ indicates that the use of the token is significantly higher in the target class than the other classes. In Table 4, we present the most frequent bi- and trigrams with $\vartheta=1.0$ for each category. From the table, we observe these n-grams clearly represent the class-wise information of the data.

Table 3. Number of reviews of different lengths in the overall data set.

Number of tokens	Reviews, n
0-20	23,602
21-40	6611
41-60	2463
61-80	1068
81-100	664
101-120	68
>120	60

Table 4. The most frequent class-wise n-grams based on valance scores.

Ranking	Negative	Positive	Technical issues
1	Battery went down	Best app	Error requesting
2	to delete this	Excellent app,	Cannot register.
3	overheating and battery	and helpful	what's wrong
4	Not happy	Very nice and	fix this,
5	uninstall due to	feel safer	I can't seem
6	Drains battery and	very good apps	Unable to proceed
7	massive drain	Good information	error while
8	too much battery,	save lives and	have error
9	Massive battery drain	very useful for	phone number. Tried

Experiments

Task Description

As discussed earlier, we obtained a large number of samples for positive, negative, and technical issues (PNT), while fewer samples were obtained in the neutral class. Moreover, the reviews highlighting technical problems in the applications could also be treated as negative reviews. Thus, to cover different aspects of the problem, we divided it into 3 different tasks.

Task 1 involved ternary classification of PNT. We treated the problem as a ternary classification problem, where PNT were considered. The models trained for this task were expected to help identify the reviews highlighting technical problems in the applications along with the positive and negative reviews.

Task 2 involved binary classification (positive or negative [PN]). The negative and technical issues classes were merged into a single negative class to form 2 classes for a binary classification problem along with positive reviews (ie, PN). One of the main reasons for treating the task as a binary classification issue was the availability of fewer samples in the neutral class.

Task 3 involved ternary classification of 3 classes: positive, negative, or neutral (PNN). We note that, in this task, the negative class is the combination of the original negative and technical issues classes.

All these tasks helped analyze how the performance of the proposed sentiment analyzer varies with different sets of annotations.

Data Splits

For the classification experiments, we divided the data set into training, validation, and test sets, at proportions of 60.3%, 6.7%, and 30.0%, respectively. While dividing the data set, we used stratified sampling to maintain class distribution across different sets. The data split or distribution was performed for each task separately, which resulted in a different number of samples for the training, validation, and test sets for each task. The data split for each task will be made publicly available, separately, to ensure a fair comparison in future work. [Tables 5-7](#) summarize the distribution of the data into the training, validation, and test sets used in Task 1, Task 2, and Task 3, respectively.

Table 5. Data split and distribution of class labels for Task 1.

Class	Train	Validation	Test	Total
Positive	9370	1041	5176	15,587
Negative	5000	556	2622	8178
Technical issues	5686	632	3178	9496
Total	20,056	2229	10,976	33,261

Table 6. Data split and distribution of class labels for Task 2.

Class	Train	Validation	Test	Total
Positive	9342	1038	5207	15,587
Negative	10,715	1191	5770	17,676
Total	20,057	2229	10,977	33,263

Table 7. Data split and distribution of class labels for Task 3.

Class	Train	Validation	Test	Total
Positive	9364	1040	5183	15,587
Negative	10,690	1188	5798	17,676
Neutral	770	85	416	1271
Total	20,824	2314	11,398	34,534

Data Preprocessing

Before proceeding with the experiments, the data were also cleaned by removing unnecessary tokens, such as non-ASCII characters, punctuation (replaced with whitespace), and other signs.

Models

For this study, our classification experiments consisted of multiclass classification using both classical and deep learning algorithms as detailed in the following sections.

Classical Algorithms

For this study, we used several classical algorithms such as MNB [32], SVM [33], and RF [34]. As a feature representation with these algorithms, we used the bag-of-ngrams, which is one of the most commonly used methods for text classification and retrieval applications, applied with classical algorithms. This has been widely used as a simple, yet effective and computationally efficient, method. Motivated by its better performance in similar types of text classification applications, such as fake news and flood detection in Twitter text [17,35,36], we experimented with this representation using the mentioned classical algorithms.

fastText

fastText is an NLP library that aims to provide efficient word embedding and text classification at a faster speed compared with traditional deep learning solutions [12]. For word embedding, the model relies on the Continuous Bag of Words, which is based on a shallow neural network, strategy by predicting a word via its neighbors. To ensure training at a higher speed, the model relies on a hierarchical classification mechanism by replacing the traditional soft-max function with a hierarchical one resulting in a reduced number of parameters.

Transformers

Bidirectional Encoder Representations from Transformers (BERT) [13] is a state-of-the-art pretrained model that has demonstrated success in many downstream NLP tasks. It is typically used for downstream classification problems either by using embedding representations as features or fine-tuning the model. The main strength of the model comes from pretraining on a very large text data set that allows the model to understand and interpret text easily in different NLP applications. Moreover, the model also possesses the ability to learn from context. For this study, we used different transformer models, including BERT [13], RoBERTa [37], XLM-RoBERTa [37], and DistilBERT [38].

Evaluation Metrics

To measure the performance of each classifier, we used weighted average precision (P), recall (R), and F1. We used weighted metrics as they have the capability to take into account the class imbalance distribution.

Classification Experiments

To train the classifiers using MNB, SVM, and RF, we converted the text into bag-of-n-gram vectors weighted with logarithmic term frequencies (tf) multiplied with inverse document frequencies (idf). To utilize contextual information, such as the n-grams that are useful for classification, we extracted unigram, bigram, and trigram features.

We used grid-search to optimize the parameters for MNB, SVM, and RF. For MNB, we optimized Laplace smoothing the α parameter with 20 values between 0 and 1. For SVM, we optimized linear kernel with C parameters with 30 values ranging from 0.00001 to 10 and radial-basis-function kernel with C and γ parameters (for γ , we used 10 values from 1e-5 to 1e-1). For RF, we optimized the number of trees (10 values from 200 to 2000) and the depth of the tree (11 values from 10 to 110). Choosing such ranges of values depends on the available computational resources, as they are computationally expensive.

For fastText, we use pretrained embeddings trained on Common Crawl and default hyperparameter settings [39].

For transformer-based models, we use the Transformer Toolkit [40]. We fine-tuned each model using the hyperparameter settings in Table 8, with a task-specific layer on top of the model. As reported in [13], training with pretrained transformer models shows instability; hence, we performed 10 runs of each experiment using different random seeds and chose the model that performed the best on the development set. To train the transformer-based models for each task, we fine-tuned the model 10 epochs with “categorical cross-entropy” as the loss function and used the hyperparameter settings provided in Table 8.

The detailed number of parameters for each model, which demonstrates the size of the models, were as follows:

- BERT (bert-base-uncased): This model was trained on lower-case English text. It consists of 12 layers, 768 hidden states, 12 heads, and 110 million parameters.
- DistilBERT (distilbert-base-uncased): This is a distilled version of the BERT model consisting of 6 layers, 768 hidden states, 12 heads, and 66 million parameters.
- RoBERTa (roberta-large): RoBERTa, using the BERT-large architecture, consists of 24 layers, 1024 hidden states, 16 heads, and 355 million parameters.

- XML-RoBERTa (xlm-roberta-large): It consists of 355M parameters with 24 layers, 1027 hidden states, 4096 feed-forward hidden states, and 16 heads.

Table 8. Hyperparameter settings used during the experiments.

Parameters	Value
Batch size	8
Learning rate (Adam)	2e-5
Number of epochs	10
Max sequence length	128

Results

Task 1: Ternary Classification (PNT)

Table 9 provides the experimental results for Task 1 in terms of weighted accuracy, precision, recall, and F1 score. Overall better results were obtained with transformers compared with the classical and deep learning-based methods. One of the main reasons for the better performance of the transformers is their text interpretation capabilities. Though no significant differences were observed in the performances of the different transformers, a slight improvement was observed for RoBERTa over the rest of transformers.

To better analyze the performance of the proposed methods, we also provide the class-wise performance. Overall, reasonable results were obtained for all 3 classes; however, the performance of all the methods was higher for the positive class. One of the possible reasons for the comparatively lower performance for the other 2 classes is the lower interclass variation. As detailed earlier, reviews in the negative and technical issues classes contained similar types of words, and there were higher chances of confusion in the classes. The experimental results of Task 1 provide the basis for Task 2, where the negative and technical issues classes were merged.

Table 9. Experimental results for Task 1: ternary classification of positive, negative, and technical issues (PNT).

Method	Positive			Negative			Technical issues			Overall (weighted average)			
	P ^a	R ^b	F1	P	R	F1	P	R	F1	Acc ^c	P	R	F1
MNB ^d	.910	.892	.901	.679	.664	.671	.751	.789	.769	.808	.809	.808	.808
RF ^e	.854	.923	.887	.809	.538	.646	.729	.833	.777	.805	.806	.805	.797

Task 2: Binary Classification (PN)

Table 10 provides experimental results for Task 2, where the models had to differentiate between positive and negative reviews. As expected, the performance was improved significantly on Task 2, which proves our hypothesis that negative and technical issues classes have similar content.

Moreover, similar to Task 1, transformers outperformed the rest of the methods.

As seen in the table, in contrast to Task 1, no significant differences were observed in the performance of the methods on different classes, which indicates that reviews highlighting technical problems in the applications evoked negative emotions or sentiments. Moreover, no significant variation in the performance of the methods on a particular class was observed.

Table 10. Experimental results for Task 2: binary classification (positive or negative [PN]).

Method	Positive			Negative			Overall (weighted average)			
	P ^a	R ^b	F1	P	R	F1	Acc ^c	P	R	F1

Task 3: Ternary Classification (PNN)

Table 11 provides the experimental results for Task 3, where the models had to differentiate among positive, negative, and neutral reviews. Similar to previous 2 tasks, transformers produced better results compared with the classical and deep learning-based methods. As seen in the table, better results were reported for all the methods on positive and negative classes.

However, the performance of the proposed methods was significantly lower, especially for the bag of words and ngram with the Naive Bayes classifier. One of the main reasons for the lower performance for the neutral class was the fewer samples in the class, as described earlier. We note that Task 2 and Task 3 were performed separately to analyze the impact of the fewer samples in the neutral class.

Table 11. Experimental results for Task 3: ternary classification (positive, negative, or neutral [PNN]).

Method	Positive			Negative			Neutral			Overall (weighted average)			
	P ^a	R ^b	F1	P	R	F1	P	R	F1	Acc ^c	P	R	F1
MNB ^d	.902	.873	.888	.854	.935	.892	.379	.027	.050	.874	.859	.874	.860
RF ^e	.875	.881	.878	.862	.916	.888	.333	.005	.010	.866	.844	.866	.851

^gBERT: Bidirectional Encoder Representations from Transformers.

We observed that the performance difference across different classical or transformer-based models was low; to understand

whether such differences were statistically significant, we conducted statistical significance tests. We used the McNemar

test for the binary classification task (ie, Task 2) and Bowker test for Tasks 1 and 3. More details of this test can be found in [41]. As can be seen in Figures 6-8, our findings suggest that, across all the tasks, the test results were statistically significantly different between transformers and the other models. The value in the cell represents the *P* value, and the light yellow color represents statistical significance ($P < .05$). Among the classical algorithms, the differences in the test results were not that significant. Similarly, among the transformer-based models, the results were low, which is also reflected in the overall F1 scores for the different tasks.

The variation in the performances of the models on the different tasks could be associated with the categories of reviews (ie, positive, negative, neutral, and technical issues) covered in each task. For instance, in the ternary classification Task 1, where 3 categories, namely positive, negative, and technical issues, were considered, the performance was lower due to the similarities between negative reviews and reviews highlighting technical issues. Similarly, in the binary classification Task 2, the performance was significantly improved when negative and technical issues classes were merged into a single class. On the other hand, in the ternary classification Task 3, the performance was degraded due to the lower number of samples in the neutral class.

Dashboard of the Potential Rapid Analysis and Feedback Tool

To facilitate different stakeholders (ie, the users of the proposed sentiment analyzer of users’ reviews of COVID-19 contact tracing applications), we also aimed to develop a web application with a user-friendly interface. Figure 9 provides a screenshot of the dashboard of the potential sentiment analyzer

web application. In the current implementation, as seen in the figure, the web application provides the distribution of the positive, negative, neutral, and technical reviews along with a searching function to analyze user feedback on a specific application. It is important to mention that the proposed tool could be extended to other health care applications by training the models on relevant data sets.

Figure 9. Screenshot of the potential tool based on the proposed solutions.

Discussion

Principal Findings

Contact tracing of COVID-19 patients has been globally recognized as one of the most effective ways of controlling the infection rate. However, there are several limitations of the existing mechanisms. Manual contact tracing is a tedious and time-consuming process. Moreover, it is difficult to keep track of all potential contacts of a patient. Digital solutions, such as the use of mobile apps, have been considered as a promising solution, with which a patient’s contacts can be traced and informed quickly. However, there are several concerns over the working mechanism and performance of the applications. This work has revealed different facets of the COVID-19 contact

tracing applications, advantages, drawbacks, and users’ concerns over these applications.

Our finding suggests that the idea or initiative for contact tracing via a mobile app is highly appreciated by people worldwide. In addition to contact tracing, the applications have also proved useful in implementing and ensuring public policies on COVID-19. However, there are also some concerns over the working mechanism and the effectiveness of the applications. In this regard, the analysis of users’ reviews of these applications helps to better understand and rectify the concerns over the applications.

We observed that the majority of the reviews lie within 3 categories, namely positive, negative, and technical issues. On the other hand, very few neutral reviews were observed. Privacy in terms of tracking via GPS and access to the gallery and other

information by the applications were the main concerns. Moreover, a vast majority of the users of these applications in different parts of the world was not happy with the high power consumption of the applications. The majority of the users also faced some technical problems while using the applications. Some key technical issues included device compatibility, registration, slow updates, connectivity issues, and lack of support for some languages (eg, English). Another important observation is that the distribution of negative, positive, neutral, and technical issues may vary over time.

As far as the performance of the AI models is concerned, a better overall performance was observed for all the models in sentiment analysis of users' reviews, allowing efficient analysis of users' responses to the application more quickly. Among the models deployed for sentiment analysis in this work, the transformers were most effective. This shows the efficacy of AI and NLP techniques in automatic analysis of COVID-19 contact tracing applications.

Conclusions

In this paper, we focused on the sentiment analysis of use reviews on COVID-19 contact tracing mobile apps and analyzed how users react to these applications. To this aim, a pipeline was composed of multiple phases, such as data collection; annotation via a crowd-sourcing activity; and development, training, and evaluation of AI models for the sentiment analysis. The existing literature mostly relies on manual or exploratory analysis of users' reviews on the application, which is a tedious and time-consuming process. Moreover, in existing studies, generally, data from fewer applications were analyzed. In this work, we showed how automatic sentiment analysis can help analyze users' responses to the applications more quickly. Moreover, we also provided a large-scale benchmark data set composed of 34,534 reviews from 46 different applications. We believe the presented analysis and data set will support future research on the topic.

We believe many interesting applications and analysis can be conducted keeping the data set as a baseline. Temporal and topical analyses are the key aspects to be analyzed in the future.

Abstract

Background: Development of artificial intelligence (AI)–based technologies in health care is proceeding rapidly. The sharing and release of real-world data are key practical issues surrounding the implementation of AI solutions into existing clinical practice. However, data derived from daily patient care are necessary for initial training, and continued data supply is needed for the ongoing training, validation, and improvement of AI-based solutions. Data may need to be shared across multiple institutions and settings for the widespread implementation and high-quality use of these solutions. To date, solutions have not been widely implemented in Germany to meet the challenge of providing a sufficient data volume for the development of AI-based technologies for research and third-party entities. The Protected Artificial Intelligence Innovation Environment for Patient-Oriented Digital Health Solutions (pAItient) project aims to meet this challenge by creating a large data pool that feeds on the donation of data derived from daily patient care. Prior to building this data pool, physician perspectives regarding data donation for AI-based solutions should be studied.

Objective: This study explores physician perspectives on providing and using real-world care data for the development of AI-based solutions in health care in Germany.

Methods: As a part of the requirements analysis preceding the pAItient project, this qualitative study explored physician perspectives and expectations regarding the use of data derived from daily patient care in AI-based solutions. Semistructured, guide-based, and problem-centered interviews were audiorecorded, deidentified, transcribed verbatim, and analyzed inductively in a thematically structured approach.

Results: Interviews (N=8) with a mean duration of 24 (SD 7.8) minutes were conducted with 6 general practitioners and 2 hospital-based physicians. The mean participant age was 54 (SD 14.1; range 30–74) years, with an average experience as a physician of 25 (SD 13.9; range 1–45) years. Self-rated affinity toward modern information technology varied from very high to low (5-point Likert scale: mean 3.75, SD 1.1). All participants reported they would support the development of AI-based solutions in research contexts by donating deidentified data derived from daily patient care if subsequent data use was made transparent to them and their patients and the benefits for patient care were clear. Contributing to care optimization and efficiency were cited as motivation for potential data donation. Concerns regarding workflow integration (time and effort), appropriate deidentification, and the involvement of third-party entities with economic interests were discussed. The donation of data in reference to psychosomatic treatment needs was viewed critically.

Conclusions: The interviewed physicians reported they would agree to use real-world care data to support the development of AI-based solutions with a clear benefit for daily patient care. Joint ventures with third-party entities were viewed critically and should focus on care optimization and patient benefits rather than financial interests.

Introduction

In recent years, research on artificial intelligence (AI)–based technologies in medicine has been proceeding rapidly [1,2]. It is assumed that AI will change medicine, health care, and the future role of physicians [3]. Among the key practical issues to be solved are the sharing and release of real-world care data prior to the development of AI-based solutions and implementation into existing clinical practice. A precondition for the development, widespread use, and acceptance of AI-based technologies in medicine and health care is an adequate, structured, and controlled data pool derived from daily patient care, with a continuous data supply to provide for the ongoing training, validation, and improvement of AI-based solutions [4]. Meeting this precondition would greatly benefit a widespread implementation of AI-based technologies and achieve improvements for health care delivery, the quality of patient care, and diagnosis and treatment outcomes. An automated and consolidated flow of deidentified real-world care data, ideally from multiple facilities in clinical and ambulatory settings, into a data pool is perceived to be a possible solution to overcome the challenge of providing a sufficient data volume for secondary use in research and implementation [4].

An example of a freely accessible data pool for AI-based research is the MIMIC-III (Medical Information Mart for Intensive Care) database in the United States [5]. Additionally, a common European Health Data Space is envisioned to facilitate the exchange of and access to different types of health data, including electronic health records, genomics data, and data from patient registries, to support health care delivery, along with the secondary use of data for health research and policy-making [6]. Several Nordic countries in Europe, such as Sweden, already offer disease-specific registries providing real-world patient data that enables researchers to analyze complex phenomena [7]. In Germany, efforts to meet the challenge of providing an adequate data pool for research and the development of AI-based technologies still need to gain momentum, though the availability of data pools derived from real-world patient care is expected to increase in the near future via the now legally regulated use of electronic patient records [8,9] and a government initiative to support the development and establishment of a nationwide research health data center [10]. The German Medical Informatics Initiative (MII) was established to make data from health care and research more useful and meaningful and develop conditions to make routinely collected clinical health care data available for medical research purposes [11,12]. The aim of the initiative is to optimize research and patient care options through innovative information technology solutions that facilitate the cross-institutional exchange and use of health care, clinical, and biomedical research data. In several large consortia, German university hospitals at more than 30 sites work together with research

institutions, health insurers, private entities, and patient representatives to establish the conditions for this exchange. Both legal and ethical conditions need to be considered when governing who will use the data and for which purposes [13]. However, to date, real-world care data are not centrally available and accessible for research purposes, including technical developments. Instead, in most cases physicians, health care facilities, or patients need to give consent for data use, even if the data were deidentified [13]. There is no uniform legal status in Germany on how and for which secondary research purposes health care data can be used [14,15]. In some German states, it is possible to use clinical health care data under certain requirements for secondary purposes, like research, without explicit patient consent. However, the data still remain within each institution and are not centrally stored with uniform quality and privacy standards. Moreover, the distinct separation of different health care settings and restrictive data privacy regulations in Germany compared to other European countries pose a challenge for the exchange and linkage of health care data [16]. For third-party entities that develop AI-based technologies for health care, access to sufficient real-world care data for training and validation remains scarce.

The Protected Artificial Intelligence Innovation Environment for Patient-Oriented Digital Health Solutions (pAItient) project aims to meet this challenge by creating a large data pool that feeds on data donated by primary care and hospital physicians, patients, and health care institutions. Prior to building this data pool, physician perspectives regarding data donation for AI-based solutions need to be studied. Insight into the attitudes and concerns of physicians working in different settings regarding data donation is central for the development and implementation of this concept into real-world health care. Therefore, the aim of this study was to explore physicians' perspectives on providing and using real-world care data for the development of AI solutions in health care in Germany.

Methods

Study Design

This study is a part of the pAItient project, which aims to develop and test a solution for providing real-world care data for AI development, validation, and implementation. In the first phase of problem identification, a requirements analysis was conducted to specifically gain insight into physicians' perspectives on providing and using real-world care data for the development of AI solutions in health care in Germany. In the exploratory approach, semistructured, guide-based, and problem-centered interviews [17] were conducted via telephone with physicians working in clinical or ambulatory settings. The study-specific interview guide was developed by the interprofessional research team (Health Services Research, Public Health, and Information Technology) at University Hospital Heidelberg and was based on a literature research and

predefined, project-specific research questions. Each draft of the interview guide was discussed within the interprofessional research team to reach consensus about the content. The interview guide focused on the exploration of knowledge and attitudes regarding AI in general and patient care, as well as the secondary use of health care data in AI applications (see [Multimedia Appendix 1](#) for a translated English version). A sociodemographic questionnaire was developed and used to collect participant characteristics. Field notes were taken after each interview and discussed within the research team. All interviews were audiorecorded and transcribed verbatim by experienced support staff at the Department of General Practice and Health Services Research, University Hospital Heidelberg. All transcripts were proofread by the research team and amended where applicable. The transcripts were not returned to the participants.

Ethics Approval

This study received ethical approval by the medical ethics committee of the Medical Faculty of Heidelberg University (S-241/2021).

Recruitment

During the first recruitment phase, a convenience sample of 33 general practitioners (GPs) and 16 hospital-based physicians was approached using known contacts in academic teaching practices and personal contacts in hospital departments in Baden-Wuerttemberg. Given the explorative nature of this study and based on prior experiences and empirical guidance [18], a targeted sample size of 10 was deemed appropriate and sufficient to identify broad categories and themes of interest in the collected data and subsequently defined in the (unpublished) study protocol. All potential participants received an invitation to participate and written information about the aim of the study via post or email. In the second recruitment phase, a reminder was sent to all physicians who had not replied after 3 weeks (n=28). Since the COVID-19 pandemic was still ongoing and potential recruits signaled that they could only participate after the pandemic was over, no further recruiting waves were initiated. Considerations of gender, work experience, or specialty balance could not be applied due to the nature of convenience sampling. Physicians who were interested in participation returned a contact form and indicated a preferred date and time for the interview. All participants gave written consent prior to

the interview. All interested physicians were included in the study. No reimbursement was offered.

Data Analysis

Qualitative data were analyzed in a structured content analysis [19] and categorized into relevant themes emerging from the data. Subsequently, 2 experienced researchers (MK and RPD) inductively identified the main categories and subcategories from the data, discussed and approved the coding, and assessed thematic saturation in close consultation with the study team. Organization and management of all text data was performed using MAXQDA Plus 2018 software (release 18.2.4; VERBI GmbH). Participant characteristics were analyzed using SPSS software (version 27; IBM Corp).

Results

General Characteristics of the Interviews

Interviews (N=8) with a mean duration of 24 (SD 7.8) minutes were conducted with 6 GPs and 2 hospital-based physicians in May and June 2021 by 2 experienced female interviewers (MK and RPD) who were members of the study team. All phone interviews were conducted either at the interviewer's workplace or home office. No other persons were present during the interviews. There were no prior connections between the participants and researchers. All participants could ask questions about the study before the interview and verbally confirmed their consent for participation. The inductive analysis identified a wide range of themes in broad categories, thus providing an indication of data adequacy. The findings outlined below reflect the physicians' perspectives on donating and using real-world care data for the development of AI solutions in health care and their general expectations and concerns regarding AI use in medicine. Represented are findings referring to general individual views, attitude toward including commercial partners in development phases, perceived prerequisites for consent to data donation and use, and perceived potential benefits of AI-based health care innovations. [Textbox 1](#) gives an overview of the main categories and subcategories identified from the collected data material. Extracted quotes supporting key statements are included for illustration, and the participant number and transcript position are provided. All quotes were translated into English with due diligence.

Textbox 1. The main categories and subcategories identified from the collected data material.

Data use for artificial intelligence (AI) solutions development

- Attitude in general and toward including partners
- Consent and conditions for data donation and use

AI in medicine

- Potential benefits and expectations
- Concerns

Participant Characteristics

Of the participants, 88% (7/8) were male. All participants could

self-rate affinity toward modern information technology (5-point Likert scale from 1=very low to 5=very high affinity). [Table 1](#) describes the participant characteristics.

Table 1. Participant characteristics (N=8).

Characteristic	Value
Care setting, n (%)	
General practice	6 (75)
Hospital	2 (25)
Medical specialty, n (%)	
General practitioner	6 (75)
Surgeon	2 (25)
Gender, n (%)	
Female	1 (12)
Male	7 (88)
Age (years), mean (SD); range	54 (14.1); 30-74
Experience as a physician (years), mean (SD); range	25 (13.9); 1-45
Affinity toward modern technologies ^a , mean (SD); range	3.75 (1.1); 1-5

^aFrom 1=very low to 5=very high affinity.

Data Use for AI Solutions Development

Attitude in General and Toward Including Partners

Participating physicians were open-minded about the idea of donating real-world care data for AI solutions development. They considered using real-world care data necessary to gain new knowledge and support evidence-based medicine, physicians' decision-making, and the development of new technologies to be used in clinical practice. Participation in the development of new AI-based technologies was seen as a chance to develop and use a target-oriented, user-centered product for patient care in a reasonable amount of time. Physicians also viewed this as a possibility for low-threshold research contributions.

This is indispensable, so if you want to develop artificial intelligence in the medical context, you cannot do it without patient data. [Physician 02, #32]

If this could be implemented into the regular administrative software and one could enable a direct data flow with relatively low expenditure, and also in such a transparent way so no misuse was possible, then I think collecting gigantic data volumes in GP practices would be low threshold. And I believe, lots and lots and lots would be participating. [Physician 07, #39]

Physicians mentioned that they would agree to donate data derived from their daily patient care if prerequisites were met. It was emphasized that even in research contexts, transparency about actual data use and strict data deidentification were of priority. High security standards and supervision of data use were expected to prevent misuse. This was mentioned especially in the context of the involvement of third-party entities with economic interests. Tight control of data use, possibly

government-regulated, was suggested, and transparency about involved parties and their interests and goals was considered necessary to mitigate potential conflicts of interest (profit-oriented vs common welfare). Voluntary patient and physician participation was seen as an important prerequisite as well as requiring minimal additional efforts by physicians, similar to an automatically generated data flow form for their practice's administration system.

...it must be ensured that data is deidentified...Overall, the process must be transparent, you must always be able to understand what is done with the data and how it is processed. Exactly...who processes the data, what research projects are being carried out... [Physician 03, #40]

...good informing would have to happen...who is involved, who does the developing, who are the potential funders of such development. This would be very important to have relative transparency about, I believe. Because this is something that is relatively important... [Physician 08, #30]

Consent and Conditions for Data Donation and Use

Sufficient information and transparency about data use and security, deidentification, and intended purpose were pointed out as prerequisites for consenting to data donation for AI solution development and use in the provision of health services. Physicians' consent was seen as mandatory for data donation, and patient consent was discussed to be necessary only in specific cases, such as rare diseases. In general, donating data from real-world care processes was classified as being voluntary on the physician side, bound to specific purposes and suitable research questions. Again, adequate data protection and deidentification were mentioned as being mandatory. Purposeful and proven benefit in terms of patient and common welfare and

a nonprofit use were further perceived as prerequisites for consent. The economic interests of third-party entities involved in development were expected to be of secondary importance in related research projects.

...I would have a strange feeling if I knew data from various practices were being tapped and I had no idea what was happening with them. So, I think that would be fundamentally the wrong way to go about it. [Physician 04, #28]

There has to be an adequate research question defined for the research project and implementation of the study, data analysis and also further data use must be transparent. [Physician 02, #47]

AI in Medicine

Potential Benefits and Expectations

Regarding patient care, the physicians saw several potential benefits of AI use when based on real-world care data. They mentioned aspects regarding the efficiency of health care provision—that more time could be left for direct patient interaction and they expected their decisions to be supported by AI. They also reflected on a potential increase of evidence-based knowledge by using real-world care data derived from their own medical specialty and assumed there would be fewer restrictions on transferability to their own practice than using data from other medical fields.

Exactly, more time for patients, then better decisions to improve mortality and morbidity of patients. Exactly, I believe these are the two most important aspects. [Physician 03, #12]

Simply because a GP's work is so incredibly complex, and I believe artificial intelligence could also support our work by optimizing our time. [Physician 07, #12]

Physicians expected strong support for daily patient care when AI technology is in place. They focused on the potential of a decreased workload, particularly in complex areas such as medication, yet final decisions were considered to remain with the physician. Another assumed benefit was that “a knowledge leap” (Physician 01, #10) would occur when enormous data volumes are analyzed.

I believe these can be supporting systems...which analyze CT data in a structured way, but certainly do not substitute the experienced radiologist who assesses them. [Physician 02, #18]

Concerns

Regarding the involvement of third-party entities with economic interests, all physicians contemplated the potential conflicts of interest. Their concerns were related to endeavors that potentially have a strong commercial interest instead of a focus on patient and common welfare and care optimization. The fear of potentially being replaced by technology was discussed by one participant. Physicians expressed that from their perspective, professional experience and diligence cannot be substituted by AI-based technology, particularly regarding their knowledge about individual patients and other possible medical findings.

Further concerns referred to potential mistrust in data derived from sources unknown to the physicians and technical feasibility limits.

There has to be good information...Who contributed to the development and possibly is a funder of this development. That would be very important to be relatively transparent, I suppose. [Physician 08, #30]

Discussion

Principal Findings

All participants in this study reported they would support the development of AI-based solutions in research contexts by donating deidentified data derived from daily patient care if subsequent data use was made transparent to them and their patients and the benefits for patient care were clear. Contributing to care optimization and efficiency were cited as motivation for potential data donation. Concerns regarding workflow integration (time and effort), appropriate deidentification, and the involvement of third-party entities with economic interests were discussed. The donation of data in reference to psychosomatic treatment needs was viewed critically.

Comparison With Prior Work

Using real-world care data and AI-based assistance systems can support prevention, early diagnostics, and individualized treatment in the future to facilitate improved outcomes and the discovery of new medical correlations and innovative preventive approaches that optimize health care [20,21]. AI-based systems can also facilitate more differentiated treatment methods and improved aftercare, thus assisting physicians and the nonphysician health care workforce by providing optimized patient care while easing their workload [20]. The development of these systems for research and health care requires a large volume of data, and data security is required to build and maintain trust in them for health care providers and patients alike. Therefore, exploring their respective perspectives on AI-based solutions in health care is just as essential as creating and implementing necessary regulation that defines the conditions and boundaries of secondary use of real-world health care data in general. Such structures have already been created in several other countries [22]. In Scandinavian countries, social and health care data of each citizen are connected with a unique identification number. For example, Finland has established legal regulations for the secondary use of social and health care data from different sources with the Finnish Social and Health Data Permit Authority [23]. In contrast, legal regulations for the secondary use of health care data in Germany are fragmented, and strict data privacy regulations, which still follow the principles of data anonymization and minimization, impede the secondary use and linkage of health care data from different sources [15,16]. Obtaining informed consent for the use of health care data by the data owner is still common in Germany to meet the legal requirements for research. The MII in Germany was created to bridge this gap, and it aims to establish a nationwide infrastructure that enables the donation and sharing of digitally available health care data for biomedical research [12]. Prior research identified the challenges to a widespread secondary use of real-world care data in Germany,

which include a traditionally high weighting of data protection and concerns about sharing and innovatively using such data [24]. These challenges are mirrored in our findings, particularly the strong emphasis the participants in our study put on transparency about the use, security, and deidentification of donated data, and the intended research purpose. The implementation of the broad consent model, as developed and approved by one of the MII expert working groups, might mitigate some of these concerns since the model will facilitate broad and pre-use transparency, allowing for consent withdrawal based on project-specific information provided in digital formats prior to actual project implementation [25]. In addition to the MII, which focuses on data sharing and the provision of data for research purposes in the clinical setting, there are further initiatives in Germany aimed at the sharing and provision of data in the primary care setting [16].

Besides transparency concerns, the physicians in our study also contemplated potential changes the use of AI-based technology might bring for their profession. These concerns were also considered in a Science for Policy report compiled by the Joint Research Centre for the European Commission. The report predicts that the incorporation of AI-based technologies into medical practice will trigger substantial changes in health care and medicine across medical, scientific, and technical grounds, as well as in workflows, clinical pathways, management, and the physician-patient relationship [26]. The report also covers ethical and social issues related to using AI-based systems in health care and medicine that were contemplated by the physicians in our study as well. It states that these issues coincide with some of the urgent priorities for the coming decade as defined by the World Health Organization in 2020, including “earning public trust” and “protecting people from dangerous products” [27]. The report also stipulates that to evaluate a patient’s clinical situation and treatment options, the integrated analysis of a qualified, trained, and real physician is necessary, a perspective clearly shared by the physicians in our study who viewed AI-based solutions as supporting tools rather than a decision-making authority.

The benefits that AI-based technologies can offer for health care are indivisibly linked to the sharing of health care data among different entities; however, resources for analyzing large data sets and developing new (AI-based) technologies for health care delivery by public research institutions or the government might be limited. The involvement of third-party entities with potential commercial interest can be a key to realizing the potential linked with large data sets and AI efforts. However, studies have shown that there are concerns about the use of health care data by third-party entities and that data sharing can lead to a deterioration of patient trust [28-30]. For instance, a recent survey regarding secondary use of health data among the German population assessed a generally positive attitude toward the use of personal health data for research purposes, and a mostly disapproving attitude regarding data use for commercial purposes, such as in the pharmaceutical industry [13]. In further research, patients in the Netherlands as well as German citizens were surveyed regarding the secondary use of health data, different options for consenting to data use, and data donation [31]. The findings indicated a willingness to permit secondary

data use depending on the beneficiary institution or purpose, as well as a wide acceptance of broad consent in Dutch patients. The majority of the 1006 (78.8%) surveyed German citizens approved of anonymized data donation from their digital health records and the sharing of these data with third-party entities for medical research. Only a small minority of participants disagreed, mainly because of worries about data security [31]. A survey assessed that the US public is more comfortable sharing health data with third-party entities for patient purposes than business purposes [32]. An increase of public comfort in sharing health care data with third-party entities might be achieved by emphasizing patient-centered benefits and transparent communication about protective actions regarding data privacy and deidentification [29,32,33]. The physicians in our study strongly supported these views and repeatedly emphasized that transparency about the purpose of data use was mandatory to facilitate and increase comfort in sharing data, especially when third-party entities were to be involved. In general, they were supportive of donating real-world health care data through an automated and consolidated flow into a deidentified data pool for secondary use in research and implementation [4]. They were also interested in the potential benefits that analyzing large sets of routinely collected health care data might offer to them and their patients. Nevertheless, the physicians clearly highlighted their perspective regarding the purpose of data use, saying that such endeavors should primarily benefit patient outcome, health care delivery, or society. Statutory and best practice guidelines will need to accommodate these considerations so that physicians and patients can donate real-world health care data while empowered with knowledge and according to their beliefs.

In summary, the findings of this interview study support the need for better access to real-world health care data with uniform rules and legal regulations. Physicians from different settings interviewed in this study seem to be open-minded toward the concept of using health care data for research purposes and the development of new AI-supported technical tools. The concept of a new, large data pool should consider the inclusion of health care data from different institutions and settings and that the way data is transferred into the data pool should not add to physicians’ workloads. Moreover, the use of data needs to follow the principle of transparency, especially if third-party entities are involved. In accordance with findings from other studies, a concept for the donation, storage, and use of health care data in Germany should also focus on increasing public comfort in sharing health care data with third-party entities.

Strengths and Limitations

This qualitative study was guided by methodological strategies aimed at minimizing potential bias and reducing the risk of losing relevant content. Conducting the interviews via telephone ensured minimal added burden to the participants. During the analysis, the inductive approach facilitated the identification of relevant themes and a high intercoder congruence was achieved, reflecting a reliable classification of the data. The density of the generated data allowed for a thorough analysis and sufficient illustration of the inductive categories, pointing to thematic saturation and effective convenience sample size as indicated by empirical guidance [18]. The reporting of this study followed

the Consolidated Criteria for Reporting Qualitative Research (COREQ) guideline [34].

However, a limitation of potential selection bias has to be considered, since a pre-existing motivation for the dissemination of personal attitude, opinion, and experience might have been present. It is also possible that socially desirable answers were given. Further, female physicians, who were underrepresented in this sample, might have shared different or additional perspectives. To limit bias, the interviewers continuously established rapport with all participants and repeatedly provided reflection-enabling prompts. The discussion of perceived tendencies and the refinement of adequate approaches was

facilitated by debriefings in regular research team meetings during data collection and analysis.

Conclusions

The physicians interviewed in this study reported they would donate real-world care data for secondary use in research contexts and the development of AI-based solutions with clear benefits for care optimization. The remaining identified concerns would need to be adequately addressed through national and international regulations for data sharing and options for consenting to provide a solid foundation for the development of new assistive AI-based solutions.

Acknowledgments

The authors would like to thank all participants for their valuable contributions. We would also like to thank Lina Weinert and Dr Oliver Heinze (Institute of Medical Informatics, University Hospital Heidelberg) for their input regarding the interview guide, and the support staff at the Department of General Practice and Health Services Research, University Hospital Heidelberg, for transcribing the data. The Protected Artificial Intelligence Innovation Environment for Patient-Oriented Digital Health Solutions (pAItient) study received funding by the German Federal Ministry of Health (funding reference 2520DAT0P1). The funder had no role in the writing of this manuscript.

Authors' Contributions

MK and RPD collaborated on the construction of the interview guide and the sociodemographic questionnaire, conducted all interviews, analyzed the data, and drafted the manuscript. Both researchers work in health services research and are experienced in qualitative research. JS is a professor and medical doctor in General Medicine, the principal investigator in the Protected Artificial Intelligence Innovation Environment for Patient-Oriented Digital Health Solutions (pAItient) project, and provided expertise to this study. All authors provided substantial input and reviewed and approved the final version of this manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Even when technology allows rural cancer survivors to connect with supportive care providers from a distance, uptake of psychosocial referrals is low. Fewer than one-third of participants in a telemedicine intervention for identifying rural survivors with high distress and connecting them with care accepted psychosocial referral.

Objective: The purpose of this research was to examine the reasons for which rural cancer survivors did not accept a psychosocial referral.

Methods: We utilized a qualitative design to address the research purpose. We interviewed participants who had been offered psychosocial referral. Semistructured interviews were conducted 6 weeks later (n=14), and structured interviews were conducted 9 months later (n=6). Data were analyzed descriptively using an inductive approach.

Results: Ultimately, none of the rural cancer survivors (0/14, 0%) engaged with a psychosocial care provider, including those who had originally accepted referrals (0/4, 0%) for further psychosocial care. When explaining their decisions, survivors minimized their distress, emphasizing their self-reliance and the need to handle distress on their own. They expressed a preference for dealing with distress via informal support networks, which was often limited to close family members. No survivors endorsed public stigma as a barrier to accepting psychosocial help, but several suggested that self-stigma associated with not being able to handle their own distress was a reason for not seeking care.

Conclusions: Rural cancer survivors' willingness to accept a psychosocial referral may be mediated by the rural cultural norm of self-reliance and by self-stigma. Interventions to address referral uptake may benefit from further illumination of these relationships as well as a strength-based approach that emphasizes positive aspects of the rural community and individual self-affirmation.

Introduction

Background

Cancer survivors from rural areas experience high-levels of cancer-related distress (the multifactorial, unpleasant, emotional experience that interferes with their ability to cope with cancer, treatment, and symptoms effectively). As recently as 10 years ago, fewer than 10% of all individuals with cancer were being screened for cancer-related distress, but with wider adoption of screening tools such as the National Comprehensive Cancer Network Distress Thermometer and Problem List [1], as many as 70% of individuals with cancer are now being screened [2-4]. Unfortunately, despite this high rate of screening, difficulty connecting rural survivors with psychosocial support persists. In fact, rates of successful referral of rural survivors to psychosocial services remains low [5-7], which leaves rural survivors highly vulnerable to a range of negative sequelae of unmet needs including a higher risk of suicide [8-11].

Rural Head and Neck Cancer Survivorship

Survivors of head and neck cancer have unique posttreatment sources of distress that may profoundly impact quality of life. Cancers of the head and neck are the seventh most common worldwide, and the ninth in the United States; more than 53,000 US men and women were diagnosed with head and neck cancer in 2020 [12], and the number of diagnoses and deaths of head and neck cancer continue to increase, outpacing those of most other cancers in the United States. Over the past several decades, survival after head and neck cancer treatment has increased [13,14]; thus, a growing number of survivors live permanently impacted by treatment. Head and neck cancer affects areas of the body that are imperative for critical activities such as speech and swallowing. Patients who undergo surgery to remove cancer and surrounding tissue are left with lasting impacts on prominent and often noticeable areas of the tongue, throat, voice box, windpipe, or jawbone and cope with lasting pain, neck and shoulder dysfunction, dysphagia, speech changes, and deformities related to loss of facial integrity [15]. Research has shown that when cancer-related distress in survivors of head and neck cancer is not addressed, it persists far beyond the immediate posttreatment period—as many as 5 years after treatment, unaddressed needs persist, including pain, difficulty chewing and swallowing, depression, and anxiety [16,17]; these unaddressed impacts are highly and negatively correlated with survivors' quality of life [17-19].

Unfortunately, rural survivors have more unmet emotional needs, significantly poorer health, and higher levels of psychological distress than their urban counterparts [20]. Ultimately, the sequelae of unmet needs likely contribute to the high suicide rate among head and neck cancer survivors, who are estimated to have the second and third highest rate of all persons with cancer [21], 3 to 4 times higher than that of the general population [22,23]. Given increasingly higher and widening risk of suicide for US rural residents, there is an urgent need to address the cancer-related distress of rural head and neck cancer survivors [24].

Rural Head and Neck Cancer Survivors' Low Uptake of Psychosocial Help

It is well accepted that distance from care is a significant factor in rural survivors' reluctance to receive referral to psychosocial care [7,25,26]. Yet, this factor does not explain survivors' unwillingness to receive psychosocial care when distance barriers can successfully be overcome via technology. For example, in a previous study [27,28], we developed and tested a telemedicine-delivered intervention for rural head and neck cancer survivors (called Comprehensive Assistance: Rural, Nursing Interventions and Guidance) to screen for cancer-related distress and make referrals for lingering posttreatment unmet needs. The intervention was designed to overcome technology barriers experienced by individuals living in broadband-poor areas, by offering options for individuals without home-based internet access to connect to a nurse with oncology specialization. Participants (n=14) who were found to have high cancer-related distress (using a combination of Distress Thermometer and Problem List measurement and a nurses assessment) were referred to a social worker with oncology specialization from the Cancer Center for psychosocial support, who initially contacted patients by phone to discuss the range of support options available (including telephone counseling or support groups in their area); however, fewer than one-third (28.6%) accepted referrals for further psychosocial care [27,28].

Given this low acceptance, even when distance barriers were removed, there is a need to better understand the psychological reasons why referrals are rejected and to develop interventions to increase acceptance; however, only one study [25] has directly examined rural cancer survivors' reasons for not seeking psychosocial services—rural cancer survivors reported that speaking with a psychologist or using a support group to deal with psychosocial issues is not an accepted social norm. This suggested that relying on those within their own personal circle is more acceptable than utilizing professional care to deal with nonphysical issues that arise from cancer treatment [25]. Another study [29], in which men reported a desire to minimize or normalize the problem and to have emotional control noted the high value (in help-seeking in rural settings) that is placed on self-reliance and privacy.

It has also been suggested that stigma may be a barrier to seeking psychosocial services, especially within rural communities [30,31]. Stigma occurs when a person is labeled as less desirable than others for having an undesirable characteristic or trait (ie, a diagnosis cancer or mental illness) or engaging in an undesirable behavior (ie, seeking help). Stigma can occur at the external (public stigma) or at the internal (self-stigma) level [32]. Research specific to individuals with head and neck cancer has found low levels of public and self-stigma related to their cancer diagnosis [33], but the impact of stigma related to seeking psychosocial services has not been explored in rural head and neck cancer survivors. Higher rates of perceived public stigma for seeking help (ie, the perception that others view those who seek help for mental health concerns as weak or crazy) and self-stigma for seeking help (ie, the perception of oneself as being inferior or a failure for seeking help with a mental health concern) have been shown to exist in rural populations [31,32,34,35]. Self-stigma associated with

seeking mental health concerns has been shown to affect the likelihood of newly diagnosed patients with head and neck cancer using psycho-oncology services [36]. However, past research has been largely limited to individuals not currently experiencing distress or who were given a hypothetical situation and asked about what they might do rather than measuring actual behavior or acceptance of service use. Research has also largely not focused on individuals currently experiencing distress when they are offered services. Given that only 28.6% of rural survivors with high cancer-related distress accepted referral for psychosocial care in our previous study [27], the purpose of this research was to directly examine the reasons rural cancer survivors accept or do not accept psychosocial referral.

Methods

Participants

We utilized a qualitative descriptive design [37] to accomplish the study purpose. Participants were patients who had been offered psychosocial referral during a telemedicine intervention [27]; these patients had been recruited from the head and neck cancer clinic at an National Cancer Institute–designated comprehensive cancer center in the southeastern United States that serves a large rural catchment area and were over 18 years of age, had completed active treatment for head and neck cancer within the past 3 months, and lived in a rural county (which we defined as small metropolitan, micropolitan, or noncore and at least 45 minutes of travel was required to reach the cancer center).

Data Collection

Demographic, cancer-related, and level of distress data were collected as part of the previous study [27].

During open-ended semistructured interviews conducted (by a graduate nursing student under the supervision of the principal investigator; audiorecorded and transcribed verbatim) 6 weeks after the telemedicine intervention, participants who had declined a referral during the intervention were asked to talk about their reasons for declining, and those who had accepted the referral during the intervention were asked if they had yet heard from the referring provider and if the process had moved forward.

To understand perspectives on the barriers to acceptance of a psychosocial referral related to stigma or rural social norms, we attempted to recontact each participant who had been offered a psychosocial referral for a structured interview (9 months after

the conclusion of the intervention). We used a structured interview guide and encouraged participants to expand on their answers in order to gain insight; interview questions were drawn from validated instruments [32,37] designed for understanding individuals' reasons for not accepting or following through on referrals. Participants were asked if their decision to accept or not accept a referral was related to self-reliance (ie, feelings of not being able to take care of one's own problems) [29], public stigma related to seeking mental health (ie, others viewing them negatively or in a less favorable light, others thinking bad things about them, or others seeing them as seriously disturbed or thinking they posed a risk to others), and self-stigma related to seeking mental health (ie, if accepting a psychosocial referral would impact them feeling "inadequate," "inferior," or "less satisfied with themselves" [32,38] (Multimedia Appendix 1). We also sought to determine if they had met with the Cancer Center social worker or other psychosocial care providers.

Data Analysis

We used inductive content analysis to guide coding of the data. This methodology is appropriate for establishing links between the research objectives and the summary findings, ensuring that these links are transparent [39] and has been used in studies to identify characteristics of social media videos about college students' mental health [40] and to guide the design of digital interventions for mental health management among construction personnel in Nigeria [37]. Two researchers collaboratively categorized data into known barriers to mental health care in rural populations. Categories were developed into themes; categories and themes were discussed among 3 members of the research team until consensus was reached.

Ethics

The institutional review board for health research at the University of Virginia approved the study (HSR-IRB 20991). Verbal consent was obtained from all participants.

Results

Participant Characteristics

All 14 individuals who had been referred for further psychosocial help had participated (Table 1) in the first round of interviews, and we were able to successfully recontact 6 of the original 14 for long-term follow-up interviews. Of the 14 participants, 2 had passed away since the intervention, and we were unable to reach 6 (Figure 1).

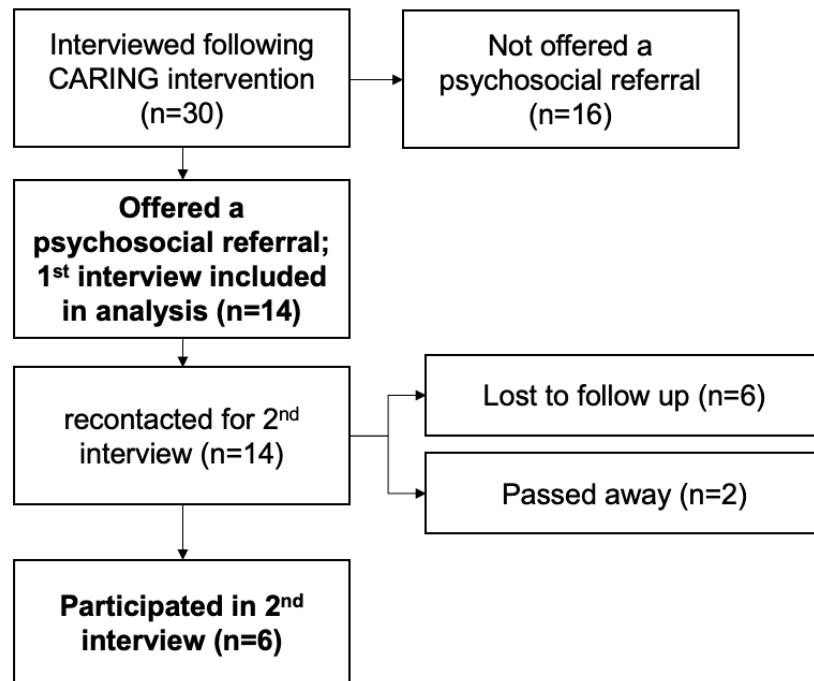

Table 1. Participant characteristics.

Characteristic	Participants (n=14)
Gender, n (%)	
Male	7 (50)
Female	7 (50)
Age (years), mean (SD)	62.0 (12.4)
Race, n (%)	
White	11 (79)
Black	2 (14)
Asian or refused	1 (7)
Ethnicity, n (%)	
Non-Hispanic	12 (86)
Hispanic	2 (14)
Cancer site, n (%)	
Oral cavity	5 (36)
Thyroid	4 (29)
Pharynx	2 (14)
Other	2 (14)
More than one site	1 (7)
Cancer type, n (%)	
Squamous cell carcinoma	8 (57)
Papillary thyroid carcinoma	4 (29)
Other	2 (14)
Cancer stage, n (%)	
Early	12 (86)
Late	2 (14)
Distress score ^a , mean (SD)	5.8 (0.3)

^aThe distress score was calculated as total number of problem areas rated as 4 or higher (out of 10); scores ranged from 5.17 to 7.17.

The sample was equally split among men and women; participants ranged in age from 39 to 80 years. The majority were White (11/14, 79%), non-Hispanic (12/14, 86%), and the most common cancer was squamous cell carcinoma of the oral cavity (5/14, 36%). Over 85% of participants (12/14) had cancer that had not spread to lymph nodes or metastasized elsewhere.

The mean distress score was 5.8 (SD 0.3) out of 10. Of note, of the 6 survivors with whom we were able to conduct second interviews, 2 women had originally accepted referrals, but when the social worker contacted them, neither had followed through with receiving further assistance.

Figure 1. Participation flowchart. CARING: Comprehensive Assistance: Rural Interventions, Nursing, and Guidance.

Themes

We ultimately extracted 3 themes: minimization and self-reliance; preference for use of informal support; and self-stigma for some but no public stigma.

Minimization and Self-reliance

When explaining their rationale for not pursuing further psychosocial care, 6 participants made light of their distress by minimizing it and instead focused on positivity and self-reliance. A positive attitude was viewed as a means to regain health:

Yeah well that's the only way to get better, isn't it?...I certainly try not to ever feel sad. I feel lucky [that the cancer is in remission]. [70-year-old male]

Several laughed while describing their distress. One participant who had declined to speak with a social worker insisted that his situation was not negative and that he could and should handle it himself:

I had a brain bleed. They drilled a couple of holes in my head. But life goes on! There was uh...a series of complications with the cancer. This is just a series of misfortunes the way I look at it [laughs], and I have to deal with them. [80-year-old male]

He then emphasized his self-reliance and strength by stating,

And I do deal with them...I'm not an invalid or anything.

One woman minimized her fear of recurrence, continuously reframing her fears of recurrence as concerns, stating

it's just those same concerns. You know I get this sore throat and it's like, it's just a concern that the cancer may come back like the other time. So, it's just a concern that it'll come back like the other two

times...it's not even the fear it's just the concern of it, of it coming back. [33-year-old female]

The idea of cancer-related distress not rising to the level of requiring outside intervention was echoed by other survivors. One woman who declined a referral to the Cancer Center social worker stated,

I just tend to view things I want to handle them myself...If I felt an absolute need [to speak to someone about my cancer-related distress] I would do it...I didn't feel an urgent need, to be honest. [71-year-old female]

Preference for Use of Informal Support

Participants described a small circle of people with whom they would speak about their cancer-related distress. They reported limiting these discussions to close family but occasionally included close friends. One turned down the referral to the Cancer Center social worker by explaining

my niece is a social worker and we've had our chats. [52-year-old female]

Two men reported only discussing distress with their spouses. When asked why he had not been interested in speaking with the Cancer Center social worker, one replied,

No. I've got great support from my wife as a caregiver. [80-year-old male]

and the other reported that he spoke to his wife about his cancer-related distress, but only minimally.

I'm uh, I'm just not a big talker [laughs]. My wife's always gettin' on me. That's just uh, just kinda the way I am. [62-year-old male]

One woman expressed a similar sentiment:

What you might consider an inadequacy, or a problem or an issue, I handle them myself, and that's just the

way I am...It would take some getting beyond the point of me handling it entirely on my own and feeling comfortable in sharing with someone else. [71-year-old female]

However, she also suggested that her family was included as part of her handling things herself:

My family is close, husband is very close...those are my anchors.

Self-stigma for Some but No Public Stigma

Participants did not report public stigma associated with seeking help for cancer-related distress. One woman who reported high distress during the intervention but had turned down a referral to the social worker stated,

I don't think anyone would say anything bad about [my speaking to a social worker]. [52-year-old female]

Despite participants' sense that society would not judge them harshly, a few of them did indicate they would judge themselves negatively if they had followed up with a social worker or other mental health care provider. One woman who had originally accepted a referral, but then never called the social worker back, was asked if speaking to the social worker would have made her feel that she could not handle her problems herself, and she confirmed,

I would question it...I don't want to learn [sic] the appearance that as I'm getting older, I am less able to handle my situation, and that's a protection on my part. I try not to view anybody else that way, but I tend to view myself more critical [sic]. [71-year-old female]

Not all survivors shared this perception. One participant with high distress who turned down the social worker referral stated that he did not believe would not have felt inadequate if he had accepted help from the social worker:

I wouldn't think there was any stigma to it. [80-year-old male]

Another participant explained that she had not accepted a referral to the social worker because

I have a therapist. [50-year-old female]

She went on to explain her perspective of the impact of socioeconomic status on her views about seeking mental health care:

I make over \$100,000, you know, I have a bunch of degrees and everything...but I do live in a rural area...I think for me there aren't those barriers to treatment.

Despite many survivors' statements suggesting that seeking mental health help for cancer-related distress is acceptable, overwhelmingly participants still declined the opportunity to speak to a social worker or counselor. During the intervention, one man had self-reported high levels of nervousness and worry related to his cancer diagnosis, treatment, and the possibility of recurrence, but he declined the offer of psychosocial support from a social worker or participation in a support group. During

the follow-up interview, he reported feeling no public or self-stigma associated with seeking help for his cancer-related distress but was unable to articulate his reasons for refusing, stating

The social worker thing was something that I did not feel would help me. [62-year-old male]

Discussion

Principal Findings

When explaining their views toward not accepting psychosocial help, head and neck cancer survivors minimized their experiences of distress while emphasizing self-reliance and a desire to only speak to close family and occasionally to friends. Research has found similar phenomena—cancer survivors living in rural populations preferred to rely on family and friends to deal with psychosocial issues [25]. Several studies [29,31,41-43] have also found self-reliance and problem-minimization to be barriers to seeking mental health treatment for rural populations. Similarly, in a qualitative study [30], psychosocial care providers serving a rural Australian region reported that the distress of residents of their region had to rise to a very serious threshold before residents would even acknowledge the existence of mental health distress. Both their findings [30] and our findings suggests that the rural social norms of self-reliance and desire to not share personal information with someone from outside the survivors' immediate circle may be key contributing factors to not seeking help for psychological distress among rural cancer survivors, as well as important points to address when developing an intervention. This is particularly important, as prior research indicates that mental health care discussions with only family and friends are insufficient to address the profound distress that survivors experience and that those who elect to seek professional care find it highly impactful [44].

Consistent with past research [29], both male and female survivors in our study emphasized positive thinking, self-reliance, and minimization of distress; our findings also suggested that there were some differences between men and women in approaches to addressing barriers to care. Men in our study reported a smaller circle of trust, which typically only included their wives, which is consistent with the findings of a study with 409 rural Australian men and women which found that rural men reported more barriers to seeking mental health care than women [29]. Certain norms, such as a desire for stoicism and emotional control, have been found to be stronger barriers to help-seeking for rural men than they are for women [42]. Because women who live in rural areas are more likely to seek mental health care than men who live in rural areas [42,45], approaches to overcome barriers may benefit from gender-focused interventions, for example, a dyadic intervention that includes their spouse or caregiver may be particularly salient for men.

Interestingly, while stigma is the most cited barrier to seeking help, rural cancer survivors in our study showed that the type of stigma was especially important. Self-stigma was a barrier to accepting a referral; public stigma was not strongly felt. None of the 6 individuals reported that others would view them negatively if they were to seek help from the Cancer Center

social worker. In turn, self-stigma associated with seeking psychosocial services was found to be a factor that limited the acceptance of a psychosocial referral, at least for some participants. These findings are consistent with assertions that stigma is a moderately important barrier to help-seeking, which have been reported by one-quarter to one-third of participants in multiple research studies included in a review [46] and in a study of patients newly diagnosed with head and neck cancer [36]. One possible explanation is that the cancer experience is viewed to be sufficiently physically and emotionally debilitating to warrant emotional support from others but still does not rise to a level that warrants breaking social norms oneself. One participant referred specifically to this, stating that she tried not to view others that way but viewed herself more critically. This finding is also consistent with most research showing that self-stigma is a more salient barrier to help-seeking than public stigma in general populations [47] and rural communities [30,32]. As such, self-stigma may be an important barrier for those whose values are aligned with not seeking psychosocial help, and thus, is not salient for everyone.

Alternatively, it may be that stigma influences other factors, and thus, its systemic effects may not always be noticeable [48]. Others have also suggested that stigma is part of interrelated network of barriers [49]. For example, Jennings and colleagues [50] examined a model and linked public stigma to attitudes toward seeking professional services through the mediators *self-stigma* and *self-reliance*, which, being proximal to decisions to seek help, may be more accessible to participants' awareness. This finding is consistent with our theme *preference for informal support* that potential mediating factors such as self-reliance and the desire to only disclose to close family and friends were widely endorsed and stigma factors less so. Thus, similar to Jennings et al [50], we encourage researchers and clinicians to continue to examine the complex relationships between different types of stigma and other factors such as self-reliance in order to be able to develop more focused interventions to increase the use of services by those who could benefit.

Implications for Cancer Survivorship Care

Our findings suggest a potential direction for developing interventions aimed at improving access to psychosocial care for rural cancer survivors. Barriers to rural access are typically grouped into 4 domains: people, place, provider, and payment [51]. In light of increased levels of insurance coverage [51], and ongoing technological advances that overcome distance-related barriers to care [52], personal and cultural belief systems need to be explored further. Thus, to continue to work toward equitable access, a more rigorous understanding of rural cultural belief systems that may limit cancer survivors' openness to receiving high-quality psychosocial support is needed. Instruments are available that differentiate barriers [32,38,53]; however, these tools were not developed specifically with rural populations; thus, customization to illuminate rural-specific barriers may be needed. As such, researchers may consider amending instruments by including questions specific to rural populations.

Clinicians caring for rural survivors may need to be aware if they hold any negative perception of or implicit bias toward

rural culture. Current approaches toward improving access to care have been developed in the context of an urban health care delivery system [54]. For example, rather than viewing aspects of rural culture through a deficit lens (ie, stigma and self-reliance as barriers to access), we should strive to develop culturally appropriate interventions that leverage the considerable strengths of the rural setting (ie, resilience, strong community networks) to design effective interventions that connect rural survivors with care [55].

A strength-based approach that might be particularly salient is one based in self-affirmation theory [56-58]. Self-affirmation theory notes that we are inherently motivated to keep a positive sense of self-worth, and when we experience information that could decrease positive self-perceptions (ie, reduce the belief that we are self-reliant and self-sufficient), we are driven to protect positive views of the self, which can result in avoidance of treatment for mental health issues [59,60]. Fortunately, self-affirmation theory also asserts that we can reduce this drive to protect our self-worth, and thus increase likelihood of seeking therapy, by using self-affirmations (ie, reflecting on a positive and self-relevant personal characteristic or values) prior to confronting information that could decrease these positive self-perceptions. Self-affirmation interventions have started to receive some support for increasing the use of psychosocial services [59-61] but need to be further evaluated with rural cancer survivors. This approach, if tailored to this population, may be able to directly reduce barriers to access such as stigma and self-reliance.

Study Limitations

Our study was qualitative, and as such, findings were meant to provide a direction for further research and were not meant to be generalizable. Still, there are several limitations that may have had an impact on our findings. The sample size (n=14) was small, and we were only able to recontact 6 individuals to discuss specific barriers. It is possible that with a larger sample size we may have found additional themes. The number of participants also made it difficult to fully evaluate differences in perceptions between rural women and men, or between people with different types of stages of cancer. Finally, we did not collect data on participants' education level, which is a significant driver of differences in stigma perceptions [62] and was also highlighted by one participant. Evaluating our findings in the context of education level and cancer stage may have provided additional insight into drivers of participants' reluctance to seek psychosocial help. Researchers should explore the impact of stigma and self-reliance on psychosocial referral uptake using quantitative instruments and with a larger sample size, to better understand which populations may be experiencing these impacts. More precise information about how self-reliance and stigma create barriers to help-seeking will be important in developing customized interventions for rural individuals and should be considered when targeting behavioral change in rural populations.

Conclusions

To the best of knowledge, this study is the first to explore self-reliance, rural social norms, and self-stigma as barriers to connecting rural survivors with psychosocial care. Our findings

suggest that rural cancer survivors who experience these barriers may be reluctant to seek psychosocial care, even when they identify themselves as having high levels of cancer-related distress. Further research, with a larger sample, to explore these barriers is needed to develop effective interventions to increase psychosocial referral uptake in this population.

Abstract

Background: Innovative digital technology systems that support and monitor real-time medication intake are now available commercially; however, there is limited knowledge of the use of such technology in patients' homes. One such smart medication dispenser, *spencer*, provides alerts to patients to take their medications and allows for tracking and reporting real-time medication adherence data.

Objective: The objectives of this study were to examine the use of a smart medication dispenser as a medication adherence and self-management support tool for community dwelling adults over a 6-month period, in addition to usability, usefulness, satisfaction, and impact on caregiver support.

Methods: This prospective, observational study invited community-dwelling adults aged 45 years and older taking at least one chronic medication and their caregivers to use this smart medication dispenser for their medication administration for 6 months. Adherence was defined as a dose intake within 2 hours post scheduled time. Real-time adherence data were collected using the smart medication dispenser and the AdhereNet platform. Usability, usefulness, and satisfaction were measured using the System Usability Scale and the Usefulness, Satisfaction, and Ease of Use questionnaire, respectively. Caregiver burden was measured on a visual analog scale at baseline and at the end of the 6-month study period.

Results: A total of 58 participants were recruited, of which 55% (32/58) were female with a mean age of 66.36 (SD 11.28; range 48-90) years. Eleven caregiver participants were recruited, of whom 91% (10/11) were female. The average monthly adherence over 6 months was 98% (SD 3.1%; range 76.5%-100%). The average System Usability score was 85.74 (n=47; SD 12.7; range 47.5-100). Of the 46 participants who provided data, 44 (96%) rated the product as easy, 43 (93%) as simple to use, and 43 (93%) were satisfied with the product. Caregiver burden prior to and following smart medication dispenser use for 6 months was found to be statistically significantly different ($P < .001$; CI 2.11-5.98).

Conclusions: Smart medication adherence products such as *spencer*, when connected and clinically monitored, can be a useful solution for medication management and have the potential to improve caregiver burden.

Introduction

Nonadherence to medications is a well-recognized global challenge. In 2003, the World Health Organization (WHO) noted that the mean adherence to chronic therapy was only 50% in high-income countries and even lower in low-income countries [1]. Numerous other studies confirm findings of significant nonadherence rates in various chronic disease populations [2-5]. Nonadherence to medications is a key contributor to potentially preventable health care utilization and costs [6-8]. Conversely, improving medication adherence can improve clinical outcomes, decrease mortality, and lower health care costs [9,10]. Several strategies to improve medication adherence have been identified, including patient education, medication regimen management, pharmacist-led interventions, cognitive behavioral therapies, medication-taking reminders, and incentivization [11]. Systematic reviews of several interventions indicate that while some interventions are effective [12,13] at improving medication adherence, others are not [14], and many are limited by the quality of studies conducted. Indeed, medication nonadherence continues to be a challenge and has led to an increasing interest in developing innovative digital technology systems that tackle medication taking and monitoring [15,16]. Some of these technologies include smart pill containers and wearable sensors that track medication access via actions such as opening containers, pouring pills, picking up pills, hand to mouth movements, or pill swallowing, while ingestible sensors detect medication ingestion [15]. Some systems, such as Medication Event Monitoring Systems, track and store the dates and times a vial is opened by simply incorporating a cap that can be fitted over prescription vials [17], while others offer multidose packaging, medication reminders via integrated alarms, text messaging, and notifications, among other things, when tracking medication adherence in real time [18]. However, the use of these smart medication dispensing aids in patients' homes has not been investigated extensively.

While medication dispensing events that are tracked by dispensing aids have been validated as an accurate marker of medication adherence [11], there are several factors that may impact the implementation of such devices in the homes of patients. A key driver of the implementation and sustainable use of a product is its usability. The International Organization of Standardization defines usability as the "extent to which a system, product or service can be used by specified users to achieve a specified goal with effectiveness, efficiency and satisfaction in a specified context of use" [19]. As the definition indicates, medication dispensing devices must be established as effective, efficient, and satisfactory among the individuals expected to use the device. Complexity, design quality, and packaging can affect the implementation of eHealth products and should also be examined [20]. Unfortunately, few studies have examined the usability of such dispensing devices [21-24].

Older adults often require assistance with activities of daily living. Research indicates that informal caregivers, often spouses and children, provide the bulk of these services and that medication management is a key component of the health care assistance provided [25-27]. Caregivers perform a number of

tasks associated with managing medications, including ordering and administering medications as well as monitoring adverse effects and the safe use of medications [28]. Medication management can be a cause of stress for caregivers. In addition to administration procedures and safety issues associated with medications, scheduling logistics such as administration of medication into care routines, scheduling multiple medications, giving medications on time, and keeping medication prescriptions filled are contributors to the burden a caregiver may experience. The use of medication reminder systems has been associated with a decrease in stress among caregivers of patients with dementia but not among those whose care recipients did not have dementia [29]. The study, however, did not specify the types of medication reminder systems that were used.

Therefore, the objectives of this study were to examine the use of one such system as a medication adherence and self-management support tool for adults in the community setting. In addition to examining the adherence to medication regimens during a 6-month period, we sought to examine the usability, usefulness, satisfaction, and impact on caregiver support. Finally, we examined the potential for pharmacists to identify and address medication related problems including concerns related to adherence with data available through AdhereNet.

Methods

Study Design

This study was designed as a prospective, observational pilot study.

Sample and Sample Size

A convenience sample of 50 adults and 15 caregivers was determined as adequate for this pilot study. Patient participants had to be at least 45 years old, speak English, be a resident of Ontario, Canada, be prescribed at least one chronic oral medication, and have the cognitive capacity to interact with the medication dispensing device. Chronic oral medications were defined as a prescription or over-the-counter medication with approved indication or generally accepted reasons for use as defined by the WHO Anatomical Therapeutic Chemical/Defined Daily Dose Index 2019. Cognitive capacity to use the smart medication dispenser was determined by the research pharmacist using clinical judgment and by assessing responses to the following questions: was the participant comfortable opening the medication package? Was the participant able to tell how they could remove medications from the smart medication dispenser? Was the participant able to play back demonstration videos? Was the participant aware and able to call the number if there were any technical difficulties? Was the participant aware of the number to call if they needed the pharmacy's assistance? If the respondent was not able to demonstrate capacity in the any of the above, they were excluded from participation.

Patient participants could have an unlimited number of scheduled medication dosing times, customized to their daily routines. All medications for a scheduled dosing time were

packaged together in single or multiple multidose pouches. Adults who had previously expressed an interest in learning about the smart medication dispenser were approached to take part in this study. In addition, health care providers, outreach programs, and independent living communities were approached to assist in identifying potential participants. The participants' caregivers were also invited to take part in this study. Caregiver participants comprised of family members, friends, volunteers, or paid support workers who had regular involvement with providing medication management support to the participants. Patient participants who were receiving assistance from a formal medication management program and those who had severe cognitive impairment were excluded from this study.

Smart Medication Dispensing Device

In this study, we investigated the use of *spencer*, [30] an at-home smart medication dispensing device that connects patients to community pharmacists to monitor medication adherence, ask active engagement questions for patient reported outcomes, link readings from Bluetooth enabled devices to medication administration, and use telehealth capabilities with an embedded camera. Medications are packaged in multidose pouches by pharmacies certified on Catalyst Healthcare's AdhereNet platform, [31] and delivered to patients at home weekly or biweekly. These multidose pouches are loaded into the smart medication dispenser at home and dispensed at individualized, appropriate preset times. The smart medication dispenser has a touch screen interface for patients to respond to reminder alerts, answer questions posed by their clinicians through the product, and participate in telehealth video calling through the device. The smart medication dispenser tracks a patient's medication intake in real time and provides reports on adherence to the patient's clinicians, including pharmacists. Clinicians can also ask questions via the smart medication dispenser and provide virtual clinical interventions as required.

Outcome Measures

Adherence

Adherence data were determined by using the smart medication dispenser and AdhereNet, which receives data from the smart medication dispenser and displays adherence in real time, allowing for remote viewing and analysis by pharmacists. Adherence was measured by tracking the removal of a medication dose no more than 2 hours after the scheduled dosing time. For instance, if a patient's medication was removed from the smart medication dispenser within this 2-hour window, the dose event was recorded as 100%. Conversely, if the dose was removed from the smart medication dispenser more than 2 hours after the scheduled time, the dose event was recorded as 0%. The daily medication adherence percentage was calculated based on the number of doses dispensed within a 2-hour window each 24-hour period. Monthly adherence reports were generated for each patient. The total average medication adherence for the study population (mean, SD) was calculated by dividing individual adherence percentage values over the course of the study by the number of study participants (N):

Daily medication intake data were collected for each participant using the smart medication dispenser. Mean monthly adherence was calculated at every 30-day interval (eg, period 1: 1-30 days, period 2: 31-60 days, period 3: 61-90 days, etc) for the duration of the study. Since participants started at different dates, we defined their first day using the smart medication dispenser as day 1. For any dates in which adherence data was not collected, the carry forward technique was utilized to impute these missing values [32]. This technique was applied to a maximum of 6 consecutive missing data points within a 30-day period. Participants with 7 or more consecutive missing data points were removed from that 30-day period of analysis.

Usability, Usefulness, and Satisfaction

Usability, usefulness, and satisfaction were measured with two tools: the System Usability Scale (SUS) and selected questions from the Usefulness, Satisfaction, and Ease of Use (USE) questionnaire. SUS is a broadly used 10-item posttest instrument that can be quickly administered to examine the usability of a product. Each item is scored on a 5-point Likert scale examining the degree of agreement. SUS has been demonstrated to be reliable and sensitive to successful task completion and identify differences in user experiences in multiple studies [33]. The USE questionnaire is a 30-item questionnaire designed to investigate the usefulness, ease-of use, ease of learning, and satisfaction of a system [34]. The 30 statements are rated on a 7-point Likert scale, ranging from strongly disagree to strongly agree. The questionnaire can be utilized over various assessments of usability, including both technology and nontechnology systems [34]. Although the questionnaire has not been studied among older adults, a psychometric evaluation among users of Microsoft Word and Amazon.com revealed a Cronbach alpha of .98 of the overall score. The USE questionnaire correlated well with SUS (r between 0.6 and 0.8) [35]. Due to the participant profile in this study, 9 statements regarding usefulness and satisfaction were selected out of the 30 total.

Pharmacist Clinical Interventions and Resolution of Drug Therapy Problems

Drug therapy problems were identified by pharmacists during their direct interactions with the participants. Direct interactions were conducted in person, over the phone, or through the smart medication dispenser's telehealth video call functionality. Pharmacists interacted with patients to assess drug therapy problems at the beginning of the study, during the study as required, and at the end of the 6-month study period. The COVID-19 pandemic impacted pharmacists' ability to conduct direct in-person interactions during the latter part of the study, resulting in most interactions occurring over the phone or over the smart medication dispenser's telehealth video calling functionality. A drug therapy problem was defined as "any undesirable event or risk experienced by the patient that involves or is suspected to involve drug therapy and that interferes with achieving the desired goals of therapy and requires professional judgment to resolve" [36]. Drug therapy problems were classified based on the Canadian Consensus of Clinical Pharmacy Key Performance Indicators [36].

Caregiver Impact

Caregiver burden was measured on a visual analog scale by asking participants to indicate their response to the question, “On a scale of 0 to 10, how would you rate your burden level with respect to managing your loved one’s medications, where 0 = no burden and 10 = most burden?” Caregiver burden was measured at baseline and at the end of the 6-month study period.

Statistical Analysis

Data were entered in a Microsoft Excel spreadsheet (Microsoft 365, version 2170; Microsoft Corp). Descriptive statistics (mean, standard deviation, and frequencies) were analyzed using Microsoft Excel. Independent *t* tests and Pearson chi-square tests were conducted using RStudio (1.2.1335) to examine if there was a statistically significant difference between participants who completed the study and those who dropped out. A paired *t* test was also conducted using RStudio to examine if there was a statistically significant change in caregiver burden from baseline to the end of the 6-month study period. Descriptive statistics were used to describe identified drug therapy problems.

Ethics Approval

This study was reviewed by and received ethical approval from the University of Waterloo Office of Research Ethics (#40820). All participants were informed of the study and provided consent before enrolling.

Results

Participant Demographics

A total of 58 participants were recruited for this study, of whom 1 participant died and 9 participants withdrew consent prior to the end of the study but did not withdraw their data collected prior to their discontinuation in this study. [Table 1](#) outlines the participants’ demographic statistics.

Of the 11 caregiver participants recruited, 91% (10/11) were female with a mean age of 57 (SD 16.6; range 28-83) years. There were no caregiver participant dropouts. [Table 2](#) outlines the caregiver participants’ demographic statistics.

Almost all caregiver participants noted forgetfulness (n=9, 81.82%) or administering medications inappropriately (n=6, 54.55%) as reasons for starting to help their family members with their medications.

Table 1. Demographic characteristics of participants.

Variable	Total (N=58)	Withdrawn (n=9)	Completed (n=49)	P value

Adherence

The average monthly adherence over 6 months was 98% (n=56; SD 3.1%; range 76.5%-100%) (see [Figure 1](#)).

Figure 1. Monthly adherence.

Usability, Usefulness, and Satisfaction

A total of 47 participants completed the SUS. The average SUS score was 85.74 (SD 12.7; range: 47.5-100). Meanwhile, 46 participants completed the 9-question USE questionnaire. Most participants ($\geq 75\%$) strongly agreed that the smart medication dispenser was pleasant and easy to use (see Figure 2). Of the participants who completed the USE questionnaire, 43 (93%)

indicated that they either somewhat agreed, agreed, or strongly agreed that they were satisfied with the product and would recommend the smart medication dispenser to a friend. Moreover, 42 (91%) participants somewhat agreed, agreed, or strongly agreed with the statement that they found the smart medication dispenser worked the way they want it to, and 40 (87%) somewhat agreed, agreed, or strongly agreed with the statement that they needed to have the product.

Figure 2. Usefulness, Satisfaction, and Ease of Use (USE) questionnaire response breakdown.

Pharmacist Clinical Interventions and Resolution of Drug Therapy Problems

Drug therapy problems were identified at the time of the participant's medication review and throughout the study time frame as part of routine practice. A total of 117 drug therapy problems were identified during the study period (see Table 3). These drug therapy problems affected 39 of the participants. Participants had on average 3 drug therapy problems (SD 2.08; range 1-9). Drug therapy problems occurred with 68 unique

medications, and the most common medications with which problems were reported were vitamin D (15%), pantoprazole (7%), and acetaminophen (4%).

Drug therapy problems were most frequently reported with over-the-counter medications (42.74%) and most frequently classified as a need for a medication to be initiated (40.17%). Pharmacists most frequently requested an initiation (41.03%) or a discontinuation (22.22%) of medications.

Table 3. Drug therapy problems (N=117).

Drug therapy problems	Values, n (%)
Type of medication	
Prescription high alert (Institute for Safe Medication Practices definition) ^a	19 (16.24)
Prescription nonhigh alert	48 (41.03)
Over the counter	50 (42.74)

Other	11 (9.40)
Pharmacist recommendations	
Discontinue medication	26 (22.22)
Start medication	48 (41.08)
Start alternative nonpharmaceutical therapy	3 (2.56)
Change dose	16 (13.68)
Change route	0 (0)
Change schedule	10 (8.55)
Dosage strength	0 (0)
Change dosage form	3 (2.56)
Change duration of treatment	1 (0.85)
Recommend monitoring	8 (6.84)
Provide patient education	7 (5.98)
Continue medication	1 (0.85)
Refer to a physician or nurse practitioner	5 (4.27)
Drug therapy problem follow-up/resolution	
Problem resolved: recommendation accepted by patient	23 (19.66)
Problem resolved: recommendation accepted by physician or nurse practitioner	6 (5.13)
Problem unresolved: recommendation not accepted by patient or prescriber	1 (0.85)

^aInstitute of Safe Medication Practices defines prescription high alert medications as “drugs that bear a heightened risk of causing significant patient harm when they are used in error” [37].

Caregiver Burden Impact

Caregiver burden scores were obtained from 11 caregivers before and following the use of the smart medication dispenser for 6 months. The average caregiver burden scores at baseline were 7/10 (SD 2.6; range 1-10) and 3/10 (SD 2.8; range 0-8) following product use, which were found to be statistically significantly different ($P < .001$; CI 2.11-5.98).

Discussion

Principal Findings

Many factors impact adherence to medications, including patient-related factors, medication-related factors, social and economic factors, and health care-related factors. Among patient-related factors, unintentional medication nonadherence may arise due to forgetfulness and physical and cognitive limitations [1]. Among medication-related factors, nonadherence may be related to multiple or complex medication regimens [1]. Automated dispensing devices may help improve adherence in such circumstances. However, the usability and effectiveness of these devices in addressing medication nonadherence need to be further examined. Our study investigated the integration of a smart multidose medication dispensing aid with real-time medication intake monitoring capacity in the home of adults taking chronic medications. Over 6 months, participants had a mean adherence rate of 98% with the use of the smart medication dispenser. The SUS score for usability was 85.74, and >75% of the participants found the product pleasant and easy to use. Finally, the integration of the smart medication dispenser into the home significantly decreased caregiver burden and provided a space for pharmacists to conduct medication reviews and identify drug therapy problems.

A total of 117 drug therapy problems were identified in 39 participants; 20% of the recommended changes to address the drug related problems were accepted by the patient, 5% were accepted by the physician or nurse practitioner, and 75% remained unresolved (1%) or not reported (74%). Unfortunately, the timing of this study intersected with the COVID-19 pandemic, which impacted the ability of pharmacists to reach prescribers and obtain follow-up on recommended changes to address drug-related problems. Most physician offices were closed or offered limited services, which impacted communication between physicians and pharmacists.

Communication between pharmacists and patients, however, was not hampered due to the availability of telephone and video calling using the smart medication dispenser. While we did not intend to track patient preference for these services, we found that participants preferred telephone calling to video calling. This coincides with the findings reported by Rodriguez et al [38]. In their study, participants who were 65 years of age or older were less likely to use video visits compared with those aged 18-64 years [38]. Similarly, in a study describing the transition to telemedicine in the geriatric primary care population, Schifeling et al [39] reported that more than half of the patients used telephone visits. Future studies should further investigate preference and rationale for preference in telemedicine care (telephone versus video calling) and its impact, if any, on patient satisfaction and the quality of care

received. Older adults may prefer interactions through telephone as it is a familiar, accessible, and easy to use mechanism of communicating. Video calling, even if enabled through medication dispensing technology, requires one to learn how to use the system, impacting its usability and uptake. Other studies have reported similar findings [38,39].

The monthly adherence rate in this observational study remained >95% over the 6 months. Our study was not designed to investigate the effectiveness of the smart medication dispenser in improving adherence. As such, we did not seek to enroll participants deemed to be nonadherent to their medications, nor did we capture medication adherence rates at baseline to permit a comparison at the end of the 6-month study period. We also deemed a participant to be adherent to their medications if they retrieved the multidose package dispensed to them within a 2-hour time frame following their scheduled medication dosing time. Other smart dispensing devices have assessed adherence in a variety of patient populations; however, in these studies, there is significant variability in the definition and measurement of adherence. Where adherence rate was determined by the use of a smart dispensing device, rates of reported adherence ranged from 93% to 97% [21]. Additionally, previous studies have demonstrated that electronic drug monitors accurately measure times of opening of pill bottles in nonclinical settings and improve adherence [11,40-42]. Furthermore, electronic drug monitoring is widely regarded as the gold standard for measuring adherence [43] and provides an insight into medication taking behavior in the home, which in turn may help to identify specific challenges patients may encounter when taking their medications in the home. For example, if patients consistently fail to retrieve the medication pouches for a particular dosing time, clinicians can design strategies to address this challenge. If a dosing schedule can be altered to meet the needs of the patient's lifestyle or needs, this can then be implemented. In this way, this system encourages a patient-centered approach to medication taking and the measurement of adherence. Furthermore, a review of medication intake data and feedback to patients can help uncover other contributors to nonadherence such as medication adverse effects and beliefs about the need for medications, among others [42]. In 2013, Demonceau et al [44] determined that adherence feedback to patients based on drug dosing histories improved adherence by 8.8%. More recently, van Heuckelum et al [45] determined that electronic medication feedback had a significantly positive effect on medication adherence.

We examined the usability of a smart medication dispenser in the home using SUS. Field testing of usability in the home is rarely conducted [19,46], and while there are other methods of testing the usability, the simplicity and ease of use of a 10-item questionnaire addressed the need for a practical measure. Furthermore, SUS is the tool most frequently used to measure the usability of products [33]. In this study, the mean SUS score of the medication dispensing device was 85.74. While there are no benchmarks against which to compare the SUS score, one study examined the usability of 21 electronic medication adherence products with SUS [47]. Although most of the medication dispensing aids tested in the study were not smart, and only one permitted electronic monitoring of medication

dispensing, many of the dispensing aids had typical features of dispensing aids used by patients. In that study, SUS scores ranged from 28.63 to 78.67, and the mean score was 52.28 [47]. In comparison to that score, the SUS score for this smart medication dispenser was substantially higher, indicating higher usability of the product. Furthermore, most participants reported the smart medication dispenser was easy and simple to use and were satisfied with the product, potentially predicting ease of implementation in the home by patients, in particular older adults.

Maintaining medication adherence is complex. When the capacity to manage medications declines, unpaid caregivers such as family members often step in to assist patients with managing their medications. Results from our study demonstrate a significant decline in the visual analog scale score for burden associated with managing medications from baseline to the end of the study period. In their study, Polenick et al [29] demonstrated that medication reminder systems decreased caregiver burden among caregivers of persons with dementia but not among those care giving for persons without dementia. However, in our study, people with cognitive impairment were excluded. Several aspects of the smart medication dispenser may have contributed to the decline in caregiver burden in our study population. The administration of prepackaged medications in pouches at appropriate times alleviates the caregiver's need to organize and administer the medications. Additionally, caregivers who do not reside with the patient no longer have to schedule multiple visits throughout the day to ensure medications are taken as appropriate, as medication taking can be confirmed virtually through medication intake monitoring.

Limitations

Although the caregiver burden decreased significantly over the study duration, this is a hypothesis generating finding, as this study was not powered to investigate caregiver burden as a primary objective. Furthermore, we utilized only one question on a visual analog scale to examine the impact of the smart

medication dispenser on caregiving burden. This question does not provide an insight into the aspects of caregiving related to medication management that the use of the smart medication dispenser produces. However, the currently available tools do not specifically measure caregiving burden related to the management of medications [48]. The Family Caregiver Medication Administration Hassles tool permits the examination of strain related to medication management but consists of domains pertaining to monitoring the safety of medications as well as scheduling and administration issues. Some components of this tool could be utilized to measure caregiver strain related to medication management and should be considered in future studies [49].

Missing adherence data were addressed by utilizing the carry forward technique. Though this technique was used to account for incidents where adherence was not tracked by the smart medication dispenser even though the patient took their medication, it may have overrepresented the true rate of adherence. Medication adherence was not tracked when system or user error led to loss of data. Examples of such system errors include disconnecting the device from the internet, removing batteries from the device, or another indeterminate system error that led to data loss.

Conclusion

This was a pilot study designed to examine the feasibility of integrating the smart medication dispenser into the homes of patients, test its usability, and explore whether caregiver burden was affected. This study was not designed to measure the effectiveness of the smart medication dispenser in these domains. The adherence was potentially driven by usability of the device, personalization of medication administration times, and decrease in caregiving burden. The results of this study can be utilized to design hypothesis testing studies in the future. In particular, given that usability scores were high, future studies can be designed to examine the impact on adherence in nonadherent populations. Similarly, the impact on caregiver stress and burnout should be further examined.

Acknowledgments

This study was supported by the Centre for Aging and Brain Health Innovation and Catalyst Healthcare and Pack4U. We thank all participants for their time. We are grateful to Julie McRae for assisting in conceptualization of the project and Jingui Qui for assisting with data entry.

Conflicts of Interest

The authors T Pitre, KA, and KO are employees of Pack4U and own stocks in the company.

Abstract

Background: Middle-aged adults (40-65 years) report higher stress levels than most other age groups. There is a need to determine the feasibility of using a meditation app to reduce stress and improve stress-related outcomes in middle-aged adults with a focus on men, as previous meditation app-based studies have reported a low proportion of or even no male participants.

Objective: This study aims to (1) determine the feasibility (ie, acceptability and demand with a focus on men) of a consumer-based meditation app (Calm), to reduce stress among middle-aged adults reporting elevated stress levels, and (2) explore the preliminary effects of Calm on perceived stress, psychological outcomes (anxiety, depressive symptoms, mindfulness, and general coping), health behaviors (physical activity and eating habits), and COVID-19 perceptions.

Methods: This feasibility randomized controlled trial evaluated an app-based meditation intervention in middle-aged adults (N=83) with elevated stress levels (ie, Perceived Stress Scale score ≥ 15) and limited or no previous experience with meditation. Participants were randomized to the intervention group (Calm app) or a control (educational podcasts; POD) group. Participants completed self-report assessments at baseline and postintervention (week 4). Feasibility was measured as acceptability and demand using Bowen framework. Feasibility and COVID-19 perceptions data were examined using descriptive statistics, and preliminary effects were evaluated using repeated measures analysis of variance.

Results: Participants were satisfied with Calm (27/28, 96%) and found it appropriate or useful (26/28, 93%). Most reported they would likely continue using the Calm app (18/28, 64%). More Calm users reported satisfaction, appropriateness or usefulness, and intent to continue app use than POD users. Calm users (n=33) completed a mean of 20 (SD 31.1) minutes of meditation on the days they meditated and 103 (SD 109.1) minutes of meditation per week. The average adherence rate to the prescribed meditation was 71% among Calm app users, compared to 62% among POD users. Recruitment rate of men was 35% (29/83). Of those randomized to Calm, 55% (15/29) were men, and retention among them was higher (14/15, 93%) than that among women (12/20, 60%). No significant within or between group differences were observed.

Conclusions: A 4-week, app-based mindfulness meditation intervention (Calm) may be feasible for middle-aged adults and a useful stress-management tool. Calm users expressed satisfaction with the app and felt it was appropriate and useful. Significant improvements in perceived stress and psychological outcomes or stress-related health behaviors were not observed. Even though men spent less time in meditation than women did and completed fewer weekly sessions, they were more likely to adhere to the prescription. Further research is needed for improving stress and stress-related outcomes among middle-aged adults with emphasis on the effects of mindfulness meditation apps for men.

Introduction

Middle-aged adults (40–65 years) [1] report higher stress levels than most other age groups [2,3], with 75% reporting moderate to high stress and 33% reporting extreme stress [4]. Major sources of stress include managing children, employment, and aging parents [5]. In 2020, 78% of middle-aged adults reported the COVID-19 pandemic as a significant source of stress, and 67% reported increased stress during the pandemic [6]. When left unmanaged, stress is a risk factor for age-related chronic health conditions [7].

Meditation is the most prevalent nonpharmacological approach known to reduce stress [8,9]. Meditation interventions of only 5 to 10 minutes for 3 to 4 sessions a week can buffer reactivity to stress [10]. The use of smartphone apps to deliver meditation and manage stress is rapidly increasing [11] owing to their reach, accessibility, and low cost [12–15]. Meditation apps may overcome in-person participation barriers, such as travel, time, costs, stigma, and risk of infectious disease [16–18].

Engagement in health behaviors (eg, physical activity and eating habits) and treatment preferences for stress reduction often differ between men and women [19]. Previous studies on meditation apps have reported a low percentage of men in their samples [20,21], whereas some studies did not include men at all [22–24]. Feasibility and efficacy studies using the meditation app Calm have been conducted [25,26], but this is the first study testing Calm specifically in middle-aged adults with a focus on recruitment of men. There is a need to conduct additional feasibility studies using meditation apps to reduce stress and improve stress-related outcomes in middle-aged men and women [27].

The aims of this study were to (1) determine the feasibility (ie, acceptability and demand with a focus on men) of a

consumer-based meditation app (ie, Calm), to reduce stress in middle-aged adults reporting elevated stress levels, and (2) explore the preliminary effects of Calm on perceived stress, psychological outcomes (ie, anxiety, depressive symptoms, mindfulness, and general coping), health behaviors (ie, physical activity and eating habits), and perceptions of COVID-19.

Methods

Research Design and Participants

This was a randomized controlled feasibility study approved by an institutional review board (STUDY00011219; NCT04272138). Middle-aged adults with elevated stress levels (Textbox 1) were recruited for an “app-based health and well-being study,” via flyers encouraging men to participate shared on social media platforms (eg, Instagram and Facebook) and the *ResearchMatch* website [28]. All participants provided electronic consent. Eligibility, consent, demographic, and survey data were collected using REDCap (Research Electronic Data Capture), a secure, web-based software platform, hosted by Arizona State University [29,30].

Participants were randomized to an app-based meditation intervention (Calm) or an app-based education control group (POD, an app that delivered podcasts on health and well-being, but excluding mindfulness, stress, or sleep content in the same context that a consumer-based mindfulness meditation app delivers content [31]) by using a randomized numbered list generated through simple randomization via the *Research Randomizer* website [32]. Participants were asked to complete 10-minute meditations daily on the Calm app or to listen to 10-minute educational podcasts daily on the POD app, for 4 weeks. All participants received weekly reminders and links to REDCap assessments via email.

Textbox 1. Eligibility criteria for participation in the study.

Inclusion criteria

- man or woman
- age 40–64 years
- report a score of ≥ 15 on the Perceived Stress Scale
- have access to a smartphone on a daily basis
- willing to download the Calm app
- willing to be randomized to a meditation group or a health education podcast control group

Exclusion criteria

- have practiced mindfulness for >60 minutes/month in the last 6 months
- currently using the Calm app or another meditation app
- currently prescribed mood medication(s)
- currently residing outside the United States

Measures

Participants completed self-report assessments at baseline and postintervention (ie, week 4). Feasibility was measured as

acceptability and demand using the Bowen framework (Table 1) [27], and feasibility benchmarks were established using a previously established methodology of feasibility trials with Calm [25,33]. Benchmarks for acceptability were more than

75% of participants reporting each of the following: satisfaction with the intervention, perceiving the app as appropriate and useful, and intent to continue using the app. Benchmarks for demand were more than 40% of the sample comprising male participants, more than 70% of the Calm app user group adhering to at least 70% of the meditation intervention (ie, ≥ 10 minutes/day of using Calm), and more than 75% retention of

men allocated to the intervention group. Adherence was measured using objective app usage data collected by both Calm and POD. The measures used to explore preliminary effects and COVID-19 perceptions are listed in [Table 2](#). The COVID-19 Perceptions Survey was added to the postsurveys in March 2020 following the start of recruitment.

Statistical Analysis

Feasibility and COVID-19 perceptions data were examined using descriptive statistics. Preliminary effects on perceived stress, anxiety, depressive symptoms, mindfulness, coping, physical activity, and eating habits were examined using repeated measures analysis of variance. Data were analyzed in SPSS (version 26; IBM Corporation) and SAS (version 9.4; SAS Institute). Results were considered significant at a 2-tailed α value $< .05$.

Results

Overview

In total, 83 middle-aged adults were consented and randomized, of which 60 (72%) were included in the analysis ([Figure 1](#)). Demographic characteristics of the sample are presented in [Table 3](#).

Figure 1. Enrollment of participants in the study. Note: Some participants did not meet more than one inclusion criteria. COPE: Coping Orientation to Problems Experienced (Scale); IPAQ: International Physical Activity Questionnaire.

Feasibility

Acceptability of Calm

Participants were satisfied with the meditation intervention (27/28, 96%) and found it appropriate or useful (26/28, 93%). Most participants reported that they were likely to continue

using Calm in the future (18/28, 64%; [Table 4](#)). There were no notable differences in satisfaction, appropriateness or usefulness, or intent to continue use by gender ([Table 5](#)). More participants in the Calm group reported satisfaction, appropriateness or usefulness, and intent to continue use than in the control group ([Table 4](#)).

Table 4. Acceptability results of the Calm app classified by study group.

Question	Value, n (%)	
	Calm group (n=28) ^a	POD group (n=19) ^b
Overall satisfaction with study	27 (96.4)	10 (52.6)
Participation of the app was appropriate and useful	26 (92.9)	8 (42.1)
Would continue to use the app	18 (64.3)	6 (31.6)
Reduced stress in short term	16 (57.1)	7 (36.8)
Will help reduce stress in long term	19 (67.9)	10 (52.6)
Increased awareness of the importance of addressing stress	23 (82.1)	12 (63.2)
Will help reduce stress in the future	17 (60.7)	4 (21.1)
Likely to recommend the app to others	22 (78.5)	8 (42.1)

^aFive participants did not complete the survey.

^bEight participants did not complete the survey.

Demand of Calm (Adherence, Recruitment of Men, and Retention of Men)

Calm participants (n=33) completed a mean of 20 (SD 31.1) minutes of meditation on the days they meditated, and a mean of 103 (SD 109.1) minutes of meditation per week during the study (Figure 1). On average, the adherence rate was 71% in the Calm group (ie, those who completed at least 70% of the meditation prescription) to the prescribed meditation, compared to 62% in the POD group. Men (n=14) completed a mean of 17.3 (SD 14.6) minutes of meditation per day (on the days they meditated), 79 (SD 37.9) minutes of meditation per week, and

8.5 (SD 5.7) meditation sessions per week during the study. Women (n=19) completed a mean of 21.5 (SD 31.1) minutes of meditation per day, 113 (SD 126.6) minutes of meditation per week, and 6.3 (SD 2.7) meditation sessions per week. Men showed greater adherence (12/14, 86%) to the Calm app than did women (12/19, 63%; Figures 2-4).

Recruitment rate of men into the study (before excluding those who were randomized and had completed baseline but did not start the study, those who dropped out, or those who did not complete the study) was 35% (29/83). Of those randomized to the Calm app, 55% (15/29) were men. Retention among men was higher (14/15, 93%) than that among women (12/20, 60%).

Discussion

Principal Findings

A 4-week, app-based mindfulness meditation intervention (ie, Calm app) may be feasible for use among middle-aged adults. Calm group participants expressed satisfaction with the intervention and felt it was appropriate and useful. However, significant improvements in perceived stress and psychological outcomes (ie, anxiety, depressive symptoms, mindfulness, and general coping) or health behaviors related to stress (ie, physical activity and eating habits) were not observed among these participants. The majority of participants reported that COVID-19 has negatively affected their stress, mental health, and physical health.

Feasibility of Calm

We exceeded our benchmark (>75%) for acceptability rating of the Calm app among middle-aged adults experiencing stress. This finding was similar to that of other studies assessing the feasibility of Calm in patients with cancer and among college students [25]. Our benchmark for adherence to the meditation prescription (ie, >70% of the sample who completed at least 70% of the meditations) was met and better than most 4-week randomized controlled trials using an app to reduce stress [13,23,40]. Men had a higher adherence to the intervention than women (86% vs 71%), but this finding is not entirely consistent with other studies and does not necessarily suggest overall gender differences in meditation app use [41,42]. Research on app-based interventions targeting stress reduction and related outcomes, including objective app-usage data in middle-aged men, is warranted.

Our benchmark was to recruit 40% men, and we recruited 35% men (29/83) in our study. We were able to recruit more men than other app-based meditation studies (5.7%-27%), including studies that focused on middle-aged adults [21,25,43-46]. The retention of men (14/15, 93%) was also higher than that of

women (19/24, 60%). Although, on average, men spent less time meditating than women did (approximately 57-91 vs 107-135 min/week) and completed fewer weekly sessions (4.7-7.5 vs 7.4-9.7 sessions/week), they were more likely to adhere to the 10-minute prescription. This finding suggests that Calm may be a useful self-management tool for both men and women to manage stress [21,44,45]. Future app-based meditation interventions should focus on recruitment and retention of men, especially because men are less likely to seek stress management strategies than women [47,48].

Stress and Health-Related Behaviors

Significant changes in stress and related psychological outcomes or health behaviors were not observed. In another study testing the efficacy of meditation delivered via Calm, changes in stress and mindfulness in college students were observed after 8 weeks of participation. When taken together with these findings, the present data suggest that any significant changes in stress levels may take longer than 4 weeks to be noticeable [25].

Few studies have tested the effects of app-based mindfulness meditation on health behaviors related to stress [49] and have reported inconsistent findings [23,40,50,51]. We observed a negative trend regarding physical activity and eating habits. These may, however, have been related to lifestyle modifications due to the COVID-19 pandemic (eg, quarantine and closure).

Perceptions of COVID-19

Perceptions of COVID-19 could have had an important impact on stress in relation to the findings of this study. It is possible that meditation helped the study participants in the intervention group to maintain their stress and anxiety levels, as well as depressive symptoms (as opposed to elevated levels), during the COVID-19 pandemic [52]. Likewise, the general health education content of the control app may have helped mitigate the impact of the pandemic through avoidance or redirecting negative thoughts [53]. However, data regarding how participants felt their app usage impacted their

COVID-19–related stress was not measured. More research on the effects of COVID-19 on stress and related health outcomes and how a meditation app may buffer that impact is warranted.

Limitations

Limitations to this study include the following: (1) the majority of the sample comprised White participants, and generalizability of the findings may thus be limited; (2) the intervention was only 4 weeks long and did not include a follow-up; and (3) the

COVID-19 pandemic may have had a notable impact on the findings of this study.

Conclusions

This study supports the feasibility of a 4-week, mobile app–based mindfulness meditation intervention (ie, Calm) in middle-aged men and women with specific application for the recruitment of men to inform future studies.

Conflicts of Interest

None declared.

Abstract

Background: Bipolar II disorder (BD-II) is associated with significant burden, disability, and mortality; however, there continues to be a dearth of evidence-based psychological interventions for this condition. Technology-mediated interventions incorporating self-management have untapped potential to help meet this need as an adjunct to usual clinical care.

Objective: The objective of this pilot study is to assess the feasibility, acceptability, and clinical utility of a novel intervention for BD-II (Tailored Recovery-oriented Intervention for Bipolar II Experiences; TRIBE), in which mindfulness-based psychological content is delivered via an integrated web and smartphone platform. The focus of the study is evaluation of the dynamic use patterns emerging from ecological momentary assessment and intervention to assist the real-world application of mindfulness skills learned from web-delivered modules.

Methods: An open trial design using pretest and posttest assessments with nested qualitative evaluation was used. Individuals (aged 18-65 years) with a diagnosis of BD-II were recruited worldwide and invited to use a prototype of the TRIBE intervention over a 3-week period. Data were collected via web-based questionnaires and phone interviews at baseline and 3-week follow-up.

Results: A total of 25 participants completed baseline and follow-up assessments. Adherence rates (daily app use) were 65.6% across the 3-week study, with up to 88% (22/25) of participants using the app synergistically alongside the web-based program. Despite technical challenges with the prototype intervention (from user, hardware, and software standpoints), acceptability was adequate, and most participants rated the intervention positively in terms of concept (companion app with website: 19/25, 76%), content (19/25, 76%), and credibility and utility in supporting their management of bipolar disorder (17/25, 68%). Evaluation using behavioral archetypes identified important use pathways and a provisional model to inform platform refinement. As hypothesized, depression scores significantly decreased after the intervention (Montgomery-Asberg Depression Rating Scale baseline mean 8.60, SD 6.86, vs follow-up mean 6.16, SD 5.11; $t_{24}=2.63$; $P=.01$; Cohen $d=0.53$, 95% CI 0.52-4.36).

Conclusions: Our findings suggest that TRIBE is feasible and represents an appropriate and acceptable self-management program for patients with BD-II. Preliminary efficacy results are promising and support full development of TRIBE informed by the present behavioral archetype analysis. Modifications suggested by the pilot study include increasing the duration of the intervention and increasing technical support.

Introduction

Background

Bipolar disorder (BD) is a chronic mood disorder characterized by episodes of depression, hypomania or mania, and mixed mood states. Although historically perceived as the *milder* phenotype, bipolar II disorder (BD-II) is associated with comparable depression severity, suicide attempts, and role impairment [1] relative to bipolar I disorder (BD-I). Notably, poorer health-related quality of life [2] and a higher risk of completed suicides [3] have been observed in patients with BD-II. These concerning features may be because of the significant depressive burden characterizing the condition, including persistent subsyndromal depression, poorer return to baseline psychosocial functioning between episodes [4-6], and mixed depressive states that are experienced as highly dysphoric [7]. Despite the best available treatments, depression relapse rates remain high [8,9] and are more frequent in patients with BD-II [10]. Therefore, there is a pressing need for improved treatments.

Several adjunctive psychological interventions have been developed for BD, but research has overwhelmingly focused on BD-I, leaving clinicians to simply extrapolate the findings to BD-II. These treatments lack face validity because of their focus on the prevention of mania and relative inattention to elevated mood states of BD-II, which, by definition, do not meet the criteria for mania. Furthermore, in the absence of research into BD-II, clinical guidelines are reduced to tentative recommendations to generalize from BD-I [11], ignoring genetic evidence of their separability [12] and clear phenomenological differences among the phenotypes [1]. Beyond the core diagnostic difference (absence of mania), people with BD-II experience higher levels of residual depressive symptoms [13-15], more frequent depressive episodes [4,6,16], and shorter *well* periods [5,17]. Indeed, a highly cited prospective study found that people with BD-II experience depression 53% of the time (approximately 32% in BD-I) [18]. Existing evidence-based psychological interventions for BD generally have the greatest impact on depressive symptoms [19]; indeed, current National Institute for Health and Care Excellence treatment guidelines for people in the depressive phase of BD recommend offering evidence-based psychological treatments for unipolar depression [20]. The importance of psychological intervention for targeting depressive symptoms of BD is particularly germane to BD-II, given its predominant and impairing syndromal and subsyndromal depression. There is growing recognition that the salience of psychotherapies for this underserved group may improve if modified specifically for BD-II [21-26] and that self-management can complement therapist-delivered interventions for BD [27-29]. Self-management is increasingly seen as a cornerstone of effective treatment, empowering individuals to play an active role in managing their condition and improving their quality of life [30,31]. Digital mental health platforms can improve access to these empowering activities [28].

The Role of Technology: Computers Versus Smartphones

The web provides economical access to tailored psychological interventions, and specifically in BD, it can overcome many barriers to accessing psychological assistance, including cost, time, and trust in professionals [31]. Web-based therapies are acceptable to patients with BD [32]. People with BD-II are already proactively seeking information on the web, and the web has untapped potential to provide worldwide access to evidence-based treatment for BD-II. Web-based interventions in mental health have primarily been investigated through websites accessed through computers.

Few studies have focused on the clinical utility of smartphones in people with serious mental illnesses. There is evidence that smartphone technology is perceived by patients as an acceptable, time-unconstrained, user-friendly, and noninvasive tool for mental health self-management [33]. In an investigation of those, aged between 18 and 30 years, with BD, 79% of those not using smartphone apps to manage their condition were interested in trying them, whereas 61% of the self-management strategies provided by these apps were viewed as desirable by the study participants [34].

Smartphones would seem to have particular application in targeting the dynamic, chronic BD-II illness course. Studies using daily smartphone-based self-monitoring have observed more fluctuations and depressive symptoms in BD-II than in BD-I [35]. Smartphone apps can facilitate regular, unobtrusive mood monitoring (through push notifications) to increase awareness of subsyndromal mood fluctuations that may herald an oncoming mood episode but can be extended further to act as a *therapist-in-the-pocket* via delivery of mood-specific coping strategies promoting in-the-moment intervention that is tailored to the individual. The clinical utility of this ecological momentary assessment and intervention (EMA/I) approach has been demonstrated in the treatment of psychotic disorders [36] and as an add-on treatment for those with mild to severe unipolar depression including residual depressive states [37].

A growing number of studies have adopted EMA/I in BD. Hidalgo-Mazzei et al [38] evaluated mood monitoring with the provision of personalized psychoeducation-based prompts via a smartphone app (SIMPLE), demonstrating feasibility and acceptability in patients with BD as an adjunct to usual clinical care [38]. A similar app developed for BD (PRISM), augmenting brief (face-to-face) psychoeducation treatment, demonstrated feasibility, high levels of acceptability and satisfaction, and high retention rates (93% at 12 weeks) in a randomized single-blind controlled trial with 82 participants with BD (10/82, 12% BD-II). A significant effect on depressive symptom severity was found, favoring PRISM over active control [39]. Although promising, critical consideration and further clarification of the role of EMA/I in BD are required, with negative study findings in relation to reduction of depressive symptoms reported in one study (MONARCA I) [40]. Two key limitations of research to date are notable. First, studies have been weighted to BD-I samples. Therefore, the utility of EMA/I for BD-II requires investigation. Second, EMA/I prompts primarily focus on psychoeducational content within a symptom-focused relapse

prevention framework. We previously argued that such frameworks may be demoralizing for some individuals with BD, particularly those who have experienced multiple episodes [32]. A recovery-oriented approach recognizing the unavailability of suffering, emphasizing the redefinition of life goals, and prioritizing other outcomes (eg, quality of life and functioning) may be more beneficial for BD [41,42]. These priorities are consistent with mindfulness-based interventions (MBIs), which elevate mindful awareness of present experience and a nonjudgmental stance toward that experience. As reviewed previously, MBIs hold particular promise for BD [43], with preliminary evidence supporting their benefits for depression, anxiety, and mood regulation in BD [44]. Mindfulness-based EMA/I approaches have not been tested for BD and have a strong potential utility for BD-II.

This Study

This study aimed to evaluate a mindfulness-based digital intervention for BD-II, delivered via a novel integrated web and smartphone platform. The objective was to assess the feasibility, acceptability, and clinical utility of the intervention. Building on our prior research into web-based psychological interventions for BD [32,41,45], a low-intensity, web-based self-help program with a companion smartphone app was developed to improve depression and related outcomes in those with BD-II: the Targeted Recovery-oriented Intervention for Bipolar II Experiences (TRIBE). We hypothesized that the intervention would reduce depression, hypomania, and anxiety severity and improve quality of life, emotion regulation, and mindfulness. The rationale for the hybrid intervention emerged from device-sensitive thinking in digital health. We postulated that an optimal digital platform for the marked symptom variation in BD-II would use the complementary strengths of computer or websites and smartphone or app devices. Computer devices are preferred for more extensive engagement with information (viewing videos, writing, undertaking reflective exercises as in traditional eTherapies), whereas apps can prompt monitoring and new behaviors in everyday life [46].

Evaluation was conducted through an open pilot trial of a prototype version of the intervention and took 3 forms. First, feasibility and acceptability were assessed using quantitative and qualitative self-reports. Second, individual differences in engagement with various features and pathways of the intervention were explored using an analysis of behavioral archetypes [47]. Finally, a preliminary investigation of clinical utility was conducted by exploring intervention-related changes in clinician-rated depression scores (primary outcome) and hypomania, anxiety, mindfulness, and emotion regulation (secondary outcomes).

Methods

Study Design

The intervention was tested using a pretest-posttest open trial design with a nested qualitative evaluation. Feasibility and acceptability were assessed via (1) retention to the study (including baseline, intervention, and follow-up) and reasons for ineligibility or withdrawal, (2) level of adherence to the intervention, and (3) detailed participant feedback exploring

the experience of and satisfaction with the intervention. To justify and guide the design of a later larger-scale evaluation, the most appropriate primary outcome measures were explored, informed by preliminary efficacy data and effect size estimates.

Ethics Approval

This study was approved by the Swinburne Human Research Ethics Committee (SHR 2018/324).

Procedure

To demonstrate international scalability, participants were recruited worldwide via three sources: (1) research participants from bipolar-specific studies (with international participants) conducted by Swinburne University of Technology who agreed to be contacted for future research, (2) contacts associated with a local community group (Bipolar Life), and (3) social media (Facebook and Twitter).

Inclusion and exclusion criteria were minimally restrictive to maximize generalizability of results. Inclusion criteria were as follows: (1) aged 18 to 65 years; (2) diagnosed with BD-II by a medical practitioner; (3) confirmation of the Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition diagnosis of BD-II as assessed by telephone interview with the Mini International Neuropsychiatric Interview (MINI) [48]; (4) ready daily access to the internet and a smartphone and adequate literacy with both technologies; (5) sufficient understanding of written and spoken English to provide consent, engage with interviews, and use the intervention; and (6) under the care of a nominated medical practitioner (at least one contact within the past 12 months) and able to provide contact details. Exclusion criteria were as follows: (1) Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition diagnosis of BD-I, schizoaffective disorder, or schizophrenia (assessed by MINI); (2) experiencing a current acute episode of depression or hypomania or being in a current psychotic episode (assessed by MINI); and (3) experiencing current acute suicidality, assessed using the Columbia Suicide Severity Rating Scale [49].

Individuals interested in participating were invited to the study website to register their details (including those of their medical health professional) and provide informed consent. The participants were then contacted by the research team to complete baseline phone interviews to determine eligibility. Eligible participants then completed a battery of web-based self-report measures and were provided with instructions on how to use the app via email and an access code for the study website. Following the 3-week intervention, participants were invited to complete the postintervention assessment, including a phone interview, self-report measures, and an optional 20- to 30-minute qualitative feedback phone interview. Participants were reimbursed for each assessment (US \$25) and an additional US \$25 for participation in the qualitative feedback interview.

Risk management procedures were followed according to a protocol developed as part of a prior randomized controlled trial testing the effectiveness of a web-based psychological intervention for BD [32]. As an adjunct to usual clinical care, participants were advised that the intervention would not provide emergency support (ie, website and app not monitored in real time) and as part of the inclusion criteria, were required to

consent to the research team contacting their medical practitioner as required.

Intervention

Overview

The overarching rationale for TRIBE’s integration of the 2 technologies was that a well-designed hybrid intervention might generate synergistic benefits for BD-II. Specifically, it was conjectured that smartphone-mediated intervention could help people moderate symptoms of depression and hypomania (real-time intervention *augments* coping) and support real-world generalization of skills, extending the reach of the web-delivered therapeutic content (real-time intervention *supports development* of new coping skills) through an EMA/I approach. We postulated that the combination of learning (so-called *offline cognition* [50], optimally delivered through a structured program of web-based materials) and doing (*online cognition*, optimally delivered through a smartphone app) and crosstalk between the 2 technologies would create a novel digital ecosystem with benefits for self-management of BD.

Next we describe the intervention’s 2 technologies separately (web-based program and smartphone app) before describing their integration in the hybrid platform.

Web-Based Program

TRIBE includes a 3-week web-based intervention fostering the development of mindfulness skills, adapted from an earlier standalone web intervention designed to improve quality of life in those with any of the BDs [32,41]. The program is entirely self-guided, wherein participants complete modules at their own pace and can return to previous modules over the course of 3 weeks. The program consists of 3 modules, as illustrated in Figure 1.

In the iteration tested here, participants were encouraged to complete one module per week over the 3-week intervention period. To help build mindfulness skills, daily practice was recommended with a suggested homework exercise provided at the end of each module. A range of optional mindfulness exercises was offered to cater to participants with differing levels of mindfulness experience. Detailed descriptions of persuasive system design features and content based on a related intervention can be found in the studies by Fletcher et al [32,45].

Figure 1. Content of the web-based program. TRIBE: Tailored Recovery-oriented Intervention for Bipolar II Experiences.

Module 2: Mindfulness in Daily Life 	Module 1 review Other ways to be mindful Moving forward with mindfulness Working with difficult experiences Module 2 plan with recommended practice and optional extras
Module 3: Advanced Mindfulness 	Module 2 review Navigating depression Navigating hypomania Mindfulness and bipolar disorder Module 3 plan with recommended practice and optional extras

Smartphone App

Owing to time and financial constraints, a pre-existing smartphone app was configured for use in this pilot test of TRIBE. MoodPrism (available for iOS and Android) was designed for mood tracking and monitoring emotional states in real time within everyday contexts [51,52]. MoodPrism is derived from research into EMA/I [53]. Here, MoodPrism also functioned to direct participants to, and remind them of, the programmatic content they were concurrently being offered through the web-based program.

Rationale and Design of an Integrated Website-App Ecosystem

The digital design translation of this rationale was as follows. To encourage real-world application of mindfulness skills learned from the web-based program, the MoodPrism app was configured to send twice-daily notifications (at random times, during a specified minimum 12-hour time window selected by the user) to prompt a mood *check-in* to capture real-time assessments of emotional well-being, event-related experiences, and user context. Mood check-ins comprised 4 items on depression and anxiety (drawn from the 4-item Patient Health Questionnaire), 3 items on emotional state (positive and negative affect, arousal, and control) based on the Circumplex Model of Emotion [54], and 5 items on positive functioning (social

connection, motivation, life meaning, self-esteem, and sense of achievement). Users were then asked if a notable event had occurred since the last check-in (with example event categories provided [51]) and to rate the event’s affective strength (from unpleasant to pleasant). The context (social, environmental, and behavioral) was assessed using single items. Following a mood check-in, participants were provided with a description of their current mood state (eg, *your mood check-in suggests you are feeling excited*) and in what context.

Critically, for integration of the 2 technologies, the MoodPrism app included the capability for participants to click on a hyperlink that redirected them to the web-based program (this

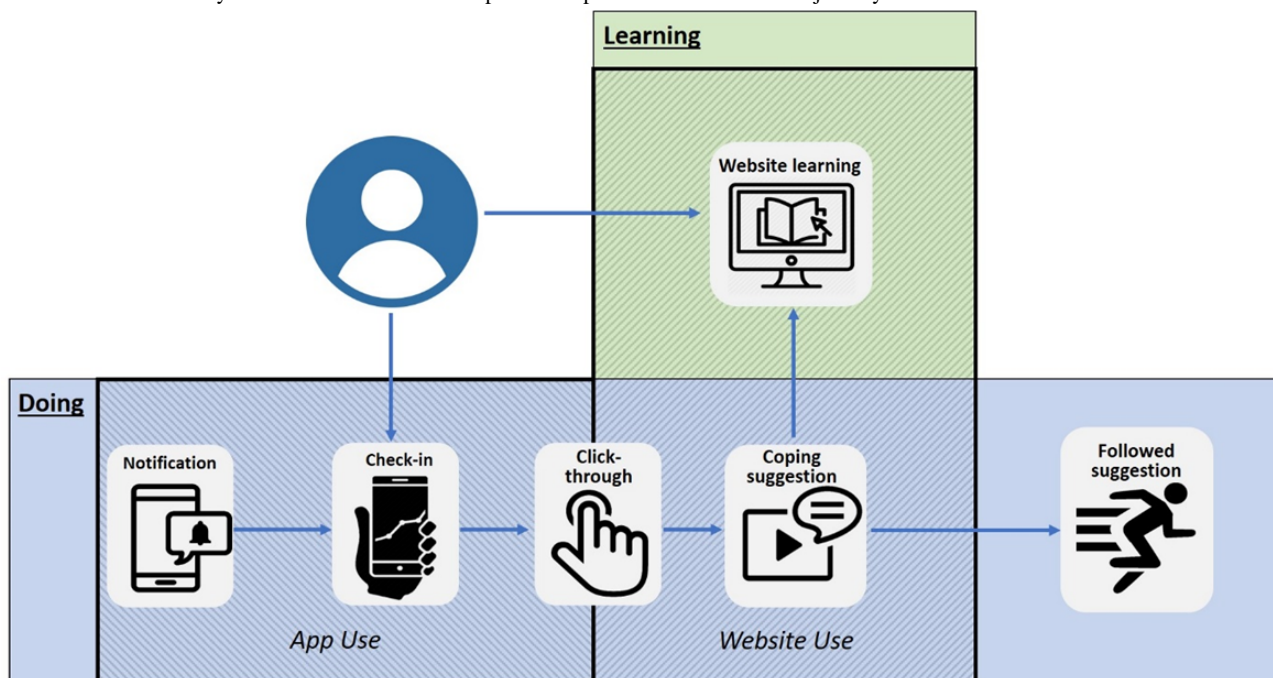

step required log-in to the website) to receive a specific coping suggestion (Table 1 provides coping suggestion examples) based on their current mood state. Two types of coping suggestions were provided for each mood state, *Try it now* suggestions, which were actions to do in the moment, and *Learn more* suggestions, which were a way of re-engaging users with web-based content (eg, redirection to a mindfulness exercise learned within the context of a specific module), to consolidate knowledge and application in daily life.

The anticipated ideal user interactive path model [55], ideal user flow, and ideal user journey map for the use of TRIBE elements is shown in Figure 2.

Table 1. Coping suggestion examples.

Mood state	Coping suggestion
Exhausted or drained	“Go for a brief walk (up to 10 minutes or longer if you wish). As you are walking, consciously notice and acknowledge as many pleasant things as possible: smiling strangers, birds chirping, the feeling of the sun on your skin (or interesting cloud formations), a cat walking across the stress, flowers, etc. Focus on those as much as possible. Notice how you feel after your walk.”
Anxious or on edge	“Find a relaxing song, plug in some headphones, and take a quick listening break. Pay attention to each of the sounds you hear in the song. When you notice thoughts come into your mind, bring yourself back to sounds in the song (instruments, voice, beat). Music has powerful emotional effects—relaxing music can help you feel calmer.”
In balance	“Do a fake yawn (this will trigger a real yawn). Say ‘ahh’ as you exhale. Notice how a yawn interrupts thoughts and feelings and brings you into the present moment. Then, stretch very slowly for at least 10 seconds. Notice any tightness in your body. Bring your arms down by your sides and roll your shoulders backwards slowly, then forwards, noticing what this feels like. End with another yawn. Take a few moments to notice how you feel.”
Excited or energized	“If you’re feeling a bit excited or wired, it might be time to bring things back into balance. Try this simple breathing exercise to slow things down. Take 10 slow breaths—on each in-breath pause and hold for a few seconds, then release. Notice your belly rise and fall as you breathe. Count each breath up to 10. If you lose count, start again.”

Figure 2. Tailored Recovery-oriented Intervention for Bipolar II Experiences ideal user flow journey.

Measures

Clinician- and self-reported measures (conducted over the telephone and on the web, respectively) were administered at

baseline and at the 3-week follow-up (immediately after the intervention).

Clinician-Rated Depression

The Montgomery-Asberg Depression Rating Scale (MADRS) [56] is a widely used, valid, and reliable 10-item clinician-administered scale for depression symptoms that is sensitive to change. Higher scores indicate more severe depression. Although the MADRS contains an item (*apparent sadness*) based on visual observation, prior studies have demonstrated that the full MADRS, including this item, can be administered reliably via telephone [57,58].

Self-rated Depression

The 16-item Quick Inventory of Depressive Symptomatology-Self-Report [59] is a self-report measure of depression symptoms with high internal consistency (Cronbach $\alpha=.87$) that correlates strongly with established clinician-rated scales including the Hamilton Depression Rating Scale ($r=0.86$) [59]. Higher scores indicate more severe depression.

Hypomania

The Young Mania Rating Scale (YMRS) [60] is an 11-item clinician-administered scale that assesses the symptoms of hypomania and mania. This scale has well-established reliability and validity [60,61]. Higher scores indicate more severe mania. The Altman Self-Rating Mania Scale [62] is a 5-item self-reported measure of hypomanic and manic symptoms. Individuals are asked to choose a statement out of 5 for each item that best describes how they have been feeling over the past week. Scores >5 indicate hypomania or mania, with higher scores representing higher severity. The measure has shown good test-retest reliability ($r=0.86-0.89$) and appropriate concurrent validity, supported by correlations with interviewer-rated scales (eg, YMRS) [62].

Anxiety

The Depression Anxiety Stress Scale (DASS)-21 items [63] is a valid and reliable self-report measure of symptoms experienced over the previous week. The DASS-Anxiety subscale score was used in this study, measuring anxiety symptoms including physiological arousal and fear-based emotions. High internal consistency (Cronbach $\alpha=.87$) has been reported for this subscale [64]. Higher scores indicate more severe anxiety.

Quality of Life

Subjective quality of life was measured using the self-report Brief Quality of Life in Bipolar Disorder (QoL.BD) scale [65]. Satisfaction with functioning is rated on a 5-point Likert scale, with higher scores representing greater satisfaction. The QoL.BD has adequate internal reliability (Cronbach $\alpha=.87$) and appropriate test-retest reliability and is comparable with similar measures [65].

Emotion Regulation

The self-reported Difficulties in Emotion Regulation Scale-16-item short-form (DERS-16) [66] measures 6 facets of emotion regulation. The DERS-16 asks individuals to rate the extent to which 16 statements apply to them on a 5-point Likert scale, with lower scores representing higher levels of emotion regulation. The DERS-16 demonstrates adequate internal

consistency (Cronbach $\alpha=.92$), test-retest reliability ($r=0.85$; $P<.001$), and good construct validity, as evidenced by correlations with other measures of emotion regulation [66]. The total DERS-16 score was used in this study.

Mindfulness

Mindfulness skills were assessed using the widely used Five-Facet Mindfulness Questionnaire (FFMQ) [67], a 39-item measure capturing 5 facets of mindfulness: observing (realizing internal and external experiences such as sensations, emotions, and thoughts), acting with awareness (focusing on one's activities in the moment as opposed to behaving mechanically), describing (labeling internal experiences with words), nonjudging of inner experience (taking a nonevaluative stance toward thoughts and feelings), and nonreactivity to inner experience (allowing the free flow of thoughts and emotions without getting caught up in by them or without rejecting them). Individuals rate each item using a 5-point Likert scale to indicate how true they believe the statement describes them; higher scores represent higher levels of mindfulness. Internal consistency of the FFMQ is shown to be good (Cronbach α between .67 and .93), and construct validity has been evidenced by correlations with meditation experience [67]. Total and subscale scores were used in this study.

Feasibility and Acceptability

Feasibility was assessed using study attrition rates, website, and smartphone use data. Acceptability was explored via a satisfaction and feedback questionnaire administered to the participants upon completion of the program. The questionnaire consisted of a mixture of scaling and open-ended questions, and feedback was sought regarding content, usefulness, overall impressions, negative effects, user-friendliness, and tolerance. Detailed information about user experience of the app was collected via optional qualitative feedback phone interviews.

Analytical Approach

Feasibility and acceptability were characterized using descriptive statistics derived from website and app use data. Evaluation of acceptability also considered descriptive statistics of participants' responses to the web-based satisfaction and feedback questionnaire and qualitative analysis (deductive coding based on research aims) of the feedback interview. To explicate TRIBE's central innovation of integrated use across app and web technologies, we used a behavioral archetype approach to describe the salient patterns of intervention use across the sample [47]. Behavioral archetypes were informed by objective log data on web and app activities and self-reports of use from interview data, primarily exploring the contextual factors and motivations for behavior. We expected that each participant would use the intervention elements in different ways, for example some using only the check-ins, others using the app and website quite separately, and so on, and the behavioral archetype approach was used to understand and characterize these differences in motivations and behaviors.

Finally, paired samples 2-tailed *t* tests were used to test for differences between baseline and postintervention clinical outcomes (symptoms, recovery-oriented outcomes, or process outcomes), where distributions were nonnormal, and the

nonparametric alternative (Wilcoxon signed-rank test) was undertaken. Effect size was measured using Cohen d (parametric) or r (nonparametric).

Results

Overview

After describing the sample, 3 major types of findings are presented as follows. First, usability and feasibility feedback are presented for app and website use separately. Within each domain, we present self-reported quantitative findings as well as relevant qualitative findings including illustrative quotes. Information about any technical difficulties encountered by participants was also presented by domain. Second, integrated use of the app and website (recognizing individual differences in use) was characterized via the behavioral archetype approach. Data on overall engagement with and safety of the integrated

intervention are also presented in this section. Finally, the pre- and postfindings related to the provisional efficacy of TRIBE are presented.

Participants

A total of 56 participants registered for TRIBE and completed informed consent procedures. Of these, 33 (59%) participants responded to the initial email from assessors and were screened for inclusion in the study. Of these, 5 (15%) were excluded on the basis of an MINI diagnosis of BD-I, 1 (3%) participant withdrew partway through the study for reasons unrelated to the research, 1 (3%) participant was lost to follow-up, and 1 (3%) participant was excluded from analyses because of using an incorrect version of the smartphone app. The final sample comprised 25 (76%) participants with BD-II (19/25, 76% female participants), mean age 42.3 (SD 11.5; range 24-59) years. Participant characteristics are reported in [Table 2](#).

Website Use and Feedback

The vast majority (23/25, 92%) of participants used the website during the 3-week intervention. The average number of sessions on the website was 9.3 (SD 8.0; range 0-32). Of these sessions,

- 63% were *Learning Only* sessions, where participants visited the website independent of the app to work through the learning materials;
- 27% were *Coping Only* sessions, where participants visited the website via the app and only accessed the coping suggestion during the session; and
- 10% were *Coping and Learning* sessions, where participants visited the website via the app, accessed the coping suggestion, and accessed learning materials.

Participants used the website for an average of 6.6 (SD 4.9; range 0-15) days and completed an average of 47% of the module content (SD 37.0; range 0-100). Participants reported that barriers to website use included time commitment required for learning, previous familiarity with content, and a current lack of symptoms. However, most participants (19/25, 76%) reported that the amount of content on the website was “about right for me” and (18/25, 72%) reported that it helped them develop new skills for managing their BD.

App Use and Feedback

All 25 participants successfully downloaded the MoodPrism app on their phones and completed at least one check-in on the app. A maximum of 42 notifications to complete check-ins were sent to each participant (2 notifications each day for a total of

21 days); however, some participants did not receive all notifications because of technical difficulties. An average of 18 check-ins (SD 10.5; range 3-42) were completed, giving a check-in response rate of 42.9%. The average number of days participants completed check-ins across the study period was 12.4 (SD 5.6; range 3-21). Time to complete check-in items ranged from 1 to 3 minutes.

Notification-prompted mood check-ins were found to be useful by most participants (18/25, 72%), with regular mood and context ratings being reported as an “instant reminder to think about your mood” (male, aged 54 years), “[keeping] you in tune with how you are feeling” (female, aged 56 years), and being an opportunity to “just be a bit more mindful of what I was doing or be more mindful about my thoughts and feelings” (male, aged 47 years). Most participants (20/25, 80%) indicated that 2 mood check-ins per day was “about right” (with 4/25, 16% indicating they wanted more) and liked the random delivery of prompts (20/25, 80%). In terms of the mood check-in questions themselves, 84% (21/25) indicated the number of questions was “about right,” 68% (17/25) reported the questions were *completely* or *mostly* relevant, and around one-third (12/25, 48%) of participants indicated they would have liked the option to set their own check-in questions. The majority (18/25, 72%) found the mood descriptions provided by the app helpful. In addition to technical difficulties, the main barrier to completing mood check-ins when notified was because of being busy at the time (17/25, 68%). However, some participants noted that the notification itself provided an opportunity to practice mindfulness even if they were not in a position to complete the check-in at the time the notification arrived. All participants (100%) indicated that they would have liked the option to use the app outside of the prompted times.

A total of 18 out of 25 (72%) participants clicked on at least one of the links provided at the end of the check-in process to access tailored coping suggestions on the website. However, technical difficulties prevented one of these participants from accessing the website. Across the whole sample, an average of 5 links were clicked in the app across the study period (SD 7.1; range 0-24), giving a click-through from a check-in rate of 27.8%. However, in this prototype version of TRIBE, accessing the coping suggestions on the website via this process required a step of logging into the website through the app; the rate of completed click-throughs from app to website was 87.2%.

Participants indicated that barriers to clicking through to the website to receive the coping suggestion included being unaware of the process of accessing the links (required clicking on the calendar presented in MoodPrism after completion of check-in), having to log into the website as part of the click-through process, being busy or not in the right environment to access or complete the suggestion, and illness-related factors (eg, did not want to be potentially triggered or felt unneeded).

Of the 2 types of coping suggestions presented after completion of a check-in, 70.6% of click-throughs were for *Try it now* suggestions and 29.4% for *Learn More* suggestions. Of the total number of website sessions that resulted from click-throughs, 26.4% incorporated additional website learning after accessing coping suggestions. Of the 17 participants who completed click-throughs to receive coping suggestions from the website, 10 (59%) reported that they followed the coping suggestion provided at least half of the time. Approximately 84% (21/25) of participants indicated that coping suggestions were useful, with participants reporting coping tips to help them bring mindfulness skills into their everyday life as well as being “helpful in helping me regain control when my anxiety levels were extremely high.” (female, aged 27 years) and “very on-point for the mood or feeling I was experiencing at the time.” (female, aged 47 years). However, only 44% (11/25) thought that the suggestions helped them “in the moment.”

A number of app-specific technical issues were observed during the study, with 76% (19/25) of the participants reporting technical difficulties during the study period and 28% (7/25) participants reporting some type of technical issue for >70% of the study period. The technical issues observed included device-related issues (eg, notification blocking setting on Android phones), app-related issues (eg, unavailability of check-in surveys when notifications were sent), and user-related issues (eg, lack of understanding of how to access coping prompts in apps) leading to potential reductions in the completion of check-ins and click-throughs. Participants were contacted regularly throughout the study to identify technical difficulties and assist in troubleshooting issues that were detected by the research staff during the study period.

A summary of the integrated use of TRIBE elements according to the ideal user interactive path model is presented in [Figure 3](#).

Figure 3. Summary of observed frequency of steps in ideal user flow journey.

Behavioral Archetypes

Individual differences in engagement patterns were classified into 5 provisional archetypes: *structured learning*, *opportunistic*

learning, *acting now*, *postponing coping*, and *tracking*. These archetypes are shown in Figure 4 and defined in Table 3. Illustrative quotes from participant feedback are provided to enrich the behavioral archetype descriptions.

Figure 4. Illustrative use pathways.

Table 3. Identified behavioral archetypes.

Behavioral archetype	Description	Illustrative quotes
Structured learning	<ul style="list-style-type: none"> Participants who engaged in structured learning chose to access TRIBE^a website content consistently at the same times of the day and followed the course in a linear manner. Structured learning often occurred when participants were routinely constrained by time demands or were motivated to engage in the TRIBE intervention at the same time of the day to fit it in to their lives. Engaging in frequent structured learning across the study (eg, doing small chunks of content daily or every couple of days) was also linked to postponing. A subset of structured learners “top and tailed” their learning. These users completed the TRIBE website learning in single large sessions at the start and end of the intervention period. These users also engaged in the content in a linear way. Learning by top and tailing was linked to acting. 	<ul style="list-style-type: none"> “I would tend to go on the website and do one module all at once and then come back a few days later and do the next one.” “I had quite a bad sort of manic phase where I was having kind of hallucinations and stuff like that, so I needed to not do it. So, I just didn’t do it for a while and then I filled in stuff on the website quite late on.” “I went on the website like every single day... It was usually when it’s decided I was sitting down. Okay, well let’s check my phone now. So it was a convenient time for me...”
Opportunistic learning	<ul style="list-style-type: none"> Participants who engaged in opportunistic learning chose to access the TRIBE website in an ad hoc manner. While completing the course in a linear way, participants did their learning components in smaller chunks across the day, when it suited them. This style of learning may have been prompted by a coping suggestion—where after viewing coping content, further opportunistic learning took place on the website by returning to the course content. Opportunistic learning had a strong link with acting. 	<ul style="list-style-type: none"> “So you would check-in and then you would do whatever mindfulness thing it told you to do, and then you would be right there and you could learn...You could learn the stuff then, right then and there, rather than being like, ‘Oh, check-in. Okay.’ Three hours later, let’s learn about how you can manage these things and let’s learn about mindfulness. But rather, it was right then and there.”
Acting now	<ul style="list-style-type: none"> Acting encompassed the behavior of participants who completed both the mood check-ins and the coping prompts when they were provided. These participants were often motivated to “do something now” to alter how they were feeling. Participants who engaged in acting now sometimes transitioned into tracking behavior only. 	<ul style="list-style-type: none"> “I found just the procedure of stopping and asking, ‘Okay what kind of mood am I in? How am I feeling?’ It really increased my awareness, made me stop and think okay what is going on and then I liked the fact that it encouraged me then to move on and try mindfulness practice...I would just be a bit more mindful of what I was doing or be more mindful about my thoughts and feelings.”
Postponing action	<ul style="list-style-type: none"> Postponing encompassed the behavior of participants who completed both the mood check-ins and the coping prompts, but at a later time than when it was provided by push notification. Postponing was often motivated by time or environmental context demands. Participants also postponed engagement with their coping prompt so that it aligned with their regular structured learning time. This included bookmarking behavior, where participants used previous coping prompts to access tailored content that was relevant to them at the time they chose to engage with the intervention. 	<ul style="list-style-type: none"> “...if you’re going about your day, you know if you’re at work or if you’re on your way to somewhere you don’t necessarily have time to do a meditation right then and there, you know.” “I clicked on the ones that looked more interesting to me first, but I always went back and did the others as well eventually. So, the ones that seemed more relevant, I did them first.”
Tracking	<ul style="list-style-type: none"> Tracking behavior only involved use of the mood check-ins. Participants who were tracking often did so at the time it was prompted. Tracking behavior was motivated by wanting to check-in with mood but not wanting to engage with other parts of the intervention. Participants often transitioned between tracking and acting. Some participants who used structured learning only used the app intervention component for tracking. 	<ul style="list-style-type: none"> “Just sort of checking in with my mood did help so I felt like I didn’t need any extra help [from the website].”

^aTRIBE: Tailored Recovery-oriented Intervention for Bipolar II Experiences.

Feedback on the Integration of 2 Technologies

Feedback from participants is presented in [Table 4](#). Although participants chose to use the elements offered to them in different ways, a combination of apps and websites made sense to most participants, and the majority also found the app to be a useful companion to the website. Approximately half of the participants (13/25, 52%) thought that the app helped them learn

skills from the website and that the website and app were well integrated. Most participants (20/25, 80%) felt that the integrated TRIBE package helped them feel more hopeful and better manage their BD, with participants reporting that the program “made me think there’s more I can do about how to feel better and improve and keep your mood stable and be more resilient to things” (female, aged 27 years). In addition, most (23/25, 90%) participants would recommend it to others with BD.

Table 4. Satisfaction and acceptability ratings of Tailored Recovery-oriented Intervention for Bipolar II Experiences (TRIBE; N=25).

	Strongly agree, n (%)	Agree, n (%)	Neutral, n (%)	Disagree, n (%)	Strongly disagree, n (%)
The website was well integrated with the app	8 (32)	6 (24)	8 (32)	1 (4)	2 (8)
The app was a useful companion to the website	10 (40)	9 (36)	5 (20)	1 (4)	0 (0)
The combination of a website and an app made sense to me	12 (48)	8 (32)	2 (8)	3 (12)	0 (0)
The app helped me learn the skills from the website	7 (28)	6 (24)	8 (32)	4 (16)	0 (0)
TRIBE helped me manage my bipolar disorder better	6 (24)	11 (44)	6 (24)	2 (8)	0 (0)
TRIBE helped me feel more hopeful about living with bipolar disorder	8 (32)	12 (48)	3 (12)	2 (8)	0 (0)
I would recommend TRIBE to other people with bipolar disorder	13 (52)	10 (40)	2 (8)	0 (0)	0 (0)

Engagement With the Intervention as an Integrated Whole

All participants engaged in at least one element of the TRIBE process, with participants engaging on average approximately 14 out of the possible 21 days with at least one element (SD 5.3, range 4-21). Figure 5 shows the number of days that each participant interacted with website and app on the same day, website only, and app only. Approximately half (10.65/21, 51%)

of the number of days participants engaged with the study were using the app only, 41% (8.63/21) with both website and app, and 8% (1.75/21) with website only. The notifications provided by the app may have also contributed to engagement with the website learning materials by acting as a reminder, even if check-ins or click-throughs were not completed, with participants reporting that “the app made me have to be more engaged on a daily basis” (female, aged 52 years).

Figure 5. Participant engagement with Targeted Recovery-Oriented Intervention for Bipolar II Experiences.

Safety

Although most (22/25, 88%) participants did not report any adverse events while completing TRIBE, 3 participants reported a negative impact: one indicated their mood worsened over the course of the study, attributing this in part to personal stressors and medication changes; the other found using the app *a bit stressful* because of technical difficulties; the final participant found that receiving mood check-ins when feeling depressed was confronting, as it made them think about the emotions they were experiencing (but acknowledged that this was most likely to be the time during which the coping strategies would have been useful). A participant withdrew before the follow-up assessment for reasons unrelated to the study.

Preliminary Analysis of Efficacy

Changes in scores from baseline to after the intervention for each measure are shown in Table 5.

Mean MADRS scores decreased significantly by 2.44 points ($t_{24}=2.63$; $P=.02$; Cohen $d=0.53$, 95% CI 0.5-4.36). Median YMRS score increased slightly by 1 point ($z=-1.59$; $P=.11$; $r=0.22$). Self-reported depression (Quick Inventory of Depressive Symptomatology-Self-Report), anxiety (DASS-Anxiety), hypomania (Altman Self-Rating Mania Scale), quality of life (QoL.BD), emotion regulation (DERS-16), and mindfulness (FFMQ) scores did not change significantly after the intervention.

Table 5. Pre- and postintervention scores (N=25).

Measure	Before intervention	After intervention	Difference, 95% CI	<i>t</i> test (<i>df</i>)	Z	P value	Effect size
MADRS ^a , mean (SD)	8.60 (6.86)	6.16 (5.11)	0.52 to 4.36	2.63 (24)	N/A ^b	.02	Cohen <i>d</i> =0.53
YMRS ^{c,d} , median (IQR)	1.00 (4.00)	2.00 (4.00)	N/A	N/A	-1.59	.11	<i>r</i> =0.22
QIDS-SR ^e , mean (SD)	7.92 (4.77)	7.44 (4.22)	-1.15 to 2.11	0.61 (24)	N/A	.55	Cohen <i>d</i> =0.12
DASS-Anx ^f , mean (SD)	4.20 (3.98)	3.96 (3.68)	-0.76 to 1.24	0.50 (24)	N/A	.63	Cohen <i>d</i> =0.10
ASRM ^{c,g} , median (IQR)	1.00 (4.00)	1.00 (3.50)	N/A	N/A	-0.38	.70	<i>r</i> =0.05
QoL.BD ^h scale, mean (SD)	37.64 (8.78)	39.04 (7.17)	-4.61 to 1.81	-0.90 (24)	N/A	.38	Cohen <i>d</i> =0.18
DEERS-16 ^{c,i} , median (IQR)	37.00 (26.00)	34.00 (18.50)	N/A	N/A	-1.68	.09	<i>r</i> =0.23
FFMQ ^{c,j} , median (IQR)	113.00 (40.00)	121.00 (37.50)	N/A	N/A	-1.81	.07	<i>r</i> =0.26

Discussion

Principal Findings

This study had several strengths. To our knowledge, this is the first study to test the specific utility of a technology-mediated intervention that integrates EMA/I with web-based learning modules for BD-II. The intervention content was novel, with mindfulness-based approaches specifically tailored for this population. The mixed method approach, a pretest-posttest open trial design with nested qualitative evaluation, provided rich insights into user behavior and engagement. Finally, ecological validity was maximized, with participants using their own devices in an entirely self-guided context, approximating real-world use of publicly available mental health apps.

Overall, the study results indicated that the approach is feasible and acceptable for those with BD-II. Preliminary investigation of efficacy was also encouraging. Exploration of the patterns of engagement across the 2 technologies and across time using a behavioral archetype approach generated useful insights for refinement of the platform. The pilot study was conducted *in the wild* and discussion of findings next also includes methodological insights from testing a prototype digital intervention in the full complexity of real-world application.

Use

Adherence to daily mood check-ins was high (65.6%). Variable adherence rates have been reported in other studies adopting smartphone self-monitoring in BD, albeit over different study timeframes. For example, 55.7% adherence was reported over a 12-month period in one study [68]; in a shorter (12-week) study, adherence was 42.1% [69]; in the MONARCA II trial,

adherence rates were higher (72.6%) over 9 months [70]; whereas Hidalgo-Mazzei et al [38] reported the highest rate (88%) over 3 months. Sustained user engagement is a challenge, with app use decreasing over time in other nonrandomized studies adopting ecological momentary assessment (EMA) in BD populations [38,71].

High rates of synergistic use of the app and website support the addition of EMA/I to web-based intervention in this population, with most (23/25, 92%) participants using both components on the same day and more than half (17/25, 68%) within 1 hour of each other (ie, app-prompted click-throughs to website or website triggering app use). In all, 2 (8%) participants used the app frequently but did not use the website at all during the 21-day study period. It is likely that this was because of user preference, as research suggests that individuals want a variety of functions, design elements, and self-management strategies in an app for BD, of which they can make a selection according to their personal needs [72]. Although study retention rates were high compared with other studies adopting similar app-based interventions in BD (eg, 30% at the 6-month follow-up reported by Hidalgo-Mazzei et al [73]), this may be attributable in part to the brevity of TRIBE (3 weeks).

Acceptability

Turning to participant feedback, most participants (17/25, 68%) experienced the TRIBE intervention positively, viewing it as being helpful in managing their BD-II. Encouragingly, 80% (20/25) of participants felt more hopeful about living well with BD-II because of TRIBE, and all indicated they would recommend the program to others with BD. App features, including notification-prompted mood check-ins and coping suggestions, were rated by most (21/25, 84%) participants as

useful, with some suggesting that certain features (eg, mood check-in questions) should be customizable. Flexibility and the ability to customize self-management apps for BD have been highlighted as important features by end users in other studies [74,75]. Participants indicated that they would have liked the option to use the app outside of the twice-daily prompted times, indicating a high level of engagement. These results support a user-centered approach in designing digital mental health interventions: design elements should be tailored to user needs, which may in turn promote engagement [76,77].

Qualitative data indicate that participants liked TRIBE for many reasons, including that the app notification prompts and mood check-ins lead to being more mindful, slowing their thoughts and feelings, and grounding them. Self-monitoring features within apps can increase emotional self-awareness (ie, the ability to identify and understand one's own emotions) [78], which in turn has been shown to improve coping skills and reduce symptoms of mental illness [51,79-81]. Most participants in this study indicated that the app facilitated increased awareness of mood fluctuations, which subsequently provided space between themselves and their feelings and allowed for implementation of a coping strategy. Participants felt that this process fostered a sense of empowerment and agency in managing their moods, which is in line with previous studies that found that the perceived control of coping with prodromal symptoms and alternating mood is a key empowering element in the self-management of BD [30].

Participants appreciated that the website taught them foundational mindfulness skills and that the app then assisted them in consolidating and applying those skills to daily life. Increased engagement results in increased exposure to the intervention and potentially affects participants' psychological health outcomes [82]. Importantly, the participants felt that the app encouraged them to engage with the website and mindful activities. Participants also described that through continued use of the app alongside the website, they began to implement mindfulness practices and coping suggestions without prompting by the app. This is reassuring given that other studies have found that continued brief weekly practice of mindfulness, following completion of a mindfulness-based intervention, is associated with improvements in depression [83].

Efficacy

In terms of preliminary efficacy, as hypothesized, a significant reduction (with a large effect size) in clinician-rated depression (MADRS score) was observed following the intervention. Depression is the most problematic pole in BD-II, and the study results are therefore highly encouraging and warrant further testing as part of a controlled design. With regard to secondary outcomes, most shifted in expected directions with (nonsignificant) improvements in self-reported depression, hypomania, quality of life, emotion regulation, and mindfulness. Clinician-rated hypomania (YMRS score) increased slightly after the intervention; however, this effect was primarily driven by a participant who experienced increased mood elevation at follow-up. As a low-intensity 3-week intervention, it is plausible that the TRIBE intervention was not long enough to produce shifts in secondary outcomes, with limited time for skill

development and consolidation. Indeed, in terms of building mindfulness skills, the amount and quality of mindfulness practice have been associated with FFMQ score changes [84]. Feedback from participants supports the testing of a longer version of TRIBE to allow adequate time for skill development:

I did not have enough relaxed time to work with the website...I wish the program lasted for a longer period of time. [Male, aged 53 years]

I found the pace of the study a little too fast. Having four weeks to complete the three sections would benefit those whose life is busy. [Female, aged 46 years]

The study results are interpreted with caution given the small sample size and study design (open pilot); nonetheless, there is exciting potential for the utility of EMA/I in those with BD-II, particularly given the higher mood instability for depression in this population and the associated stress, reduced quality of life, and impaired functioning [85]. Early and immediate intervention (facilitated by smartphone technology) may help temporarily avert oncoming psychopathology, empowering individuals with BD to feel more in control of their symptoms [86]. EMA/I has strong potential to support real-world generalization of skills, extending the reach and impact of web-based platforms to optimize care and specifically reducing depression in those with BD-II.

Understanding Use Patterns via Behavioral Archetype Analysis

Behavioral archetype, or persona analysis, aims to characterize different varieties of use to support a more tailored approach to user experience. Here, the integrated web and smartphone platform enabled multiple use patterns across TRIBE's offerings of module-based learning, EMA, and ecological momentary intervention. On the basis of automatically collected real-time use data, these patterns can be described as structured learning (logging on to website modules regularly), opportunistic learning (logging on to modules haphazardly), acting now (engaging with EMA prompts and coping suggestions at the time of the prompt), postponing action (engaging with prompts and coping suggestions when circumstances allowed), and tracking (using EMA only). These styles were not independent, with participants often shifting among use patterns (Figure 4 and Table 3). These analyses will inform the future development of TRIBE, in which a systematic co-design phase will invite end users to view involvement through these multiple archetypes and optimize the user interface to account for these different use cases. The analyses also help clarify that *intended use* of such a complex digital platform is multifaceted, and basic research may be able to identify subpopulations of BD-II who are a better fit for some forms of use over others.

Testing a New Digital Intervention in the Real World

In addition to our aim of establishing proof of concept, this study sought to maximize its ecological validity, generating new insights about investigating prototype digital interventions. To maximize the translational significance of the findings, participants in this study were instructed to use their own device and download and install the app themselves. Furthermore,

mood monitoring was entirely self-guided rather than being reviewed by a mental health professional. This design approximates how the majority of the publicly available mental health apps are used in practice, such as naturalistic and self-guided apps [52].

This *in the wild* study invited technical challenges from a user and hardware and software standpoint. Although instructions were provided on how to download, install, and use the app, user errors compromised use and user experience. Examples of this included downloading an incorrect version of the app and logging in and out of the app, resulting in front-end data loss (ie, participant being unable to view prior days of monitoring), failing to update the app (therefore experiencing *bugs* from older versions), and being unaware of the need to click on the calendar to access the mood description and associated coping suggestion. Hardware challenges included app incompatibility with certain smartphones (eg, Samsung 9s). Finally, software challenges arose in terms of Android versus iOS. For example, check-in notifications may not have been received if the *Do Not Disturb* function was set on an iPhone, whereas the Android priority system may inadvertently block notifications (requiring the user—if the issue was detected—to change settings back to *high priority* to receive notifications from the app). International time zones also present a challenge for this study. A data capture error was detected because of a mismatch between the server time (GMT+10) and the participant's local time. This time zone mismatch also affects the delivery of push notifications. Push notifications were delivered correctly in a user's local time, but access to the app content (mood check-in) was unlocked in the server's time zone. As a result, participants may have received a notification to complete a mood check-in, but it was not available to them until the corresponding time was reached in the server location. Both errors required an app update to be fixed and may have disrupted the user experience for some participants. The trade-off between ecological validity and technical challenges is a key issue to consider in future smartphone-based studies. Positively, technical challenges in this study did not have a significant negative impact on end user experience. Qualitative feedback from participants indicated that they continued to draw value from the app, in particular, appreciating the fact that it reminded them to be mindful:

The very act of stopping and taking a moment to really think through every section of the questions. It really makes you practise mindfulness, and that was helpful. [Female, aged 27 years]

I think sometimes I'd get a reminder and not be able to do it at the time, and I'd come back to fill in the little questions later and I wouldn't be able to...I'd just close the app. I'd try and be mindful of how I was thinking. [Female, aged 24 years]

Participants also saw value in having the app, in addition to and as a companion to the website:

It was the app that was, I feel like, cementing the importance of going to the website. So, I think, if I hadn't had the app going off twice a day, I may have found a reason not to go and do my mindfulness. [Male, aged 54 years]

Limitations

The study's results must be considered in the context of several limitations. As noted by other authors [85], smartphone-based studies may attract participation from individuals who are more technically oriented and motivated to complete their daily assessments. Women were overrepresented, and study participants were highly educated; the latter characteristic may affect the use of and receptivity to health technology [86]. Taken together, the study results may not be generalizable to broader BD populations. As an open pilot study, although reductions in clinician-rated depression were observed—after the intervention, the lack of an alternative intervention or control group to rule out a potential placebo effect disallows any firm conclusions to be drawn about the efficacy of the intervention. Furthermore, concomitant medication and other treatments were not assessed, limiting our ability to differentiate the efficacy of the intervention from that of routine care. The study results will inform further development of TRIBE and testing via randomized controlled trials to establish efficacy.

Future Directions

Despite the proliferation of digital mental health interventions, efficacy studies are lacking. A multitude of smartphone apps for BD, and mental health conditions more broadly, are publicly available and have not been subjected to clinical trials [87]. Of those developed within academic settings, most have been tested in pilot designs with small populations: real-world, naturalistic studies with larger sample sizes are needed to facilitate integration of these interventions into everyday mental health care [76]. Co-design with end users in the population of interest is an essential component to promote sustained and ongoing engagement. Finally, the integration of EMA/I using integrated digital platforms (including the potential for incorporating passive collection of physiological data) is likely to extend the utility of self-management for those with BD-II and other mental health conditions characterized by chronic mood dysregulation.

Conclusions

To our knowledge, this is the first study to test the specific utility of a technology-mediated MBI incorporating an EMA/I for BD-II. Pilot testing suggests that TRIBE is a feasible and acceptable intervention for BD-II, and preliminary efficacy results suggest that it is effective in reducing depression. TRIBE now warrants full development and evaluation as an adjunct to usual clinical care via randomized controlled trial.

Acknowledgments

The authors would like to thank the study participants for their time, lived experience experts for video footage, Jaimi Murray for assistance with recruitment and data collection, the ORBIT research group, Associate Professor Nikki Rickard of MoodPrism Ltd, Spark Digital for MoodPrism configuration, and Media Insights for website development and maintenance.

Abstract

Background: Many men with HIV (MWH) want to have children. HIV viral suppression minimizes sexual HIV transmission risks while allowing for conception and optimization of the health of men, their partners, and their infants.

Objective: This study developed and evaluated the feasibility and acceptability of an intervention to promote serostatus disclosure, antiretroviral therapy (ART) uptake and adherence, and viral suppression among MWH who want to have children in South Africa.

Methods: We developed a safer conception intervention (*Sinikithemba Kwabesilisa* or *We give hope to men*) to promote viral suppression via ART uptake and adherence, HIV serostatus disclosure, and other safer conception strategies for MWH in South Africa. Through 3 counseling and 2 booster sessions over 12 weeks, we offered education on safer conception strategies and aided participants in developing a safer conception plan. We recruited MWH (HIV diagnosis known for >1 month), not yet accessing ART or accessing ART for <3 months, in a stable partnership with an HIV-negative or unknown-serostatus woman, and wanting to have a child in the following year. We conducted an open pilot study to evaluate acceptability based on patient participation and exit interviews and feasibility based on recruitment and retention. In-depth exit interviews were conducted with men to explore intervention acceptability. Questionnaires collected at baseline and exit assessed disclosure outcomes; CD4 and HIV-RNA data were used to evaluate preliminary impacts on clinical outcomes of interest.

Results: Among 31 eligible men, 16 (52%) enrolled in the study with a median age of 29 (range 27-44) years and a median time-since-diagnosis of 7 months (range 1 month to 9 years). All identified as Black South African, with 56% (9/16) reporting secondary school completion and 44% (7/16) reporting full-time employment. Approximately 44% (7/16) of participants reported

an HIV-negative (vs unknown-serostatus) partner. Approximately 88% (14/16) of men completed the 3 primary counseling sessions. In 11 exit interviews, men reported personal satisfaction with session content and structure while also suggesting that they would refer their peers to the program. They also described the perceived effectiveness of the intervention and self-efficacy to benefit. Although significance testing was not conducted, 81% (13/16) of men were taking ART at the exit, and 100% (13/13) of those on ART were virally suppressed at 12 weeks. Of the 16 men, 12 (75%) reported disclosure to pregnancy partners.

Conclusions: These preliminary data suggest that safer conception care is acceptable to men and has the potential to reduce HIV incidence among women and their children while supporting men's health. Approximately half of the men who met the screening eligibility criteria were enrolled. Accordingly, refinement to optimize uptake is needed. Providing safer conception care and peer support at the community level may help reach men.

KEYWORDS

men with HIV; HIV prevention; safer conception; U=U; treatment as prevention; reproductive health; South Africa

Introduction

Worldwide, many men with HIV want to have children [1-5]. For men with HIV who want to father a child with an HIV-negative partner, antiretroviral therapy (ART)-mediated viral suppression effectively eliminates the risk of sexual HIV transmission while improving their health and life span. In South Africa, an estimated 78% of men with HIV know their serostatus, 67% of those who know their status are on ART, and 82% of those men (42% of men with HIV) are virally suppressed [6]. Population cohorts observed large declines in HIV incidence among men in the Test and Treat era in South Africa; however, incidence declines among women lag, largely because of limits in ART uptake and retention of care among men [7,8]. The promise of Test and Treat to reduce individual-level incidence has not yet translated into population-wide benefits [9], and Treatment as Prevention trials only highlight the challenges of reaching, engaging, and retaining men in care [10-13].

Safer conception care is an important strategy for decreasing HIV transmission within the context of intended conception among HIV-serodifferent couples. Counseling and promotion of ART-mediated viral suppression for partners with HIV, pre-exposure prophylaxis (PrEP) for partners without HIV, and education regarding condomless sex timed to peak fertility can dramatically reduce the likelihood of sexual or perinatal transmission of HIV among individuals and couples aiming to conceive [14,15]. However, the reproductive goals of people with HIV, especially men, are not discussed as part of routine clinical care. Men with HIV who want to have children feel stigmatized and are unlikely to ask providers for advice [16,17], and few people with HIV are aware of the opportunities to meet reproductive goals without HIV transmission [18-21].

Worldwide, many decisions around conception and HIV prevention are not equally decided between heterosexual partners, with the determination often made by men [22,23]. Most reproductive health interventions appropriately focus on women; however, providing reproductive health interventions for both men and women is critical to ensuring the health of men with HIV and their families [24]. Therefore, based on

formative work with people living with or exposed to HIV in KwaZulu-Natal, South Africa, we developed a male-focused intervention based on cognitive behavioral therapy (CBT) skills to encourage and support men with HIV who want to have children to adopt safer conception behaviors, including HIV serostatus disclosure and initiation of ART (trial registration: ClinicalTrials.gov NCT03818984). The development of the intervention was described previously [25] and was focused on men as the primary intervention recipient while encouraging the inclusion of female partners to optimize their opportunities for testing, treatment, and prevention in the context of their reproductive goals. This study describes an open pilot intervention consistent with Phase Ib of the Obesity-Related Behavioral Intervention Trials (ORBIT) model for behavioral intervention development [26]. We evaluated the feasibility and acceptability of the *Sinikithemba Kwabesilisa (We give hope to men)* intervention to offer comprehensive safer conception counseling to men with HIV planning to have a child with an HIV-negative or unknown serostatus partner in South Africa. We also explored the impact of the intervention on ART uptake, adherence to ART, viral suppression, and HIV serostatus disclosure to inform proof of concept for clinical impact and future study planning.

Methods

Study Site

Participants were recruited from a collaborative clinic between the AIDS Healthcare Foundation nongovernmental organization and the South Africa Department of Health in Umlazi near Durban, South Africa. Umlazi is a township community 10 miles southwest of the Durban City Center, where HIV prevalence among antenatal clinic attendees is estimated at 42%, and HIV incidence is approximately 6.4 per 100 woman-years [27].

Inclusion and Exclusion Criteria

Eligible men were male-identifying, aged 20 to 45 years, accessing ART for <3 months (including not on ART), and HIV-positive. In the first phase of recruitment, men were eligible if they had known their serostatus for at least 6 months. Due to

recruitment challenges, this criterion was relaxed to knowing their status for at least 1 month. They reported wanting to have a child in the next year with a stable female partner (together for at least 6 months) and that their desired pregnancy partner was HIV-negative or of unknown serostatus and not known to be pregnant. Eligible men had access to a mobile phone and were fluent in either English or isiZulu.

Pregnancy partners of the enrolled men were invited to participate. Eligibility criteria for female partners included age ≥ 18 years, identifying as a woman, and partnering with an enrolled man (using a couples verification screening tool [28]). In addition, as we did not want the study team to inadvertently disclose a male participant's serostatus to their pregnancy partner, eligible female partners reported knowing their male partner's HIV-positive serostatus. Men were recruited independently of their plans or expectations to include their pregnancy partners.

Exclusion criteria for men and women included planning to relocate to a location incompatible with study participation in the next 12 weeks, active drug or alcohol use or active illness requiring treatment within 30 days before study entry that, in the opinion of the research team, could interfere with study participation.

Recruitment

All men at the clinic site (for HIV care, HIV counseling and testing, sexually transmitted infection [STI] testing, and medication collection) were approached. Men were also invited to participate through mobile vans organized by the same clinic site to test for HIV across the clinic catchment area. Those interested in the study were screened for inclusion, and eligible men were invited to provide informed consent to enroll in the study. Men who claimed interest but did not complete the screening at that time because of other commitments or concerns were provided with a study flyer that included information about the study and contacts for the recruitment team. Interested men could also provide their contact details in a locked study box,

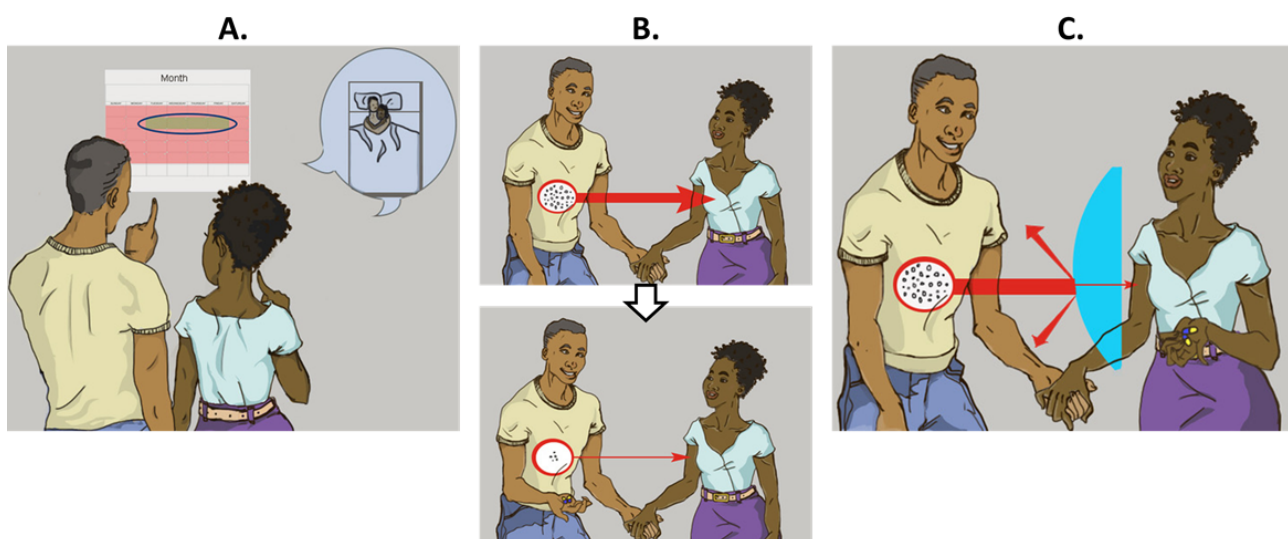

one of which was at the clinic at all times and one of which circulated with the mobile testing unit. The study team contacted potential participants for screening and scheduled appointments for enrollment.

Intervention Content

We conceptualized the design of our intervention based on formative research studies conducted between 2010 and 2015 with men with HIV, women with recent pregnancies with an HIV-serodifferent partner, and providers at public sector clinics in the eThekweni District, South Africa. The process for developing the intervention was described in Khidir et al [25].

As described previously, although men maintain a great degree of relationship power related to decisions about conception, they are less involved in reproductive health care counseling, which results in poor outcomes for both men and women. Thus, our study recruited men as individuals in an attempt to close this gap. We aimed to promote safer conception strategies, development of a safer conception plan, planning and problem solving around plan execution, and communication and HIV serostatus disclosure training for a broad population of men with HIV, including those who might not yet be in a mutually disclosed partnership. On the basis of our findings that men with HIV have limited knowledge of HIV serodifference and safer conception strategies, the intervention provided comprehensive safer conception education based on safer conception strategies recommended by international and national guidelines, including (1) Couples HIV Counseling and Testing (CHCT) and other strategies for serostatus disclosure, (2) initiation of ART and delaying condomless sex until achieving viral load suppression (Treatment as Prevention), (3) timing condomless sex to peak fertility, (4) treatment of STIs, (5) sperm washing and in vitro fertilization, and (6) adoption. HIV PrEP was not yet available in or recommended as part of safer conception care in South Africa at the time this study was conducted. We developed a counseling tool that integrates relevant illustrations to simplify and explain key medical concepts (Figure 1) [16].

Figure 1. Locally relevant images used to present key safer conception strategies such as (A) timed condomless sex to peak fertility, (B) Treatment as Prevention, and (C) pre-exposure prophylaxis for the HIV-negative partner.

The behavioral component of the intervention (led by CP and SAS) used strategies drawn from CBT and included a brief motivational exercise, problem solving, and communication skills training [29-31]. The *Life-Steps* intervention was also included to support medication adherence [30]. Communication skills training was based on elements from the Stepping Stones [32-34] and Horizons programs developed in South Africa and aimed to foster forthright and respectful communication between partners and support participants in negotiating disclosure and reproductive goals [35,36]. The multisession intervention comprised 3 core sessions and 2 follow-up sessions to allow

men time to update their safer conception plans while accessing support from the study as changes were implemented. The 3 core sessions at weeks 0, 2, and 4 offered education on safer conception strategies and motivational interviewing for behavioral change. Follow-up sessions at 2 and 4 weeks and check-ins at 8 and 12 weeks included a review of safer conception plans and motivational interviewing and problem solving to execute the plan. This also allowed time for men to disclose their serostatus, think through prevention options, and learn skills to communicate with their partners regarding reproductive goals. Session content is outlined in Figure 2.

Figure 2. Diagram highlighting Sinikithemba Kwabesilisa session content over 12 weeks and key outcomes (adapted from Mathenjwa et al [16], which is published under Creative Commons Attribution 4.0 International License [37]). ART: antiretroviral therapy.

*** Potential Elements of Safer Conception Plan:**

- Initiate ART and adhere to ART
- Delay sex without condoms until HIV-RNA is suppressed
- HIV disclosure to partner and couples HIV counseling and testing
- Understanding HIV serodiscordance
- Safer conception knowledge
- Timing condomless sex to peak fertility

Intervention Delivery

Mechanism of Delivery

The manualized CBT intervention was facilitated by 1 of 3 South African men with fluency in both isiZulu and English, training in HIV counseling, and training in the intervention strategies (Figure 2). A female interventionist with >5 years' experience as an HIV, sexual, and reproductive health researcher with training in HIV counseling and testing was also trained to conduct sessions that included female partners. Interventionists were trained in couples-based HIV counseling and testing by the Centers for Disease Control and Prevention in South Africa [38]. Intervention content training was provided through several in-person sessions: content related to safer conception behaviors was led by LTM, and CBT-based content was led by CP. Training modules included basic counseling skills (nonjudgmentalism, active listening, and reflection), evidence for the use of CBT to support behavior change, and training in skills specific to the intervention (eg, motivational interviewing strategies, problem solving, and communication skills). The training included both didactic components and experiential

exercises. Education on gender norms and safer conception strategies was also included.

Intervention Fidelity

Interventionists completed standardized training on the intervention manual, filled in session checklists detailing the completion of key intervention components for each session, and completed a same-day debriefing session with a team member trained in the intervention and with a master's degree in research psychology to review session goals and content. Sessions were audio recorded, with a subset of sessions translated into English and transcribed. The transcripts and interventionist notes were reviewed independently by CP during supervision sessions, and feedback was provided.

Interventionist Supervision

Supervision, conducted biweekly via web conferencing, was provided by the study psychologists and intervention developers. Supervision involved a review of cases, discussion, and problem solving of clinical challenges, planning of subsequent sessions, and general support for the interventionists.

Data Collection

Questionnaire

A face-to-face questionnaire was completed at enrollment and exit with enrolled men and women by a researcher distinct from the interventionist. Demographic data, HIV clinical data (diagnosis date and clinical history), and reproductive health history (number of prior partner pregnancies, number of prior live births, number of living children, and HIV status of children) were collected.

Questionnaires also assessed disclosure to partners and other contacts using a sexual networks instrument to assess the full spectrum of disclosure [39,40]. Personal and partner fertility desires were assessed using the Centers for Disease Control and Prevention Pregnancy Risk Assessment Monitoring System instrument [41-44]. We asked participants about safer conception plans, whether they had completed couples-based HIV counseling and testing, and partner pregnancy.

On the basis of our conceptual framework [45], we measured the potential mediators and moderators of the outcomes. HIV knowledge was assessed using the brief HIV Knowledge Questionnaire [46]. Stigma toward HIV was measured using the Internalized AIDS-Related Stigma Scale [47]. We measured attitudes toward gender relations using the Gender Equitable Men scale, validated in KwaZulu-Natal [48-51]. This scale includes 24 items in 2 subsets. Subset 1 measures inequitable gender norms and includes items such as "It is the man who decides what type of sex to have." Subset 2 measures equitable gender norms and includes items such as "A couple should decide together if they want to have children." Response options are *agree*, *partially agree*, and *disagree*. When combined, the scores can be used as a continuous variable or categorized as low equity=1 to 23, moderate equity=24 to 47, and high equity=48 to 72.

We used the Decision-Making Dominance (DMD) subscale of the Sexual Relationship Power Scale. This 8-item subscale comprises questions such as, "Who usually has more to say about whether you have sex?" The DMD subscale was constructed to measure the balance of decision-making power (1=your partner has more power, 2=both of you have equal power, and 3=you have more power) on each of the 8 items, with higher scores indicating higher relationship power for the respondent. DMD scores were totaled and divided by the number of nonmissing items to calculate the mean individual score. The responses subsequently indicate whether the participant, their partner, or both equally demonstrate DMD. We also described the number of participants with *high* (>2.82), *medium* (2.82-2.43), and *low* (<2.43) levels of DMD [28,52].

We assessed social support using a 10-item subscale of the Social Support Inventory [53,54]. Alcohol consumption was assessed using the 10-item Alcohol Use Disorders Identification Test questionnaire, with questions labeled 0 to 4 and a maximum score of 40 [55]. Drug use was assessed using the Alcohol and Substance Involvement Screening Test interview questionnaire [56]. We screened for depression and anxiety using the Hopkins Symptom Checklist [57].

ART Adherence

For men taking ART, adherence to therapy was measured using the Medication Event Monitoring System (MEMS; Aardex), a bottle cap with a chip that clocks openings, downloaded at study visits [58] after ART initiation. Adherence was defined as the proportion of days with at least one bottle opening during the follow-up period.

Sexual Behavior

Sexual behavior was assessed through weekly password-protected SMS text messaging to request participant reports on intercourse frequency and timing, condom use, and partners. These data were collected to calculate secondary outcomes, including the proportion of men who delayed sex without condoms until viral load suppression, or limited sex without condoms to peak fertility.

Medical Record Review

Research assistants collected data on CD4 cell count at enrollment (viral load would not yet have been collected for men meeting inclusion criteria) and HIV viral load at 12 weeks after commencing ART from the medical record. Viral load assessment as early as 8 weeks after initiating therapy was not part of the standard of care but organized for this pilot intervention, given the 12-week follow-up period.

Exit In-depth Interviews

Exit interviews were conducted with 11 men and 1 female partner to explore perceptions of intervention delivery logistics, intervention content, female partner participation, HIV serostatus disclosure, and a participant-centered evaluation of their participation. The interviews lasted for approximately 60 to 90 minutes. The interviews were audio recorded, transcribed when indicated, and translated into English.

Outcomes and Analysis

Measurement of Outcomes of Interest

We used the ORBIT model for the development of behavioral interventions to frame this phase of the research as Phase Ib preliminary testing to refine the intervention [26]. Primary outcomes of interest include those described in the following sections.

Feasibility

The proportion of men screened who were eligible to participate and the proportion eligible who elected to participate are described. We also describe the proportion of men who completed the 3 primary intervention sessions.

Acceptability

Acceptability was inferred based on client participation. In addition, in-depth interviews were conducted with a subset of men to explore participant experiences with the intervention. We report on codes categorizing client perceptions of acceptability based on their experience with the intervention, including affective attitude (codes included *satisfaction with session content* and *satisfaction with number of sessions*), perceived efficacy (*benefits of the safer conception program*

and *peer referral to the program*), and self-efficacy to benefit (*what makes participation easier and community demand*) [59].

Owing to the small sample size and open pilot design, we were not powered to evaluate HIV-related outcomes. However, in line with the ORBIT framework and to inform future trial planning, we describe the clinical outcomes of interest discussed in the following sections.

Disclosure

We measured disclosure based on participant responses to an item in our questionnaire: “Does your partner know your HIV-status?” As disclosure is a complex process that is subject to desirability bias, and some partnerships changed, we did not censor men who reported disclosure at enrollment from reporting disclosure at the exit interview.

HIV-RNA Viral Suppression

As the pilot intervention was brief, we provided HIV-RNA testing to men 8 weeks after initiating therapy, which was not the standard of care. Therefore, our outcome for viral suppression was a combined outcome of the proportion of men retained in the study who suppressed viral load. We also describe the proportion of all men who initiated therapy for at least 8 weeks who achieved viral suppression (including all men in the denominator even if they did not remain in the study long enough to have a viral load assessed).

ART Uptake

Men who were prescribed ART in their medical records were categorized as initiating ART. The start of ART was corroborated by the men in the intervention sessions.

ART Adherence

MEMS caps were used to measure daily pill-taking behavior for all men who initiated ART with medication bottles that fit the MEMS cap. As we did not provide ART, some men received ART in nonstandard pill bottles that did not accommodate the MEMS cap size.

Quantitative Analysis

The baseline characteristics of the participants and outcomes were described. SAS analytic software (SAS Institute Inc) was used to conduct all quantitative analyses.

Qualitative Analysis

Transcripts were reviewed by several members of the research team (MM, LTM, HK, and LG). Using an inductive and deductive approach informed by an ecological conceptual framework [45], we developed a codebook to organize text into categories. Data were organized using thematic analysis [6]. The thematic analysis results have been described elsewhere [16]. This manuscript reports findings from categories regarding intervention acceptability (positive and negative codes), including affective attitudes toward the intervention, perceived efficacy, and self-efficacy to benefit from the intervention. [59].

Ethics Approval

The competing concerns regarding respecting the privacy of male participants and doing our best to protect female partners were carefully considered [60]. We created letters for men to

give their pregnancy partners, informing them of the risk of acquiring HIV and encouraging them to seek HIV counseling and testing. Men were reminded that these letters would effectively disclose their HIV serostatus to their partners. We encouraged men to include their female partners in counseling sessions to encourage the transfer of safer conception counseling to partners, although we recognized that not all men, particularly those unable to disclose, would be willing to do this. We created a separate information session led by a female research assistant for the female partners who chose to participate. Ethics approval for the study was obtained from the human research ethics committee at the University of Witwatersrand (Johannesburg, South Africa; approval#M150426) and the institutional review board at Partners Healthcare (Boston, United States; approval#2013P002693). Site permission was also obtained from the study clinic.

Results

Enrollment

Between November 2015 and December 2017, 216 men were screened. Of the 31 eligible men, 16 (52%) were enrolled in this study. The remaining 48% (15/31) of eligible men were not enrolled as they did not answer or return phone calls, did not attend scheduled appointments, or articulated that personal business and/or life circumstances made it difficult to schedule an appointment. The most common reasons for ineligibility were reporting a pregnancy partner living with HIV (75/216, 34.7%) or not wanting to have a child in the next year (51/216, 23.6%). In addition, 19.9% (43/216) of men were excluded based on ART use (initially, any ART use was an exclusion criterion; this was later modified to include those with ART use for <3 months). Approximately 14.4% (31/216) of men were excluded based on knowing their HIV serostatus for <1 month and 31/216 (14.3%) were excluded based on knowing their serostatus for less than six months (the original serostatus knowledge criterion). Approximately 9.7% (21/216) of men were excluded based on not being in a stable relationship for at least 6 months. Additional exclusions are noted in Figure 3.

Among the 16 enrolled men, the median age was 29 years (IQR 24-44); all were Black South African, 56% (9/16) had completed high school or above, and 44% (7/16) had full-time employment. Men had been living with HIV for a median of 1.7 years. At the time this work was completed, the standard of care included checking the viral load at 6 months after treatment initiation but not at baseline [61]. Therefore, all enrolled men who had access to ART for 0 to 3 months had no viral load data and were unlikely to be virally suppressed because of this timing. Enrolled men reported a median of 1.5 sexual partners in the prior 3 months. Most participants (13/16, 81%) had children. The desired pregnancy partner was described as a long-term girlfriend by all participants, and no participant reported consistent condom use with this partner. Approximately 44% (7/16) of men reported having disclosed their HIV serostatus to their pregnancy partners at enrollment (Table 1).

A total of 3 women partnered with the index male participants enrolled with a median age of 27 years, all of whom were Black South African women reporting 1 sexual partner. All women

who approached the research team were eligible to enroll; women were enrolled 1 to 3 months after the male index was enrolled (Table 1).

Half of the enrolled men (8/16, 50%) and all of the women scored within the top one-third for gender-equitable responses. In addition, most of the enrolled men (15/16, 94%) reported

equal decision-making power between themselves and their partners. Only one of the men (1/16, 6%) had discussed having children with a health care worker or counselor since knowing their HIV serostatus. Of note, a large proportion of participants screened positive for depression, including 31% (5/16) of men and 67% (2/3) of women (Table 2).

Fidelity to Intervention Delivery

On the basis of a review of recorded sessions and session checklists, there was high fidelity to the intervention delivery, with interventionists routinely adhering to the manual and covering all the modules in each recorded session.

Outcomes

Feasibility

As stated previously, 7.4% (16/216) of the screened men were enrolled in the study. The main reasons for not meeting the eligibility criteria were generally related to the intervention not being applicable to their current situation: partners already knowing their status, not interested in having a baby, already on ART, knowing HIV status for shorter or longer than the study window, or not having a current partner. The main reason for eligible nonenrollments was related to challenges in scheduling.

Intervention sessions varied in length, although among the recorded sessions, all sessions were at least 40 minutes in length. The longest session was 75 minutes in length.

For the 3 women who enrolled, each participant completed 1 baseline intervention session.

ART Use

Of the 16 men, 13 (81%) were receiving ART upon exiting the study. Approximately 75% (9/12 with nonmissing data at week 12) of men reported disclosure of serostatus to their partner, including 56% (5/9) who reported participating in couples-based HIV counseling and testing. Among men accessing ART, contributing a median of 35 (IQR 28-85) days of MEMS cap follow-up with adherence, men took a median of 89% (range 67%-100%) of doses. Of the 8 men with adherence data, 6 (75%) took at least 80% of doses.

Viral Suppression

Among those for whom HIV-RNA was sampled, all (7/7, 100%) achieved viral suppression by 12 weeks. Approximately 13% (2/16) of men who started ART during the sessions were lost to study follow-up. An additional 25% (4/16) of men were not yet eligible to have their HIV-RNA checked, given <8 weeks since ART initiation at the end of the study.

Sexual Behavior

Approximately 44% (7/16) of men participated in the SMS text messaging surveys, responding to a median of 93% (range 63%-100%) of messages. Of these 7 men, none attempted to time condomless sex to peak fertility based on their selections. [Table 3](#) shows the other safer conception methods that men selected.

Table 3. Safer conception method selection and outcomes by participant.

Acceptability

Of the 16 men, 14 (88%) completed all 3 intervention sessions. We conducted in-depth interviews with 11 enrolled men and 1 female partner at the study exit. Participants described personal satisfaction with session content and structure while also suggesting that they would refer peers to the program and that

with time, it became easier to participate in the sessions as they gained trust with the counselor (Textbox 1). They also described the perceived effectiveness of the intervention and self-efficacy to benefit by reporting that the sessions provided new knowledge, instilled hope, and were perceived as helpful overall (Textbox 1).

Textbox 1. Quotes from exit interviews related to the acceptability of the intervention.

Personal satisfaction

- “Everyday if I had come to you guys and discuss, there was always something that I would have gained” [M1002, man with HIV aged 31 years]
- “My brother, I think what is more important for the crisis that we are facing is us as males, we are afraid of coming out onto the open about things, we end up not talking about things. So getting such a programme, perhaps you would start picking up on the third or the fourth sessions...and that is when you start opening up and realising that these are good people and so forth, because we are the kind of people who do not want to be sympathised for...” [M1007, man with HIV aged 35 years]
- “I found it very helpful, because it shows, even though things have been happening in a way that...to be honest I was not comfortable about the whole situation that we were in, but then after we were counselled and told that there are right ways of doing things I thereafter felt great actually...I even began to trust him, my partner, again.” [F1007, woman partnered with M1007]
- “...there are also people outside that I have even been able to explain to them like ‘guys there are things like this in life, if perhaps you are able to have time and go there if you have an HIV-negative woman and you are HIV-positive and have time with those guys and sit with them, there is some information that they will give you so that you can also be proud and realise that you are still a person.’” [M1008 man with HIV aged 34 years]

Perceived effectiveness of intervention

- “It has encouraged me that, what is right is that you check and know your status so that you can be able to start treatment if you have the virus and if you are negative you will be able to look after yourself and avoid having to get to a critical stage. I would say the programme has really helped me.” [M1007, man with HIV aged 35 years]
- “And your dream becomes that...and you no longer focus on the idea that you are sick and that life is now on a standstill. When one is here with you guys, hopes come back and you feel hopes revived that you could actually still have babies, you can still be able to plan for your family and so forth. So I would have liked for [the program] to move forward because it will help a lot of people.” [M1013, man with HIV aged 30 years]
- “I think it [the program] had a good impact. It helped me a lot. Psychologically, I was not able to even live, and I feel like a person once again. Because what came through my mind was that I will not by any chance have a baby, so it means I will just die in pain. All those thoughts have been washed away. If you can just take treatment as prescribed.” [M1002, man with HIV aged 31 years]

Discussion

Principal Findings

Our findings highlight the acceptability of a clinic-based intervention offering male-centered care to address reproductive goals to engage and retain men in HIV care in South Africa. We describe the first pilot safer conception intervention for

South African men with HIV who are not yet virally suppressed and are planning to have a child with a partner of unknown or HIV-negative serostatus. Of the 16 men, 14 (88%) completed all 3 intervention sessions and reported satisfaction with the content. There were promising signals that the intervention supported men to disclose, use ART, and suppress HIV; based on 12-week exit data, 75% (12/16) of men with complete data

disclosed HIV serostatus to a partner, 81% (13/16) of men initiated ART, and 100% of those who accessed ART had viral suppression. This is an improvement over the standard of care in South Africa, where only an estimated 78% of men with HIV know their serostatus, 67% of those who know their status are on ART (52% of men with HIV), and 82% of those men (42% of men with HIV) are virally suppressed [6]. The *Sinikithemba Kwabesilisa* open pilot study provides proof of concept that male-centered care that addresses reproductive goals is a promising strategy for engaging and retaining men in HIV care in South Africa, with opportunities to promote men's health while reducing HIV incidence and perinatal transmission among women of reproductive age.

Gaps in meeting HIV treatment goals for men are well-articulated; to the best of our knowledge, this is the first program to attempt to bridge these gaps by addressing the reproductive goals of men [62,63]. Although some community programs for men have been successful [64-66], we are not aware of other clinic-based programs that provide male-centered HIV care in South Africa. In Lesotho, a male-centered HIV clinic program staffed by male providers has demonstrated high demand and reach [67]. Safer conception care, or programs that aim to reduce HIV transmission in the context of heterosexual HIV-affected couples pursuing reproductive goals, has focused on couples or individual women and has not been aimed at meeting the needs of men [14,68,69]. The empiric question of whether HIV treatment in the context of reproductive goals would be acceptable and feasible for men in South Africa was addressed by this program, in which most men completed the sessions, and exit feedback was positive. This work has also been adapted to a rural Ugandan setting, with encouraging data regarding service uptake and clinical outcomes for men [70].

Men were pleased with the content and structure of the intervention; however, some considerations for further refinement of the intervention emerged. The first was to streamline the content. The intervention included 3 primary sessions and 2 boosters informed by effective behavioral interventions [71]. Most (14/16, 88%) of the men attended all the sessions, and in exit interviews, they articulated wanting more sessions, given the novelty of the information, value of role-plays, and time needed to develop rapport and trust [16]. Given the lack of male-centered care in the health system [72,73], men may have appreciated individual counseling. The interventionists and participants felt that their time together was relatively short, highlighting the importance of focusing on achievable, easy-to-understand prevention strategies that also align with broader HIV treatment and prevention goals [68]. We believe that future iterations of this work can simplify messages to the following essential components: ART for partners with HIV, disclosure, PrEP for partners without HIV, and STI testing and treatment. This would remove the discussion of timing condomless sex to peak fertility as it is challenging and time consuming to teach and implement [74]. Although most men in our cohort included timing condomless sex to peak fertility, none were able to execute this based on sexual behavior SMS text messaging data. A recent study in rural Uganda showed low uptake and poor implementation of this complex strategy [69], and data from systematic reviews suggest that it

may not help couples identify peak fertility periods [69,75]. Indeed, given infrequent HIV-RNA monitoring in most resource-limited settings, it may be more practical and better aligned with HIV prevention goals, to time condomless sex to periods of known virologic suppression instead of peak fertility. Another component to consider for removal to allow for streamlining is sperm washing. Multiple studies with diverse populations across sub-Saharan Africa have observed that most people affected by HIV are not motivated to pursue sperm washing and assisted reproductive technologies unless necessary to address infertility [17,76,77].

The intervention was delivered by male lay counselors trained in CBT strategies by the study team. The idea that these concepts could be delivered by counselors, who may have more time than providers, has been proposed [68] and is an important aspect of task shifting to allow stretched health care systems to provide patient-centered care [3]. Counseling by team members who have time to spend with clients is critical—in exit interviews, men reported the need to have time to develop rapport and learn the basics of HIV treatment and prevention, as well as more complex skills such as communication.

Among the enrolled men, most started ART, and adherence was excellent. Of the 16 enrolled men, 13 (81%) were taking ART upon exiting the study, and men took a median of 89% (range 67%-100%) of doses. Among those for whom HIV-RNA was sampled, all (7/7, 100%) achieved viral suppression by 12 weeks. Longer-term adherence and retention in care are challenging for men in South Africa; thus, future iterations of this intervention will include longer-term evaluation of outcomes to measure effectiveness. We believe that these data serve as compelling proof of concept that this may be an important novel strategy for promoting the HIV care cascade for a traditionally difficult to retain and suppress population.

The intervention was successful at promoting disclosure, and the findings provide insights into novel strategies for promoting disclosure among men who have sex with women. At 12 weeks, 75% (12/16) of the men with complete data reported disclosure to their partners. This is based on self-report and is subject to social desirability bias; however, because of the small sample size and the rapport developed with the interventionists, we know that participant disclosure stories shared in the sessions aligned with the survey data. CHCT is a key component of HIV serostatus disclosure interventions. Many of these interventions include group-based sessions or standard HIV counseling and testing, followed by couples counseling sessions with trained health workers [78-80]. A study in KwaZulu-Natal found that only 42% of couples who participated in a couples counseling intervention participated in CHCT within a 9-month follow-up period [70]. Multiple studies have found that factors influencing the uptake of CHCT include the perceived benefits of HIV testing, perception and knowledge of CHCT, suspicions of infidelity, fear of HIV test results, and gender power imbalances [81-83]. Our intervention provided participants with education on CHCT, disclosure counseling, and problem-solving skills. We also supported and role-played individual-level disclosure to partners. Only 3 women attended the clinic for sessions, and they and their partners reported the challenges of accessing CHCT in busy public sector clinics with limited hours for people

with full lives. As CHCT does not work well for everyone, we maintain that empowering men to disclose to partners through role-play and supported communication may be an important additional strategy to promote.

The largest challenge to feasibility was recruitment. We screened very few men over the period because of the absence of men in the clinic setting where our intervention was based; only 78% of men with HIV in South Africa know their status, fewer are in care, and low testing is a trend across the continent [84]. The challenges of clinic recruitment highlight the importance of community engagement to reach men who are often not available during clinic hours and who experience or anticipate health care worker stigma at clinics [66,85]. In exit interviews, men discussed that this program was unique in supporting their reproductive goals; ongoing provider stigma toward men with HIV who want to have children may have made other men reluctant to engage in the clinic-based program [16]. Future iterations of this work will require community recruitment to meet men where they are. In exit interviews, men suggested that future work should include broader public health messages; radio spots; and venue-based recruitment at community centers, football clubs, bars, and factories [16]. The intervention may be maximally effective when combined with other efforts to minimize structural barriers to care engagement and retention [66,86-92], reduce health care provider stigma [93], and link HIV care to other needed services [94,95]. We hope to evaluate this approach with a larger sample of men recruited from the community than from the standard of care in future work.

Including a broader range of men in this study could also enhance reach. In this trial, many interested men were ineligible. Approximately 40% (75/185) of the men we excluded reported that their desired pregnancy partner was living with HIV. On the basis of the understandings of disclosure and assumptions that people with HIV make about partner seroconcordance, many men reporting a partner living with HIV may not know their partner's serostatus but assume concordant serostatus

across the partnership [18,80]. Furthermore, seroconcordant-positive couples with HIV and planning for a child can benefit from interventions to promote ART use, viral suppression, STI testing, and treatment for both partners. Future iterations of this work will include men with HIV regardless of partner status and emphasize a serostatus-neutral approach such that enrolled partners can be tested for HIV and linked to HIV care and treatment or prevention (eg, PrEP). Men were also ineligible based on not knowing their serostatus for at least 1 month and not having a stable partnership. Given the near ubiquity of fertility goals and fluidity in partnerships where pregnancies can occur, future iterations of this study will not require these elements.

Limitations

There are limitations to this pilot study because of the small sample size, men who overcame barriers to enroll and attend sessions, lack of comparison arm, or ability to report on longer-term outcomes. In addition, the qualitative component had a small sample size, and saturation was not met (particularly with respect to input from female partners). Nonetheless, the trial was designed to be an important proof of concept, following ORBIT guidelines as part of intervention development.

Conclusions

These preliminary data suggest that HIV care that is male-centered and addresses reproductive goals is acceptable to men and has the potential to reduce HIV incidence among women and their children while supporting men's health. The next steps include adapting the intervention to reach men who have not yet been tested or are not yet in care to evaluate the impact. Future work should include men regardless of partner serostatus; larger-scale randomized projects are needed to evaluate the impact and examine cost-effectiveness. Finally, understanding whether and how health care workers, public health administrators, and other key stakeholders would adopt the elements of this intervention needs to be explored.

Abstract

Background: Climate change, driven by human activity, is rapidly changing our environment and posing an increased risk to human health. Local governments must adapt their cities and prepare for increased periods of extreme heat and ensure that marginalized populations do not suffer detrimental health outcomes. Heat warnings traditionally rely on outdoor temperature data which may not reflect indoor temperatures experienced by individuals. Smart thermostats could be a novel and highly scalable data source for heat wave monitoring.

Objective: The objective of this study was to explore whether smart thermostats can be used to measure indoor temperature during a heat wave and identify houses experiencing indoor temperatures above 26°C.

Methods: We used secondary data—indoor temperature data recorded by ecobee smart thermostats during the Quebec heat waves of 2018 that claimed 66 lives, outdoor temperature data from Environment Canada weather stations, and indoor temperature data from 768 Quebec households. We performed descriptive statistical analyses to compare indoor temperature differences between air conditioned and non-air conditioned houses in Montreal, Gatineau, and surrounding areas from June 1 to August 31, 2018.

Results: There were significant differences in indoor temperature between houses with and without air conditioning on both heat wave and non-heat wave days ($P < .001$). Households without air conditioning consistently recorded daily temperatures above common indoor temperature standards. High indoor temperatures persisted for an average of 4 hours per day in non-air conditioned houses.

Conclusions: Our findings were consistent with current literature on building warming and heat retention during heat waves, which contribute to increased risk of heat-related illnesses. Indoor temperatures can be captured continuously using smart thermostats across a large population. When integrated with local heat health action plans, these data could be used to strengthen existing heat alert response systems and enhance emergency medical service responses.

Introduction

Background

Our planet is getting warmer, and climate experts report that the frequency of extreme heat days has been increasing—record-setting temperatures have been reported in major cities around the world [1]. Driven by the output from human activities (such as the greenhouse effect from gas emissions), the frequency and duration of extreme heat events are only expected to increase [2].

In the United States, heat waves kill more people than all other weather-related events (earthquakes, tornadoes, hurricanes) annually [3]. Periods of extreme heat are dangerous because heat stress occurs when the human body is unable to cool itself [4]. Heat waves in Europe in 2003 and Russia in 2010 caused over 100,000 deaths combined [5]. In 2018, Quebec, Canada experienced a severe heat wave that resulted in 66 deaths [6].

Older adults, persons with disabilities, and persons with chronic conditions such as respiratory diseases and heart disease are more vulnerable during extreme heat days due to their impaired ability to regulate body temperature [7,8]. Individuals with low sociodemographic status are at a higher risk for suffering the detrimental and even deadly effects of a heat wave [9] because cooling methods may be cost-prohibitive [10] or they may live in older buildings without air conditioning units. Those living in urban areas are at greater risk for extreme heat events. Urban areas are often several degrees hotter than rural areas [11]. Densely populated urban areas experience *heat domes*, wherein the built environment absorbs and traps heat instead of reflecting it into the atmosphere [12-15]. Even at night, the temperatures remain high because building materials (such as concrete and asphalt) continue to radiate heat [16-19].

To prevent heat-related deaths, many governments have adopted heat health action plans that include ensuring residents are appropriately informed, providing resources such as cooling centers, and door-to-door checks by emergency services [17]. Heat health action plans are localized and specific to each municipality, tailored to local needs [2,18,20]. These action plans rely upon heat alert and response systems [21] or heat health warning systems. Weather forecasts, based on outdoor meteorological data, are used to predict weather conditions that could be potentially hazardous to health [22].

There are no universal criteria used for issuing a heat wave warning [23]. Environment and Climate Change Canada issues heat warnings for each province. For example, in Quebec, a heat warning is issued when (1) the temperature is 30°C or higher, with a humidex value of 40 or higher for at least one hour, or (2) when the temperature is 40°C or higher [22]. Local health departments also issue extreme heat alerts and often use different criteria. *Santé Montréal* [24], a local health department, defines an extreme heat episode as either 3 consecutive days when the average maximum temperature reaches 33°C and the average minimum temperature does not drop below 20°C or when the temperature does not drop below 25°C for 2 consecutive nights.

Current heat alert and response systems rely upon outdoor meteorological data, yet individuals now spend most of their time indoors [25]. Indoor temperatures during heat waves can be significantly higher than outdoor temperatures [26]. There are discrepancies between temperature data being used to make decisions about heat waves and temperatures actually experienced indoors by individuals. Our understanding of indoor temperature trends is relatively limited because studies on indoor environments can be challenging, time-consuming, and cost-prohibitive due to factors such as sensor costs, cost of study deployment and duration, resources, and disturbances to home life. Traditional studies on heat waves and urban heat islands typically use satellite imagery data [27,28], local or airport weather stations [29], or emergency room visit, mortality, and ambulance call data [30] to set thresholds or examine outdoor heat exposure risk. Only a few studies have investigated indoor temperature related to mortality and morbidity [31] or indoor temperature exposure [32,33].

The advent of smart home technology (ie, indoor temperature sensors) coupled with the Internet of Things (IoT) offers a unique opportunity to monitor residential indoor environments across a large population. IoT sensors have been successfully used to monitor indoor health behaviors including sleep [34,35], gait [36], breathing, and heart rate [37]. Smart thermostat adoption has been driven by government incentives, such as the Ontario Government's Green Ontario Fund, and a desire save on heating and cooling costs [38,39].

We searched Scopus and Google Scholar, with no language restrictions, for publications since database inception until December 31, 2020, using the search string ("*smart home thermostat*" OR "*smart thermostat*") AND ("*heatwave*" OR "*heat wave*") OR ("*public health*"). We identified 2 studies [34,35] that used smart thermostats for public health surveillance, with focuses on healthy behaviors such as sleep, physical activity and sedentary behavior. One study [34] validated the use of smart thermostats for measuring sleep, physical activity, and sedentary behavior and found results to be highly comparable with results captured through traditional survey methods used by the Public Health Agency of Canada. The other study [35] found that using smart thermostats allowed for insights into differences (which were significant) in time spent indoors during the weekend versus during weekdays. Both studies [34,35] demonstrated that smart thermostats and remote motion sensors can be used with minimal interference to individual to monitor activity levels routine in real-world settings (ie, in the home).

To the best of our knowledge, this is one of the first studies to use smart home thermostat data to investigate the effects of heat waves. As heat waves increase in frequency, intensity, and duration, the use of indoor cooling methods such as air conditioning will increase. The use of smart thermostats to capture indoor temperature data has several benefits, such as minimal disturbance to study participants, and overcomes barriers associated with many environmental data collection studies (ie, high overhead costs, equipment costs, small sample sizes, short study durations). In many cases, temperature, motion, and humidity data are already being collected. This overlooked source of indoor temperature can be used to

strengthen public health response and climate mitigation efforts for decision-making during extreme heat events.

Objective

We aimed to compare indoor temperatures during heat wave and non-heat wave periods between air conditioned and non-air conditioned houses with ecobee smart thermostats and identify extreme indoor temperatures posing a health risk.

Methods

Data Collection

We used smart home thermostat data (collected by ecobee and made available to researchers through the Donate Your Data program [40]) and Environment and Climate Change Canada [41,42] data from in Quebec, Canada between June 1 and August 31, 2018, which included a multiday heat wave event. Outdoor temperatures at weather stations were obtained from Environment and Climate using an amended Python3 script [42,43]. Indoor temperature and occupancy data had been collected via the smart thermostat and remote motion sensors at 5-minute intervals.

Smart Thermostat Data Processing

Thermostat metadata (number of sensors in a home, HVair conditioning mode setting, and household ID) and indoor temperature timeseries data were available from a total of 768 households. The metadata file also contained information used to associate the house with the nearest weather station. We calculated the mean indoor temperature for each house each hour and each day.

For each day in the period from June 1 to August 31, houses were labeled as non-air conditioned if the cooling stage status was 0 and *cool* was not recorded for *HVair conditioning mode* in the metadata, and houses were labeled as air conditioned if the cooling stage status was 1, 2, 3, or 4 and *HVair conditioning mode* was *cool* at any point during the day. Data from days for which a given house was unoccupied were removed.

To determine whether non-air conditioned houses were more likely than air conditioned houses to have elevated indoor temperatures, we focused on a subset of 82 non-air conditioned households and 96 air conditioned households in the areas of greater Montreal and Outaouais. This was done after data cleaning, remove of incomplete data and filtering for occupancy (determined by activation of motion sensors).

Mapping Indoor to Outdoor Data

Each house was assigned to the nearest Environment Canada weather station using thermostat metadata. Houses with incomplete data were removed. Three weather stations—Ottawa Gatineau, Montreal/St Hubert, Montreal Intl A—were selected

for further study based on having a minimum of 30 houses with data within their associated region and being within a region for which a heat wave had been declared (Multimedia Appendix 1). Montreal and Outaouais (Gatineau and surrounding areas) experienced a 6-day heat wave (from June 30 to July 5, 2018) [41].

Data Analysis

We developed and used an app (RShiny) to visualize and compare indoor and outdoor temperature trends.

We compared the indoor temperatures of non-air conditioned houses during heat wave and non-heat wave days. After combining all the daily records from each group, we used t values to examine temperature differences between air conditioned and non-air conditioned houses.

A 1-tailed t test (with unknown variance) was performed to comparing the indoor temperatures of all houses in the same region, with the assumption that they experienced the same outdoor temperature during extreme heat events and that the indoor temperatures for non-air conditioned households was consistent.

Literature indicates that 26°C (72°F) is the threshold for a safe indoor temperature (ASHRAE 55 indoor temperature standard [44]). Exposure to indoor temperatures greater than 26°C has been associated with increased premature mortality and emergency medical service calls [45]. We sought to determine whether above-threshold indoor temperatures were recorded during the heat wave in regions of Quebec (Montreal and Gatineau) for which heat waves had been recorded on specific dates [41,46]. Remaining households were further filtered to remove those not in areas where heat waves were officially declared so that analysis contained only houses that experienced the heat wave. Thus 47 non-air conditioned homes from Montreal, Laval, Montérégie, and Outaouais health regions of Quebec remained after removing households that used air conditioning between June 1 and August 31, 2018 and houses with no occupancy on heat wave days (who may have turned off air conditioning while away). To examine which time of day the highest indoor temperatures occurred, we created a heat map of the non-air conditioned home temperatures for each hour on each official heat wave day.

Results

On certain days, some non-air conditioned homes recorded indoor temperatures similar to, or even exceeding, the outdoor temperature on heat wave dates (Figure 1). These results demonstrate that using IoT devices such as the ecobee smart home thermostats are a logical means of monitoring indoor residential temperatures, especially during extreme heat events.

Figure 1. Screenshot from the RShiny app, which shows a comparison of indoor (gray lines) and outdoor (blue line) temperatures for non-air conditioned houses in the Montreal/St. Hubert weather station region on June 30, 2018.

Indoor Temperature Differences Between Air Conditioned and Non-air conditioned Houses

There is a significant difference of indoor temperature between the houses with air conditioning and without air conditioning in heat wave and non-heat wave days ($P < .001$). On heat wave days, the average daily indoor temperature was lower (mean 1.3°C) for air conditioned homes than that for non-air conditioned homes. This difference is lower in non-heat wave days (mean 0.5°C) (Table 1).

Indoor temperatures of houses with air conditioning during the heat wave days and non-heat wave days remained relatively

stable, with mean temperatures 22.3°C and 22.4°C for non-heat wave and heat wave days, respectively.

For houses without air conditioning, there was a statistically significant difference ($P < .001$) between indoor temperatures on heat wave days (mean 23.7°C) and non-heat wave days (mean 22.8°C), which were, on average, 0.90°C hotter (Table 1).

There were significant differences in indoor temperatures between houses with and without air conditioning for all 3 regions (all $P < .001$).

Table 1. Indoor temperature comparisons.

	Mean difference (°C)	Standard difference (lower, upper) or 99% CI	P value
Air conditioned vs non-air conditioned houses			
During heat wave days ^a	-1.320	-0.730 (-1.90, -0.73)	<.001
During non-heat wave days ^b	-0.500	-0.021 (-0.615, -0.40)	<.001
Non-air conditioned houses only			
Heat wave vs no heat wave ^c	0.906	0.784 (0.350, 1.45)	<.001

^aAir conditioned: n=465; non-airconditioned: n=151.

^bAir conditioned: n=6045; non-airconditioned: n=2713.

^cNon-air conditioned—during heat wave: n=151; non-heat wave: n=2713.

Non-air conditioned Houses With Indoor Temperatures Above Safe Thresholds in Health Regions With Heat Waves

Figure 2 shows the number of non-air conditioned houses, out of 47 located in regions with recorded heat waves, that experienced a daily temperature of or above 26°C between June 1 and August 31. There were consistently a number of non-air conditioned households with temperatures of or above 26°C, on heat wave days as well as non-heat wave days, especially during July and August.

Figure 3 illustrates the average duration (in hours) that the 47 non-air conditioned households recorded indoor temperatures to equal to or greater than 26°C from June 1 to August 31.

Indoor temperatures were highest during the afternoon, evening, and night-time periods of the day (Figure 4); the hottest time of the day was between 4 PM and 7 PM on heat wave days. During the 5-day heat wave from June 29 to July 3, it is possible to see the accumulation of residual heat later into the evening and into the early hours of the day.

Figure 2. The number of households that experienced indoor temperatures equal to or greater than 26°C for each date. Official heat wave days indicated by a red dot.

Figure 3. The average duration (in hours) with indoor temperature equal to or greater than 26 °C for houses without air conditioning. Official heat wave days indicated by a red dot.

Figure 4. Average indoor temperatures for 47 households on heat wave days over time.

Discussion

Principal Findings

There were high indoor temperatures for prolonged periods of time that may put people at risk; indoor temperatures may be important to consider in policies and heat mitigation strategies. In Quebec, current heat alert and response systems rely upon outdoor meteorological data, which do not reflect actual indoor temperatures experienced by individuals. There were statically significant differences between air conditioned and non-air conditioned houses: non-air conditioned homes experienced a greater than 1°C difference in temperature between heat wave and non-heat wave days. Because there were only 6 official heat wave dates during the summer of 2018, comparison dates were limited. We also found a statistically significant difference between indoor temperatures for non-air conditioned houses and air conditioned homes during a heat wave ($P<.001$). Additionally, we found that there were significant differences between indoor and outdoor temperatures across all households ($P<.001$).

During the summer of 2018, there were numerous non-air conditioned houses that experienced indoor temperatures greater than the ASHRAE 55 standard of 26°C for extended periods of time. This indoor temperature standard [47], which is used widely in spaces such as office buildings, does not take into account factors such as age or health. The threshold was exceeded both on official heat wave days and on non-heat wave days. We also observed that the hottest time of the day indoors was between 4 PM and 7 PM, with increases in temperature over the 5-day heat wave.

We were specifically interested in indoor temperatures recorded during the official heat wave from June 30 to July 5, 2018. Unsurprisingly, the indoor temperatures of homes with air conditioning remained relatively stable (mean 22.3°C or approximately 72°F) with no dramatic temperature spikes. Some air conditioned homes did record higher indoor temperatures. This may be due to homeowners having programmed the thermostat to maintain a higher indoor temperature to save on energy costs. Several non-air conditioned dwellings with ecobee thermostats had indoor temperature readings between 27°C (81°F) and 32°C (90°F), which is above the safe indoor

threshold of 26°C (79°F) that is recommended by numerous health policy documents [44,45,48]. Smart home technology was able to capture continuous temperature data, which allowed the identification of houses that had experienced higher than ideal indoor temperatures. This technology could allow local governments to develop hyperlocal, real-time heat alert and response systems to protect health [49].

On official heat wave days, many homes recorded indoor temperatures reaching 26°C. Temperatures as high as 32.7°C were recorded over multiple hours in several households on heat wave days. This information is important considering that spending more than a few hours indoors in a hot room can be hazardous to health [47]. Non-air conditioned homes experienced indoor temperatures above 26°C for an average of 4 hours; there was an upward trend in duration as the heat wave persisted. A second official heat wave event was declared on August 4 in the Outaouais health region. In this region, homes without air conditioning experienced indoor temperatures for more than 9 hours above 26°C. Prolonged periods with indoor temperatures above 26°C were also experienced by non-air conditioned dwellings on unofficial heat wave days (July 14, July 23, July 31 to August 3, August 7, August 11 to August 15). In fact, houses in the Montreal and Outaouais areas consistently recorded indoor temperatures above 26°C throughout the summer of 2018. While definitions of extreme heat vary by region, heat warnings are issued in Canada when temperatures of 30°C or higher are expected for at least one hour [50]. Consistent with the findings of previous literature [51,52], our findings showed that higher indoor temperatures were reached in the late afternoon, and the coolest temperatures typically occurred in the early morning. Our results emphasize that outdoor temperature is not always a good indicator of safe indoor temperature; thus, there is a need to include indoor temperature monitoring capacity in our public health units.

We plan to explore indoor humidity data in the future. While the humidex is not widely used and critiqued by many, indoor humidity plays a role in human comfort especially during extreme heat events [26,49,53].

There is still relatively little known about indoor temperatures; the ability to study a large number of dwellings is both costly and time-consuming. This study is one of the first to use indoor smart thermostat data to investigate extreme heat events in Canada.

Strengths and Limitations

Our ability to identify at-risk households has implications for the delivery of emergency services. While in this study, data were not collected in real time, the technology can be used for real-time alerts. For example, the data can be integrated directly with real-time temperature updates to ensure caregivers, community care organizations, emergency medical response, paramedic, or hospital teams can reach at-risk populations. These data can also be used to dispatch emergency medical services to respond to calls and improve the safety of those aging in place or vulnerable individuals who may require alternate care levels. Furthermore, smart thermostats can be used to replace existing thermostats and bring energy and cost savings to home owners while meeting moral, pro-environment

values and low-carbon targets [54]. Leveraging smart thermostats instead of introducing new technology could mean less barriers to adoption and easier integration to support heat health warning systems. The volume of data available is another strength of this technology. Although we focused on a short timeframe in a single province, there are still hundreds of datapoints available from location across Canada.

There are currently several limitations to the use of ecobee data to study indoor temperatures. The number of occupants is unknown. In addition, the location of the residence is limited to the city level. This made grouping and matching homes with outdoor weather stations a challenge. This limitation protects anonymity and encourages voluntary enrollment in ecobee's Donate Your Data program [40]. We were unable to account for technology malfunctions, such as a dead battery in a remote sensor, internet disconnection, or a power outage, that may have resulted in missing data. The location of the smart thermostat is entered in a text field by the user during setup, thus, could be inaccurate. Another limitation is that we do not know if other cooling methods, such as a fan or window air conditioning unit, were used in the home. This could explain why some non-air conditioned dwellings experienced stable indoor temperatures. Furthermore, smart thermostats are more likely to be in higher socioeconomic status households, in detached homes that are owned by the resident [55].

Implications

A greater understanding of indoor temperature is necessary, given the risks of high temperature to human health [44] and the rise in extreme heat events over recent decades [56]. Many factors can contribute to increased indoor temperatures, including the surrounding environment and building materials [57,58]. Canada has put in place some policies to address urban heat, such as planning that include green urban areas with trees and living roofs, encouraging the use of materials that reflect heat into the atmosphere, and retrofitting old buildings with smart, energy-efficient technologies [13].

These results also have implications for schools, hospitals, and long-term care facilities looking to prepare for future decades of warmer temperatures [17,59,60]. We must consider and ensure safe indoor temperatures, particularly for at-risk populations [47,61-63]. Preparation for extreme challenges is vital (ie, lockdowns due to a pandemic). During the COVID-19 pandemic, many public spaces traditionally used for cooling centers (ie, libraries and community centers) were closed, and previous strategies (ie, visiting an indoor mall) were not feasible when public gathering was prohibited due to social distancing measures [64,65].

Our study demonstrates the use of smart thermostat data for heat wave monitoring. The adoption of smart home devices, such as smart thermostats, can be used for a greater purpose and have public health benefits. This technology can be used to build on existing public health heat adaptation interventions and programs; for example, the strategic placement of sensors across neighborhoods can help cities understand how heat affects their citizens. The use of secondary data overcomes some of the challenges associated with a traditionally environmental study. Further research is needed to understand better indoor

temperatures in low-income housing or in institutions, such as long-term care and hospitals, that house individuals who are less able to cope with extreme heat and more vulnerable to its effects.

Acknowledgments

We thank the University of Campinas team (Dr. Paula Dornhofer Paro Costa and Guilherme Abreu) for retrieving the Environment and Climate Change Canada weather station data, ecobee Inc for their continued support and technology and use of the thermostat data, and our colleagues at the Ubiquitous Health Technology Lab at the University of Waterloo for their support. We thank Suzanne Osborne for feedback on the manuscript. This project was funded by the São Paulo Research Foundation (grant 20013/17-0), the National Science and Engineering Research Council, and the Ontario Centre of Innovation (VIP grant 33080).

Data Availability

Readers may contact the authors for more information on the RShiny app [66]. The code used for the app is available upon request to the corresponding author. The ecobee data are available by reaching out to ecobee directly to become an affiliated researcher.

Conflicts of Interest

None declared.

Abstract

In South Korea, COVID-19 pandemic responses, namely the 3T (testing, tracing, and treating) strategy, emerged as a new biosurveillance regime actively using new information technology (IT) and digital tools. The foundation of the Korean 3T system is epidemiological investigation efforts and clinical practices exploiting the use of new digital and IT tools. Due to these unique features, the Korean 3T system can be referred to as a “contact-based biosurveillance system,” which is an advanced version of the traditional biosurveillance models (indicator-based or event-based models). This article illustrates how the contact-based biosurveillance system originated from the experience with the 2015 Middle East Respiratory Syndrome (MERS) outbreak. The post-MERS Korean biosurveillance regime actively adopted the utility of new digital and IT tools to strengthen not only the ex-ante epidemic intelligence capabilities (by traditional models) but also the ex-post response and recovery capabilities (digital contact tracing and digital health intervention). However, critics claim that the Korean 3T system may violate individuals’ privacy and human rights by addressing the fact that the Korean biosurveillance system would strengthen social surveillance and population control by the government as a “digital big brother” in the cyber age. Nevertheless, 3T biosurveillance promises a positive future direction for digital health practice in the current biosurveillance regimes.

Introduction

The significance of biosurveillance—the real-time pandemic surveillance models enabled by new information technology (IT) and digital tools—emerged following the 2009 H1N1 influenza pandemic [1]. The post-2009 H1N1 biosurveillance regime aimed to strengthen epidemic intelligence capabilities for early warning and timely situation awareness by leveraging new IT and digital tools. Despite the fact that epidemic intelligence integrates and interprets data from both indicator-based and event-based biosurveillance systems, the most recent technological trends in biosurveillance focus primarily on event-based systems [2]. Progress in IT contributes

to the development of event-based biosurveillance systems by collecting and monitoring enormous volumes of open internet sources such as news media and social networking services (SNS). While the post-2009 H1N1 biosurveillance regime has highlighted the significance of epidemic intelligence for early warning and timely situation awareness, the world faces the hopeless spread of disease due to an unprecedented pandemic (COVID-19).

Basically, most state-of-the-art surveillance solutions aim to provide intelligence capabilities for either *ex-ante* prevention and preparedness or *ex-post* response and recovery [3]. In particular, the post-2009 H1N1 biosurveillance regime has primarily focused on technological application of epidemic

intelligence capabilities for *ex-ante* prevention and preparedness only while downplaying the significance of *ex-post* damage mitigation activities. This article aims to demonstrate that the new Korean biosurveillance regime, which emerged following the 2015 Middle East Respiratory Syndrome (MERS) outbreak, satisfies both the *ex-ante* and *ex-post* biosurveillance objectives during the COVID-19 pandemic. The new coronavirus (SARS-CoV-2) producing the COVID-19 pandemic, like the MERS virus (MERS-CoV), is highly contagious among humans, albeit the novel coronavirus has nonspecific symptoms (flu-like) and asymptomatic transmission. Studies indicate that at least 40% to 50% of those who test positive for COVID-19 exhibit no symptoms [4]. In other words, it was hard to detect and prevent the virus's influx with flu-like symptoms in the initial phase of the COVID-19 outbreak. As the virus enters and spreads within a community, large-scale testing is essential for successful *ex-post* response and recovery missions.

This article examines how Korea's past experiences with biosurveillance failures in the 2015 MERS outbreak led to the establishment of the new Korean biosurveillance system capable of conducting both *ex-ante* prevention and *ex-post* response missions. In addition to traditional biosurveillance missions, the post-MERS Korean biosurveillance regime places a strong emphasis on the use of digital and IT technology for *ex-post* response activities, especially digital contact tracing and digital health intervention practices. Unlike other post-2009 H1N1 biosurveillance systems that only focus on *ex-ante* prevention and preparedness efforts (eg, epidemic intelligence), the post-MERS Korean biosurveillance system includes digital contact tracing and digital health intervention practices to respond to and recover from public health emergencies by testing, tracing, and treatment missions. This new system can be referred to as a "contact-based" biosurveillance system because the *ex-post* response activities of the Korean biosurveillance system primarily aim to cut the chain reaction of disease transmission within the community by contact tracing and sending alarms through mobile network systems such as text messages or SNS postings.

Biosurveillance and New Information Technology

Basically, the biosurveillance regime consists of 2 different systems: event-based and indicator-based surveillance systems. The former model predicts and explains disease outbreaks that could be a serious risk to public health by collecting all reports, stories, rumors, and other information, whereas the latter model is similar to the traditional way of reporting and monitoring clinical cases of specific diseases from hospitals or laboratories [5]. Although technology innovation enables indicator-based biosurveillance systems (or syndromic surveillance) to collect and analyze epidemic data from clinical facilities in near real time, the available literature often emphasizes its complementary role for new event-based systems [6-8].

Scholars praise the increasing role of digital technology and IT that is resulting in the remarkable advance in event-based surveillance systems. New technological advances in

information science enhance epidemic intelligence capabilities such as the early warning of infectious disease outbreaks and pandemic situational awareness by collecting voluminous data from multiple internet sources [9]. However, public health groups frequently argue about the existence of huge technological hurdles that new event-based surveillance models should overcome [10,11]. Furthermore, there are inherent concerns about the reliability of sources of event-based epidemic intelligence, which frequently come from various open sources such as news media and SNS as well as official reports from governments and nongovernment organizations [12]. Regardless of these technological limitations and source quantification issues, timeliness is the biggest advantage of new IT-based biosurveillance systems compared with the traditional format of surveillance systems [13]. This is because traditional epidemiology practices are primarily focused on pathogen identification and specific disease ecologies. Thanks to new IT and big data science that improve epidemic intelligence capacities, state-of-the-art biosurveillance systems can develop more reliable predictive models by recognizing and monitoring disease drivers (antecedent conditions) such as climate, weather, war, famine, and human susceptibility to infection [14]. On an international level, advances in digital technology and IT enable international public health regimes (eg, the World Health Organization [WHO]) to establish web-based reporting systems such as the Global Public Health Intelligence Network (GPHIN) based on the International Health Regulation 2005, which enhances the quality of epidemic information and reduces the time it takes to share information among state parties [15].

Public health expertise aims to enhance epidemic intelligence capabilities for early warning and timely situation awareness by taking advantage of new IT and digital tools. Therefore, the most extensive academic discussions on technology and biosurveillance systems extensively focus on event-based biosurveillance models when considering how to provide more timely, reliable, and accurate epidemic intelligence. However, following the COVID-19 pandemic outbreaks throughout the world, event-based biosurveillance models have proven less effective for disease control and prevention efforts. Flu-like symptoms caused by the coronavirus often make it difficult to identify patients quickly [16]. US public health authorities have no option but to encourage people to "Stay Home When You Are Sick" [17]. In response to this grim reality, South Korea introduced a new form of biosurveillance that demonstrates more effective disease control and prevention performances, namely the 3T practice, comprising testing, tracing, and treatment [18]. Unlike most event-based biosurveillance systems that focus on early warning and situation awareness capabilities, the Korean 3T biosurveillance employs an "Active Search strategy," which aims to actively search and trace all suspected cases that may have had close contact with confirmed cases through preemptive testing practices [19]. All confirmed cases, as presented in Figure 1, should be isolated. Based on the mobility history of confirmed cases, all suspected cases who may have had close contact with or are patients under investigation (PUI) associated with a COVID-19 cluster should go to public health centers for preemptive testing.

Figure 1. Flow chart depicting the preemptive testing work in the Korean biosurveillance system. PUI: patients under investigation.

Failed Biosurveillance: Lessons Learned From the 2015 MERS Outbreak

To better understand the features and origins of the contact-based surveillance system in South Korea, it is necessary to examine what is considered a “focusing event” and how this system has evolved. The concept of the focusing event often accounts for the origin of institutional changes in the language of *critical juncture*, which is a decisive moment of innovation caused by crises (exogenous shocks) such as a revolution, war, or regime change [20-23]. Disasters (eg, pandemic or 9/11 terrorism) often provide lessons that a country can learn from; these disasters are *focusing events* that lead to the adoption of new policies due to the increased attention on a new agenda and for the mobilization of interest groups [24,25]. Indeed, after the 2015 MERS outbreak, disease containment and epidemiology became the center of the public health policy agenda in Korea, which highlights nonpharmaceutical interventions in considering how to build effective “diagnose and detect” capabilities to break the chain reaction of infectious disease transmissions [26]. Therefore, the lessons learned from the 2015 MERS experiences affected all public health–related areas in Korea and laid the groundwork for the institutionalization of the post-MERS Korea public health systems to function efficiently during the COVID-19 pandemic [27].

The 2015 MERS outbreak facilitated a major revision of the biosurveillance regime in South Korea due to the biosurveillance failures. The first lesson that the Koreans gained from the MERS

outbreak was to recognize the flaws of the event-based system. Although the event-based biosurveillance system is technologically advanced, it contains a loophole that allows the inflow of infectious diseases. The WHO delivered a MERS-related epidemic advisory via the GPHIN, a secure Internet-based multilingual early warning tool developed by Health Canada in collaboration with the WHO [28]. Based on GPHIN sources, the South Korean government did not include Bahrain as a MERS-dangerous zone because, despite its geographical proximity to Saudi Arabia, the country with the largest MERS outbreak, no cases were initially reported in Bahrain. Indeed, the first case of MERS infection was reported in Bahrain on April 10, 2016 [29]. In May 2015, when a sick businessman (patient zero) sought medical treatment for a high fever and other flu-like symptoms, the South Korean public health authorities ignored the possibility that the patient, who had recently returned from Bahrain, may have been infected with MERS. Even though patient zero had visited Saudi Arabia, the country with the MERS outbreak, no public health system could track his travel history. Since patient zero entered Korea through a breach in the Korean biosurveillance system relying on the GPHIN, almost 2 weeks had elapsed before he was officially confirmed to be infected with MERS on May 20, 2020.

The second lesson is that, during highly infectious disease outbreaks, the traditional model of an indicator-based surveillance system could not work for disease control and prevention practices. While relying on the international

event-based biosurveillance system (the GPHIN) as the primary source of epidemic intelligence, the Korean public health authority has adhered to the traditional indicator-based models. However, when medical and health care systems were overloaded or damaged due to uncontrollable disease spread, the indicator-based systems reporting cases from health care providers, physicians, or laboratories were completely dysfunctional. For 2 weeks, patient zero visited 3 different hospitals before finally being admitted to the Samsung General Hospital, infecting 82 other people. MERS-CoV, the virus that causes MERS, is a member of the *coronaviridae* family, which amplified nosocomial infection within hospitals during the MERS outbreak in Korea [30]. In general, hospitals are hubs for sick people who are vulnerable to any kind of contagious disease. Due to the nosocomial feature of the MERS virus, hospitals unwittingly became major sites for MERS transmission. For example, St. Mary's Hospital in Pyeongtaek, 1 of the 3 hospitals visited by patient zero, became the most notorious virus breeding spot because 28 people were infected.

Since the MERS outbreak emasculated both the biosurveillance systems, a super-spreader issue was highlighted in Korean society. A super-spreader is someone who, before being confirmed with MERS infection, had spread the disease to many other people, exacerbating the uncontrollable chain reaction of disease transmissions. Patients 0, 14, and 16 were labeled as super-spreaders [31]. Patient zero initiated a chain reaction of illness transmission in numerous institutions by unwittingly infecting so many health care workers and patients. Patient 14, a secondary infection from patient zero, also visited the Samsung General Hospital, which resulted in 85 cases. Patient 16, another secondary infection from patient zero, infected 23 people in other hospitals. The super-spreaders were not only staying at hospitals but also freely walking down streets. The mild flu-like symptoms in the early phase of the MERS infection made disease control and diagnosis much harder. During the MERS outbreak, no one knew who was infected or which hospitals were contaminated. The super-spreader issues increased public

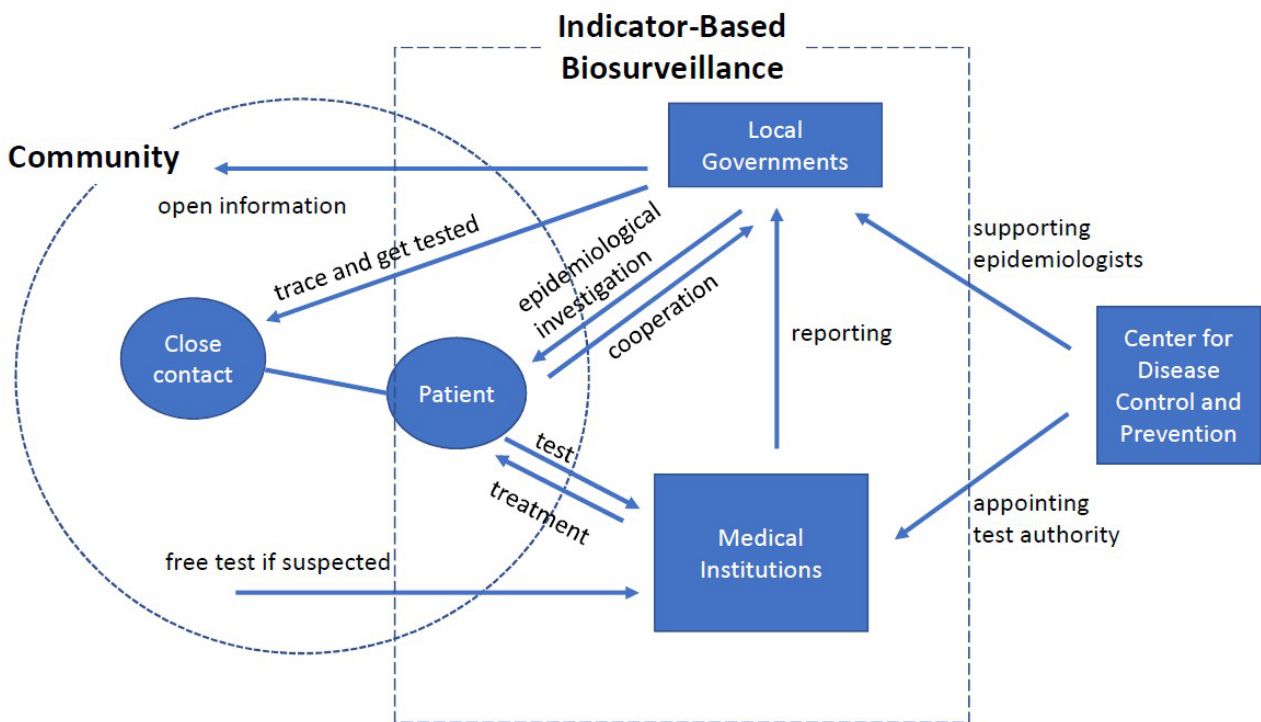

fear of possible contact with confirmed cases or unknown carriers in any public space, aggravating social chaos in Korea.

Application of Digital and IT Tools to New Contact-Based Biosurveillance

Since the MERS outbreak, the Korean public health authority has realized the significance of upgrading the public health surveillance system to respond to public health emergencies. It is especially necessary to strengthen real-time epidemic information-sharing capabilities among international and domestic stakeholders and increase interagency communication capabilities in the post-MERS biosurveillance regime [32]. Following MERS, the Korean biosurveillance regime began to strengthen domestic event-based surveillance systems for early warning and timely threat awareness, which can complement the limitations of the established indicator-based surveillance system [33]. In addition to early warning surveillance capabilities, the new post-MERS biosurveillance regime aims to strengthen the rapid implementation of control measures (*ex-post* intervention for response and recovery) through rigorous epidemiological investigations, contributing to the successful defense of the MERS inflow in 2018 [34].

Interestingly, closer scrutiny reveals that the post-MERS Korean biosurveillance implementation of control measures seems like an extended version of the traditional indicator-based biosurveillance system. As presented in Figure 2, the operational mechanism of post-MERS Korean biosurveillance is similar to indicator-based models (within the dotted-line box), although it performs more extensive activities. When a patient is diagnosed with a disease, medical institutions (eg, public health centers) conducting polymerase chain reaction (PCR) tests immediately report the testing result to the local government that has jurisdiction over the patient's address. However, the differences from other indicator-based systems start from epidemiological investigations.

Figure 2. The extended operation mechanism of the Korean biosurveillance system [35]. Govts: governments.

A prominent feature of the post-MERS biosurveillance system is digital contact tracing by epidemiological investigations utilizing new digital and IT tools. In contrast to other biosurveillance models utilizing digital and IT tools for developing computerized predictive models, new IT and digital tools are mainly exploited for epidemiological investigation in the Korean biosurveillance system. It is because the post-MERS Korean biosurveillance regime institutionalizes the use of new digital and IT platforms such as GPS tracking to strengthen contact tracing capabilities, thus preventing unknown routes of disease transmission from super-spreaders. To foster the new biosurveillance regime, the Infectious Disease Control and Prevention Act, often called the MERS Act, was enforced in January 2016 as follows [36]:

...the Minister of Health and Welfare shall promptly disclose information with which citizens are required to be acquainted for preventing the infectious disease, such as the movement paths, transportation means, medical treatment institutions, and contacts of patients of the infectious disease. [The Republic of Korea, Article 34-2]

Article 34-2 of the MERS Act establishes a legal basis for digital contact tracing practices, allowing the government to utilize all possible digital and IT resources to trace all PUIs through epidemiological investigations. This legislative effort allows the local governments to document the mobility history of the patients down to the minute based on a comprehensive epidemiological investigation through testimony, closed-circuit television (CCTV), smartphone GPS, and credit card transactions. Digital contact tracing practices—epidemiological investigation utilizing different

digital and IT resources—can contribute to the timely collection of epidemic information to search for all PUIs.

Another outstanding feature of the new Korean biosurveillance system is the utility of digital and IT tools for active interventions when the government performs *ex-post* response and recovery missions during a public health emergency. First, since they collect all epidemic information through digital contact tracing practices, the local governments have released all information on the movements of the patients to the public by text messages and SNS postings, including where they went, when they were there, and how they got there. Because the epidemic information was made public, other people in the same community could avoid the areas the patients had visited. Furthermore, the public disclosure may encourage people who have visited those places at the same time to seek medical attention as soon as possible and to enter self-quarantine if they have similar symptoms. Second, based on the collected epidemic information from epidemiological investigations, local governments can identify and trace all PUIs and notify them via text messages that they need to get tested. All PUIs who have received a text message are required to visit public health centers and get tested. Public disclosure of epidemic information and notices or alarms sent via text messages to get tested are forms of mobile health (mHealth) practices, which is one of the main pillars of digital health intervention.

Digital health is an emerging concept and a new form of medical practice described as “the broad scope of digital health that includes categories such as mHealth, health IT, wearable devices, telehealth and telemedicine, and personalized medicines” [37]. Disease diagnosis by new digital health is the most applicable component of digital health, and medical artificial intelligence has been highlighted as the future direction

of digital health in clinical practice [38]. In this vein, the Korean 3T biosurveillance system, exploiting new digital and IT tools for digital contact tracing practices (identifying and tracing all PUIs) and for intervening in clinical practice (notices to all PUIs getting tested), is more than just a biosurveillance regime in general. The 3T surveillance works for national-level digital health intervention practices for *ex-post* response and recovery missions during a public health emergency, beyond the *ex-ante* prevention missions by traditional event-based and indicator-based biosurveillance models.

Limitations and Side Effects

The Korean 3T practice is a new type of biosurveillance model—a contact-based model—which actively uses digital and IT tools to identify and trace all PUIs. Furthermore, this model is tailored for digital health intervention practices by requiring PUIs to be diagnosed and treated, which can help break the chain reaction of disease transmission within communities. Despite its success in disease control and preventive techniques, the contact-based biosurveillance system is plagued by privacy and human rights violations. For example, basic personal information, including age, gender, and place of residence, is made public. When collecting and disclosing their personal information, patients' consent was not required. Patients must cooperate with public health authorities during the epidemiological investigation phase; if they do not cooperate or give false information, patients are subject to punishment under the law. In addition, a person's travel history, describing when he or she arrived at X and moved to Y and stopped by Z, is documented down to the minute; for example, the person entered a restroom at 18:05, left at 18:08, walked from C to D, drove their car in front of E library, arrived home at 18:16. In some cases, it is not difficult to figure out who he or she is. Due to such detailed private information, several media outlets warn that Korean biosurveillance risks violating the privacy and human rights of citizens [39,40]. Scholars are doubtful that the United States and other developed countries can adopt such an aggressive digital contact tracing practice because they are worried about the loss of privacy and civil liberties [41,42]. Later, in June 2020, as a result of acrid debates in terms of privacy issues, the Korean government released a rigid "guideline for public disclosure," which aims to protect patients from unwanted exposure of their personal identity and privacy. Local governments should provide just the minimum information essential for public health missions, such as guidelines requiring no home address and no age, sex, nor nationality.

Contact-based biosurveillance systems, in particular those that rely on epidemiological investigation and tracing all PUIs, are harsh for minority groups, and those who intentionally violate the consensus of the community abiding by the biosurveillance regime become a target for normative criticisms. The Itaewon case exemplifies the dark side of the Korean surveillance regime. Itaewon is an international district of Seoul, the capital city of South Korea, that symbolizes freedom and liberation for young people. Unsurprisingly, many famous clubs in the LGBT community are located in the Itaewon district, and one of them became a hotspot for the COVID-19 outbreak. News media

outlets were scrambling to report the new possible pandemic wave, using an incendiary and pejorative term—Gay Club—which sparked a huge backlash against the Korean LGBT community [43]. People at the club were worried about their sexual identities being revealed. They attempted to avoid the government's testing guidelines to conceal their identities, thus leaving 5000 people uncontactable [44]. The Korean government finally decided to adopt the most aggressive measures to trace these people. The government worked with telecom carriers to determine who accessed the Itaewon cell towers at the time to trace down the people who were in Itaewon [45]. Consequently, the people listed as wireless providers stand at the center of public outrage and have even been accused by the public health authorities.

Conclusion

Both event-based and indicator-based biosurveillance systems offer remarkable predictive public health models that work for effective disease control and prevention practices. Much research has been conducted on the application of new IT and digital tools to enhance the reliability and accuracy of biosurveillance systems. Since the COVID-19 outbreak, the world has realized that current biosurveillance systems are ineffective in dealing with the unprecedented pandemic. In particular, the spread of the novel coronavirus, which is highly contagious but has no unique symptoms, is hardly detectable and traceable within communities. When responding to the COVID-19 outbreak, however, the 3T practices of South Korea can present a new biosurveillance model exploiting new IT and digital tools in the cyber age. This Korean biosurveillance system is specialized in digital contact tracing practices that conduct epidemiological investigations on all close-contact people through new IT and digital tools. As the epidemic information (eg, a patient's travel history) is acquired by CCTV or other digital resources and is disclosed to the public, people who have been to those places at the same time can seek medical attention quickly and be tested. Based on the collected epidemic information, the Korean public health authority identifies and traces those who may have been in close contact with patients and reaches out to all PUI to ensure they are tested. This biosurveillance system, consisting of test, trace, and treatment practices enabled by the new digital and IT tools, performs well when it comes to breaking the chain reaction of disease transmission within a community.

In other words, the conventional models of both event-based and indicator-based biosurveillance systems optimize the epidemic intelligence operation that predicts the potential and actual infectious disease outbreaks only during prepandemic conditions, while the 3T practice works for *ex-post* response missions such as digital contact tracing and digital health intervention practices during an ongoing pandemic. Despite these merits, it is necessary to caution people about the side effects of the Korea 3T biosurveillance system. Korean public health authorities should be aware of the potential risks of violating human rights and privacy when operating contact-based biosurveillance. Therefore, it is necessary to develop complementary measures that can close the gaps of 3T practice.

Abstract

The COVID-19 pandemic has profoundly impacted the world, having taken the lives of over 6 million individuals. Accordingly, this pandemic has caused a shift in conversations surrounding the burden of diseases worldwide, welcoming insights from multidisciplinary fields including digital health and artificial intelligence. Africa faces a heavy disease burden that exacerbates the current COVID-19 pandemic and limits the scope of public health preparedness, response, containment, and case management. Herein, we examined the potential impact of transformative digital health technologies in mitigating the global health crisis with reference to African countries. Furthermore, we proposed recommendations for scaling up digital health technologies and artificial intelligence-based platforms to tackle the transmission of the SARS-CoV-2 and enable equitable vaccine access. Challenges related to the pandemic are numerous. Rapid response and management strategies—that is, contact tracing, case surveillance, diagnostic testing intensity, and most recently vaccine distribution mapping—can overwhelm the health care delivery system that is fragile. Although challenges are vast, digital health technologies can play an essential role in achieving sustainable resilient recovery and building back better. It is plausible that African nations are better equipped to rapidly identify, diagnose, and manage infected individuals for COVID-19, other diseases, future outbreaks, and pandemics.

KEYWORDS

COVID-19; SARS-CoV-2; Africa; preparedness; response; recovery; digital health; artificial intelligence; vaccine equity

Introduction

The COVID-19 pandemic is a novel coronavirus caused by a pathogen known as SARS-CoV-2 [1]. The virus, which is rapidly transmitted via respiratory droplets, was first identified in late 2019 as a potential public health threat in Wuhan, China. Since its identification, the SARS-CoV-2 has had immense adverse impacts across the globe, taking the lives of more than 6 million individuals [1]. The disease often causes mild to moderate respiratory illness; however, older people and those with comorbidities such as hypertension, diabetes, obesity,

asthma, or HIV are more likely to develop severe complications as a result of the infection [1]. As the disease rapidly progressed, the World Health Organization (WHO) declared a global health emergency in January 2020, leading to public health preventive and restrictive measures such as lockdowns, stay-at-home orders, quarantine, shelter-in-place orders, curfews, mask mandates, hand hygiene practices, and social distancing, which were swiftly implemented to facilitate emergency response and case containment [1].

After the WHO's global health emergency declaration, Africa saw its first wave of COVID-19 infections, with the earliest

cases reported in Egypt in early February 2020. A few weeks later, subsequent reports of infection were made in Algeria, Cameroon, Morocco, and Nigeria [2,3]. Although the prevalence of Africa's first wave seemed paradoxical given the comparatively lower-than-expected reported case numbers, the second wave of infection was more severe [2,4]. By December 31, 2020, only 36 countries had implemented at least 5 of the public health preventive measures; that is, international travel restrictions; workplace, school, and university closures; stay-at-home requirements, etc [2]. While the number of cases fell as the region began to emerge from its second wave, officials warned that the resurgence of the SARS-CoV-2 was inevitable [5]. The rapid spread of the Delta (B.1.617.2) and Omicron (B.1.1.529) mutants have largely driven the most recent surge in cases. As of March 27, 2022, COVID-19 had resulted in an overall estimated prevalence of 11.32 million cases and 250,948 deaths in Africa [6]. At the time, these accounted for 2.4% of cases and 4.1% of deaths recorded globally. Moreover, over 250,000 COVID-19 confirmed cases have been recorded in each of these 10 out of 55 African countries, respectively [6]. There is scientific consensus that COVID-19 vaccines' acceptance and uptake are effective in limiting the transmission of SARS-CoV-2 as well as reducing disease severity, hospitalizations, and deaths [7]. Considering that some higher-income countries have begun to offer booster shots, it is concerning that only 15.3% of the population in African countries has been fully vaccinated [7].

Without rapid tracing and containment of new cases, Africa could see a prodigious increase in morbidity and mortality. The reemergence and resurgence of the SARS-CoV-2 continues to have enormous negative impacts on psychosocial, economic, and health care systems. This warrants an immediate call to action for innovative, state-of-the-art digital health interventions that expedite a resilient recovery and mitigate this and future pandemic crises in African countries. Accordingly, our current investigation examined the potential impact of transformative digital health in alleviating the spread of SARS-CoV-2. In addition, we highlighted digital health technologies adopted worldwide to tackle SARS-CoV-2 transmission and proposed recommendations for scaling up digital health and artificial intelligence while also facilitating equitable vaccine access within the African continent.

Application of Digital Health and Artificial Intelligence in Preparedness and Rapid Responses

The all-encompassing framework of digital health incorporate components such as mobile health (mHealth) and medical mobile apps, health information technology, smart devices, wearable sensors, wireless medical devices, personalized medicine, telemedicine, and telehealth, which have revolutionized health care systems [8,9]. Moreover, digital health incorporates the application of artificial intelligence and machine learning to enable gathering, management, integration, mining, and interpretation of enormous heterogeneous data or information that includes biomarkers (e.g., disease prevalence and physical activity) and socio-markers (e.g., zip code-level or neighborhood characteristics, education, income level, housing quality, and nearest health facility) [10].

Consequently, we propose that the availability and access to real-time health data through digital health technologies (DHTs) in Africa could facilitate (1) the application of rapid predictive monitoring systems, geographic information, and dashboards for disease surveillance, data visualization, and health decision-making; for example, vaccine and masks mandates, lockdowns, and quarantine measures; (2) good governance or policy decision-making and an inclusive regulatory or legal framework to deter excess bureaucracy and minimize the depletion of scarce resources; (3) leveraging of mHealth and social media analytics to obtain data that assess public sentiments, opinions, or information gaps and enable the creation and dissemination of tailored messages that address mis- or disinformation, vaccine hesitancy, and vaccine inequity; (4) comprehensive educational or training programs that expand digital literacy, health information-seeking behaviors, and precision health education or promotion. Overall, in this pandemic era, the fast-tracking adoption of digital technologies to collect, share, and analyze socio-behavioral and health data could further transform disease preparedness and response, mitigate the spread of infections, and optimize health care delivery services; for example, vaccine delivery, contact tracing, case containment, and management [11-13].

Social Determinants of Health Risk Factors and Other Barriers to Rapid Recovery

The re-emergence of mutant variants has heightened awareness for the reassessment and reinforcement of current surveillance methods to evaluate behavioral risk factors and ensure protection against future variants [14]. However, given that Africa's health system is particularly vulnerable, efficient policy rollout and implementation may be quite difficult. Poor access to health care, long hospital wait times, ill-equipped and severe shortage of health care professionals, scarcity of personal protective equipment and medical commodities, socioeconomic devastation, as well as disruptions to HIV, tuberculosis, and vaccination programs exacerbate the current COVID-19 burden [5,15-19]. Moreover, lack of government policy and legal framework, inadequate infrastructure, poor maintenance culture, and costly computing resources negatively impact DHT implementation [19]. Inadequate coordination and knowledge for a large-scale rollout of digital health setups, low-level utilization of electronic health records (EHRs), restricted access to reporting systems, and miscalculation of the disease burden owing to limited testing capacity also limit widespread preventive efforts; for example, vaccinations and contact-tracing [20,21]. Besides, some African countries are disproportionately impacted by widespread poverty, low digital literacy levels, internet shortages, food insecurity, climate, and environmental injustices, as well as war, conflicts, and terrorism. Despite the barriers to gathering and retrieving indigenously owned digitally generated data for integration into artificial intelligence systems, the alternate use of externally generated data (from other countries) ultimately creates a predicament [22].

Digital Health Best Practices That Have Tackled Outbreaks and the Current Pandemic

Digital health technologies have played a central role in the mitigation of the pandemic globally. Even with the myriad of

challenges, Africa has seen a number of its own health care advances. In recent years, digital health has come to play a vital role in Africa's public health disease containment efforts. The Africa Centres for Disease Control and Prevention (Africa CDC) and Prevention, a centralized unit for public health surveillance and emergency responses, was created in 2017 [3]. During Nigeria's first COVID-19 surge, social media platforms, text and electronic messaging, telecommunication media, and an artificial intelligence–interactive voice response systems were leveraged by the Nigeria CDC to rapidly and simultaneously disseminate accurate information and debunk myths [23,24]. In Morocco, South Africa, Sierra Leone, and Tunisia, drones were used to enforce compliance with lockdown and social distancing guidelines [25]. Whereas, in Rwanda, the District Health Information Software system presented real-time surveillance data that enabled timely contact-tracing and case management of infected individuals [26].

Similarly, Africa has benefited from a wide range of health emergency responses related to tuberculosis, HIV, and malaria [15]. Ghana, Kenya, and Tanzania adopted an integrated cloud-based mHealth smart reader system to rapidly interpret and transmit diagnostic malaria test results to patients [27]. Other open-access web-based platforms used for comprehensive displays of data have been proposed to condense the plethora of malaria surveillance systems that are in use and scattered across a number of sectors. This integrated and organized approach collects all necessary tools for accurate data retrieval, management, and disease forecasting into one digital space for interoperability [28,29].

Most notably, many African countries have relied on contact-tracing driven by digital health technologies in their fight against Ebola outbreaks since 2014 [23,30]. Consequently, effective contact-tracing strategies originating from networks on Ebola, HIV, Tuberculosis, and Lassa fever have revolutionarily changed how data are collected and transmitted to regional public health centers within Africa. Traditional contact-tracing methods (i.e., paper reports) have been expanded and decentralized to incorporate the use of smartphones, other mobile apps, cell phone tower data, and geospatial mapping [5,21,27] so that real-time data (temperature readings and symptom questionnaire responses) become immediately available as opposed to the lengthy process of collecting paper reports [27,30].

It is widely known that surveillance of population movement and interaction is important in controlling disease transmission, prompting many countries to place a focus on DHTs capable of recording both movement and relevant environmental biomarkers. These location-based biomarkers range from fine particulate matter in the air to descriptive statistics detailing local access to green space and public transportation [31]. Nongenetic biomarkers such as these are reflective of a population's "exposome," a public health concept demonstrating the connection between environmental pressures and overall health status [32]. Over time, external pressures from environmental determinants influence an individual's biological index, making disease development and progression unique [32]. For instance, as mis- or disinformation, politicized debates on vaccine safety, and socio-contextual barriers worsen vaccine

hesitancy, public health surveillance methods (e.g., topic modeling, semantic network analysis, and sentiment analysis) can be used to assess and improve the population's "digital exposome" [33,34]. Furthermore, these methods can be used in conjunction with informatics from innovative technologies—for example, wearable sensor devices, smartphone-based sensors, environmental hyperspectral and remote sensing campaigns, and geolocation technologies—to investigate exposome complexities and aid in region- or site-specific, culturally sensitive mitigation plans for African populations.

Moreover, best practices from other countries can also be adapted in Africa within an appropriate sociocultural context. Being the first country affected by the COVID-19 pandemic, China mobilized the use of smartphone apps to keep record of all human movement via public transportation during major outbreaks [13]. This app allowed users to quickly determine exposure during travel and expedite quarantine measures for disease containment [13]. Further, artificial intelligence systems were employed to expedite diagnostic reading time for investigative imaging tools. This resulted in better clinical decision-making and forecast of workforce needs, thus limiting the strain on health care systems [13]. Moreover, Israel used digital vaccine certificates through smartphone apps, termed the "green pass," which allowed admission to certain places; for example, social events for those who are vaccinated [35]. Icelandic scientists developed an app where COVID-19 symptom data (fever and cough) were entered for physicians' monitoring. If symptoms were severe or life-threatening, patients were admitted to a hospital, thus limiting unnecessary hospital visits and health care workers' burnout or exhaustion [36]. In New Zealand, the Ministry of Health developed and distributed the NZ COVID Tracer app, which allowed users to keep digital diaries of their travels and receive alerts following exposed to COVID-19 [37]. In Colombia, the CoronApp was adopted by the National Institute of Health in conjunction with the Columbian Field Epidemiology Training Program (FETP). This digital tool enabled access to FETP teams with data for approximately 5.5 million active users, thus facilitating rapid coordination with local health officials to identify new cases as well as inform preparedness and response decisions [38]. In the United States, 32 states developed mobile apps for contact-tracing using location, Bluetooth, Google or Apple, or DP-3T. Depending on the app's design, capabilities and functionalities varied from a public health official's phone call to travel diaries or notifications on a smartphone.

Recommendations to Prioritize Scaling up of Transformative Digital Health Technologies in Africa

The application of digital health initiatives has shown considerable success globally. Although digital health technologies have played a large role in facilitating better health outcomes over the past decade, their implementation has become substantially pivotal and timely during the current COVID-19 pandemic. Using existing technologies in combination with those that have demonstrated success in other nations could prove to be advantageous for African countries to manage health crises, facilitate pandemic response or recovery, and promote vaccine uptake. Following the post-COVID-19 era, African

countries can be better positioned to overhaul their health care systems to advance the quality of health care, increase cost-effectiveness, bolster health care infrastructure and resources, as well as alleviate the already limited health care workforce. Herein, we examined the potential impact of transformative digital health technologies in alleviating the pandemic's adverse effects on health and health care systems. Furthermore, we proposed recommendations for scaling up digital health technologies and artificial intelligence-based platforms to tackle transmission of the SARS-CoV-2 and enable equitable vaccine access through the following: (1) application of rapid predictive monitoring systems, geographic information, and dashboards for disease surveillance, data visualization, and health decision-making; for example, vaccine and mask mandates, lockdowns, and quarantine measures; (2) good governance or policy decision-making and an inclusive regulatory or legal framework to deter excess bureaucracy and minimize the depletion of scarce resources; (3) leveraging of mHealth and social media analytics to obtain data that assesses public sentiments, opinions, or information gaps and enable the creation and dissemination of tailored messages that address mis- or disinformation, vaccine hesitancy, and vaccine inequity. In addition, the application of DHTs could advance (4) comprehensive educational or training programs that facilitate digital literacy, health information-seeking behavior, and precision health education or promotion.

Despite all the challenges in eHealth investment [39], Africa has taken giant steps forward in using artificial intelligence in precision health [40-42] and precision agriculture [43]. The observation of success stories in using advanced analytics and digital health solutions by researchers and scientists in several African countries, shows a significant hope in term of feasibility of the suggested innovations. Although advancements in African technology and digital health solutions are sure to bolster disease response, investments in policy, and data governance are arguably most essential in moving the needle forward. Web-based open-source, modular digital health platforms with a user-friendly graphical interface and disease surveillance tools that provide accurate, timely depictions of disease case totals, geographic hotspots, vaccine distribution mapping, and supply chain management are crucial to intercepting the spread of SARS-CoV-2 [15,21]. Real-time systematic collection and analysis of data could be useful in guiding governmental support of public health responses, such as vaccine delivery and education, tailored to areas or regions that are more susceptible and with high infectivity rates. Moreover, the development of disease projection and prediction models using machine learning techniques could inform general evidence-informed policy. These integrated disease surveillance tools should be leveraged to not only fight against COVID-19 but also influence future health policy, decision-making, and program implementation.

Notably, a major challenge in some African countries is the lack of adequate infrastructure for internet connectivity, power or electricity supply, and EHR management, which are needed for any real-time application for disease surveillance and monitoring. While countries such as Kenya, Libya, and Nigeria have considerably good internet coverage (approximately 80% on average), others including Madagascar, South Sudan, and

Western Sahara have minimal coverage (less than 10%) [44]. African nations with high internet access are suitably positioned to leverage applications for contact-tracing, disease surveillance, data visualization, and vaccine distribution [13,45]. For harder-to-reach or rural areas (without internet access), satellite internet devices and offline digital health strategies can be adopted to collate, integrate, and analyze population data. It is imperative for countries with densely populated city centers and limited internet connectivity (e.g., Egypt and South Africa) to improve and stabilize their capacity for implementation. A positive future outlook is the internet coverage that has rapidly increased by approximately 12,000% in 2020-2021) within Africa [44,45].

Given the complexity of system implementation, it is also essential that barriers such as weak infrastructural investments, lack of funding, absence of regulatory or legal framework, low cost-effectiveness, and poor maintenance and governance are addressed [46,47]. To tackle cyber threats, data insecurity, legal and ethical issues (e.g., end user's consent and privacy, and data ownership), and other unforeseeable related events, countries' regulatory and legal frameworks should be reassessed, reinforced, as well as socioculturally and contextually responsive. Moreover, these legal processes ought to protect individuals' legitimate rights without jeopardizing the implementation of innovative technologies. Additionally, the use of noncomplex, interoperable, integrated, and synchronized methodologies to implement digital health systems could deter excess bureaucracy and duplication of efforts as well as minimize the depletion of scarce resources. While Africa's mobile phone usage falls below that of the global average, its increasing prevalence is adequate to harness and ramp up digital health initiatives [44]. Driven by population migration to cities and urban renewal, it is expected that cell phone use will increase by approximately 1 billion users, including 50% who will have mobile internet access by 2025 [44,48]. This growing use of smartphones and wearable devices or sensors should be leveraged to collate and manage real-time heterogeneous data. Moreover, there is potential for large-scale performance and connectivity emanating from multilateral collaborations, cross-border mHealth programs, and private-sector partnerships to ensure cost-effectiveness and sustainability [49].

In addition to concerns surrounding structural connectivity and mobile phone usage, mistrust in public or government institutions and COVID-19 mitigation strategies, such as vaccination, remains high in many African countries. A recent study examining vaccine sentiments in African societies found that out of more than 30,000 participants, only 48% of them reported acceptance of the COVID-19 vaccine [50]. The significant number of families unwilling to vaccinate themselves and their children could lead to increased infectivity rates, severe diseases, hospitalization, and deaths in many communities. As a result, vaccine hesitancy has become a more frequently discussed topic of conversation among researchers in Africa, who are raising awareness about vaccine safety and effectiveness [51]. The use of social media analytics, engagement-driven platforms—for example, social media and social listening tools—enable the collection of heterogeneous data that inform the creation and amplification of tailored messaging, which

target populations that are vaccine-hesitant and with limited access to care. This has the potential to tackle the infodemic crises, mis- or disinformation, vaccine hesitancy, and vaccine inequity.

Comprehensive educational programs focused on preventive health care and COVID-19 are becoming more widely accepted across Africa, creating opportunities for the scaling up of digital health technologies to facilitate digital literacy and precision health education or promotion. Training, capacity building, continuing professional development, and awareness or educational campaigns to bolster digital proficiency for both health care professionals and decision-makers can be achieved through structured web-based learning (e-learning) and mHealth technologies that provide access to comprehensive training programs in resource-limited areas that do not have access to the required personnel. With proper training, health care professionals are adequately equipped to assess patients and accurately report collected data via digital health systems. Importantly, communities and end users should be fully engaged and educated on digital health literacy, health information-seeking behaviors, vaccine safety or efficacy, etc. Institutions of learning (e.g., schools, colleges, and universities) should be adequately funded and equipped to offer courses or programs on big data analytics, digital health, and artificial intelligence [46]. Further, participation and infrastructure from private sector stakeholders (e.g., information and communication

technology companies) should be enlisted to facilitate efficient operationalization and optimization of digital health initiatives.

Notably, the unique socio-multicultural make-up of African societies has led to misrepresentation and misunderstanding of inequality measures. The conventional and monocultural viewpoints of evaluating Social Determinants of Health (SDoH) indicators fall short of fully encompassing inequality measures within African societies. Therefore, the application of inequality measures from western countries to less industrialized countries may not generally represent the same outcomes [47,52]. Implementation of digital health could undoubtedly improve monitoring and reporting of SDoH indicators. This could accelerate attaining the sustainable development goals and universal health coverage and facilitate a more efficient response to future outbreaks and pandemics. It is pertinent that the most vulnerable within societies and hardest-to-reach regions are taken into account during policy- or decision-making and implementation of digital health systems architecture.

The African continent should have a formidable infrastructure moving into the mid-2020s with increasing opportunities to implement digital health solutions. Overall, these efforts toward digital health scalability ought to be government-driven, government-funded, nationally owned, sustainable, coordinated, ethical, cost-effective, and socioculturally aware. Accordingly, it is conceivable that Africans will be much better prepared to tackle and control future disease outbreaks, epidemics, and pandemics.

Abstract

Background: Latino communities are among the most heavily impacted populations by the COVID-19 pandemic in the United States due to intersectional barriers to care. Crowdsourcing open contests can be an effective means of community engagement but have not been well studied in Latino populations nor in addressing the COVID-19 pandemic.

Objective: The aims of this study are to (1) implement and evaluate a crowdsourcing open contest to solicit a name for a COVID-19 social marketing campaign for Latino populations in Maryland and (2) conduct a thematic analysis of submitted entries to guide campaign messaging.

Methods: To assess the level of community engagement in this crowdsourcing open contest, we used descriptive statistics to analyze data on entries, votes, and demographic characteristics of participants. The submitted text was analyzed through inductive thematic analysis.

Results: We received 74 entries within a 2-week period. The top 10 entries were chosen by community judges and the winner was decided by popular vote. We received 383 votes within 1 week. The most common themes were collective efficacy, self-efficacy, and perceived benefits of COVID-19 testing. We used these themes to directly inform our social marketing intervention and found that advertisements based on these themes became the highest performing.

Conclusions: Crowdsourcing open contests are an effective means of community engagement and an agile tool for guiding interventions to address COVID-19, including in populations impacted by health care disparities, such as Latino communities. The thematic analysis of contest entries can be a valuable strategy to inform the development of social marketing campaign materials.

Introduction

Latino communities are among the most heavily impacted populations by the COVID-19 pandemic in the United States, with 1.9 times the infection rate of non-Hispanic White individuals and 2.3 times the age-adjusted mortality rate [1]. Latino individuals account for 18% of the US population but 27.1% of all COVID-19 cases. Among individuals 18-50 years of age, the disparity widens, with Latino adults comprising 42% of COVID-19 cases and 40% of COVID-19 deaths, with mortality rates up to 8 times higher than among non-Hispanic White individuals [2]. Certain subgroups within the diverse Latino populations have been shown to be disproportionately impacted by COVID-19. Latino immigrant populations have experienced a disproportionate burden of COVID-19 infections given occupational exposures, higher household occupancy, and barriers to accessing health care (eg, lack of insurance, fear of deportation, and limited English proficiency) [3-5].

Similar to national trends, the impact of systemic inequities has been painfully evident in our community in Baltimore, Maryland. Baltimore is an emerging immigrant-receiving city that has seen a marked influx of Latino immigrants from Central America over the last 2 decades [6]. Data from Johns Hopkins Health Systems showed that as the pandemic unfolded between March 11, 2020, to May 25, 2020, the overall SARS-CoV-2 positivity rate was 16.3%, but the rate was significantly higher for Latino patients (42.6%) compared to Black (17.6%) and White (8.8%) patients [7]. As the pandemic unfolded, our team partnered with community-based organizations (CBOs) to develop and implement a comprehensive Latino COVID-19 response strategy that addressed systemic barriers to care for Latino populations. The team focused on expanding access to free COVID-19 testing and, later, vaccination through trusted community sites, a bilingual hotline, and a team of bilingual and bicultural peer navigators (or *promotoras*). Although these components were positively received and used by community members, positivity rates remained disproportionately high among Latino populations in Baltimore [8]. Given this disparity and the need to dynamically respond to the evolving COVID-19 pandemic, our team developed and implemented a social marketing intervention as part of the Rapid Acceleration of Diagnostics for Underserved Populations (RADx-UP) initiative [9]. The intervention aim was to use crowdsourcing and a web-based platform to develop culturally congruent messaging to facilitate access to testing as well as expedite linkage to care services and/or *promotora* support.

Crowdsourcing is an effective means of community engagement, based on the principles of collective wisdom and open access [10,11]. Crowdsourcing is defined as “an approach to problem solving which involves an organization having a large group attempt to solve a problem or part of a problem, then sharing solutions” [12]. Open contests are a form of crowdsourcing that allow community members to provide solutions to a problem through a contest; the solutions are then consolidated into a unified product [13,14]. Open contests incorporate local knowledge and culture by directly involving a large number of community members in developing and vetting ideas [15].

The crowdsourcing approach avoids the less effective alternative of top-down interventions and can incorporate community-based participatory research (CBPR) principles by involving community stakeholders throughout the process [16]. In fact, the impetus for this crowdsourcing open contest arose when the name originally proposed in the research grant, *Juntos* (“Together”), was poorly received by community health workers (CHWs) on our team. The CHWs found it reminiscent of political propaganda and military *juntas*; if CHWs did not have such integral roles within our team, we may not have received this important feedback. Thus, we sought community input through this crowdsourcing open contest to develop more representative messaging for the COVID-19 social marketing campaign.

Crowdsourcing methods have been shown to be feasible among Latino populations regardless of English- or Spanish-language preference and thus are suitable to guide our approach to the COVID-19 pandemic [17]. Latino individuals have been shown to have high rates of internet and smartphone use, making web-based outreach a reasonable approach; in 2016, 84% of Latino respondents reported internet and social media use and this use has increased during the COVID-19 pandemic [18,19]. To our knowledge, no studies have been published evaluating crowdsourcing open contests for Latino audiences. The ability to crowdsource virtually makes it an apt tool for efforts to combat COVID-19 given social distancing practices. However, few studies have been published detailing the use or results of crowdsourcing for COVID-19-focused interventions.

To understand and incorporate community members’ attitudes, beliefs, and norms toward the COVID-19 pandemic, we implemented a crowdsourcing open contest to solicit the central messaging for a social marketing campaign promoting equitable COVID-19 testing for Latino populations in Maryland. In this paper, we describe the process and outcomes of a crowdsourcing open contest and thematic analysis of contest entries, which we subsequently used to guide campaign messaging. Prior studies have used the thematic analysis of contest entries to understand community attitudes [20-23]. To our knowledge, this is the first study to use the thematic analysis of contest entries to directly inform intervention development.

Methods

Overview

In November 2020, our team implemented a crowdsourcing open contest to name a COVID-19 social marketing campaign for Latino populations in Maryland. The focus of the contest was on COVID-19 testing and general prevention given that vaccines were not publicly available at that time. The contest was guided by CBPR principles in that our team consisted of diverse stakeholders involved in each aspect of the project (eg, CHWs, physicians, researchers, and designers) in addition to the community advisory board (CAB).

Participants were invited to submit a name, hashtag, and an optional call to action (1-2 sentences) for what was referred to as the COVID-19 public health campaign in Maryland. The announcements were written primarily in Spanish with an

English translation provided as the target audience for the campaign was Spanish-speaking Latino individuals who may not be reached by city-wide public health campaigns with English messaging (Figure 1).

The implementation and evaluation of the open contest consisted of the following steps: (1) organize a CAB, (2) establish contest

rules and incentives, (3) solicit crowd input via community partner social media profiles, (4) evaluate contest entries using both community judge assessments and popular voting, (5) disseminate contest results, and (6) use thematic analysis to understand community values and perspectives so that they may be emphasized in the campaign [20-25].

Figure 1. Call for entries for the open contest ("Contest! Name the COVID-19 campaign in Maryland").

Organizing a Community Advisory Board

A CAB was established to represent various CBOs, religious organizations, advocacy groups, and government sectors (ie, the Mayor's Office on Immigrant Affairs) within Baltimore's Latino community. Members of the CAB were involved in every stage of this study and the subsequent social marketing intervention. CAB members from nongovernment organizations were compensated with US \$50 per meeting. The CAB met monthly to provide guidance on how to promote the open contest to relevant communities, recruit contest participants, translate the winning entry into social marketing messages, and implement the social marketing campaign.

Establishing Contest Rules and Incentives

The contest was open for entries for 2 weeks (November 13, 2020-November 26, 2020), using a brief timeline given the urgency of the COVID-19 pandemic. Participants submitted a name, hashtag, and an optional call to action (1-2 sentences) via a brief Qualtrics form. Participants were given the option to enter a raffle for 1 of 5 US \$25 Visa gift cards by including an email address or phone number. The top 3 entries received US \$200, \$100, and \$50 respectively. At the end of the contest period, 2 study team members independently verified entry eligibility based on the completion of all required fields and relevance to the contest focus of COVID-19.

Soliciting Crowd Input via Community Partners' Social Media Profiles

To tailor contest recruitment to Latino immigrants, we announced the contest with Spanish-language posts on community partner social media profiles with established followings, including Somos Baltimore Latino, Centro SOL

(Center for Salud/Health and Opportunities for Latinos), Comité Latino, and Sólo Se Vive Una Vez. We primarily focused on CBO Facebook profiles for recruiting given our prior experience with social media reach among Latino immigrants in Baltimore [26]. Our experience and previous studies also showed that complementing web-based activities with in-person recruitment is important for contest inclusivity [23-27]. The contest was advertised in person at our community-based COVID-19 testing site, with a goal to expand the pool to participants who are less engaged in social media.

Evaluating Contest Entries Using Community Judge Assessments and Popular Voting

Entries were judged based on 3 criteria: creativity, appeal to the local community, and potential for increasing COVID-19 testing and prevention; each criterion was scored on a scale of 1-10. The criteria for judging were shared with all participants at the top of the Qualtrics form. No examples were provided to avoid cognitive fixation, a known obstacle to developing innovative ideas [28-30].

A total of 17 individuals were invited to serve as judges, including 14 Latino community members or leaders, some of whom were also CAB members, and 3 non-Latino individuals who worked in social or health services for the Latino community. A total of 6 judges participated. Judges were provided with a deidentified list of all entries, including the proposed name, hashtag, call to action, and any optional comments submitted. Judges were given 5 days to score all entries in the contest and were compensated US \$30 for their time. We totaled the judges' scores for each entry and used the cumulative score to identify the top 10 entries.

The top entries were shared across the same community partner profiles for a public vote via a Qualtrics form, which was open for 1 week. We notified the participants who submitted the top entries to congratulate them and encourage them to mobilize their social networks to vote. Voters were offered the option to enter a raffle for 1 of 5 US \$25 Visa gift cards. At the end of the popular vote, the top 3 finalists were reviewed by the study team to ensure the feasibility of their ideas, meaning they were relevant to the COVID-19 pandemic and there was no overlap with existing campaigns or brands.

Disseminating Contest Results

The finalists were personally notified and were announced to the public via community partner social media pages, including a weekly live video segment on a popular CBO Facebook page. The winner was also recognized on the campaign website with a photo and a quote sharing their inspiration for participating.

Mixed-Methods Analysis

To assess the level of community engagement with the crowdsourcing open contest, we measured descriptive statistics for the number of entries and votes and demographic characteristics of the contestants (eg, gender).

The text (campaign name, hashtag, and call to action) was analyzed through inductive thematic analysis by 3 team members. The analysis followed 4 steps: (1) data familiarization, (2) initial coding generation and reduction of codes, (3) development of themes, and (4) development of the hierarchical thematic structure. One team member independently reviewed the text from each entry and developed a formative coding scheme. Then, 2 additional team members reviewed the text and coding scheme, which was revised through discussion among the 3 team members. The codes were then applied to the text, and the resulting coded text was reviewed and discussed by the 3 team members to develop the hierarchical thematic structure [31].

Application of Themes to the Social Marketing Intervention

We partnered with Altavista Studios, a company with expertise in Spanish-language social marketing campaigns, to design and implement the campaign advertisements. In addition to providing the name of the campaign from the open contest, we also shared the key themes that emerged to guide the content of campaign advertisements. Altavista Studios incorporated these themes in a range of advertisements and provided regular

evaluations of advertisement performance through web-based metrics, such as reach and engagement [26,32].

Ethics Approval

This project was deemed exempt by the Johns Hopkins University Institutional Review Board (CIR00066868).

Results

Contest Results

We received 75 submissions in 2 weeks, of which 1 entry was deemed ineligible as it was an advertisement for a business unrelated to the COVID-19 pandemic. Of the 74 eligible entries, 72 (97%) were in Spanish. Over one-quarter (20/74, 27%) of participants were men and 73% (54/74) were women.

The 74 eligible entries were then scored by 6 community judges. With a total possible score range of 18-180, the contest entries ranged from the lowest score of 59 to the highest score of 161. The highest scoring entry was *Descoronando el COVID-19* (“Dethroning COVID-19,” a play on *corona* or “crown”). There was a tie for the 10th best score and thus the top 11 entries were included in the popular vote (see [Multimedia Appendix 1](#)).

During the popular vote period for the top entries, we received 383 unique votes within a week. The entry with the most votes was *¡Yo te cuido y tú me cuidas!* (“I take care of you and you take care of me!”). Regrettably, this popular entry was already a name for an established COVID-19 social marketing campaign. A concurrent COVID-19 campaign for a Latino audience with the same name and similar content would confound the evaluation of our intervention, not to mention the potential trademark infringement. We discussed the options with the CAB and collectively decided to announce a tie for first place, with both winners receiving US \$200. We also discussed the rationale for selecting the campaign name with the winners for full transparency. The next most popular entry, which was selected to be the name for the campaign, was *Vive Sin Duda* (“Live Without Doubt”).

Thematic Analysis

A total of 3 themes emerged from the crowdsourcing entries. In [Table 1](#), the themes are presented in order of most to least relevant entries. Although the majority of campaign names related to only 1 theme, many entries touched on more than 1 of the 3 themes through their suggested campaign name, hashtag, and call to action.

Table 1. Thematic analysis of crowdsourcing entries.

Themes and subthemes	Number of con-test entries ^a	Mean judges' score (range) ^b	Examples
Collective efficacy			
Community effort	25	90.1 (72-114)	<i>Juntos contra COVID-19</i> ("Together against COVID-19"). <i>Todos unidos</i> ("Everyone united").
Taking care of each other	7	90.6 (59-111)	<i>Nos cuidamos entre todos</i> ("We take care of each other"). <i>¡Yo te cuido y tú me cuidas!</i> ("I take care of you and you take care of me!").
Perceived benefits			
Ending COVID-19	11	105.3 (72-161)	<i>Por un mañana sin COVID-19</i> ("For a tomorrow without COVID-19"). <i>Hazte la prueba. Vivamos sin COVID</i> ("Take the test. Let's live without COVID").
Protecting others	9	83.9 (59-103)	<i>Hagamos hoy por nuestra familia</i> ("Let's do it today for our family"). <i>Tu salud es primero. Cuidate y cuida a los demás. Haste la prueba</i> ("Your health is first. Take care of yourself and others. Take the test").
Saving life, preventing death	8	81.3 (75-89)	<i>Salvando vidas</i> ("Saving lives"). <i>Ningún contagiado más y menos funerals por COVID-19</i> ("No more infected and fewer funerals due to COVID-19").
Knowing your status	8	92.8 (74-115)	<i>Vive sin duda</i> ("Live without doubt"). <i>¡Siéntete como nueva! ¡Haste la prueba!</i> ("Feel like new! Take the test!").
Self-Efficacy			
N/A ^c	16	95.0 (72-115)	<i>Luchadores de COVID-19</i> ("COVID-19 fighters"). <i>Ama, confía y protégete</i> ("Love, trust and protect yourself").

^aSome entries are counted in more than 1 category. A total of 6 entries were not included under the themes in this table, including the following: *El COVID-19 no es un juego* ("COVID-19 is not a game"), *Pruebas gratis de COVID-19* ("Free COVID-19 tests").

^bTotal scores for each entry could range from 18 to 180.

^cN/A: not applicable. There is no subtheme for this category.

Application of Themes to the Social Marketing Intervention

We shared the 3 themes with our social media partner to develop advertisements that would resonate with the local community. These themes were integrated into the *Vive Sin Duda* ("Live without a doubt") campaign, hereafter referred to as the *Sin Duda* campaign. Campaign messaging was initially focused on COVID-19 testing but was then adapted to include advertisements on vaccines and COVID-19 variants; we

continued to incorporate the 3 themes as messaging topics evolved with the pandemic. Figure 2 provides an example of an advertisement based on the theme of collective efficacy, created in response to the emergence of the Delta variant in fall 2021. An example of messaging based on the theme of perceived benefits with a focus on protecting oneself and one's family is displayed in Figure 3. In fact, we found that these advertisements were among the highest performing in terms of reach and engagement in comparison to advertisements created independently by the design team.

Figure 2. Advertisement aligned with theme of collective efficacy ("The delta variant may be strong, but not as strong as our community!").

Figure 3. Advertisement aligned with theme of perceived benefits ("By getting vaccinated I'm not only protecting myself, but also my family.").

Discussion

Principal Results

Overall, we successfully crowdsourced to guide the messaging for a COVID-19 social marketing campaign for Latinos in Maryland. The winning entry, *Vive Sin Duda*, has since been used for the development of a public health campaign and website [33]. The *Sin Duda* campaign initially focused on COVID-19 testing and, after the approval of the COVID-19 vaccine, subsequently expanded to include vaccination information. This study fills an important gap in the literature as we are the first team to document how to tailor crowdsourcing open contests to Latino populations, especially in response to a public health emergency.

First, in a 2-week period limited by the urgency of the COVID-19 pandemic, we received 74 eligible entries, which were scored by a panel of community judges and a popular vote. The brief duration and specific audience make this project difficult to compare to the existing literature as most published

studies were conducted over longer durations of time, with larger populations, and did not focus specifically on Latino populations [16,21]. Compared to contests of similar scope, however, we achieved a similar number of entries [27,34]. We succeeded in soliciting relevant Spanish-language entries from local immigrant community members through targeted CBO recruitment. Given the diversity within Latino populations, it is important to tailor recruitment strategies to reach a specific community through the careful selection of partnerships, platforms, and language. For example, although platforms like Instagram and Tiktok have surpassed Facebook in use among younger populations, our experience has taught us that for Latino immigrant adults in Baltimore, Facebook, and specifically CBO Facebook pages, are most effective [26].

Second, we identified themes that may be useful for future public health campaigns or initiatives that seek to address COVID-19 testing and prevention for Latino populations. The most popular theme, collective efficacy, has been shown to facilitate addressing other health conditions, such as obesity, in Latino populations and has been associated with the potential

to reduce health care disparities [35,36]. Another theme that emerged was that of the perceived benefits of COVID-19 testing, mainly the ability to protect oneself and others. The importance of protecting one's family has emerged as a common driving force among Latino populations, including among young Latino fathers [37].

The final theme that emerged was self-efficacy, defined as an individual's belief in their ability to plan and execute a course of action [38]. Self-efficacy is a well-known predictor of positive health behaviors across races and ethnicities, including behaviors related to nutrition, physical activity, medication adherence, and HIV testing [39-41]. Recent media coverage of the impact of COVID-19 on Latino populations has often focused on vaccine hesitancy. Our team has found that in addition to addressing intersectional factors that drive vaccine hesitancy, it is important to include strength-based messaging along the theme of self-efficacy, as opposed to deficit-based messaging, while concurrently removing barriers to care [42-44].

Our novel approach of using thematic analysis to directly inform campaign materials resulted in advertisements with high performance and reach. Crowdsourcing open contests offer a low-cost and prompt way to solicit community perspectives and facilitate community-engaged interventions. The findings from this study provide a timely opportunity to document community-driven strategies to make COVID-19 services more accessible and acceptable to marginalized communities.

Given the lack of publications on crowdsourcing open contests focusing on Latino populations, particularly for COVID-19 initiatives, this manuscript provides an important addition to the literature and may guide future crowdsourcing initiatives in similar populations. By building the *Sin Duda* campaign on the foundation of community input, we not only arrived at a name but also elicited key perspectives within the community that helped guide the creation of successful messaging throughout the campaign.

Limitations

This study has noteworthy limitations. First, although the web-based form facilitated prompt participation and voting, this modality inherently excluded community members who lacked internet access. We selected the web-based modality based on high internet and smartphone use rates among Latino individuals as this is the target audience for the social media campaign [18,19]. However, this contest may have excluded people from more disadvantaged backgrounds who lack internet access or are not engaged with CBOs and are disproportionately impacted by COVID-19. Second, given the short duration of the contest, the number of entries and therefore viewpoints were limited. We tried to optimize community input by using a public vote to choose the winning entries, and we ensured that all campaign messaging incorporated community viewpoints based on input from the CAB and community members obtaining COVID-19 testing. A further limitation is that the entry with the most popular votes was not a feasible choice as it was already in use for another COVID-19 campaign for a Latino audience. We navigated this issue with the guidance of the CAB and thus announced a tie for first place after openly discussing the rationale with the winners. In future contests, all entries should be checked upon submission such that any options that are not original may be disqualified early on to avoid confusion. Lastly, although our findings support the use of crowdsourcing, more rigorous evaluations through randomized controlled trials are needed to compare the effectiveness of crowdsourcing approaches to noncrowdsourcing approaches in campaign development [45,46].

Conclusions

Crowdsourcing is an effective means of community engagement and an agile tool for guiding interventions to address COVID-19, including in populations affected by health care disparities, such as Latino communities. In considering the role of crowdsourcing in community-engaged research, the thematic analysis of contest entries is a useful and timely way of understanding community values such that they may be prioritized in the content of the intervention.

Abstract

Background: The emergence of the novel coronavirus (COVID-19) has introduced additional pressures on an already fragile mental health care system due to a significant rise in depression, anxiety, and stress among Canadians. Although cognitive behavioral therapy (CBT) is known to be an efficacious treatment to reduce such mental health issues, few people have access to CBT in an engaging and sustainable manner. To address this gap, a collaboration between the Centre for Addiction and Mental Health (CAMH) and the National Research Council of Canada (NRC) developed CBT-based self-led, online, clinician-tested modules in the form of a video game, named Legend of Evelys, and evaluated its usability in the attenuation of a COVID-19–related increase in stress.

Objective: We here present the conceptualization and design of new self-care modules in the form of a video game, its implementation in a technological infrastructure, and inclusivity and privacy considerations that informed the development. A usability study of the modules was performed to assess the video game’s usability, user engagement, and user perceptions.

Methods: The development of the video game involved establishment of a technology infrastructure for secure implementation of the software for the modules and a clinician-led assessment of the clinical utility of these modules through two “whiteboard” sessions. The usability study was informed by a mixed methods sequential explanatory design to evaluate the intervention of the mobile app through two distinct phases: quantitative data collection using in-app analytics data and two surveys, followed by qualitative data collection by semistructured interviews.

Results: A total of 32 participants trialed the app for 2 weeks. They used the video game an average of six times and rated the game as “good” based on the Systems Usability Scale score. In terms of stress reduction, the study demonstrated a significant difference in the participants’ Perceived Stress Scale score at baseline (mean 22.14, SD 6.187) compared with that at the 2-week follow-up (mean 18.04, SD 6.083; $t_{27}=3.628$, $P=.001$). Qualitative interviews helped participants identify numerous functionality issues and provided specific recommendations, most of which were successfully integrated into the video game for future release.

Conclusions: Through this collaboration, we have established that it is possible to incorporate CBT exercises into a video game and have these exercises adopted to address stress. While video games are a promising strategy to help people with their stress and anxiety, there is a further need to examine the real-world effectiveness of the Legend of Evelys in reducing anxiety.

Introduction

Background

Stress levels and anxiety are elevated at a population level during crises. The impact of COVID-19 being declared a pandemic predictably had a negative effect on the mental health of many Canadians. Researchers worldwide have shown that the mental health of the general population has deteriorated since the onset of the pandemic, with significant rises in depression, anxiety, and stress [1-3]. Approximately 19% of Canadians reported experiencing moderate to severe anxiety and 19% reported feeling depressed occasionally since the start of the pandemic [4]. Even prior to the pandemic, anxiety disorders were among the most prevalent mental health problems in Canada [5], having a profound negative impact on life expectancy, quality of life, and health care utilization [6,7].

Cognitive behavioral therapy (CBT) has been shown to be an efficacious treatment to reduce anxiety [8-10], stress [11], and acute stress disorder [11,12]; however, few people have access to this treatment [13]. In efforts to make CBT more accessible, many Canadian institutions offer CBT online, which has been shown to be effective [11]. However, when CBT is provided online, there are more problems with adherence (completing the intervention to the extent that the developers intended it to be used) and engagement (the extent, both in terms of time and frequency, that participants visit the website/app) [14]. Video games are a promising solution to overcome many of these barriers [15], as they can provide a way of motivating and engaging users [16] and can promote adherence to treatment [16]. Video games have been found to be beneficial in reducing stress and anxiety among children, adults, and older adults, even in the instances of single or short sessions of play [17,18]. In 2020 alone, 35% of Canadians reported playing online video games and 10% reported playing for more than 10 hours a week [19]. A recent study found that playing video games has a positive effect on players' perceived well-being during the COVID-19 pandemic [18]. Furthermore, 84% of Canadians reported using smartphones for personal use daily [19]. Given that in the past decade smartphones have become a common possession, irrespective of gender, race/ethnicity, or socioeconomic status [20], disseminating CBT interventions via smartphones allows for greater, more equitable accessibility regardless of geographic and economic restrictions [21].

In 2020-2021, the National Research Council of Canada (NRC) and the Centre for Addiction and Mental Health (CAMH) developed a video game to help people reduce their stress in the context of COVID-19. The video game is a mobile role-playing game based on CBT principles, which supports users in building the necessary skills to take care of their mental health during a pandemic. The version of the video game used

in this study was in an early development stage with a short storyline and was limited to four CBT features.

In this manuscript, we describe the development of the video game as well as the results of a usability study, which assessed the video game's usability, user engagement, and user perceptions. We situate this work within the Medical Research Council guidelines for complex intervention research [22].

Development

As part of the development of this video game, two whiteboard sessions with eight clinicians were held virtually at the CAMH. The whiteboard sessions took place in two 1.5-hour meetings (July 22, 2020, and August 12, 2020). The main purpose of the sessions was for mental health experts to explore the platform, develop CBT and other evidence-based interventions and content, and provide creative feedback on the storyline and video game. The meetings with clinicians generated effective feedback, and encouraged collaboration and knowledge-sharing that were integral to the conceptualization and design of the video game. The first meeting focused on the demonstration of the first idea for the video game and elicitation of the clinicians' input. The second meeting focused on CBT content/activities planning and storyline development.

Initial recommendations from clinicians after viewing the demonstration of the prototype was that the video game should complement existing CBT resources. The team agreed that the context and characters included in the video game should be accessible, inclusive, and culturally diverse, and offer choice to the user. Discussion and feedback were provided on the multiple CBT strategies and other interventions or activities that would be useful to include, such as cognitive restructuring, mindfulness, and journaling. Other suggestions included to focus on positive feedback, conduct a needs and readiness assessment, create incentives/rewards, link exercise results to other exercises, and have peer-to-peer support built in/discussion board.

Prior to the second whiteboard session, the feedback from the first whiteboard session was consolidated and incorporated into another version of the game. The second whiteboard session included a demonstration of the updated features. The clinical team shared CBT strategies that worked in practice with their patient population, and brainstormed on the CBT tools that could be included in the video game and may be easier to gamify. The developers included a novel feature, a "cognitive monsters activity," which the team agreed was appropriate for the video game but further thought it would be important to provide some psycho-education and positive feedback on this cognitive monster feature. Cognitive monsters represent unhelpful ways of thinking (formerly known as cognitive distortions). The team recommended a "dashboard" feature based on the CBT model to provide a rationale and cohesive

narrative/framework (storyline) to make the app easier to follow for users. Other suggestions included: integration into the health care system, allow customizable affirmations, and prompts for goal setting. In general, the team liked how the content was presented but expressed concern about reaching the wider population.

After the two whiteboard sessions, two CAMH clinicians (RD and PS) outlined the CBT features that ended up being included, and the NRC (CD) came with creative ideas on how to gamify them in the COVID-19 context.

This video game, developed in Unity, involves a fantasy storyline centered on the experience of negative emotional states among citizens in a fictitious place, intended to mirror the experience of the COVID-19 pandemic and negative mental health outcomes. Unity is an industry-standard cross-platform game engine, which holds the largest market share for mobile game development. Players of the video game can customize their own avatars via a customization “closet,” where users can pick a skin color, choice of pronouns, hairstyle, and color and type of clothing, and then proceed through adventures in the village. The video game includes a storyline before entering the game screen, which narrates the concept behind the game. The video game allows for interactions between characters in the environment and dialog boxes appear prompting the user to engage in specific CBT-related exercises (see [Multimedia Appendix 1](#)).

Strategies

Overview

We included core CBT strategies such as cognitive restructuring, journaling, and tracking behaviors, as well as some additional evidence-based strategies such as mindfulness exercises and community support.

Cognitive Restructuring

An educational module was included, which intended to teach the user how to identify unhelpful ways of thinking (biased or distorted thoughts) by encountering “cognitive monsters” [23].

Exercises that would typically be proposed to participants in a cognitive behavioral program were transformed into confrontations with virtual monsters. Through multiple battles with the “cognitive monsters,” users learned about cognitive restructuring strategies. Monsters “attacked” the user with a statement, and the user had to correctly respond to that statement in order to deflect the attack. Monsters were transformed into tame creatures when participants responded to the monsters with more balanced statements (see [Multimedia Appendix 2](#)).

Journaling and Goal-Setting (Behavioral Activation)

A journaling and behavior-tracking feature called the “blue book” was included in the design [24]. The journal allowed free-form entries, where users could reflect on their mental health and write down their thoughts. The goals module in the journal allowed users to set and check personal goals (free-form entry) or select from a list of predefined daily goals (daily activities).

Breathing Meditation (Mindfulness)

A guided breathing activity was included, named the “breathing sphere” [25]. The “breathing sphere” exercise guided the user through a paced breathing sequence with various customizable options for pace, duration, music, and art.

Community Support

The community support module enables interactions with characters who experienced mental health issues and suggests coping mechanisms.

Characters in the virtual environment of the video game embodied different user stories related to their experiences during the COVID-19 pandemic. Through conversations with the player, they presented their own mental health challenges and proposed coping strategies. These stories were inspired by the main issues identified in the COVID-19 National Survey Dashboard from May 2020 to December 2020 [26].

Connectivity

Together, the CAMH and NRC articulated the necessary technological infrastructure parameters for hosting the video game app. This included a cloud-based online microservices RESTful interface and a database to collect anonymized usage analytics. The user service was used for login and user management. After login, usage data were sent via the user entry service. Later, administrative users fetched the data and received a JavaScript Object Notation (JSON) file. Working with personnel from the CAMH’s Informatics Department, an internal security analysis of the NRC modules was conducted as well as a third-party Privacy Impact Analysis and Threat Risk Analysis. Overall, no critical severity vulnerabilities were found within these infrastructures, which confirmed that the security controls and measures were properly implemented. All necessary security risk findings from these assessments were configured prior to the start of this study.

Inclusivity

The need for an inclusive and accessible experience led the game design process along three axes: diversity, accessibility, and technological capacity. In addition to providing avatar customization, the game also featured a diverse cast of characters. Avatars and characters can be customized with four skin colors; custom hair color; multiple hairstyles, including hair coverings; and three choices of pronouns (male, female, and nonbinary). Accessibility features included high-contrast user interface elements, large fonts and buttons, and voice-over for dialogs. In addition, two navigation modes were available to provide alternate modes of moving the character: an on-screen joystick and a “click on destination” mode. The design team also validated that the game was usable with a variety of adaptive styluses.

In terms of technological capacity, care was taken to support older operating systems (minimum Android application programming interface level 19) so that usage of the game would not be limited to users with high-performance devices. This was a decision that needed to be taken at the very beginning of the design stage, as it determined the features and libraries available for development. In addition, the game did not require

continuous connectivity, and data usage could be restricted to take into account the cost and possible unavailability of cell phone data in remote communities.

Balanced Use and Privacy

Given the concern about the abusive use of video games and the potential vulnerability of our users, care was taken to avoid features that might cause users to overuse the game, such as random treasures with variable value (“loot boxes”). The game could be stopped at any time with no loss, and the core game loop was designed for short sessions.

Care was also taken to respect the sensitive nature of participants’ input into the game. The app did not ask for access to the device’s GPS, camera, microphone, contacts list, gallery, or any other feature that could breach confidentiality. In addition, all personal fields (diary, custom goals, personal thoughts and concerns) were encrypted on the device and were not included in the collected analytics data.

Future versions of the video game will incorporate additional features to encourage balanced play, such as pause prompts, rewards for coming back after a hiatus rather than punishment for breaking a streak, and features that require calendar time to advance to encourage frequent check-ins rather than long sessions.

Methods

Study Design

For this usability study, we utilized a mixed methods sequential explanatory design, which consisted of two distinct phases: quantitative data collection and analysis followed by qualitative data collection and analysis [27]. The qualitative (semistructured interviews) data help explain and put in context the quantitative results obtained in the first phase.

Ethics Approval

The study was approved by the CAMH Research Ethics Board (111-2020).

Participants and Recruitment

We used a purposive sampling approach with the aim of recruiting a diverse group of 40 participants from different ages and genders. Participants who were (1) 18 years or older, (2) owned an Android smartphone or tablet, (3) were willing to provide an email address, (4) were able to read and speak English, and (5) self-reported stress were eligible to participate in the study. Participants were excluded if they had any severe psychiatric illness that could impact the consent process.

We stratified our recruitment by age and gender identity. Our aim was to have representation from people of four different age groups (18-28 years, 29-39 years, 40-50 years, 50 years or older) and different gender identities. We aimed to recruit 10 participants in each of the age categories with representations from the different genders.

Participants were recruited using several cost-free strategies, including advertisements on the CAMH Nicotine Dependence Clinic website (a unit within the CAMH where the study was

conducted), Kijiji, and Twitter. Interested participants emailed or called the research coordinator as instructed on the study advertisement and completed a screening call to assess eligibility. Eligible participants completed a consent discussion call with the research coordinator and were emailed a copy of the consent form to sign if they agreed to participate. All participants provided digitally signed informed consent prior to initiating the study.

Study Procedure and Data Collection

After screening and consent procedures, participants completed an online baseline survey and were given access to the video game. Participants were asked to notify the research team once they had successfully downloaded and logged into the video game. A 15-minute check-in phone call was set up within the first week of the study, during which the participants could ask the research team any questions they had about the video game following their initial use. Two weeks after receiving access to the video game, participants completed an online follow-up survey and participated in a semistructured interview. The semistructured interview was conducted over the phone and lasted approximately 30 minutes. They were paid CAD \$35 (approximately US \$28) for completing all surveys and participating in the semistructured interview.

In the baseline assessment, participants completed measures of their sociodemographic characteristics, perceived physical and mental health status, substance use activities in the past month, and subjective stress levels. Subjective stress levels were assessed using the widely used Perceived Stress Scale (PSS-10) developed by Cohen Sheldon [28]. This 10-item validated tool has good internal reliability (Cronbach $\alpha=.78-.91$) and is scored on a 5-point Likert scale ranging from 0 (never) to 4 (very often) [28,29]. Scores in the range of 0-13 are considered to indicate low perceived stress, scores in the range of 14-26 are considered moderate perceived stress, and scores in the range of 27-40 are considered high perceived stress.

The follow-up survey also collected the following information: (1) subjective stress levels using the PSS-10; (2) measures of usability of the video game, using the System Usability Scale (SUS) [30]; and (3) overall satisfaction and perceptions about the video game. The SUS is a 10-item measure assessing usability and user satisfaction with technology. The average SUS score for most technology is 68 at the 50th percentile. An SUS score greater than 68 is considered above average or “good,” whereas a score below 68 is considered below average or “poor” [30]. Overall satisfaction and perceptions were assessed using three 11-point Likert-scale questions in the survey: (1) overall satisfaction with the video game (0=not satisfied at all and 10=extremely satisfied), (2) burden of using the video game (0=not a burden at all and 10=extremely burdensome), and (3) the impact of the video game in reducing stress (0=did not help at all and 10=helped a lot).

All participants were scheduled for a 30-minute semistructured interview over the phone or a video conferencing system. Qualitative semistructured interviews were used to further elaborate on the usability of the video game and to explore how it could be improved. Usability was defined as the degree to which a program can be used easily, efficiently, and with

satisfaction [31]. Participant ideas on how the video game could be improved were also explored. All interviews were audio-recorded and transcribed verbatim.

The CAMH server collected in-app analytics data on the use of the video game, such as the number of times participants opened the video game, number of times they used each component of the video game, and time spent engaged in those exercises. The app also collected general metadata about the device, such as the device model and operating system. Participants were asked to connect to a Wi-Fi network at the end of the 2 weeks of the study to transfer the analytic data onto the CAMH server.

Analysis

Quantitative data were analyzed using SPSS (version 25). The SUS questionnaires in the follow-up survey was analyzed using scoring guidelines provided by the US Department of Health and Human Services [32]. Scores for each question were converted into a new number, summed, and then multiplied by 2.5 to obtain a score between 0 and 100, which informed the usability of the video game. Descriptive statistics are used to report sociodemographic characteristics, usability, and engagement. The PSS-10 was analyzed by first reversing scores for four of the positive items on the scale and then summing across all 10 items to obtain a score between 0 and 40 for each participant. A paired-samples *t* test was then used to compare subjective stress at baseline and after 2 weeks of trialing the video game. The data from the app logs were exported, tabulated, and analyzed using descriptive statistics with tools from Microsoft Excel.

Qualitative data analysis for the study involved an iterative, team-based process. Transcribed interviews were entered into

NVivo 12 for qualitative data management and analysis. Interview transcripts were read multiple times by two research staff to achieve immersion prior to code development. One author (AG) crafted the initial codebook, and then AG and AS jointly coded the first four transcripts to refine the codebook and defined the codes through consensus. Two other transcripts were coded independently by AG and AS and the calculated interrater reliability was 80.2%. Remaining transcripts were independently coded either by AG or AS. Data were analyzed using thematic analysis [33]. A deductive approach was utilized to identify the coding scheme for the transcripts, which allowed for the development of codes corresponding to the components of usability and stress management.

We first analyzed our quantitative data, which helped to inform some of the probes we used when conducting the interviews. After we analyzed the interviews, we merged the results from both analyses (quantitative and qualitative) to provide a full interpretation of participants' perceptions of the video game.

Results

Participants

A total of 185 individuals contacted the research team after coming across the advertisement for the study (Figure 1). Eighty-nine individuals were screened for eligibility and the remaining 96 individuals were unreachable after the initial contact. A total of 32 participants completed the study by trialing the app for 2 weeks and completing the baseline assessment, follow-up survey, and qualitative interview. Participants' sociodemographic characteristics and descriptive statistics for all baseline variables are presented in Table 1.

Use of Video Game

In-app analytic/usage data were collected from 31 of the 32 participants. Analytic data from one participant were missing as they did not connect to a Wi-Fi network to transfer the data onto the server. Of the 31 participants, a few participants' data on time spent within the video game were inaccurate due to app

issues and were therefore omitted from the analysis where applicable.

During the 2 weeks participants were asked to use the video game, it was used a mean of 6 times (SD 8.75, range 1-47; n=31) and for an average of 21 hours (SD 33, range 0-147 hours; n=30).

In terms of the CBT features included in the video game, participants interacted with the characters in the video game an average 24 times (range 0-171) and spent an average of 10 minutes (SD 7.33; n=28) on the game. Participants completed exercises related to cognitive restructuring (wererabbits) an average of 10 times (range 1-48) for an average of 9 minutes (SD 11.25; n=28). The mindfulness exercise (the breathing sphere) was used an average of 4 times (range 0 -18) for an

average of 10 minutes (SD 20.04; n=30). The average usage of the behavioral activation activities (journaling) was approximately 4 times (range 0-27) and participants spent an average of 40 minutes (SD 184.37; n=30) on these activities. On average, males and people over the age of 50 years used the video game more than people under the age of 50 years. The frequency of participant interaction with specific activities is shown in [Table 2](#) by age and in [Table 3](#) by gender.

Table 2. Analytic data of video game usage in sessions by age group.

Age group (years)	Participants, n	Total sessions of app usage		Journal sessions		Guided breathing activity sessions		Educational module sessions (ie, “cognitive monsters”)		Interaction with characters sessions	
		Mean (SD)	Range	Mean (SD)	Range	Mean (SD)	Range	Mean (SD)	Range	Mean (SD)	Range
18-28	10	2.9 (1.29)	1-4	1.1 (1.73)	0-5	1.5 (1.58)	0-4	4.5 (3.54)	0-10	8.7 (5.12)	1-16
29-39	9	5.6 (3.50)	2-12	2.6 (3.430)	3.430-11	4 (5.66)	0-18	14.6 (16.32)	0-54	19.7 (20.14)	0-62
40-50	5	4 (2)	2-6	3.4 (2.19)	1-7	4.8 (2.77)	2-9	10.6 (4.77)	5-17	18.4 (12.54)	8-40
50+	7	13.3 (17.1)	3-47	9 (10.02)	1-27	6 (5.45)	0-15	14.3 (13.3)	0-38	48.4 (57.06)	10-171

Table 3. Analytic data of video game usage in sessions by gender.

Gender	Participants, n	Total app usage sessions		Journal sessions		Guided breathing activity sessions		Cognitive monsters sessions		Interaction with characters sessions	
		Mean (SD)	Range	Mean (SD)	Range	Mean (SD)	Range	Mean (SD)	Range	Mean (SD)	Range
Male	13	7.7 (12.18)	1-47	4.5 (7.48)	0-17	4.2 (5.2)	0-18	4.5 (3.54)	0-10	13.2 (14.18)	1-171
Female	17	5.1 (5.83)	1-26	3.1 (4.55)	0-19	3.1 (3.69)	0-15	8.2 (9.23)	0-38	14.1 (14.26)	0-66

Participants’ comments during the interviews shed some light on the variability observed in the use of the video game. It is possible that participants who used the game more frequently did so because it was relatable to their circumstances: “I mean, it’s pretty relatable” (Female, age 25), “...you could see areas of where it would apply to any anyone, you know?” (Male, age 72).

They also mentioned that they liked the diversity of the characters and could relate to the scenarios being presented:

Like, for example, when I was talking to the lady and she was explaining how they couldn’t have visited her for a while...her family members. It did come like it’s something that I correlate to my own story... I did come to realize that, hey you know what? It’s not me only. Different people are going through different troubles in their life under this pandemic and obviously...different people are being affected in a different way. [Male, age 28]

However, participants who did not use the game very frequently thought that the content and design did not apply or seem relevant to them:

I mean, you know a lot of times it didn’t apply to me as a person. I guess I would have liked something where it was more...I know you can’t do it, but more of a live chat where I’m saying, I’m feeling this way, and then it would be more like...okay let’s see what we can do to help you, you know what I mean? So

more of that versus the stock, kind of, things and stuff. Like to appeal to me as an adult, you know? And depending on the age category that this is being marketed to, I mean, if it’s a younger, yeah, it would be fine as is, totally, you know? But people that are older, like myself, have dealt with plenty as most older people have that...people as they’ve gotten older have. I just want more challenges so I really would have to think and strategize and think, okay, this is what I would do and if I want to be positive and, you know...um, and I want to conquer the negativity this is what I got to do, you know? [Female, age 54]

I noticed that there was a theme just related to COVID there in it...and some of it is relatable and some of it isn’t...I think there was a bit of a limitation in that feature. Like when going back to work and putting myself and there or sending kids to school. Like those don’t apply to me so... [Male, age 28]

Participants also mentioned that they enjoyed being able to select their avatars and make the avatar look like them, and they liked the diversity (n=15) of the avatar options:

I mean, that was the first thing that I did when I opened the app. Um, I really...I enjoyed that probably the most right at the beginning...I enjoyed having my little character, and it looked like me, running around the island. [Female, age 31]

I really liked the diversity in the other avatars that were there. So to be able to customize my own avatar,

I feel like that's nice and like that's a bonus. ...make it a male or a female, you know, make it a different skin color; be able to wear a different color of clothes 'cause, you know, like I feel like colors also calm me down. So if I see a lot of bright colors, I don't like it. I like it light coloring. So, I would definitely personalize it to like a white or something like that to just, again, calm me down and like, you know, I can release my stress basically. [Female, age 25]

Several participants (n=20) also mentioned they would have used the video game more often if there was more variety in the activities, if the activities were more interactive (n=10), and if there were additional levels (n=10). Participants recommended having increased complexity in the video game in terms of unlocking levels and having a sense of progression over time with the advancing levels (n=10):

Uh, but I think it could improve if there were more stress related exercises. More like that breathing exercise. That helped me... to bring down my stress, to you know, have my, um, let's say my breath more normal. It helped me to relax but ...it's like okay, what else? I want to learn another exercise and there are no more exercises. [Age 50]

The star system made no sense to me. It seemed pointless. I just need progression. I just need to continue going forward. Um, I'm not into stuff...or just like constantly battling the rabbits, getting knocked down. I think there's eight or nine of them on that little island, and you bring them back down to normal rabbits, you turn off the app, you open it back up, and they're all back there...kind of deterrent. So just some sort of forward progress. [Male, age 30]

Usability of the Video Game

After 2 weeks of using the video game, participants reported a mean SUS score of 73 (SD 17; median 76, IQR 43-95; N=32). Almost two-thirds of the participants (21/32, 66%) scored greater than 68 on the SUS tool, indicating a score above average. Specifically, the majority of the participants (28/32, 88%) found the video game easy to use and believed that most people can learn to use the video game quickly. The majority of the participants did not find the video game to be too complex (26/32, 82%) or cumbersome (24/32, 75%). The video game scored lower on being inconsistent to use (63%, 20/32) and being well-integrated (17/32, 53%). Participants were divided on how often they would like to use the video game; 28% (9/32) of participants reported they would like to use it frequently, 34% (11/32) disagreed with this statement, and 38% (12/32) were neutral.

When we asked participants about the usability of the video game during the interviews, the responses echoed the quantitative findings; the majority of participants reported that the video game was easy to use (28/32, 88%) and easy to learn (28/32, 88%).

However, many participants shared some functionality issues with the video game, which could explain why it scored lower in the SUS scale with being consistent to use and with being

well-integrated. The most common complaint was the login process. Nineteen participants (out of the 32 we interviewed) mentioned experiencing issues with the password and login process. There was some indication the preference would be to have a login and password that could be easily remembered or saved; the experience of having to copy and paste the password limited their ease of access to the video game. Participants mentioned that immediate access would be preferable during times of stress:

...the annoying part was at...it doesn't save your username and password...because the password is like this long thing, I had to keep copying and pasting it...and then the username, I just had to like remember it and that that like turned me off from using it. Like if it if it saved your login, that'd be much easier, like when you're stressed, you can just click on it and go in. But then it stresses you more out to have to go into your notes on your phone and copy and paste the password. [Female, age 23]

Another common complaint was not being able to find instructions on how to navigate the video game and a lack of detailed descriptions of the features:

So, for me, it would have been helpful if maybe there was some signs or labels, um, or arrows or something like that to kind of help me move around the app so I could go back to these favorite things that I like to do, [Hmm, hmm] uh, 'cause I found...I did get kind of lost a couple times. [Female, age 31]

These complaints were expressed by participants across all age groups and genders as well as stress levels.

Another finding from the interviews was that many participants were unaware or were unable to find certain features of the video game. For example, a number of participants mentioned that they would have liked to customize some aspects of the video game, including changing the music, joystick, and timing for the breathing sphere, which were all features that were already present. Therefore, the video game settings were not visible or readily accessible to the participants.

The SUS result showing that participants were divided in how frequently they would like to use the video game was partially explained by how they perceived the design and why they were using the video game.

In terms of the design, some participants expressed that they found the design appealing (n=17) while others did not (n=15). Their like or dislike of the design was linked with how frequently they would like to use it. Of those who liked the design, they found the video game to be “creative,” “appealing to the eye,” and “liked the 80s vibe, the nostalgic, happier times.” Participants who did not like the appearance of the app remarked that it was not sophisticated, “rudimentary,” “amateur,” and not “polished.” Two participants thought that the characters needed to be more realistic in 3D and less pixelated and clunky.

I liked the cartoon aspect. ...there's a lot of different games and apps that are so focused on their graphics...that it's just like it's too overplayed. I liked

the kind of like fantasy world. I like the cartoony stuff. It is...it just sets a different tone. You know that you are not necessarily yourself and you get like a break from, uh, reality type thing. So it's just...I like that concept. I liked the outlook and the way everything was laid out...So it was good. [Male, age 30]

But they look...I mean, I prefer a little bit more intensity in the character...just more advanced looking, you know, in terms of the character designs...they have little...kind of jaggedy. Like, because of the way it's designed, the characters. I just prefer it being a better...better in quality, I guess...of design...it looks too...like not current, you know, in terms of design, um, and that's the coding, I guess. I just want them to look more sophisticated and more modern, even though it's a it's a quaint village. It's just the coding, uh, the programming of it... [Female, age 54]

We found that participants' experiences with the video game varied depending on their motivations for using it. For example, those who specifically sought to explore strategies for addressing stress and anxiety (n=23) found that certain features were useful or helpful in dealing with their stress, or if it was not useful, that it was a feature that could potentially be useful to others. For those who were curious or interested in the gaming aspect (n=7), we found that they did not engage with the features to any great extent and therefore did not like the features or find them to be useful.

...definitely I liked the fact that the...it is in the format of a game, uh, which I can control. Um, the other feature I really liked was how it would give me different stress coping methods or like different techniques, um, to try out and see if it can really help me with stress management...cause, as I said, you know, um, the reason of feeling stress was, you know, when you're alone in COVID, you don't get to go out with your friends. So I guess I was...with the use of app, I was using it as a friend, [Hmm, hmm] um, to kind of have conversations with those different, um, you know...the people that were in the app and, uh, just exploring the different areas and, you know, exploring what activities are in built in the app... But, yeah, overall, it's a great, creative app, which will...I feel will really help out, um, people in terms of stress management. [Female, age 25]

Table 4. Perceived Stress Scale scores at baseline and follow-up (n=28).

Time point	Mean (SD)	Range
Baseline	22.14 (6.19)	10-33
2-week follow-up	18.04 (6.08)	6-29

During the interviews, some participants thought that the video game was “great” for “winding down” and found that the video game offered a distraction (n=5), particularly from everyday life, and the gaming feature was engaging.

...like it was too obvious that it was, you know, um, not a game. There was, you know, very like okay, all right, this is an educational thing. This isn't actually meant to be fun. It's just trying to teach you something....like I didn't read it in depth. I was more okay with, you know, a quest for me or are you going to give me an item or something like that. So, I clicked through it and I didn't get anything, so I think that was it. like I'm not really getting much out of this. [Male, age 23]

Several participants (n=15) said they may reengage if improvements were made, including more interactions, better defined goals, and having more levels:

Well to be honest, if it is kept as is, I'll be honest with you I don't think so I'll be using it much. Maybe once in a blue moon but obviously if the app is updated and like I said you have more interaction and the overall aspect feels more connected, sure like maybe even once a day I wouldn't mind just for like two or three minutes in between breaks just to have refreshing change in scene basically. [Male, age 28]

...I didn't continue to engage because it would just say the same thing. I think that if they said something different, like depending on the day of the week, and they had like more things to say, then I would go to them... [Female, age 23]

Perceived Stress

Twenty-eight out of the 32 participants completed the PSS at baseline and follow-up. To compare the baseline PSS score to the follow-up PSS score, we conducted a paired *t* test using SPSS.

Results indicate that there was a significant difference in the participants' PSS score at baseline compared with that at the 2-week follow-up ($t_{27}=3.628$, 95% CI 2.785-6.430; $P=.001$; Table 4). The mean difference between baseline and follow-up PSS score was a decrease of 4.1 points and a medium effect size of $d =0.67$.

However, results from the question “To what extent do you think this app reduced your anxiety?” showed that most participants found the app to be neutral in reducing anxiety with a mean score of 4.59 (SD 2.769, range 0-10)

...because it is sort of like a distraction, if you know what I mean? ... So it was...it was useful I would say. It was actually useful too. [Male, age 39]

It just gave me those couple seconds to kind of calm down, think, and not be so wound up. [Male, age 30]

In the interviews, participants suggested that the “breathing sphere” had the most direct impact on their stress reduction (n=13), and that it was a skill they incorporated into their lives, even when they did not use the video game. The other features seemed to help in terms of providing a distraction.

When you breathe in and then it will shrink in size indicating when to breathe out. I think that was probably, in terms of stress reduction...that was probably the most important feature of the whole app because that was when I could feel that, okay, this is really designed to help me in terms of stress levels. And I think that was probably my favorite feature of the app as well. And, uh, I found it useful actually in in that goal as well for reducing stress. Maybe not a...maybe not too much but a little bit it did...I feel reduce a little bit of my stress. [Male, age 39]

...the breathing exercise just kind of helped me focus and it did a really good job with me using that app and not being distracted with other stuff in the room and helping me slow my breathing down and take some deeper breaths. It seemed to kind of relax my body quite a bit, which was nice. ... even though I wasn't using it, what I remembered was the breathing and then...I was deepening my breathing and kind of doing slow breathing. So it was the one that impacted me the most even when I wasn't using the app, I remembered about it and I did deeper breathing, slowing breathing. So it reduced my stress the most. [Female, age 31]

While there was recognition of the cognitive restructuring and community support in the video game through combating the wererabbits and interaction with the characters, respectively, only a few participants specifically mentioned that they found it to be effective in addressing their stress. Others found it to be a fun, distracting activity.

I think one of my favorites was probably like the understanding yourself through the characters and, um, and how psychology was kind of integrated into the storyline like for example, cognitive restructuring. That's something I knew of but I didn't know what it was called like it just made me realize and getting to know myself better and the way I think. And putting the name to that and that was interesting. But, um, at the...in terms of the interactions themselves and, and the tips that they provide, they were useful in understanding your feelings. [Male, age 28]

...the six monsters that...evolved from rabbit...and they kind of like, uh, represent...stressful ideas that you may have, uh, psychologically. So in this case, you are able to try to correct your thoughts in order to relieve the pressure. So I think in this way...I mean the steps seem very good...when I to try to fight each of the monsters into rabbits, I find that there's actually kind of thoughts and family experience about how hard it is. But in that case those are other stressful situations but once you fight the monsters you'll be able to find your correct thoughts I believe and they

help you to relieve your stress. So those are the useful steps. I think it's very good for young people and the older people if they are very stressful. [Male, age 25]

There were also various perspectives about behavioral activation features, which included the journal and goal-setting exercises. Some participants (n=16) thought that the features were helpful and that it helped them reflect and reduce their stress:

I could look back and see what I wrote and just like, oh yeah, that was kinda crappy that day... Or maybe cause it was raining out and it minus two and I was just not happy or whatever. But, yeah. I could reflect on the past journals which was helpful. I found that more kind of helpful than maybe writing for the day although when I wrote for the day, I would write all like...like that's where I'd write everything, so I was kinda dark. Like, I wasn't like looking optimistic...if I was negative, I'd blurt it all out. If it was, uh...you know, if I was mad at somebody I'd blurt it all out like I didn't hold back so that was the place to do it rather than, you know, carrying it with me. So, yeah. Oh, yeah. It did. It helped me [with stress], uh...yeah. There was stuff I wrote, and I'd look back and go yeah, okay I keep saying I'm going to do this so now I gotta do this. You know, so it challenged me. Yeah. The whole put up or shut up kinda thing. Right? Um, I found that was good [goal-setting] because I put some stuff on there that I never really have done recently in the last...not just COVID, just in my life so I thought, you know, no I'm going to write things in there that I'm going to maybe make a life changing, you know...like just to try and alter my whole mindset so, uh, yeah I found it...I mean I'm still...there's still a couple of goals that I haven't hit but I'm keeping them there just to, you know, maybe one day I'll be able to get past it. [Male, age 56]

Most participants who did not use behavioral activation features (the journal) thought that it could potentially be helpful to others:

So I would say I didn't use it. I wasn't too frequent in using it. But they were okay. Like there's nothing wrong with them when they're just for other people. I personally don't use journals and like activity. Like I don't really note things down like that...uh, like in a book or somewhere, so on a...I mean it in in one way you could say that that really didn't attract my attention either. [Male, age 39]

Discussion

Principal Findings

This manuscript describes the development and usability of a video game designed to help people reduce their stress during COVID-19 by gamifying CBT features. A variety of clinical recommendations were derived from the whiteboard consultations, where the results directly informed the game content, including having exercises related to behavioral activation, cognitive restructuring, mindfulness, and community supports. Further, the developers were mindful about developing a game that did not have addictive qualities, followed strict

privacy requirements, did not involve an intent to commercialize (in order to maximize uptake and help as many people as possible), and was developed with inclusivity and ethical standards. Having these features in place might help with the adoption and longevity of the video game following the pandemic [34]. In particular, ensuring privacy concerns were met and that the video game was not addictive were particularly important, since several researchers have highlighted the need to enhance security and raised concerns on unhealthy use of technology in digital games related to mental health [35-37].

This study showed that most participants used the video game an average of six times, and the mean usability score was 73 on a scale of 0 to 100 as measured by the SUS. This SUS score corresponds to being “good,” as proposed by Bangor et al [38]. These findings are similar to other digital interventions addressing stress [39-42] and are encouraging, since Champion et al [42] found that improvements in stress can be achieved through short-term engagement (an average of six times) with a mindfulness-based cognitive therapy mobile app. Participants echoed some of the quantitative findings in the interviews, saying that the video game was easy to use, but mentioned a few functionality features that could be improved. They also mentioned they would have used it more often if there were more features.

In terms of stress reduction, this study showed that there was a significant difference in the participants’ PSS scores at baseline (mean 22.14, SD 6.187) compared with those at the 2-week follow-up (mean 18.04, SD 6.083; $t_{27}=3.628$, $P=.001$). The mean difference between the baseline and follow-up PSS score was a decrease of 4.1 points and a medium effect size of $d=0.67$. This mean difference in PSS score is similar to the results found in other studies examining the effectiveness of mobile-based stress management apps [42-46]. Likewise, the findings from this study add to the existing array of literature that have demonstrated video games such as the Legend of Evelys to be effective in lowering psychological stress and improving mood [17,18,47-49]. Participants mentioned that using the video game distracted them from their daily stressors, and that the mindfulness exercise was particularly useful at moments of stress.

The usability results are encouraging and warrant further study on the real-world effectiveness of the video game.

Limitations

This study had several limitations. First, the sample size for the study was small. We recruited a minimum of 3 and a maximum

of 5 participants in each age and gender group, with the exception of males aged 40-50 years, where we were unable to recruit any participant. For the purpose of assessing usability of the video game, studies have demonstrated that most usability problems are detected with three to five users [50]. As a result of the small sample of participants, we were limited in our ability to stratify the findings by age, gender, and other variables of interest. Second, there was no control condition, which limits our ability to understand if any changes in the PSS score are due to using the video game rather than other factors. While we assessed participants’ self-reported stress at baseline, we did not account for any past or current COVID-19 exposure and its possible impact on stress. However, the majority of the participants reported experiencing moderate to high level of stress at baseline (25/30, 83%), which may be attributed to the impact of the pandemic on their mental health. Furthermore, we excluded individuals reporting any other psychiatric illness. It is important to note that the purpose of this study was to examine if people would use the video game and their perceptions on playing it as a stress reduction strategy. Assessing the effectiveness of the video game as a stress reduction strategy was beyond the scope of this study. Third, it should be noted that 66% (21/32) of participants were single (never married), which is higher than the case reported in Ontario’s 2016 census [51]. Similarly, compared to the 2016 census [51], a larger proportion of participants in this study had a college or university degree. Another limitation is the limited period that the video game was tested by each participant; however, given that the video game had a short storyline and only four CBT features to test, the time was likely of sufficient length.

Conclusion

Through this collaboration and development of the video game, we have established that it is possible to gamify CBT exercises to address stress while also establishing an inclusive, secure, and ethical design that is inclusive of users with different abilities. Participants used the video game an average of six times over a span of 2 weeks. The findings demonstrated good usability of the video game and significant reduction in users’ perceived stress within this short time frame. While we recognize video games as a promising strategy to help people with their stress and anxiety, we have also identified several limitations of the study that limit our ability to fully understand its impact on stress reduction. As a next step, further study is needed to examine the real-world effectiveness of the Legend of Evelys in reducing anxiety.

Acknowledgments

This study was funded by the National Research Council of Canada (NRC) Pandemic Response Challenge Program in collaboration with the NRC’s Collaborative Science, Technology and Innovation Program (CSTIP). We thank all the people who participated in this study. PS would like to acknowledge salary support for his clinician-scientist position from the Centre for Addiction and Mental Health and the Department of Family and Community Medicine at the University of Toronto. We would also like to thank Freni Jivani for her support with organizing the in-app analytics data.

Authors' Contributions

PS and NM conceptualized, designed, and supervised the usability study. AS coordinated the study recruitment and conducted the interviews. AS and AG coded and analyzed the interviews under the supervision of NM. PS and RD provided the clinical guidance on the features for the video game. CP and EG created the video game. NM, AS, AG, RD, and CP drafted the manuscript. All authors participated in critical revision of the manuscript and read and approved the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: During the COVID-19 pandemic, to prevent the spread of the virus, federal regulatory barriers around telemedicine were lifted, and health care institutions encouraged patients to use telemedicine, including video appointments. Many patients, however, still chose face-2-face (f2f) appointments for nonemergent clinical care.

Objective: We explored patients' personal and environmental barriers to the use of video appointments from April 2020 to December 2020.

Methods: We conducted qualitative telephone interviews of Mayo Clinic patients who attended f2f appointments at the Mayo Clinic from April 2020 to December 2020 but did not utilize Mayo Clinic video appointment services during that time frame.

Results: We found that, although most patients were concerned about preventing COVID-19 transmission, they trusted Mayo Clinic to keep them safe when attending f2f appointments. Many expressed that a video appointment made it difficult to establish rapport with their providers. Other common barriers to video appointments were perceived therapeutic benefits of f2f appointments, low digital literacy, and concerns about privacy and security.

Conclusions: Our study provides an in-depth investigation into barriers to engaging in video appointments for nonemergent clinical care in the context of the COVID-19 pandemic. Our findings corroborate many barriers prevalent in the prepandemic literature and suggest that rapport barriers need to be analyzed and problem-solved at a granular level.

KEYWORDS

COVID-19; telehealth; video appointment; telemedicine; qualitative; pandemic; outpatient; clinical care; virtual health; patient perspective; healthcare; clinical practice

Introduction

Telemedicine consists of using technology and telecommunication infrastructure to deliver health care-related

services remotely. Options for telemedicine include speaking to a health care provider live over a phone or video call and sending and receiving messages using a secure online messaging platform (eg, a patient portal) [1]. Before the COVID-19 pandemic, use of telemedicine and video appointments, in

particular, was minimal. At the onset of the pandemic, however, regulatory barriers limiting reimbursement for telemedicine were lifted [2] to increase consumer and provider willingness to use telehealth options that would have the potential to improve patients' access to care, reduce demand for overburdened emergency health services, limit potential disease exposure, and minimize the need for scarce personal protective equipment [3]. Despite efforts by health care systems to promote telemedicine during the pandemic, many patients still chose face-to-face (f2f) appointments for nonemergent and noninterventional clinical care [4]. This qualitative study examined patients' perceived and environmental barriers to the use of telemedicine during the COVID-19 pandemic from April 2020 to December 2020.

A systematic review conducted before the pandemic indicated that non-English speaking patients living in low socioeconomic status neighborhoods were significantly less likely to choose a video visit. Other barriers to adopting telemedicine found that top barriers included lack of reimbursement by insurance companies, patient reluctance to engage with technology, low levels of digital literacy, and a lack of access to internet and digital devices [5]. Although insurance companies and the federal government mitigated the lack of insurance coverage for video visits shortly after the pandemic began [6], other personal- (eg, age, gender, digital skills, and knowledge) and environmental-level (eg, where the person lives, internet access, support, household size, set-up) barriers during the pandemic require investigation. We focused on personal and environmental factors that might have affected patients' willingness or ability to use telemedicine, opting to conduct a qualitative study because little is known about how the pandemic may have shifted patients' perceptions of telemedicine. Our results will inform strategies to support the future use of telemedicine.

Methods

Participants

We used a stratified, purposeful sampling strategy [7] to identify participants using the Mayo Clinic electronic health record. The eligibility criteria were (1) age greater than 18 years as of April 2020; (2) established patient at Mayo Clinic Midwest (Rochester or Mayo Clinic Health System), Florida, or Arizona; and (3) attended f2f appointments at the Mayo Clinic but did not utilize Mayo Clinic video appointment services from April 2020 to December 2020. Our goal was to include an equal number of participants by race, sex, location (Midwest, Florida, and Arizona), and outpatient primary care practice and psychiatry. We chose to focus on both primary care and psychiatry as they are settings where patients visit for health maintenance monitoring and medical management that are nonemergent, are noninvasive, and include a broad number of medical and psychiatric conditions, therefore making them suitable for a video appointment. We were especially interested in psychiatry patients and those seeking mental health care due to mounting evidence showing that anxiety and stress have increased significantly among these patients during the COVID-19 pandemic [8]. We estimated we would need about 36 interviews (12 interviews per Mayo Clinic enterprise location) to achieve

data saturation whereby no new themes are being identified [9-11]. Furthermore, the goal of our purposeful sample was to glean rich in-depth information from individual interviews, and we plan to use our results to design and subsequently administer a quantitative survey assessing barriers [12]. To assess saturation, we reviewed interviews completed on an ongoing basis to assess if we were capturing an adequate range of patient experiences with our interviews.

Participants' resident zip code was used to determine rurality based on Rural-Urban Commuting Area (RUCA) codes. For this study, we defined rural as RUCA 4-10 (vs urban if RUCA=1-3) [13]. Zip code data also allowed us to use the 2015 American Community Survey to estimate median household income as a surrogate marker for participants' socioeconomic status [14,15].

Study Procedure

Eligible patients were recruited via email, the Mayo Clinic Patient Portal, telephone, and mail. Social media ads were also posted on Mayo Clinic's Facebook and Twitter accounts so patients could call to participate in the study. Patients who responded were enrolled in the study after being screened via phone and deemed eligible. Patient recruitment ended when we met the target sample size of 36 participants. Once consent was obtained, participants completed semistructured interviews via telephone, and interviews were digitally transcribed. Transcriptions were then verified for accuracy by 2 study team members (NMR, IWW). After completing the interview, participants were provided with a US \$25 remuneration in the form of a cash card. Interviews were conducted between July 2021 and September 2021.

Ethical Approval

This study was approved by the Mayo Clinic institutional review board (21-00452).

Semistructured Interviews

We developed a semistructured interview guide that was pretested with volunteers (nurses, providers, and study staff) for duration, flow, and content. The interview guide was developed by the authors (PS, PS, TAB, CAP) and sought to elicit the following domains based on our study objectives: (1) COVID-19 experience that shaped the decision to engage in f2f appointments, (2) perceived benefits of f2f appointment and barriers to video visits, and (3) recommendations to increase future use of video appointments (see [Multimedia Appendix 1](#)). Interviews lasted approximately 45 to 60 minutes and were conducted in English by 3 study team members (NMR, IWW, and LMW). The interviews were highly flexible with probes for elaboration and clarification to obtain detailed accounts. This type of interview is advantageous when limited knowledge exists about the phenomena of interest [10,11].

Qualitative Analysis

QSR NVivo software, version 10 [16], helped facilitate response-theme generation with codes and categories based on themes emerging from the interviews. Two study team members (PS2 and ARS) coded responses together, discussing any coding discrepancies until reaching consensus and consulting a third

study member (PS1) when necessary [17]. We extracted themes for analysis with code endorsement or elaboration in several interviews. In addition to open coding, we conducted planned comparisons by sex, age, and clinic site.

Results

Participant Characteristics

The final study sample was composed of 36 participants who attended f2f appointments during the April 2020 to December 2020 period of the pandemic. The median age of participants was 60 (SD 14.31) years. Of the 36 participants, 12 resided in the Midwest, 12 resided in FL, and 12 resided in AZ. Our sample of participants was diverse in gender (16 women and 20 men), race (21 White, 11 Black, 2 biracial, and 2 Asian), and education (15 with a bachelor degree, 13 with a graduate degree, 3 with some college degrees, 2 with associate degrees, and 1 with some school). All the participants had English as their preferred language. Most participants (32/36, 89%) were urban residents, and the estimated median household income was US \$75,417 (IQR \$61,730-\$91,045).

COVID-19 Experiences That Shaped the Decision to Engage in F2F Appointments

We found that nearly all participants adhered to some degree of COVID-19 safety precautions. For example, 1 participant stated the following:

Well, the only thing is, we just were following the rules of wearing facemasks and not dealing with crowds and things like that. That was the change, but other than that. We got our shots as quickly as we could during the time. We would continue to go shopping and things like that but using the precautions of six-foot distances and different—whatever was recommended at that time.

Only 2 participants expressed skepticism about the pandemic: one concerning the severity of COVID-19 infections and the other doubting the information related to COVID-19 through

authorities and news media. For example, a White, male participant with some college credit mentioned:

I did get COVID personally. I didn't feel that it was that bad. It was no worse than any other illness that I've had before like getting the flu...I guess I don't feel like that the illness affected me in any way, shape, or form, or anything that I know. I don't really believe that it's as serious as the media or anybody makes it out to be. I personally had it. My entire family had it. I know dozens of people that have had it, and no one even went to the doctor for it.

Nearly all participants expressed that they felt safe from COVID-19 infection when attending f2f appointments. However, a few participants stated they would prefer a video appointment if infection rates were high in their area.

All participants conveyed a general trust in the Mayo Clinic, implying that the institutional guidelines limiting the number of persons in the patient waiting rooms and the patient screening of COVID-19 symptoms entering the hospital made them feel safe attending f2f appointments. Participants emphasized that personally adhering to masking and social distancing guidelines also made them feel safe attending in-person appointments at the Mayo Clinic. For example, a White, male participant with a bachelor's degree stated:

I never thought about delaying care. I always felt safe coming to the clinic. I think about it even then when Mayo required masks. It's like, well, yeah, it relieves you a little bit...Well, if we need to go, well, we'll go. We felt safe. I think if I see the rate—if the rates went [up] or it's been getting bad, I would prefer to use a virtual appointment if I could.

Patient Perceived Barriers to Video Appointments

We identified 9 major themes within this domain that are reported subsequently: (1) f2f rapport, (2) f2f diagnostic and therapeutic advantages, (3) habit, (4) privacy and internet security, (5) digital literacy, (6) internet access, (7) bodily intimacy, (8) billing, and (9) patient portal. The corresponding quotes related to themes can be found in [Table 1](#).

Table 1. Overview of thematic barriers to video appointments, with representative quotes.

Barrier and subdivision	Representative quotes from participants
Face-to-face rapport	
Personability	<ul style="list-style-type: none"> “Just the comfort level. If we just met with somebody, it’s so much easier to explain.” [57-year-old Asian man, Midwest] “I can express myself more, maybe, with her [provider], with her [provider] questions and answers and whatever when I’m there.” [82-year-old White woman, AZ] “I think video visits are just not personal enough. They can see maybe a hundred people on video a day.” [60-year-old African American man, AZ] “You just have a little screen to look at...I’m old fashioned I suppose.” [57-year-old White man, Midwest]
Visual emphasis	<ul style="list-style-type: none"> “...I’m a visual person. I have to see for talking to—I prefer that rather than doing—I know it would have been too, but it’s just not the same as things upfront and person to me.” [70-year-old African American woman, AZ] “I just like to look in the eyes and be there when the provider’s talking to me versus doing it on the video.” [72-year-old White man, FL] “Actually, seeing the person.” [67-year-old African American man, FL]
Auditory emphasis	<ul style="list-style-type: none"> “When I want to go see the doctor, I want to speak to my doctor.” [30-year-old White man, Midwest] “When I go for a visit to my doctor, I like to speak to my doctor, I’m old. I’m not into all these texting people, phoning people. I like to talk to people. That gets the true picture of who they are when you sit and talk to them.” [60-year-old African American man, AZ]
Therapeutic emphasis	<ul style="list-style-type: none"> “I like my doctor a lot, and I just thought I’d feel better if I could be there and visit with her [provider], especially when I started getting depressed.” [82-year-old White woman, AZ] “It’s the physical medicine doctor, and we’re about seven years apart in age. I’ve known her for perhaps five years, and the two of us just click, and I talk to her [provider] on the phone sometimes, but seeing the actual person, your friend, your doctor, that tends to be a comfort to me.” [40-year-old White woman, Midwest] “I wanted to see her [provider] in person because also, then I could briefly talk to her about more personal things just for briefly, not for a mental health visit, but in a way it was a tiny mental health visit too.” [73-year-old White woman, AZ]
Face-to-face therapeutic advantages	<ul style="list-style-type: none"> “I believe when you’re looking at somebody from a distance of feet, your understanding of basic condition is much better than across a screen. Simple things like ADHD patients, I was talking to my cousin who’s a psychiatrist, he thinks he thinks just the way the person sits, or moves, or fidgets, and the things like that you get a lot of—an experienced doctor can make out those things that are unwritten. You miss those signals when you’re across the screen.” [57-year-old Asian man, Midwest] “I’ve been to appointments with just a regular routine physical where my doctor’s seen something that I didn’t see.” [30-year-old White man, Midwest] “For some of my appointments, I think they’re okay, but when somebody needs to really check out what’s going on inside, I think a person-to-person is much better.” [61-year-old White man, FL] “The other thing is, given that this was an orthopedic complaint, I felt that there would probably be limitations to what could be observed, diagnosed, etcetera over a zoom call, and in fact, I ended up being fitted with a brace there for a few weeks during that appointment, which would have been offered if it was something.” [36-year-old White man, Midwest]
Habit	<ul style="list-style-type: none"> “Yeah, because I was going to see a psychiatrist...I would say it was probably just out of routine.” [50-year-old African American man, Midwest] “Other than just being new to me—I’ve never done it that way, so I guess that initial change to doing it with that method. Yeah, other than just being new to me, I’d be open to it.” [48-year-old White man, Midwest]
Privacy and security	<ul style="list-style-type: none"> “...when you’re on a computer, you have no idea who could be listening or who it could be—who could hear you or see you or whatever. There’s a security risk there too, and not on the hospital’s end, but on your personal computer’s end or phone or whatever. There’s always a slight security risk.” [30-year-old White man, Midwest] “I know that I would feel very, very private with it the other way. I’m not sure who would be listening to me otherwise.” [76-year-old White woman, FL] “I think that’s a wonderful platform for it, if we’re staying on top of the security, the information security, but there’s enough times that you just got to have that capability to be seen in-person.” [36-year-old White man, Midwest] “to do a telemedicine visit with a psychiatrist, I had absolutely no place in my home away from my husband to have a private conversation...For me, my husband was—it’s hard to believe that a well-educated woman, like me, I mean, I always vowed this would never happen, but I couldn’t even have my door closed to my room while I am on the phone or doing anything.” [73-year-old White woman, AZ]

Barrier and subdivision	Representative quotes from participants
Digital literacy	<ul style="list-style-type: none"> “First of all, I would’ve had to have my daughter come and help me if the appointment was online.” [82-year-old White woman, Arizona] “The barriers are we aren’t set up for it here at the house. I personally struggle with the technology probably more than somebody almost 73 should.” [72-year-old White man, FL] “I’m an older person, but people who are older than me have a problem using computers sometimes. It’s more a mental thing than anything. I think they don’t want to learn computers or do anything with them.” [66-year-old White woman, AZ]
Internet access	<ul style="list-style-type: none"> “I do not have internet, and as a matter of fact, I’m standing in the one place on my property where I have service right now.” [30-year-old White man, Midwest] “Yeah, ‘cause some places it may take them a while to link up, and by the time they send it, it’s dead.” [62-year-old African American man, Midwest] “The internet connection living in a rural area is a harder thing. We use a DSL line, so it is supposedly high-speed internet over a phone line, but it’s really not high speed, and a lot of the video sorts of things, the few times I did have to do Zoom calls for work or other social clubs, etcetera, part of my dissatisfaction with it was just that it was choppy, cutting out, etcetera, a lot.” [36-year-old White man, Midwest]
Body intimacy	<ul style="list-style-type: none"> “Well, yeah, there are a couple I would prefer face-to-face. One of them is urology...I would prefer that because I’ve had surgery in that area, and I would prefer talking face-to-face.” [84-year-old African American man, AZ] “I really don’t want to point the camera in some places that you need to point in a doctor’s visit.” [62-year-old American Indian man, AZ]
Billing	<ul style="list-style-type: none"> “I don’t know that I would be comfortable getting charged the same amount if it was a telehealth appointment versus face-to-face.” [55-year-old White man, Midwest] “Well, what they need to do for billing is they need to know a hundred percent whether the insurance covers it or not before do it. The thing about it, I should not pay 240\$ for something and come to find out my insurance paid for it.” [60-year-old African American man, AZ]
Patient portal difficulties	<ul style="list-style-type: none"> “Well, I guess it comes on where you have to put in your password or whatever. That’s where I’m stuck. I don’t know what I’m doing wrong. I just have trouble.” [82-year-old White woman, AZ] “If you’re depending entirely on a phone, it’s harder because it’s a little screen. Then you have to get into the app, you have to type it with two fingers. Not everybody is good with that.” [57-year-old Asian man, Midwest] “I had some confusion trying to find the link to get to Zoom.” [54-year-old White woman, Midwest] “It’s just that it’s that technology barrier, and there’s so many people on the wrong side of that barrier right now that I think the patient portal is just—it’s not—I don’t want to say useless, but it’s not the right way to handle the situation.” [30-year-old White man, Midwest] I just loathe the portal, and even if I type in emails I get back these cryptic answers from who knows who it is in the department, and I end up calling picking up the phone and waiting and waiting and discussing it...the information doesn’t make sense, and to me it’s more stressful than just waiting for my appointment...” [71-year-old White woman, FL] “I didn’t know that I needed to download Zoom, so that was a barrier before the appointment. It was not a seamless link from your portal.” [53-year-old White woman, FL]

Recommendations for improving telehealth appointments

Initial visits face-to-face; follow-ups on video	<ul style="list-style-type: none"> “It helps if you have one physical visit. For example, if you’re seeing somebody for the very first time, and you’ve never met them before, it might help that first visit is in-person...Because that way you’ve actually met. You’ve made eye contact once. Your comfort level has gone up a little bit. Now to conduct a second, third or follow-up calls on video might be a good idea.” [57-year-old Asian man, Midwest] “Maybe have the initial visits face-to-face and then subsequent visits over video.” [54-year-old White woman, Midwest] “...If I knew the provider, if I felt confident that the provider knew about the condition we were talking about, I think it would be idea for some follow ups.” [36-year-old White man, Midwest]
Recommendations to help those with low digital literacy or limited internet access	<ul style="list-style-type: none"> “Just making sure that their systems are not bloated or bogged down to the point that if you are talking to a person that has DSL internet or even dial-up, you get out into the really rural areas where you don’t have cables for traditional high-speed internet, and that’s still a common reality in Minnesota and Wisconsin.” [36-year-old White man, Midwest] “Maybe you guys do this already but make sure that-make people aware that they can do that [receive help setting up telehealth appointments], and that people do that all the time. There’s help available to help get you set up. Once they do one and it goes well, I’m sure they would do it again.” [66-year-old White woman, Midwest]

F2F Rapport

One of the most frequently mentioned barriers to engaging in video appointments was what we have coined “f2f rapport” (ie, the feeling that the typical flow of a social encounter or empathetic connection with a patient’s provider is disrupted in a video appointment). Further, 4 subdivisions of this barrier were identified based on the way it was expressed: visual, personability, auditory, and therapeutic.

Visual

Many participants suggested that not *seeing* one’s provider properly negatively affects rapport. These participants tended to be older patients. On further probing, several participants elaborated that it was the *feeling* of visual connection that is being lost during the video appointments.

Personability

Several participants expressed that video appointments lacked the “personal touch” of an f2f appointment and emphasized a higher level of comfort with their provider that allowed them to share their concerns more readily. These themes tended to cross all types of visits (primary care and psychiatry).

Therapeutic

Across psychiatry and primary care appointments, several participants stressed that they considered an f2f appointment therapeutic and appreciated engaging in f2f interaction with their provider, especially due to the social isolation and loneliness brought on by the COVID-19 Pandemic.

Auditory

A relatively small number of participants conveyed the f2f barrier in auditory terms. This was approximately half as common as expressing this barrier in visual terms. Participants emphasized their preference to “talk” or “speak” with their doctor and hear them directly rather than through a computer or smart device speaker.

F2F Diagnostic and Therapeutic Advantages

Many participants believed that, although their medical concerns could be addressed virtually, seeing their provider f2f would confer a diagnostic and therapeutic benefit (ie, participants felt that care they received in person would be superior to that received virtually). Furthermore, several participants called attention to the fact that physical examinations often discover unanticipated issues that would not be discovered over video.

Habit

Several participants expressed that their preference for f2f appointments was due to habit, routine, or preference for familiarity (ie, because they were not used to video appointments, had always done f2f appointments, and therefore implicitly felt more comfortable in f2f appointments).

Privacy and Internet Security

Several participants expressed a wide variety of concerns relating to patient privacy that can be categorized along 2 lines: fear of who might be listening in on either end of a video appointment and fear of who otherwise might have access to the content of a video appointment. The latter concern typically

related to patient concern for compromise of the security of their internet connection. This concern was expressed in both psychiatry and primary care appointments.

Digital Literacy

Another common barrier was a lack of digital literacy. Numerous participants expressed concern that their lack of skill in operating technology prevented them from feeling comfortable utilizing video appointments. Moreover, many participants who themselves felt comfortable with technology expressed concern that elderly family members would struggle. Participants who communicated low digital literacy were overwhelmingly elderly or rural residing. In addition, with only one exception, participants with low digital literacy did not feel comfortable with nor regularly use the patient portal—a prerequisite for using video appointments. Some elderly participants noted that they generally depend on a family member to help them use technology (ie, a digital navigator), mostly their children, and this person is not always present and available to help.

Internet Access

Internet access was primarily a barrier to engaging in video appointments if the participant was from a rural area. All participants who identified themselves as rural residing conveyed that internet access was a barrier to engaging in regular video appointments.

Bodily Intimacy

A few participants mentioned that they felt uncomfortable exposing certain parts of their body over video or in uploading photographs of private parts. Concerns of this kind were limited to the patients who scheduled appointments with their primary care physicians for urological, gynecological, and dermatological problems.

Billing

Several participants expressed concerns with how billing would be handled and conveyed and that this constituted a barrier to engaging in video appointments. The participants conveyed that uncertainty about co-pays and how much expense the insurance company would cover created a barrier to video appointments. Furthermore, a few participants expressed that they would be uncomfortable being charged the same amount for a video appointment, feeling they were being provided a lower level of service compared to an in-person visit.

Patient Portal

Participants were also asked about their experiences with the patient portal, because the ability to use the portal is required to participate in video appointments. Most participants used the portal and found it to be mostly user-friendly, though participants who expressed they had low digital literacy nearly all struggled with the portal or did not use it. A few participants had trouble accessing the teleconferencing application required for video appointments from the portal. Most concerns with the patient portal, however, were particular to single patients and not recurrent. These individual concerns were highly reminiscent of low digital literacy concerns.

Patient Suggestions for Increasing Utilization of Video Appointments

Few participants had suggestions to offer. However, the recurrent theme among those who did was that video appointments were inappropriate for the first appointment with a new provider but acceptable for follow-up visits once rapport had already been established. A few participants noted the need for an institutional digital navigator who could immediately provide assistance if they are not able to connect to their provider virtually.

Discussion

Principal Findings

Our qualitative study provides information on personal and environmental factors that affected patients' choice to not use video appointments during the COVID-19 pandemic within a large multistate institution for nonemergent and noninterventional outpatient clinical care. This preliminary study qualitatively explores patients' telemedicine perceptions including barriers. Our findings will help inform the development of a large-scale survey that will guide future targeted interventions to increase the utilization and ease of use of telemedicine services.

The accumulated evidence from the early period of the COVID-19 pandemic (when this study was designed) showed that people had several misconceptions about the spread of COVID-19 [18] as a result of misinformation spread through social media platforms and other outlets. For example, some people believed COVID-19 was just a severe common cold without significant mortality [19]. In addition, before the development of vaccines, erroneous claims of achieving herd immunity by exposure to the virus were made [20]. Through the questions within domain 1 of our study, participants were prompted to talk freely about their COVID-19-related beliefs and perceptions and if those beliefs affected their decision to participate in f2f appointments. Our study is the first to explore such an association qualitatively. The results of our study indicate that the COVID-19 misconceptions may not have played a role in participants' decisions to engage in f2f appointments. All participants in our study followed institutional and federal measures to mitigate the spread of COVID-19 during f2f clinical encounters, which probably motivated them to continue with f2f clinic care.

Within the second domain, we explored barriers associated with video appointments and factors that led participants to continue engaging in f2f appointments during the pandemic. We were interested if historical barriers to video appointments continued to exist during the pandemic. Like studies before the pandemic [5], our results indicate that participants who reported digital access and digital literacy as barriers to engaging in telemedicine were mainly older adults. Studies conducted before the pandemic highlighted that older adults struggled more with a poorly designed end user interface such as small text and computer screens and other digital skill tasks (scrolling down a menu tab, familiarity with a patient portal, or accessing a video conference link via the patient portal), which was supported by the

participants in our study. These findings add to the existing body of literature and demonstrate that digital barriers (broadband access, digital literacy, and poor end user interface) continued to exist during the pandemic. Therefore, people with interrupted and limited digital access, such as those living in rural areas and those with limited digital literacy, such as older adults, may have no choice but to rely on traditional health care delivery methods such as f2f appointments. However, prepandemic studies have shown that older adults have demonstrated willingness to engage in technology and participate in telemedicine programs if the noted barriers are addressed [21,22]. Therefore, we propose a clinical practice change of assessing the digital competency of every patient so that digital solutions can then be applied based on the identified problem area. For example, people with no broadband access could be referred to a nearby free public hotspot or Wi-Fi access while also highlighting strategies to reduce privacy and data security concerns. We believe that those with limited digital literacy could be connected with institution digital navigator or support [23].

Lack of rapport has been highlighted in prior studies as a barrier to engaging in telemedicine care across different demographic subgroups [24]. Through the qualitative nature of our research, we present new findings by exploring this barrier in-depth with respect to patient sensory inputs and perceived therapeutic satisfaction with telemedicine care. This granular categorization reflects the diversity in which participants perceive lessened feelings of personability or connection with the clinician in video appointments. The most common subdivision of the "lack of rapport" category was the visual emphasis, followed by personability, then therapeutic, and finally auditory. We anticipate that these subcategories may not work in isolation and often interact with one another to define patient experience and perception. For example, patients who have trouble visualizing or hearing their clinician may report poor personal connection (personability). Future studies using quantitative approaches could explore how these subdivisions interact with one another.

More importantly, the unique nature of each subcategory, as highlighted in our results, has practical implications and suggests that attempts to alleviate the "lack of rapport" barrier cannot be one-size-fits-all. Accordingly, we recommend that digital access solutions be investigated to ameliorate rapport-related concerns. For example, digital navigators could provide and help patients use loaner devices with higher resolution screens, superior audio quality, or better internet connectivity to reduce latency and delays during video visits. Yang and colleagues [25] studied the implementation of loaner smartphone devices to patients who did not have smartphones; however, only 72% returned the loaned smartphone within a 30-day window. Future research is necessary to assess the feasibility of this approach for health care delivery. Together, these efforts could help reduce the awkwardness or degree of disruption to the flow of a conversation between patients and providers and increase the degree to which patients feel they can generate social rapport with their providers over video appointment.

Our results indicate that another common barrier to engaging in video appointments was perceived f2f therapeutic advantages.

Participants believed their clinician would render better care in person (f2f) than over video. Participants pointed out that video appointments cannot replicate their perceived benefits of physical exams during f2f appointments. Assessing “lack of rapport” and “f2f therapeutic advantages” themes together, it can be inferred that patients perceive a video appointment as subpar (ie, of lower value either monetarily or therapeutically or diagnostically than an f2f interaction). Without providing exact reasons, several participants believed that psychiatry was a specialty well suited to video appointments. Participants could be inferring that psychiatry, unlike many other specialties, does not use physical exams to the same extent and thus would translate more effectively into a virtual format. The participants, however, did not elaborate if they would be comfortable discussing sensitive and personal topics in psychiatry via video.

On the contrary, participants were hesitant to engage in video appointments when they had dermatological, gynecological, or urological concerns. Several participants communicated that they needed to be examined in person and struggled with the possibility of using uploaded photographs of problem areas or exposing such sites to their webcams for providers to view. As highlighted by a few participants, this barrier could be due to concerns about privacy and security as well as awkwardness and discomfort relating to exposing more intimate body parts over video or uploading a photograph of the intimate body area. Although it seems probable that awkwardness and discomfort are the reasons driving the expression of this barrier, it is also possible the security or privacy barrier is at least compounding the concern if not occasionally replacing it. Moreover, concerns about security are potentially compounded by patient discomfort with the possibility, no matter how remote, of others gaining access to images of their bodies. Many patients expressed data privacy and security concerns when engaging in video visits, which has been highlighted as a barrier in the prepandemic literature [26]. Health care institutions need to vet their technological collaboration to assure patients by demonstrating the best practices regarding patient information privacy, data transfer, and storage [27]. A patient concerned about internet security for telemedicine from their end (user Wi-Fi or internet

safety) could be connected to the digital navigator within the institution to assist patients.

Limitations and Strengths

As this was a qualitative study, our findings cannot be generalized beyond our purposeful sample. However, we opted for a purposeful selection to ensure that we interviewed a diverse group of patients who would express a wide range of views. The study sample was from Mayo Clinic patients; therefore, the participant’s perception of a “safe environment” may not be transferred to other institutions. Additionally, we asked patients to recall a health care experience that had occurred almost a year prior. Hence, it is possible that their recollections and details about events could be biased or incorrect. To help ease such a concern, we did verify eligibility and the existence of an f2f appointment via the medical record. Even though we tried to enroll the participants from diverse backgrounds, most of the participants in our study had bachelor degrees and higher education, which adds to education bias.

Our study’s primary strength was the use of qualitative means to gain a thorough, rich, in-depth understanding of participants’ perceptions relating to barriers to health care and telemedicine during the COVID-19 pandemic. We underscore that such qualitative exploration is a necessary precursor to further investigation by more rigorous, quantitative means. As a next step, we plan to develop a quantitative survey using a larger and more representative sample to determine the extent to which our findings can be generalized

Conclusion

Our study provides an in-depth investigation into barriers to engaging in video appointments for nonemergent clinical care. Limited f2f rapport, poor digital access and literacy, and concerns about privacy and security continued to be significant factors for patients not engaging in video appointments during the pandemic. Most importantly, this study highlighted that rapport-related concerns need to be looked at and problem-solved based on individual needs. Considerable clinical practice changes are required in the future at the institutional and policy level to encourage patients to engage in virtual care.

Acknowledgments

This work was supported by a Mayo Clinic Clinical Practice Committee Eradicating Racism Award and Clinical and Translational Science Awards (CTSA) Grant Number UL1 TR002377 from the National Center for Advancing Translational Science (NCATS). Its contents are solely the responsibility of the authors and do not necessarily represent the official views of the National Institutes of Health (NIH). The funding source had no role in the study design in the collection, analysis, and interpretation of data; in writing the manuscript; or in the decision to submit the article for publication. We would also want to thank Dr. Chung II Wi for his contribution to the calculation of rurality and median household income of the participants.

Authors' Contributions

PS and CAP conceptualized the study, performed the investigation, acquired funding, provided resources, wrote the original draft of the manuscript, and reviewed and edited the manuscript. ARS and PS performed the formal analysis, designed the methodology, wrote the original draft of the manuscript, and reviewed and edited the manuscript. TAB performed the investigation and reviewed and edited the manuscript. LRS and AEG extracted the data and reviewed and edited the manuscript. IWW, NMR, and LMW interviewed the participants and reviewed and edited the manuscript. ALH reviewed and edited the manuscript.

Conflicts of Interest

None to report.

Abstract

Background: Although the benefits of yoga are well established across the world, there are limited studies exploring the long-term interrelation between yoga, meditation, and health. Specifically, there is limited research exploring the differences in health-related quality of life (HRQOL) among regular meditators and nonmeditators.

Objective: This study explored the differences in 7 domains of HRQOL (including quality of life, ability to adopt a healthy lifestyle, ability to relax, frequency of nervousness and stress, coping with day-to-day stress, workplace productivity, and staying healthy during the COVID-19 pandemic) among practitioners of yoga and meditation.

Methods: A cross-sectional, online survey was distributed to all members who participated in a 100-day yoga and meditation program, culminating in the International Day of Yoga event, organized by the Heartfulness Institute in partnership with the Central Council for Research in Yoga and Naturopathy, Ministry of Ayush, SVYASA Yoga University, and Patanjali Yoga Institute, India. The program consisted of daily virtual yoga, meditation, and speaker sessions. The data were analyzed by nonparametric Mann-Whitney *U* test and Kruskal-Wallis tests for continuous variables and chi-square test for categorical variables.

Results: A total of 3164 participants from 39 countries completed the survey. Mean age was 33.8 (SD 13.6) years. The majority of the participants were female ($n=1643$, 52%) and students ($n=1312$, 41.5%). Regular yoga and meditation practice was associated with a positive impact on all 7 domains of HRQOL (Mann-Whitney $P<.05$ and $\chi^2 P<.05$). Notably, experienced Heartfulness (≥ 2 years) meditators reported better outcomes in all the domains of HRQOL as compared to those not currently practicing this form of meditation and participants with ≤ 1 year of Heartfulness meditation experience ($P<.05$).

Conclusions: This is one of the first cross-sectional studies to explore HRQOL outcomes among participants of a 100-day virtual yoga and meditation program. Overall, a yoga and meditation practice was found to be an effective tool for promoting HRQOL. Regular yoga and meditation practice was associated with factors promoting health and well-being, with long-term meditation practice associated with increased benefits.

Introduction

The COVID-19 pandemic is an unprecedented crisis, the effects of which have been felt globally [1-3]. In March 2020, there were 372,757 reported cases from 170 countries, followed by a rapid rise in cases and geographical spread, with over 440 million people affected by COVID-19 globally as of February 2022; during the past 2 years, the pandemic caused disruptions in physical, mental, and emotional health, severely impacting health-related quality of life (HRQOL) [4-6]. HRQOL is an individual's or a group's perceived physical and mental health over time [7]. It is an important measure used to assess the impact of diseases or disabilities on the physical, mental, and social domains of population health [8]. A growing body of evidence suggests the current pandemic has had a substantial negative impact on various dimensions of HRQOL, thus highlighting the need to prioritize both mental and physical health dimensions in these challenging times [9-11].

Prior literature has suggested the practice of yoga and meditation can significantly improve an individual's HRQOL [12-14]. Yoga, a mind-body practice that includes a combination of physical poses, regulated breathing, and meditation, is one of the world's most popular practices for general well-being [15]. Yoga and meditative practices are an effective intervention for chronic health conditions including diabetes, cardiovascular disease, metabolic syndrome, and cancer [16,17]. Furthermore, the practice is beneficial in decreasing inflammation and improving immune system function, favorably affecting mental health by reducing depression and anxiety [18-24]. Although the benefits of yoga and meditation are well established around the world, there are limited studies exploring the long-term interrelation between yoga, meditation, and health [14]. Specifically, there is limited research exploring the differences in HRQOL among meditators and nonmeditators. The aim of this study was to explore the differences in 7 domains of HRQOL (quality of life, ability to adopt a healthy lifestyle, ability to relax, frequency of nervousness and stress, coping with day-to-day stress, workplace productivity, and staying healthy during the COVID-19 pandemic) among individuals who participated in a 100-day virtual yoga and meditation program, culminating in the International Day of Yoga event.

Methods

Study Design

This is a cross-sectional study that included participants aged ≥18 years from 39 participating countries. The online survey was administered to all participants registered for the International Day of Yoga event, organized by the Heartfulness Institute in partnership with the Central Council for Research in Yoga and Naturopathy (CCRYN), Ministry of Ayush, SVYASA Yoga University, and Patanjali Institute, India. Individuals included in the study (1) were at least 18 years of age, (2) had internet access and the ability to complete an online

survey either in English or Hindi, and (3) had registered to participate in a 100-day virtual yoga and meditation program. Participants for the event were recruited by multiple channels including social media, partner organizations, and word of mouth. All participants completing the survey and consenting to the use of data for research purposes were included in the analysis. Ultimately, 3164 participants were included in the analysis.

Intervention

The virtual 100-day yoga and meditation program ran from March 14, 2021, through June 21, 2021. The event was telecasted on YouTube and social media pages including Facebook. The program was facilitated by certified yoga and Heartfulness meditation trainers and consisted of live yoga asanas (postures) in the tradition of Ashtanga yoga, meditation, and speaker sessions. Asana sessions consisted of breathing exercises (pranayama), sun salutation (surya namaskar), yoga practice (beginner, intermediate, and advanced levels as the program progressed), and meditation sessions. Meditation sessions were based on Heartfulness practices. Participants were requested to sit comfortably with eyes closed and gently focus their attention on the source of light within their heart. Participants were asked to simply tune into their hearts and be open to any experience they may have as opposed to trying to visualize the light. If their attention drifted, participants were advised to gently redirect their attention toward their heart. This form of meditation practice has been studied in multiple settings, demonstrating favorable outcomes on burnout, sleep, loneliness, heart rate variability, and emotional well-being [25-33]. Further, speaker sessions included subject matter experts on yoga and meditation from around the world who spoke about topics including but not limited to history of yoga, yoga for unity and well-being, effect of yoga on different systems in the body, benefits of meditation, and research in yoga. The duration of the daily sessions was approximately 1 hour.

Survey Instrument and Data Collection

The survey was designed using standardized scales for well-being-related measures along with questions on demographics and patterns of yoga and Heartfulness meditation practice and administered as a Google Form. The survey was developed in partnership with the CCRYN, Ministry of Ayush, Government of India, to ensure representation of global yoga and meditation practices. Administered in both English and Hindi languages, the survey consisted of 20 items and was divided into three parts: (1) participant demographics including age, gender, country of residence, and occupation, (2) regularity of yoga practice and duration of meditation practices, and (3) HRQOL questions rated on a scale from 0-10 on quality of life, ability to adopt a healthy lifestyle, coping with day-to-day stress, workplace productivity, and staying healthy during the COVID-19 pandemic. Further, a Likert scale was used to assess the domains of ability to relax and frequency of nervousness and stress. Data were collected over a 2-week period.

Ethical Considerations

This study was cross-sectional in nature and was conducted as a program evaluation. As such, it was exempt from institutional review board approval. However, informed consent and password protection for data collection were included. This e-survey design was reported using the CHERRIES (Checklist for Reporting Results of Internet E-Surveys) guidelines [34]. Participation was voluntary and included signing an electronic informed consent form prior to accessing the survey questionnaire.

Cost to Participants

Participants did not incur any costs associated with the event and did not receive any incentives for study participation. All participants received a certificate of participation from the Heartfulness Institute, India, at the end of the program.

Data Analysis

Survey results were cleaned to identify miscoded, missing data and outliers. Data were entered in Microsoft Excel and analyzed using SPSS (version 22; IBM Corp). Descriptive statistics (frequencies, percentages, and standard deviations) were obtained to describe the demographic data, yoga and meditation practice patterns, and attendance across the 100-day virtual yoga event. Participants were asked to report on the frequency of yoga to examine its relation to HRQOL. The differences in HRQOL among participants who practiced yoga regularly was compared against participants not practicing yoga regularly. Similarly, participants were asked to report on their experience with Heartfulness meditation and duration of practice in years. The differences in HRQOL among participants who practiced Heartfulness meditation regularly (≥ 2 years) were compared

against participants with less experience with this form of meditation (≤ 1 year) and participants who had previously tried this form of meditation but were not currently practicing. Kolmogorov-Smirnov normality test showed that most data were not normally distributed. Thus, Mann-Whitney U test and Kruskal-Wallis tests were used for continuous variables and chi-square test was used for categorical variables. Further, a post hoc analysis of continuous variables was conducted to examine differences in HRQOL within the Heartfulness meditation practitioner group. A P value of $<.05$ was considered statistically significant throughout the analysis.

Results

Overview

Participants' demographic characteristics are described in [Table 1](#). Of the 3164 participants included in the analysis, the majority were female ($n=1643$, 51.93%) and students ($n=1312$, 41.47%). Participants' mean age was 33.87 (SD 13.61, range 18-80) years. Of the 39 countries that participated in the program, most of the participation was from India ($n=3020$, 95.45%), followed by the United States ($n=29$, 0.92%) and United Arab Emirates ($n=17$, 0.53%). Of 3164 participants in the sample, 1647 (52.05%) were regular yoga practitioners, and 1517 were categorized as nonregular yoga practitioners (47.95%). Further, 64.89% ($n=2053$) reported experience with Heartfulness meditation practice and 35.11% ($n=1111$) did not practice Heartfulness meditation. Among the Heartfulness meditation practitioners, 38.28% ($n=786$) reported ≤ 1 year of practice, 59.28% ($n=1217$) had practiced for ≥ 2 years, and 2.44% ($n=50$) of participants reported not currently practicing this form of meditation.

Program Engagement

A total of 3164 individuals completed the survey and reported an average participation rate of 71 (SD 32) days. Most participants ($n=1684$, 53.22%) attended daily yoga and meditation sessions throughout the 100 days.

Effect of Yoga on HRQOL

Participants who practiced yoga regularly reported a statistically significantly higher positive impact on all domains of HRQOL as compared to participants who were not regular yoga

practitioners, including quality of life ($U=924263.5$, $P<.001$), ability to adopt healthy lifestyle ($U=915778.500$, $P<.001$), coping with day-to-day stress ($U=898958.000$, $P<.001$), improving work productivity ($U=908140.500$, $P<.001$), and staying healthy during the COVID-19 pandemic ($U=896486.500$, $P<.001$; Table 2). Further, regular yoga practitioners had a greater ability to relax ($df=3$, $P<.001$) and experienced lower frequency of nervousness and stress ($df=3$, $P<.001$) as compared to nonregular yoga practitioners (Table 3).

Table 2. Effect of yoga on health-related quality of life.

Effect of Heartfulness Meditation on HRQOL

Notably, regular Heartfulness meditation practitioners reported a higher statistically significant impact on all HRQOL domains: quality of life ($U=993578$, $P<.001$), ability to adopt healthy lifestyle ($U=1012703.500$, $P<.001$), coping with day-to-day stress ($U=984983$, $P<.001$), improving work productivity

($U=998981.500$, $P<.001$), staying healthy during the COVID-19 pandemic ($U=995166.500$, $P<.001$; Table 4). Further, the Heartfulness meditation practice group had a greater ability to relax ($df=3$, $P<.001$) and experienced a lower frequency of nervousness and stress ($df=3$, $P<.001$) as compared to the non-Heartfulness meditation group (Table 5).

Table 4. Effect of Heartfulness meditation on health-related quality of life.

Effect of Years of Heartfulness Meditation Practice on HRQOL

Participants were categorized in three groups based on their response to the number of years of experience with Heartfulness meditation practice: (1) not currently practicing but had previously tried the form of meditation, (2) ≤ 1 year, and (3) ≥ 2 years of meditation practice. A total of 1217 participants (59.28%) reported ≥ 2 years of Heartfulness meditation experience, 786 (38.28%) reported ≤ 1 year of Heartfulness meditation experience, and 50 (2.44%) reported having previously tried this form of meditation but not currently practicing it.

Significant differences within the groups were observed through a Kruskal-Wallis test. The test indicated that quality of life ($H=77.33$, $P<.001$), adopting a healthy lifestyle ($H=55.54$, $P<.001$), coping with day-to-day stress ($H=61.78$, $P<.001$), improving workplace productivity ($H=67.64$, $P<.001$), and staying healthy during the COVID-19 pandemic ($H=64.79$, $P<.001$) differed between at least one group within the Heartfulness meditation practice group. Post hoc analysis revealed that there was a higher HRQOL for all domains observed for participants with ≥ 2 years of meditation practice as compared to the other two groups ($P<.001$; Table 6).

Table 6. Post hoc analysis within the Heartfulness meditation practice group.

Health-related quality of life domain and comparison between groups with different years of Heartfulness meditation experience	Mean difference (group 1 – group 2)	SE	P value ^a	Confidence interval

Discussion

Principal Findings

Overall, this study showed that a regular yoga and meditation practice was associated with factors promoting health and well-being, with long-term meditation practice associated with increased benefits. This study is one of the first cross-sectional studies to analyze the effects of a 100-day virtual yoga and meditation program and has 3 key findings. First, the demographic results suggest most practitioners are female and students/educated. Our findings corroborate those of other studies in several countries such as the United Kingdom, United States, and Australia, where yoga and meditation practitioners were mostly female and educated [35-38]. Although those studies reported an average age between 39-41 years, this study, in contrast, had a younger population with an average age of 33.8 years and mostly student participants. These findings concur with recent studies in the Indian setting reporting that students and a younger population make up most participants for yoga events [39,40]. Recent literature has reported an increased interest among young people in India to incorporate yoga as part of their fitness regimen [40]. Nevertheless, we speculate the larger participation from India in this global event, as compared to other countries, is because of the broader presence of the event organizers (Heartfulness Institute, CCRYN, Ministry of Ayush, SVYASA Yoga University, and Patanjali Yoga Institute) in India.

Second, participants were highly engaged throughout the program period, given that 100 days of yoga and meditation is a substantial time commitment. A notable average participation rate of 71 days (SD 32), with 53.22% attending sessions every day for 100 days, suggests that participants were willing to engage in an online activity to enhance their well-being. Limited research exists to compare engagement rates of programs centered around International Yoga Day events with previous literature [39,40].

Third, results examining the effect of yoga demonstrated that regular practice had a statistically significant positive impact on all 7 domains of HRQOL. Similar results have been reported by several studies examining the effect of yoga on mental and

physical health [40]. There is overwhelming evidence indicating that the frequency of yoga practice positively predicts its health benefits [35,36,38,41,42]. Another important finding of this study was that meditation had a statistically significant positive impact on all the HRQOL domains ($P < .05$). Interestingly, participants with ≥ 2 years of experience reported a higher impact on all domains of HRQOL as compared to participants with ≤ 1 year of meditation practice. The findings imply that sustained practice may cumulatively increase the benefits for well-being. This contrasts with a recent study that found no association between years of meditation practice and mental well-being [42]. Nevertheless, findings from this study concur with previous literature suggesting a positive correlation between perception of health, well-being, and years of meditation practice [43-45].

Limitations

Although this study provided new evidence about characteristics of yoga and meditation practitioners in a 100-day virtual yoga and meditation program, there were several limitations. The data were cross-sectional in nature; therefore, causality cannot be inferred. A priority for future research includes using longitudinal designs to examine the causal relationship between meditation practice and key outcomes of interest of the study. Moreover, all participants included in the evaluation self-selected to participate in the program. This may have contributed to a potential inclusion bias of those with an interest in yoga and meditation. Further, 100 days of yoga is a substantial time commitment and such a program may have limited active participation from a broader population (eg, full-time employees). Additionally, there was an uneven distribution of members from participating countries and findings of the study may be generalizable only to Heartfulness meditation practitioners.

Conclusion

This is one of the first cross-sectional studies to analyze the effects of a 100-day virtual yoga and meditation program. Overall, a yoga and meditation practice was found to be an effective tool to promote HRQOL. Regular yoga and meditation practice was associated with factors promoting health and well-being, with long-term meditation practice associated with increased benefits.

Acknowledgments

The authors would like to express their gratitude to the Central Council for Research in Yoga & Naturopathy, Ministry of Ayush, SVYASA Yoga University, Patanjali Yoga Institute, yoga and meditation trainers, program speakers, and volunteers of Heartfulness Institute for development, promotion, and facilitation of the program.

Conflicts of Interest

All authors are volunteers of Heartfulness Institute or members of the Central Council for Research in Yoga and Naturopathy, and declare no financial conflicts of interest.

Abstract

Background: When the first COVID-19 cases were noticed in China, many racist comments against Chinese individuals spread. As there is a huge need to better comprehend why all of these targeted comments and opinions developed specifically at the start of the outbreak, we sought to carefully examine racism and advocacy efforts on Twitter in the first quarter of 2020 (January 15 to March 3, 2020).

Objective: The first research question aimed to understand the main type of racism displayed on Twitter during the first quarter of 2020. The second research question focused on evaluating Twitter users' positive and negative responses regarding racism toward Chinese individuals.

Methods: Content analysis of tweets was utilized to address the two research questions. Using the NCapture browser link and NVivo software, tweets in English and Spanish were pulled from the Twitter data stream from January 15 to March 3, 2020. A total of 19,150 tweets were captured using the advanced Twitter search engine with the keywords and hashtags #nosoyunvirus, #imNotAVirus, #ChineseDon'tComeToJapan, #racism, "No soy un virus," and "Racismo Coronavirus." After cleaning the data, a total of 402 tweets were codified and analyzed.

Results: The data confirmed clear sentiments of racism against Chinese individuals during the first quarter of 2020. The tweets displayed individual, cultural, and institutional racism. Individual racism was the most commonly reported form of racism, specifically displaying physical and verbal aggression. As a form of resistance, Twitter users created spaces for advocacy and activism. The hashtag "I am not a virus" helped to break stereotypes, prejudice, and discrimination on Twitter.

Conclusions: Advocacy efforts were enormous both inside and outside the Chinese community; an allyship sentiment was fostered by some white users, and an identification with the oppression experienced by the Chinese population was expressed in the Black and Muslim worldwide communities. Activism through social media manifested through art, food sharing, and community support.

KEYWORDS

COVID-19; racism; Chinese; advocacy; Twitter

Introduction

Background

The SARS-CoV-2 (COVID-19) outbreak increasingly generated a sense of xenophobia and hate crimes in Asian communities across the world [1-4]. Some survey-based research has highlighted a positive association between the outbreak of COVID-19 and discrimination experienced among Asians, specifically Chinese individuals [5,6]. In the United States, many racist and xenophobic incidents, notably verbal abuse and physical attacks, have been explicitly on display [5]. Moreover, 1 out of 4 participants in a survey conducted with 1904 Chinese individuals living overseas across 70 countries reported having experienced discrimination amid the pandemic, such as forced layoff, discrimination in rental housing, and abuse in the public arena [7]. In addition, a rising level of a collective sentiment of backlash and racism is manifested in the digital world, such as anti-Chinese hashtags and the use of hateful language [8-11]. In response to racist attacks and stigmatization, Asian groups in France began to use a new hashtag on Twitter, #JeNeSuisPasUnVirus, to engage in telematic activism. As social media provide permanent access to the discussion of topics related to racism, this hashtag promoting activism was rapidly translated into different languages such as English, Spanish, and Chinese (#ImNotAVirus, #NoSoyUnVirus, and #我不是病毒, respectively). The use of these hashtags led to a rapid evolution of discourses and debates on Twitter, unfolding many racial attacks and advocacy efforts toward Chinese individuals. As some existing research suggests, Twitter is a good communication tool to understand public sentiment and behaviors surrounding racial issues triggered by COVID-19 [12-14].

Accordingly, the aim of this study was to investigate the types of racism that developed amid the beginning of the COVID-19 outbreak and how people reacted toward these discourses on Twitter. Analyzing public reactions at the first phase of the pandemic can enable predicting racism and discriminatory actions toward certain ethnic groups in a future pandemic. Based on Tatum's theory [15], we elaborate an *aims to describe* approach to conceptualize racist online discourses.

Historical Racism and Oppression Faced by the Chinese

Racial discrimination against Chinese individuals is not a new phenomenon. In the 19th century and the first half of the 20th century, the Chinese became underpaid small business owners in the Americas. In the host society, they were segregated in Chinatowns and experienced constant harassment from white Americans [16]. As a result, the term "yellow peril" was used to describe Chinese migrants as a threat to the white civilization [17]. Australia also prohibited Chinese migrant laborers from entering the country and denied them a civic status, as they were seen as fierce competitors to local economies. These events were rooted again in white supremacist cultural ideas [18]. A relevant date in history was 1882, when the Chinese Exclusion Act was approved in the United States. This new order explicitly denied access to all Chinese laborers from the country considering their race and ethnicity. Due to China's restriction

of labor migration, the US government recruited cheap laborers from other Asian countries such as Japan, India, Korea, and the Philippines; however, this resulted in new waves of racial exclusion [19]. In the second half of the 20th century, with the arrival of migrants from the global South, there has been a rise of xenophobia toward Chinese migrants in Europe. In Great Britain, Chinese individuals were considered as "Red threats," "Blue ants," and "laundry-lords" [17]. In Italy, the Chinese have been stereotyped as "making too much noise" and "stealing jobs from locals," which has provoked a hostile sentiment toward the Chinese diaspora [20]. After the severe acute respiratory syndrome (SARS) outbreak in 2003, the Chinese experienced discrimination in many countries such as Canada, the United States, and the United Kingdom [21,22]. With the outbreak of COVID-19, these racial dynamics might increase. A recent study analyzed the role of stigmatizing words on Twitter during the first quarter of 2020 [9], showing that the novel respiratory virus was predominantly called the "Chinese virus." Other nomenclatures such as "Wuhan coronavirus" or "China coronavirus" were constantly used, which acted as an accelerator for stigmatization, bias, and backlash.

Tatum's Antiracist Theorization

In the present study, Twitter messages (tweets) were classified into different typologies of racism to understand how systems interplay during the outbreak of COVID-19-related anti-Chinese attacks. In this regard, alongside the historical context displayed, Tatum's [15] theorization is a social justice-oriented framework that strengthens social and political leaders' capacity to put in motion antiracist social policies and practices considering all possible levels of oppression. With the collection of a variety of tweets, it is possible to gain a better understanding of the social implications of racism and the antiracist practices to anticipate. The main important themes found in the study were individual racism (divided by active racism and inactive racism forms), cultural racism, and institutional racism. *Individual racism* has been defined as all beliefs of prejudice, power balances, attitudes, and actions that support and perpetuate racism between individuals [15]. Cultural racism is based on cultural images and messages that affirm whites' assumed superiority. By contrast, institutional racism represents the network of institutional structures, policies, and practices that create advantages and benefits for whites, while maintaining discrimination, oppression, and disadvantage for people from targeted racial groups [23].

Bell [24] explains that some individuals overtly use racism. In acts of overt racism, the oppressor is aware of the use of prejudice and discrimination. Racism can occur on an unconscious level and can be both active and passive [23]. Tatum [15] uses the terms "active racism" and "inactive racism" to talk about this level of consciousness, adapting the concept to having an explicit or an implicit goal to racism. In particular, active racism comprises all of the intentional actions with a stated or explicit goal to maintain a system of racism and the oppression of those in targeted racial groups [15]. One of the main beliefs for perpetuating active racism is that white individuals are superior to other ethnic groups in terms of culture and values [23]. Inactive racism is defined as beliefs, attitudes, and actions that actively contribute to the maintenance of racism

without openly using violence or oppression [15]. In other words, inactive racism is maintained through attitudes, beliefs, and behaviors that support the system of racism, racial prejudice, and racial dominance [23]. Inactive racism has also been termed “passive racism.” Tatum [15] conveyed that some clear examples of this phenomenon are seen when a racist joke is told and receptors laugh, when conversations on difficult race-related issues are silenced, or when Black candidates are eliminated in hiring processes.

With respect to cultural racism, Tatum [15] supports the idea that we cannot always identify who is responsible for an individual act, as society is behind the maintenance of certain prejudices and stigmas. Other authors such as Wijesinghe et al [23] added that the conceptualization of cultural racism needs to include the notion of inferiority or devaluation. They further argued that institutional racism is often confused by “rights” and the system of advantages created for white individuals [23].

Social Media Activism and Advocacy

Hashtag activism is a new term that was coined to describe protests on social media. Users can report their personal history or make social and political claims by tweeting, retweeting, or commenting on others’ tweets [25]. For example, the #BlackLivesMatter movement triggered by the death of George Zimmerman in 2012 rapidly evolved into demonstrations in the virtual space. Similarly, during the initial phase of the COVID-19 pandemic, various racial attacks toward the Chinese were reported around the globe. Consistently, Twitter users utilized the hashtags #JeNeSuisPasUnVirus and #I’mNotAVirus as an attempt to unfold the existing racist practices. To the best of our knowledge, this is the first study to directly focus on the racist discourse toward the Chinese ethnicity, along with actual advocacy and activism actions displayed on Twitter during the COVID-19 outbreak.

The aims of this study were to describe (1) which type of racism was displayed against Chinese individuals amid the COVID-19 outbreak (first quarter of 2020), and (2) how Twitter users reacted to news, posts, and tweets that had a positive or negative sentiment toward Chinese individuals.

As a hypothesis, it was expected that due to the worldwide situation of discrimination and hate against the Chinese during the new coronavirus outbreak in Wuhan, tweets in the first quarter of 2020 would exhibit verbal and physical aggression forms of racism against Chinese individuals (ie, individual racism with an emphasis on active racism). We further hypothesized that even with the racist dialog exposed on Twitter, users would paradoxically create advocacy and activism spaces on this social media platform.

Methods

Design

Content analysis of tweets was utilized to address our aims. Content analyses transform the symbolic content of a document, such as words and images, into a systematic set of categories and codes [26].

Data

Collection of Tweets

Using the NCapture browser link and NVivo software, tweets in English and Spanish were pulled from the Twitter data stream from January 15 to March 3, 2020. A tweet is a limited virtual message of 280 words [26]. Twitter is a microblogging site in which users engage in real-time messages and can connect with other users by following the feed of other user accounts [26]. A total of 19,150 tweets were captured using the advanced Twitter search engine with the keywords and hashtags #nosoyunvirus, #imNotAVirus, #ChineseDon’tComeToJapan, #racism, “No soy un virus,” and “Racismo Coronavirus.” From the full Excel data set, 1173 tweets were repeated and consequently excluded. A total of 17,575 tweets were not related to our research questions’ topics. After reading all of the tweets, an exclusion criteria checklist was created to tag the tweets (1) not considering the coronavirus outbreak; (2) not related to Chinese and Asian discrimination; and (3) targeting other topics such as immigration in the United States, worldwide politics, new scientific facts related COVID-19, and general opinions about the pandemic and the disease. Finally, 402 tweets were included and coded by three researchers.

Themes

The main subcodes for *active racism* include *physical aggression, verbal aggression, change in relationships, rejection, and bullying*. Relevant codes for *inactive racism* were *prejudices, rumors, and jokes*. Separately, a new category termed “*internalized domination*” emerged.

For the second aim, gauging Twitter users’ reactions to the anti-Chinese sentiment, the main topics of discussion were *advocacy and activism*. Different subcodes for advocacy emerged, including *Black and Muslim identification with Chinese discrimination; white allyship; and the break of stereotypes, prejudice, and discrimination* as a form of advocacy using Twitter. In an activism effort, subcodes such as an *antiracist fight* were revealed. We also detected some tweets related to unintentionally internalized racist discourses by certain Chinese individuals.

Ethical Considerations

No application for an ethical review board assessment was submitted as the study only involved preanalysis of secondary data with no identifying information.

Coding of Tweets

For the validity of the data process, a codebook based on axial coding was developed, along with instructions on how to use the code and the associated definitions. Before beginning the process, two research team meetings were necessary to determine and clarify the meaning of the codes and the coding strategy. The idea was to be immersed in an intense analysis surrounding a few specific sets of codes and categories, and to preserve selectiveness [27]. The research team reviewed the tweets using an inductive approach to finalize the codebook. As theories were identified behind the tweets, definitions included relevant racism conceptual frameworks, specifically based on Tatum’s [15] concepts. Memos were also used in the

analysis processes to improve the gathering of information. [Table 1](#) provides the relevant codes and their definitions.

Once all of the tweets were coded, the codes were compared between two researchers to discuss possible conflicts using a Google Sheet. In the case of disagreement, each remaining tweet was coded independently again by at least two members of the team. Differences were reconciled through discussion between

the two coders until reaching 100% agreement. The rate of code conflict was 38/402 (9.4%) tweets for research question 1 and 23/402 (5.7%) tweets for research question 2. To estimate the intercoder reliability, we selected a strategy of group consent rather than statistical consent. Group consent was based on establishing an agreement between coders during the decision-making process and in-depth discussions of the tweets' content.

Table 1. Relevant codes, subcodes, and definitions.

Codes and subcodes	Definition
Active racism	
Physical aggression	Behavior causing or threatening physical harm toward others, including hitting, kicking, biting, using weapons, and breaking toys or other possessions
Verbal aggression	Message that attacks self-concept, including insults or name-calling, shouting, teasing, and mockery (eg, "yellow peril" or "Alerte Jaune")
Change in relationships	Change in relationships in a negative/derogatory manner; always takes into consideration that the prior established relationship was based on respect
Rejection	Refusing someone for being Chinese without a previous relationship
Bullying	Harm, intimidation, or coercion of an individual in the school context
Inactive racism	
Prejudice	Preconceived judgment or opinion, usually based on limited information
Rumors	Actual circulating story of uncertain or doubtful truth
Jokes	Use of humor to maintain racism
Cultural racism	Cultural images and messages that assumed superiority of whites and the assumed inferiority of Chinese individuals, along with negative stereotypes as oversimplified generalizations about the Chinese
Institutional racism	The network of institutional structures, policies, and practices that create advantages and benefits for whites and disadvantage for targeted racial groups, including the Chinese
Internalized domination	Members of the agent group (whites) accept their socially superior status as normal and deserved
Advocacy	Twitter users consciously defending an idea or a purpose; being involved in an activity or action with the idea of influencing social change
White ally	White person who actively works to eliminate racism in social media
Advocacy	
Asian food sharing	Food sharing in the community to defend the cause that Chinese individuals are not viruses
Community support	Supporting through hug performances and donations
Engage in racist discourse	
Intentionally racist	When the message is communicated with the explicit goal to hurt or harm another person
Unintentionally racist	Online messages where the communicator is not aware that their arguments have a racist impact
Strategically racist	Using discourse to make a point that is part of a broader argument designed to persuade the public or gain political support but is still racist

Results

Research Question 1: Racism Toward the Chinese Amid the COVID-19 Outbreak

Overview

A total of 402 tweets displayed some racist content. To address our first aim, we considered whether the racism occurred at the

individual, cultural, or institutional level. With Tatum's [15] conceptualization in mind, the vast majority of tweets showed individual racism (100 tweets) and cultural racism (41 tweets), whereas institutional racism tweets were limited (9 tweets). [Table 2](#) summarizes the codes obtained, which are described in further detail below.

Table 2. Summary of the codes for tweets related to racism against the Chinese at the beginning of the COVID-19 outbreak.

Codes and subcodes	Example tweet
Individual racism (n=100)	
Active racism (n=68)	
Physical aggression (n=39)	Also seeing some news reports that people who are definitely “Not Racist” around the world are attacking Asian people who are not from China, because #COVID19 started in China. #Racism
Verbal aggression (n=28)	Yesterday when I was in this small town, several people referred to us “Coronavirus”. When they realized we understood Spanish, they stopped chatting... Then, they rationalized their actions by claiming that they didn’t say anything about.
Change in relationships (n=3)	Due to perpetuation of #racism like this, my 13 yr old + teammate endured the Judge of their #debate round avoid her assigned seat next to them for a seat across the room from them.
Rejection (n=23)	I did a test on the bus the other day, I was sneezing all the time on the trip, no one told me off, but as soon as Asians are associated with any symptoms people turn away #auspol #Auspolsocorrupt.
Bullying (n=5)	This is Constantine, a Chinese student studying in Oz. He was recently beaten up and verbally abused with #racism all cuz he spoke #Chinese. The racial hysteria as a result of the #CoronavirusOutbreak has made this country unsafe for students.
Inactive racism (n=32)	
Prejudice (n=15)	Let’s be clear. #COVID2019 or #coronavirus is not the common cold. It is not carried by solely asians. It is a huge threat but this does not mean we should stop supporting Asian businesses. I will be having Chinese food for lunch. #racism #fearmongering
Rumors (n=14)	Just lost a few brain cells listening to that ‘instagram influencer’ on your Thurs show. Also, is it not reasonable to assume that those working in /patronizing Chinese restaurants have increased chance of traveling or being in contact with persons traveling to China? #racism?
Jokes (n=5)	What I enjoy best is the concept: I catch the virus and then become entirely immune, so I can travel about Wuhan liking Chinese and everything will be OK!
Cultural racism (n=41)	
Journalist photos (n=12)	The @nypost once again demonstrated their poor journalistic standards by placing a picture of asians in Flushing with their article regarding the first confirmed case of the corona virus. #coronavirus #Coronavirusnyc #WorldHealthOrganization #nypost #racism
Yellow peril (n=2)	None of that shields me or anyone else. I’m still just a target because I’m east Asian. #JeNeSuisPasUnVirus #ImNotAVirus #Coronavirus #COVID19 ‘They yelled Coronavirus’ – East Asian attack victim speaks of fear
Institutional racism (n=9)	What’s scary is that just because Mexico has 4 confirmed cases of Coronavirus, Trump wants to close down the border, meanwhile the US has 74 confirmed cases of Coronavirus, so if anything Mexico should close down their border. #coronavirus #TrumpVirus #racism #COVID19US
Internalized domination (n=6)	I’m just saying. If this virus started in Europe or America from some Caucasian folks, y’all wouldn’t say a thing to attack them physically or verbally #coronavirus #COVID2019 #racism

Individual Racism

Active Racism

Instances of individual racism were broken down into active racism and inactive racism (Table 2). A total of 68 tweets exhibited active racism, characterized by the main subcodes physical aggression, verbal aggression, change in relationships, rejection, and bullying.

Manifestations of physical aggression were diverse and included attacking, assaulting, and beating: “He is an Italian-Chinese man who was violently assaulted for racial reasons.” Some tweets exhibited a combination of physical aggression and verbal aggression in their content, underlying how physical and verbal aggressions go hand-in-hand (n=14):

A student in Great Britain was physically attacked by a group of people yelling him “#coronavirus” and

“I don’t want #coronavirus here”. This is the outcome. This #racism is no longer a joke

Verbal aggression was frequent, especially name-calling. The most commonly used insults were “Corona” and “Coronavirus,” although allegations such as “Yellow peril,” “Yellow Alert,” and “Yellow Face” also manifested:

Yesterday when I was in this small town, several people referred to us “Coronavirus”. When they realized we understood Spanish, they stopped chatting... Then, they rationalized their actions by claiming that they didn’t say anything about

Change in relationships as part of active racism was also evident: “An Asian-Australian woman whose family has been in this city for a long time: I had a friend who rejected to have a drink with me.” Verbal aggression was also associated with this behavior:

As much as I admire this guy, this was a mistake. I'm sure he's regretting it, but let's deal with it, he's not the only one. People are refusing to get their meals at Chinese restaurants, Chinese children are being segregated at their educational centers, and so on....

This type of rejection was also frequent in the medical field, including rejecting doctors that appear to be Asian: "Patients at an Australian hospital are rejecting to be treated by Asian doctors, because they are afraid of getting #COVID19." Chinese restaurants also lost business:

On my way home tonight, all take-aways were crowded except the three Chinese restaurants. "Next people will quit eating pasta!" I told to my daughter. Ok, be cautious. This is just obvious racism.

Manifestations of active racism in the school context were also present. Signs of bullying such as intimidation, coercion, and harmful behaviors were detected:

A Chinese student living in Australia was recently attacked and verbally abused with racism because he spoke Chinese. The Coronavirus outbreak has generated racial panic, making our country dangerous for students. Please, donate.

Bullying was also associated with rejection in certain cases such as Chinese children being segregated in educational centers (Table 2).

Inactive Racism

Inactive racism denoted the use of *prejudice*, the *promotion of "rumors,"* and racism through disrespectful "*jokes*" (Table 2).

The concept of "I am not a virus" emerged from the idea that wearing a mask is having the virus. On Twitter, the mathematical form "ASIAN+MASK=VIRUS" is recurrent to explain prejudice. The hashtag "I am not a virus" appeared to break this prejudice or as a form of advocacy:

I got these from a New Zealand webpage section. It is racist to refuse to breathe the same air as Asian people when making an assumption that Chinese are infected based off a five second glimpse.

During the first quarter of 2020, rumors about Chinese individuals started to appear. Several untruthful stories were circulating, such as that all Chinese individuals have the virus and that they are dangerous:

A twitter user assumes only that Coronavirus primary affects Asians, so he is unconcerned. The racism and cruelty are always a thing. Moreover, his president informed him it will be gone by April so he is just counting down days until it's done.

More specifically, rumors affected Chinese individuals who work in Chinese restaurants, as there was a rumor about Chinese employees getting coronavirus: "It is not congruent to assume that those working in Chinese restaurants have increased chance of traveling or being in contact with people traveling to China."

A Twitter user confronted this rumor:

Listening to an 'Instagram influencer' on a Thursday show, I just lost a few brain cells. It is not normal to

presume that folks who work in Chinese restaurants have a higher possibility of traveling to China or coming into contact with people who are traveling there.

Rumors about the Chinese eating pets were also frequent. One Twitter member attempted to educate users on this rumor:

It's time to address the notion that people in China eat their pets. It has been stated to me since I was a child, but this is not true; this practice does not exist in China, and only occurs in really poor areas. Chinese are humans, and they also have pets.

Some individuals used harmful jokes to attack Chinese individuals. An example is provided: "What I enjoy best is the concept: I catch the virus and then become entirely immune, so I can travel about Wuhan liking Chinese and everything will be OK!"

Cultural Racism

Cultural racism was exhibited in general messages, but also through the subcodes *journalism photos* and *promoting "Yellow Peril" stereotypes* (Table 2): "It appears that other ethnicities enjoy bat soup as well. Please don't make a racial attack on them right now. This Twitter user prefers them to be fresh."

The *journalism photos* code was used when detecting photos and images in the public media that contained discriminative or prejudiced content toward Chinese individuals. For instance, some Twitter users denounced: "Why every Western media always utilizes images of Asians when they announce that coronavirus has been detected in Europe?" In this regard, the *journalism photos* code complemented the *advocacy* code: "The @nypost once again proved their terrible journalistic standards by accompanying an article on the first confirmed case of the corona virus with a photo of Asians in New York State."

Specifically, subcodes on how *journalism photos* reflect a cultural racist image (ie, Chinese people wear masks because they are infected) can be appreciated regularly during this period. Another important subcode was *yellow peril*, as this historical idea strongly persisted during the first quarter of 2020 on different cultural racist tweets:

Thank you to these specific Twitter users for inviting me to speak on this fantastic podcast regarding the coronavirus outbreak and racism. The COVID-19 racism is just one manifestation of Australia's long-standing yellow peril and anti-Chinese sentiment

Institutional Racism

Institutional racism was less frequently mentioned, with a total of 9 tweets pointing to this problem. The institutional racism issue was generally brought up indirectly: "Universities have already lost 100,000 Chinese students; if Indian parents learn of this, they may withdraw the remaining 100,000 students."

Internalized Domination

Six tweets demonstrated the existence of internalized domination. The following comment reflects how a white US Twitter user indirectly treats Chinese and Iranian individuals as inferior:

It's funny how the death rate from the coronavirus is higher in heavily inhabited POC [people of color] areas like Iran and China. However, in nations where Whites are the majority, such as the United States and Italy, the rate is quite low.

Another tweet was found in which a user expressed a sentiment of superiority of Black individuals to Asians:

I witnessed a black man abusing an elderly Chinese man. Many Black folks have historically waved the flag in support of anti-racist causes. This time, though, Black people are against Asians.

However, internalized domination was also criticized by another Twitter user: “How come you don’t think about how much your predecessors suffered because of prejudice when you do the same to other races?”

Research Question 2: Advocacy and Activism Through Social Media

Advocacy

After confirming that racism was displayed on Twitter at different levels, we next inquired about the most common user responses to this racist sentiment on social media, as highlighted by the high number of tweets related to *advocacy* and *activism* (Table 3).

Table 3. Summary of tweets associated with advocacy and activism against Chinese racist sentiment.

Code and subcode	Example
Advocacy (n=298)	
Break stereotypes, prejudice, and discrimination (n=100)	I don't wanna be 'that guy' but..This is what I mean about the double standards of #racism. If a white person had written that about a black person then #Twitter would be in meltdown. Is #coronavirus #racist? Are #scientists racist?No that Tweet is. #Equality is EQUAL.
White allies (n=33)	Please stop the #racism, #Xenophobia, and open hatred against Asians because of the #coronavirus. A virus is not and should not be a means to discriminate and Other human beings.
Black identification (n=12)	Some folks whose minds are so debased have started exhibiting stereotypical disposition towards Chinese whom at this critical time need the world's support to overcome #coronavirus #CoronaVirusUpdates #COVID-19 #racism #ourHealthMatters #stopracism #Health
Muslim identification (n=9)	#FreedomOfSpeech vs #Racism. #Sinophobia is the new #Islamaphobia or #AntiSeminitism
Activism (n=43)	#Coronavirus: #Wuhan natives in US unite to support their city during crisis New York people order fund raising for #medical supplies; But some NY Chinese encounter virus sparked #racism

Some subcodes help to understand who was involved in these advocacy efforts. The code “toward others” (149 tweets) helped to determine that not only Chinese individuals were involved in this process, but that non-Chinese individuals also advocated for racism experienced by the Chinese amid the coronavirus outbreak. Chinese users also advocated for themselves (64 tweets). In some cases, advocacy efforts were not only about oneself on an individual level (45 tweets), as some Chinese individuals included their Chinese community or Asian community as a whole in their advocacy tweets. The following tweet reflects the awareness of advocating against racism toward Chinese individuals:

The only actual threat of the corona virus is the prejudice directed at any Asian person, which many people now believe is acceptable. While in the train, a woman films a racist coronavirus rant.

Most of the tweets with an advocacy goal were meant to break stereotypes, prejudice, and discrimination (Table 3):

In the wake of the #coronavirus outbreak, the Human Rights Commission has offered advice: wash your hands and avoid being #racist and #xenophobic. Coronavirus makes no distinction between your skin color, whether you are black or white. We need to pray for each other. #racism #blacklivesmatter

White allies played an active social media role to deconstruct ideas about the Chinese as viruses (33 tweets). As a team, we faced some difficulties in identifying a Twitter user’s nationality

and/or ethnicity; if this information was not explicitly stated on their Twitter profile, we did not make any inferences. The same applied to the codes *Muslim identification* and *Black identification*:

People on my Facebook page believe that China produced the Corona virus as a type of biological warfare. They cite SARS and avian flu as examples. Why would they do anything like that to their own economy? I'm starting to lose faith in human intelligence.

The Black identification code emerged as some Black Twitter members—who claimed their chosen identity in their Twitter profile—identified with the struggle of racism experienced by the Chinese amid the coronavirus outbreak. A total of 12 tweets were coded as Black identification: “Some people with degraded minds have started acting stereotypically against Chinese people who, at this vital time, they need the world’s support.”

A total of 12 tweets were coded as Black identification. An example is given: “Some people with degraded minds have started acting stereotypically against Chinese people who, at this vital time, they need the world’s support.”

A hypothesis that may need to be explored in future studies is the possible relationship between the discrimination faced by Black communities during the AIDS and Ebola outbreaks as a parallel to Chinese discrimination during the COVID-19 pandemic. Unfortunately, our study’s qualitative data were too vague to establish any solid relationship on why Black

individuals felt particularly empathetic with respect to Chinese racist attacks. Notably, in some countries, including the United States, a recent allyship has been exhibited with the hashtags #asians4blacks during the recent #blacklivesmatter movements in 2020. This code is thus a processor for the reciprocal allyship recently reported.

Muslims also appear to identify with the struggle of racism experienced by the Chinese amid the coronavirus outbreak (9 tweets). When a member of another group experienced oppression, empathy emerged with other communities: “I am mixed race (Arab) and Arabs are racist, they treat Black, desi, east & southeast Asians unrespectfully.”

Activism

A total of 298 tweets were coded as showing activism. Different types of actions were coded under *Antiracist fight* (n=43), including *art creation*, *Asian food sharing*, and *community support* through hug performances and donations (Table 3). In the following example, a Chinese student is asking for donations via GoFundMe. He was assaulted, and is asking for reparations denouncing his situation:

A Chinese student living in Australia was recently attacked and verbally abused with racism because he spoke Chinese. The Coronavirus outbreak has generated racial panic, making our country dangerous for students. Please, donate.

The following initiative used art to combat racism:

Online exhibitions, live museum visits, and special social media events are the answers that Iranian museums promoted to avoid COVID-19. We have initiated a movements against anti-Asian racism within the museums.

In Toronto, a food initiative to fight racism emerged:

This is also true here in Toronto. I've recently made it a point to eat out and order takeaway from an Asian restaurant whenever possible. People will arrive at their favorite late-night eateries in the summer and be perplexed as to why they are closed.

Similarly, in the United States, a Twitter user was promoting eating Chinese food for lunch as the rejection against Chinese businesses increased:

Let's be clear about something. The coronavirus, also known as COVID-19, is not the same as the common cold. Not only Asians get them. It's a significant threat, but it doesn't mean we shouldn't continue to support Asian businesses. For lunch, I'm going to get Chinese food. #fearmongering #racism.

Racist Discourse on Twitter

Apart from the advocacy tweets and activist actions against racism, there were also some tweets demonstrating racist discourse (n=13). Two tweets were intentionally racist and 11 tweets were classified as *unintentionally racist*. None of the tweets analyzed was codified as strategically racist. The following tweet exemplifies an intentionally racist discourse, as the message is communicated with the explicit goal to hurt, harm, or discredit the Chinese community [28]: “Prepare for a

Coronavirus pandemic around the World. Thank you, China. Up yours to everyone who claimed racism. Your hands will be stained with blood!”

By contrast, the following Twitter member engaged in unintentionally racist discourse, as they were not aware or concerned that their arguments could have a racist impact [28]:

People who believe that avoiding vulnerable or compromised communities is #racist deserve no respect. Why do you think prejudice evolved in humans? To keep themselves safe from something far worse! Everyone: To avoid a plague, avoid sick individuals like the plague!

Discussion

Principal Findings

The present work investigated the typology of racism manifested against Chinese individuals amid the COVID-19 outbreak in the first quarter of 2020, and how Twitter users reacted toward racism against Chinese individuals on this specific social network. As main findings, the data support the presence of individual, cultural, and institutional racism against Chinese individuals. Individual racism was the most reported form of racism, especially conveying physical and verbal aggression. Positive reactions that supported the Chinese community were more widely shared. As a form of resistance against racism, Twitter users reacted by engaging in advocacy and activism within their social network. Advocacy was claimed with the hashtag “I am not a virus,” which served to break stereotypes, prejudice, and discrimination. Activism messages showed resistance through art, food sharing, and community support.

Notably, the interpretation of these findings are relevant at three levels: (1) Twitter messages can predict acts of racism and discrimination in advance; (2) Twitter posts help to detect different forms of racism, which works as a tool to fight racism per se; and (3) the online advocacy and allyship work conducted on Twitter can help to break stereotypes in the virtual environment and real world simultaneously. For this reason, the descriptive data provided in this study can strengthen social leaders' capacity to predict racism in the public arena, and begin to implement policies and practices before acts of racism occur, taking into consideration a systematic level for each of the antiracist interventions.

Despite the limited literature on this topic, our study findings line up with the most recent work available [5,7,8,29]. Verbal abuse and physical aggression were the most common forms of racism identified during the outbreak of COVID-19. He et al [7] also found a range of discriminatory acts that varied from verbal abuse to violent attacks. Similarly, we found that discrimination against Chinese individuals occurred in different contexts, with narratives displaying racism on public transportation and schools being prominent. Criss et al [8] reported that racist statements covered overt and subtle expressions against Black, Latinx, and Chinese individuals. However, they did not analyze the direct impact of the COVID-19 outbreak targeting only Chinese individuals [8].

Nevertheless this study and previous work showed that subtle, or inactive, forms of racism manifest in our communities.

Data from 2020 also suggest that Chinese individuals living abroad experienced stigmatization during the COVID-19 pandemic, ranging from overt racism to covert microaggressions [29]. We identified expressions of racism both in overt and subtle forms, including from international students, endorsing previous data regarding this topic. For example, as an overt manner of manifesting racism, Ma and Zhan [29] noticed that Chinese individuals reported verbal abuse, hearing “coronavirus” yelled at them. In our study, Chinese individuals also reported the same type of overt verbal aggression. It is also relevant to highlight that Criss et al [8] detected a vast number of stereotypes against Chinese individuals. Even though their study was not strictly targeted to understanding anti-Chinese racism during the COVID-19 outbreak, they found that the Chinese were highly stigmatized based on their physical features [29]. In our study, these manifestations on Twitter were also noted in the context of name-calling.

Abd-Alrazaq et al [30] analyzed tweets to identify the top concerns of Twitter users. Although the main topic of the study was not racism per se, this subject emerged indirectly as they found a clear increase of racism against Chinese individuals as a form of distress. Their data seem to align with the idea that the Chinese have been impacted by racism during the COVID-19 outbreak. Specifically, the current study demonstrates that racism against Chinese individuals during the COVID-19 outbreak was displayed in many manifestations, including physical, verbal aggressions, and bullying, as reported in past studies, and well-established relationships also changed. Rejection or refusing someone simply for being Chinese or Asian was also common. Rumors and jokes were actively present as a form of uncovered racism. Thus, this study denotes that racism occurs on a broad spectrum and at different system levels—individual, cultural, and institutional—and all forms must be considered.

One of this study’s main strengths is the use of Twitter as a social media network to analyze manifestations of racism against the Chinese amid the COVID-19 outbreak. Twitter was selected as it constitutes a developing setting in which racism and related stress manifest [9]. Twitter is also an important social media platform because it includes information for users to express their worries, opinions, and feeling about the pandemic [8]. Additionally, in recent years, most online social media movements and social forms of denouncement originated or were consolidated on Twitter (eg, #Blacklivesmatter, #sayhername, #asians4blacks).

Nevertheless, limitations should be considered when interpreting the results of this social media study. Although we aimed to analyze tweets in different languages, we were only able to focus on tweets in English and Spanish. As the process of intercoder reliability requires two or more researchers speaking the same language, we could not include tweets in Japanese, Chinese, German, Italian, or French. To prevent bias, we excluded the analysis of certain hashtags such as #ichbinkeinvirus, #jenesuispasunvirus, and #IoNonSonoUnVirus. Furthermore, a small number of tweets were not available (as

some users erased a tweet or Twitter blocked specific messages). In this sense, some tweets no longer existed once captured by NCapture and put in the Excel sheet.

Another major point is that most of the studies on this topic tend to be general when using terminology related to racism. For example, the main goal of the study of Criss et al [8] was to evaluate how information about the virus originated and how fake news spread and fluctuated on Twitter along with its impacts. In their work, racism was a subjacent topic. In this sense, it was quite complex to find research that gathered information directly on racism, specifically against the Chinese, on Twitter during the COVID-19 outbreak. Similarly, the target population of related studies was also broader, and the methodology used varies from qualitative to quantitative designs. As the online hashtag “I am not a virus” was still new when we began this research, and we only analyzed tweets from January 15 until March 3, 2020, we cannot evaluate the connection with subsequent events.

Finally, it is important to mention that when some of the first COVID-19 cases were identified in Italy, discrimination against the Chinese had already been reported on Twitter. As the oppression increased against Chinese individuals, three tweets exhibited how some individuals developed an anti-Italian sentiment and discriminated against Italians during the novel coronavirus outbreak. However, we did not find instances of anti-Italian sentiment systematically in this research. Nevertheless, it is interesting to consider these types of tweets to understand how a group’s oppression can evolve to the oppression of another group during a pandemic. Future studies should take a closer look at this issue and how the relationship between communities evolves. Additionally, we noticed that the terminology used to define the different classifications of racism differs among authors. We used Tatum’s [15] conceptual framework to guide this study; however, no theoretical perspectives were explicitly identified in the other related articles reviewed. Given this situation, it would be convenient to begin theoretically based conversations between researchers to establish a common ground and standardized terminology for future studies.

Conclusions

Most of the tweets analyzed exhibited individual racism from January 15 to March 3, 2020. Specifically, physical and verbal aggressions were denounced during this period, with active forms of racism being more widespread. At lower intensity, rejection as an active form of racism was highlighted (eg, canceling taxi reservations only once seeing a person’s Chinese name or rejecting doctors that appear to be Asian in the medical field). The hashtag “I am not a virus” was used during the first quarter of 2020 as a form of antiracist advocacy. Twitter is used as a form of advocacy to denounce mainly physical and verbal aggressions. The hashtag “I am not a virus” helped break stereotypes, prejudice, and Twitter discrimination. Allyship relationships were also evident, including white, Black, and Muslim allyship. Activism through social media manifested through art, food sharing, and community support.

As social implications and considerations for the future, policies and practices must be concentrated on preventing physical

aggression and verbal abuse against the Chinese. This is necessary to fight racism considering the different systems implied, as antiracist interventions have to be targeted at the individual, cultural, and institutional levels. Covert manifestations are also present in society, and thus interventions in this direction must not be forgotten. Overall, this study

highlights that Twitter could be a useful tool for advocacy and activism, helping to break stereotypes, prejudice, and discrimination at a population level. Thus, social interventions should consider both real life and cyberspace for antiracism education in the general population.

Abstract

Background: Evidence suggests that economic, social, and psychological circumstances brought about by the COVID-19 pandemic may have a serious impact on behavioral health. Men who have sex with men (MSM) are disproportionately impacted by HIV and stimulant use, the co-occurrence of which heightens HIV transmission risk and undermines nationwide treatment strategies as prevention efforts for ending the HIV epidemic. There is a paucity of information regarding the potential impact of the COVID-19 pandemic on the substance use and HIV medication adherence in this key vulnerable population—MSM who use stimulants and are living with HIV.

Objective: The aim of this qualitative study was to identify ways in which the COVID-19 pandemic has affected stimulant use and antiretroviral therapy (ART) adherence among a sample of MSM living with HIV.

Methods: Two focus groups were conducted in August 2020 via videoconferencing technology compliant with the Health Insurance Portability and Accountability Act. Potential participants from an established research participant registry at State University of New York Downstate Health Sciences University were invited and screened for study participation on the basis of inclusion criteria. A semistructured interview guide was followed. A general inductive approach was used to analyze the data. Findings in two general areas of interest, the impact of the COVID-19 pandemic on stimulant use and ART adherence, emerged directly from the raw data.

Results: A total of 12 ethnically diverse participants over the age of 25 years took part in the study. Results were heterogeneous in terms of the effects of the pandemic on both stimulant use and ART adherence among MSM living with HIV. Some men indicated increased or sustained stimulant use and ART adherence, and others reported decreased stimulant use and ART adherence. Reasons for these behavioral changes ranged from concerns about their own health and that of their loved ones to challenges brought about by the lack of daily structure during the lockdown phase of the pandemic and emotion regulation difficulties.

Conclusions: The COVID-19 pandemic has had a differential impact on stimulant use and ART medication adherence among MSM living with HIV. The reasons for behavioral change identified in this study may be salient intervention targets to support ART medication adherence and lower stimulant use among MSM in the aftermath of the of the COVID-19 pandemic, as well as beyond.

KEYWORDS

stimulants; HIV; ART; antiretroviral therapy; MSM; men who have sex with men; COVID-19; pandemic; therapy; drug use; virtual focus groups; virtual health; medication adherence

Introduction

As the world encounters the most significant pandemic since 1918, caused by SARS-CoV-2, studies have begun investigating the direct and indirect impact of the pandemic on various health outcomes. Recent evidence suggests the myriad economic, social, and psychological challenges introduced by the pandemic and related prevention measures (eg, shelter-in-place orders) have been associated with serious behavioral health consequences, including increased substance use [1].

Gay, bisexual, and other men who have sex with men (MSM) in the United States face disproportionate rates of substance use and are specifically more likely to use stimulants (eg, methamphetamine, powder cocaine, and crack cocaine) than heterosexual men [2-4]. MSM are also disproportionately impacted by HIV, accounting for approximately 66% of annual diagnoses [5]. The co-occurrence of these conditions poses unique challenges: stimulant use among MSM living with HIV has been associated with lower antiretroviral therapy (ART) adherence, substantially elevated viral load, and amplified HIV transmission risk [6-12], thus undermining national treatment as prevention efforts for ending the HIV epidemic.

There is reason to believe that MSM who are living with HIV and use stimulants may be particularly at risk for negative health outcomes related to the COVID-19 pandemic [13]. However, there is a paucity of information regarding the impact of the pandemic on the health behaviors of this population. To address this knowledge gap, we sought to identify ways in which the COVID-19 pandemic has affected stimulant use and ART adherence in a sample of MSM living with HIV.

Methods

Methods Overview

We conducted 2 virtual focus groups with a total of 12 participants in August 2020. Potential participants were invited to screen for eligibility via emails sent out in July 2020 to a research participant registry at State University of New York Downstate Health Sciences University. Eligibility criteria for the study included identifying as a cisgender man, having had sex with another man in the past 12 months, currently living with HIV (self-reported diagnosis obtained by a health care provider), and currently taking ART. Furthermore, to be included in the study, participants had to indicate at least some difficulties with ART adherence in the past 30 days on the 3-item Wilson measure [14,15] and screen positive for moderate to severe stimulant use (ie, cocaine or amphetamine-type stimulants) on the abbreviated version of the Alcohol, Smoking, and Substance Involvement Screening Test [16]. Finally, all participants were required to be at least 18 years of age, speak English, and reside in the United States. Men who met the eligibility criteria, consented to take part in the study, and

participated in one of the two focus groups received a US \$50 Amazon gift card as compensation for their time.

Procedures

Both focus groups were conducted remotely using Health Insurance Portability and Accountability Act-compliant videoconferencing technology. Participants and facilitators joined the virtual focus group with both video and audio, though only an audio recording was retained for review and transcription. The groups were facilitated by a clinical psychologist with expertise in conducting multiple research studies with MSM living with HIV who use stimulants. He introduced himself as a cisgender white gay man sharing his professional interests and position. The study coordinator, a white cisgender woman with a master's degree in public health, was also present at each focus group call to provide technical assistance. The focus groups were conducted in English and a semistructured interview guide with suggested probes to elicit and clarify responses was followed. The participants were asked about the impact of the COVID-19 pandemic on their stimulant use and ART medication adherence.

Analysis

A general inductive approach was used to analyze the data [17]. In unison with the approach, findings emerged directly from the raw data, even though the focus groups were conducted with broad areas of interest in mind. Both transcripts were read by a PhD-level prevention scientist and licensed mental health counselor with long-standing clinical and intervention development expertise in the field of substance use prevention. A comprehensive codebook was developed with areas of interest, codes, and subcodes based on the participants' responses. The person who developed the codebook and a first-year PhD student in clinical psychology independently coded one of the interviews to assess the functionality of the codebook and to refine it.

The final codebook contained 8 codes and 28 subcodes. Each of the coders coded both focus transcripts using the final codebook. Initial agreement on the first transcript was 86%. The agreement rate on the following transcript was 80%. The two coders discussed and reached 100% consensus on all final codes. Changes and refinements of the codebook were made after coding each transcript. After coding all interviews, the 2 coders met to discuss the most salient and commonly endorsed codes across the 2 focus groups. These codes were then merged into higher-order themes within the broad areas of interest (categories) identified prior to conducting the interviews.

Ethical Considerations

Study procedures were approved by the institutional review board of the University of Miami (20190578).

Results

Participants

Table 1 shows the participant demographic data. A total of 12 stimulant-using MSM living with HIV took part in the 2 focus groups (7 men in one group and 5 in the other). All participants were over 25 years of age: 3 (25%) men were in the 26-35-year age bracket, 3 (25%) were in the 36-45-year age bracket, and

6 (50%) were aged 46 years or older. In total, 3 (25%) participants identified as Black or African American, 6 (50%) identified as Latinx, and 3 (25%) identified as white. Only 1 (8%) participant reported an HIV diagnosis in the last 12 months, while all others (n=11, 92%) reported having been living with HIV for longer than 1 year. In total, 9 (75%) participants reported amphetamine use alone, 2 (17%) reported cocaine use alone, and 1 (8%) reported both amphetamine and cocaine use.

Table 1. Participant demographic data (N=12).

Category	Frequency, n (%)
Sex	
Male	12 (100)
Female	0 (0)
Age (years)	
26-35	3 (25)
36-45	3 (25)
≥46	6 (50)
Race and ethnicity	
Black or African American	3 (25)
White	3 (25)
Hispanic or Latinx	6 (50)

Qualitative Themes

The results are shown in accordance with the distinct themes that emerged during the data analysis in the two categories of interest: ART adherence and substance use. **Table 2** provides a summary of the results. Regarding the effects of the COVID-19 pandemic on stimulant use, two dominant themes emerged:

increased or sustained versus decreased stimulant use. Higher versus lower ART adherence were the 2 categories that were identified during the discussions regarding ART adherence. Our analysis also sought to elucidate the participants' reasons underlying the differential impact of the COVID-19 pandemic on stimulant use and ART medication adherence among MSM living with HIV.

Table 2. Qualitative results summary.

Themes	Subthemes	Subtheme examples
Category: stimulant use		
Perceived reasons for increased or sustained stimulant use (4, 33% participants)		
	Avoidance of negative affect during the stay-at-home orders	“Ever since corona I pretty much just been getting high all the time... I get lonely. Normally I'd be at work for an extra eight hours.”
	Re-experiencing of enjoyable activities during the stay-at-home orders	“‘Oh, I miss the feeling’ and I'll go back to it. So, since I've been home more, I feel like I have used [stimulants] more than I have in the couple months prior to that per se.”
	Simultaneous availability of free time and financial resources	“They [workers] were getting 2,000 dollars a month... it's unusual for me [to have] both free time and money coming in... I kind of got to the point from sort of the end of March until the end of May where I had never really been sort of a constant user but I turned into one.”
Perceived reasons for decreased stimulant use (4, 33% participants)		
	Concern for the one's own well-being	“I had time on my hands... but I really wanted to make sure I stayed in, and it was good, you know?”
	Concern for others' well-being	“Well, my case is because I have family so I don't want to put them at risk and, going out, it would be a risk for them more than for me.”
	Lack of opportunities for social interaction	“Less [stimulant use]... only because there's nothing to do once I've used.”
Category: antiretroviral therapy adherence		
Perceived reasons for decreased antiretroviral therapy adherence (3, 30% participants)		
	Lack of life structure owing to the stay-at-home orders	“For the first month, month and a half, my adherence percentage went way down... I didn't know what day it was. It was very hard, although I was working from home certain times... it's like, ‘Did I take it, did I not take it?’ I don't remember.”
	Medication access	“I could only get a one-month supply at a time when it wasn't being mailed to me. I had to, you know, because of how it was being paid for, I had to actually physically go into the drugstore and then there was this whole thing around doing that safely, so... my adherence went down.”

Category 1: Stimulant Use

Of the total number of focus group participants (n=12), 4 men endorsed increased stimulant use and 4 reported that their stimulant use had decreased as a result of the COVID-19 pandemic.

Theme 1: Perceived Reasons for Increased or Sustained Stimulant Use

Among men who reported an increase in stimulant use, our findings were varied: one participant resumed consistent stimulant use after 18 months of sobriety, one progressed from occasional to daily use, one expressed an elevation in the frequency of his occasional use, and one transitioned from social to a greater amount of solitary use. The most endorsed reason for increased or sustained stimulant use consistently stayed at home during the lockdown phase of the government's response to the pandemic. Men reported three other reasons for their increased or sustained stimulant use during the stay-at-home orders: to avoid negative affect, to re-experience activities that

were enjoyable or exciting, and the simultaneous availability of time and financial resources. One participant associated loneliness with spending more time inside, which he related to his recent relapse in stimulant use:

I was clean for about 18 months before that and then I lost my job due to corona... Ever since corona I pretty much just been getting high all the time... I get lonely. Normally I'd be at work for an extra eight hours.

Another participant explained the following:

I'll do it [use stimulants] pretty often, then I'll stop for a year or two, then it's like, ‘Oh, I miss the feeling’ and I'll go back to it. So, since I've been home more, I feel like I have used [stimulants] more than I have in the couple months prior to that per se.

A third participant expressed that the combination of free time and the availability of unemployment or stimulus financial

support during the pandemic may have facilitated his increased stimulant use:

They [workers] were getting 2,000 dollars a month... it's unusual for me [to have] both free time and money coming in... I kind of got to the point from sort of the end of March until the end of May where I had never really been sort of a constant user but I turned into one.

Theme 2: Perceived Reasons for Decreased Stimulant Use

Three main subthemes regarding reasons for participants' decreased stimulant use during the COVID-19 pandemic emerged. The first subtheme was concern for the well-being of oneself and of others. One participant expressed the following:

When we were locked down, I really curtailed mine [stimulant use], because I would not let myself fuck up... I took it very seriously in terms of...sheltering in place.

Similar to the men who increased their stimulant use, those who curtailed their use experienced having a lot of free time. However, the participants who reported lower stimulant use attributed that to their strong desire to remain healthy:

I had time on my hands... but I really wanted to make sure I stayed in, and it was good, you know?

Participants were motivated to decrease their stimulant use owing to not only personal health concerns but also concern regarding the health of those around them. Two participants explained the following:

Well, my case is because I have family so I don't want to put them at risk and, going out, it would be a risk for them more than for me.

But now with COVID and I, like, I have a daughter and I have someone who lives with me actually recovering from their drug addiction, so I wouldn't do nothing serious [stimulants] at home.

The third major driving force behind curtailing one's stimulant use was the lack of opportunities for social interaction:

Less [stimulant use]... only because there's nothing to do once I've used."; "For me, the hard stuff [stimulants] will be socializing with my friends.

Category 2: ART Adherence

Similar to its effect on stimulant use, the COVID-19 pandemic appeared to have had an impact on ART adherence of the men in our study: equal numbers of participants expressed increased (n=3) and decreased (n=3) adherence to their HIV medication.

Theme 1: Perceived Reasons for Decreased ART Adherence

In total, 2 of the 3 participants who reported lower medication adherence since the beginning of the pandemic expressed that the lack of structure in their lives due to the stay-at-home orders made it difficult to keep track of their medication intake. One expressed the following:

For the first month, month and a half, my adherence percentage went way down... I didn't know what day it was. It was very hard, although I was working from home certain times... it's like, 'Did I take it, did I not take it?' I don't remember.

One participant attributed his lower ART medication adherence to medication access:

I could only get a one-month supply at a time when it wasn't being mailed to me. I had to, you know, because of how it was being paid for; I had to actually physically go into the drugstore, and then there was this whole thing around doing that safely, so... my adherence went down.

Theme 2: Perceived Reasons for Increased ART Adherence

Two main subthemes emerged as perceived reasons for participants' increased adherence to ART medication: curtailed stimulant use and self-compassion.

Two men attributed their increased adherence to ART medication to their curtailed stimulant use:

I've found that since COVID I've actually used less [stimulants]. Before I would always just use at home and I would find that I would miss my doses [ART medication]

Well, for me when it comes to that, to that binge [stimulant use] like you call it, I'm usually out of the house... And then it's more of not having the medication accessible than forgetting... So then, as soon as I get in the house, I start again, but during COVID it hasn't been more than one day.

One of the participants, who expressed higher medication adherence since the beginning of the COVID-19 pandemic, spoke about concern regarding his well-being and understanding of his potentially increased susceptibility to COVID-19:

COVID has really made me want to stay on top of my medication simply because I figure I don't need anything else. On top of that having a compromised immune system.

Discussion

Principal Findings

It is of particular importance to gain insight into the impact of the COVID-19 pandemic on stimulant use and ART adherence among MSM living with HIV who use stimulants, as such factors could undermine the clinical and public health benefits of HIV treatment as prevention [18]. This study sought to investigate how the COVID-19 pandemic has impacted stimulant use and HIV medication adherence among MSM. Our analysis revealed that the COVID-19 pandemic had different effects on stimulant use and ART adherence for men living with HIV who use stimulants. Of the men who discussed their experiences with stimulant use during the pandemic, half reported increased or sustained stimulant use and half disclosed that their stimulant use had decreased. Similarly, of the participants who expressed

how the pandemic has impacted their medication adherence, half experienced improvements in their medication adherence and half reported that they were less likely to be fully compliant with their ART regimen.

Improved ART Adherence and Lower Stimulant Use During the COVID-19 Pandemic

One of the most prominent perceived reasons for experiencing improved health outcomes (lower stimulant use or higher medication adherence) during the pandemic was men's concern for their health. Participants who had lower stimulant use displayed a clear understanding that owing to their HIV diagnoses, they may be more susceptible to contracting COVID-19 and that staying at home (rather than engaging in stimulant use, which, for many people, is achieved in social settings) and taking their ART medication is what would keep them protected. This finding is consistent with the health belief model, which postulates that a person's perception regarding a personal threat of an illness together with their belief in the effectiveness of a recommended health behavior will predict the likelihood that they will adopt the behavior [19]. These results suggest that during major health crises, such as the COVID-19 pandemic, supporting vulnerable populations (eg, MSM with co-occurring HIV and stimulant use) in understanding their potentially heightened disease susceptibility, along with providing clear directions for disease prevention (eg, wearing masks in public), may be an effective public health strategy for some persons.

Altruism was another prominent feature of the narrative regarding ways in which the COVID-19 pandemic has influenced our participants to lower their stimulant use. Altruism can be broadly defined as the practice of selfless concern for the well-being of others [20]. Men in our focus groups expressed that they curtailed their use because the behaviors associated with partying (going out and interacting with others) would expose their family members to the risk of contracting COVID-19 or because stimulant use at home may compromise the substance use recovery of people living in the same household.

Prior research has found that helping others is associated with better mental health [21] and significantly protects against engaging in serodiscordant condomless anal intercourse [22]. People who use drugs are among the most stigmatized and mistreated in the United States [23,24]. Nonetheless, our results suggest that some MSM living with HIV who use stimulants are motivated by altruism for the benefit of others' health and will alter their own substance use to protect others. Thus, altruism may be an important intervention target for stimulant use reduction among MSM.

Our findings demonstrate that decreased opportunities for social interaction during the COVID-19 pandemic appeared to have reduced some participants' stimulant use. Stimulant use has been consistently described as facilitative of seeking and engaging in risky sexual practices (eg, condomless sex and multiple sexual partners) [12,25-29] and as increasing sexual arousal, lowering sexual inhibitions, and increasing personal confidence [30-32]. One study on MSM living with HIV who use stimulants identified two themes regarding motivation:

sexual enhancement and negative affect associated with an HIV-positive serostatus [33]. Although interview questions in this study did not investigate participants' motivations for stimulant use, it is plausible that men who were more motivated to use stimulants for sexual enhancement may have curtailed their use because of decreased opportunities to meet sexual partners during the lockdown stages of the pandemic. Thus, identifying the motivations underlying stimulant use among MSM and addressing those motivations (eg, by shifting the social norms around them or by additional skill-building to address the specific need) may be a viable means of stimulant use prevention during the COVID-19 pandemic and beyond.

Lower ART Adherence and Increased Stimulant Use During the COVID-19 Pandemic

The extended, unstructured time spent at home during the initial lockdown phase of the COVID-19 pandemic emerged as a dominant theme during the discussion regarding reasons for lower ART medication adherence. Our participants struggled with the lack of daily anchoring activities (eg, work schedule) and found it more difficult to take their HIV medication consistently. Thus, an important public health strategy during the COVID-19 pandemic and beyond may consist of mental health clinicians, medical staff, and other health personnel who interact with MSM on ART to assist patients with creating a regimen or utilizing a mobile reminder system to ensure timely medication uptake.

During the prolonged periods of time spent at home, our participants also reported using stimulants to avoid negative emotions (eg, loneliness) as well as to experience positive ones, both of which are aspects of impulsivity. In the literature, impulsivity is regarded as a multidimensional construct consisting of five facets: negative urgency (tendency to act rashly when experiencing negative affect), positive urgency (tendency to act rashly when experiencing positive affect), sensation seeking (tendency to enjoy and pursue exciting activities), lack of premeditation (not considering the consequences of an act before engaging in it), and lack of perseverance (difficulties remaining focused on a tedious task) [34,35]. Thus, it may be that some participants described negative urgency (to avoid negative feelings such as loneliness) and positive urgency (to experience positive feelings) as reasons for increased or continued stimulant use during the pandemic. These findings are well supported by studies that show a significant association between impulsivity and severity of drug use among cocaine and methamphetamine users [36,37]. Both our qualitative findings and prior data suggest that impulsivity may be an important intervention target for the prevention or reduction of stimulant use among vulnerable populations such as MSM living with HIV.

Finally, men in our study highlighted how the response of the larger social systems to the COVID-19 pandemic may have impacted their medication adherence and stimulant use. Having to pick up medication in person and not having a medication supply for more than 3 months were barriers to participants' ART adherence. Our analysis also made evident the notion that while distributing financial support during a large public health crisis is certainly necessary, it is simply not sufficient. In

addition to monetary support, many people with co-occurring health risks and conditions may need additional assistance (eg, to help them structure their budgets, create daily routines, or maintain stable psychosocial functioning) while in quarantine.

Limitations

Our results should be interpreted in light of some limitations. The focus groups were conducted with a small sample of MSM living with HIV who use stimulants. Although Guest et al [38] have provided evidence that thematic saturation occurs within the first 12 interviews with purposefully sampled participants, it is essential to recognize that during focus groups, not all 12 participants voiced responses regarding their drug use and medication adherence. Thus, thematic saturation may have not been reached, and there is a need for larger qualitative studies on the topic. This study's results serve as potential avenues for exploration in larger examinations of the impact of COVID-19 on stimulant use and ART adherence among more robust samples. Finally, we acknowledge that this qualitative study was not intended to be generalizable, but rather to gain an initial understanding of the impact of the COVID-19 pandemic on a specific group of people (MSM living with HIV with suboptimal ART adherence) and thus should not be interpreted as such.

Conclusions

Our qualitative findings suggest that the COVID-19 pandemic is not having the same impact on all MSM who are living with HIV and are using stimulants. Indeed, our results show that different men may be responding differently to the pandemic in terms of stimulant use and ART adherence. This formative qualitative study identified some potentially salient intervention targets to support HIV medication adherence and lower stimulant use among MSM (eg, impulsivity, altruism, and motivation for stimulant use) during the COVID-19 pandemic and beyond. Importantly, the results from this study show nuanced reasons for adjusting their stimulant use and ART adherence patterns. The narrative of this study's participants demonstrated that MSM living with HIV who use stimulants and have suboptimal compliance with ART medication practice self-compassion and altruism, modifying their health risk behaviors to strengthen their own health and to protect that of others. Finally, this study highlights the importance of easy and flexible access to medication, as well as the need to provide comprehensive support (eg, financial and psychosocial) to vulnerable populations.
