Abstract

Background: The collaborative care model is a well-established system of behavioral health care within primary care settings. There is potential for mobile health (mHealth) technology to augment collaborative behavioral health care in primary care settings, thereby improving scalability, efficiency, and clinical outcomes.

Objective: We aimed to assess the feasibility of engaging with and the preliminary clinical outcomes of an mHealth platform that was used to augment an existing collaborative care program in primary care settings.

Methods: We performed a longitudinal, single-arm feasibility study of an mHealth platform that was used to augment collaborative care. A total of 3 behavioral health care managers, who were responsible for coordinating disease management in 6 primary care practices, encouraged participants to use a mobile app to augment the collaborative model of behavioral health care. The mHealth platform's functions included asynchronous chats with the behavioral health care managers, depression self-report assessments, and psychoeducational content. The primary outcome was the feasibility of engagement, which was based on the number and type of participant-generated actions that were completed in the app. The primary clinical end point was a comparison of the baseline and final assessments of the Patient Health Questionnaire-9.

Results: Of the 245 individuals who were referred by their primary care provider for behavioral health services, 89 (36.3%) consented to app-augmented behavioral health care. Only 12% (11/89) never engaged with the app during the study period. Across all participants, we observed a median engagement of 7 (IQR 12; mean 10.4; range 0-130) actions in the app (participants: n=78). The chat function was the most popular, followed by psychoeducational content and assessments. The subgroup analysis revealed no significant differences in app usage by age ($P=.42$) or sex ($P=.84$). The clinical improvement rate in our sample was 73% (32/44), although follow-up assessments were only available for 49% (44/89) of participants.

Conclusions: Our preliminary findings indicate the moderate feasibility of using mHealth technology to augment behavioral health care in primary care settings. The results of this study are applicable to improving the design and implementation of mobile apps in collaborative care.

Introduction

Background

The reach of behavioral health services is insufficient for meeting the needs of the population [1,2]. The collaborative care model (CoCM) is a framework that attempts to meet this vast need for behavioral health services by embedding these services in primary care settings [3]. The CoCM is a system of outcome-driven, stepwise care for systematically identifying individuals who would benefit from behavioral health treatment and supporting primary care clinicians in their management. The model has been adapted by many health systems since its introduction in the 1990s and is considered best practice [4-6]. Unfortunately, there are challenges that limit the scalability of the CoCM, including financial and operational barriers [7,8]. Innovative approaches are needed to support these existing models of behavioral health care [9].

There is emerging evidence that digital and mobile health (mHealth) technologies have the potential to improve the reach of the CoCM [9-12]. Given the near ubiquity of smartphones with app capabilities, health systems are increasingly interested in understanding whether these tools can be harnessed to further extend collaborative care [13,14]. There are several meaningful ways that mobile apps could be used to augment collaborative care. The CoCM relies strongly on a measurement-based system of care in which validated clinical assessments (eg, the Patient Health Questionnaire-9 [PHQ-9]) are regularly collected to assess clinical responses [15]. mHealth platforms could help decrease care providers' workload by automating the collection of these measures [12,13]. Apps could also support clinical decision-making by collecting clinical information more frequently than what is currently possible [10]. Moreover, apps could facilitate more frequent communication between patients and care providers [16,17]. Finally, apps can act as repositories for educational materials and self-guided modules for reinforcing concepts that are learned in therapy and promoting patient engagement [13,18-20]. All of these factors have the potential to increase patient engagement in care and, eventually, result in improved clinical outcomes.

Despite the theoretical benefits of app-augmented collaborative care, relatively little is still known about the feasibility of app usage in collaborative care. It is unknown whether patients in collaborative care settings are likely to use apps, what features of mobile apps are the most beneficial in this setting, and what patient population(s) may be the most likely to benefit from app-augmented collaborative care [11]. For example, in the broader literature on mHealth, there is concern that older individuals may be less familiar with technology and may therefore be less inclined to engage with it [21]; however, this has not been systematically examined, to our knowledge, in the collaborative care setting. The limited existing studies suggest that overall, app usage among patients in collaborative care can be variable [9,12]. Understanding app usage is applicable to the optimization of mHealth platform interventions and their implementation in collaborative care [22]. If known, this information could lay the groundwork for improving the design and implementation of mobile apps in collaborative care.

Objectives

This study describes a feasibility study of the Valera Health mobile platform and app (Valera Health Inc), which was used to augment collaborative care within primary care practices in a large health care system. Our primary aim was to assess the feasibility of app usage, which was measured based on engagement. A secondary outcome was preliminary clinical improvement in depression scores.

Methods

Ethics Approval

The study methods were approved by the Institutional Review Board of Northwell Health (approval number: 20-0545-NH). Informed consent was not sought due to the retrospective nature of the study.

Study Overview

This was a retrospective review of a longitudinal, single-arm implementation initiative wherein individuals who were referred to the collaborative care program by their primary care providers (PCPs) were invited to participate in app-augmented collaborative care by the behavioral health care manager (BHCM). Individuals who were qualified to participate and agreed to do so were asked to download the Valera Health mobile app. Participants were told to use the app to complete in-app PHQ-9 measures, which were sent by the BHCM at preset monthly intervals; communicate with the BHCM through asynchronous chats as needed; and access the psychoeducational content in the app. Participants also experienced all usual collaborative care interventions, as described in the *Study Setting* section, including office visits and telephone contacts with the BHCM, short-term psychotherapy, care coordination, psychiatric case reviews, follow-ups with their PCPs as indicated, and the prescription of recommended psychiatric medications if indicated. PHQ-9 assessments were able to be completed through the app or on paper during office visits with the BHCM. For our primary outcome—feasibility—usage data on the number of user actions that were completed in the app were recorded by the app throughout the participation period. For our secondary outcome—clinical improvement—baseline and final PHQ-9 scores were compared.

Study Setting

The study was conducted in a large, primarily suburban, academic health care system with multiple affiliated primary care practices. The primary care practices that were involved in this study provide behavioral health services through a system that was modeled after the CoCM introduced in the Improving Mood—Providing Access to Collaborative Treatment trial [6]. Briefly, in this model, patients presenting for routine primary care are systematically screened for depression by their PCPs using the PHQ-9—a tool that has been validated for this purpose [23]. Patients who screen positive on the instrument and/or, in the opinion of the PCP, display clinical features that are concerning for a behavioral health disorder are referred to a BHCM who is physically embedded in the clinic. The BHCM maintains a registry of patients, tracks outcomes via serial PHQ-9 assessments, provides time-limited psychotherapy,

coordinates referrals to continued treatment and/or a higher level of care when necessary, and liaises with a psychiatrist who provides remote supervision to multiple BHCMS. Psychopharmacologic recommendations are relayed to the PCP, who remains the prescriber and clinician of record.

Recruitment

Recruitment was planned in 2 phases. The first phase lasted from November 2018 to June 2019 and included 1 primary care practice with 1 BHCM. A total of 5 additional practices and 2 BHCMS were added in phase 2, which lasted from November 2019 to March 2020. There were no differences in procedures between the two phases except for the number of clinics and BHCMS involved. Patients who were referred to the collaborative care program were invited to participate in app-augmented collaborative care by the BHCM during initial appointments. During recruitment at the initial visits, the BHCM guided the participants through the process of downloading and using the app, answered any initial questions, and provided written instructions on the use of the app. After the initial visits, the BHCM was available by phone to troubleshoot the app as needed. Recruitment was halted in March 2020 when the social distancing measures that were required to prevent the spread of COVID-19 in New York resulted in the remote provision of ambulatory behavioral health services.

Individuals who declined to participate or were excluded received usual collaborative care, including primary care and behavioral health services. Those who agreed to participate

received usual collaborative care, as described above, with the Valera Health mobile app as augmentation.

Individuals were included if they were adults with a diagnosis of depression or anxiety. Individuals were also excluded if they did not speak English or had severe mental illnesses, suicidal or violent ideation, or substance abuse disorders. Also excluded were children and individuals who required a referral to a higher level of care or continued treatment after the completion of the program.

Participation flow is illustrated by [Figure 1](#). Between November 2019 and March 2020, a total of 245 individuals were referred by their PCPs to the collaborative care program for behavioral health services. Further, 58% (n=142) of these patients were eligible for and were recruited to participate in our study using the Valera Health mobile app ([Figure 2](#)), and 62.7% (89/142) of recruited patients consented to participate; 34 consented during the first phase of piloting the Valera Health mobile app, and 55 consented during the second phase. The time required to train patients in the use of the app was a barrier to recruitment among a sizable minority of individuals in the target population (38/245, 15.5%; [Figure 1](#)). In addition, a portion of our eligible patient population was unable to participate due to technical barriers (22/142, 15.5%; [Figure 1](#)). Further, 7 individuals declined to participate due to privacy concerns ([Figure 1](#)). Participants were mostly female (60/89, 67%) and middle-aged (mean 38.6, SD 14 years). Participants were enrolled in the study for an average of 22 weeks.

Figure 1. The flow of patient participation in the Valera Health mobile app pilot for behavioral health.

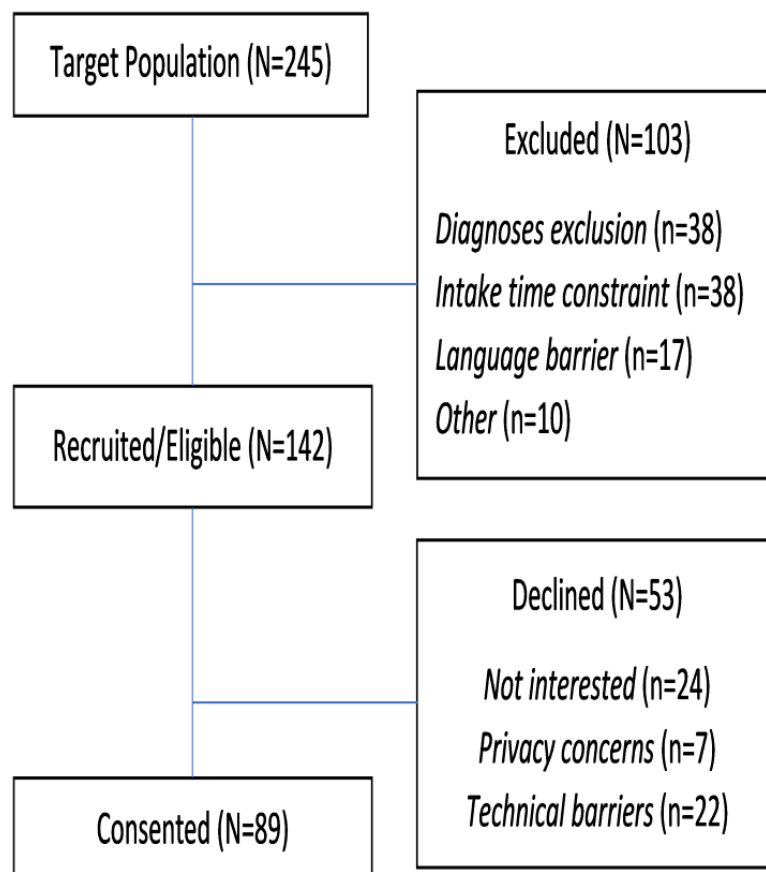

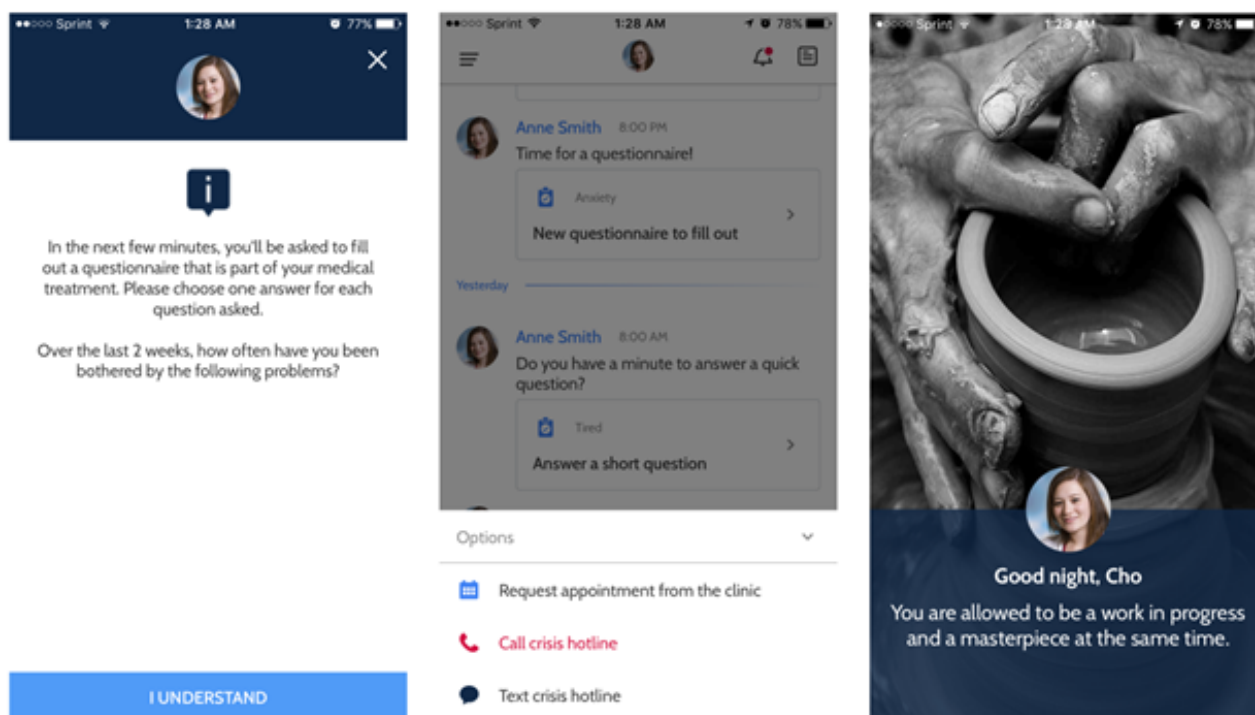

Figure 2. The patient user interface of and the experience on the Valera Health app.

Intervention

The Valera Health mobile app is an English-language secure platform with several functionalities. Figure 2 shows screenshots of the app. First, the app automatically sends PHQ-9 assessments to participants at monthly intervals that are preset by the BHCM. Second, the app allows for secure asynchronous messaging between participants and the BHCM. BHCMS typically responded to chat messages from participants within 1 business day. The app also contains psychoeducational content. This content includes written material about common behavioral health conditions such as depression and anxiety, education about treatments like medication and psychotherapy, instructional guides on topics such as mindfulness, and video and audio clips on these topics. The BHCM had the option of prompting the participants to access psychoeducational content that was relevant to the participants' care via the app. The Valera Health app was not integrated into the electronic health record (EHR). Relevant clinical information from the app, such as PHQ-9 scores, was documented into the EHR by the BHCM.

Outcomes

We assessed the feasibility of the mHealth intervention by investigating engagement with the app and improvement in clinical outcomes. The primary outcome—the feasibility of engagement—was assessed based on app usage, which was measured as the number of participant-generated actions completed in the app. Possible participant-generated actions were (1) the in-app completion of PHQ-9 assessments, (2) the sending of a chat message, or (3) the accessing of in-app psychoeducational material. App usage was monitored throughout the study by the Valera Health app. Engagement was stratified by age and sex. A secondary outcome was clinical improvement, which we defined as a final PHQ-9 score of less than 10 or a greater than 50% reduction in PHQ-9 scores.

Baseline PHQ-9 scores were assessed during intake by the BHCM. The final PHQ-9 scores were the last ones recorded for the participants and were extracted from the EHR. Any PHQ-9 assessment, whether it was completed through the app or on paper during office visits with the BHCM, was considered in the analysis of clinical improvement.

Data Analysis

Data were analyzed by using Microsoft Excel, and an α of .05 was set as the a priori level of significance. Simple descriptive statistics of app usage were used to report on feasibility and engagement metrics. A Kruskal-Wallis equality-of-populations rank test of median differences in total mobile app actions was used to analyze differences in app usage between age and sex groups. For our secondary outcome—clinical improvement—a 2-tailed, 2-sample Welch *t* test with unequal variances was used to analyze the difference between baseline and follow-up PHQ-9 scores.

Results

Table 1 describes the brief demographic and engagement characteristics of participants. Only 12% (11/89) never engaged with the app during the trial. Across all participants, we observed a median engagement of 7 (IQR 12; mean 10.4; range 0-130) actions in the app. At least 1 action in the mobile app was completed by 87% (78/89) of participants. Psychoeducational content was reviewed by 75% (67/89) of participants (number of articles reviewed: median 2, IQR 4; range 0-18). Chat messages were sent by 62% (55/89) of participants. Participants sent a median of 1 (IQR 5; range 0-115) chat message used for either scheduling an appointment or reporting symptoms.

A baseline PHQ-9 score was reported for 97% (86/89) of study participants. However, follow-up PHQ-9 assessments were

available only for 49% (44/89) of participants. PHQ-9 scores improved from baseline to follow-up for 73% (32/44) of participants for whom we had baseline and follow-up PHQ-9 scores (n=44). The percentages of participants with improved PHQ-9 scores were not different by sex ($P=.53$) or age groups

(18-35, 36-55, and ≥ 56 years: $P=.90$), although as previously noted, the sample of participants with recorded follow-up PHQ-9 scores was notably smaller than the sample of participants with baseline PHQ-9 scores.

Discussion

Principal Findings

This study reports on the evaluation of one of the first implementations of mobile app-augmented care within a collaborative care program. The overarching purpose of this feasibility study was to understand whether patients in collaborative care are likely to participate in app-augmented care, what features of the app are used, and whether demographic differences exist among app users in this context. Overall, our results indicate the acceptability and feasibility of app usage; the overwhelming majority of participants (78/89, 87%) used the app at least once, and a modest median of 7 actions were completed in the app. Encouragingly, all of the features of the app were used at similar rates. In particular, the psychoeducational materials and chat feature were both popular functions, suggesting that the app may indeed act to reinforce the concepts that are learned during clinical encounters and can enhance communication between patients and care providers as postulated in the literature [13]. There was no significant difference in app usage by age group ($P=.42$). Finally, we were encouraged by the finding that privacy—a concern in the broader literature surrounding app usage—was an infrequent cause for declining to participate (n=7) in our study, further suggesting acceptability [24,25].

With regard to our secondary outcome, the preliminary clinical outcomes of app-augmented care in this study were encouraging, with 73% (32/44) of participants for whom follow-up PHQ-9

data were available experiencing improvements (n=44). Our findings on clinical outcomes are limited by the considerable drop-off in the number of participants who completed a follow-up PHQ-9 assessment. The reasons for such decreases are not completely known and include app attrition, which is consistent with previous literature showing that attrition is a challenge to the implementation of mobile technologies [12,26]. The missing data also introduced bias into the study, as the population of participants who did not complete follow-up assessments may not be random.

Implications

Our findings reveal several issues that deserve consideration and optimization prior to subsequent implementation efforts. First, despite the prevalence of smartphones, a nontrivial portion of our eligible patient population was unable to participate due to technical barriers (22/142, 15.5%). In addition, the time required to train patients in the use of the app was a barrier to recruitment among a sizable minority of individuals in the target population (38/245, 15.5%). To address these issues, previous literature has postulated the need for a digital health navigator—a new team member with expertise in digital and mobile strategies who can help educate patients on the use of these tools, thereby reducing the burden among staff who may lack this expertise and have insufficient time to address these topics during appointments [14,27,28]. Digital health navigators can be instrumental to training staff in rapidly developing competencies for mHealth [29]. The CoCM, which already operates in a framework of interdisciplinary collaboration, may

be uniquely suited to the adoption of the digital health navigator role in the future.

Second, future implementation efforts should carefully consider measures for mitigating the potential unintended negative consequences of app use. For example, the chat function could give participants the perception of continuous access to the clinician. Though most participants in our study used the chat a moderate amount of times, there was substantial variability, with some participants sending more than 100 messages. Care provider burnout is a concern in the face of such significant increases in patient communication. The future implementation of this and similar technologies would benefit from integration with existing health information systems and care provider workflows to better support care provider decision-making.

Finally, while our results indicate preliminary evidence that patients are willing to participate in app-augmented collaborative care, there exist many opportunities for the optimization of engagement. For example, our intervention allowed the BHCM to nudge patients to engage with psychoeducational materials. Higher engagement can potentially be achieved by personalizing technology to deliver the right content in the right amount and at the right time [11,30,31]. Future research should identify

pathways for personalization and investigate its effects on engagement and clinical improvement.

Limitations

Our study has several limitations. First, qualitative data for contextualizing findings were not systematically collected as a part of this study. Second, the experiences of the BHCMS were also not systematically evaluated. This study examined app usage among participants, which was stratified by age and sex; however, other demographic factors of potential interest, such as race, ethnicity, insurance status, were not tracked. Finally, this was a feasibility study; thus, conclusions are limited by the lack of a control group and the unknown characteristics of nonparticipants. Future research should employ a rigorous clinical trial involving patient and/or clinic randomization to evaluate clinical effectiveness.

Conclusions

In conclusion, our preliminary findings indicate the moderate feasibility of using mHealth technology to augment behavioral health care in primary care settings. The results of this study are applicable to improving the design and implementation of mobile apps in collaborative care.

Abstract

Background: Although cardiometabolic diseases are leading causes of morbidity and mortality in the United States, computerized tools for risk assessment of cardiometabolic disease are rarely integral components of primary care practice. Embedding cardiometabolic disease staging systems (CMDS) into computerized clinical decision support systems (CDSS) may assist with identifying and treating patients at greatest risk for developing cardiometabolic disease.

Objective: This study aimed to explore the current approach to medical management of obesity and the need for CMDS designed to aid medical management of people living with obesity, at risk of being obese, or diabetic at the point of care.

Methods: Using a general inductive approach, this qualitative research study was guided by an interpretive epistemology. The method included semistructured, in-depth interviews with primary care providers (PCPs) from university-based community health clinics. The literature informed the interview protocol and included questions on PCPs' experiences and the need for a tool to improve their ability to manage and prevent complications from overweight and obesity.

Results: PCPs (N=10) described their current approaches and emphasized behavioral treatments consisting of combined diet, physical activity, and behavior therapy as the first line of treatment for people who were overweight or obese. Results suggest that beneficial features of CDSS include (1) clinically relevant and customizable support, (2) provision of a comprehensive medical summary with trends, (3) availability of patient education materials and community resources, and (4) simplicity and ease of navigation.

Conclusions: Implementation of a CMDS via a CDSS could enable PCPs to conduct comprehensive cardiometabolic disease risk assessments, supporting clinical management of overweight, obesity, and diabetes. Results from this study provide unique insights to developers and researchers by identifying areas for design optimization, improved end user experience, and successful adoption of the CDSS.

Introduction

Cardiometabolic diseases are leading causes of morbidity and mortality in the United States, including a wide array of diseases, typically beginning with insulin resistance and progressing later into a cluster of conditions that increase the risk of type 2 diabetes, stroke, and cardiovascular disease [1,2]. Being overweight (BMI ≥ 25 kg/m²) is associated with double the risk of developing cardiometabolic multimorbidity, while having mild and severe obesity (BMI ≥ 30 kg/m²) increases the risk 4 and 10 times, respectively [3]. However, current diagnostic categories that are based on standard BMI ranges defining overweight and obesity have high specificity but low sensitivity for identifying insulin resistance and cardiometabolic disease [4]. For example, with the current diagnostic categories, some individuals with overweight and obesity might not have cardiometabolic risk factors and may exhibit low rates of future diabetes and cardiovascular-related mortality; alternatively, some individuals who do not meet criteria for either metabolic syndrome or prediabetes exhibit risk of future diabetes [4]. Thus, risk assessments for cardiometabolic disease with greater sensitivity should be an integral component of medical practice, with tools to evaluate preventive and therapeutic options in patients at greatest risk for developing disease. Currently, there

is no stratification of the population by level of obesity-related disease and mortality risk [5].

An estimated 42.5% of US adults aged 20 years and older are living with obesity, including 9.0% with severe obesity, and another 31.1% are overweight [6]. Because this group is at high risk of developing diabetes and other obesity-related complications, there is a need for risk stratification approaches to identify early those at highest risk and identify weight loss programs with appropriate treatment intensity. To provide appropriate medical management of obesity and facilitate the diabetes risk assessment of people with excess adiposity, a comprehensive staging system that establishes 5 stages of cardiometabolic disease risk—the cardiometabolic disease staging system (CMDS)—was developed [7,8]. This validated staging system is based on Adult Treatment Panel III metabolic syndrome risk factors and includes waist circumference, systolic and diastolic blood pressures, fasting and 2-hour blood glucose levels, triglycerides, and high-density lipoprotein cholesterol (HDL-C; Table 1) [4]. The purpose of this system is to help clinicians select treatment modality and intensity in the management of cardiometabolic diseases while balancing benefit and risk. Evidence demonstrates the CMDS has higher predictive and discriminative ability compared with other systems and relies on data typically collected during primary care visits; thus, it is more feasible to integrate into busy workflows of primary care providers (PCPs) [5].

Table 1. The cardiometabolic disease staging (CMDS) system.

Stage	Descriptor	Criteria
Stage 0	Metabolically healthy	No risk factors
Stage 1	One or two risk factors	Have 1 or 2 of the following risk factors: <ol style="list-style-type: none"> 1. High waist circumference (≥ 112 cm in men and ≥ 88 cm in women) 2. Elevated blood pressure (systolic ≥ 130 mm Hg and/or diastolic ≥ 85 mm Hg) or on antihypertensive medication 3. Reduced serum HDL-C^a (< 1.0 mmol/L or 40 mg/dL in men; < 1.3 mmol/L or 50 mg/dL in women) or on medication 4. Elevated fasting serum triglycerides (≥ 1.7 mmol/L or 150 mg/dL) or on medication
Stage 2	Metabolic syndrome or prediabetes	Have only 1 of the following 3 conditions in isolation: <ol style="list-style-type: none"> 1. Metabolic syndrome based on 3 or more of 4 risk factors: high waist circumference, elevated blood pressure, reduced HDL-C, and elevated triglycerides 2. Impaired fasting glucose (IFG; fasting glucose ≥ 5.6 mmol/L or 100 mg/dL) 3. Impaired glucose tolerance (IGT; 2-h glucose ≥ 7.8 mmol/L or 140 mg/dL)
Stage 3	Metabolic syndrome + prediabetes	Have any 2 of the following 3 conditions: <ol style="list-style-type: none"> 1. Metabolic syndrome 2. IFG 3. IGT
Stage 4	T2DM ^b and/or CVD ^c	Have T2DM and/or CVD: <ol style="list-style-type: none"> 1. T2DM (fasting glucose ≥ 126 mg/dL or 2-h glucose ≥ 200 mg/dL or on antidiabetic therapy) 2. Active CVD (angina pectoris or status post a CVD event such as acute coronary artery syndrome, stent placement, coronary artery bypass, thrombotic stroke, nontraumatic amputation due to peripheral vascular disease)

^aHDL-C: high-density lipoprotein cholesterol.

^bT2DM: type 2 diabetes mellitus.

^cCVD: cardiovascular disease.

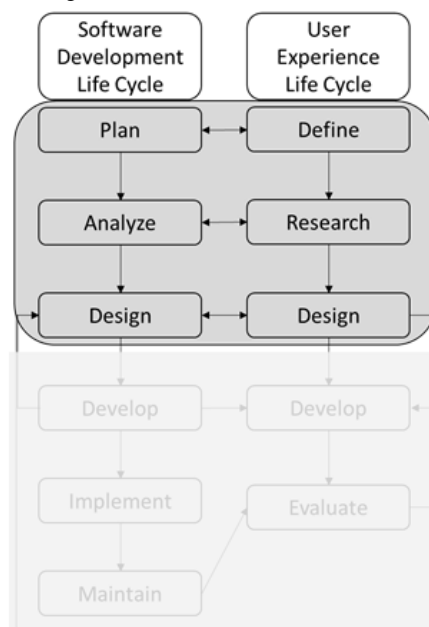

Vigilance in the management of modifiable risk factors is critical, given that people with overweight and obesity are at increased cardiovascular risk. Primary care settings, as familiar and accessible clinical venues for patients, are well positioned to screen people with overweight and obesity and recommend appropriate weight loss treatment plans to prevent complications and weight progression. Many studies found that the largest weight losses were achieved with high-intensity counseling by PCPs and referral of interested individuals to appropriate interventions [9-13]. However, a study of a nationally representative sample of adults aged 35 years and older found that, despite more adults reported being screened for obesity (78.6%) and of those screened, nearly 40% had a BMI of 30 kg/m² or higher (39.2%), only slightly more than one-half (53.5%) of obese adults screened reported receiving counseling about weight management [14]. Furthermore, BMI is the most preferred screening tool, though literature indicates it could be a poor indicator of cardiovascular disease and overall mortality risk [7,15]. Research finds BMI is not a good index of visceral fat, which is the basis of metabolic disorders associated with increased cardiovascular risk, whereas waist circumference might be superior as a risk assessment tool [16]. PCP-indicated practice improvements, helpful in treating and managing overweight and obesity, include better tools for early identification of risk and preventive treatment for those with multiple risk factors [11].

Providing CMDS to PCPs via computerized clinical decision support systems (CDSS) may assist in stratifying the population

by obesity-related disease risk and targeting those patients who are at greater risk for obesity-related complications. To the authors' knowledge, this would be the first electronic health record-integrated CDSS that would incorporate CMDS. Despite literature indicating CDSS may have a positive impact on provider performance and patient outcomes [17], evidence also indicates that CDSS rarely reach their full potential [18]. As with any innovation, user acceptance and integration within the clinical workflow are critical for successful uptake and routine use [19].

System analysis and design involve the process of planning, analyzing, designing, developing, implementing, and maintaining systems. A user-centered approach focusing on the user experience necessitates coordinated relationships between the system specialists, designers, and developers and the nonspecialists and users with outcomes knowledge. The system development life cycle, when combined with the user experience life cycle, allows for that coordination to occur and has been shown to lead to better system adoption [20]. Figure 1 illustrates our conceptual model for system analysis and design of the CMDS. This paper reports on the first 3 phases of each cycle: (1) plan and define, (2) analyze and research, and (3) design. As such, with the aim of involving users at key milestone stages of system development, this study explored the current approach to management of overweight and obesity and a need for the CMDS system at the point of care to facilitate specificity in treatment modalities.

Figure 1. Conceptual model for system analysis and design.

Methods

To ensure we adhered to qualitative reporting standards, we followed the 32-item consolidated criteria for reporting qualitative studies (COREQ) checklist (Multimedia Appendix 1).

Sampling

Participant recruitment used convenience sampling where the research team coordinated with the medical director for primary care of a large academic medical center in the southeastern United States. Recruitment emails to potential candidates indicated the study purpose and invited participation. The number of participants was determined to be sufficient when saturation was reached (N=10) [21]. All participants were

provided with a US \$100 gift card. The present study is a foundation for ongoing research aimed at developing and implementing a CDSS based on the CMDS.

Data Collection

From August 2020 to January 2021, 10 semistructured interviews were conducted by 2 research team members, consisting of the principal investigator (TM; male) and a graduate research assistant (AK; female). Two senior female researchers (AH and SF) with training in qualitative interviewing provided guidance and supervision. The interviewers did not have prior relationships with the participants. Only the interviewers and participants were present during data collection. The duration of the interviews varied between 30 minutes and 45 minutes and were conducted via a collaborative, cloud-based videoconferencing service at a mutually agreed-upon time. Interviews were transcribed verbatim by a commercial transcription company. The interview guide was informed by the literature review and included questions designed to (1) understand how PCPs manage overweight and obesity and facilitate prevention and management of diabetes and cardiovascular disease risk during a standard primary care visit and (2) explore PCP needs for CMDS and preferences for a CDSS ([Multimedia Appendix 2](#)). Broad, open-ended questions along with permissive prompts were used to facilitate each semistructured interview. Prior to conducting interviews, the semistructured interview guide was pilot tested with several providers to ensure questions were clear, generated in-depth discussion, were acceptable to participants, and resulted in usable information. Feedback from pilot testing was used to modify the wording, content, and order of the interview questions.

Ethical Considerations

All investigations were conducted in conformity with ethical principles of research. Consent for participation and interview recording was obtained verbally before each interview. This study was determined to be exempt by the University of Alabama at Birmingham Institutional Review Board (IRB Protocol Number 300003559).

Data Analysis

Transcribed interviews were coded using an inductive thematic analysis approach with NVivo 12 Plus (QSR International, Melbourne, Australia). To increase reliability and reduce bias, all transcripts were coded by 2 team members (AK and JA) with expertise in thematic analysis [22,23]. The analysis consisted of 2 phases: codebook development and codebook refinement. First, during open coding, coders examined an initial set of transcripts for categories (processes or events that share an attribute) of information related to our research questions. The second phase of our analysis focused on comparing and applying our initial codes to both existing and new data generated from subsequent interviews. This constant comparative analysis [24] across data sets allowed merging and clarifying codes. Following the initial coding process, research team members (AK and JA) discussed questions and discrepancies until 95% agreement was reached. Then, coders identified key points and recurring categories and themes that were central to the experience described by the participants. The process consisted of both coders dividing the text into semantic segments, labelling the segments with codes, together examining the codes for overlap and redundancy, and aggregating these codes into broader categories and themes [25].

Results

Sample Characteristics and Suggestions

We recruited 10 PCPs (7 physicians and 3 certified registered nurse practitioners) with practice experience ranging from 3 years to 43 years, with a mean of 12.2 years. Out of 10 respondents, 4 were male, and 6 were female. The most common practice-based barriers included lack of time and knowledge of resources, including access to evidence-based medical models and affordable community options. Considering the results of this study, 4 factors emerged as important for consideration in the development of a CDSS for metabolic conditions: (1) clinically relevant and customizable information delivery, (2) provision of comprehensive medical summary with trends, (3) availability of patient education materials and community resources, and (4) simplicity and ease of navigation. [Table 2](#) describes the key suggestions voiced by the PCPs for future design of the CDSS to be successfully adopted.

Table 2. Suggestions from primary care providers regarding preferable clinical decision support system features.

Suggestions	Quotes
Speed of the information technology	“The other thing would be – does it run efficient? There are parts of Cerner that literally if you click the button, you’re going to be sitting there for 2 minutes just waiting, waiting, and waiting.” [Primary care physician, male]
Synthesis of available information	“I think what would be good is if you had a piece of software that could extract that [lab] data out of the record. And then you could click on a button at the top of the record, and it said ‘weight management’. If you click, it would have a drop down algorithm and it was connected to the orders.” [Primary care physician, male]
Fit in the workflow	“So, whatever you come up with has to be something that’s integrated and uses the data that’s there, and gives you immediate feedback. It can’t be something that takes three minutes to enter the data.” [Primary care physician, male]
User-friendly with minimalist design	“So, ideally something self-contained, within the same page gives me kind of risk information and recommendations based on that, especially if it could be set up such that off of that page, I could directly order things. That would be amazing.” [Primary care physician, female]
Flexibility	“I think you definitely need to maintain the ability to customize or edit because, again, these are just sort of recommendations and sort of a part of the picture that the risk calculator gives you, but, you know, as long as you know, you could sort of edit to customize and individualize to a patient.” [Primary care physician, female]
Justification of treatment based on guidelines	“If there was something to standardize [management of] obesity and would give you a quantifiable number that puts them at a higher risk factor. So, if there was something that took in more either genetic versus biological markers that could be influential, I think that would be very useful and something that we would definitely want to implement and make it more of a standardization and not just an extra research tool.” [Primary care physician, male]

Current Management Practice of Obesity in PCP Clinics

Focus Not on Prevention But on Comorbidities

Almost all respondents reported that a significant portion of their patient populations was overweight, and they also noted that about 60% to 70% of patients had hypertension, diabetes, or other comorbidities. Even young populations presenting to primary care tended to have elevated BMIs or abnormal glucose levels. However, the respondents noted that they gave priority to management of the comorbidities rather than focusing on prevention and management of obesity. Respondents also noted they did not routinely use pharmacologic treatments for overweight or obesity but more to treat comorbidities, such as hypertension or elevated blood glucose levels.

About 80% of the patients I see are going to have one of the three: hypertension, diabetes, or obesity; and probably safe to say 60-70% definitely have all three. A lot of what I'm seeing is for blood pressure and diabetes management specifically. [Certified registered nurse practitioner, female]

I try not to [prescribe medicine]. I have a fair number of patients that would like a pill to fix their weight problem. And sometimes they break me down and I do [prescribe medicine]. If I prescribe something, an appetite suppressant to help lose weight, it's under the premise that it's very short term, no more than three months. [Internist, female]

Probably due to the acuity of our patient population, I feel like by the time people get to us specifically in the health system we're working under, there are usually a lot more problems that we're juggling, and

obesity is always important, but it's probably like number 10 on the list of concern. [Certified registered nurse practitioner, male]

BMI as a Main Diagnostic Measure

According to the respondents, BMI remains the primary tool for assessing obesity, as it is easy to access, is affordable to measure, and can conveniently be used to monitor weight changes. Additionally, participants responded that waist circumference measurement has not been integrated into routine practice. Patient risk factors associated with being identified or diagnosed as overweight or obese by their physician included higher BMI, family history, lifestyle, and habits. Respondents noted that they provided metabolic screening depending on patient's BMI, including blood glucose and blood lipids levels.

We don't measure it [waist circumference] in our clinic. We do have the BMI. So, the first point is BMI—this is all I look at because that's what I have available, and it's just a measure of numbers and the calculation. So, it's easy. [Internist, female]

I look at their medical and family history. Like if they have diabetes in the family, then obviously that puts them at a higher risk automatically. Or if they have family members with hypertension. So, family history is very important for my understanding. [Internist, female]

Reliance on Lifestyle Modifications

Most of the respondents' approaches to weight management were limited to assessing physical activity and assessing readiness for change, dietary habits, and expectations. The most common recommendations were to increase physical activity and dietary changes. Interestingly, half (5/10, 50%) of the

respondents noted they did not have any formalized treatment plan to manage overweight or obesity and did not follow specific treatment guidelines. In addition, there was limited use of external sources of weight management support, with only few patients being referred to weight loss clinics, mainly due to limited coverage of services by health insurance companies. External resources frequently included a nutritionist and a commercial weight loss program (eg, Weight Watchers).

I do not have sort of very specific treatment guidelines. I'm not saying I'd be opposed to that. I just have my own practice at this time. It really will depend, because I'm trying to gauge a person's willingness to change, so I will certainly ask some typical, open-ended questions about what have they tried in the past. It really becomes an individualized approach. [Internist, male]

I would say exclusively exercise and diet. More recently, I [started] referring patients with BMI 30 or higher with multiple comorbidities to the weight loss management program. [Primary care physician, female]

Lack of Knowledge About Referral Options in the Community

Respondents agreed that resources for intense lifestyle intervention and social support were important for the patients; however, respondents also noted the lack of knowledge about referral options in the community, including commercial-based programs. Because of the range in the socioeconomic status of their patient population, respondents expressed wanting point-of-care information about various affordable and convenient options that would be readily accessible and affordable for patient engagement.

I think there are a lot of resources out there but to be honest with you, I don't think that we really know where the resources are. Everyone, probably, has their own little list of resources that they use, I think. [Primary care provider, male]

I don't think I necessarily have a good handle on it [the local resources]. I have certain things that I would say as a 'go to' that are probably out of date and missing a lot of some of the newer [resources]. [Certified registered nurse practitioner, female]

Lack of Patient Education Literature

One of the challenges voiced by respondents was lack of appropriate, "meet them where they are" weight management educational materials accessible for use at the point of care or after consultation.

Time during a visit is at a premium. In theory, our visits are 20 minutes, by the time the patient gets here, checks in, and triaged, I generally have about seven minutes out of 20 minutes to see a patient. Maybe a little bit more, sometimes a little less. [Primary care physician, male]

The printed materials are not very good that we have available. They are not very helpful. That is why I

don't give them out very often. [Primary care physician, female]

Need for CMDS

Need for a Risk Stratification Tool Embedded Into the CDSS

Almost all respondents (9/10, 90%) expressed an interest in having a CDSS that would incorporate diabetes and cardiovascular disease risk assessment and, based on the risks, outline a treatment plan. As respondents noted, the advantage of using a CDSS would be providing "legitimate justification" for a treatment plan with an assumption that patients understand their risk and the reason for the proposed treatment. To the authors' knowledge, there is no decision support system available to assist providers in evidence-based weight loss treatment intensification. There is, however, a diabetes management protocol that has been developed but is not part of the electronic health records at this institution.

Currently, I have to pick up my phone, get on my coronary app and then put all the information. So, you could see where a tool like this that is incorporating the coronary risk score would be quite helpful built within Cerner. If it could even populate the data that we have with more recent blood pressure, that would be even more useful. [Primary care physician, male]

Ideally, it would be something that I could just turn the computer monitor and show the patient, saying "Okay, well, this is why I'm recommending it. Your A1C is 5.9, up from 5.6 last year. Your cholesterol is up, your weight is up. So, this gives you a 17% chance of diabetes in the next two years. And these are the steps that we recommend..." [Primary care physician, male]

Diagnostic-Supported CDSS

Respondents noted a need for an CDSS that would consider diagnostics, such as relevant patient data and lab results. In addition, respondents indicated it would be useful to have access to clinically meaningful trends and track risk scores for complications. A majority of respondents manually calculate various risk scores, such as the 10-year Atherosclerotic Cardiovascular Disease (ASCVD) risk; therefore, embedding such a calculator in the CDSS could increase efficiency and reduce error.

If we had a good algorithm based on BMI and any potential risk factors that was easy to follow and implement, with good handouts and appropriate referral or community resources there, and if we could collate that information, I think it could be helpful. [Primary care physician, male]

The main risk calculator that I use is the 10-year cardiovascular risk when I'm trying to decide if somebody should be on a statin. I just have on my phone and I just pull it up when I get their [patients'] labs back and plug in the numbers. Risk calculator

would be helpful to have [embedded] in the computer as well. [Primary care physician, female]

Incorporating Evidence-Based Practice

Respondents thought that having a CDSS that incorporates evidence-based clinical guidelines for management of obesity or overweight, both medical and behavioral, and that provides intervention recommendations would standardize and streamline the care provided and interventions suggested to their patients. The general idea was that such a system might help assist with managing patients with required tests, follow-up appointments, and preventive care.

I wouldn't say that I could speak for the whole clinic, I may just not be getting something that everyone else is doing. But we would be very open to having a tool that brings a standardization and also makes sure you're not overlooking anything and following a best practice guideline on initial management, and then also routine follow up. [Internist, female]

I think what would be most beneficial is having suggested treatment plans. It would help me to know that I am on the right track if I had a treatment plan that was suggested based upon their [patient] other chronic co-morbidities and their current A1C results or current blood sugar trends. [Certified registered nurse practitioner, female]

Ability to Have Resources to Make Referrals and Educate Patients

Respondents expressed a strong interest in information about accessible and affordable resources in the local community for patients struggling with overweight or obesity. They believed that it would enhance patient engagement and motivate patients toward behavior change. In addition, several respondents suggested that, if the CDSS had the means to efficiently provide appropriate educational materials to patients, it could improve the patient's participation in their own care:

...having good patient-friendly handout material that was easy to attach in the patient portal in terms of a new diet, recommendations based on ADA or other more popular diets like the DASH (Mediterranean Diet) or other types of things based on the patient's history. I do think that would be helpful. [Primary care physician, female]

Maybe [CDSS] gives you an option that you can click on, like option A "Would this person be interested in nutritional counseling?", option B "Do you want to print this list of printouts to give them and present to them during your clinic visit?", or "Would they want a referral to weight loss clinic?" I mean, it would be awesome if we had some way to refer people to some community resource near them where they could be contacted and offered some kind of like exercise class or a way to get into a walk group or something. [Certified registered nurse practitioner, female]

Discussion

Principal Findings

In this study, we sought to understand and capture user requirements for a system that evaluates the stage and severity of cardiometabolic disease that would be incorporated into a CDSS. The idea to involve intended users early in the design process is well supported in the literature [26] and results in aligning user expectations with the resulting functionality [27]. Currently, the PCPs' approach to management of overweight and obesity largely focuses on treating comorbidities and counseling lifestyle modifications such as diet and exercise. There is limited use of medications to combat overweight and obesity. Although there are existing guidelines for obesity treatment [28] and related cardiometabolic conditions such as diabetes [29] and hypertension [30], our respondents were not consistently using them for diagnosis or treatment purposes.

Comparison With Prior Work

Findings from this study are consistent with a growing body of literature on how PCPs manage overweight and obesity, as well as on what CDSS features increase likelihood of its uptake. Turner et al [31] found, among a nationally representative sample of active health care providers, that (1) knowledge of physical activity and dietary guidelines was limited and (2) understanding of the appropriate initiation, intensity, and duration of pharmacotherapy was often inconsistent with evidence-based guidelines. Another study found that PCPs were least likely to say they would prescribe medication or refer a patient to counseling [32]. Regarding CDSS features, a systematic review by Groenhof et al [33] found that design and usability were important drivers behind the success, noting that information should be displayed all at once and at one glance. In addition, the lack of insight into the automated computation and source of information decreased user satisfaction. Further, the most recent systematic review by Kouri et al [34] identified important CDSS features that significantly predict uptake, such as averting the need for provider data entry by mining patient data from within electronic health record systems to inform CDSS.

Implication for Practice

An important consideration would be providing easy access to the latest evidence-based clinical standards and protocols by embedding them in the CDSS. As a first step, CDSS could include measurement tools to perform a diagnostic evaluation based on evidence-based guidelines. If currently only BMI is considered, a more comprehensive evaluation must include additional measures such as measurement of waist circumference. Further, for the treatment, the physicians should be able to obtain clinical decision support by using CDSS to analyze pertinent information about the patient's current clinical condition, including information about medication, lab results, and treatment compliance. Given support for the CDSS among our sample, we propose a design of a CDSS that provides suggestions for treating the primary and augmenting medications with explanations. For the purposes of follow-up, the CDSS should have reminders to ensure the important considerations are not overlooked. Moreover, it could also recommend and

display when the patient should return for a visit. All entries should be automatically stored, providing electronic documentation and record keeping, thus providing access to complete patient information. Overall, information about a patient's demographic characteristics and other clinical records should be accessible by a single click.

Implications for Development

Results from this study were used to better understand user requirements within a parallel system analysis and design framework (see Figure 1), the importance of which was to ensure the voice of the user was adequately and accurately represented [20]. In this phase, we present the conceptual framework with the findings applied as high-level categories (see Figure 2). These categories and the details behind them as presented throughout this study will be used to inform the evaluation.

Figure 2. The conceptual framework with the findings as high-level categories.

Limitations

There are several limitations of this study. First, the 10 participants, predominantly non-Hispanic White (9/10, 90%), represented PCPs at a large academic center in the southeast. A small homogenous sample size could potentially limit the generalizability of our findings, and we recognize the need to add breadth and depth to this participant sample as development ensues. In addition, the strength of the study was our consideration of assuring intercoder reliability. Thus, we feel confident that we are correctly representing the voices of our participants.

Conclusion

Implementation of a CMDS system in the form of a CDSS could be used as a risk assessment tool that also provides risk-based and evidence-based treatment or program recommendations to better manage overweight and obesity and prevent diabetes. Results from this study provide unique insight to developers and researchers to identify areas for design optimization for improved end user experience to ensure successful adoption of the CDSS.

Abstract

Background: Digital mental health interventions have shown promise in reducing barriers to effective care for depression. Depression and related mental disorders are known to be highly comorbid with common chronic physical conditions, such as obesity and type 2 diabetes. While some research has explored the interaction dynamics of treating populations living with both mental and physical disorders, very little is known about such dynamics in digital care.

Objective: We aimed to examine the effectiveness of a 12-week, therapist-supported, app-based cognitive behavioral therapy program in improving symptoms of depression and anxiety. The studied population included adults with a heavy burden of chronic physical disease, including obesity and type 2 diabetes.

Methods: A total of 1512 participants with at least moderate depression were enrolled. The treatment cohort consisted of 831 (54.96%) participants who completed a follow-up assessment. The program included structured lessons and tools (ie, exercises and practices) and offered one-on-one weekly video counseling sessions with a licensed therapist for 12 weeks and monthly sessions thereafter. The clinically validated 8-item Patient Health Questionnaire (PHQ-8) and the 7-item Generalized Anxiety Disorder scale (GAD-7) were used to assess depression and anxiety, respectively. Linear mixed-effects modeling was employed to examine changes in depression and anxiety over time. Given correlation among various measures of program usage, a composite variable for depth of usage was used to analyze the correlation between usage and changes in depressive symptoms. Body weight changes from baseline were assessed primarily with digitally connected scales.

Results: Out of 831 participants in the treatment cohort, 74.5% (n=619) showed a clinically significant reduction in depressive symptom severity after 12 weeks, where follow-up PHQ-8 scores had shifted downward by at least one diagnostic category. In total, 67.5% (n=561) of the participants showed a reliable improvement in PHQ-8 scores as measured by the reliable change index. There was an average reduction of 5.9 (SD 5.2) points ($P<.001$) between baseline and follow-up. Greater program usage was correlated with greater likelihood of reliable improvement in depressive symptoms (odds ratio 1.3, 95% CI 1.1-1.5; $P=.002$). An exploratory analysis of body weight changes with a multilevel, mixed-effect model suggested that reliable improvement in depressive symptoms at follow-up was associated with significantly greater weight loss at 9 months ($\beta=-1.11$, $P=.002$).

Conclusions: The results provide further support that digital interventions can support clinically meaningful improvements in depression. Some form of synergy in treatment of comorbid depression and obesity or diabetes could be studied in future research. The study was limited by postintervention participant attrition as well as the retrospective observational study design.

KEYWORDS

depression; anxiety; CBT; digital mental health intervention; cognitive behavioral therapy; digital health; obesity; diabetes; mental health

Introduction

In 2016, mental health disorders affected more than 1 billion people worldwide [1]. Among mental health disorders, clinical depression carries a lifetime risk of 15% to 18% [2] and has the strongest association with disability-adjusted life years, a global benchmark of disease burden [1,2]. Depression is also the psychiatric condition most strongly associated with suicide [3]. The relationships among clinical depression, well-being, and health care costs have been well documented, with costs of care for patients living with depression higher across spending categories [4,5].

It has been estimated from nationally representative surveys that the prevalence of depressive symptoms in the United States increased 3-fold during the COVID-19 pandemic, with the majority of those affected already having been at elevated risk [6]. Simultaneously, the pandemic has accelerated the adoption of digital technology to deliver health care, particularly for mental health, and highlighted the promise of remotely delivered health services when traditional models may not have been available or accessible [7].

Digital mental health interventions (DMHIs) are potentially scalable and effective treatment solutions for mental health. Although research evaluating the effectiveness of DMHIs notes significant heterogeneity in terms of study design, clinical model, and intervention characteristics, meta-analytic reviews of smartphone-based interventions have observed a clinically significant treatment effect compared to both wait-list and active controls for depression and anxiety symptoms [8-10].

There is considerable research consensus that cognitive behavioral therapy (CBT) is a highly effective therapeutic modality for the treatment of clinical depression and anxiety because of relatively short intervention durations with strong outcomes [11,12]. Specifically, CBT-based digital interventions were associated with a significantly greater reduction in depression compared to non-CBT therapeutic approaches (eg, mindfulness, psychoeducation, and mood monitoring) [9]. In the context of DMHIs, digital CBT interventions appear to be equivalent to face-to-face interventions in terms of treatment efficacy [13-16]. Furthermore, a recent assessment of digital CBT offerings that evaluated patient preference, cost savings, and clinical benefit concluded that a provider-guided digital CBT program was likely the most effective approach for depression and anxiety compared to self-guided and face-to-face interventions [17].

In addition to evaluating the efficacy of CBT-based digital interventions, there has been growing research interest in exploring their mechanisms, particularly in the role of program engagement in DMHIs. Recently, Chien et al [18] employed a machine learning-based approach to explore patterns of engagement with a digital CBT program and their relationship with improvements in depression and anxiety. While the study did identify five distinct classes of program engagement, from low to high engagement, all classes were all positively associated with clinical improvement. Higher engagement classes were associated with greater improvement in depressive symptoms, so a possible dose-response effect was suggested.

However, it has been observed that user engagement can be difficult to define and measure [19]. Where usage generally measures observable actions, engagement implies some subjective experience of the digital intervention with a focus on the quality of the experience [20,21]. Furthermore, as Torous et al [22] note, usage over time, a commonly used measure of engagement, cannot distinguish a user whose mental health needs have been met by an app with a single instance of usage from one who needs repeated access for support.

One app feature that has been previously operationalized as a measure of DMHI engagement is lesson completion [23]. Lessons are typically brief pieces of evidence-based content intended to support a skill or health habit. They can also serve a crucial function in mental health interventions, digital or otherwise. CBT, in particular, emphasizes the practice of skills in between sessions by way of “homework assignments” or lessons in order to reinforce practices such as cognitive reappraisal [24]. Kazantzis et al [25] observed a stronger treatment effect size for CBT-based therapeutic interventions that incorporated homework when compared to interventions without a homework component. Lesson completion has also been used as a measure of treatment adherence and has shown a positive association with improvements in depression and anxiety [17,25-29]. It has been noted that the ubiquity of smartphones and the flexibility of the technology enables access to extensive content, on demand or needs based, that is difficult to replicate in traditional delivery models [28,30].

Lastly, an often-overlooked dimension of clinical depression, particularly in the context of DMHIs, is its frequent co-occurrence with chronic health conditions, such as type 2 diabetes and obesity [31-33]. Among other aspects, depression is known to hamper self-care and medication adherence [33]. Cross-sectional research suggests a 1.18 times greater likelihood of depressive symptoms in individuals with obesity than in those without [34]. Similarly, the risk of prediabetes and related measures appears to be markedly elevated among those newly diagnosed with depression [35,36]. This relationship tends to be stronger among women [34,35]. In their meta-analytic review of collaborative care to treat depression and diabetes in tandem, Atlantis et al [31] observed significant improvements in both depression and glycemic management with tandem treatment. Another systematic review showed that psychological interventions tailored for people with diabetes were effective in improving both glycemic management (ie, hemoglobin A_{1c} [HbA_{1c}]) and elevated diabetes distress [37]. There are indications that the relationship between chronic conditions and depression are bidirectional, with an increased incidence of diabetes among those with diagnosed depression [38-40]. Many app-based health interventions have a singular health focus (eg, depression, weight, or diabetes management), making it more challenging to fully understand the impact and the influence of co-occurring conditions on treatment adherence and health outcomes [41].

In sum, research suggests that CBT-based DMHIs are feasible and effective solutions for depression and anxiety disorders [42-44]. There are some preliminary indications that the extent of program usage may influence treatment adherence and

outcomes [45]. There remain open research questions on how intervention type, mode of delivery, and mechanisms may affect treatment outcomes. There has also been less focus on DMHIs in populations living with co-occurring depression and chronic health conditions.

In this study, we evaluated the Vida CBT Program for moderate depression and anxiety in a polychronic adult population, that is, one with a high prevalence of chronic health conditions. Vida Health is a Health Insurance Portability and Accountability Act-compliant, app-based platform for management of both mental and physical health that combines tailored content with counseling by licensed therapists and other health education specialists. The platform is available directly to consumers or as a benefit from select employers and health plans. The primary objective of this study was to assess changes in depression following a 12-week digital CBT program: the Vida CBT Program. We hypothesized that participants who completed the program would show a reduction in depressive symptoms and that measures of program usage would be positively associated with these improvements. As part of a preliminary exploratory analysis, we also evaluated changes in weight among participants concurrently enrolled in a Vida physical health program. We suspected that improvements in depression would be positively associated with stronger weight loss.

Methods

Study Design

This study used a single-arm, retrospective design to evaluate changes in depression and anxiety following the Vida CBT Program.

Ethics Approval

The study protocol and informed consent statement was reviewed and approved by the Western Institutional Review Board Inc (protocol No. 20192591), an independent institutional review board. All data were fully anonymized prior to data analysis. Informed consent statements were sent to participants upon enrollment in the Vida CBT Program.

Measures

The 8-item Patient Health Questionnaire (PHQ-8) was used to assess severity of depressive symptoms. The following standard scoring cutoffs were applied to classify depressive symptom severity: 0 to 4 (asymptomatic or minimal), 5 to 9 (mild), 10 to 14 (moderate), 15 to 19 (moderately severe), and 20 or higher (severe). Anxiety symptoms were assessed using the 7-item Generalized Anxiety Disorder scale (GAD-7) using the following standard score cutoffs to classify anxiety symptom severity: 0 to 4 (asymptomatic or minimal), 5 to 10 (mild), 11 to 17 (moderate), and 18 or higher (severe). The PHQ-8 and GAD-7 are widely used in clinical settings and have shown robust reliability and validity [39,40]. The assessments were administered in the app automatically at program start, week 6, week 12, and every 3 months thereafter for up to 1 year. Participants were encouraged to complete the survey on the day of receipt but had the option to complete the assessment at any point during the 2 weeks following receipt, after which the survey would disappear until the next assessment time point.

Therapists also had the option of sending the instrument to the participant at any point during the intervention as they deemed clinically appropriate.

Body weight was a secondary outcome measure in this study. Weight outcomes were either recorded via a connected wireless scale or self-reported by the participant using a logging tool available in the Vida Health app. Participants could either sync their personal wireless scale to the app or order a digitally connected scale via the app.

Study Sample and Recruitment

The study was open to adults, 18 years of age or older, who were fluent in English and had access to a smartphone or tablet. Participants were recruited between September 2019 and January 2021 using a combination of emails, mailers, and phone outreach efforts. The Vida Health app is available to individuals across the United States and can be downloaded from the Apple App Store or Google Play. Participants were drawn from several insurance plans and employers for whom Vida Health was offered as a covered benefit.

Upon downloading the app, participants completed a brief intake questionnaire that included name, contact information, basic demographics (ie, age, gender, height, and weight), and existing health conditions. Participants were offered a variety of health domains to focus on. Some participants chose to begin the Vida CBT Program directly. Others began in the Vida digital programs for weight loss or diabetes management described previously [46,47]. Participants received and completed an intake PHQ-8, and those with a score of 10 or greater (moderate depression) were included in the study. All participants also completed a baseline GAD-7 assessment. Eligible participants were paired with a licensed therapist based on their state of residence and preferred times for consultations. Therapists were mental health professionals working for Vida Health, licensed by their state's respective licensure board. Participants with severe depression (PHQ-8 score ≥ 20) or severe anxiety (GAD-7 score ≥ 15) were ineligible for the Vida CBT Program and were referred to alternative sources of care. Additional exclusion criteria included eating disorders, substance use disorder, suicidality, homicidality, acute posttraumatic stress disorder, and episodes of mania or psychosis. Participants who presented with any of the above symptoms during the intervention were referred for care outside of Vida Health. Participants who chose to enroll initially in weight loss or diabetes management programs and were then screened into the Vida CBT Program had the option to continue both programs simultaneously.

Therapeutic Approach and Intervention

A fundamental focus of CBT is to address maladaptive thinking patterns by understanding the associations among thoughts, emotions, and behaviors [48]. As part of the Vida CBT Program, participants received structured multimedia (ie, audio, video, or text) lessons, activities, and practices within the app. Based on core CBT principles, such as guided discovery and conscious re-evaluation, these lessons were designed to increase awareness of one's thinking patterns and support the practice of alternative, adaptive thoughts [24]. Ahead of their initial consultation with a Vida therapist, participants completed an informed consent

form for psychotherapy that detailed their rights to confidentiality and limits to confidentiality, including mandated reporting requirements as stipulated by the therapist's licensing board and state regulations. At the initial consultation, therapists performed a comprehensive biopsychosocial assessment that included a review of previous treatments and diagnoses, current presenting problem, and symptoms. Participants could communicate with their therapist using live video or audio consultations as well as with asynchronous messaging in the app.

Following the intake, therapists documented their initial diagnostic impressions and developed individualized treatment plans with short-term and long-term goals. Participants were offered weekly video or audio consultations with their therapist for the first 12 weeks and shorter monthly follow-up sessions

thereafter for up to 1 year. Each therapist consultation comprised setting goals and homework activities for the upcoming week along with a review of strategies for further cultivating concepts and skills learned from earlier sessions. In between sessions, participants could complete assigned homework and use a thought tracker in the app. Lessons, once shared, remained available in the app for the participant to review and revisit concepts. The thought tracker feature allowed participants to record current thoughts using a Likert scale to assist in identifying, evaluating, and restructuring distorted thought patterns. In program weeks 10 through 12, therapists worked with participants to create a Wellness Recovery Action Plan intended to support maintenance of acquired skills and improved functioning and to prevent relapse [49]. Select screenshots from the program are shown in Figure 1.

Figure 1. Screenshots from the Vida CBT Program. CBT: cognitive behavioral therapy.

Participants who were concurrently enrolled in a program for chronic disease management also worked with an additional Vida provider (ie, a certified health coach or registered dietitian) who could collaborate on care with the relevant therapist. As in the Vida CBT Program, they were offered synchronous consultations weekly for up to 12 weeks and monthly thereafter for up to 1 year. All providers received extensive training on motivational interviewing, an approach that leverages improving perceived self-efficacy and autonomy to facilitate healthy behavior change [50]. Additionally, participants received app content covering topics such as nutrition, exercise, and medication adherence. All content was informed by evidence-based research and literature on health behavior change as described previously [46,47,51].

Statistical Plan

Change in depression, based on PHQ-8 scores, between baseline and follow-up was the primary dependent variable. We performed a paired, 2-tailed *t* test to assess if there was a significant change in PHQ-8 scores from baseline. We used a second paired *t* test to evaluate changes in anxiety scores among participants who scored in the moderate anxiety range at baseline (ie, GAD-7 score ≥ 11). Mean normalization was applied to all continuous predictors (eg, age). A Boolean variable was created for the presence of co-occurring anxiety (1 = baseline GAD-7 score ≥ 11). Gender was also coded as a binary variable (1 =

female). Since we could not assume that all therapists were equally effective, all regression analyses were conducted using a cluster-robust approach with therapist as a cluster group variable [52]. The reliable change index (RCI) for depression and anxiety was also computed. RCI, a commonly used measure in psychometrics, is the ratio of the difference in pre-post assessment scores to the standard error of measurement [47,48]. An RCI score of 1.96 or higher (ie, 1 above the 95% CI) is regarded as an indication of reliable, statistically meaningful change [53].

To explore the interaction between program usage and changes in depression, we tabulated five program features that broadly encompass the program experience: number of therapist consultations, number of messages sent to the therapist, number of "core" lessons opened, number of thoughts logged, and total number of content pieces opened. Core lessons were those related to fundamental CBT concepts (eg, cognitive restructuring, behavioral activation, and techniques for addressing maladaptive thinking) [24]. Data exploration revealed a right skew for each of the usage factors, that is, a subpopulation of participants who used the app features quite extensively. In order to retain these heavy app users, but to limit their influence on downstream analyses, all usage factors were right-winsorized at the 99th percentile [54]. The treatment cohort showed a notable female predominance, a finding not unusual

in studies of mental health service use in the United States [55-57]. In this study, in order to adjust for this, the established technique of oversampling was employed, wherein 715 participants were drawn at random from the 116 participants who did not identify as female [58,59].

Finding, as expected, that features of program usage were correlated, we constructed a composite variable to limit collinearity. Participants were assigned an ordinal variable from 0 to 5, where 1 unit was assigned for each usage feature in which the participant was above the 25th percentile. Thus, someone with a depth-of-usage score of 5 had activity above the 25th percentile in each of the usage factors, while a score of 0 indicated usage within the 25th percentile across all usage features. We chose the 25th percentile as it empirically separated users into high and low usage categories without selecting only for the right tail of usage as alluded above. With reliable change as the binary dependent variable (1 = reliable improvement in depression symptoms), a cluster-robust logistic regression evaluated the relationship depth of usage and improvement in depression symptoms. Controls included therapist cluster, baseline PHQ-8 score, gender, presence of anxiety, and age.

A supplementary analysis evaluating changes in weight outcomes among participants concurrently enrolled in the Vida weight loss program was conducted. Analysis was restricted to participants who had been enrolled for at least 6 months and had logged weight at least twice in that period. A linear, mixed-effects model was used to address potential heterogeneity in the frequency and number of weight logs by participants and provider-level differences [60]. Percent change in weight from baseline was regressed on the following fixed factors: program time (in months), baseline BMI category (obesity or overweight), and reliable change (1 = reliable improvement in PHQ-8 scores; 0 = no reliable improvement) [61]. Participants and providers were specified in the model as random factors.

All data preparation and analyses were performed using Python (version 3.7.9; Python Software Foundation) and Stata (version 16.1; StataCorp LLC).

Results

Overview

A total of 1512 participants enrolled in the Vida CBT Program between September 2019 and January 2021. A schematic of the participant flow is presented in Figure 2. Of those, 54.96% (n=831) had a follow-up PHQ-8 assessment between weeks 6 and 12 and were considered part of the treatment cohort. Analyses evaluating changes in depression scores from baseline were restricted to the treatment cohort. The remainder of the study cohort, equal to 45.04% (n=681) of the participants, failed to complete a follow-up PHQ-8 during the assessment window. These participants were excluded from the primary analyses; however, we performed a supplementary intention-to-treat (ITT) analysis to evaluate overall changes in PHQ-8 scores from baseline across the entire cohort. Among those without a valid follow-up, 71.5% (487/681) did not have any assessment after their baseline. For these members, a baseline carryforward approach was employed. The remaining 28.5% (194/681) of the participants completed an assessment before finishing 6 program weeks. For these members, a last-value carryforward approach was applied.

Baseline characteristics of the study cohort are reported in Table 1. In addition to depression, the entire study cohort self-reported living with at least one chronic physical health condition (ie, type 2 diabetes, cardiovascular disease, or obesity). There were no significant differences in baseline PHQ-8 scores between the treatment and incomplete groups at baseline ($t_{1510}=1.2$, $P=.22$). There was a significantly lower rate of comorbid anxiety, defined as a GAD-7 score of 11 or higher, among participants in the treatment cohort ($\chi^2_1=19.5$, $P<.001$). A 2-tailed chi-square analysis indicated that there were significantly more women in the treatment cohort compared to the program noncompleter group ($\chi^2_1=7.1$, $P=.01$). There were also more participants concurrently enrolled in a health coaching program for a chronic condition in the treatment cohort ($\chi^2_1=171.1$, $P<.001$). Lastly, we observed a significant average difference in age of 2.3 years between the treatment cohort (mean 48.5, SD 11.4 years) and noncompleters (mean 46.2, SD 12.4 years; $t_{1510}=-3.8$, $P<.001$).

^aPHQ-8: 8-item Patient Health Questionnaire; depressive symptom severity by score is classified as follows: 0 to 4 (asymptomatic or minimal), 5 to 9 (mild), 10 to 14 (moderate), 15 to 19 (moderately severe), and 20 or higher (severe).

^bGAD-7: 7-item Generalized Anxiety Disorder scale; a score of ≥ 11 indicates moderate to severe anxiety.

Principal Results

Out of 831 participants in the treatment cohort, 74.5% (n=619) showed a clinically significant reduction in depressive symptom severity in 12 weeks, where follow-up PHQ-8 scores had shifted downward by at least one diagnostic category. A total of 67.5% (n=561) of the treatment cohort participants showed a reliable improvement in PHQ-8 scores as measured by the RCI. There was an average reduction of 5.9 (SD 5.2) points between baseline and follow-up (Table 2). A 2-tailed, paired *t* test revealed a significant reduction in scores between baseline and follow-up ($t_{830}=32.9$, $P<.001$). A cluster-robust linear regression examining the association between change in PHQ-8 scores and baseline scores, co-occurrence of anxiety, gender, age, and concurrent enrollment in physical health revealed a significant inverse relationship between baseline and change in PHQ-8 scores ($\beta=-1.7$, $P<.001$). That is, greater baseline depression

severity was, unsurprisingly, associated with greater reduction of depression at follow-up. We observed that the co-occurrence of anxiety was associated with a smaller reduction in depression scores ($\beta=1.33$, $P<.001$). In supplementary analyses, a 2-tailed, paired *t* test including the entire ITT cohort, using carryforward as above, indicated a slightly attenuated but still significant reduction in PHQ-8 scores at follow-up (mean -3.6 , SD 4.99; $t_{1511}=29.1$, $P<.001$).

Among the 478 participants with moderate anxiety or higher at baseline (ie, GAD-7 score ≥ 11), 89.7% (n=429) provided a follow-up assessment between weeks 6 and 12. A paired *t* test revealed a significant average reduction in anxiety scores of 6.1 (SD 5.4) points from baseline ($t_{428}=22.96$, $P<.001$; Table 2). Additionally, 57.7% (n=276) of these participants had a reliable improvement in anxiety scores from baseline. A cluster-robust linear regression showed that higher baseline GAD-7 scores

were associated with greater reductions in anxiety scores at follow-up ($\beta=-3.5$, $P<.001$). Age, gender, and baseline PHQ-8 scores were not significantly associated with anxiety score changes.

Table 2. Estimated marginal means of PHQ-8 and GAD-7 scores at baseline and follow-up.

Assessment type and time point	Score, estimated marginal mean (bootstrapped 95% CI)
PHQ-8^a	
Baseline	14.4 (14.2-14.6)
Follow-up (12 weeks)	8.5 (8.1-8.8)
GAD-7^b	
Baseline	14.8 (14.5-15.0)
Follow-up (12 weeks)	8.8 (8.3-9.3)

^aPHQ-8: 8-item Patient Health Questionnaire; depressive symptom severity by score is classified as follows: 0 to 4 (asymptomatic or minimal), 5 to 9 (mild), 10 to 14 (moderate), 15 to 19 (moderately severe), and 20 or higher (severe).

^bGAD-7: 7-item Generalized Anxiety Disorder scale; anxiety symptom severity by score is classified as follows: 0 to 4 (asymptomatic or minimal), 5 to 10 (mild), 11 to 17 (moderate), and 18 or higher (severe).

Program Usage Outcomes

Program usage was evaluated in the treatment cohort across a set of five program features: number of therapist consultations, number of messages sent to the therapist, number of times core lesson content was accessed, number of thoughts logged via the thought tracking tool, and number of program-related content cards viewed. As expected, there were notable correlations among these program usage factors, with Pearson coefficients ranging from 0.17 to 0.43 (Table 3).

In order to limit collinearity while evaluating the association between program usage and changes in depressive symptoms, we created a composite feature of overall depth of usage. For each usage feature, a score of 1 was assigned when activity for that specific feature was above the 25th percentile of the distribution. We then summed across each of the factors. Thus, depth-of-usage scores could range from 0 to 5, with a score of 5 indicating usage in excess of the 25th percentile of activity

across the features, and a score of 0 indicating usage below the 25th percentile across the features. As noted above, the data were then resampled to adjust for the female predominance in the treatment cohort. From the resulting balanced cohort of 1430 participants, a cluster-robust logistic model controlling for age, gender, co-occurrence of anxiety (ie, baseline GAD-7 score ≥ 11), and baseline PHQ-8 score revealed a significant association between depth of usage and likelihood of reliable improvement in depression scores at follow-up (odds ratio [OR] 1.3, 95% CI 1.1-1.5; $P=.002$). In other words, greater usage across the platform was associated with improvement in depression symptom severity. The summary statistics for the features of program usage were as follows: mean number of therapist consultations was 7.04 (SD 3.4), mean number of messages sent to the therapist was 33.2 (SD 46.9), mean number of times core lesson content was accessed was 39.2 (SD 33), mean number of thoughts logged via the thought tracking tool was 13.6 (SD 16.5), and mean number of program-related content cards viewed was 8.35 (SD 12.4).

Exploratory Weight

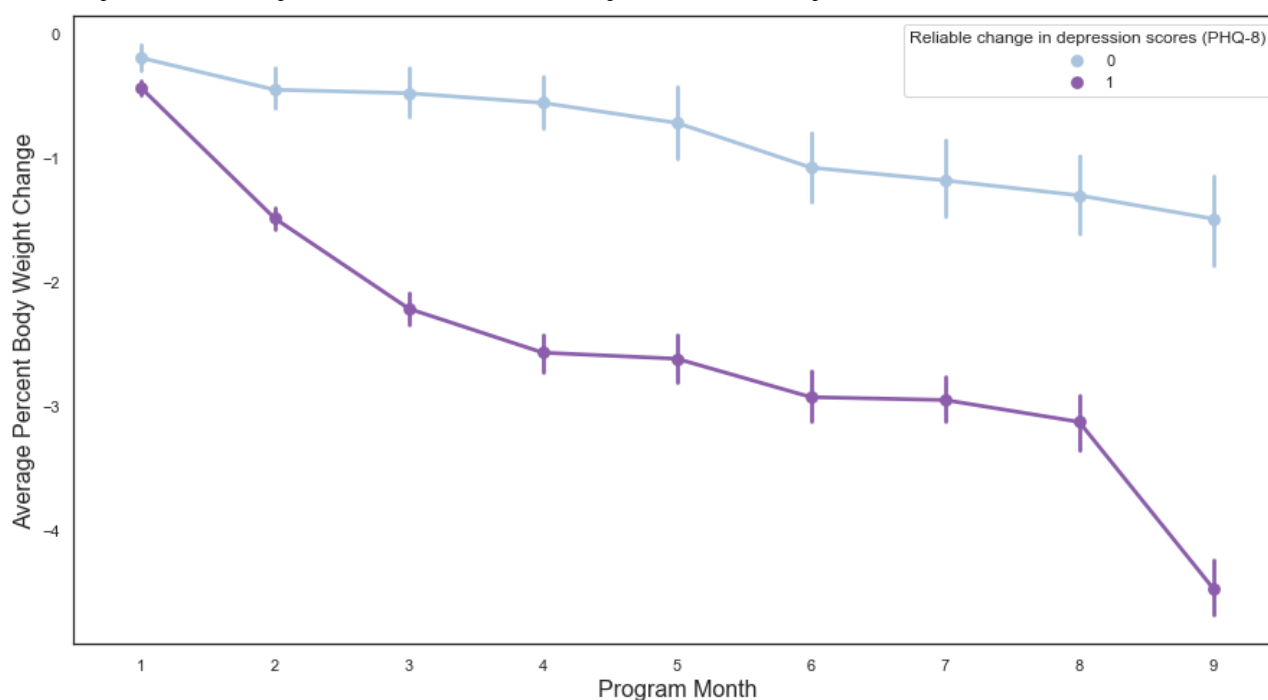

We performed additional analyses to explore changes in body weight and diabetes management among participants simultaneously enrolled in the Vida CBT Program and a physical health program.

For body weight, in order to provide adequate time for meaningful clinical change, the analysis was restricted to the 595 participants with overweight or obesity (ie, BMI ≥ 25) who had been enrolled for at least 6 months and had logged weight at least twice in the period with the latest weight coming at least 2 months after the initial enrollment. Out of these participants, 86.6% (n=515) had a baseline BMI indicative of obesity and 13.4% (n=80) had a baseline BMI indicative of overweight. This population logged a total of 34,469 body weight values. Out of these entries, 83.17% (n=28,667) were logged using a wirelessly connected scale, and the remainder were entered manually by the participant. The majority of the participants (n=387, 65.0%) had logged their most recent weight in the ninth program month. The most recent weight was logged at least in the eighth program month for 78.8% (n=469) of the participants

and at least in the sixth program month for 89.2% (n=531) of them.

To account for heterogeneity in the number and frequency of weight logs among participants, as well as to handle the nested structure of the data (ie, weight observations nested within participants who were nested within providers), a multilevel mixed-effects model was used to evaluate changes in body weight across participants. Fixed factors in the model were time (program month), baseline BMI category (obesity or overweight), and reliable change in depressive symptoms (1 = reliable improvement in PHQ-8 scores; 0 = no reliable improvement). Random factors included participants and providers. We observed a significant effect of program time on percent weight loss ($\beta = -0.37$, $P < .001$). Baseline weight had a small but significant inverse association with weight loss such that higher baseline weight was associated with greater percent weight loss ($\beta = -0.01$, $P = .002$). As shown in Figure 3, reliable improvement in depression symptoms at follow-up was associated with significantly greater weight loss at 9 months ($\beta = -1.11$, $P = .002$).

Figure 3. Estimated marginal means and SEs of average percent weight loss as a function of program month and reliable change in depression symptoms. A value of 1 represents reliable improvement in PHQ-8 scores and 0 represents no reliable improvement. PHQ-8: 8-item Patient Health Questionnaire.

Discussion

Principal Findings

The aim of this retrospective study was to evaluate the therapist-supported, digitally delivered Vida CBT Program for the treatment of moderate depression in an adult population. The treatment cohort of 831 participants with baseline PHQ-8 scores of 10 or greater were enrolled in the digital intervention and provided at least one follow-up assessment 6 to 12 weeks into the program. We observed a significant reduction in depression scores at follow-up (mean -5.9 , SD 5.2), with 74.5% of participants shifting downward in symptom severity by at least one diagnostic category. A similar pattern of reduction was observed for anxiety scores among participants who had moderate anxiety (mean -6.1 , SD 5.4). Supplementary ITT analysis that included the entire cohort of 1512 participants with baseline data or last-value carryforward showed a slightly attenuated but still significant reduction in PHQ-8 scores at follow-up.

Examining the relationship between program usage and improvement in depression symptoms revealed that participants who more extensively used features across the platform had a modestly greater likelihood of reliable improvement in depression scores at follow-up (OR 1.3, 95% CI 1.1-1.5). This limited dose-response relationship was seen in the context of highly right-skewed usage data overall.

Drawn largely from a medically complex adult population, cardiometabolic conditions, particularly diabetes and obesity, were highly prevalent in this population. Given the very high burden of metabolic disease in this population and the availability of interventions for these conditions on the Vida platform, although the study was not specifically designed for

this, we wanted to explore these relationships in order to prepare for future research.

Our preliminary analyses showed significantly greater reduction in body weight among participants who had a reliable improvement in depression symptoms compared to those who did not show symptom improvement at follow-up. As [Figure 3](#) illustrates, this trend was consistent throughout the program tenure and culminated in a mean body weight change of 4.5% (SD 6.3; reliable improvement in PHQ-8 scores) versus 1.5% (SD 6.1; no reliable improvement in PHQ-8 scores) at month 9 of the program.

As with much of the literature, it is impossible to infer causation from these results, but it opens a hypothesis for future research that there may be opportunities for synergy in the treatment of co-occurring mental and metabolic disorders [37,62]. Given the massive and overlapping burden of these diseases in the US population, if such synergy could be realized through efficient, digitally delivered interventions, it would certainly be welcome.

Comparison With Prior Work

The principal finding of improvements in depressive symptoms is consistent with the broader body of research on digitally delivered CBT programs for the treatment of mild to moderate depression and anxiety [9]. This finding reinforces, in a larger population, similar results previously published from the Vida CBT Program [23].

The relationship between program usage and outcomes in digital interventions, broadly, and DMHIs, in particular, remains a rich area of research. While this study was not designed to evaluate this, our results are consistent with several similar studies suggesting a limited dose-response phenomenon. That is, greater usage seems to correlate with improved outcomes but may not do so monotonically, as participants self-regulate their usage

to their needs, needs that are difficult for a researcher to observe with any meaningful precision [18,63-66].

Throughout the literature, interrelations among treatments for comorbid mental and physical disorders have been noted before. The direction of causality is unclear and, indeed, may be expected to run in both directions; that is, depression and anxiety may contribute to obesity and diabetes just as much as the reverse is true. In some cases, other factors may be driving both [62,67-69]. Preliminary research in this vein has, like this study, shown some hint of synergistic treatment effects in traditional care settings [70-72].

Limitations

This study had several important limitations. The lack of a control group and the retrospective design prevents drawing any causal inferences. Missing follow-up data was also a challenge, with data unavailable for 45.0% of the overall cohort (Table 1). We attempted to mitigate this limitation with an ITT analysis using baseline data or last-value carryforward as appropriate. While this still showed a significant relationship, the improvement in depression scores was weaker when accounting for those participants.

The gender imbalance across the study cohort was notable, with 83.8% females overall and 86.0% in the treatment group. At the overall level, this is a well-characterized phenomenon of care use, particularly for mental health, in North America and Europe. Despite seemingly comparable prevalence of mental distress by gender, ratios of 2 women for every man seeking care are not unusual in the literature [73,74]. The US National Institute of Mental Health has even sponsored campaigns to address barriers to males seeking mental health care, and there

is literature on this phenomenon's underlying causes [56,75]. In this study, there was also a small but significant increase in the proportion of females in the treatment group. It may have been that whatever phenomenon inhibits males from seeking care, in general, also made males in this study less likely to follow up with treatment and assessment. This and the difference in age between the two groups could represent some self-selection of participants into the treatment group who were more likely to improve. While the ITT analysis attempts to adjust for this, some bias remains a possibility. More broadly, the limited uptake of the Vida intervention by males may limit its generalizability in a larger population.

This study was not specifically designed to investigate changes in body weight and glycemic control as related to improvements in depression and was underpowered to detect a change in HbA_{1c}. Future research is certainly needed to explore these potential relationships. Causality in any such relationship, should it bear out, could take any possible form and would need careful study to dissect.

Conclusions

This study provides further evidence that CBT-based DMHIs can be effective tools in treating symptoms of depression and anxiety. Improvements by whole diagnostic categories were common in this cohort. Usage of the platform correlated with improved outcomes in a pattern consistent with participants self-regulating usage to their individual needs. Furthermore, this was seen in a population with a very high prevalence of co-occurring physical disorders. More research is required to determine if there may be opportunities for synergistic treatment of mental and physical disorders through a similar modality.

Acknowledgments

We are deeply indebted to the hard work of all the therapists, dietitians, and health coaches who supported these participants. We are grateful to Chris Mosunic for helpful comments on the manuscript.

Authors' Contributions

AV and MS conceived and designed the study. MM led the intervention design. AV, PR, and BF acquired, analyzed, and interpreted the data. AV and MS drafted, structured, and edited the manuscript. All authors discussed the results and contributed to the final manuscript.

Conflicts of Interest

All authors are current or former employees of Vida Health and hold share options.

Abstract

Background: The prevalence of peritoneal dialysis (PD) in Thailand is increasing rapidly in part because of Thailand's *Peritoneal Dialysis First* policy. PD is a home-based renal replacement therapy in which patients with chronic kidney disease perform up to 4 exchanges of dialysate fluid per day in the peritoneal cavity. Overhydration is one of the most common complications in patients on PD and is associated with increased morbidity and mortality. To monitor hydration status, patients collect hydration metrics, including body weight, blood pressure, urine output, and ultrafiltration volume, from each dialysis cycle and enter this information into a PD logbook. This information is reviewed bimonthly at PD clinic appointments. The chronic kidney disease-PD (CKD-PD) app with near-field communication (NFC) and optical character recognition (OCR) was developed to automate hydration metric collection. The information was displayed in the app for self-monitoring and uploaded to a database for real-time monitoring by the PD clinic staff. Early detection and treatment of overhydration could potentially reduce the morbidity and mortality related to overhydration.

Objective: This study aims to identify usability issues and technology adoption barriers for the CKD-PD app with NFC and OCR and a monitoring system and to use this information to make rapid cycle improvements.

Methods: A multidisciplinary team of nephrologists, PD clinic nurses, computer programmers, and engineers trained and observed 2 groups of 5 participants in the use of the CKD-PD app with NFC and OCR and a monitoring system. The participants were observed using technology in their homes in 3 phases. The data collected included the Unified Theory of Acceptance and Use of Technology questionnaire, *think-aloud* observation, user ratings, completion of hydration metrics, and upload of hydration metrics to the central database. These results were used by the team between phases to improve the functionality and usefulness of the app.

Results: The CKD-PD app with NFC and OCR and a monitoring system underwent 3 rapid improvement cycles. Issues were identified regarding the usability of the NFC and OCR data collection, app stability, user interface, hydration metric calculation, and display. NFC and OCR improved hydration metric capture; however, issues remained with their usability. App stability and user interface issues were corrected, and hydration metrics were successfully uploaded by the end of phase 3. Participants' scores

on technology adoption decreased but were still high, and there was enthusiasm for the self-monitoring and clinical communication features.

Conclusions: Our rapid cycle process improvement methodology identified and resolved key barriers and usability issues for the CKD-PD app with NFC and OCR and a monitoring system. We believe that this methodology can be accomplished with limited training in data collection, statistical analysis, and funding.

Introduction

Chronic Kidney Disease and Peritoneal Dialysis in Northeast Thailand

Chronic kidney disease (CKD) is a major health problem in Thailand because of its high prevalence, cost of treatment, significant morbidity and mortality, and substantial impact on the quality of life of patients and their families. From 2017 to 2018, the Chronic Kidney Disease Prevention in the Northeast of Thailand (CKDNET) project found that the prevalence of CKD was 27% in the rural provinces of northeast Thailand [1], primarily because of rising rates of diabetes, hypertension, and other primary renal diseases [2]. Despite this increased need, there is only 1 nephrologist for every 593,000 population compared with every 44,000 population in Bangkok [3]. In 2008, the Thai government adopted the *Peritoneal Dialysis First* policy for renal replacement therapy under its universal health care coverage scheme, increasing access in low-resource settings, with approximately 21% of patients on peritoneal dialysis (PD) in northeast Thailand [4]. Patients on PD manage their PD at home manually or by using a PD cycler to deliver dialysate fluid through a catheter placed in the peritoneal cavity, where the fluid remains for several hours. They enter hydration metric data, including body weight, blood pressure, urine output, and ultrafiltration volume for each cycle, in handwritten notebooks for review by a nephrologist at bimonthly clinic appointments.

User Design and Evaluation of Successful Adoption of the CKD-PD App

In 2018, the Data Management and Statistical Analysis Center, Faculty of Public Health, Khon Kaen University, developed the CKD-PD mobile app to help nephrologists and patients on PD manage fluid status to prevent overhydration. It is a common complication in patients on PD. Overhydration increases morbidity because of PD-related peritonitis, stroke, congestive heart failure, major adverse cardiac events, and mortality [4-9]. The CKD-PD app has been of interest not only to nephrologists but also to the Thai Health Security Office as an intervention for improving the care of patients on PD. Early treatment of overhydration can decrease these related complications, thereby reducing hospitalization and health care expenses [10].

Many apps fail because of a lack of evaluation and removal of barriers to user adoption, fidelity of the technology, and design

of the health care delivery system in which the app will be deployed [11,12]. Achieving rapid design and deployment of digital health interventions are 2 challenges facing the successful adoption and implementation of mobile health (mHealth) technologies [13]. This is especially true in low- and middle-income countries where mHealth interventions have been touted as solutions to a wide variety of health care challenges [14-16]; however, little is known about how they perform [17-19]. Before studying the effectiveness of the CKD-PD in managing overhydration in a real-world setting, a user design study was conducted using rapid cycle process improvement methods.

The objectives of this study were to (1) optimize the design and usability of the CKD-PD app and test the app in the context in which it is deployed using rapid cycle process improvement methods; (2) evaluate automatic data entry features using near-field communication (NFC) and optical character recognition (OCR) technology; and (3) identify and address the practical challenges that influence the successful adoption of the CKD-PD app and remote monitoring system in a real-world, low-resource setting.

Methods

Study Population

The study was conducted at Srinagarind Hospital, Khon Kaen University, between November 1, 2020, and April 30, 2021. Patients on PD for >3 months without a change in their PD prescription were invited to participate if they met the following inclusion criteria: aged ≥ 18 years, having access to a smartphone capable of running the CKD-PD app, and willing to allow research staff to observe their use of the CKD-PD app with NFC and OCR features and monitoring equipment in their home. Vulnerable populations specified as pregnant women, children, prisoners, individuals who were institutionalized, or those unable to participate in home data collection were excluded. Informed consent was obtained by the trained research staff. A total of 10 participants were enrolled and divided into group 1 (participants 1-5) and group 2 (participants 6-10). Baseline demographic data, including age, sex, education level, time on PD, and whether they used continuous ambulatory PD (CAPD) or automated PD (APD), were collected at enrollment. Participants were given prepaid cards to cover the cost of study related to internet or cellular data expenses.

CKD-PD App and Its Features

The CKD-PD app is available for free download in Android and iOS formats and is designed for daily hydration metric collection for patients on PD (Multimedia Appendix 1). Users can enter hydration metrics using manual input or voice recognition. The CKD-PD app graphically displays a patient's hydration metrics over time and uploads them to the CKDNET database stored in the Thai Care Cloud data repository [20], which is accessible to the PD clinic staff. Nephrologists can set individual hydration parameters for a patient so that they can self-monitor their hydration status. Alerts can be set to notify patients on PD and PD clinic staff when there are actionable hydration metric abnormalities, triggering a prompt review by a nephrologist and allowing the early detection and treatment of overhydration. Another key feature of the CKD-PD app is a direct link using LINE, a social messaging app widely used in Thailand, between the patient and PD clinic, facilitating communication about symptoms and changes in PD management.

A new prototype using NFC and OCR to automate the entry of hydration metric data into the CKD-PD app from measurement devices was developed. NFC uses radio frequency communication and wirelessly transmits data to an NFC-enabled device when it is placed within 4 cm. This offers a simple,

low-cost solution that does not require an external power source or pairing, similar to Bluetooth. It is commonly used for mobile payments and transit cards and, more recently, with subdermal glucose sensors [21-25]. NFC radio frequency tags with unique ID numbers can be added to medical devices such as scales. Users tap a card with an NFC receiver tag on the NFC-equipped scale and then tap it on the NFC card reader, and the data are transferred to the CKD-PD (Multimedia Appendix 2). The CKD-PD app is also equipped with OCR technology, which uses a smartphone camera to capture the digital output from the blood pressure machine and store it in the CKD-PD app.

Study Design

Overview

There were 3 user design phases separated by 2 improvement cycles. During the improvement cycle, the app improvement team analyzed the results from the previous phase and revised the CKD-PD app using the NFC, OCR, and monitoring system (Table 1). The app improvement team included study nephrologists, computer engineers and app developers, and the Data Management and Statistical Analysis Center Thai Care Cloud database team. The app improvement team met as needed to define technology and user design issues, develop solutions, and test modifications.

^cPD: peritoneal dialysis.

Phase 1

Overview

Group 1 participants received training on the use of the CKD-PD app with the NFC and OCR and monitoring system during week 0. In-home observations were conducted once during weeks 1 to 4, followed by research activities 2 to 3 (see the following sections) during weeks 1 and 2. During weeks 3 and 4, the participants used the CKD-PD app with the NFC and OCR system at their homes and completed research activities 4 to 6 (see in the following sections).

Improvement Cycle 1

After completion of phase 1, the results were summarized and presented with the completion of hydration metrics and clinical contact results to the app improvement team. The app improvement team analyzed the results and modified the components of the system, including measurement devices, NFC, OCR, app design, and programming. The user processes were also adjusted.

Phase 2

Overview

Group 2 participants received training in the use of the CKD-PD app with the NFC and OCR and monitoring system during week

8. In-home observations were conducted during weeks 9 to 12 using the modified CKD-PD app with the NFC and OCR and monitoring system. Research activities 2 to 3 were conducted during weeks 9 and 10, followed by research activities 4 to 6 in weeks 11 and 12.

Improvement Cycle 2

After the completion of phase 2, the app improvement team reviewed the new results from participant observations, hydration metric completion, and clinic contacts. Additional issues were identified, and new solutions were developed and tested. Phase 3 was launched after the completion of the improvement cycle 2 modifications.

Phase 3

Overview

Participants from groups 1 and 2 performed research activities 2 to 6 again during weeks 17 to 20 using the modified CKD-PD app and monitoring system modified without NFC and OCR. This allowed for the evaluation of the usability and functionality of the CKD-PD app without NFC and OCR. In phase 3, participants were asked to rate the entry of body weight and dialysate volumes with NFC again based on their earlier experience for comparison with phases 1 and 2. In addition, research activity 7 (see the following sections) was performed to compare using the usual practice of entering their hydration metrics by hand into a logbook with the CKD-PD app.

Final Improvements

After completion of phase 3, the app improvement team made final improvements based on the results of the phase 3 home observation and hydration metric collection using the CKD-PD app and monitoring system without NFC and OCR.

Description of Study Activities

The details of the study activities are described in the following sections.

In-Clinic Training

Participants were trained to use the CKD-PD app with NFC and OCR and home monitoring equipment in the PD clinic by research staff and PD nurses, starting with the CKD-PD app downloaded onto the participant's mobile phone and account registration. Research assistants demonstrated the use of the CKD-PD app, followed by instructions on how to use the NFC and home monitoring equipment, how the uploaded hydration metrics can be monitored by the PD clinic, and how they can self-monitor at home on the app. A set of NFC hydration metric data collection equipment (body weight scale, NFC card, NFC card reader and connectors, and blood pressure machine) was prepared for each participant to use at home. They were trained to set up the equipment using a teaching video ([Multimedia Appendix 2](#)) followed by hands-on practice with a research assistant. During the study period, the participants were instructed to use the NFC data collection system and equipment, in addition to the standard method of recording their hydration metrics in a logbook.

Unified Theory of Acceptance and Use of Technology Survey

A structured interview questionnaire based on the Unified Theory of Acceptance and Use of Technology (UTAUT) model was completed at the beginning and end of each phase to collect perceptions of user technology acceptance and usability [26]. The questionnaire has 6 domains, each with 3 questions representing different factors affecting technology use and adoption. It was translated into the Thai language, and each question was scored on a 5-point Likert scale, with 1=strongly disagree and 5=strongly agree. The final score for each domain is the sum of the scores of the 3 questions for that domain and ranges from 3=strongly disagree to 15=strongly agree. The questionnaire was explained by the research staff and self-administered by the participants ([Multimedia Appendix 3](#)).

Home Observation

Research staff conducted the home observation of participants using the CKD-PD app with NFC and OCR using an observation guide ([Multimedia Appendix 4](#)), using the *think-aloud* method [27]. They asked the participants what they *liked and disliked* about each task and feature. Participants were asked to rate each feature as follows: 1=good, 2=neutral, and 3=not good. This information was recorded by research assistants using handwritten notes and summarized for use by the app improvement team.

Completion of Hydration Metrics

During the 2-week home use period, the number of times the participant successfully uploaded each of the required hydration metric values (body weight, blood pressure, and use of the CKD-PD app) was recorded. Participants using CAPD required 4 dialysate exchange volumes per day, whereas those using APD only required 1 each day; thus, the number of required hydration metrics varied among participants. Successful completion of hydration metrics included the entry of hydration metrics into the app and accurate upload to the CKDNET database.

Contact With PD Clinic

The number of times the participants contacted the PD clinic during all 3 phases was collected, along with the reason for contact.

Validation of Hydration Metrics

The hydration metrics collected by each participant were validated by comparing the values uploaded to the CKDNET database with the results recorded in their logbooks during the study period. Participants sent screenshots from the app, or the research staff reviewed the data on the participant's smartphone to confirm the correct data entry in the CKD-PD app. Successful validation of hydration metrics was defined by the completion of data entry by the participant and agreement between values recorded in their logbook and the uploaded results.

Observation of Logbook Use

Participants were observed while entering hydration metrics in their logbooks. They were asked what they *liked and disliked*

about each task and feature and rated each feature as 1=good, 2=neutral, and 3=not good.

Ethics Approval

This study was approved by the Ethics Committee for Human Research, Faculty of Medicine, Khon Kaen University, Thailand (project number HE621494), and the Mass General Brigham institutional review board (protocol number 2019P002648). All participants provided written informed consent in the Thai language.

Results

Participant Characteristics

Phase 1 participants characteristics had a mean age of 46 years (SD 10.3) and a mean time on PD of 5.5 years (SD 3.8); were female (2/5 40%); used the PD method of CAPD (3/5, 60%) or APD (2/5, 40%); and had educational backgrounds of high school (2/5, 40%), bachelor's degree (1/5, 20%), and postbachelor's degree (2/5, 40%).

Phase 2 participant characteristics had a mean age of 48 years (SD 15.7) and a mean time on PD of 1.3 years (SD 2.5); were

female (3/5, 60%); used the PD method of CAPD (1/5, 20%) or APD (4/5, 80%); and had educational backgrounds of high school (2/5, 40%), bachelor's degree (2/5, 40%), and postbachelor's degree (1/5, 20%). One of the group 2 participants did not complete phase 3 because of sudden death.

In comparison, the characteristics of patients on PD at Srinagarind Hospital were as follows: mean age 49 years (SD 13); mean time on PD 3 years (SD 29.7); female (33/74, 45%); PD method CAPD (42/74, 57%) or APD (32/74, 43%); and educational background of primary school (37/74, 50%), high school (12/74, 16%), bachelor's degree (23/74, 31%), and postbachelor's degree (2/74, 3%).

UTAUT Survey

The UTAUT survey scores for each participant are presented in [Table 2](#) as the total score (sum of all 6 domains) and the scores for each domain. The difference in the total score between the beginning of phase 1 or phase 2 and the end of phase 3 is also presented. Detailed results, including the scores at the beginning and end of all phases, are available in [Multimedia Appendix 5](#).

Table 2. Difference in Unified Theory of Acceptance and Use of Technology total scores^a by participant and domain between the beginning of phase 1 or 2 and end of phase 3 (detailed results in [Multimedia Appendix 5](#)).

Participant number ^b	1	2	3	4	5	6	7	8	9	10	Values, mean
Total score											
Phase 1 or 2	89	63	86	81	87	79	66	75	71	77	77
Phase 3	74	76	80	74	77	72	N/A ^c	80	79	72	76
Difference	-15	13	-6	-7	-10	-7	N/A	5	8	-5	-2.7
Difference by domains											
Performance expectancy	-2	3	1	1	-1	-1	N/A	1	1	0	0.33
Effort expectancy	-2	4	1	-1	1	-1	N/A	0	0	1	0.33
Social influence	-3	3	1	0	-2	-1	N/A	-1	1	-1	-0.67
Voluntariness	-3	-3	-5	-2	-3	-3	N/A	2	3	-4	-2
Intention to use	-2	3	-4	-4	-6	0	N/A	2	3	0	-0.9
Facilitating conditions	-3	3	0	-1	1	-1	N/A	1	0	-1	-0.1

^aScores for individual questions from 1 (strongly disagree) to 5 (strongly agree). The domain scores ranged from 5 to 15. The total score for all the domains ranged from 30 to 90.

^bParticipants 1 to 5: phase 1 and phase 3; participants 6 to 10: phase 2 and phase 3.

^cN/A: not applicable; participant 7 expired before phase 3.

Of the 9 participants who completed phase 1 or 2 and phase 3, 6 (67%) individuals had a decrease in the total UTAUT score, ranging from -5 to -15 points. There were 33% (3/9) of individuals who had an increase in the total UTAUT score, ranging from 5 to 13 points. The mean score at the beginning of phases 1 or 2 was 77 (SD 8.8), with a range of 63 to 89. The mean score at the end of phase 3 was 76 (SD 3.2), with a range of 72 to 80. In group 1, the domains of voluntariness (-3) and intention to use (-2.6) showed the largest decrease in mean difference between the beginning of phase 1 and the end of phase 3, with all participants reporting a negative score in voluntariness and 80% (4/5) of participants reporting a negative

score in intention to use. In group 2, there were small decreases in voluntariness (-0.5), social influence (-0.5), and facilitating conditions (-0.25) and an increase in intention to use (1.25) between phases 2 and 3 ([Multimedia Appendix 5](#)).

Participant Observation

The home observation results for each participant using the CKD-PD app with the NFC and OCR and monitoring system during the home observations are summarized by phase for all participants in [Table 3](#), with detailed responses in [Multimedia Appendix 6](#). Feature ratings are provided for each phase. The participants rated almost all features as *good*, except for some

data entry tasks using NFC, which were rated as *neutral*. Participants liked automatic data entry with NFC; however, technical issues such as slow transfer of time and difficulty tapping the card resulted in lower scores. Participants were asked to rate the entry of body weight and dialysate volume using NFC at the start of phase 3 based on their experience in phases 1 or 2 for comparison with manual data entry used in

phase 3. The average rating for data entry with NFC was 2.3 for each task compared with 1.1 for manual data entry (Multimedia Appendix 6). Scores for all tasks using the handwritten logbook were nearly all higher than the CKD app with or without NFC and OCR, consistent with the preference for using the app.

Table 3. Feature and task ratings^a from participant observation in phases 1, 2, and 3 (detailed results in Multimedia Appendix 6).

Feature	Phase 1 ^b , mean (range)	Phase 2 ^c , mean (range)	Phase 3 ^d , mean (range)	Phase 3 ^e , mean (range)

^eGroup 1 and 2 using logbook; participants 1 to 10, excluding 7.

^fN/A: not applicable.

In general, participants found that manual data entry was easier to perform than using the NFC and OCR system. The use of NFC and OCR presented multiple challenges. Some of these issues were solved by providing tools such as an extension device for tapping the card to eliminate the need to bend over and touch the card to the scale on the floor and training participants to wait long enough for data transfer. Some issues were more difficult to troubleshoot within the time frame of this study, such as (1) lack of space in participants' homes for NFC setup and access to power outlets; (2) internet instability resulting in slow data transfer; (3) size and design of the NFC-assembled weight scale, making it difficult for older or obese patients to stand on; and (4) lack of an alert to indicate that the NFC device was ready to place the NFC card for reading. Most patients also did not like to use the OCR function to enter the blood pressure readings because of poor image clarity and variations in ambient home lighting conditions.

Several important issues related to the functionality of the CKD-PD app were detected and corrected. The dialysate in and out volumes were reported by PD cycle, and the net daily ultrafiltration volume was not accurately calculated and displayed. There were issues with the display of hydration metrics, such as incorrect scale on the graph and a lack of previous results for comparison. During home observation of participants using the CKD-PD app with the NFC and OCR and monitoring system, participants expressed concerns about the usability of the app. An example was slowness when opening

each icon, which was determined to be from opening multiple apps at once, and slow cellular or Wi-Fi network speeds were contributing factors. BMI was misinterpreted as *overweight* because of translation issues between the English and Thai languages. This was corrected by changing the wording so it would not be confused with *weight*. Participant height had to be entered daily to calculate the BMI. As this measurement did not change, the app was modified so that it automatically entered the participant height obtained daily. The original font was small and difficult to read. This was adjusted, and the readability of the screens was improved.

Completion and Validation of Hydration Metrics

The percentage completion of the hydration metrics for each participant was collected for all 3 phases (Table 4). The mean percentages of completion in phases 1 and 2 were 88% (SD 19) and 83% (SD 6.3), respectively, with a range of 57% to 100%. This was compared with the mean percentage of completion in phase 3 for all participants (68%, SD 18.6, range 18%-100%; Multimedia Appendix 7). The most common reasons for not collecting the hydration metrics in phases 1 and 2 were not knowing how to enter the data, forgetting to enter the data, problems with the system uploading the data to the CKDNET database, and switching from Android to iOS systems. The reasons for incomplete hydration metric collection in phase 3 (not using NFC) were forgetting to send the data to the CKDNET and switching from Android to iOS.

Table 4. Percentage completion of hydration metrics (detailed in [Multimedia Appendix 7](#)).

Participant	Phase 1 ^a		Phase 2 ^b		Phase 3 ^c		Difference (%) ^d
	Total, N	Done, n (%)	Total, N	Done, n (%)	Total, N	Done, n (%)

^fParticipant 7 expired before completion of the study.

^gN/A: not applicable.

Of the 9 participants who entered hydration metric data in phase 1 or 2 and phase 3, there were 4 participants who had a greater than 29 percentage point decrease in their hydration metric completion. The other 5 participants had minimally decreased or increased hydration metric completion, ranging from –11% to 9%.

Validation of the hydration metrics improved from phases 1 or 2 and phase 3 ([Table 5](#)). In phases 1 and 2, the main issues were

the upload of inaccurate body weight and ultrafiltration metric results to the CKDNET. This was because of problems with the NFC weight scale and app calculation of the ultrafiltration volume. In phase 3, these issues were resolved, the hydration metrics were fully validated with participants correctly entering the data in the CKD-PD app, and the results entered were accurately uploaded to the CKDNET.

Clinic Contacts

The number of times each participant contacted the PD clinic during each phase is presented in [Table 6](#). All contacts were made using the Line messaging app by chat, audio, or video

calls, except for 1 in-person contact during phase 1. In phase 1, there were 104 clinic contacts compared with 13 and 22 in phases 2 and 3, respectively, and most were related to issues using the CKD-PD app. In phase 3, 59% (13/22) of the contacts were related to clinical concerns.

Table 6. Number and reason for contacting the peritoneal dialysis clinic by phase.

Phase	Total number of contacts, N	Clinical issue, n (%)	App issue, n (%)	Other, n (%)
Phase 1	104	0 (0)	99 (95.2)	5 (4.8)
Phase 2	13	3 (23.1)	10 (76.9)	0 (0)
Phase 3	22	13 (59.1)	9 (40.9)	0 (0)

Improvement Team Activities

After the completion of each phase, the research team summarized the findings for the app improvement team ([Multimedia Appendix 8](#)). In phase 1, troubleshooting issues with NFC and OCR were the focus of the improvement

activities, along with app design issues. In phase 2, additional work was performed with the NFC data entry; however, more focus was given to resolving issues with how the hydration metric data were displayed and uploaded to the CKDNET database. In phase 3, the NFC prototype was not used as the participants preferred to input data manually into the CKD-PD

app, and the upload of the hydration metric data to the CKDNET database was not reliable using NFC. The app improvement team made final improvements to improve the stability of the data transfer from the CKD-PD app to the CKDNET database, added the total daily ultrafiltration volume to the CKDNET, and set parameters for overhydration alerts.

Discussion

Principal Findings

Overview

mHealth apps are touted as having great potential to transform the delivery of health care; however, the real-world development of mHealth apps in low- and middle-income countries reveals few success stories [12,17]. Often, a good app idea fails to succeed as the design does not meet the users' needs and is difficult to use. Our research describes how a rapid cycle process improvement strategy helped researchers understand the benefits and challenges of using an mHealth app for use by patients on PD in a low-resource setting and optimize its features. The process revealed valuable insights into the factors influencing user attitudes, identifying technological and design flaws, and addressing barriers to user adoption of the CKD-PD app and monitoring system. Moreover, we believe that this methodology can be accomplished without requiring significant training in data collection, statistical analysis, or funding. The general principles of the user design process are applicable to a wide variety of locations, contexts, and subject domains.

User Adoption

The total scores for all the participants for most domains were in the *agree* and *strongly agree* categories, demonstrating a strong willingness to adopt the technology at the beginning of the study. Over the course of the study, 67% (6/9) of participants who completed both assigned phases demonstrated decreased interest in using the technology, although the total scores remained in the *agree* range or above. The decreases in the total score were primarily driven by decreases in the domains of voluntariness and intention to use. We believe this is likely because of issues with the NFC and OCR data entry features and app speed and functionality. We acknowledge that the UTAUT questionnaire is not typically used to evaluate technology adoption over time; however, we found that it provided insights into how our participants' views changed over the course of using the CKD-PD app and monitoring system, although they had limited generalizability. The small sample size limited the statistical validity of our findings. However, we found the information useful as a *sentiment analysis* regarding user experience and provided insights into how different individuals may adopt the CKD-PD app.

CKD-PD App Issues

Design issues centered on simplicity and ease of use compared with a pencil and paper logbook. Simplifying the use of the app, for example, opening the app and the organization of the screens, readability of the fonts, input of the data, and graphical representation of trends, clearly needed to be refined based on user feedback. PD requires a substantial commitment of time to collect and record data from patients and their families

throughout the day, whether in a logbook or an app. Our participants generally reacted positively to the self-monitoring features and quickly engaged with this new functionality but became frustrated when some features did not work well for them.

Technology Issues

Technology issues included problems with the NFC devices, unstable internet access, slow internet speed, app stability, uploading data to the CKD-NET cloud, and software issues causing it to freeze or not upload data properly. The participant observation revealed that NFC and OCR were good solutions for automatic data entry but that they need to be seamlessly integrated into the measurement devices; for example, the location of NFC on the scales on the floor was inconvenient, slow data transfer, and poor quality image capture with OCR. Despite these barriers, participants liked the concept, and with further development, we believe that NFC and OCR could be simple and effective methods of mitigating the barrier of data entry [28,29], as has been done with other devices such as glucose monitors.

Internet access, especially in low-income rural areas, is frequently slow or unstable, making the use of digital apps cumbersome. Some patients were concerned about the cost of sending or receiving data, although internet access was subsidized for the participants in this study. These will be challenging issues to remedy; however, if successful in reducing complications from overhydration, it may prove cost-effective in the long run to provide financial support for internet access for patients on PD, given the alternative costs of not using the app.

Programming issues resulting in app instability and data upload errors were critical problems that were identified. These were fixable by our software engineers and resulted in improved validation of the hydration metrics in phase 3. The completion of the hydration metrics dropped between phases 1 and 3. We believe this occurred as participants in phases 1 and 2 used NFC, which automatically uploaded the hydration metrics, and decreased after the team elected not to use NFC and OCR in phase 3 because of usability issues and inaccurate upload of the hydrate metrics to the CKDNET with NFC and OCR. The hydration metric accuracy improved with this change and resulted in 100% validation of the hydration metrics in phase 3. However, when manual entry was used in phase 3, participants had to remember to upload their data, resulting in incomplete hydration metrics. In the final improvements, a reminder alert addressed this issue.

Communication Issues

Contact with the PD clinic was much more frequent in phase 1 than in phase 2, although the participants in both phases were new users of the app. The study staff felt that this was because of differences in individual comfort when using the CKD-PD app. In phase 3, there were fewer contacts about the app, although there were 10 participants compared with 5 in phases 1 and 2. The contacts in phase 3 were about clinical concerns, suggesting increased confidence in self-monitoring features. In general, participants gave high ratings and positive comments

about the ease of communication with the PD clinic using the CKD-PD app.

Impact on Future Deployment and Development of CKD-PD

Our research findings provided critically useful information for the optimization of the CKD-PD app and monitoring system. We plan to use it in a randomized controlled trial to further evaluate the efficacy of CKD-PD in the early detection and treatment of overhydration.

We have developed training materials for CKD-PD app users based on the insights gained from this study and plan to share them with future CKD-PD app users. We have improved awareness of user adoption issues and realize that this will be an iterative process as more patients on PD use the app. We believe that with additional engineering and design work, NFC is a potential solution for automating data entry, and we plan to pursue the further development of these features.

Limitations

Our study has several limitations. The NFC system and CKD-PD app were initially tested together; however, the NFC issues were too complicated to solve within the time frame and budget of the study period. Through targeted observations and data collection, we were able to tease out NFC and data entry issues from the app design and cloud-based monitoring processes.

We identified potential sources of bias. Observation bias could have influenced our results as participant observations were conducted by research staff from the PD clinic. Patients on PD, cared for by nephrologists and PD nurses from their clinic, may be inclined to report feedback they thought the PD staff wanted to hear. Confirmation bias may also be a concern as research staff may be looking for patterns or use issues that confirm opinions they already hold about the CKD-PD app, NFC and OCR data entry, and the monitoring system. Our sample size was small; however, this is consistent with recommendations for user design studies, indicating that a few participants can uncover most usability issues [30]. We also acknowledge the potential for selection bias in our participants, given their higher educational level than the average population in rural northeast Thailand, although the participants were representative of the Srinagarind Hospital PD patient population. We selected participants who had baseline comfort with smartphones for the

user design study, although it limits generalizability as they were more interested and engaged in the design process.

An additional weakness is that we did not conduct an in-depth investigation into why our participants responded to the UTAUT questionnaire as much as they did. Although it has been validated and used in Thai populations [26,31], we did not consider the impact of age, gender, education, and cultural influences on UTAUT scores [32,33]. We acknowledge that UTAUT results have limited generalizability.

Comparison With Prior Work

Our research included several recommended strategies for mHealth app development and evaluation [34,35]. Our iterative rapid cycle process improvement approach used a multidisciplinary team, including patients, computer engineers and programmers, nephrologists, and PD nurses, to evaluate the CKD-PD app. We conducted our study activities in the participants' homes and PD clinics where it would be used [36,37]. Our structured observation using the think-aloud method provided the app improvement team with a broad sense of what worked and what did not work, in addition to specific actionable feedback. Finally, our study participants were selected from the same study population as those who will use the CKD-PD app in northeast Thailand.

Our research team found several critical usability and functionality issues during the study. This experience reinforces the importance of these steps before an mHealth app can be successfully implemented [12,13,17]. Although our current NFC and OCR data entry features are not optimized, our results support the idea that app users want these features [27].

Conclusions

In conclusion, using rapid cycle progress improvement methodologies with a multidisciplinary team proved to be a useful strategy for optimizing the CKD-PD app and monitoring system. Our experience aligns with insights and recommendations regarding mHealth technology design and evaluation that using a multidisciplinary team in the context of the system in which it is used is essential for successful deployment. This process revealed critical issues that once addressed, position the CKD-PD app and monitoring system to achieve its potential to improve health outcomes.

Acknowledgments

The research reported in this publication was supported by the Fogarty International Center of the National Institutes of Health under award number R21TW010963. The content is the sole responsibility of the authors and does not necessarily represent the official views of the National Institutes of Health. The authors would like to acknowledge the Chronic Kidney Disease Northeast Thailand research project staff for their assistance in organizing and assisting with home observations. The authors would like to thank Ms Thankyalak Rattanasawad; the staff of the Center of Excellence in Kidney Diseases, Srinagarind Hospital, Faculty of Medicine at Khon Kaen University; Dr Jessica Haberer and the Massachusetts General Hospital Center for Global Health; Dr Nathaphop Chaichaya, Data Management and Statistical Analysis Center, Faculty of Public Health, Khon Kaen University Thailand; the other staff from the Data Management and Statistical Analysis Center and the Faculty of Public Health at Khon Kaen University; and Pobporn Danvirutai from T. Robotics, Co Ltd, Bangkok, Thailand.

Authors' Contributions

SA, EL, KEM, MGM, and BT designed the study, including working with the Data Management and Statistical Analysis Center app development team. CS developed and oversaw the use of near-field communication or optical character recognition and integration with the chronic kidney disease–peritoneal dialysis app. EL, SK, WC, TC, and PW collected and analyzed the data and drafted the manuscript. SA, KEM, and MGM assisted with the data analysis and critically revised the manuscript. All authors have read and approved the final manuscript.

Abstract

Background: With the aging society, the number of emergency transportations has been growing. Although it is important that a patient be immediately transported to an appropriate hospital for proper management, accurate diagnosis in the prehospital setting is challenging. However, at present, patient information is mainly communicated by telephone, which has a potential risk of communication errors such as mishearing. Sharing correct and detailed prehospital information with emergency departments (EDs) should facilitate optimal patient care and resource use. Therefore, the implementation of an app that provides on-site, real-time information to emergency physicians could be useful for early preparation, intervention, and effective use of medical and human resources.

Objective: In this paper, we aimed to examine whether the implementation of a mobile app for emergency medical service (EMS) would improve patient outcomes and reduce transportation time as well as communication time by phone (ie, phone-communication time).

Methods: We performed an interrupted time-series analysis (ITSA) on the data from a tertiary care hospital in Japan from July 2021 to October 2021 (8 weeks before and 8 weeks after the implementation period). We included all patients transported by EMS. Using the mobile app, EMS can send information on patient demographics, vital signs, medications, and photos of the scene to the ED. The outcome measure was inpatient mortality and transportation time, as well as phone-communication time, which was the time for EMS to negotiate with ED staffs for transport requests.

Results: During the study period, 1966 emergency transportations were made (n=1033, 53% patients during the preimplementation period and n=933, 47% patients after the implementation period). The ITSA did not reveal a significant decrease in patient mortality and transportation time before and after the implementation. However, the ITSA revealed a significant decrease in mean phone-communication time between pre- and postimplementation periods (from 216 to 171 seconds; -45 seconds; 95% CI -71 to -18 seconds). From the pre- to postimplementation period, the mean transportation time from EMS request to ED arrival decreased by 0.29 minutes (from 36.1 minutes to 35.9 minutes; 95% CI -2.20 to 1.60 minutes), without change in time trends. We also introduced cases where the app allowed EMS to share accurate and detailed prehospital information with the emergency department, resulting in timely intervention and reducing the burden on the ED.

Conclusions: The implementation of a mobile app for EMS was associated with reduced phone-communication time by 45 seconds (22%) without increasing mortality or overall transportation time despite the implementation of new methods in the real

clinical setting. In addition, real-time patient information sharing, such as the transfer of monitor images and photos of the accident site, could facilitate optimal patient care and resource use.

Introduction

With the aging society, the number of emergency transportation has been growing [1]. Researchers used a nationwide database in Japan and reported that the annual emergency transportations increased from 4 million in 2000 to 6 million in 2020 [1]. The substantial increase in emergency transportation causes depletion of medical resources and emergency department (ED) overcrowding, resulting in poor patient outcomes [2,3]. Indeed, in Japan, approximately 10,000 emergency patients were turned away by at least 6 hospitals annually [4].

When a patient has stroke, acute myocardial infarction, or severe trauma, it is important to transport them to an appropriate hospital in order to provide appropriate management immediately [5-9]. Although accurate diagnosis in the prehospital setting is challenging, real-time sharing of detailed patient information should facilitate appropriate transportation and management [10,11]. However, at present, patient information is mainly communicated by telephone, which has the potential risk of communication errors such as mishearing. In addition, photos of the patient, patient monitors (eg, electrocardiogram), and the accident scene can contain important information that emergency physicians would want to know in advance. Therefore, the implementation of an app that provides on-site, real-time information to emergency physicians could be useful for early preparation, intervention, and effective use of medical and human resources [5-8,10-12].

Thus, in this study, we examined whether the implementation of a mobile app for emergency medical services (EMS) could improve patient outcomes. We hypothesized that patient mortality would be improved by shortening the transportation time and time for EMS to negotiate with ED staffs for transport requests.

Methods

Study Design and Settings

We performed an interrupted time-series analysis to examine the change in outcomes before and after the introduction of a mobile app for EMS. This study was conducted using data on EMS transportations by Kamakura City Fire Department to Shonan Kamakura General Hospital, a tertiary care hospital in Japan, from July 8, 2021, to October 27, 2021. Kamakura City is a city in Kanagawa Prefecture, Japan, with a population of 172,948 people and an average age of 48.8 years as of 2020. The city has a high ratio of the aging population, with 53,517 (31.1%) people aged ≥ 65 years. Kamakura City has 8 fire departments that make 29.9 emergency transportations per day

and 10,896 per year [13]. The Emergency Department of Shonan Kamakura General Hospital had 43,506 ED visits by patients in 2020. Among these patients, 14,925 (34.3%) were transported to the emergency department by EMS, which was the highest annual number of emergency transportations of all hospitals in Japan that year. All patients transported by EMS were accepted [14]. The number of patients transported by the Kamakura City EMS during the study period (16 weeks) was estimated to be approximately 2000 based on the number of patients transported in the past.

Ethics Approval

This study protocol was approved by the Ethics Committee of Shonan Kamakura General Hospital (approval number: TGE01663-024; approval date: February 25, 2021). The need for informed consent was waived due to the retrospective nature of the study. For the publication of images and personal information, the patients' consent was obtained, and their consent was recorded in their medical charts. The institutional review board approved the use of patient information for this study.

Apps Used and Their Features

We implemented an app for EMS named NEXT Stage ER mobile (NSER mobile) on September 2, 2021. The NSER mobile is an app that was developed to reduce the complexity of information entry for EMS teams and to increase the efficiency of information sharing with EDs. The app is equipped with high-precision voice input and optical character recognition functions that enable timely information sharing by sending information to hospitals in the original text (eg, medications and past medical history) and in coded form (eg, International Statistical Classification of Diseases and Related Health Problems, 10th revision codes). We provide a description of the usage process of the NSER mobile by EMS and hospitals in [Multimedia Appendices 1](#) and [2](#). All EMS staffs took 3-hour lectures to learn to use the app before implementation.

The developer of NSER mobile is TXP Medical Co Ltd. A free trial for this product is available through the website of TXP Medical [15]. The system's accuracy and validity are now being examined in a multicenter study (UMIN-CTR ID: UMIN000045775), but it is fundamentally the same as the NEXT Stage ER system, which is a well-validated ED information system [16]. In addition, in this study, we did not use table data from the app. All data are abstracted from the Kamakura City Fire Department and patient registry of ED patients of Shonan Kamakura General Hospital. Thus, the only data we extracted from the NEXT Stage ER mobile system for

this study are images (though more detailed data exist in the cloud server of the system).

Study Population

All patients transported to Shonan Kamakura General Hospital by the Kamakura City EMS during the study period were included in the study. Exclusion criteria were cases with missing data on call times between the hospital and EMS and EMS activity times (26/1992, 1.3%).

Outcome Measures

The primary outcome was inpatient mortality. Secondary outcomes were the overall transportation time (the time from the patient's call for an ambulance to arrival at the hospital), and phone-communication time (the time for EMS to negotiate with ED staffs for transport requests).

Statistical Analysis

Cases with missing data on the time spent in EMS and the emergency department (ED) were excluded from the analysis (26/1992, 1.3%). Using data that met the inclusion criteria, we performed an interrupted time-series analysis with a linear regression model to examine whether the implementation of the mobile app had an impact on the outcomes. An interrupted time-series analysis is a quasi-experimental design for evaluating

the effectiveness of population-level health interventions implemented at a clearly defined point in time and is thus widely used to evaluate the effectiveness of interventions [17-19]. The time unit was weeks (ie, 8 time points before and 8 time points after implementation).

Additionally, we described specific cases where the immediate sharing of patient information and photos with NSER mobile led to rapid diagnosis and intervention.

All statistical analyses were conducted using R version 4.1.1 (R Foundation for Statistical Computing).

Results

Among the 1992 patients transported by EMS, we excluded 26 patients (1.3%) with missing data on the transport time or the phone communication time, and the remaining 1966 (98.7%) patients were eligible for this study. The mean age was 66.7 years (SD 25.4), and 49% (n=963) were men. Of the 1966 patients, 1033 (53%) were transported during the preimplementation period, and 933 (47%) were transported in the postimplementation period. The patient characteristics in the pre- and postimplementation periods were similar. Additionally, there were no significant differences in the region of transportation and the EMS team numbers (Table 1).

Table 1. Characteristics of patients transported by emergency medical services.

Patient characteristics and variables	Patients transported using the app (n=1033)	Patients transported in the usual way (n=933)	P value

Death	18 (1.7)	21 (2.3)	
Prognosis, n (%)			.56
In-hospital death	53 (5.1)	46 (4.9)	

^aJCS: Japan Coma Scale.

^bThe severity of illness at the emergency department is classified as follows: minor illness—patient can return home after treatment; moderate illness—patient requires inpatient treatment, but the disease severity is low and can be managed in a general ward; serious illness—multiorgan failures such as respiratory or circulatory failure requiring monitoring, a ventilator, vasopressors such as catecholamines, and admission to an intensive care unit; death—cardiac arrest on arrival at the hospital.

^cED: emergency department.

Inpatient Mortality

Of the 1966 eligible patients, 53 (5.1%) died in hospital in the preimplementation period and 46 (4.9%) died in hospital in the postimplementation period. From the pre- to postimplementation period, the proportions of in-hospital deaths among patients who were transported to EDs during each period decreased by 5% (95% CI –11% to 1%), followed by a decreasing trend relative to preimplementation of –1% per week (95% CI –2% to 1%). There was no significant change in inpatient mortality. [Figure 1](#) shows the proportions of in-hospital deaths among

patients who were transported to emergency departments during each period. On September 2, 2021, EMS began transportation using the new app in place of the traditional method. The proportion of in-hospital deaths among the transported patients is plotted for 8-week periods before and after the implementation. For in-hospital mortality, the R^2 for the preimplementation model was 0.26, while the R^2 for the postimplementation model was 0.23. The results of interrupted time series analysis on inpatient mortality are shown in [Table 2](#).

Figure 1. Interrupted time-series analysis of inpatient mortality.

Table 2. Results of interrupted time-series analysis on inpatient mortality.

Time-series analysis	Estimate (95% CI)	P value
Trends in inpatient mortality before implementation	0.01 (0.00 to 0.02)	.07
Absolute change in the inpatient mortality before and after implementation	-0.05 (-0.11 to 0.01)	.11
Trends in inpatient mortality after implementation	0.00 (-0.01 to 0.01)	.50
Change in slope before and after implementation	-0.01 (-0.02 to 0.01)	.40

The Transportation Time From EMS Request to ED Arrival

The mean transportation time from EMS request to ED arrival was 35.9 minutes (SD 9.7 minutes) in the preimplementation period and 36.1 minutes (SD 8.5 minutes) in the postimplementation period. From the pre- to postimplementation period, the mean transportation time from EMS request to ED arrival decreased by 0.29 minutes (95% CI -2.20 to 1.60 minutes), followed by a decreasing trend relative to

preimplementation of -0.33 minutes per week (95% CI -0.74 to 0.07; Table 3). Figure 2 shows the mean transportation time from the emergency call to arrival at the hospital. On September 2, 2021, EMS began transporting using the new app in place of the traditional method. The mean transportation time is plotted for 8-week periods before and after the implementation. For transportation time, the R^2 for the preimplementation model was 0.30, and the R^2 for the postimplementation model was 0.28.

Table 3. Results of interrupted time-series analysis on transportation time from emergency medical services to emergency department arrival.

Time-series analysis	Estimate (min), 95% CI	P value
Trends in mean transportation time before implementation	0.23 (-0.06 to 0.51)	.11
Absolute change in the transportation time before and after implementation	-0.29 (-2.20 to 1.60)	.70
Trends in mean transportation time after implementation	-0.10 (-0.39 to 0.18)	.40
Change in slope before and after implementation	-0.33 (-0.74 to 0.07)	.10

Figure 2. Interrupted time-series analysis on transportation time from emergency medical services to emergency department arrival.

Phone-Communication Time Between EMS Teams and Hospital

The mean time of phone communication between EMS and ED staffs was 216 (SD 107) seconds in the preimplementation period and 171 (SD 120) seconds in the postimplementation period. From the pre- to postimplementation period, the phone-communication time decreased by 45 seconds (95% CI -71 to -18 seconds), followed by an increasing trend relative

to preimplementation of +2.9 seconds per week (95% CI -2.7 to 8.6; Table 4). The mean phone-communication time between EMS and the hospital is shown in Figure 3. On September 2, 2021, the EMS started using the app for transportation in place of the conventional method. The mean phone-call time is plotted for 8-week periods before and after the implementation. For phone-communication time, the R^2 for the preimplementation model was 0.78, while the R^2 for the postimplementation model was 0.72.

Table 4. Results of interrupted time-series analysis on phone-communication time.

Time-series analysis	Estimate (s), 95% CI	P value
Trends in mean phone-communication time before implementation	-0.44 (-4.4 to 3.6)	.80
Absolute change in the phone-communication time before and after implementation	-45.0 (-71.0 to -18.4)	.003
Trends in mean phone-communication time after implementation	2.5 (-1.5 to 6.5)	.20
Change in slope before and after implementation	2.9 (-2.7 to 8.6)	.30

Figure 3. Interrupted time-series analysis on phone-communication time.

Specific Cases

We experienced several cases where the immediate sharing of patient information and photos using the NSER mobile has led to rapid diagnosis and intervention. For example, a 47-year-old man with a history of diabetes mellitus, who had visited the hospital the day before for chest pain, called for EMS again complaining of persistent chest pain. Upon EMS's arrival, his electrocardiography monitor showed ST-segment elevation in lead II ([Multimedia Appendix 3](#)). Before arriving at the hospital, he was diagnosed with ST-segment elevation acute myocardial infarction. Upon consulting with the cardiologist, he was able to start percutaneous coronary intervention within ten minutes after the patient's arrival at the ED. [Multimedia Appendix 3](#) shows the monitor screen in the ambulance transporting a 47-year-old man who called EMS complaining of chest pain. Lead II showed ST-segment elevation, and the images were transmitted from EMS to the ED staff, leading to early diagnosis of acute myocardial infarction and percutaneous coronary intervention within 10 minutes of arrival at the hospital.

In another example, a 35-year-old man was riding a bicycle when he collided with a car traveling at 60 kilometers per hour. He had no memory when he was injured. While the mechanism of injury suggests a highly serious one, real-time information sharing (initial assessment of the patient, vital signs, photos of the injury scene, and damage to the bicycle) allowed us to determine that the injury was minor, with only a contusion on the left lower leg and the scalp. Consequently, we were able to reduce unnecessary preparation for the initial treatment, including surgery for damage control ([Multimedia Appendices 4-6](#)).

Discussion

Principal Findings

In this ITSA study, there was no substantial decrease in in-hospital mortality and overall transportation time between pre- and postimplementation periods. On the other hand, the implementation reduced phone-communication time by 22% without increasing mortality or overall transportation time despite the implementation of new methods in the real clinical setting.

The conventional communication between EMS and ED staff by telephone only poses substantial stress on EMS staff, exemplified by difficulty hearing and misidentification of information. Data related to patient demographics, vital signs, past medical history, and medications are likely misclassified due to such technical difficulties, and real-time information sharing could reduce such miscommunication. In addition, the app's feature to share visual information via optical character recognition in a timely manner was useful to ensure that ED staffs are fully prepared to receive patients. For ED staff, timely monitoring and understanding of the situation offered by the EMS were useful for maintaining a high quality of clinical practice.

Comparison With Prior Work

Appropriate use of medical apps could lead to a seamless transition of management from prehospital to post-ED arrival. As reported in this study, apps can be used to obtain information such as medical history and prehospital electrocardiograms in advance. From such information, physicians can prepare for urgent interventions (eg, catheterization) before the patient arrives at the hospital. There have been several reports on the

usefulness of apps that provide prehospital information in emergency medicine. A system called ORION (Osaka Emergency Information Research Intelligent Operation Network system), introduced in Osaka City in 2013, reduced the number of cases that are difficult to transport [12]. Another study reported that the communication-type medical apps can be accurately used remotely, and information can be shared with the stroke team to prepare for rapid treatment [5,20,21].

The NSER mobile app is a digitalization tool for EMS in the clinical setting, and there are no patients for whom the app cannot be used. Nevertheless, we think that the system is more suitable for patients who need emergency interventions (eg, cardiac catheterization) [2-5,7] rather than those with cardiac arrest (EMS may not have enough time to use the app). Due to the limited sample size, we could not analyze data after stratifying by these variables. Thus, we are conducting further study in different settings to examine the effectiveness of the app.

Strengths and Limitations

This study has several strengths, a few of which are as follows. First, there were no similar studies on prehospital information transfer apps aimed at improving the efficiency of emergency patient transport without assuming a specific disease. Second, the interrupted time-series analysis estimates the effect of intervention on a population and is a study design without a control group. Third, the advantage of reducing phone-communication time through real-time information sharing is noticeable especially when the EMS is consulting multiple hospitals to accept patients at the same time, not to mention that in many cases it is difficult to transport patients, particularly in urban areas in Japan. Indeed, according to statistics from the Ministry of Health, Labor, and Welfare in 2016, even for critically ill patients, there were 10,039 cases (2.3%) in which the number of consultations to medical institutions was ≥ 4 times and 22,104 cases (5.0%) in which the time spent on site was 30 minutes or longer [22]. In such cases, given the tough negotiation with hospitals, the reduction of phone-communication time while efficiently sharing prehospital information should reduce the burden on EMS. We believe that the findings from this study allow us to consider the substantial contribution and potential benefits of mobile apps to emergency medical care.

Our study has several limitations. First, although we performed a 3-hour lecture for using the app prior to implementation, users may not have been able to get accustomed to the app quickly enough in the clinical setting. Despite this, there was clear

improvement in phone-communication time immediately after its implementation. Second, there was no control group in our ITSA design [23]. Nonetheless, our findings are likely robust, given that there were no interventions other than the implementation of the app that may have affected the outcome. While the COVID-19 pandemic may have affected the assumptions of the interrupted time series analysis, the implementation of personal protective equipment for EMS was initiated on March 2, 2020. Therefore, change in practice due to the pandemic may not have substantially affected the EMS during the study period (July 8, 2021, to October 27, 2021). Third, we did not have information on the time to intervention at the ED (eg, time to urgent catheterization) and ED overcrowding. Therefore, further studies are needed to examine the impact of the app on clinical practice. Fourth, in this study, we only evaluated the observed values for 8 weeks before and after the intervention. A recent simulation-based study on ITSA reported that 12 preintervention and 12 postintervention time points may be required for a moderate intervention effect sizes [24]. Lastly, there is limited generalizability of our findings because our study was a single-center, retrospective observational study in Japan with a small sample size. In addition, EMS systems are different across countries. The extrapolation of our findings to other settings should be done with caution, and therefore additional large-scale studies are warranted.

Future Directions

As shown in the 2 cases, the implementation of a mobile app for efficient real-time sharing of prehospital patient information has potential to reduce the time to intervention, resulting in better patient outcomes. In addition, in Japan, especially in the urban areas, there is the difficulty in determining the hospital for emergency patient [1]; however, for instance, the average number of hospitals that EMS phoned to transport patient was 1 in Kamakura city during this study period, so the decision to transport a patient did not take extra time. Therefore, the app may reduce the overall transportation time by decreasing the number of calling from EMS to hospitals.

Conclusions

The implementation of a mobile app for EMS reduced phone-communication time by 22% without increasing mortality or overall transportation time despite the implementation of new methods in the real clinical setting. Real-time patient information sharing, such as the transfer of monitor images and photos of the accident site, could facilitate optimal patient care and resource use.

Abstract

Background: The usability of mobile health (mHealth) apps needs to be effectively evaluated before they are officially approved to be used to deliver health interventions. To this end, the mHealth App Usability Questionnaire (MAUQ) has been designed and proved valid and reliable in assessing the usability of mHealth apps. However, this English questionnaire needs to be translated into other languages, adapted, and validated before being utilized to evaluate the usability of mHealth apps.

Objective: This study aims to improve, further adapt, and validate the Chinese version of the MAUQ (C-MAUQ; interactive for patients) on *Left-handed Doctor*, one of the most popular “reaching out to patients” interactive mHealth apps with chatbot function in China, to test the reliability and cross-cultural adaptability of the questionnaire.

Methods: The MAUQ (interactive for patients) has been translated into Chinese and validated for its reliability on *Good Doctor*, one of the most influential “reaching out to patients” mHealth apps without chatbot function in China. After asking for the researchers’ approval to use this Chinese version, we adjusted and further adapted the C-MAUQ by checking it against the original English version and improving its comprehensibility, readability, idiomaticity, and cross-cultural adaptability. Following a trial survey completed by 50 respondents on *wenjuanxing*, the most popular online questionnaire platform in China, the improved version of the C-MAUQ (I-C-MAUQ) was finally used to evaluate the usability of *Left-handed Doctor* through an online questionnaire survey (answered by 322 participants) on *wenjuanxing*, to test its internal consistency, reliability, and validity.

Results: The I-C-MAUQ still retained the 21 items and 3 dimensions of the original MAUQ: 8 items for usability and satisfaction, 6 items for system information arrangement, and 7 items for efficiency. The translation problems in the C-MAUQ, including (1) redundancy, (2) incompleteness, (3) misuse of parts of speech, (4) choice of inappropriate words, (5) incomprehensibility, and (6) cultural difference–induced improper translation, were improved. As shown in the analysis of data obtained through the online survey, the I-C-MAUQ had a better internal consistency (ie, the correlation coefficient between the score of each item and the total score of the questionnaire determined within the range of 0.861–0.938; $P < .01$), reliability (Cronbach $\alpha = .988$), and validity (Kaiser–Meyer–Olkin=0.973), compared with the C-MAUQ. It was effectively used to test the usability of *Left-handed Doctor*, eliciting over 80% of informants’ positive attitudes toward this mHealth app.

Conclusions: The I-C-MAUQ is highly reliable and valid for *Left-handed Doctor*, and suitable for testing the usability of interactive mHealth apps used by patients in China. This finding further confirms the cross-cultural validity, reliability, and adaptability of the MAUQ. We identified certain factors influencing the perceived usability of mHealth apps, including users’ age, gender, education, profession, and possibly previous experience with mHealth apps and the chatbot function of such apps.

Most notably, we found a wider acceptance of this new technology among young Chinese female college students who were more engaged in the interaction with health care chatbots. The age-, gender-, and profession-induced preference for new digital health interventions in China aligns with the findings in other similar studies in America and Malaysia. This preference identifies areas for further research on the social, cultural, and gender adaptation of health technologies.

Introduction

Background

Mobile health (mHealth) apps have been applied to deliver health interventions (eg, health education, health monitoring, recommendations on treatments) to alleviate the overburdened health systems in many countries. These apps can perform versatile tasks, including health management, behavior intervention, health data collection, self-diagnosis, disease management, medication management, rehabilitation, and acting as patient portals [1,2], improving medication compliance, saving time in diagnosis and treatment, and reducing medical costs [3-6]. Given these wide applications and diverse advantages, these apps need to be assessed for hidden expenses, heavy data entry burden, and interest loss [7] to ensure accurate data analysis before being put into use [8].

To effectively evaluate the usability of mHealth apps, different questionnaires were designed [9], among which the most popular are the System Usability Scale (SUS) and the Post-Study System Usability Questionnaire (PSSUQ) [10,11]. Although used to reliably measure certain usability aspects of mobile apps, the SUS and the PSSUQ, among others, failed to provide tailored information on the factors unique to mobile apps [10,12]. Zhou et al [9] developed and validated the mHealth App Usability Questionnaire (MAUQ), which was solely designed for assessing the usability of mHealth apps, attesting its reliability and validity. The MAUQ [9] was exclusively developed to evaluate the usability of mHealth apps. It has 4 versions designed to assess interactive or standalone mHealth apps among patients or health care providers. It shows a strong internal consistency, evidenced by the Cronbach α coefficients of its 3 dimensions (.895 for *ease of use and satisfaction*, .829 for *system information arrangement*, and .900 for *usefulness*) and the overall Cronbach α of .914. The items in the 3 dimensions are rated on a 7-point Likert scale from 1 (extremely strongly agree) to 7 (extremely strongly disagree). The usability of an app can be determined by calculating the total points and determining the average points of the responses to all statements: the closer the average is to 1, the higher the usability of the app [9].

Two more recent studies translated and adapted the MAUQ into Chinese [13] and Malay [14], respectively, finding that the Chinese and Malay versions exhibited high reliability and validity similar to those of the original English version [13,14]. The Chinese version of the MAUQ (C-MAUQ; interactive for patients) was testified to be reliable and valid, with content validity index of 0.952, Cronbach α of .912, value of test-retest reliability of 0.896, and value of the split-half reliability of 0.701

[14]. The Malay version of the MAUQ (standalone for patients) was proved to be reliable for evaluating the usability of the mHealth apps (Cronbach α =.946) [13]. Considering the painstaking efforts and considerable time and cost investment involved in developing new questionnaires [14], Marzuki et al [12] strongly recommended that established, accessible, and reliable questionnaires should be adapted, validated, and recorded cross-linguistically.

Left-handed Doctor is one of the most popular “reaching out to patients” [15] interactive mHealth apps in China. It integrates artificial intelligence technologies, such as deep learning, big data processing, semantic understanding, and interactive medical dialog with medicine and is committed to using artificial intelligence technology to expand the supply of high-quality medical resources. The *Left-handed Doctor* open platform provides solutions, such as smart hospitals, diagnostic robots for consultation rooms, intelligent online consultation, intelligent postdiagnosis management, and artificial intelligence internet hospitals. In combination with different application scenarios, it provides high-quality medical services for all parties, empowering the health care industry. Although it is popular among many people in China, no studies have empirically tested its usability using the C-MAUQ.

Objective

Informed by the MAUQ and its culturally adapted versions, this study aimed to testify further the reliability, validity, and cross-cultural adaptability of the MAUQ for its suitability to the mHealth app usability test. This was achieved by applying the improved version of the C-MAUQ (I-C-MAUQ) to *Left-handed Doctor*, one of the most popular “reaching out to patients” interactive mHealth apps with chatbot function in China. Two facts warrant this study: (1) the *Left-handed Doctor* app is different from the *Good Doctor* app: the former is empowered with the chatbot function, while the latter is not, and we thought that this difference would influence users’ perceived usability of these apps; and (2) the informants differ from those in Mustafa et al [13] in terms of age, gender, education, and profession, and we believed that these differences would also impact users’ perceived usability of these apps.

Methods

Overview

This study used the C-MAUQ [15] but made some improvements. The study was conducted from February 18 to March 8, 2022.

Improvement of the C-MAUQ

We first obtained the approval of the researchers [15] to use the C-MAUQ. Afterward, 2 translators (YS and MJ) independently adjusted this version by checking it against the original English version and improving its readability and idiomaticity. The I-C-MAUQ still retained the 21 items and 3 dimensions of the original MAUQ and the C-MAUQ: 8 items for usability and satisfaction, 6 items for system information arrangement, and 7 items for efficiency. Improper translations of all the 21 items in the C-MAUQ were modified through discussion among the whole research team.

Improvement of Cross-cultural Adaptation

The C-MAUQ has been adapted cross-culturally through experts' comments and a prediction test [15]. Based on this adaptation and drawing on Conway et al's translatability assessment (TA) [16], this study further adapted the C-MAUQ by inviting a group of bilingual translators and health educators to assess the comprehensibility of the content as well as the cultural relevance and appropriateness of each item. Subsequently, the revised version was subjected to a trial survey online, in which 50 college students participated to identify problems that needed to be resolved.

Informants and Online Survey

Participants were students of the School of Foreign Studies, Nantong University, China. Impacted by varying degrees of psychological problems that became increasingly serious during the repeated COVID-19 attacks, these students urgently needed mHealth apps for self-diagnosis and general health information to relieve their psychologically strained minds. The questionnaire was administered using the online questionnaire survey platform named *wenjuanxing* [17] on February 18, 2022, and the survey lasted until no additional questionnaire was submitted online for 2 consecutive days (March 4, 2022). Over this period, the survey was announced to the entire student body of over 1000 at the School of Foreign Studies, Nantong University, through emails and WeChat groups. Meanwhile, the candidate informants were requested to use the *Left-handed Doctor* app for 2 days to become familiar with it before answering the questionnaire. The majority of participants in this study were female, which is characteristic of all schools of foreign studies in China.

Data Collection

The survey was conducted through *wenjuanxing* [17], the most popular online questionnaire platform in China. Two categories of data were collected via online questionnaires: the demographic information of the participants and their ratings on the 21 items concerning the usability of *Left-handed Doctor*. The demographic data included the informants' age, gender, grade, and channel to obtain health care information. The usability test elicited data concerning the informants' ratings of the 21 items based on a 7-point Likert scoring system from 1 to 7 points (representing "strongly agree," "agree," "somewhat agree," "neither agree nor disagree," "somewhat disagree," "disagree," and "strongly disagree," respectively).

Data Analysis

Quantitative analyses were conducted using SPSS version 22.0 (IBM, Inc.). First, demographic data were presented in a table and briefly described as the background information of the analysis. Subsequently, item analysis, weight analysis, and Pearson correlation analysis were conducted, followed by the reliability, validity, test-retest reliability, and split-half reliability tests. Finally, the range, mean values, and SD of the collected usability data were calculated and described for each of the 21 items.

Ethics Considerations

This study was approved and supported by the Student Affairs Office and the Humanities and Social Sciences Office of Nantong University, which is authorized to provide such approval before collecting data from students.

Results

Improvement of the C-MAUQ

Both translators (YS and MJ) found items 1, 2, 5, 9, 11-14, 17-21 problematic after checking the C-MAUQ against the original English version independently. They modified these items independently, and then, through discussion, agreed on the corresponding revisions and the classification of translation problems, which were subjected to further amendments before a final consensus among the study researchers. The translation problems in the C-MAUQ were related to (1) redundancy (items 1, 2, and 18); (2) incompleteness (item 12); (3) misuse of parts of speech (items 5, 9, and 17); (4) choice of inappropriate words (items 5, 9, 14, and 18-21); and (5) incomprehensibility (items 9, 11, and 13).

Further Cross-cultural Adaptation

The I-C-MAUQ was further adapted cross-culturally through a panel meeting attended by a group of bilingual translators and health educators. This meeting identified and agreed on a common problem concerning inappropriate cultural adaptation of items 18-21. In English-speaking countries, a patient always visits the same doctor and addresses the doctor as "my health care provider." By contrast, in China, a patient usually sees different doctors when becoming ill and thus never uses "my" when referring to his/her "health care provider." Therefore, "my" was crossed out from these 4 items. No other problems were detected during the panel meeting. After the panel meeting, the comprehensibility, readability, idiomaticity, and cultural adaptability of the questionnaire content were further improved. Subsequently, the I-C-MAUQ version was validated in an online trial survey completed by 50 informants. The trial survey turned out to be successful (Cronbach $\alpha=.992$), and so the I-C-MAUQ did not require further improvement. The I-C-MAUQ, together with the C-MAUQ and the MAUQ, is provided in [Multimedia Appendix 1](#).

Informant Demographics

[Multimedia Appendix 2](#) shows the informants' demographic information. A total of 322 responses were collected online, including 292 (90.7%) from female respondents. This can be explained by the fact that over 90% of students studying in the

School of Foreign Studies, Nantong University, are females. The age of the participants ranged from 18 to 33 years (mean 21.68, SD 2.30 years). The overwhelming majority (n=316, 98.1%) were aged between 18 and 26 years. The informants included freshman (n=64, 19.9%), sophomore (n=29, 9.0%), junior (n=88, 27.3%), senior (n=48, 14.9%), first-year postgraduate candidates (n=46, 14.3%), and second-year postgraduate candidates (n=47, 14.6%). The majority of the informants (n=306, 95.0%) obtained health care information by visiting a doctor; logging into the internet; and communicating with families, friends, and classmates. Only a minor percentage of participants (n=9, 2.8%) used mHealth apps to obtain health care information.

Questionnaire Item Analysis

The 21 items in the I-C-MAUQ were valid and appropriately designed (Table 1), as evidenced by the distinction between the high-score group (n=94) and the low-score group (n=149). Data

below the 27% quantile belonged to the low-score group, and those above the 73% quantile belonged to the high-score group. There was a significant difference in each of the 21 items between the high-score group and the low-score group, with *P* value in each case being <.001 (ie, *P*<.01). This indicates that all 21 items could well be distinguished from one another and thus should all be retained in the final version of the questionnaire. Besides, all the 21 items were significant (Table 2), with critical values (CR) determined within the range of 14.751-19.449 and the *P* value (CR) calculated at <.001 (ie, *P*<.01). The correlation coefficient between the score of each item and the total score of the questionnaire was determined within the range of 0.861-0.938 (*P*<.01). Thus, all the 21 items were retained. According to the Pearson correlation values (Table S1 of Multimedia Appendix 3), all the 21 items were significantly and positively correlated, with the correlation coefficients ranging from 0.688 to 0.921 and *P*<.01.

Table 1. Item analysis.

Items ^a	Group, mean (SD)		<i>t</i> (critical values)	<i>P</i> value ^b
	Low-score group (n=149)	High-score group (n=94)

Weight of the 21 Items in the Questionnaire

Through the analytic hierarchy process, the weight of each of the 21 items in the questionnaire was determined. Based on the judgment matrix of the 21 items (Table S2 of [Multimedia Appendix 3](#)), the eigenvector and weight of each item were determined (Table 3). Drawing on the eigenvectors, the maximum eigenvalue (21.000) was worked out. According to

the maximum eigenvalue, the CI (<0.001) was computed. According to Table 4, the random index (RI) of the judgment matrix was 1.6358. From the CI (<0.001) and the RI (1.6358), CR (<0.001) was finally calculated (Table 5). This CR value (<0.1) indicated that the judgment matrix passed the consistency test. Therefore, the weights of the 21 items in Table 3 were valid. These weight values meant that the 21 items were almost equally important in the questionnaire.

Table 3. Analytic hierarchy process analysis of the 21 items in the questionnaire^a.

Items	Eigenvectors	Weight (%)
1	1.018	4.846
2	0.954	4.541

^aRI: random index.

Questionnaire Reliability and Validity

The statistics in [Table 6](#) indicate the high reliability of the questionnaire. The corrected item-total correlation values of the 21 items all fell within 0.845-0.931, far exceeding 0.4. This meant that the 21 items were strongly correlated, and that they all had a high degree of reliability. Besides, the Cronbach α did not apparently increase when each of the 21 items was deleted,

which implied that all items should be retained in the questionnaire. The overall Cronbach α (.988) for the 21 items was well above 0.9, indicating that the data collected for each item in the questionnaire were highly reliable. The values of test-retest reliability and split-half reliability were 0.918 and 0.828, respectively. Therefore, all the data were suitable for further analysis.

Table 6. Questionnaire reliability (and internal consistency).

Items	Corrected item-total correlation	Cronbach α if item deleted ^a
1	0.860	.988
2	0.873	.988
3	0.891	.988
4	0.897	.988
5	0.845	.988
6	0.870	.988
7	0.877	.988
8	0.912	.987
9	0.866	.988
10	0.917	.987
11	0.931	.987
12	0.915	.987
13	0.896	.988
14	0.914	.987
15	0.905	.987
16	0.866	.988
17	0.900	.987
18	0.902	.987
19	0.885	.988
20	0.855	.988
21	0.895	.988

^aCronbach α (standardized)=.988.

Table 7 reveals that the questionnaire is highly valid. The communalities for all 21 items ranged from 0.738 to 0.881, well above 0.4, indicating that the data can effectively be extracted from all these items. The Kaiser–Meyer–Olkin (KMO) value (0.973) was above 0.9, which showed that all the data

concerning the 21 items could effectively be extracted. The percentage of variance (rotated) for factor 1 was 81.053%, considerably above 50%, meaning that all the data on all the items can validly be extracted.

Table 7. Questionnaire validity.

Usability of the *Left-handed Doctor App*

Table 8 presents the results of the descriptive analysis of the usability of *Left-handed Doctor*. The range, mean (SD), and median scores were based on the rating of each item (1=strongly

agree; 2=agree; 3=somewhat agree; 4=neither agree nor disagree; 5=somewhat disagree; 6=disagree; and 7=strongly disagree). The mean scores of the 21 items were between 2.224 and 2.497, indicating that the respondents were inclined to agree

with the statements in all 21 items. In other words, they found the *Left-handed Doctor* app usable on the whole.

There were no significant differences ($P=.35$) in the mean scores concerning the 3 dimensions of usability and satisfaction (items 1-8), the arrangement of system information (items 9-14), and efficiency (items 15-21). This implied that the participants found the *Left-handed Doctor* app equally usable when it comes to the 3 dimensions.

Multimedia Appendix 4 shows the proportion of respondents falling into each of the 7 ratings of the 21 items. Over 60% (205/322, 63.7%; 223/322, 69.3%; 209/322, 64.9%; 206/322, 64.0%; 199/322, 61.8%; 206/322, 64.0%; 210/322, 65.2%; 203/322, 63.0%; 208/322, 64.6%; 219/322, 68.0%; 211/322, 65.5%; 218/322, 67.7%; 198/322, 61.5%; 208/322, 64.6%;

216/322, 67.1%; 207/322, 64.3%; 198/322, 61.5%; 203/322, 63.0%; 208/322, 64.6%, for items 1-6, 8-19, and 21, respectively) of informants *strongly agreed* or *agreed* with all items but items 7 (183/322, 56.8%) and 20 (187/322, 58.1%). More than 80% (267/322, 82.9%; 285/322, 88.5%; 277/322, 86.0%; 277/322, 86.0%; 271/322, 84.2%; 277/322, 86.0%; 259/322, 80.4%; 282/322, 87.6%; 270/322, 83.9%; 279/322, 86.6%; 287/322, 89.1%; 285/322, 88.5%; 288/322, 89.4%; 277/322, 86.0%; 280/322, 87.0%; 280/322, 87.0%; 282/322, 87.6%; 276/322, 85.7%; 276/322, 85.7%; 258/322, 80.1%; 277/322, 86.0%, for items 1-21, respectively) of participants *strongly agreed*, *agreed*, or *somewhat agreed* with all the 21 items. This meant that the vast majority of the participating students showed a positive attitude toward the usability of the *Left-handed Doctor* app.

Table 8. Descriptive analysis of the usability of the *Left-handed Doctor* app.

Item	Samples, n	Range	Mean (SD)	Median
1	322	1.000-7.000	2.373 (1.180)	2.000
2	322	1.000-7.000	2.224 (1.079)	2.000
3	322	1.000-7.000	2.307 (1.125)	2.000
4	322	1.000-7.000	2.354 (1.160)	2.000
5	322	1.000-7.000	2.379 (1.176)	2.000
6	322	1.000-7.000	2.348 (1.170)	2.000
7	322	1.000-7.000	2.497 (1.246)	2.000

Discussion

Principal Findings

Informed by Zhou et al [9] and Mustafa et al [13], the study improved the C-MAUQ translated, adapted, and validated in Zhao et al [14], and then used the I-C-MAUQ to test the usability of *Left-handed Doctor*, one of the most popular “reaching out to patients” interactive mHealth apps in China. The I-C-MAUQ had a better internal consistency (the correlation coefficient between the score of each item and the total score of the questionnaire ranging from 0.861 to 0.938; $P<.001$),

reliability (Cronbach $\alpha=.988$), validity (load factor ranging from 0.859 to 0.939, percentage of cumulative variance [rotated]=81.053%, KMO=0.973), test-retest reliability (0.918), and split-half reliability (0.828) than the C-MAUQ [14]. Such better performance of the I-C-MAUQ resulted from 4 factors: (1) better comprehensibility, readability, and cultural adaptation of the I-C-MAUQ; (2) different categories of participants in terms of age, gender, education, profession, and sample size; (3) different functions of the tested interactive mHealth apps used by patients (with vs without the chatbot function); and (4) respondents’ experience with mHealth apps. Similarly, we found

that the reliability of the I-C-MAUQ was relatively higher than those reported in Mustafa et al [13] (Cronbach α =.946; corrected item-total correlation values between -0.057 and 0.868) and Zhou et al [9] (Cronbach α =.914). We once again attributed the reliability difference to the aforesaid 4 factors, which will be discussed in the following sections.

Cross-cultural Adaptation of the Translated Questionnaire

It is imperative to adapt questionnaires cross-culturally, but there is a lack of evidence for the best approaches to cross-cultural adaptation (CCA) [18]. The most adopted methods for CCA are Brislin's Translation Model [19], the use of panels or committees [20-26], and focus groups [27]. However, this study adopted another effective but a commonly neglected model: TA [16]. Drawing on the cross-cultural issues proposed in TA, we improved the C-MAUQ [15] by making further cultural and linguistic adaptations, solving the translation problems concerning redundancy, incompleteness, misuse of parts of speech, choice of inappropriate words, incomprehensibility, and relevance and appropriateness on the cultural, semantic, syntactic, and pragmatic facets. The newly adapted questionnaire was equivalent to the original questionnaire [18]. TA thus makes it possible to identify alternative versions for translation purposes, modify original versions to optimize subsequent translation efforts, and detect and discuss irrelevant or inappropriate items early [16]. Thus, TA needs to be adopted as an effective CCA method in prospective translation and adaptation of questionnaires.

Participant Differences in Age, Gender, Education, Profession, and Sample Size

Most (318/322, 98.8%) of the informants in this study were aged 18-28, compared with the majority (91.04%) of respondents aged 29-65 in Zhao et al [14], with just over half (52.3%) of the participants aged 18-28 and just below half (48.3%) aged 29-65 in Zhou et al [9], and with all (100%) those surveyed aged 22-25 in Mustafa et al [13]. We concluded that younger age potentially led to relatively positive ratings of questionnaire items and thus higher questionnaire reliability and internal consistency.

The proportions of male and female participants (30/322, 9.3% vs 291/322, 90.4%) were different from those (53.76% vs 46.24%) in Zhao et al [14], those (38.3% vs 61.7%) in Zhou et al [9], and those (8% vs 92%) in Mustafa et al [13]. Therefore, considerably higher percentages (292/322, 90.7%) of female respondents seemed to contribute to a higher degree of the questionnaire's internal consistency and reliability. This result showed that females were more interested in participating in surveys on the usability of mHealth apps and that more female users of mobile apps were keen on using mHealth apps for health care. This has been also testified by Zhou et al [9].

All informants in this study and Mustafa et al [13] were college students at the undergraduate or graduate level, but those in Zhao et al [14] and Zhou et al [9] had different levels of education: 33.24% and 67.2% held an undergraduate or above in Zhao et al [14] and Zhou et al [9], respectively. The overall higher level of respondent education may explain the relatively

higher degree of questionnaire's internal consistency and reliability in our study and Mustafa et al [13], in comparison with that in Zhao et al [14] and Zhou et al [9]. However, the vast gap in participant education at or above the undergraduate level between Zhao et al [14] and Zhou et al [9] merely resulted in a considerably minor difference in questionnaire reliability (Cronbach α =.912 vs .914).

In terms of profession, being a student—100% (322/322) in this study and Mustafa et al [13], 31.4% in Zhou et al [9], and 1.56% in Zhao et al [14]—also likely impacted the questionnaire's internal consistency and reliability, with the rate of students participating positively proportional to the degree of reliability and internal consistency.

These findings concerning age, gender, education, and profession contradicted the result in Zhou et al [9], which asserted that the demographic factors (eg, age, gender, education, occupation) failed to significantly impact the answers to the individual statements or the overall score on the MAUQ.

The sample size was indeed not a contributing factor to the high internal consistency and reliability of the questionnaire. Zhao et al [14] recruited the largest number of participants ($n=346$) but reported the lowest internal consistency and reliability, whereas this study achieved the highest internal consistency and reliability of the questionnaire based on the data contributed by a similar number of informants ($n=322$), followed by a slightly lower internal consistency and reliability derived from the information provided by the smallest number of informants in Mustafa et al [13].

Respondents' Experience With mHealth Apps

The informants in Zhou et al [9] used mobile apps for an average of 6.64 years; 86.42% of participants in Zhao et al [14] used mHealth apps more than 3 times during the month before the survey. Only 2.8% (9/322) of respondents in this study resorted to mHealth apps for health care information, but they were requested to install the *Left-handed Doctor* app 2 weeks beforehand to become familiar with it. The informants in Mustafa et al [13] were also asked to do the same. Therefore, experience with mHealth apps did not seem to influence the users' perceived usability, and thus the internal consistency and reliability of the questionnaire adopted remained unaffected.

Interactive mHealth Apps for Patients Equipped With or Without the Chatbot Function

This study tested the usability of the I-C-MAUQ on the *Left-handed Doctor* app, which is empowered with the chatbot function. By contrast, Zhao et al [14] adopted the *Good Doctor* app, which was not equipped with the chatbot function. This difference in apps may somewhat explain the notable discrepancy in the questionnaire's internal consistency and reliability between this study (Cronbach α =.988) and that by Zhao et al [14] (Cronbach α =.912). The mHealth apps used in Krebs and Duncan [7] and Mustafa et al [13] did not have the chatbot function. Thus, further research needs to be conducted to pinpoint the impact of this function on the usability of mHealth apps.

Implications

It is worth adapting established and appropriate questionnaires with recorded validity because designing a new one is effort-, time-, and cost-consuming [12]. Proper translation and adaptation and TA [16,28] are essential to ensure equivalence between the original questionnaire and the translated version. Cultural and linguistic sensitivity is a prerequisite for ironing out the translation problems resulting from cultural and linguistic differences and making the translated questionnaire culturally relevant and appropriate. Therefore, qualified translators highly proficient in the source and target languages and health educators or practitioners need to make joint efforts to complete this challenging task.

Validation is crucial for ensuring the equivalence between the original version and the translated one. Content validity index has been used to quantify the questionnaire validity in some studies [9,13,15,29,30]. It has been widely used because of its simple measurement, accessibility, power to provide details for each item, and indication of item modification or deletion [30].

Limitations

This study has several limitations. First, the convenient sampling of college students from a single university made it challenging

to generalize the findings to the whole population in China. The recruitment of only healthy students also made the generalization of the results less convincing. Finally, the sample size was not sufficiently large to guarantee the generalization of findings.

Conclusions

The I-C-MAUQ is highly reliable and valid for the *Left-handed Doctor* app, and thus suitable for testing the usability of interactive mHealth apps used by patients in China. This finding is in line with the study by Marzuki et al [12], further confirming the cross-cultural validity, reliability, and adaptability of the MAUQ. We identified certain factors that influence the perceived usability of mHealth apps, including users' age, gender, education, profession, and possibly previous experience with mHealth apps as well as the chatbot function of such apps. Most notably, we found a wider acceptance of this new technology among young Chinese female college students who were more engaged in the interaction with health care chatbots. The age-, gender- and profession-induced preference for new digital health interventions in China aligns with the findings from other similar studies in the United States [9] and Malaysia [13]. This preference identifies areas for further research on the social, cultural, and gender adaptation of health technologies.

Abstract

Background: Incorporating insights from social media into the patient-provider encounter is increasingly being explored in health care settings. Less is known about the utility of these data in mental health therapy.

Objective: This study aims to prospectively investigate and characterize how social media and digital data are used in mental health therapy from both the patient and mental health therapist perspective.

Methods: Patients enrolled in mental health therapy and mental health therapists were interviewed using a semistructured interview guide. All interviews were transcribed and coded using a deductive framework analysis. Themes and subthemes were identified. Participants completed a sociodemographic survey, while mental health therapists also completed a behavioral norms and elicitation survey.

Results: Seventeen participants, that is, 8 (48%) mental health therapists and 9 (52%) patients were interviewed. Overall, participants identified 4 themes and 9 subthemes. Themes were current data collection practices, social media and digital data in therapy, advantages of social media and digital data in therapy, and disadvantages of social media and digital data in therapy. Most subthemes were related to the advantages and disadvantages of incorporating digital data in mental health therapy. Advantage subthemes included convenience, objective, builds rapport, and user-friendliness while disadvantage subthemes were nonreflective, ethically ambiguous, and nongeneralizable. The mental health therapists' behavioral norms and elicitation survey found that injunctive and descriptive normative beliefs mapped onto 2 advantage subthemes: convenience and objectivity.

Conclusions: This qualitative pilot study established the advantages and disadvantages of social media and digital data use in mental health therapy. Patients and therapists highlighted similar concerns and uses. This study indicated that overall, both patients and therapists are interested in and are comfortable to use and discuss social media and digital data in mental health therapy.

Introduction

Background

Adults in the United States are frequent users of social media platforms such as Facebook, Instagram, and Twitter [1,2]. Such platforms have a profound impact on everyday life and provide

new opportunities for understanding behavioral, social, and environmental determinants of mental health and well-being [3-5]. Social media data (eg, Facebook wall posts) and digital data (eg, search engine use, step data, smartphone metadata) are increasingly used to support patient mental health care [6]. Previous mental health research has demonstrated that social

media data can reveal and predict risk for mental health conditions such as depression, loneliness, suicide ideation, posttraumatic stress, schizophrenia, and bipolar disorder [6-12]. Furthermore, prior research has demonstrated that data from these digital platforms can provide critical information not readily attained through in-person or remote health care encounters to help therapists identify, address, or discuss mental health concerns [3,13,14].

In response to these findings, several researchers are increasingly capturing how and how often therapists incorporate social media data into mental health therapy and treatment. For example, Fisher and Appelbaum [15] report that some mental health clinicians incorporate parts of their patients' Facebook feeds in their care delivery, whereas Hobbs and colleagues [13] found that nearly two-thirds of outpatient psychotherapists report viewing at least one patient's social or electronic media (such as email messages, SMS text messaging, and other messaging apps) as part of psychotherapy. Hobbs et al [13] also report that the psychotherapists who access their patients' electronic or social media data indicated that it improved their ability to provide effective treatment. These findings underscore the utility of social media and digital data in mental health therapy. These examples reflect the growing body of research on the mental health care therapist experience using social media data in mental health therapy; however, research on the patient perspective remains limited. Accordingly, research exploring both patient and therapist perspectives on the use of social media data in mental health therapy is warranted.

Objective

This qualitative study aimed to provide new knowledge on mental health patient and therapist perspectives regarding the use of social media data in mental health therapy. The aims of this study were to (1) explore patients' and therapists' current use(s) of social media data in mental health therapy and (2) identify the advantages and disadvantages of sharing social media data in mental health therapy.

Methods

Recruitment

Individuals in mental health therapy (referred to as patients) were recruited through a clinical research registry at a large academic institution (a private university and medical center in the northeastern region of the United States) from March to May 2018. Thirteen applicants expressed interest from the registry, of which 9 were available for an in-person interview. Patient inclusion criteria included that they attended mental health therapy for anxiety or depression and were aged 18 years and older. Patients completed informed consent and received a US \$20 gift card as compensation for their study participation. Mental health therapists (referred to as therapists) were recruited at the same large academic institution through behavioral health research consortiums and word-of-mouth sampling (approximately 50 received an email invitation) from October to December 2018. Twelve therapists expressed interest and 8 were available for an in-person interview. Therapist inclusion criteria included that they provided behavioral health care and worked with clients aged 18 years and older with depression or

anxiety disorder(s). The therapists completed informed consent and received a US \$100 gift card as compensation for study participation. All participants were willing to complete an in-person interview at a large academic hospital, which was held in a secure private room and lasted for 50-70 minutes.

Qualitative Interview

Two semistructured interview guides were constructed based on a review of the published literature on social media data in therapy and co-design techniques [15,16]. The interview guide was structured as follows: introduction, discussion of interview expectations, current use of data in therapy, experience with social media data (eg, Facebook, Instagram, Twitter) in therapy, and advantages and disadvantages of incorporating social media data in therapy. Interview questions were tailored to separately address the patient and therapist experiences. All interviews were conducted by 2 team members. One individual (a cisgender female researcher with >10 years of experience in qualitative interviewing) acted as the lead facilitator, while the other interviewer (a cisgender female service designer with 5 years of experience) took notes and contributed to probing and follow-up questions. Prompts were included, where appropriate, to elicit participant elaboration about each topic. The full interview guide is available from the authors upon request.

Survey

Patients completed a brief in-person survey at the end of the interview. The survey assessed sociodemographic characteristics such as gender, race/ethnicity, highest level of education, and the Social Media Use Questionnaire (SMUQ) [17]. The SMUQ assesses problematic use of social media and comprises 9 items (eg, "I feel anxious when I am not able to check my social network account"), with response options on a 5-point Likert scale from "Never" to "Always." All items were averaged into a scale for which higher scores corresponded with excessive social media use.

At 24 hours after the interview, therapists received a "thank you" email and a link to a web-based survey, programmed in Qualtrics software. The survey was intended to elicit participants' beliefs pertinent to using data about patients' social media use in therapy sessions, given little existing research on social media in mental health therapy. Survey questions were drawn from established procedures for elicitation studies [18]. These open-ended questions elicited beliefs about using social media data in therapy sessions in the next month. Types of beliefs elicited included behavioral beliefs (ie, potential benefits or drawbacks of using social media data in therapy sessions), injunctive normative beliefs (ie, individuals or groups of people who may or may not approve of using social media data in therapy sessions), descriptive normative beliefs (ie, individuals or groups of people who may or may not use social media data in therapy sessions), and control beliefs (ie, circumstances that may help or hinder the use of social media data in therapy sessions). The survey also assessed the sociodemographic characteristics of the participants, including gender, race, ethnicity, highest level of education, and work environment characteristics (eg, type of practice, caseload).

Ethics Approval

This study protocol was reviewed and approved by the University of Pennsylvania Institutional Review Board (protocol 831246).

Analysis

Qualitative Interviews

Therapist interviews were audio recorded and transcribed verbatim. Patient interviews were not recorded; a research assistant observed the interviews and took detailed notes and collected quotes. After multiple readings, the transcripts and interview notes were then coded by authors LS and RS. The coders created a codebook using the interview guide as themes, whereas subthemes emerged from the transcripts. The transcripts and interview notes were then analyzed using a deductive framework analysis [19] and coded according to the 6 stages of framework analysis: familiarization, identifying a thematic framework, indexing, charting, mapping, and interpretation. Identified subthemes were deduced from the coded passages and placed into separate coded charts. The authors then independently reviewed the charts for consistency and agreement. The coders met regularly to resolve disagreements for any theme or subtheme by consensus following discussion. The codebook is available from the authors upon request.

Survey Findings

All quantitative analyses (ie, descriptive statistics) were conducted in a Microsoft application (Microsoft Excel, version 16.58).

Results

Study Sample

The sociodemographic characteristics of the patients and therapists are provided in [Table 1](#). Patients were mostly female (6/9, 66%) and non-Hispanic White (6/9, 66%). Patients were aged 22-60 years; half reported having completed college while the other half completed graduate school. According to the SMUQ, all patients reported using social media platforms (eg, Facebook, Instagram) more than 3 times a day and exhibited nonproblematic social media use (mean score 22, range 9-32). All therapists were females and non-Hispanic White, with a mean age of 37 years. Most reported that they work in a hospital/medical setting and practice cognitive behavioral therapy (CBT). However, therapists were at various stages in their careers, ranging from graduate student to psychologist or associate professor ([Table 1](#)).

Table 1. Sociodemographic characteristics of the patients and therapists.

Sociodemographic variables	Patients (n=9)		Therapists (n=8)	
	Frequency/mean	Range	Frequency/mean	Range
Age (years)	34	22-60	37	29-43
Female	6	N/A ^a	8	N/A
Ethnicity/race				
White	6	N/A	8	N/A
Black	1	N/A	0	N/A
Asian	1	N/A	0	N/A
Non-Hispanic, Latinx	1	N/A	8	N/A
Highest level of education				
College graduate	5	N/A	0	N/A
More than college graduate (eg, master's, doctoral degree)	4	N/A	8	N/A
Social media use questionnaire	22	9-32	N/A	N/A
Cognitive behavioral therapy orientation	N/A	N/A	8	N/A
Clinical experience (years)	N/A	N/A	5.3	2-9
Clinical setting				
Community outpatient	N/A	N/A	1	N/A

Prep time prior to session (minutes)	N/A	N/A	N/A	3-30

^aN/A: not applicable.

Thematic Areas

The interviews captured patients' and therapists' social media use in mental health therapy. The interviews identified the advantages and disadvantages of sharing social media data in mental health therapy and highlighted the contextual and

logistical considerations to incorporating these new data. The interviews were structured on the following themes: (1) current data use in therapy, (2) experience with social media in therapy, (3) advantages of social media in therapy, and (4) disadvantages of social media in therapy ([Table 2](#)).

Table 2. Emerging interview subthemes with illustrative quote(s).

Themes, subthemes	Illustrative quote(s)	
	Therapist	Patient
Current data use in therapy		
Applications	<i>...I think it is a great idea because if you get the notification from the app and it is kind of fun, it's visually enticing, and people are more likely to do it. And then some of them have the built-in mindfulness tracking.</i>	<i>...I use the eMoods app to track my triggers and love the biometrics information. It tracks a lot things like eating vegetables, how much bread I eat, or if I went outside. I show my therapist it. eMoods doesn't feel like it's judgmental because I am creating the field(s).</i>
Surveys	<i>...Implement surveys during treatment to see change over time in symptoms or quality for life.</i>	<i>...Surveys are infrequent, I attend a self-determined care model.</i>
Experience with social media in therapy		
Patient-initiated	<i>...The patient brought up Snapchat and showed conversation around the video...It was sharing a sexting video with someone they were interested in and were having anxious thoughts about having done that and the individual saved/downloaded the video.</i>	<i>...I am comfortable sharing social media because it's already out there, and everyone puts their business out on social media. ...I am willing to share [with my therapist] if I can explain and provide context.</i>
Provider-initiated	<i>...There's a lot of videos on YouTube to use for exposures. So...if I have somebody that comes in with like a serious vomit fear or emetophobia or fear of like, could be anything like scary movies or clowns. We just go on YouTube and look stuff up.</i>	<i>...I trust my instincts [on what to share].</i>
Advantages of incorporating social media in therapy		
Convenience	<i>...I would also love for there to be more technology where the person doesn't have to enter anything themselves. That's why the Fitbit is nice or this sleep app where you basically put under your pillow (and) it tracks your sleep... because requiring them to do any work when they're already depressed and anxious [and it can be] a huge burden.</i>	<i>...It would be nice to look back [at previous posts].</i>
Objective	<i>...I think sleep data could be really useful... Like I've had a lot of patients who tell me that they sleep for like 3 hours and I'm like that's not possible every single night. I think this could be useful.</i>	<i>...It would help flag my memory... keep me on track.</i>
Builds rapport	<i>...I don't think it derails anything... mostly it's very relevant and helpful. They're willing to share, and I think it builds rapport. Often times it helps me to like really understand what they're talking about.</i>	<i>...We talk about [text messages] as a "how are you?"</i>
User-friendly	<i>...It's nice that it graphs it for you...I would use it in the beginning of session when I'm asking how they are feeling right now and how they feel how the last month has been to sort of see if their self-report in the moment lines up.</i>	<i>...If therapy is holistic having this data might not be bad.</i>
Disadvantages of incorporating social media in therapy		
Nonreflective	<i>...I think that people sometimes present very differently in therapy than they might on social media. If I'm thinking of somebody who is super depressed or maybe [have] chronic mental health issues, I think that that person probably doesn't post a lot on social media about their depression.</i>	<i>...I trust my instincts on what to share. ...I want to disclose what I need to [in each session]... maybe it's my eating disorder [that] has been more on my mind, not my substance abuse.</i>
Ethically ambiguous	<i>...For them to know that I have access to everything they post could make them feel pretty watched. They don't have any privacy because anything they do online the therapist will see it and will pull it up on their portal and judge them for it.</i>	<i>...My phone is so personal and feels like an invasion of privacy. It feels too "big brother." ...I am not confident in accuracy of an algorithm.</i>
Nongeneralizable	<i>...I think there are different social media personalities. There are some people who are very explicitly like "I don't talk about politics on Facebook." And other people who use it as their diary where they are posting every thought. And then people who don't post very much because they're more private.</i>	<i>...I [would like to] annotate them (ie, text message or social media post) because things are left out. ...I don't [want to be] judged by my digital data.</i>

Current Data Use in Therapy

When asked about current data collection practices, both patients and therapists noted using mental health and well-being apps in their sessions. Apps were mainly used during their practice to augment mental health services. For example, a patient reported using an app designed for patients with bipolar disorders I and II, depression, posttraumatic stress disorder, and anxiety disorder to keep track of symptoms and triggers (Table 2). However, several therapists expressed concern with selecting the “right” app, whereas others noted security and confidentiality issues for their patients. One therapist said, “[My patient] didn’t want to put the app in her phone because her friends look at her phone and she thought that they would ask about it” (Participant #1, female, aged 42 years). In addition to using apps, therapists reported that they routinely collect patient-reported outcome data. As a common practice of CBT, validated surveys such as Beck’s Depression Inventory, Patient Health Questionnaire 9-item, or Generalized Anxiety Disorder 7-item scales are collected at every therapy visit to track progress. Patients in this sample did not report completing validated surveys at their therapy sessions.

Experience Discussing Social Media in Therapy

The patients interviewed reported sharing and discussing social media data with their therapist. Most patients reported sharing or discussing Instagram posts (n=10), Facebook posts or statuses (n=8), tweets (ie, Twitter posts) (n=3), and YouTube videos (n=3). One patient noted, “I show my therapist my Facebook, it’s evidence of my life; yes, I have friends, I exist” (Participant #3, genderqueer, aged 24 years).

Approximately half of the patients reported that they have directly shown or summarized social media posts to their therapist in the last month. Therapists noted similar interactions; one elaborated as follows, “So for [instance] a patient that is dating and wants to show me some of the people that she’s talking about... she’ll show me on social media. Or they want to show me what they post, a story that’s going, something that they are involved with, like a family member or friends” (Participant #2, female, aged 35 years). Once social media data are introduced in therapy sessions, both patients and therapists detailed how social media platforms such as Facebook or YouTube can also be used as homework or in exposure therapy. For example, 1 patient explained that their therapist would have them write on a friend’s Facebook wall to address their social anxiety and phobia.

Advantages of Incorporating Social Media in Therapy

Both patients and therapists highlighted how social media data can be convenient, objective, user-friendly, and allow them to build rapport when used in therapy (Table 2). Both patients and therapists focused on how data are shared, may it be automatic or manual and how the algorithm could select posts as an advantage. Patients indicated a general acceptance of an algorithm selecting their social media posts but emphasized a desire to annotate or provide context to the post. One patient said, “I need to be there with [my therapist] to review” (Participant #5, male, aged 34 years). Therapists highlighted a desire for objective metrics derived from social media posts.

They commonly referenced social media’s metadata such as time of post and language used. For example, therapists noted that patients recounting of events may be influenced by recall bias when individuals have a partial account of prior events [20], whereas seeing metadata provides an objective source of information. Both therapists and patients highlighted their comfort with and interest in digital data such as steps walked via a smartphone’s built-in pedometer or screen time metrics.

Social media data are seen to aid discussions and accelerate a patient’s account of events. Both participants and therapists highlighted how they would like to see trends over time. A therapist said, “I’m asking how they are feeling right now and how they feel how the last month has been to sort of see if their self-report in the moment lines up” (Participant #2, female, aged 35 years). Therapists also noted instances when their patient would show pictures of friends or family from a social media platform to add a “*face to the name*,” implying that the use of such data builds rapport, which in turn could enhance the patient-provider communication.

Disadvantages of Incorporating Social Media in Therapy

Our results underscored perceived disadvantages of using social media data in therapy. Specifically, it can be nonreflective, nongeneralizable, and its use could be ethically ambiguous. Patients reported a sense of fear and uneasiness “*always*” sharing social media data with their therapist. They noted concerns about being “*watched*” and saw it as “*a little creepy*.” Few therapists expressed concern that it could also elicit a Hawthorne effect, altering one’s behavior due to the awareness of being observed [21]. As 1 therapist noted, “And again, me seeing all of [the] posts patients put up, even if they are agreeing to that...Patients may change [the way] they engage with that social media platform” (Participant #6, female, aged 43 years).

Therapists expressed concern that sharing social media data is nonreflective and would not provide accurate depictions of the patient’s true thoughts and emotions. They highlighted how social media posts are often public-facing accounts of people or events and may not be genuinely authentic. One patient said that “*things are left*” out of posts, whereas therapists highlighted how their patients may have a social media personality.

Several participants raised important questions regarding the security of the data collected, with 1 patient saying, “I want to protect [my] autonomy” (Participant #7, female, aged 29 years). Similarly, a patient highlighted that that they trust their intuition on what social media posts to share with their therapist (Participant #7, female, aged 29 years). Half of the therapists expressed concern regarding the social media platforms’ security policies. Several therapists also indicated that consistently including social media data in their therapy sessions could negatively impact their workflow.

Furthermore, utility of social media data in therapy may hinge on a patient’s age or comfort with technology. Both therapists and patients agreed that including these data would be the most beneficial for younger or more technologically inclined patients. One patient participant noted that social media in their therapy session may not be “beneficial for me [and my treatment goals]

but for a younger generation because they post so much” (Participant #6, female, aged 60 years).

Additional Therapist Beliefs About Social Media Use in Therapy

After the interviews concluded, therapists were asked a series of open-ended survey questions to assess their normative and control beliefs relevant to using patients’ social media data in therapy sessions. See [Table 3](#) for the elicitation questions asked and the illustrative quotes. Therapists were asked to indicate what types of individuals or groups of people would be more or less likely to use social media in therapy (descriptive normative beliefs). Responses included being a younger therapist or patient and a digital native and someone who grew up with

technology who might be more technologically inclined. Therapists indicated that their colleagues who would be open to this type of data exchange must be made aware of the social media platform themselves and be oriented toward CBT or other measurement-based care orientations. Therapists reported that individuals or groups who would be less likely to use social media in therapy included those who are older, have limited experience with social media platforms, and do not use measurement-based care. When asked to indicate what circumstances would make it difficult or easy to use social media in therapy (control beliefs), responses underscored the importance of convenience of use for both the therapist and the patient and ease of understanding in the context of therapy.

Table 3. Examples of open-ended responses and the corresponding theme categorization for each type of belief elicitation question.

Belief category, elicitation questions, illustrative open-ended responses	Subtheme(s)
Normative beliefs (injunctive)	
Generally, what types of individuals or groups would approve or think you should use data about clients' social media use in therapy sessions in the next month? Please list general groups or personas; do not include specific names.	
Younger clinicians, clinicians who work with young adults, clinicians who use a measurement-based care framework (ie, track their clients' progress using measures)	Convenience Objective
Younger therapists, data-driven/number-oriented people	Objective
Generally, what types of individuals or groups would disapprove or think you should not use data about clients' social media use in therapy sessions in the next month? Please list general groups or personas; do not include specific names.	
Potentially psychodynamic practitioners, individuals with strong privacy concerns	Ethically ambiguous
Individuals who do not use or have social media, clients who may be mistrusting or not have a strong therapeutic rapport with their therapist	Builds rapport Ethically ambiguous
Normative beliefs (descriptive)	
Generally, what types of individuals or groups are most likely to use data about clients' social media use in therapy sessions in the next month? Please list general groups or personas; do not include specific names.	
Younger, more number-oriented practitioners	Convenience Objective
Clinicians who are familiar with and comfortable using social media, clinicians who treat young adults, clinicians who incorporate technology into their treatments (eg, give measures on a computer or iPad, email, or text their clients)	Provider-initiated
Generally, what types of individuals or groups are least likely use data about clients' social media use in therapy sessions in the next month? Please list general groups or personas; do not include specific names.	
Older clinicians: clinicians in an environment in which it is inconvenient to do so	Convenience
Clinicians who do not use social media themselves and may have limited knowledge about how to use it (likely older clinicians), clinicians from orientations that do not emphasize measurement	N/A ^a
Control beliefs	
Please list any factors or circumstances that would make it easy or enable you to use data about clients' social media use in therapy sessions in the next month.	
Easy-to-use interface that logs all the information on the patient unobtrusively	User-friendly Convenience
Electronic platform, automated data collection and reminders	Convenience
Easily downloadable app(s), clear directions on how to use it in sessions with clients	Apps Convenience
Please list any factors or circumstances that would make it difficult or prevent you to use data about clients' social media use in therapy sessions in the next month.	
Lack of perceived need or benefit for a client, privacy concerns, difficult user interface for either myself or my client	Nonreflective
If I had to go through several steps to access the data	Convenience
A client's hesitancy or anxiety	Ethically ambiguous

^aN/A: not applicable.

Discussion

Principal Findings

This qualitative study provides new knowledge on patient and therapist perspectives regarding the use of social media in mental health therapy. The interviews captured patients' and therapists' current use(s) of social media in mental health therapy and that both patients and therapists initiated its use and discussion in prior sessions. Of note, the individuals interviewed expressed

comfort reviewing and discussing social media data. They identified several advantages and disadvantages of sharing social media data in mental health therapy (Table 2), underscoring the utility of and the potential concerns associated with integrating elements of our digital lives into mental health therapy in a world that increasingly relies on digital technologies.

To our knowledge, this is the first account of patients' experiences and perspectives on this novel data source. Patients highlighted how social media posts provide objective evidence

of their social lives or networks. They discussed previous experiences of self-curating posts and questioned if they want an algorithm selecting social media posts to share. Throughout the interviews, a clear understanding of how the data are generated and shared was of great importance. Previous research has captured individuals' willingness to share digital data for health research [3,22]. However, researchers have yet to devise a way to provide comprehensive feedback or snapshots to better inform patients, let alone their health care provider.

Despite already using social media data in therapy, both patients and therapists questioned the utility of certain social media platforms. They noted that social media posts may not fully reflect their true thoughts or feelings. This speaks to a growing trend among Instagram users with 2 types of accounts: "finsta" accounts, on which users post less polished photos of themselves and "rinsta" accounts, which include more authentic posts [23]. "Finsta" and "rinsta" accounts highlight how social media posts may not always accurately portray individuals' experiences. However, there might be clinical relevance if a patient has a "rinsta" account.

The desire for objectivity was noted throughout the interviews. Although the interview questions specifically asked about social media data, therapists discussed the incorporation of objective digital data such as the number of steps taken per day or hours slept per night and highlighted them as variables that can contribute to one's mental health and well-being. Although our interviews did not specifically capture the use of digital data such as steps and screen time, Di Matteo and colleagues [24] reported general acceptance sharing this type of data through their interviews with new patients referred to a tertiary care mood and anxiety disorder clinic. Since Di Matteo et al's work [24] and our interviews were both hypothetical scenarios, further research is needed to assess patient and therapist comfort with sharing social media data in the context of therapy sessions.

Lastly, when discussing how to systematically incorporate social media data into sessions, both patients and therapists stressed the importance of person-centered design. As demonstrated by Yoo and colleagues [25], who conducted co-design workshops to build a social media tool for therapists, the data must map onto the end users' expectations, both in terms of analyses and organization, to avoid being "another layer of noise" [25]. Therapists in this sample questioned how social media data would fit in their workflow (Tables 2 and 3). Despite these concerns, overall, our interviews highlight how sharing social media insights with the patient and therapist could also be clinically relevant and informative. Further work is needed to explore and test how to systematically collect social media and present it to patients and their therapists in a user-friendly format for use in mental health therapy.

Implications and Recommendations

To our knowledge, this is the first study to capture the patient perspective on their experience sharing and discussing social media data in mental health therapy. The patients interviewed provided critical insights that have yet to be characterized. Our findings uniquely underscore the importance of patient autonomy on what and when to share social media data. As the study sample included mostly female, White, college-educated

patients and female, White, and CBT therapists, future research should be conducted with more diverse samples in terms of gender, race/ethnicity, therapeutic orientation, and educational attainment. Additional and special attention is also needed to explore how social media is used and discussed in other cultural contexts.

Our interviews were conducted in 2018 and 2019 prior to the COVID-19 pandemic and may not reflect current norms and beliefs of social media data sharing in the therapeutic encounter. During the COVID-19 pandemic and recovery phases, there has been a dramatic increase in individuals with depressive and anxiety symptoms seeking mental health care [26]. Further research is warranted to capture how social media data are shared in virtual sessions via videoconference or telephone call. We also recommend additional research on the use of digital data such as smartphone metadata as viable data sources in therapy [27]. The combination of social media and digital data could enhance tailored treatment plans and impact therapeutic alliance, a cooperative working relationship between client and therapist, often seen as an essential aspect of successful therapy [28]. Since previous research found that therapeutic alliance is maintained and even enhanced with the introduction of digital mental health interventions [29,30], further research in this area is needed.

Lastly, there are clear educational, practical, and policy implications. As detailed in the American Psychological Association Guidelines for the Optimal Use of Social Media in Professional Psychological Practice (October 2021) [31] and indicated by our findings, mental health therapists should be encouraged to undergo specific educational training on how to safely and ethically use social media data in therapy. The training should encompass core elements of ethics, informed consent, comfort with technology, social media trends per population segment (eg, age, gender, race, ethnicity, sexual identity, language, culture), and how to integrate these new data sources into their workflow. Clinics and practices would need to reserve additional time, personnel, and technology infrastructure to support this training. Noel and colleagues [11] recommend a technology specialist, a new type of health care worker who identifies and reviews electronic resources that may support a client's specific recovery goals. Data infrastructure and protections are critically important and require special attention. Furthermore, if social media data were incorporated into therapy and demonstrated to improve patient outcomes and reduce costs to the clinic and patient, national/state policies and insurance companies could modify current plans and coverage.

Limitations

This study has several limitations. First, the study sample was small and largely homogeneous with respect to sociodemographic data. All participants were recruited from a convenience sample in 1 large metropolitan region in northeastern United States. It is possible that the results from this study do not apply to other population segments or geographic regions. As we advertised for this study online, it is possible that study participants were drawn to the study because of their prior experience with social media in mental health therapy. We were unable to audio record patient

participant interviews. As such, our transcripts were not as robust for patient participants as they were for therapist participants. Our interviews were conducted with patients and therapists separately; future research could interview patient and therapist dyads for further insights. With respect to analyses, there are limitations to thematic coding as a methodological approach, such as inferences made from a small study sample size and coding at the phrase level, which may not fully capture the participants' intended meaning. Furthermore, we were unable to use qualitative data analysis software such as NVivo. Interviews were conducted prior to the COVID-19 pandemic. Accordingly, findings may not fully reflect the current state of mental health delivery in the United States, as most mental health therapy is now delivered virtually via videoconference [32]. Despite these limitations, findings from this pilot study can inform social media use practices and norms in mental health therapy.

Conclusions

In this study, patient and therapist interviews provide important insights on the current utilization of social media in mental health therapy, including the advantages and disadvantages of social media use in such contexts. Our findings highlight that social media data used in therapy provide convenient, objective information that is user-friendly and can promote rapport between the patient and the therapist. However, the use of social media data in mental health therapy is also perceived as nonreflective, ethically ambiguous, and potentially nongeneralizable. Future research is needed to explore and test how to systematically collect social media and present it to patients and their therapists in a user-friendly format for use in mental health therapy.

Acknowledgments

We would like to acknowledge and thank Andrea Ngan and Jessica Diaz who assisted with the interviews and interview transcriptions.

Abstract

Background: Psoriasis is a chronic disease characterized by inflammation, increased scaling, itching, and other symptoms. Psoriasis is not contagious, but patients have often felt shunned. Therefore, in addition to psoriasis symptoms, stress, anxiety, and depression can also affect quality of life (QoL). Surveys show that only a quarter of patients are satisfied with the success of their therapy. However, in addition to medical therapy, self-management can also make it easier to deal with chronic diseases like psoriasis.

Objective: The aim of this project was to develop a smartphone-based self-management tool (SMT) specifically for patients with psoriasis using a community-driven process. The impact of the SMT on QoL as well as its acceptance and usability were evaluated.

Methods: In collaboration with an internet-based self-help community, 2 user surveys were conducted to determine the requirements for a smartphone-based SMT. The surveys consisted of semistructured questionnaires asking for desired features in an SMT for psoriasis. A pilot study was conducted to evaluate QoL, acceptance, and usability. Community users were recruited to use the app for 21 days and complete the Dermatology Life Quality Index (DLQI) questionnaire at the beginning (T_0) and end (T_1). Afterward, participants were asked to complete another questionnaire on usability and ease of use.

Results: SMT requirements were collected from 97 members of an internet-based community. The SMT was built as a progressive web app that communicates with a server back end and an Angular web app for content management. The app was used by 15 participants who also provided qualitative feedback, and 10 participants answered all questionnaires. The average DLQI score was 7.1 (SD 6.2) at T_0 and 6.9 (SD 6.6) at T_1 . The minimal required sample size of 27 was not reached.

Conclusions: The high degree of community participation in the development process and the responses during the requirement engineering process indicated that there is a general need for an independently developed SMT for patients with psoriasis. However, the feedback received after app use shows that the SMT does not meet the needs of the community. It can be concluded that a more customizable app is needed. The focus and needs of the users were very heterogeneous. Similar developments and research could benefit from the findings of this project.

psoriasis; self-management; mobile apps; quality of life; mobile phones; smartphones

Introduction

Overview

Psoriasis is a chronic skin disease that manifests itself with inflammation, increased scaling, itching, and other symptoms [1]. Flares can be aggravated by stress, medical drugs, or infectious diseases [2-4]. Psoriasis affects approximately 2% to 3% of the German population [1,5]. In addition to psoriatic symptoms, stress, anxiety, and depression can affect quality of life (QoL) [6-8]. Compared to healthy individuals, anxiety disorders were identified more frequently in patients with psoriasis [4,9]. It is not possible to cure psoriasis, but symptoms could be mitigated with medical drugs, special therapies, or complementary methods [10,11]. Nevertheless, approximately 30% of patients do not consult a physician [12,13].

Interviews reveal that a quarter of patients are dissatisfied with the success of their treatment [14,15]. Problems regarding drug therapies are present in up to 40% of patients [15,16]. To increase patient satisfaction and adherence, evidence-based decision guidance for psoriasis therapy is available as an S3 guideline [17]. However, in addition to medical therapy, self-management can facilitate the management of chronic diseases such as psoriasis [18-20]. In comparison to other chronic diseases, there are less evidence-based self-management tools (SMTs) for patients with psoriasis [20].

Related Work

Self-help and self-management can be effective tools for patients to better cope with their (chronic) disease [18-20]. Traditionally, self-help involves in-person group meetings or counseling. In recent years, a shift toward mobile apps, information websites, and web-based communities can be observed. Self-help can also include aspects of citizen science approaches. For example, self-help groups and other organizations collect and organize information on people with a disease [21]. Internet-based communities are often used by patient experts who share information and generate hypotheses. This is done based on shared experiences. Modern technologies can facilitate new approaches to citizen science projects [22].

Citizen science also includes the involvement of patients in the development process of SMTs. Some examples are given in the following paragraphs. Safdari et al [23] conducted a study on the requirements for a self-management app for patients with psoriasis. In a requirements analysis, 100 patients provided information about their requirements for educational information and lifestyle management, among other features. This included information on the disease on the one hand and factors such as physical activity, nutrition, or stress management on the other hand.

Trettin et al [24,25] have developed an app for Danish patients with psoriasis treated with biologics. In the development process, patients were interviewed, and various workshops and a prototype test were carried out. In the app, vital signs, and the Dermatology Life Quality Index (DLQI) [26] can be recorded in preparation for video or telephone consultations. Patients, doctors, and nurses have reported that consultations are more structured, and patients feel safe [24,25].

Aims of the Study

Currently, there are few SMTs in German app stores and no German-speaking apps (co-) developed by self-help organizations (ie, the patients themselves). Therefore, the 2 major objectives of this study are to (1) present an SMT especially developed by and for patients with psoriasis and (2) evaluate the app's impact on QoL as well as its acceptance and usability.

Methods

Recruitment and Requirement Engineering Phase

In Germany, there are 2 main organizations for psoriasis self-help. The larger one is the Deutscher Psoriasis Bund e.V. (German Psoriasis Association) and the smaller one is the Psoriasis Selbsthilfe Arbeitsgemeinschaft e.V. (Psoriasis Self-Help Association, PSOAG) [27,28]. The latter offers self-help on its website. The internet-based community consists of approximately 28,000 users (as of November 2019) and concerns itself with topics such as therapies or nutrition. There are various expert forums and groups that can be joined. Knowledge articles are also published [29]. The project was initiated with PSOAG members. The community collected requirements of a (potential) smartphone-based SMT during 2 online surveys (published via the web-based forum).

The first survey started on February 2, 2019, and was closed on March 15, 2019. It consisted of a semistructured questionnaire that asked about the desired features of an SMT for psoriasis. A translated version of this questionnaire can be found in [Multimedia Appendix 1](#). After completion of the first survey, the responses were read and clustered to capture different categories of functionalities. In the next step, categories were checked for technical feasibility and focus on SMTs.

The second survey that incorporated the community feedback from the first round was open from June 25, 2019, to August 31, 2019. During this phase, 11 mock-ups of the SMT were presented and discussed with the community members. The mock-ups were built with the Balsamiq Mockup software (version 3.5.17; Balsamiq Studios, LLC) [30].

Changes needed in the design of the app and the expansion of certain functionalities were again checked for technical feasibility and incorporated into the final app requirements.

After the requirements were determined, the SMT development started. The system was implemented by one of the authors using software components previously developed [31] as blueprints. The app development and the pilot study were carried out as part of a master's thesis at Heilbronn University.

SMT Evaluation

QoL Assessment

Numerous instruments of QoL assessment exist [32,33]. Fitzpatrick et al [34] developed a list of criteria to select the most appropriate measurement instrument. According to these criteria, we decided to use the DLQI by Finlay et al [26] for this study. The DLQI consists of 10 questions that cover the dimensions of symptoms and daily activity, leisure, work or

school, personal relationships, and therapy [26]. The average response time is 2 minutes [35]. The score of the DLQI ranges from 0 to 30. The larger the value, the worse the QoL [26]. The minimal clinically important difference is 4 score points [36]. A license for the use of the German Translation DLQI was applied for and was provided by Cardiff University [35].

Use and Usability

Considering usability and further use, an additional questionnaire was introduced. It included questions about handling, use, further use, and the severity of psoriasis, and were self-reported and/or measured by the Psoriasis Area and Severity Index (PASI) [37]. This additional questionnaire can be found in [Multimedia Appendix 2](#).

Recruitment for QoL Assessment

Participants for the QoL assessment were recruited through various channels:

1. A call for participation was given via the PSOAG website and forum. The call provided the opportunity to contact the study team directly or to access a study information website.
2. Information flyers were sent to dermatology clinics (13 rehabilitation clinics and 11 university clinics), the Professional Association of German Dermatologists, and the Psoriasis Association.
3. Social media channels were used to actively promote the study (eg, regular tweets, posts on Instagram, and the creation of a Facebook page about the study).

For inclusion in the study, the participants had to have psoriasis and be at least 18 years old.

Study Design

As the study measured the change in QoL, it was necessary to record it at a minimum of 2 time points (T_0 and T_1). The DLQI measures QoL in relation to the last 7 days. A break of at least 7 days is recommended, and frequent questioning is discouraged; otherwise, participants may remember their previous response. Based on these requirements, the intervention duration was set at 21 days.

After 21 days had elapsed, the second DLQI and the extra questionnaire on usability and further use of the SMT were completed. Then, the participants dropped out of the study.

Statistical Analysis

Based on the German-specific data provided by Lesner et al [7] and the minimal clinical effect of 4 points, a sample size of 27 participants is calculated to reach $\alpha=.05$ and $\beta=.2$ [38]. Data were analyzed with the statistical software MATLAB (version 2019b) [39].

Ethical Approval

No ethical approval was obtained for the conducted study. The local ethics committee of Heilbronn University is only an advisory board (see §1(1) [40]), and it does not provide formal ethical approval. This was a community-led project involving interested persons with psoriasis who enrolled voluntarily and by general invitation in the development and evaluation of an app. These were not patients treated by the authors. Treatment

changes or any interaction with the medical care delivery team were not included in the objectives of this study.

As the data collected were worthy of protection, a high scientific standard was applied here. All participants were informed about the study details and received written information in accordance with the Declaration of Helsinki [41]. This information was available on the study information website and could be downloaded for offline reading (see [Multimedia Appendix 3](#)). All participants had one-to-one contact with the principal investigator and questions from them were answered by email or telephone, as requested.

All participants signed an informed consent form (see [Multimedia Appendix 4](#)), which could be revoked at any time. In this case, all documents that could still be assigned were destroyed. To ensure a high level of data security, the questionnaires were recorded under a pseudonym generated by the participants themselves.

Results

Requirement Engineering and SMT

More than 90 community members participated in the survey ($N=97$). They determined the scope of the SMT's features, created the medical content, and curated it.

During the first user survey, the requirements for the SMT were collected. Nearly 90% (87/97) of the participants indicated willingness to test the SMT. The suggestions of the community about the desired features were evaluated for their feasibility and purpose of use. Four categories emerged during the analysis of the community responses: (1) communication, (2) drug management, (3) tracking of complementary methods, and (4) rate/score doctors. Selected examples of the feedback from the SMT users are presented in [Table 1](#). Furthermore, mock-ups (ie, drafts of the user interface) were created. These were presented to the community and the community members could provide their comments.

The final SMT framework consists of three components, as shown in [Figure 1](#): (1) an Angular web application for the management of the SMT content used by the editorial team, (2) a server back end built with Java Spring Boot and Spring Security, and (3) the SMT for the study participants as an Angular application. The SMT app was implemented as a progressive web app (PWA) to be available for all types of smartphones.

Both web components were built with the Angular Framework (Google; version 7.2.15) [42]. The server back end was built with Java Spring Boot (The Spring Team; version 2.1.5) [43] and Java (Oracle Corporation; version 11) [44].

One feature focus of the SMT is to suggest interaction-free complementary measures to the user, with which physical complaints, such as itching, skin blisters, and dry skin, can be alleviated. Patients can document their psoriasis type, medical drugs, and complaints each day. Based on these data, the SMT suggests complementary methods that are free of interactions. The complementary measures were suggested by the community itself and were reviewed by the forum's editorial team. In total,

55 complementary measures were found, described, and incorporated into the knowledge base of the SMT (see component 1 in Figure 1). The complete list is available in Multimedia Appendix 5. The knowledge was embedded in a PostgreSQL database (PostgreSQL Global Development Group; version 10.9) [45], as shown in Figure 1.

Another aspect of the app was the documentation of psoriasis and the possibility to view the severity of symptoms as they

progressed and in relation to the complementary methods that were considered. Moreover, individual body parts could be documented in more detail with the help of photos and text. Figure 2 shows representative screenshots.

A comprehensive data protection concept was developed. All the app data were stored exclusively on the user's own smartphone.

Table 1. Results of the first requirement analysis involving the web-based community^a.

Feedback from the community	Category	Realization in the SMT ^b

"All [measures] that improve my quality of life, take away pain, and build me up"	3	+
"It could remind me to take medication"	2	—
"Study situation and results on complementary therapy methods would be good"	3	✓
"Some kind of daily checklist to check off to-dos related to (psoriasis] would be great. That way you can see correlations, if necessary (eg, if you forgot a supplement or only applied cream once a day instead of twice)."	3	+
"Could you name and comment on current dermatologist (recommend, yes/no and why)"	4	—
"That you can print out the diary would be good to present to the doctor who treated you!"	3	✓
"A list of my current medications as well as a list of medications I have tried but no longer use (and why!)"	2, 3	+
"A chat or a link to a forum where users can exchange information directly. Because I see the main problem with the app as being that something different helps everyone. It's so hard to generalize."	1	+
"Calendar in which one can enter appointments for the doctor, taking one's medication or other things."	1, 2	—
"Logging what you have eaten and then automated evaluation of whether patterns are recognizable, how nutrition affects you. The same with stress/well-being."	3	✓
"Maybe refer to competent doctors, dermatologists and rheumatologists in the respective federal states of the people concerned."	4	—
"To find other patients with psoriasis nearby and find experts or good doctors from the patient's point of view."	1, 4	—
"A digital (medication plan) for all medications, not only for psoriasis treatment; in my case, for example, this was accompanied by a CHD ^g disease."	2	—

^aAll statements were translated from German. Additions or replacements for better understanding are denoted in square brackets.

^bSMT: self-management tool.

^cCRP: c-reactive protein.

^dThe function is not implemented.

^eThe function is fully implemented.

^fThe function is partially implemented.

^gCHD: congenital heart defects.

Figure 1. System architecture. The 2 Angular components are shown on the left. These are provided on a web server that communicates with the back-end server. A Spring Security module protects the back end and the connected database from security attacks. The back-end component is shown on the right. DB: database; SMT: self-management tool; SQL: structured query language.

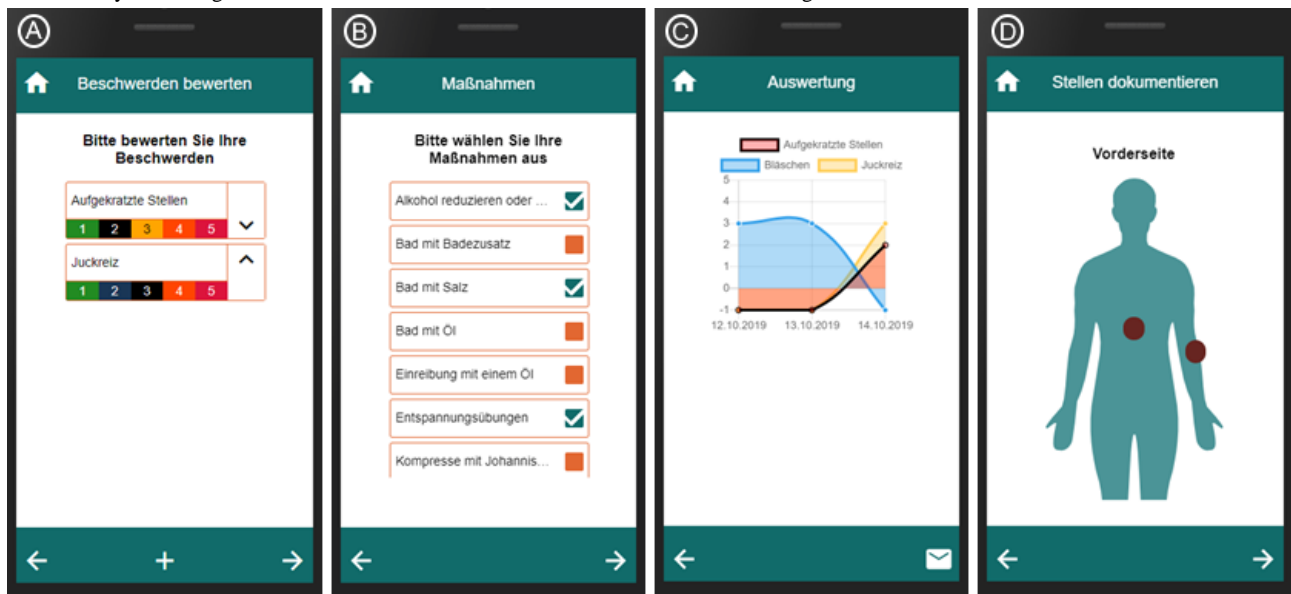

Figure 2. Screenshots of the smartphone app. Left to right: (A) Rating and sorting physical complaints. Complaints can be added via the “plus” sign in the footer. (B) Choosing complementary methods, including reducing alcohol, taking a bath with bath salts, and relaxing. (C) The course of complaints. By clicking on one of the dots in the chart, the complementary methods used during this day are shown. (D) Documentation of the front of the body. A click on the body adds a region of interest. Photos and text could be documented for each region of interest.

SMT Evaluation

QoL Analysis

During the call for participation, 29 persons showed interested in participation, with 21 of them providing consent to the processing of their data. Of these, 18 submitted the initial questionnaires. All persons who returned the first questionnaire are counted as participants. Participants who revoked consent (3 participants) or did not return the second questionnaire (5 participants) are counted as dropouts. Only 10 participants returned both questionnaires that were subsequently analyzed.

In total, 15 valid preintervention and 10 postintervention QoL questionnaires, and questionnaires about acceptance and usability were collected and transcribed into a CSV format. Additionally, 6 participants did not return any questionnaires but gave consent.

The mean DLQI for the preintervention questionnaire was 7.1 (SD 6.2) score points and 6.9 (SD 6.6) score points for the postintervention questionnaire. A lower score after the intervention corresponds to an increased QoL. However, the

reduction of the DLQI by 0.2 score points does not correspond to a clinically relevant effect.

Use and Usability

The survey on difficulties in using the app shows that users did face challenges (see Table 2).

The results showed that 4 participants had no difficulties in using the app, and 3 participants found it quite or very difficult to use. Moreover, 3 other participants had slight difficulty in using the app. This was also reflected in the feedback from the participants. When returning the second questionnaire or withdrawing from the study, there was additional qualitative feedback on the SMT given by various participants, which is documented in Textbox 1.

The participants were also asked about their continued use of the app. None of the participants would continue to use the app daily. Only 2 participants continued to use the app regularly, 1 participant used it as needed, and 6 participants did not continue to use the app at all. In 1 questionnaire, this question remained unanswered.

Table 2. Study results^a.

Participant	DLQI _{T0} ^b	DLQI _{T1} ^c	Usage period (days) ^d	Difficulty ^e	Further use ^f	Severity level ^g	PASI ^h score
1	1	1	3	A little	Not at all	Mild	Not replied
2	5	3	12	Fairly	Not replied	Heavy	Not replied
3	1	0	4	A lot	Not at all	Heavy	Not replied
4	9	19	6	A little	Not at all	Mild	0
5	7	2	21	Not at all	Regularly	Mild	Not replied
6	2	2	4	Fairly	Not at all	Moderate	Not replied
7	1	4	8	Not at all	Not at all	Moderate	<3
8	20	17	5	A little	As needed	Moderate	Not replied
9	15	9	5	Not at all	Regularly	Heavy	Not replied

15	10	—	—	—	—	—	—

^aAverage values for participants 1 to 10: DLQI_{T0}, 7.1, DLQI_{T1}, 6.9, and usage period (days), 7.1. Average DLQI_{T0} value for participants 1 to 15 was 8.3.

^bDLQI_{T0}: Dermatology Life Quality Index before using the app.

^cDLQI_{T1}: Dermatology Life Quality Index after using the app.

^dIndicates the number of days the app was used.

^eRepresents the difficulties experienced when using the app.

^fRepresents further use of the app.

^gShows the subjective perception of the severity of psoriasis.

^hPASI: Psoriasis Area and Severity Index.

ⁱIndicates participants who only completed the first questionnaire but did not withdraw their agreement.

Textbox 1. Qualitative feedback of participants. All statements were translated from German. Additions for better understanding are shown in square brackets. Detailed information on date, time, and medication are omitted because of privacy reasons.

Person A

- “I have psoriatic arthritis and unfortunately the app does not relate to that.”
- “And unfortunately, I also have to say that I find the handling very complicated.”
- “Basically, I find the idea good, but so [the app] is unfortunately not further usable for me.”

Person B

- “It worked great.”
- “The “problem” is the photos. I live alone and find it difficult to photograph the back. But that is my only issue at the moment.”

Person C

- “I have tried a few apps, but they were all not applicable. Maybe theirs is a little better and more supportive.”

Person D

- “Also, I found it inconvenient and difficult to use at times because there was no explanation whatsoever.”

Person E

- “The “app” is not a native iOS or Android app, but a web application. I prefer here, especially for my sensitive health data, an app running locally on the iPhone/iPad, where the data is local on the device or encrypted in my own or the iCloud (optional).”
- “Using the app in parallel from multiple devices (smartphone, tablet, smartwatch) would be of great benefit.”
- “Such an app would also have to be individually “customizable” for me: Creation of own “therapies”. For the individual therapies, storage of more details (eg, for light therapy, the duration of the respective irradiation or the set Joule dose), for ointments, the name, PZN, etc.”
- “Usability would also have to be significantly optimized. For regular documentation (skin condition, condition, medication), the [documentation] must happen as quickly and easily as possible.”

Person F

- “The app is very interesting and helpful for people who don't have this background knowledge.”
- “The documentation via photos, I think is very good, I could have used that a lot from ***.”

Person G

- “I only used the app for a very short time, as I perceived filling it out as annoying.”
- “However, I think small changes to the app could fix this for the most part.”

Person H

- “Since I don't do therapy other than *** and *** and don't yet know what things help me, it would have also become difficult for me to use it meaningfully.”
- “I'm just looking more the other way around for a template where I can document what I've done and eaten (how much sleep, how much sun, etc) to figure out what factors are negatively impacting me.”

Statistical Analysis

The targeted sample size (N=27) was not achieved. Therefore, the testing of the hypotheses was disregarded.

Discussion

Requirements Engineering and SMT Development

A special feature of the development process was the high level of participation. Community members were asked about additional features and could comment on the designs and mock-ups. Unfortunately, it was not possible to implement all the desired functions (see [Table 1](#)). Reminders could not be

implemented due to the technical restriction of a PWA. Notifications are possible with this design but cannot be individually configured. Ratings of doctors and exchanges with other patients were not implemented, as these functions would overlap with the internet-based forum of the community. Some suggestions of the stakeholders have been partially implemented because the documentation should be in a structured form instead of a free form to avoid incorrect entries and simplify usage.

When examining for possible confounders, the usability aspects stood out. This was reinforced by the feedback from the individual participants. There were difficulties in dealing with

the app. This was partly due to the handling and partly because patients have a greater need to document their illness than that assumed. In particular, the behavior for which therapy is currently being provided and secondary diseases should be documented more precisely and as quickly as possible. The heterogeneity of the users' feedback shows that the app should be highly customizable. The suggestion to implement the app as a standalone one rather than as a PWA certainly warrants further IT security requirements and offers possibilities for including more features.

The feedback from the community shows a certain ambivalence regarding the privacy aspect. On the one hand, previous experience and feedback on the app show that a high level of data protection is desired. Therefore, all data remain locally stored on the user's device. On the other hand, the fact that the data cannot be accessed on several devices was perceived as a negative feature. Apparently, there are services that enjoy a higher level of trust regarding data protection than others. Further developments to the app must ensure that users can decide whether they want to use the SMT data on 1 or more devices.

Despite the low number of study participants, the project shows the possibility of using citizen science in biomedical projects and research. The community-supported software development process successfully led to a functional SMT. In particular, the internet-based community provided the list of complementary measures, which were used as textual content in the SMT. Therefore, the SMT users could benefit from the collected patient knowledge about complementary measures without the effort of searching information on the internet.

Limitations

There are 2 major limitations of this project. The first is the low overall sample size and the second is a small observed effect.

For showing a statistically significant improvement of a minimum of 4 score points, 27 participants would have been necessary for the study. This number was not reached despite previous experience about the active internet-based community and high involvement in the requirement engineering process. Only 21 participants could be recruited. Of these, only 10 participants completed all questionnaires. We identified potential reasons for this: (1) failure to reach the target group via social media channels, (2) an admission process that was perceived as too complicated, and (3) the Christmas holidays. One indication of this is an increase in the dropout rate in the month of December. The additional leaflets sent in December could not mitigate the low involvement.

Acknowledgments

The authors would like to thank all the members of the psoriasis-netz.de community who provided feedback; all the participants of the study for their time, effort, and feedback on the app; the team from Cardiff University for their support in granting the DLQI license; and the staff in Heilbronn University (especially the groups in E112 and E117) for their continuous support throughout the SMT development.

The observed effect of 0.2 score points reported in the results is negligible. The fact that the desired effect with a difference of 4 DLQI points could not be measured can be attributed to different causes. Besides the low effectiveness of the intervention, the intervention period (21 days) may play a role. The reason is that regular use over a long period of time may be necessary to effect changes. Therefore, a measured effect could be considered a placebo effect. In addition, the DLQI was recorded without considering the occurrence of relapses, possible rehabilitation stays, or an existing concomitant disease such as psoriatic arthritis. Comparing the average DLQI score determined in this study with the results of the study by Augustin et al [46] (mean 7.5, SD 6.4 points) reveals that the values do not differ much. Moreover, the variances in the respective samples are similar. This difference of less than 1 score point with the score in this study is noteworthy because Augustin et al included not only patients of dermatology outpatient hospital clinics but also patients of dermatologists in ambulant care. In this study, the participants were recruited via the community, which is why it is unlikely that the sample consists exclusively of dermatology outpatient hospital clinic patients.

Future Directions

Based on the feedback provided by the community and app users, the existing smartphone app should be completely revised. The authors strongly recommend developing such an app using a community-driven process again.

The improvements to the subsequent versions of the SMT can be roughly divided into four areas: (1) therapies including conventional medical therapies, hospital and rehabilitation stays, and complementary measures; (2) psoriasis relapses and triggers that can be analyzed; (3) behavioral patterns or environmental data in everyday life; and (4) QoL, as well as psychological and physical factors measured textually or visually using questionnaires.

To implement SMTs sustainably in care, it should be better integrated into the existing structures of care processes and medical practices. Direct data transmission to practitioners and further development of SMTs as approved medical products are conceivable.

Conclusions

The high participation of the internet-based community in the development process and the response to the first survey (N=97) shows a general need for independently developed SMTs for people with psoriasis. However, the collected feedback shows that the solution presented in the paper does not meet the needs of the community. The authors conclude that a more customizable app is needed.

Abstract

Background: Engagement with smartphone apps for smoking cessation tends to be low. Chatbots (ie, software that enables conversations with users) offer a promising means of increasing engagement.

Objective: We aimed to explore smokers' experiences with a quick-response chatbot (*Quit Coach*) implemented within a popular smoking cessation app and identify factors that influence users' engagement with *Quit Coach*.

Methods: In-depth, one-to-one, semistructured qualitative interviews were conducted with adult, past-year smokers who had voluntarily used *Quit Coach* in a recent smoking cessation attempt (5/14, 36%) and current smokers who agreed to download and use *Quit Coach* for a minimum of 2 weeks to support a new cessation attempt (9/14, 64%). Verbal reports were audio recorded, transcribed verbatim, and analyzed within a constructivist theoretical framework using inductive thematic analysis.

Results: A total of 3 high-order themes were generated to capture users' experiences and engagement with *Quit Coach*: anthropomorphism of and accountability to *Quit Coach* (ie, users ascribing human-like characteristics and thoughts to the chatbot, which helped foster a sense of accountability to it), *Quit Coach*'s interaction style and format (eg, positive and motivational tone of voice and quick and easy-to-complete check-ins), and users' perceived need for support (ie, chatbot engagement was motivated by seeking distraction from cravings or support to maintain motivation to stay quit).

Conclusions: Anthropomorphism of a quick-response chatbot implemented within a popular smoking cessation app appeared to be enabled by its interaction style and format and users' perceived need for support, which may have given rise to feelings of accountability and increased engagement.

KEYWORDS

chatbot; conversational agent; engagement; smartphone app; smoking cessation; accountability; mobile phone

Introduction

Diseases caused by cigarette smoking are a leading cause of preventable death, killing approximately 8 million people each year globally [1]. Smoking-attributable diseases place significant financial burden on health care systems, with costs estimated to be approximately 5.7% of the total annual global health care expenditure [2]. Therefore, improved behavioral or pharmacological smoking cessation support is a priority for individuals, public health bodies, and governments. However,

in-person smoking cessation services are challenged by scalability and face substantial funding cuts across many countries [3], especially after many had to offer only remote services owing to the COVID-19 pandemic [4]. With growing internet access and smartphone ownership, digital interventions (including smartphone apps) provide a low-cost means of scaling up the delivery and optimizing the reach of evidence-based smoking cessation support [5]. However, the available smoking cessation apps tend to generate low average levels of user engagement [6,7]—although estimates vary between apps

[8]—which may reduce the likelihood of success in quitting smoking. Therefore, identifying modifiable factors (eg, content and design elements) that positively influence engagement with smoking cessation apps is important. A promising means of improving digital engagement is through provision of concurrent health care professional support [9,10]. However, this is limited by the cost and availability of health care professionals. Therefore, an underexplored and relatively low-cost means of improving engagement is to replicate health care professional support via chatbots (ie, software that enables 2-way conversations with app users). This study aimed to explore smokers' experiences with a quick-response chatbot (*Quit Coach*) implemented within a popular smoking cessation app and identify factors that influence users' engagement with *Quit Coach*, using a qualitative approach.

Engagement with digital interventions can be defined as (1) the extent (eg, amount, frequency, duration, and depth) of use and (2) a subjective experience characterized by attention, interest, and affect [9]. A distinction between *microengagement* (ie, engaging with the technology itself) and *macroengagement* (ie, engaging in the behavior change process, such as abstaining from smoking) has also been proposed [11]. A common pattern observed across several studies is that engagement is positively associated with intervention effectiveness [12-14]. Therefore, many researchers and intervention designers have focused their efforts on identifying factors that increase engagement with digital interventions in general and with smoking cessation apps in particular. These studies have identified factors such as app content or behavior change techniques (eg, goal setting, reminders, self-monitoring, social support, and health care professional support), design elements (eg, tailoring of content, using a nonjudgmental message tone, and gamification), and cognitive considerations (eg, minimizing cognitive load and providing user guidance) as being important for increased engagement [10,15-17]. However, despite such studies, early disengagement from smoking cessation apps remains common.

Chatbots (also referred to as *conversational agents*) are computer programs that have tailored conversations with users via text or audio-visual messaging [18]. Some chatbots are specifically designed to appear as social actors (ie, *relational agents*), with the intention that users form social-emotional relationships with the bot [19,20]. Current chatbot implementations include structured (or decision tree-based) and unstructured bots. The former type enables the user to select relevant options from a list of predefined responses, with the bot responding with prewritten messages following conditional if-then rules (also referred to as *quick reply responses* or *quick-response* bots [21]). The latter type typically relies on natural language processing, with the user inputting open or unstructured messages that are processed and responded to by the bot. According to the Model of Supportive Accountability, human support (eg, from a health care professional or coach) is expected to promote engagement with digital interventions by fostering a sense of accountability to a trustworthy, benevolent, and competent coach [22]. Although underexplored, it is plausible that chatbots may fulfill the role of such human support by offering *human-like* support [19].

Chatbots are a relatively new addition in the health care domain, with recent systematic reviews identifying only a handful of studies of chatbots for improving mental health [23] and increasing physical activity and healthy diets [24]. Within the substance use and smoking cessation domains, a few early single-arm and 2-arm randomized studies have yielded promising results [25-28]. For example, a chatbot incorporating the principles of motivational interviewing—designed specifically to support smokers who are unmotivated to stop—tested positively in an early user-testing study [25]. An adapted version of the cognitive behavioral therapy-informed chatbot, *Woebot*, for people who use addictive substances was found to be acceptable to deliver, engaging, and associated with improvements in mental health and substance use outcomes in a single-arm study [28]. We found that the addition of a supportive, quick-response chatbot to a popular smoking cessation app more than doubled the user engagement and improved short-term quit success in a large, 2-arm, experimental study [27]. However, the available single-arm and 2-arm quantitative studies have not focused on the potential mechanisms underpinning this increased engagement (eg, owing to limited data collection). Qualitative studies of users' experiences with the relational agent, *Replika*, have found that such companion chatbots can mimic human interaction, with users perceiving their relationships with the designated bot as rewarding [20,29]. However, qualitative investigations of users' experiences with chatbots designed specifically to support smoking cessation are lacking. Therefore, this qualitative study aimed to address the following research questions:

1. What are smokers' experiences with a quick-response chatbot (*Quit Coach*) implemented within a popular smartphone app?
2. What are the factors that influence users' engagement with *Quit Coach*?

Methods

Study Design

The Consolidated Criteria for Reporting Qualitative Research checklist was used in the design and reporting of this study [30]. Semistructured, one-to-one interviews were conducted.

Theoretical Framework

A constructivist theoretical framework was used to inform data collection and analysis [31]. This theoretical approach was selected because constructivism recognizes the active role of the researcher in the generation and interpretation of qualitative data.

Participants

For pragmatic purposes, participants were recruited across 2 periods: June 2020 to August 2020 (led by KS and OP) and April 2021 to August 2021 (led by AA and OP). Owing to the COVID-19 pandemic, it was challenging to recruit as planned during the summer of 2020. Therefore, we continued the recruitment in 2021. The project team decided that it would be useful to recruit participants from 2 different subgroups (ie, past-year smokers who had voluntarily used *Quit Coach* in a recent smoking cessation attempt and current smokers who

agreed to download and use Quit Coach for a minimum of 2 weeks to support a new cessation attempt) as a form of triangulation [32]. We reasoned that such triangulation of results when varying the eligibility criteria (rather than the methods) would either help to validate the results (eg, if smokers who did not self-select to download and use the Smoke Free app had similar experiences with Quit Coach as those who had voluntarily used the app) or highlight different experiences owing to smoking status or treatment-seeking behavior.

Participants recruited in 2020 were eligible to participate if they (1) were aged ≥ 18 years, (2) were fluent English speakers based in the United Kingdom, (3) were past-year smokers and had used the *pro* (ie, paid) version of the Smoke Free app (ie, the app version that included Quit Coach) for at least two weeks, and (4) had interacted with Quit Coach at least once during the 2-week period.

Participants recruited in 2021 were eligible to participate if they (1) were aged ≥ 18 years; (2) were fluent or highly competent English speakers, with no restrictions on geography; (3) were current cigarette smokers; (4) were willing to make a quit attempt within 1 week from initial contact with the researchers and use Quit Coach for at least two weeks; and (5) owned a smartphone.

All the participants used the *pro* version of the Smoke Free app for a period of at least 2 weeks before participating in the semistructured interviews. We expected this time window to be sufficient for enabling detailed conversation about participants' chatbot experiences.

Sampling

Participants recruited in 2020 were approached through advertisements (unpaid) shared on social media platforms (ie, Facebook and Twitter) and through a mailing list of Smoke Free app users. The recruitment materials stated that Smoke Free users were invited to participate in a web-based interview about their experiences with the app (good or bad), with particular focus on the Quit Coach feature. Participants were incentivized to win 1 of 5 gift vouchers worth £20 (approximately US \$24).

Participants recruited in 2021 were approached through advertisements (unpaid) shared on social media platforms (ie, LinkedIn, Facebook, and Instagram), directly through the researchers' networks (ie, WhatsApp, email, SMS text messages, and flyers), and through professional web-based recruitment platforms (ie, Prolific and Call for Participants). The recruitment materials stated that smokers interested in making a quit attempt with the use of a smartphone app were invited to participate in a web-based interview about their experiences with the app (good or bad), with particular focus on its chatbot feature. Participants received a gift voucher worth £10 (approximately US \$12) after completing the interview.

Participants were recruited in batches of 4 to 5 participants each until theoretical saturation was judged to have occurred (ie, a point in the data collection process when no new information alters the identified themes) [33]. Preliminary data analysis was conducted by KS and subsequently by AA after each batch of 4 to 5 participants, to determine whether additional participants were needed.

Measures

Eligibility and Sample Characteristics

Data were collected to determine eligibility and characterize the sample based on (1) age; (2) gender (female, male, or in another way); (3) country of residence; (4) whether they were fluent or highly competent English speakers (yes or no); (5) time to first cigarette (< 5 , 6-30, 31-60, or > 60 minutes or not applicable); (6) cigarettes smoked per day (< 10 , 11-20, 21-30, ≥ 31 , or not applicable); and (7) motivation to stop, measured with the validated Motivation to Stop Scale [34].

Participants recruited in 2020 were asked the questions mentioned previously and to provide additional information on the following: (1) job type (manual or nonmanual); (2) smoking status ("I smoke cigarettes [including hand-rolled] every day"; "I smoke cigarettes [including hand-rolled], but not every day"; "I don't smoke cigarettes at all, but I do smoke tobacco of some kind [e.g. pipe, cigar or shisha]"; "I have stopped smoking completely in the last year"; "I stopped smoking completely more than a year ago"; or "I have never been a smoker [i.e. smoked for a year or more]"); and (3) self-reported use of Quit Coach (none at all, a little, moderately, a lot, or extremely).

Participants recruited in 2021 were asked the questions mentioned previously and to provide additional information on the following: (1) the number of past-year quit attempts and (2) whether they had ever used any app-based support to help stop smoking (and if so, the name of the app).

Interview Topic Guide

The topic guide was informed by the Model of Supportive Accountability [22] to address specific theoretical concepts (eg, information quality, reliability, and accountability) and split into 3 sections: an introductory section to allow participants to warm up, covering general experiences with the app; a second section exploring users' experiences with Quit Coach; and a final section exploring situations in which participants engaged with Quit Coach (Multimedia Appendix 1). Prompts were used to encourage participants to elaborate on their impressions and experiences. The topic guide was pilot-tested by KS on 2 graduate colleagues from the MSc program in Behavior Change and adapted following their feedback. The topic guide was further adapted following the interviews conducted in 2020 to facilitate elaboration by adding specific probes in addition to a new question ("To what extent would you say you formed a relationship of sorts with the chatbot? How was this?"). As participants mentioned their relationship with the chatbot, we considered it useful (and consistent with the flexible, semistructured style of interviewing) to specifically prompt subsequent participants about this. The adapted topic guide was piloted by AA on a graduate colleague from the MSc program in Behavior Change and a current smoker from AA's network and updated according to their feedback. Interviews remained flexible, facilitated by the semistructured style of questioning.

Procedure

Upon expressing interest, participants were asked to read the participant information sheet, provide informed consent, and complete the eligibility questionnaire via Qualtrics (Qualtrics

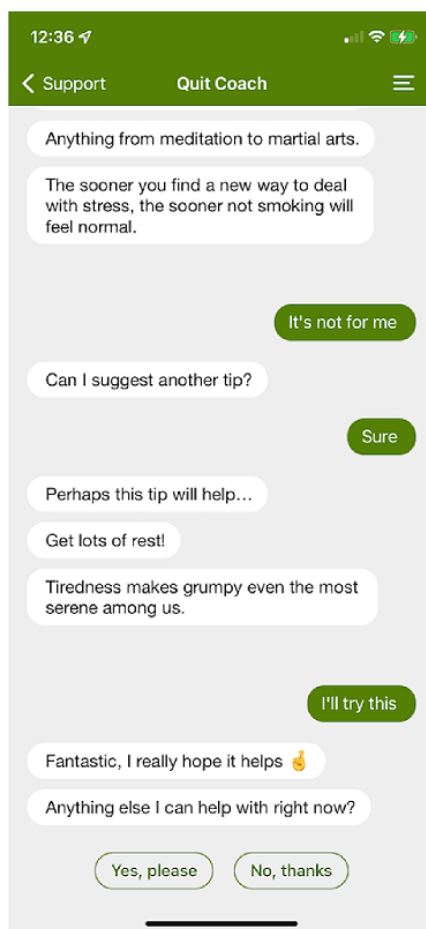

International Inc). If eligible, participants recruited in 2020 were contacted by the researchers to arrange the interview. If eligible, participants recruited in 2021 were contacted to confirm study acceptance and provided with information on how to download the *pro* version of the Smoke Free app (using a free access code). Participants were asked to select a quit date and nominate a day that was 2 weeks from their quit date to complete the interview.

Owing to the COVID-19 pandemic, in-person interviews were not possible. Therefore, interviews were conducted via the web by KS or AA (graduate students enrolled in an MSc program in Behavior Change) via Microsoft Teams. Besides the participant and the researcher, no one else was present during the interviews. KS had limited experience in conducting qualitative interviews before this study; AA had extensive experience from working for a consultancy firm. Before conducting the interviews, OP (PhD in Health Psychology, extensive experience in conducting qualitative interviews through previous academic work) provided training to KS and AA. Interviews were audio recorded and lasted between 30 and 45 minutes. Following completion, the participants were thanked, verbally debriefed, and presented with an incentive.

The Smoke Free App and Quit Coach

Smoke Free [35] is an evidence-informed app with a large user base (approximately 4000 downloads per day). The app contains behavior change techniques that are expected from theory and evidence from other settings to aid smoking cessation [17,36]. Refer to the study by Jackson et al [37] for a summary of the behavior change techniques included in the Smoke Free app, coded against a 44-item taxonomy of techniques used in individual behavioral support for smoking cessation [36].

The *pro* (ie, paid) version of Smoke Free contains a text-based, quick-response chatbot called *Quit Coach* (Figure 1). During the first 2 weeks of a user's quit attempt, Quit Coach initiates twice-daily check-ins with users regarding their cessation attempt through a push notification. Check-in frequency is programmed to reduce after 1 month and cease entirely after 90 days (when users are anticipated to have quit smoking). Users engage with Quit Coach via text messages, selecting from prewritten responses. There are a few exceptions to this format, such as when users complete certain exercises that require free-text input (eg, typing the mantra, "not another puff, no matter what"), to occasionally type what is influencing their craving, or for providing feedback on whether they found a piece of advice useful (refer to [Multimedia Appendix 1](#) for additional screenshots of such interactions). A bespoke Node.js natural language processing framework (adapted from freely available, state-of-the-art source code by Smoke Free's developers) is used to map free-text inputs onto their likely intent—this constitutes the only machine learning element of the chatbot. Users can also initiate check-ins themselves by opening Quit Coach to record a craving or ask for assistance via a *get help now toolkit*, which provides different options for directing the conversation with Quit Coach. The conversational options include craving management, relapse, difficult situations, and withdrawal. Quit Coach's communications (typically in text form, but also through emojis and Graphics Interchange Formats [GIFs]) contain information about the health consequences of smoking, quitting tips, and motivational messages, simulating a text message conversation.

Figure 1. Example screenshot of the Smoke Free chatbot (Quit Coach).

Data Analysis

Interviews conducted in 2020 and 2021 were combined to form a single data set. Analysis was performed through an inductive thematic approach following the methodology by Braun and Clarke [38,39]: (1) familiarizing with the data, (2) generating initial codes, (3) searching for themes, (4) reviewing the themes, (5) defining and naming the themes, and (6) producing the report. We focused on latent (rather than semantic) meanings [39]. Although the Model of Supportive Accountability was used to inform the interview topic guide, terminology from this model was used for coding only if deemed relevant, with alternative codes considered throughout the process.

Interviews were coded using Microsoft Word in batches of 4 to 5 by AA to facilitate an iterative and reflexive approach. Each transcript was read multiple times to familiarize with the data. Then, initial codes were generated. Coded transcripts were reread following initial code generation and discussed with OP, adding or refining codes as appropriate. Then, the coded extracts were examined and used to generate preliminary themes. Next, a second, independent coder (another student from the same MSc program in Behavior Change) helped to assess coding reliability. The second coder coded 2 interviews, 1 each from the 2020 and 2021 samples, which were selected using a random number generator. The second coder was instructed to inductively code each interview. The resulting codes were

compared with those of the first coder conceptually, rather than for perfect word matching. Discrepancies were discussed and reconciled. Then, themes were reviewed, refined, named, and agreed upon through discussion among AA, OP, and JB. During coding, the possibility for differences between the 2020 and 2021 samples was considered. Theoretical saturation was judged to have been reached after 12 interviews.

External Validation

A subsample of 14% (2/14) of randomly selected participants were contacted and agreed to read the results and comment on the congruence of the themes and narrative generated by the researchers with their own experiences. Both participants agreed with the researchers' interpretations.

Reflexivity

The interviewers (women, White ethnicity, nonsmokers, and unfamiliar with most participants before the interview) felt that a good rapport was built with all the participants. Some were more immediately verbose, whereas others took a little time to open up, but did so with prompting and encouragement. For the first few interviews conducted, the interviewers closely followed the topic guide; however, as salient conversation topics emerged, a more discursive style of questioning was adopted to explore salient topics in great depth. Before commencing the interviews, participants were told about the goals of the study and that the interviewers were not directly involved in the development of

the Smoke Free app; however, participants were unaware of the interviewers' smoking status or theoretical assumptions regarding user engagement or smoking cessation.

Ethics Approval

Ethics approval for this study was obtained from University College London's Research Ethics Committee (CEHP/2020/579). Participants provided written informed consent before participating in the study.

Results

Participant Characteristics

A total of 40 participants completed the screening survey and were eligible to participate in the study. Of the 40 participants, 26 (65%) participants did not complete an interview, as they later decided that it was not the right time to quit, became uncontactable, or failed to attend the interview. [Table 1](#) shows a summary of the demographic and smoking characteristics of the 35% (14/40) included participants.

Table 1. Participants' demographic and smoking characteristics (n=14).

Participant ID	Recruitment year	Age (years) ^a	Country	Gender	Cigarettes per day at baseline	Smoking status at the time of interview	Quit Coach use	Number of past-year quit attempts	Use of app-based support to stop smoking (name of the app)
P1	2020	30	United Kingdom	Female	N/A ^b	I have stopped smoking completely in the last year	Moderate	N/A	N/A
P2	2020	20	United Kingdom	Male	N/A	I have stopped smoking completely in the last year	A lot	N/A	N/A
P3	2020	33	United Kingdom	Female	N/A	I have stopped smoking completely in the last year	Extreme	N/A	N/A
P4	2020	39	United Kingdom	Female	N/A	I have stopped smoking completely in the last year	A lot	N/A	N/A
P5	2020	44	United Kingdom	Female	N/A	I have stopped smoking completely in the last year	A lot	N/A	N/A
P6	2021	25-34	United Kingdom	Male	7	Quit ^c	N/A	1	No (N/A)
P7	2021	18-24	France	Female	3	Cut down ^c	N/A	3	Yes (Qwit)
P8	2021	18-24	France	Female	10	Cut down ^c	N/A	1	No (N/A)
P9	2021	25-34	France	Male	12	Cut down ^c	N/A	3	Yes (Smoke Free)
P10	2021	18-24	United Kingdom	Female	5	Cut down ^c	N/A	0	No (N/A)
P11	2021	18-24	Mauritius	Female	10	Cut down ^c	N/A	1	No (N/A)
P12	2021	25-34	India	Male	6	Cut down ^c	N/A	2	No (N/A)
P13	2021	18-24	United Kingdom	Male	10	Quit ^c	N/A	3	No (N/A)
P14	2021	18-24	United Kingdom	Male	8	Quit ^c	N/A	1	No (N/A)

^aFor participants recruited in 2021, age was measured as a range.

^bN/A: not applicable.

^cAscertained qualitatively during the interview.

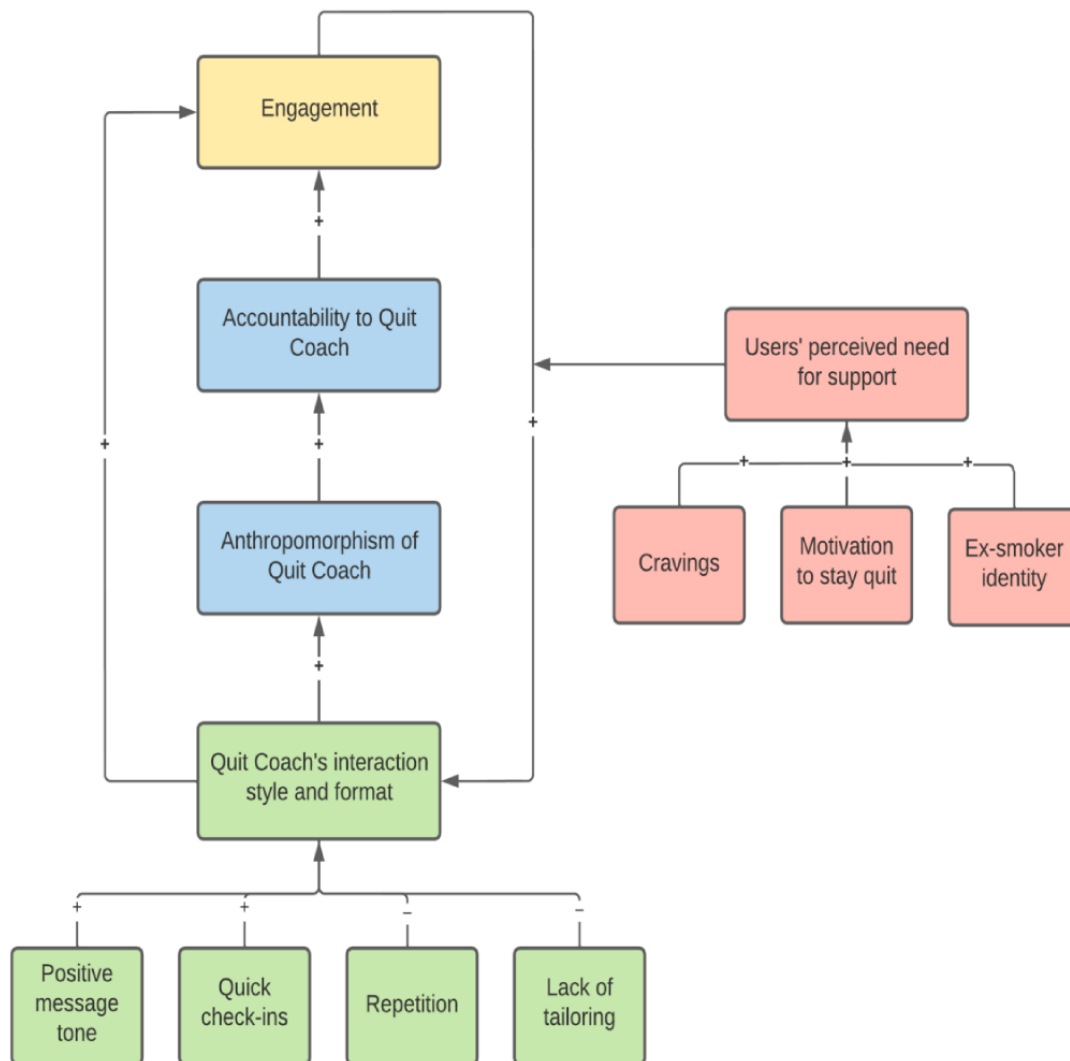

Themes

Overview

A total of three high-order themes were developed to capture the participants’ experiences with Quit Coach and the potential mechanisms underpinning user engagement: (1) anthropomorphism of and accountability to Quit Coach, (2) Quit Coach’s interaction style and format, and (3) users’ perceived need for support. Refer to [Multimedia Appendix 1](#)

for additional quotations. [Figure 2](#) presents a thematic map of the themes. Here, anthropomorphism of Quit Coach, which is influenced by its interaction style and format, and users’ perceived need for support leads to feelings of accountability and increased engagement. Continued engagement with Quit Coach reinforces this accountability through a bidirectional relationship. In addition to this indirect link, Quit Coach’s interaction style and format directly influences users’ engagement.

Figure 2. Thematic map. Arrows indicate the direction of relationships and the + and – signs indicate their valence. Blue boxes relate to theme 1, green boxes relate to theme 2, and red boxes relate to theme 3.

Anthropomorphism of and Accountability to Quit Coach

Many users ascribed human-like characteristics, thoughts, and behavior to Quit Coach—despite the awareness that it was fully automated—following an interaction experience (eg, colloquial language, GIFs, and emojis) that closely mimicked those with peers and family members via SMS text messages or WhatsApp. Users’ anthropomorphism of Quit Coach was evident from almost all users frequently referring to it as an embodied entity (ie, him, them, or someone) rather than an object (eg, it, Quit Coach, or chatbot):

It felt like you were really connected to someone. [P5; 2020; quit smoking]

Throughout this conversation I have referred to “someone” rather than “something” quite a few times, which I haven’t done on purpose. [P6; 2021; quit smoking]

Users compared Quit Coach’s motivational and monitoring support with that of close friends or family members. Consequently, users described feeling that Quit Coach *cared* about them, which helped foster a relational bond and promoted

a feeling of accountability to Quit Coach to succeed in cessation. Feeling that Quit Coach was fulfilling a supportive, social role justified the daily monitoring (ie, push notifications), which was experienced by some participants as very frequent, boring, or annoying. This social presence promoted continued app engagement, as users were motivated to succeed and willing to engage and cooperate with Quit Coach:

It felt like a friend or family member seeing how I was...It cared about whether I was smoking or not...You feel like you've got someone who cares enough [that you] stop. A reason not to... [P10; 2021; cut down smoking]

Many users even described Quit Coach's support as superior to human friends or family members, owing to its immediate availability, single purpose (ie, smoking cessation support), and nonjudgmental tone of voice (particularly when reporting a lapse) and the relationship being *1-way* (ie, users do not have to reciprocate support or worry about being boring or bothering Quit Coach). Such responses contradict the users' comparison of Quit Coach's support with that provided by friends or family members, indicating that they may instead have experienced the support as similar to that provided by a therapist or coach (ie, a 1-way rather than 2-way relationship). However, users' perceptions of Quit Coach's support as superior to that of human friends or family members appeared to serve as an advantage rather than to negate the human-like experience. A minority of users anthropomorphized Quit Coach to a lesser extent, owing to previous experience with using chatbots and great awareness of their synthetic nature. Nonetheless, they still embraced the support offered by Quit Coach:

[Friends/family] don't wanna talk about it every evening...To have the QC for that purpose [is helpful]...You're not always gonna be lucky enough to have someone who's just gonna be there to just listen to what you want to talk about on any given evening. [P6; 2021; quit smoking]

It's cool that he wasn't judgemental...He says "lots of people do smoke again when they start to stop but it doesn't mean that it's their loss and that they need to start all over again, it's just the first step"...The point is that long term you are trying not to smoke. [P8; 2021; cut down smoking]

Many users perceived having access to Quit Coach's thoughts and feelings, reporting that they worried that Quit Coach would feel angry, upset, or disappointed if they did not check in or reported a lapse and wanting to *please* it by checking in regularly. Consequently, many users felt positively accountable to Quit Coach for frequent engagement and abstinence. For example, many users reported feeling proud or particularly motivated to engage when they could report not smoking. In addition, most users reported feelings of worry or shame about Quit Coach's anticipated reaction if they had lapsed. For a few users, this caused an unintended consequence; their feelings were so significant that they reported completely avoiding checking in or lying in their reports. However, for most users, this anticipated worry or shame appeared to be beneficial, representing a source of motivation to stay quit. A few

participants who failed in their quit attempt over time reported that they started ignoring check-ins, possibly owing to negative avoidance as the prompts would remind them of their *failure*:

I wanted to find an opportunity to make it happy. [P3; 2020; quit smoking]

[I didn't want] to tell that [I smoked] to the robot every morning and every afternoon...I felt that I was accountable to it. [P11; 2021; cut down smoking]

Some self-contradiction was observed in how accountable users reported feeling to Quit Coach. At some time points during the interviews, users stated feeling accountable to Quit Coach, but at different time points, they stated feeling accountable to themselves, friends, or family members. This contradiction typically arose after being specifically prompted about accountability. Users may have retrospectively changed how accountable they felt to Quit Coach, because the interviewer brought to the fore that Quit Coach was not real, despite an anthropomorphic experience:

The accountability thing was definitely my relationship with [people] rather than my relationship with the app. [P6; 2021; quit smoking]

Quit Coach's Interaction Style and Format

Quit Coach's interaction style and format appeared to both directly and indirectly (ie, by giving rise to anthropomorphic experience of Quit Coach) influence users' engagement. Quit Coach's motivational and positive tone of voice encouraged many users to stay on track by reminding them of and praising them for their progress. GIFs and emojis were used alongside written text messages to create a positive mood and inject humor, thus enhancing the motivational and positive tone beyond that created through written text alone. Many users noted that the GIFs and emojis promoted a human-like perception of Quit Coach:

There was a certain level of wanting to go back and get those little GIFs or whatever...I was always glad to go and have a check-in. [P6; 2021; quit smoking]

Engagement was generally driven by Quit Coach prompting check-ins rather than by the users themselves. The prompts were perceived as useful, as users may otherwise have forgotten to check in. Most users reported that the daily check-in time requirement was acceptable; it did not take up much of their day. During working hours, some users felt that check-ins were sufficiently short to be manageable, whereas some users were very busy, preferring to complete check-ins before or after working hours. This was supported by the ability to set preferred check-in times. Where users reported check-ins being *long*, it typically referred to a subjective experience of *long*, which was linked to boredom and lack of interest, often driven by repetition, forced choice, or limited opportunities for free-text inputs. Many users reported that forced choice made engagement feel less burdensome (ie, easy and less time-consuming), which contributed to check-ins being "just the right amount of time" and was particularly welcome when users were craving cigarettes. In contrast, many users reported that forced-choice interactions quickly became boring as they could not express what they wanted more precisely (as they would with a human).

This reduced the interest in engagement with Quit Coach, with many users indicating a preference for typing free-text questions and responses:

[If you're] distracted by wanting a cigarette [it's] just easier if you've got options in front of you to just pick one. [P10; 2021; cut down smoking]

It was a bit...Samey. Sometimes I would just kind of click through it all and not have to react as much...You feel like you're just going through the motions a little bit rather than actually thinking about it. [P6; 2021; quit smoking]

Most users mentioned that they would have liked tailoring of the chatbot interactions on 2 levels. First, although Quit Coach broadly aligned with most users' cessation motivations, it did not discuss the specific personal motives that users had inputted elsewhere in the app. Second, many users wanted Quit Coach to remember more about what worked for them and modify the messages and advice accordingly. Although users did not report the lack of desired tailoring to be particularly detrimental to engagement, most users indicated that enhanced tailoring could have a positive impact. The ability to set check-in times according to personal preferences or anticipated times of need promoted engagement. Several users agreed that if Quit Coach could prompt them to engage before or during triggering situations, it would be very useful:

It wasn't really a tailored fit for myself. It talked about infertility and [that's] not something that bothers me. [P13; 2021; quit smoking]

A reminder of what I've done so far [that worked] would be helpful. [P9; 2021; cut down smoking]

[It] would've been great if...he could send me a notification at [or before a] time [of anticipating being triggered] saying "you're gonna be OK" or "you're gonna make it!" [P7; 2021; cut down smoking]

Users' Perceived Need for Support

For all users, the perceived need for support from Quit Coach appeared to be related to the frequency and intensity of cravings. Engaging with Quit Coach provided a useful behavioral alternative to smoking or attentional distraction from cravings. This was particularly helpful when check-ins aligned with strong cravings. In moments where users were not *smoking or thinking about smoking*, the need for support and, consequently, engagement interest appeared to be low. For some users, Quit Coach triggered cravings by reminding them of smoking:

It was [a] great thing to keep my hands [busy] [and] just give me time to let the craving pass. [P2; 2020; quit smoking]

When it was going well and when I didn't smoke I just didn't even use the app because I was OK...I was like I'm doing well so what can the app give me right now? [P8; 2021; cut down smoking]

As cravings reduced, users' perceived need for support decreased, leading to reduced engagement interest. However, several users recruited in 2020 (all of whom had successfully

quit smoking) reported engaging with Quit Coach even after their cravings reduced or disappeared. For these users, the need for support shifted from primarily needing a distraction from cravings to maintaining motivation to stay quit and reinforce ex-smoker identity. Self-selection bias may explain this prolonged engagement; users recruited in 2020 were already using Quit Coach, had successfully quit smoking, and self-identified as *heavy* Quit Coach users:

[Usage] kind of dwindles down to kind of extreme need, its more about the check-ins in the morning...The chatbot doesn't have much use now it's like ten weeks or something since I stopped. [P2; 2020; quit smoking]

For users recruited in 2021 who were unsuccessful in cessation, the motivation to engage with Quit Coach decreased after a period of *failing*. These users felt discouraged and despondent and did not want to be reminded of their *failure*. Interestingly, this was sometimes accompanied by a reversal of the anthropomorphic experience (eg, referring to Quit Coach as a *robot*):

[Not succeeding in quitting] made me resent – not resent, that's a big word – but made me not want to tell that to the robot every morning and every afternoon. [P11; 2021; cut down smoking]

Discussion

Principal Findings

Using a qualitative approach, this study aimed to explore smokers' experiences and engagement with a quick-response chatbot implemented within a popular smoking cessation app. Users' experiences with the chatbot were largely positive. Anthropomorphism of the chatbot (ie, ascribing human-like characteristics, thoughts, and behavior to the chatbot) was enabled by its specific interaction style and format (eg, positive message tone and quick and easy-to-complete check-ins) and users' perceived need for support, which appeared to give rise to feelings of accountability to the chatbot and increased engagement. Our results build on and extend previous qualitative findings pertaining to users' experiences with companion chatbots [20,29] to a chatbot specifically designed to support smoking cessation.

A previous experimental study has shown that social responses to computers—that is, a direct consequence of anthropomorphism—are common and relatively *easy* to generate (eg, by providing the computer with human-like attributes, such as a language output) [40]. However, according to the *uncanny valley hypothesis*, chatbot designers have a fine line to tread [41]. Strong feelings of affinity are generated by great human-like qualities in a robot or computer program up to a point. Once it becomes very similar to or indistinguishable from a real human, people's reactions can reverse because they may find them *creepy* or *eerie* [41]. Although the quick-response Quit Coach in this study was relatively simple (eg, it did not allow many free-text inputs from users) and made it clear to users that it is an automated bot, the presence of social cues (eg, its positive message tone and communication format similar to

text messaging with GIFs and emojis) appeared to be sufficient for generating social responses from many users without entering the territory of the uncanny valley. This is positive, as it implies that simple (and relatively low-cost) chatbots generate feelings of affinity and that more complex chatbots that can more closely mimic human interactions may not be necessary.

However, users mentioned that they would have liked it if Quit Coach tailored its questions and responses to their unique situations and momentary needs. Therefore, future studies would benefit from exploring—for example, through user-centered design activities and experimental studies—additional design elements that can enhance Quit Coach's similarity to humans, as this may further promote user engagement. In addition, some design elements appeared to detract from users' anthropomorphism of and engagement with Quit Coach, such as its repetitive questions and responses and forced-choice interactions. For users who struggled to stay quit, the repetitiveness and inflexibility of Quit Coach appeared particularly salient, sometimes leading to a reversal of the anthropomorphic experience. Previous studies indicate that users' perceived need for support and the target behavior itself (eg, progress toward smoking cessation) are important for continued engagement [9,10,15]. Similarly, high perceived need for support may be important for users to *suspend disbelief* and anthropomorphize conversational agents within the health care domain. The *Three-Factor Theory of Anthropomorphism* predicts that people are more likely to anthropomorphize nonhuman agents or objects (1) when anthropocentric knowledge is readily accessible and applicable (ie, when knowledge about how humans interact, think, and feel is judged as relevant for the interaction), (2) when motivated to be effective social agents (ie, motivation to master one's environment by increasing its predictability and controllability), and (3) when lacking a sense of social connection to other humans (ie, feeling lonely or isolated) [42]. Future studies would benefit from building on and empirically testing such a theory of anthropomorphism within the human-computer interaction domain, with a view to improving the design of future conversational and relational agents for health and well-being.

Our findings also lend partial support to the Model of Supportive Accountability [22] in that users reported feeling accountable to checking in and updating the nonjudgmental and supportive Quit Coach. Finding a balance between nonjudgmental tone of voice and human-like social cues to generate feelings of affinity and accountability (as discussed previously) may be important for future behavior change chatbots. However, trust and competence (which are additional cornerstones of the Model of Supportive Accountability) were largely missing from users' accounts. It is plausible that competence (eg, legitimacy of the information provided) and trust (eg, data security and confidentiality) were already assumed by users who had either voluntarily downloaded the Smoke Free app from a digital

marketplace—likely selecting an app they trusted among the myriad of available apps [15]—or were asked to download it based on recommendation from university researchers. Alternatively, trust and competence may not be necessary conditions for supportive accountability to arise within human-chatbot relationships; this should be further explored in future studies.

Strengths and Limitations

This study was strengthened by recruiting both experienced and novice app users, having a second coder to help in validating the coding, using external validation to ensure that the researchers' interpretations aligned with participants' narratives, and achieving theoretical saturation. However, this study also had several limitations. First, self-selection bias may limit the applicability of the findings to other populations and settings. For example, the 36% (5/14) of participants recruited in 2020 had quit smoking successfully and were considered as *heavy* Quit Coach users, and most participants were young (ie, aged 18-44 years). Second, we did not record any additional support used by participants during their quit attempts (eg, pharmacological support), which may have influenced their perceived need for support. Third, for pragmatic purposes, we did not record participants' actual engagement with Quit Coach, but instead relied on self-reports. Going forward, triangulation of qualitative and quantitative findings would be an important addition to the research literature. Fourth, the study was conducted during the COVID-19 pandemic—a time of significant change in people's life and work conditions, including their smoking behavior [43]—which may also limit the applicability of our findings to other periods and contexts.

Implications for Research and Practice

Findings from this study have both theoretical and practical implications. First, our results indicate that the Model of Supportive Accountability [22] may usefully be extended from human to *human-like* support within digital interventions. However, future studies should further explore the specific conditions under which chatbot interactions lead to feelings of accountability and whether accountability is more easily generated within human-to-human (rather than human-to-bot) interactions. Second, our findings suggest that chatbots for smoking cessation may benefit from including more variation in conversations to prevent boredom and incorporating different levels of tailoring (including context-sensitive tailoring).

Conclusions

Anthropomorphism of a quick-response chatbot implemented within a popular smoking cessation app appeared to be enabled by its interaction style and format (eg, positive message tone and quick check-ins) and users' perceived need for support, which may have given rise to feelings of accountability and increased engagement.

Acknowledgments

OP receives salary support from Cancer Research UK (C1417/A22962). AA, KS, JB, and OP are members of Shaping Public Health Policies to Reduce Inequalities and Harm—a UK Prevention Research Partnership Consortium (MR/S037519/1). The authors gratefully acknowledge the funding.

Data Availability

Participants did not provide consent for their anonymized transcripts to be shared openly. Therefore, the qualitative data underpinning the analyses are available to bona fide researchers upon reasonable request.

Conflicts of Interest

JB has received unrestricted funding to study smoking cessation outside the submitted study from Johnson & Johnson and Pfizer, who manufacture smoking cessation medications. JB and OP are unpaid members of the scientific advisory board for the Smoke Free app.

Abstract

Background: In recent years, there has been increasing interest in implementing digital technologies to diagnose, monitor, and intervene in substance use disorders. Smartphones are now a vehicle for facilitating telepsychiatry visits, measuring health metrics, and communicating with health care professionals. In light of the COVID-19 pandemic and the movement toward web-based and hybrid clinic visits and meetings, it has become especially salient to assess phone ownership among individuals with substance use disorders and their comfort in navigating phone functionality and using phones for mental health purposes.

Objective: The aims of this study were to summarize the current literature around smartphone ownership, smartphone utilization, and the acceptability of using smartphones for mental health purposes and assess these variables across two disparate substance use treatment sites.

Methods: We performed a focused literature review via a search of two academic databases (PubMed and Google Scholar) for publications since 2007 on the topics of smartphone ownership, smartphone utilization, and the acceptability of using mobile apps for mental health purposes among the substance use population. Additionally, we conducted a cross-sectional survey study that included 51 participants across two sites in New England—an inpatient detoxification unit that predominantly treats patients with alcohol use disorder and an outpatient methadone maintenance treatment clinic.

Results: Prior studies indicated that mobile phone ownership among the substance use population between 2013 and 2019 ranged from 83% to 94%, while smartphone ownership ranged from 57% to 94%. The results from our study across the two sites indicated 96% (49/51) mobile phone ownership and 92% (47/51) smartphone ownership among the substance use population. Although most (43/49, 88%) patients across both sites reported currently using apps on their phone, a minority (19/48, 40%) reported previously using any apps for mental health purposes. More than half of the participants reported feeling at least neutrally comfortable with a mental health app gathering information regarding appointment reminders (32/48, 67%), medication reminders (33/48, 69%), and symptom surveys (26/45, 58%). Most patients were concerned about privacy (34/51, 67%) and felt uncomfortable with an app gathering location (29/47, 62%) and social (27/47, 57%) information for health care purposes.

Conclusions: The majority of respondents reported owning a mobile phone (49/51, 96%) and smartphone (47/51, 92%), consistent with prior studies. Many respondents felt comfortable with mental health apps gathering most forms of personal information and with communicating with their clinician about their mental health. The differential results from the two sites, namely greater concerns about the cost of mental health apps among the methadone maintenance treatment cohort and less experience with downloading apps among the older inpatient detoxification cohort, may indicate that clinicians should tailor technological

interventions based on local demographics and practice sites and that there is likely not a one-size-fits-all digital psychiatry solution.

Introduction

Handheld phones evolved at a lightning pace over the past 2 decades. Once devices that were solely used to text or call, smartphones now connect millions through social media, track health metrics, and have GPS-sensing capabilities. Smartphones also have a burgeoning role in telepsychiatry, which has been widely adopted during the COVID-19 pandemic. Tens of thousands of mental health apps are available through app stores. Digital phenotyping, which involves using passively and continuously collected sensory and user data to track movement, phone utilization, and communication, has potential apps for relapse prediction in schizophrenia [1], relapse prediction in bipolar disorder [2], and depressive episode detection [3].

Smartphone apps have expanded and can be used for the diagnosis, monitoring, and treatment of substance use disorders [4]. For instance, Reset-O is the first US Food and Drug Administration–approved prescription mobile app for the treatment of opioid use disorder with evidence of improving abstinence and treatment retention [5]. Additionally, a smartphone app may be able to detect an opioid overdose by using a short-range active sonar [6]. Further, A-CHESS (Addiction-Comprehensive Health Enhancement Support System) is a mobile app suite that buttresses alcohol recovery through features such as delivering alerts to patients when they approach known triggers, such as a bar or liquor store, via GPS [7].

With smartphones playing an increasingly integral role in the delivery of substance use care, addressing equity and understanding the adoption and utilization of smartphones and the acceptability of related technologies have become ever more pressing. We performed a nonsystematic review of literature around smartphone ownership and utilization among individuals with substance use disorders, and we present original data from our 2-site, cross-sectional survey study assessing smartphone ownership, smartphone utilization, and the acceptability of using mental health apps. We hypothesize that a vast majority of individuals own smartphones and would be open to using smartphone apps to address substance use. The aim of this study is to inform clinicians who plan to develop or implement digital interventions for patients with substance use disorders on how to anticipate and optimize adoption and engagement.

Methods

Literature Review

The purpose of the literature review was to identify articles that assessed smartphone or phone ownership and/or utilization to

answer the following questions: what proportion of patients with substance use disorders own mobile phones or smartphones, how did they utilize their phones, and how open were they to mobile health (mHealth) intervention through smartphones?

A nonsystematic search was conducted in January 2022 within PubMed and Google Scholar, using the key terms *smartphone ownership*, *phone ownership*, *access to a mobile phone*, *access to a smartphone*, *substance use disorder*, *addiction*, and *substance abuse*, by two independent researchers. The selected publication types included primary survey or questionnaire studies, systematic or nonsystematic reviews, and secondary research studies based on prior survey or census data published in or after 2007 (the year that the Apple iPhone was introduced). Other inclusion criteria included articles written in the English language and participants with substance use disorders. The exclusion criteria included clinical trials of specific digital interventions, such as a smartphone app, as the purpose of this study was to understand general smartphone ownership and use. Other exclusion criteria included papers written in foreign languages and studies on participants with behavioral addictions, such as internet gaming disorder, internet addiction, or gambling disorder, as opposed to substance use disorders. A total of 8 abstracts were identified by using these criteria. Study purposes, study designs, descriptions of methods, sample sizes, sample demographics, smartphone or phone ownership rates, and smartphone utilization and acceptability data were extracted.

Cross-sectional, 2-Site Survey Study

We developed a survey that closely mirrored the one developed by Torous et al [8] (Textbox 1). The 5- to 10-minute survey was completed via paper and pencil and included sections on demographics, phone ownership, phone utilization, and the acceptability of using phones for mental health care purposes. Surveys were administered between June 2021 and February 2022 at two sites—a level 4 inpatient detoxification unit at a community hospital in Massachusetts (Brigham and Women's Faulkner Hospital [BWFH]) that predominantly treats individuals with alcohol use disorder and an outpatient methadone clinic in Rutland, Vermont (West Ridge Clinic). Participants were offered a US \$5 *Dunkin' Donuts* gift card for completing this study. There was a total of 51 participants from both sites—22 from the inpatient detoxification unit and 29 from the outpatient methadone clinic. Descriptive statistics were used to summarize the data; all analyses were performed by using Stata Statistical Software: Release 17 (StataCorp LLC). Demographic and mobile phone use variables for those at the detoxification unit and those at the outpatient methadone clinic were compared by using a chi-square test for categorical variables and a 2-tailed Student *t* test for continuous variables.

Textbox 1. Survey questions. Demographic questions are excluded.

Questions

1. Do you currently own any type of phone?
 - If no, for what reason do you not have a phone?
2. Is your phone a smartphone (eg, iPhone, Android, etc)?
3. What is the name of your smartphone (eg, Samsung Galaxy)?
4. How comfortable are you sending text messages on your phone?
5. What type of payment plan do you use for text messages?
6. Do you download apps onto your phone?
7. Have you ever downloaded an app for your mental health?
8. Do you currently use any apps for your phone?
9. How comfortable or uncomfortable would you feel about a mental health app gathering and/or sending the following data from your smartphone to your clinician in the context of your care?
 - Appointment reminders
 - Medication reminders
 - Symptom surveys (eg, survey questions about your mood or thoughts throughout the day)
 - Your location (phone GPS sensor)
 - Your social information (call and text logs without any phone numbers or context of messages; eg, how many people you called and for how long)
 - Coaching for healthy living (eg, exercise, sleep, and diet)
 - Mindfulness or therapy exercises
 - Communicating with my clinician about my mental health
10. Select up to 3 top concerns you may have about mental health apps or apps for substance use disorders:
 - Privacy
 - Accuracy of recommendations from app
 - Hard to use
 - Sharing information with clinician
 - Cost
 - Time
 - Hard to set up
11. Select up to 3 top benefits you may see in mental health apps or apps for substance use disorders:
 - Privacy
 - Accuracy of recommendations from app
 - Easy to use
 - Sharing information with clinician
 - Cost
 - Time
 - Easy to set up

Ethical Considerations

This study was approved and monitored by the Mass General Brigham Institutional Review Board (approval number 2020P001656) and Rutland Regional Hospital Institutional Review Board (approval number 2020P001656/RRMC24). This

study was identified as human subjects research and was classified as exempt by the Mass General Brigham Institutional Review Board, given the minimal risk to subjects and the use of a survey tool with no identifiable information obtained. This study adheres to the ethical guidelines set forth by the Mass

General Brigham Human Research Protection Program [9]. Participants were consented prior to the survey study and were given the choice to opt out of specific questions or this study entirely at any time. No personal health or identifiable information was recorded.

Results

Participant Characteristics

For the inpatient detoxification cohort, the study team approached 35 participants, of whom 25 consented to answering the survey and 22 completed it (response rate: 22/35, 63%). Further, 2 participants were discharged from detoxification prior to completion, and 1 participant dropped out.

The BWFH inpatient detoxification sample skewed toward male (12/22, 55%) and White (20/22, 91%) patients, and the West Ridge Clinic sample skewed toward female (18/29, 62%) and White (23/29, 79%) patients (Table 1). Notably, the West Ridge Clinic had a relatively higher proportion of individuals experiencing homelessness (10/28, 36%) compared to that of the inpatient detoxification clinic (1/22, 5%), though this did not reach statistical significance ($P=.10$). There were no additional differences in demographics between the two clinic sites except for the fact that the mean age at the methadone maintenance treatment (MMT) clinic was significantly lower (48.71 vs 36.04 years; $P<.001$).

Table 1. Summary of participant demographic characteristics (N=51).

Variable	All participants (N=51)	BWFH ^a inpatient detoxification clinic (n=22)	West Ridge Clinic (n=29)	P value

Phone Ownership in the Substance Use Population

Prior studies indicated that mobile phone ownership among the substance use population from 2013 to 2019 ranged from 83% to 94%, while smartphone ownership ranged from 57% to 94% [10-17] (Table 2). Individuals of the baby boomer generation (aged >52 years) may be less likely to own a mobile phone with app capability when compared to Generation X (age: range 36 to 51 years; $P=.001$; odds ratio 3.52, 95% CI 1.65-7.52) and

millennials (age: range 18 to 35; $P<.001$; odds ratio 4.53, 95% CI 2.19-9.35) [14].

In our study, a large proportion of respondents reported owning a mobile phone (49/51, 96%) and smartphone (47/51, 92%). All patients (22/22, 100%) at the inpatient detoxification clinic reported owning a mobile phone, while 27 of 29 patients (93%) reported owning a mobile phone at the outpatient methadone clinic. Of the 49 respondents who owned mobile phones across both sites, 47 (96%) categorized them as smartphones; 2 participants opted out of this question.

Table 2. Mobile phone and smartphone ownership among individuals with substance use disorders across studies.

Authors, year	Patient population	Sample size, N	Mobile phone ownership, %	Smartphone ownership, %
McClure et al, 2013 [16]	Adult patients who were undergoing substance abuse treatment and were enrolled at 8 drug-free psychosocial or opioid-replacement therapy clinics in Baltimore	266	91	N/A ^a
Dahne and Lejuez, 2015 [12]	Adult patients admitted to a residential substance use treatment center in Washington, District of Columbia	251	86.9	68.5
Tofighi et al, 2015 [17]	Adult patients with opiate dependence in an urban, safety-net office-based buprenorphine program in New York City	71	93	63

Tofighi et al, 2019 [15]	Adult patients enrolled in an inpatient detoxification program at a safety-net tertiary referral center in New York City	206	86	66

^aN/A: not applicable.

Phone Utilization in the Substance Use Population

Based on our review of the literature, 79% to 96% of individuals with substance use disorders have phones with text messaging capabilities [12,15,16], with one study published in 2015 suggesting that 55% of mobile phone owners use their phones to text daily [13]. Between 61% to 68% of individuals use their mobile phones to access the internet [10,12,15], and 61.3% of adult smartphone owners use mobile apps on their phones [12]. One study found that of individuals who accessed the internet, 80% accessed it primarily through their mobile phones, with no generational differences in terms of using phones to access the internet versus other means [14]. Masson et al [11] concluded that 40% (n=70) of their participants used their mobile devices as a reminder to take medications, while 8% (n=13) of smartphone users utilized a medication reminder app. McClure et al [16] found that 44% of their adult participants reported being called by substance use clinic staff, while 0.4% reported being texted by them.

Patients were also asked about their mobile phone use patterns in our study (Table 3). Nearly all patients across both sites (45/49, 92%) reported feeling extremely, very, or somewhat comfortable with sending text messages. Of the 47 patients who reported their type of text message payment plan, most (42/47, 89%) reported paying a flat fee for unlimited text messages. The remaining 5 patients reported either paying a flat fee for a limited text message plan (2/47, 4%) or using a pay-per-text plan (3/47, 6%). The majority of respondents (43/49, 88%) reported having downloaded apps, although this differed significantly across sites (West Ridge Clinic patients: 26/27, 96%; inpatient detoxification clinic patients: 17/22, 77%; $P=.04$). Although most patients (43/49, 88%) across both sites reported currently using apps on their phone, only a minority (19/48, 40%) reported having previously used any app for their mental health; this did not differ significantly across sites ($P=.21$).

Table 3. Mobile phone use patterns (N=51).

Variable	All participants (N=51), n (%)	BWFH ^a inpatient detoxification clinic (n=22), n (%)	West Ridge Clinic (n=29), n (%)	P value
Mobile phone ownership	49 (96)	22 (100)	27 (93)	.21

^cTwo participants did not answer questions regarding their comfort with sending text messages.

^dFour participants did not answer questions regarding their current text message payment plan.

^eTwo participants did not answer questions regarding downloading apps onto their phones.

^fThree participants did not answer questions regarding their comfort with mental health apps gathering personal information.

Acceptability of Using Smartphones for Mental Health Purposes

Based on our review of the literature, 70.4% of adult participants in one study stated that they would use a relapse prevention app [14], though a different study by Curtis et al [10] suggested that 36.9% of millennials and 45.3% of the Generation Z population thought that a mobile phone app would be helpful toward recovery. In another study, 46% of participants found it unacceptable to use geolocation in a smartphone app for health care purposes [13], but 86% of surveyed adults were willing to be contacted via mobile phone by their clinicians, with telephone calls (53%) being the most preferred method when compared to text messages (41%) and letters (41%) [13]. The most preferred frequency of contact was 1 to 2 messages weekly (46%) [13]. Further, 72% of adults surveyed by Ashford et al [14] in 2018 reported that it was acceptable to receive text messages for relapse prevention. Curtis et al [10] found that 28.8% of millennials and 45.3% of the Generation Z population thought that texting could be helpful toward recovery.

Over half of all participants at both sites were at least neutrally comfortable with a mental health app gathering information

regarding appointment reminders (32/48, 67%), medication reminders (33/48, 69%), and symptom surveys (26/45, 58%). Most participants also found it acceptable to use mental health apps to engage in coaching for healthy living (27/48, 56%), mindfulness or therapy exercises (31/48, 65%), and communication with their clinician about their mental health (30/48, 62%). Notably, most of our sample expressed concerns about privacy (34/51, 67%) and reported being uncomfortable with an app gathering information about location (29/47, 62%) and social information (27/47, 57%) for health care purposes. The top three noted concerns about using mental health apps were privacy, cost, and time; patients at the outpatient methadone clinic were significantly more likely to perceive cost as a top-three concern (13/29, 45% vs 2/22, 9%; $P=.006$). Overall, the top three perceived benefits of using mental health apps or apps for substance use disorders were ease of use, the ability to share information with clinicians, and time. Patients at the outpatient methadone clinic were also more likely to perceive ease of setup as a benefit of using such apps (14/29, 48% vs 4/22, 18%; $P=.03$). The acceptability results are summarized in Table 3 and Figures 1-3.

Discussion

Principal Findings

The overall rate of mobile phone ownership was 96% (49/51), and the overall rate of smartphone ownership was 92% (47/51). The participants recruited at the community inpatient detoxification site were overall older (mean 48.71 vs mean 36.04 years; $P < .001$), and a greater percentage were housed. Participants at the MMT clinic were more likely to report downloading apps when compared to the detoxification sample (26/27, 96% vs 17/22, 77%; $P = .04$), which could be potentially explained by the younger mean age of the methadone cohort (36.04 vs 48.71 years; $P < .001$) [18]. Most patients (43/49, 88%) reported regularly downloading and using apps on their phone, although only 40% (19/48) reported ever downloading an app specifically for mental health or substance use disorder purposes.

A majority of participants across both clinic sites indicated feeling comfortable with mental health apps gathering most forms of personal information, specifically appointment reminders (32/48, 67%), medication reminders (33/48, 69%), symptom surveys (26/45, 58%), coaching for healthy living (27/48, 56%), mindfulness or therapy exercises (31/48, 65%), and communications with their clinician about their mental health (30/48, 62%). Most individuals were uncomfortable with a mental health app tracking location (29/47, 62%) or social information (ie, their call and text logs; 27/47, 57%). The differential views on cost as a barrier to using a mental health app across the two sites (methadone clinic: 13/29, 45%; inpatient detoxification clinic: 2/22, 9%; $P = .006$) might reflect socioeconomic differences across the cohorts. As previously mentioned, the MMT sample had a relatively higher proportion of individuals experiencing homelessness (10/28, 36%) compared to that of the inpatient detoxification sample (1/22, 5%), though the comparative rates of homelessness across the

two samples did not reach statistical significance ($P=.10$). Most participants cited privacy (34/51, 67%) as a primary concern with using mental health apps and reported that they would not be comfortable with geolocation (29/47, 62%) or social information tracking (27/47, 57%). The participants recruited at the MMT site were significantly more likely to perceive the ease of setting up a mobile app as a perceived benefit when compared to those of the inpatient detoxification unit (14/29, 48% vs 4/22, 18%; $P=.03$), which may again speak to participants at the MMT clinic being more comfortable with using app functionalities.

Overall, our cross-sectional study suggests that individuals with substance use disorders are generally amenable to using a smartphone app for mental health monitoring or treatment purposes. Interestingly, while smartphone ownership was slightly lower among participants in the MMT site compared to that among the detoxification site participants, which is unsurprising given that the participants at the MMT site were of lower socioeconomic status, our data suggest that the individuals recruited at the MMT site had higher digital literacy, as reflected by their comfort with downloading apps and their perception that ease of use is a benefit of using a mental health app for substance use interventions. In conclusion, clinicians should consider patient demographics, digital literacy, and practice sites when implementing mHealth interventions for substance use disorders in an equitable fashion.

Comparison to Prior Work

To our knowledge, this study represents the first literature review of smartphone ownership, smartphone utilization, and the acceptability of using mHealth among individuals with substance use disorders and the first cross-sectional survey study to address this topic since the beginning of the COVID-19 pandemic. Smartphone and mobile phone ownership rates in our cross-sectional survey study were higher than those reported in all prior studies, likely reflecting the growing adoption of smartphones. Overall rates of downloading apps across both survey sites (43/49, 88%) were also higher than the 61% to 64% of participants who reported downloading mobile apps in a study by Dahne and Lejuez [12], which recruited patients from 2014 to 2015. The proportion of participants who felt uncomfortable with location being tracked (29/47, 62%) was slightly higher than that reported by Milward et al [13]. Comfort with utilizing specific functions of apps for substance use disorders, such as appointment reminders or social functions,

and specific perceived benefits of using mobile apps for substance use disorders were not assessed in prior studies of individuals with substance use disorders.

Strengths and Limitations

This study has several limitations. First, we performed a brief, nonsystematic review, and it is likely that relevant papers may not have been included. We attempted to strengthen the robustness of this focused literature review by utilizing two independent reviewers, two separate search engines, and broad key words to capture and screen more abstracts. Future works should incorporate a PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses)-based systematic review to capture a broader range of studies. Second, the relatively small sample of our cross-sectional survey study precluded our ability to explore the impacts that race, socioeconomic status, age, and other factors have on smartphone ownership, utilization, and acceptability. Third, the predominantly White sample, especially the predominantly White inpatient detoxification cohort, limits the generalizability of this study. However, we recruited from two disparate clinical sites in two very different geographic locations to expand the diversity of recruited participants. Fourth, the degree of selection bias among our outpatient methadone clinic cohort is difficult to assess without ascertaining a survey response rate and consequently may impact the reliability of our results. However, we were able to obtain a survey response rate among individuals at our inpatient detoxification site. Those who turned down the survey at the inpatient detoxification site were asleep, were medically unwell, or were preoccupied at the time of survey distribution.

Future Directions

Future work in this area should include larger patient populations across various sites, which might include non-methadone outpatient substance use clinics. Further, in vivo, randomized controlled studies of promising mental health apps for substance use disorders are needed to establish clinical efficacy. Studies clarifying the effects of socioeconomic status, race, and other factors on digital literacy, smartphone utilization, smartphone ownership, and the acceptability of using apps for substance use interventions among individuals with substance use disorders are needed. Privacy and security concerns around mental health apps will need to be addressed, especially given that individuals with mental health and substance use disorders are particularly vulnerable.

Abstract

Background: Digital technology, the internet, and social media are increasingly investigated as promising means for monitoring symptoms and delivering mental health treatment. These apps and interventions have demonstrated preliminary acceptability and feasibility, but previous reports suggest that access to technology may still be limited among individuals with psychotic disorders relative to the general population.

Objective: We evaluated and compared access to and use of technology and social media in young adults with psychotic disorders (PD), young adults with clinical risk for psychosis (CR), and psychosis-free youths (PF).

Methods: Participants were recruited through a coordinated specialty care clinic dedicated toward early psychosis as well as ongoing studies. We surveyed 21 PD, 23 CR, and 15 PF participants regarding access to technology and use of social media, specifically Facebook and Twitter. Statistical analyses were conducted in R. Categorical variables were compared among groups using Fisher exact test, continuous variables were compared using 1-way ANOVA, and multiple linear regressions were used to evaluate for covariates.

Results: Access to technology and social media were similar among PD, CR, and PF participants. Individuals with PD, but not CR, were less likely to post at a weekly or higher frequency compared to PF individuals. We found that decreased active social media posting was unique to psychotic disorders and did not occur with other psychiatric diagnoses or demographic variables. Additionally, variation in age, sex, and White versus non-White race did not affect posting frequency.

Conclusions: For young people with psychosis spectrum disorders, there appears to be no “technology gap” limiting the implementation of digital and mobile health interventions. Active posting to social media was reduced for individuals with psychosis, which may be related to negative symptoms or impairment in social functioning.

KEYWORDS

social media; psychosis; clinical high risk; technology; digital health

Introduction

Digital Health in Psychiatry

The increasing availability of technology has opened a new avenue for making health care more accessible to a broader population and for the development and implementation of digital interventions. In recent years, mobile and web-based health interventions have been used with great promise to assess and coordinate with mental health clients [1]. Social media and mobile health interventions present a unique opportunity to engage young people experiencing the emergence of a psychotic disorder (PD) or at clinical risk (CR) for psychosis, when there are clinically significant symptoms of psychosis, but threshold criteria are not yet met. The importance of early intervention and prevention in psychosis is a key factor in long-term success, and it has been shown that decreasing the duration of untreated psychosis increases long-term treatment outcome [2,3].

Mobile and social media interventions and assessment tools are relatively new in psychiatry, but initial studies show promising engagement, efficacy, and prognostic utility [4,5]. For example, a classification model based on social media language was able to identify early relapse signs for people experiencing first episode psychosis [6]. Relapse events were also predicted in another study by changes in smartphone-enabled social activities [7]. Among interventions, patients with PD benefitted from a combined treatment protocol involving monitoring via mobile health interventions and psychosocial services. Digital social networks have been integrated into mobile health apps to facilitate peer support and improve amotivation symptoms [8]. Other promising mobile health interventions include reminders for medication adherence and appointments, interventions, and case management via SMS text messages and apps on a smartphone. Mobile interventions can also vary from standardized communication to live interactions with clinicians; for example, the patient can have live sessions with a therapist via videoconferencing or SMS text messaging, or they can receive standardized communications like prerecorded videos, and tip sheets based on their input at the time of communication [9].

Access to Technology

Access to technology among the target population is critical for the feasibility of mobile and social media-based interventions. Globally, access to technology has increased dramatically across all age groups, but a “technology gap” may exist for individuals at risk for or diagnosed with psychotic disorders [2]. Among adult patients recruited from an inpatient and outpatient clinic, only 48% have access to the internet, and only 27% used social networking sites on a daily basis [10]. However, younger age may be associated with greater access to technology. In one study of young people in their first episode of psychosis, 100% used social media, and 90% of those reported daily use for an average of about 2 hours daily [5]. Another study completed in Spain showed that patients with first episode psychosis had similar interest in but decreased access to digital technologies including computers and smartphones [11]. If young people with psychosis commonly access digital technology and social media, it would provide an avenue for outreach, and could be

a method of monitoring symptoms and side effects and providing treatment.

Objective

To our knowledge, no study has directly compared access to and use of technology and social media across the psychosis spectrum among CR, PD, and psychosis-free (PF) youths. Most studies also do not distinguish between passive access of social media and active posting. In this study, we surveyed CR and PD youths and PF comparison participants about their access to digital technology, the internet, and both access and posting to Facebook and Twitter. We hypothesized that the “technology gap” is decreased or absent among young adults with psychosis and clinical risk for psychosis, suggesting that social media and mobile health interventions would be feasible and implementable in this population.

Methods

Participants

For this study, three groups were evaluated: PD, CR, and PF. A total of 59 participants aged 18-32 years were included. PD participants were recruited from the University of Pennsylvania Psychosis Evaluation and Recovery Center, a coordinated specialty care clinic dedicated toward early psychosis. CR and PF participants were recruited among participants of other ongoing studies at the University of Pennsylvania and Children’s Hospital of Philadelphia Lifetime Brain Institute. We were interested in the main effect of psychosis on access to technology and use of social media. Because mental health disorders are common in the community for young adults and adolescents [12], our PF comparison group did not exclude people with nonpsychotic disorders.

All stable outpatients at the Psychosis Evaluation and Recovery Center aged 18-35 years as well as potential participants in Lifetime Brain Institute studies were approached and asked for their consent to participate in this survey as a screening procedure for larger studies. Participants all resided in the greater Philadelphia area, which includes both an urban and surrounding suburban environment. There was no remuneration for completing this survey. Several eligible individuals were not interested in research in general, but no one specifically refused to participate in this survey. This was a brief single timepoint assessment and no one withdrew prior to its completion.

Ethics Approval

All procedures were approved by the Institutional, Review Board at the University of Pennsylvania under protocol 831509, and the Children’s Hospital of Philadelphia, protocol number 16-013305.

Study Design and Assessments

The survey was completed verbally with a research coordinator either in person or over the telephone. Individuals who agreed to participate were surveyed via a questionnaire regarding their access to technology and use of social media (Facebook and Twitter). Access to technology was defined generally as the ability to use the technology in a dependable manner, including

personal ownership, shared devices, and public access points. Active posting was defined as commenting, posting status updates, or otherwise contributing original content, versus passive access of social media, which includes scrolling, viewing, or liking. We did not distinguish between accessing the internet via Wi-Fi or a data plan.

The PF and CR groups underwent semistructured interviewing with the Structured Interview for Prodromal Syndromes, which assessed threshold and subthreshold symptoms of psychosis. Determination for CR or PF status was made by consensus case conference. The PD group underwent consensus clinical diagnosis by psychiatrists and psychologists specializing in psychotic disorders and were determined to have one of the following Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5) psychotic disorders: schizophrenia ($n=13$), schizoaffective disorder ($n=4$), bipolar I disorder with psychotic features ($n=1$), or unspecified psychotic disorder ($n=3$). Comorbid nonpsychotic disorders were evaluated based on DSM-5 criteria and were also present in all 3 groups, in proportion to expected population rates.

Statistical Analysis

Statistical analyses were conducted in R (version 3.5.2; R Foundation for Statistical Computing). Categorical variables were compared among groups using Fisher exact test, including the main outcomes of technology access and posting frequency versus group. Fisher exact test was also used to compare social media access and posting rates for other diagnoses as well as for sex and race effects. Age differences among the groups and between active versus nonactive users were compared using 1-way ANOVA. To account for group differences in age, sex, and race, we additionally performed logistic regressions predicting social media access and posting with group as the

independent variable of interest, and covarying for the demographic variables. Significance was 2-tailed with $\alpha=.05$.

Results

Table 1 displays details for 21 PD, 23 CR, and 15 PF participants. There was uniformly high access to mobile phones (96%-100%, $P>.99$), smartphones (95%-100%, $P>.99$), computers (85%-95%, $P=.84$), and the internet (95%-100%, $P=.61$). The majority of young adults accessed Facebook, but not Twitter. Social media access rates were similar for all 3 groups (62%-74% at least weekly, $P=.73$). However, there was a significant main group effect for social media posting (5%-43% at least weekly, $P<.009$). CR actively posted at a similar rate compared to PF individuals (CR 43% vs PF 27%, $P=.31$), but PD actively posted at a significantly lower rate than the nonpsychotic groups (5%, $P<.01$). When examining Facebook use alone, as this was the platform with the most users, we found consistent results: access was not affected by psychosis group ($P>.99$), but there was a significant main effect for group on posting ($P=.02$). When covarying for sex, age, and race, psychosis diagnosis remained a significant predictor of decreased active social media posting (standardized $\beta=-1.22$, $P=.03$), but it was not a significant predictor for social media access (standardized $\beta=-0.29$, $P=.40$).

Decreased active social media posting was unique to psychotic disorders and there was no group effect for diagnosis with attention-deficit/hyperactivity disorder ($P=.67$), mood ($P=.54$), or anxiety disorders ($P>.99$) when comparing prevalence of weekly or greater use. Variation in age ($P=.63$), sex ($P=.13$), and White versus non-White race ($P=.77$) did not affect posting frequency.

Table 1. Sample characteristics, access to technology, and social media use.

Variable	PF ^a (n=15)	CR ^b (n=23)	PD ^c (n=21)	P value
Age (years), mean (SD)	23.5 (4.2)	22.0 (2.9)	24.2 (3.4)	.10

^aPF: psychosis-free.

^bCR: clinical risk for psychosis.

^cPD: psychotic disorder.

Discussion

Principal Findings

We found that youths with PD and CR who participate in our clinical care and research programs have similar access to technology and use social media to a similar degree compared with PF individuals. This supports the feasibility of mobile health and social media interventions in young CR and PD populations in terms of access to technology. Our results were consistent with those found in previous studies, which showed that the use of digital technology in the treatment of people with psychosis spectrum disorder and other chronic serious mental illnesses is a viable method of delivery of services. In our study, the absolute rate of mobile phone and smartphone ownership

and internet use was higher than those reported by Young et al [13], likely because of the younger age of our participants. Most previous studies have compared access to technology between mental health clients and published normative data for the general population but have not directly compared across groups using a consistent standardized methodology. One study directly compared the use of (not access to) technology between patients with first episode psychosis and healthy control subjects; they found significant but small to moderate effects of decreased frequency of use for computers, tablets, smartphones, and smart televisions (but not game consoles) [11]. However, it is unclear whether demographic differences may have accounted for some of the disparity. No studies have included a psychosis clinical risk comparison group.

Another relevant consideration is comfort with technology among clinicians. A recent study by Camacho and Torous [14] surveyed 42 Coordinated Specialty Care clinics and found that health care providers were supportive of implementing technology in their care model for early psychosis; although 69% of surveyed staff were confident in their ability to provide technical assistance for others, 78% indicated that additional digital skills training would be beneficial.

We also found a psychosis-specific decrease in active social media posting. Social cognitive impairments and negative symptoms may contribute to this finding. This interpretation is supported by a study by Rehki et al [15] showing that an increase in severity of negative symptoms is associated with a lower likelihood of social media use. In that study, they suggested that social interactions via social media should be considered in the clinical evaluation of individuals with schizophrenia, as it is a prominent form of communication and fostering relationships. Although individuals with CR may also experience significant negative symptoms, our results suggest that these are not reflected in significant changes in social media posting and access rates. Although youths with PD post significantly less frequently than youths with CR and PF, individuals with PD nevertheless access social media at a similar rate, which provides a potential avenue for intervention. To our knowledge, no other study has distinguished between social media access and posting, so we are the first to report a decrease in social media posting for individuals with psychotic disorders while there was no difference in level of passive use of social media. This effect did not appear with mood disorders, attention-deficit/hyperactivity disorder, and anxiety, and therefore appears to be specific to psychosis.

Limitations of this study include sampling of one geographical area and limited sample size. Socioeconomic status may also

influence access to technology but was not consistently measured in this sample. It is possible that patients with access to a specialized psychosis treatment center and those who volunteer for research participation may have higher access to technology than the general population of people with psychosis. Moreover, our survey only included two social media platforms, Facebook and Twitter. Future studies may consider including access and use of other social media platforms that have recently become more popular among youths, as well as questions about their willingness to share their digital access and to receive therapeutic interactions via a digital platform. Objective usage statistics and other metadata may also provide useful signals. Privacy risks and concerns may also be technical as well as subjective barriers to implementation of such interventions. These were not addressed with this study.

Conclusions

Overall, our findings encourage further development of mobile health and social media-based interventions and monitoring for young people with psychosis and youths at clinical risk for psychosis. There appears to be no significant “technology gap” for young people with psychotic disorders relative to young people without psychosis. Lower active engagement may reflect impairments in social cognition and functioning. Notably, access to technology does not mean that digital health interventions will be ultimately efficacious or implementable—however, the availability of technology to young people with psychosis does provide some basis for feasibility. Future studies are needed to directly evaluate the efficacy and usability of digital health and social media-based strategies for intervention and assessment, while considering additional potentially harmful effects related to privacy concerns and increased time spent on social media.

Acknowledgments

Abstract

Background: Despite their growing popularity, there are very few mobile health (mHealth) interventions for Aboriginal and Torres Strait Islander people that are culturally safe and evidence based. A co-design approach is considered a suitable methodology for developing health interventions with Aboriginal and Torres Strait Islander people.

Objective: The aim of this study was to co-design an mHealth intervention to improve health knowledge, health behaviors, and access to health services for women caring for young Aboriginal and Torres Strait Islander children.

Methods: Aboriginal researchers led engagement and recruitment with health services and participants in 3 Aboriginal and Torres Strait Islander communities in New South Wales, Australia. Focus groups and interviews were facilitated by researchers and an app developer to gather information on 3 predetermined themes: design characteristics, content modules, and features and functions. Findings from the co-design led to the development of an intervention prototype. Theories of health behavior change were used to underpin intervention components. Existing publicly available evidence-based information was used to develop content. Governance was provided by an Aboriginal advisory group.

Results: In total, 31 mothers and 11 health professionals participated in 8 co-design focus groups and 12 interviews from June 2019 to September 2019. The 6 design characteristics identified as important were credibility, Aboriginal and Torres Strait Islander designs and cultural safety, family centeredness, supportive, simple to use, and confidential. The content includes 6 modules for women's health: Smoke-free families, Safe drinking, Feeling good, Women's business, Eating, and Exercising. The content also includes 6 modules for children's health: Breathing well; Sleeping; Milestones; Feeding and eating; Vaccinations and medicines; and Ears, eyes, and teeth. In addition, 6 technology features and functions were identified: content feed, social connection, reminders, rewards, communication with health professionals, and use of videos.

Conclusions: An mHealth intervention that included app, Facebook page, and SMS text messaging modalities was developed based on the co-design findings. The intervention incorporates health behavior change theory, evidence-based information, and the preferences of Aboriginal and Torres Strait Islander women and health professionals. A pilot study is now needed to assess the acceptability and feasibility of the intervention.

Introduction

Background

The health and well-being of Aboriginal and Torres Strait Islander people have been significantly affected by dispossession, interruption of culture, and intergenerational trauma since the colonization of Australia [1]. The ongoing impact has resulted in an unequal opportunity for good health. The life expectancy of Aboriginal and Torres Strait Islander women is 8 years less than that of non-Indigenous Australian women [2]. In the 2018-2019 National Aboriginal and Torres Strait Islander Health Survey, the majority of women aged ≥ 15 years were not meeting guidelines for physical activity, vegetable intake, or fruit intake; 36% reported that they smoked tobacco daily; and 35% reported that they experienced high or very high levels of psychological distress [3]. Infant mortality continues to be unacceptably high for Aboriginal and Torres Strait babies at 2.1 times the rate of non-Indigenous infants (6.3 and 3.1 per 1000 live births, respectively) [4]. Mothers and babies getting the best possible care and support for a good start to life is 1 of 12 health priorities of the National Aboriginal and Torres Strait Islander Health Plan 2013-2023 [1].

Aboriginal and Torres Strait Islander people make up 3.3% (798,400/24,193,939) of the Australian population [5] and include many distinct groups with their own language and culture. In total, 44% of Aboriginal and Torres Strait Islanders live in regional areas, 37% in cities, and 18% in remote or very remote areas [5]. Those living in regional and remote areas have less access to primary health care and overall poorer health [6]. Nationally, Aboriginal and Torres Strait Islander people have less access to the internet at home (75.3% compared with 85.8% of all Australians); there are significant differences based on location: 82.8% in cities, 73.2% in regional areas, 61.3% in remote areas, and 49.9% in very remote areas [7]. More than 1 in 3 (35%) Aboriginal and Torres Strait Islander people are mobile-only users compared with a national rate of 1 in 5 (19.9%); these figures are linked to socioeconomic factors [8]. Using only a mobile is likely to incur more costs for data, less capability, and less access to more sophisticated digital health information and tools [8]. It is of importance that mobile health (mHealth) interventions are developed with a goal to increase digital inclusion.

mHealth is the use of mobile technology to improve health. Functions include SMS text messaging, multimedia messaging service, voice, internet access, and software apps, which range in complexity. mHealth is used for a variety of purposes, including health education, health behavior change, sensors and point-of-care diagnostics, registries and vital-event tracking, and data collection [9]. mHealth is being used increasingly for health promotion because of its reach, with >7 billion mobile phone subscriptions globally [10]; the Be He@lthy, Be Mobile initiative by the World Health Organization has reached >3.5 million people [11]. There are limited recent national figures on smartphone ownership among Aboriginal and Torres Strait Islander people, although available data indicate that ownership is high; a survey with 400 Aboriginal and Torres Strait Islander people in 2014 reported that 70% of Aboriginal and Torres

Strait Islander people owned a smartphone and 69% used Facebook compared with 66% and 40% respectively for non-Indigenous Australians [12]. The top reason for using a mobile phone in this group was to send SMS text messages [12].

Studies focused on Aboriginal and Torres Strait Islander people using SMS text messaging to improve health show high acceptability of the modality [13-15]. SMS text messaging has the advantage of being accessible on all mobile phones and not requiring access to a data service. There are few technical barriers to SMS text messaging and high acceptability of the modality among new mothers [16,17]. In a metareview (23 systematic reviews, 371 studies, and 79,665 participants) on the impact of mHealth on a range of outcomes, including clinical outcomes, adherence to treatment and care, health behavior change, disease management, and attendance rates, SMS text messaging was the most frequently examined function and reported to be the most successful overall [18]. SMS text messaging seems to be particularly effective at increasing smoking cessation rates (in adult smokers from mostly high-income countries) [19]. The evidence for SMS text messaging helping to improve nutrition and physical activity is not as strong; however, SMS text messaging used in conjunction with other mHealth functionality has shown significant positive effects for healthy eating [18].

Health apps continue to be popular, although the evidence suggests that apps have limited effectiveness on changing health behaviors [18,20-22]. Some studies have found that apps can be effective at changing behavior among some clinical groups [18], although overall there is limited evidence to date. Of the few trials focused on Indigenous populations, app use has been reported to be low [23,24]. A recent pilot randomized controlled trial of a smoking cessation app with 49 Aboriginal people in Australia reported low to moderate level of app use, and at 6-month follow-up, only 1 participant was abstinent [24]. The authors concluded that although there was broad acceptability for the app, mHealth interventions should be designed with functions that are commonly used, including social media platforms [24]. A co-designed mHealth app developed in New Zealand with Māori and Pacific Islander people was tested in a cluster randomized controlled trial in 2019 (n=1451) [23]. Adherence to health-related-behavior guidelines increased at 12 weeks in both groups, with no difference between the groups. Engagement with the app overall was low, although those who did engage with the app as it was designed saw greater benefit. The co-design approach was reported to have drawn a very positive response from the community, as was reflected in the high participation and follow-up rates [23].

Social media is a form of mHealth, with potential to support health. The Aboriginal and Torres Strait Islander health sector was an early adopter of social media networks to promote health [25,26]. Social media campaigns on COVID-19 by Aboriginal and Torres Strait Islander health organizations is a recent example [27]. A recent Cochrane review on behavioral interventions delivered through social media for health behavior change, health outcomes, and health equity (88 studies; n=871,378) reported varied effects; overall, social media was found to improve physical activity, weight loss, and general

well-being, and small to no effects were found for other outcomes [28]. No studies focusing on Aboriginal and Torres Strait Islander people were included in the review.

Objectives

In response to the limited mHealth interventions available for Aboriginal and Torres Strait Islander women and children, we aimed to co-design a prototype focused on the needs and ideas of Aboriginal and Torres Strait Islander mothers. Co-design is a partnership approach where end users are actively involved from conception to dissemination [29]. Using co-design methodologies is one of the guiding principles of the Aboriginal Health and Medical Research Council of New South Wales (NSW) Ethical Guidelines for conducting health research with Aboriginal people [30]. In this paper, we describe the co-design processes and findings, as well as provide a description of the mHealth prototype.

Methods

Study Design

In total, 8 focus groups and 12 interviews were conducted from June 2019 to September 2019. Surveys were used to collect demographics at the start of focus groups and interviews. An Aboriginal advisory group that included Aboriginal team members who were also members of the participating communities met quarterly to oversee design, implementation, analysis, and reporting. An expert mHealth research group was consulted for opinion on research and intervention design.

Ethics Approval

Human research ethics approval was received from the Aboriginal Health and Medical Research Council (1485/19) and the University of Newcastle (H-2019-00760).

Co-design Framework

A co-design framework for an mHealth intervention with Māori and Pacific communities in New Zealand [29] based on work by Bratteteig et al [31] was used to guide the methods used in this study. Co-design is a coherent methodology with a range of tools and techniques used to favor the preferences of end users [31]. The co-design methods used included focus group and interview discussions, card sorting, storyboarding, design activities, survey, guidance from expert groups, and an iterative design phase with the research team.

Setting

Focus groups and interviews were held at 3 regional NSW locations: Newcastle, Coffs Harbour, and Inverell. In total, 5 Aboriginal organizations (including 3 Aboriginal health services, an Aboriginal preschool, and an Aboriginal corporation) and 3 NSW Health sites participated. Venues for focus groups and interviews were decided in consultation with participants.

Participants

Women aged ≥ 16 years who were either mothers or primary carers of an Aboriginal or Torres Strait Islander child aged 0 to 5 years or were pregnant (≥ 30 weeks gestation), owned or regularly used a smartphone, and had accessed a participating service (Aboriginal health service or NSW Health service) were

eligible to participate. Health professionals at participating services who worked with women or children were eligible.

Procedures

Convenience sampling was used to recruit participants. Aboriginal researchers (BH, NS, and BL) who worked within the participating communities used their personal networks. In addition, participants were asked if they would like to recommend a friend or family member to the study. Potential participants were screened for eligibility when they contacted the researcher on the telephone. The researcher explained the study and gained informed consent over the telephone initially and again in person before the start of the focus group or interview. Participants were reimbursed with a shopping voucher worth Aus \$30 (US \$21.6) for attending focus groups and interviews and provided with refreshments. Health professionals were recruited using a snowball methodology through the participating services. Health professionals were not reimbursed.

Mothers and health professionals participated in separate focus groups and interviews. Focus groups and interviews were cofacilitated by a combination of Aboriginal researchers (NS and BH), a PhD student (SJP), and an app developer. Interviews and focus groups were 20 to 90 minutes in length. The number of participants in focus groups ranged from 2 to 6. Focus groups and interviews were recorded and transcribed, and field notes were taken.

Measures

Different surveys and discussion guides were used with mothers and health professionals. Discussions and activities were used to identify (1) design characteristics, (2) content modules, and (3) features and functions.

Mothers

Survey

The survey comprised 16 items, including demographic, cultural, and socioeconomic items. The items were selected from a previous study [32], with all items having been tested with Aboriginal and Torres Strait Islander mothers previously.

Discussion Guide

In all focus groups and interviews with mothers, 3 main questions were asked. Follow-up questions were asked depending on responses. Additional questions about mobile phone use to inform features and functions were asked in focus groups cofacilitated by the app developer. The three main questions were as follows:

How would an mHealth intervention designed for healthy living for Aboriginal and Torres Strait Islander people differ from other mHealth interventions?

Are you more interested in mHealth for your own health or your child's health? What topics and features interest you?

What do you think stops or prevents some women from accessing health information and services for themselves and their children?

Activities

Card-sorting activities were used to identify current mobile phone use (functions used, frequency of use, and reasons for use). Storyboarding activity was used to elicit creative descriptions of the mHealth intervention using drawings and words on what the intervention should include. Design activity was used to gain feedback on potential designs.

Health Professionals

Survey

The survey comprised 5 items related to demographic and professional practice characteristics.

Discussion Guide

In all focus groups and interviews with health professionals, 3 main questions were asked. Additional follow-up questions were asked depending on the response. The three main discussion questions were as follows:

1. What do you think are the most important health and well-being topics to include for Aboriginal or Torres Strait Islander women, children, and family?
2. What are the barriers for Aboriginal or Torres Strait Islander families to having good health?
3. What types of mobile technology do you think could support Aboriginal or Torres Strait Islander women's and children's health?

Co-design Analysis

A generalized thematic analysis was completed. An Aboriginal researcher (BH) and a PhD student (SJP) independently coded themes. NVivo software (version 12.0; QSR International) was used to complete independent coding and comparison by the 2 coders. In total, 3 predetermined codes were used based on a similar co-design study [29]. These codes included (1) design characteristics, (2) content modules, and (3) features and

functions. The coders met to agree on subcodes and definitions. Survey findings are presented using descriptive statistics.

Intervention Development

The findings from the co-design stage were subsequently used to develop a prototype intervention incorporating an app, SMS text messaging, social media, and videos. The intervention development was an iterative process, with meetings held among the team members to decide the final features and functionalities. Not all ideas could be adopted because of various reasons, such as time, funding, and technology constraints. We used a combination of building new functions (app) and using existing functions (Facebook page and SMS text messaging).

The intervention was grounded in behavior change theory. The Health Belief Model was used to underpin the app portion of the intervention. The Health Belief Model is considered to be well suited to mHealth interventions with use of the *cue to action* component [33]. The basic constructs are perceived threat of illness, perceived benefits of health behavior change, perceived barriers to change, cues to action, and self-efficacy [34]. Behavior change techniques were used to formulate SMS text messages. The SMS text messages were coded for behavior change techniques by 2 coders (Sam McCrabb and SJP) using behavior change technique taxonomy (version 1) [35] and the process outlined by Michie et al [36]. Of the 2 coders, 1 was experienced in coding behavior change techniques (Sam McCrabb) and the other was a PhD student (SJP). Disagreements were resolved through discussion and key messages adapted to include further effective behavior change techniques.

Key messages were developed on health topics identified from the focus groups and interviews. Content was formulated from publicly available evidence-based health resources. Key messages were adapted to SMS text messages, small pieces of written information for the app, and Facebook posts.

The prototype intervention included an app, videos, Facebook page, and SMS text messaging (Textbox 1).

Textbox 1. Components of the prototype intervention.**App**

- A web-based prototype app was developed. Rapid iterative cycles between the app developer and research team were used to refine the design. An Aboriginal graphic designer developed graphics for each module and logo.

Videos

- A total of 12 short videos were captured on a Canon camera. All presenters were health professionals from participating sites or contacts of the research team. Short scripts were provided to health professionals based on key messages. Staff were encouraged to use their own knowledge and expertise on each topic. Videos were filmed by a videographer and professionally edited. Captions were completed by Rev, and voiceovers were completed by 2 Aboriginal researchers (BH and NS). The videos ranged from 112 to 300 seconds in length. Vimeo was used as the platform to host the videos.

Facebook page

- A Facebook group was developed and administrated by 2 Aboriginal researchers (BH and NS). Both researchers were regular Facebook users and had significant networks and knowledge of Aboriginal and Torres Strait Islander organizations, events, and health services. Key messages were predeveloped in text and video format. Other content shared was decided by the administrators, including sharing posts from their personal accounts if they were suited to the broad aim of the intervention.

SMS text messaging

- SMS text messages were developed based on the processes described by Abrams et al [37]. Steps include choosing a behavior change goal, choosing communication objectives and behavioral techniques, designing a framework, and writing an SMS text message library [37]. SMS text messages were written to allow tailoring using the mother's and child's names, child's age, and topic interest of the mother. Tailoring SMS text messages around the timing of key behaviors, such as after a baby is born, can improve saliency and likelihood of behavior change [38]. SMS text messages were written by an Aboriginal researcher (BH) and a PhD student (SJP). A web-hosted SMS text messaging server (SMS Express) will be used to send all SMS text messages.

Results

characteristics of mothers are presented in [Table 1](#), and demographics of health professionals in [Table 2](#).

Overview

A total of 42 participants were recruited to the study: 31 mothers and 11 health professionals. Demographics and cultural

Table 1. Demographic and cultural characteristics of mothers (N=31).

Design Characteristics

We identified six main design characteristics: (1) credibility, (2) Aboriginal and Torres Strait Islander designs and cultural safety, (3) family centeredness, (4) supportive, (5) simple to use, and (6) confidential.

Credibility

Mothers talked about the difficulty of finding information on the web that was evidence based. Most of the mothers said that they used Google to find real-time health information for themselves and for their children: "Literally, I Google everything." Many of the mothers said that it can be difficult to know which websites are most up to date and accurate and that it is difficult to find information: "The biggest thing I find on Google, you get everything. You don't get the ones that are

reputable." Another mother said, "I'm finding you're having to like scroll, scroll, and scroll to try and find that information." Mothers said that they want current health information from reputable health professionals and organizations, including "useful websites links." Health professionals talked about the importance of credible health information to improve health literacy: "I think lack of knowledge that they are so sick. Recognizing the signs of illness that can lead to them being really, really [sick]." This highlighted why it is important that all content included in the prototype intervention be sourced from credible evidence-based health resources and broken down into palatable small chunks with links to further information.

Aboriginal and Torres Strait Islander Designs and Cultural Safety

Most of the mothers said that Aboriginal designs, language, and representation were important for engagement. A mother said, “I think if it had Aboriginal designs that would be really good because if I download an app and it doesn’t have the look, like being culturally aware [I don’t use it].” Another mother said, “Don’t make it black and white, it’s got to be like colorful.” A mother spoke about the intervention needing Aboriginal representation in images and videos: “If it’s going to be an Aboriginal app, I think you have to have Aboriginal people.” Another mother discussed using an app for quitting smoking that was not representative of Aboriginal people: “It was easy to use, but I couldn’t relate to it...didn’t seem like it was aimed at Blackfellas even though we thought it was.”

It was evident from the mothers’ experiences of racism that the intervention needed to be centered in cultural safety. Some mothers talked about feeling fearful and judged when seeking health care. A mother said, “Being an Aboriginal mum especially, I was just worried about DoCS [Department of Child Services]. Like whether they could see if I was handling having two children on top of my own family breakdown. Like my mum’s kids are in DoCS. So that’s what my biggest fear was.” Other mothers expressed feeling judged about certain health behaviors and topics, and a mother said, “The biggest thing is why people do hide it [smoking], because they don’t want to be judged. They don’t want to hear all that stuff.”

To center cultural safety in the intervention, all aspects of the intervention were codeveloped by Aboriginal people: the research was governed by an Aboriginal advisory board and coled by an Aboriginal academic (KH); 4 of the 8 members of the research team are Aboriginal; an Aboriginal graphic designer designed the module icons and logo; Aboriginal researchers were administrators of the Facebook page and shared cultural links, events, activities, affirmations, and images; an Aboriginal videographer filmed all the videos; Aboriginal health professionals presented in the videos; an acknowledgment of Country and a *welcome* message by an Aboriginal researcher was placed on the main page; and all content was cowritten by Aboriginal researchers.

Family Centeredness

It was decided unanimously that the intervention should include content for both mother and child. A mother said, “Is this just for children’s health? Because I feel like it should incorporate the mother’s health too.” The mothers asked for information on “things to do with our kids,” and “stuff for us women too. Pap smears and stuff like that.” Many of the mothers and health professionals suggested that the intervention needed to encompass the entire family, including the extended family. A health professional said, “Put the main focus on the child and then how their [family] health affects the baby’s health,” and a mother said, “I think a family app would be really good. Like, I know my husband, he’s never been around babies.” Some participants talked about how other family members help bring up children: “It’s nothing to see an aunt bringing up a child, or a grandparent or a sister” [health professional]. Family centeredness in the intervention was therefore conveyed through

messaging that families are the most important role models for jarjums (an Aboriginal word meaning children) across modules and functions. Links to websites, events, and health information for partners and other family members were included.

Supportive

Most of the mothers and health professionals indicated that it was important that the intervention promoted positive self-esteem and well-being of mothers. A health professional said that the intervention should give new mothers “understanding [of] how tired you are going to be, and it’s okay, ask for help, everyone feels like that but you’re not failing or not doing something wrong.” A mother suggested that we include “some sanity sayings or something like that, or some little sage advice from mums that have been there, done that before, that’d be really helpful,” and another mother said that the intervention could be “like a reassurance type thing.” Mothers and health professionals recognized that motherhood can be “totally exhausting” [health professional] and challenging at times. A mother described the initial period after coming home from hospital: “I didn’t know what to do with him. What do I do with this kid? I was lost.” To create an intervention that was supportive of motherhood and of Aboriginal and Torres Strait Islander women, positive and affirming messages were posted on Facebook, sent through SMS text messages, and included in the app. Links on where to seek help for mental health concerns were included.

Simple to Use

Mothers and health professionals recommended that the intervention be intuitive, use simple language, and have few technical barriers. Some of the mothers talked about trying to use other health apps; however, they were unable to do so because of technological challenges. For example, a mother said, “It was just too hard to log in and get started so I gave up or just called someone.” Many of the mothers and health professionals emphasized that the language used in the intervention needed to be nonjargon. A mother said, “Don’t put it in a textbook. Because I’m telling you, if my family member downloaded that and it was a textbook way, they would be like—No.” Another mother said that the content should be “just little pieces of information...then links to the bigger pieces.” We aimed for simple, intuitive app design and used other mobile functions commonly used by mothers (Facebook and SMS text messaging). To ensure that the intervention was simple and easy to use, health information was presented in short key messages with links to websites for further information. All key messages were written to be at an 8th grade reading level using the Flesch-Kincaid Grade Level Test as recommended by Abroms et al [37].

Confidential

Mothers and health professionals talked about the importance of confidentiality. Health professionals focused on confidentiality in the health care setting and the complexities for some staff regarding knowing patient health details. A health professional said, “There are big things surrounding our health services confidentiality. People don’t know or want to know what other people’s business is.” Some of the mothers spoke

about confidentiality; regarding being anonymous when communicating with other mothers or health professionals in a hypothetical mHealth intervention, a mother said, “Oh God, yeah. I’d ask an anonymous person on a phone. Rather than ask the doctor face to face.” Other mothers were happy to not be anonymous: “It wouldn’t bother me having my name because it would just be, this is my experience, and it is what it is. But I would understand if some women didn’t.” To ensure that women can choose to remain anonymous and keep their information confidential, the intervention design meant that no personal data were collected in any part of the intervention, other than a mobile number for the SMS text messaging component. Joining the Facebook group is an optional part of the intervention.

Content Modules

Most of the mothers and health professionals suggested that the intervention needed to cover a wide range of health topics for both the mother and child. Health topics identified in the data included *pains after birth*, *breastfeeding*, *normal speech for toddlers*, *signs of autism*, *earaches*, *behavior*, *rashes*, *high temperatures*, and *coughs*. Similar topics were grouped by the research team and combined into 6 key content modules for women’s health and 6 key content modules for children’s health. For example, *birth*, *reproductive health*, *urinary leaking*, and *pap smears* became *Women’s business*. All health topics captured in the interviews and focus groups were included in the intervention within a module on the app, SMS text messages, or through Facebook posts. Health modules for women included Smoke-free families, Safe drinking, Feeling good, Women’s business, Eating, and Exercising. Health modules for children were Breathing well; Sleeping; Milestones; Feeding and eating; Vaccinations and medicines; and Ears, eyes, and teeth.

Features and Functions

We identified eight features and functions: (1) content feed, (2) social connection, (3) diary and storage of health information, (4) local context, (5) reminders, (6) rewards, (7) talk with health professionals, and (8) use of videos.

Content Feed

A content feed was chosen to be a feature of the intervention based on the mothers’ current mobile phone use. During the card-sorting activity, most of the mothers reported scrolling the content feed on Facebook numerous times per day. Of the 13 women who were asked how many hours per day they used Facebook, 12 (92%) reported using it >4 hours per day. When asked what kept them going back to Facebook, a mother responded, “The content keeps changing.” Mothers frequently talked about watching photo and video stories that were uplifting, funny, or motivating on Facebook. They talked about using Instagram and Snapchat, too, although less frequently. The intervention was therefore designed to include a Facebook page with daily posts covering a variety of health content.

Social Connection

Mothers talked about the social connection and learning from other women when becoming a mother, including from their “mum,” “mother-in-law,” and “girlfriends.” The importance of positive relationships when first becoming a mother was well

recognized by health professionals as well as mothers. It was acknowledged by many of the mothers that some new mothers “don’t have a big support network.” A mother described mothers at playgroup being “more like a family to each other.” Some of the mothers said that connecting to other mothers would be helpful because they may be going through the same situation or challenge: “Yeah [I would like to chat with mums in the intervention] because they might have experienced something that I’m starting to experience.” Some of the mothers talked about the possibility of meeting up with mothers outside of the intervention: “It’s hard to meet people...[could there be] like a mums and bubs [babies] thing [as part of the intervention],” and another mother said, “Say, if I needed to ask them a question or something that I wouldn’t want to write on Facebook [I would like to meet up with them in person].” Another mother identified that connection is important for mental health: “When they [new mothers] don’t have anybody, depression kicks in.” The Facebook page was designed to make it easy for mothers to connect and share stories and ideas. Discussion points were created to be posted on the Facebook page to facilitate discussion; for example, “Tell us how you engage your jarjums in cooking or take a pic or video of your deadly (great or excellent) li’l chef in the kitchen.”

Diary and Storage of Health Information:

A feature that enabled users to store specific information about a child’s health received mixed responses. Some of the mothers thought that having their child’s health information on hand would be of practical benefit when attending medical appointments: “Like a diary section...I found, when [my child] was sick I started recording when I gave the medication, those sorts of things. That’d be good to have an app when you go into the hospital, you go, this is his recordings.” Another mother said, “So they [health professionals] could just add in medication, add in reports...it’d be good because like [the health service] is only open during the week. Usually, like on the weekend, I’d have to go up to the hospital...So it would be good if there was information like after the visit. Because you don’t always take everything in. It goes right over your head.” Other mothers and health professionals thought there would be confidentiality concerns. Because of the confidentiality concerns raised in the co-design process, a diary feature was not included, although it may be considered as an optional feature in future iterations.

Local Context

Many of the mothers and health professionals spoke about the uniqueness of their community and said that the intervention needed to be relevant to each community, including language and environment (eg, coastal and desert), as well as health services and other resources. A mother suggested, “You could put in your postcode, location, or area or something and then it could be localized,” and a health professional said, “The contact numbers, if they can’t get into emergency, the [local] health line numbers where they can get a bit of advice would be handy on there as well.” The intervention included phone numbers of local health services for each community in the app, and Facebook posts were designed promoting local health services, events, organizations, and languages.

Reminders

Many of the mothers talked about the usefulness of SMS text messaging reminders from their health services for appointments, and they said that reminders for other areas of health care would be useful too. A mother said, “I would probably like all of them [milestone reminders]. I’d like the whole lot, make sure I’m not missing anything.” Another mother said, “If someone notified me on this app that I’m due for a [pap smear] or something like that, I would like being reminded of things like that.” Most of the mothers said that they would prefer reminders through SMS text messages rather than a push notification from an app because they could go back to the message and reread it. For the intervention, SMS text messages were developed covering a range of reminders, including vaccinations, developmental milestones, check-ups, smoking quit date, exercise, and eating well. Reminders about local health initiatives and events were also created for posting on the Facebook page.

Rewards

The mothers talked about rewards and incentives from health programs and services increasing their motivation. They talked about material rewards such as “shirts,” “caps,” and “supermarket vouchers,” as well as social rewards, including “comments” and “likes” on social media and “clapping” and “cheers” on health apps. The mothers who were asked about receiving rewards for a variety of health behaviors were unanimous in their opinion that rewards were enjoyable and motivating. In the intervention, weekly competitions were created for posting on the Facebook page involving mothers sharing a picture of a health activity; for example, active play or exercising with their children. Prize draws were also incorporated into the intervention for those who participated in the competitions.

Talk With Health Professionals

Some of the mothers suggested that being able to communicate with health professionals using SMS text messages or a live chat function would be beneficial. Some of the mothers said that this function would be useful to confirm whether they required face-to-face health care and for reassurance. A mother said, “Sometimes you don’t know if you should go up there [health service] or not, so you could kind of message and say, ‘Hey, this is what’s happening...is it worth coming up or is it just a viral thing going around?’” Another mother said, “I know a lot of women are just like, ‘What do I do?’ So just having that reassurance I suppose online.” Another mother suggested that it would be helpful to be able to ask health questions anonymously: “The option to be anonymous or not known by people [health professionals] would be handy I guess for more embarrassing health concerns.” Mothers living in rural areas mentioned being anonymous more often in the discussions. Although it was suggested, facilitating a chat with health professionals directly was out of the scope of the current prototype because of cost and resources. Telephone numbers for national, state, and local health services were listed in the app to enable users to connect with health professionals, if needed, regarding the questions they might have.

Use of Videos

Most of the mothers reported during the card-sorting activity that they frequently watched short videos on social media and YouTube. A number of mothers and health professionals advised us that videos and images may be more accessible and preferable for some mothers. A health professional said, “Videos, everyone can watch a video and understand.” Therefore, a video for each health module was developed for the intervention. Each video was stored in the app and added to the Facebook page. Additional health videos from external sources were also able to be shared on the Facebook page.

Final Prototype

The final mHealth intervention, named Growin’ Up Healthy Jarjums, aimed to improve health knowledge and health behaviors, along with providing access to health services. The intervention comprises 3 delivery modalities: app, SMS text messaging, and Facebook page.

App

The app is a central place for users to access all content. The app is primarily for the user who wants in-depth information and has the necessary digital device, internet connection, and literacy skills to access it. It is designed to allow the user to navigate to the topic of interest; for example, *exercise*, where they will find small amounts of written information, videos, links to websites, and useful contacts. The user may choose to access any topic, in any order, and consume as much information as they like.

The app has four menu screens: (1) home screen, (2) women’s health, (3) children’s health, and (4) contacts (Figure 1). The home screen includes four buttons: (1) *My Health*, (2) *Jarjums Health*, (3) *Facebook Page*, and (4) *Contacts*. The user may click on a button to move to the next screen or scroll down to access the embedded Facebook content feed. The embedded Facebook content feed allows the user to remain in the app and read the posts, but to comment or *like* a post, the user needs to access the Growin’ Up Healthy Jarjums Facebook page. An acknowledgment of Country and a spoken welcome message are also included on the home screen. The women’s health (*My Health*) menu page includes six buttons, one for each of the women’s health modules: (1) Smoke-free families, (2) Safe drinking, (3) Feeling good, (4) Women’s business, (5) Eating, and (6) Exercising. The *Jarjum’s Health* menu page has the same layout, including six buttons for the children’s health modules: (1) Breathing well; (2) Sleeping; (3) Milestones; (4) Feeding and eating; (5) Vaccinations and medicines; and (6) Ears, eyes, and teeth. Each module, for example, *Breathing well*, includes (1) *Key messages* incorporating perceived threat of illness and benefits of changing health behavior; (2) *Tips* to address barriers to change through reassurance and credible advice; (3) cues to action; for example, “Each time jarjum sees a nurse or GP ask them to have a quick look in bub’s ears to check if there is any infection”; and (4) links to further information, including skills and activities; for example, exercises and healthy recipes to support self-efficacy. The information is presented using small chunks of written information and videos using the same layout in each module.

Figure 1. Examples of Growin’ Up Healthy Jarjums app screens: (top, from left) home, women’s menu, and children’s menu; (above, from left) contacts, Breathing well, and Our health advice (accessed from Breathing well).

SMS Text Messaging

Alongside the app, the prototype included an SMS text messaging library comprising 112 SMS text messages (Table 3). The SMS text messaging component allows users access to health information regardless of mobile phone type, Wi-Fi access, or digital literacy. The SMS text messages covered the

content topics identified by the participants. The SMS text messaging portion of the program is 1-way (unidirectional), other than 3 SMS text messages developed for users who indicate that they want to quit smoking when registering for the program. In total, 23 behavior change techniques from 15 behavior change clusters were incorporated in the SMS text messages (Multimedia Appendix 1).

Table 3. Example SMS text messages developed for the Growin' Up Healthy Jarjums modules.

Module	Example SMS text message
Women's health	
Smoke-free families	Text4jarjum: Giving up the smokes is the best thing you can do for your health. Be a role model and be smoke free. Get support from Quitline 13 78 48 or a doctor and quit for good!
Safe drinking	Text4jarjum: While under the influence of alcohol, people can make less safe decisions about their jarjums. Check out 'Safe drinking' for tips to set limits.
Feeling good	Text4jarjum: You're probably not getting much sleep right now. Try to make time for yourself, ask for support from family & friends, and nap when bub does. If you feel that you are not coping, talk to your doctor or midwife. There is help.
Women's business	Text4jarjum: Be kind to yourself. Your body has gone through some big changes during and after birth. It will take time to bounce back. Whether you had a caesarean or vaginal birth, both may require rest & time for recovery. Here's what to expect after birth.
Eating	Text4jarjum: The Australian Breastfeeding Association has some useful tips on nutritional needs for breastfeeding mums.
Exercising	Text4jarjum: Any amount of movement is good for you. Start by doing a little, and gradually build up. You could start with a walk around the block a few times a week and then gradually increase.
Children's health	
Breathing well	Text4jarjum: A cough is often caused by a cold. Usually, a cough gets better on its own and is not serious, but if your child has a cough that doesn't go away after TWO weeks, or if you are concerned sooner – see your doctor or child health nurse.
Sleeping	Text4jarjum: A routine that includes relaxing time like bath, book, a gentle song before bed and a regular bedtime each night can help your child settle better.
Milestones	Text4jarjum: Playgroups, day care and pre-school are great places for jarjums to play and develop. Contact your AMS (Aboriginal Medical Service) or health nurse and find out what's on.
Ears, eyes, and teeth	Text4jarjum: Ear infections are really common and can cause long term hearing loss if not treated. Often there are no signs. Ask your doctor to have quick look in [insert child name] ears each visit to make sure there is no infection.
Vaccinations and medicines	Text4jarjum: Immunising [insert child name] is a safe and easy way to keep jarjums healthy and prevent disease. To check that [insert child name] is up to date with immunisations click here.
Feeding and eating	Text4jarjum: It's recommended you breastfeed exclusively until [insert child name] starts solid foods at around 6 months of age. Keep breastfeeding until at least 12 months and beyond.

Facebook Page

The final modality included in the prototype was the Facebook page. The purpose of the Facebook page was to create community and connection, allow 2-way communication, and use a platform that is highly popular among users. Daily content was designed to be added to the Facebook page, including (1) links to reliable health websites, (2) activities for families, (3)

weekly competitions, (4) key messages (written and video), (5) events in the community, and (6) supportive affirmative posts. The page was administrated by 2 Aboriginal team members (NS and BH), who shared posts relevant to their community and region. The Facebook page was embedded into the main screen of the app; it could also be accessed through Facebook. Examples of posts are presented in [Figure 2](#).

Figure 2. Examples of the content feed shared on the Growin' Up Healthy Jarjums Facebook page.

Discussion

Principal Findings

We codeveloped a prototype mHealth intervention focused on the knowledge of mothers of young Aboriginal and Torres Strait Islander children. The aim of the intervention was to improve health knowledge, health behaviors, and access to health services. The final prototype incorporates 3 modalities—app, SMS text messaging, and Facebook page—and includes a range of health topics. In addition, it is centered on being supportive of mothers and culturally safe.

The modality choices were based on a few factors: (1) early discussions with mothers and health services about the need for an app that is culturally relevant and safe, (2) evidence suggesting that SMS text messaging is the most effective mHealth function for health behavior change, and (3) findings from focus groups and interviews indicating that Aboriginal and Torres Strait Islander women were high users of Facebook and SMS text messaging. As suggested in a recent pilot study of a smartphone app with Aboriginal Australians, a *one app fits all* approach is unlikely to be successful [24]. Using mHealth modalities commonly used by the target group to deliver a health intervention may appeal to more families.

Strengths and Limitations

The first limitation of this research is that it was initiated by a research institution rather than by the community itself. True co-design should begin with completing a needs assessment with communities to see what the health priorities and potential solutions are for that community [38]. This is well described in a New Zealand co-design study [29,40]. To ensure that adequate time and resources are available for relationship building and

needs assessment, both should be specified in protocols and funding applications so that sufficient budgets and time frames are allocated. Second, although the intervention covers a range of topics in brief, it does not cover any topic in depth. Although an mHealth intervention with wide-ranging topics seems to be preferred by participants, this may dilute the impact of the intervention on any one risk behavior. Providing links within the *Growin' Up Healthy Jarjums* intervention to specific mHealth interventions for target behaviors may overcome this limitation by providing tips for more intense behavior change for those people who are *ready* to change. Third, because the participants were from only 3 NSW communities, the intervention may have limited generalizability in other Aboriginal and Torres Strait Islander communities. Aboriginal and Torres Strait Islander communities are made up of >250 language groups in which there is great diversity. If this intervention is to expand to other communities, systematic adaptation of the intervention would need to be carried out to ensure that the intervention is suitable to the context of each community [41].

A key strength of this study is that Aboriginal researchers (BH, NS, and BL) led engagement with participants and community organizations. Understanding the importance of trusted and strong cultural relationships, we only engaged with communities that the Aboriginal researchers had a relationship with, which likely resulted in trust as well as interest in participating in this study. Another strength of this study is the thorough reporting of the co-design processes. Inadequate reporting of intervention development was identified as a weakness in a recent systematic review on mHealth development (33). An additional strength is the involvement of primary health services and professionals. A recent review on health promotion programs in Aboriginal

communities highlighted that an important consideration is to partner with primary health care services because they are well placed with frequent patient contact, health expertise, and often intricate knowledge of the community [42]. A final and important strength is that we developed a flexible portal for ongoing development and enhancement. The COVID-19 experience has reinforced how important it is to have alternatives to face-to-face health care. Useful additions in future iterations of this mHealth intervention might include development of a flexible platform suitable for inclusion of initiatives inspired by the COVID-19 pandemic, such as subsidized telehealth and videoconferencing. There are also opportunities to develop content on this platform in Aboriginal and Torres Strait Islander languages to better suit users.

Comparison With Prior Work

Design characteristics identified in this study, including *social connection* and *family centeredness*, reflect Aboriginal and Torres Strait Islander perspectives of health. Connection to family, community, and culture, among other factors, are understood to be equal contributors to health [43]. Arabena et al [44] suggest that community and social connection can ultimately be the health promotion intervention for Aboriginal and Torres Strait Islander communities.

The finding that Aboriginal and Torres Strait Islander women were high users of social media, in particular Facebook, was unsurprising. Aboriginal and Torres Strait Islander health organizations have capitalized on the popularity of Facebook among Aboriginal and Torres Strait Islander people and have been early and adept users of social media for health promotion [25]. An Aboriginal-led social marketing campaign for health promotion, *Deadly Choices*, has 94,035 Facebook followers, 19,300 Instagram followers, and 9000 TikTok Followers [26,45].

As stated earlier, the methodologies used in this study were based on a co-design study for a health app with Māori and Pacific Islander people [29,40]. There were a number of similar co-design findings. In both studies, participants expressed a holistic view of health and connections to people and place as being central components of health. Participants in both studies talked about a family approach to health, rather than an individual approach, as well as accessible healthy activities in the community. Social support was found to be an important strategy in both studies.

Culture was also identified as important in both studies, although cultural representation may have been a more nuanced finding

in the New Zealand study. In our Australian-based study, participants expressed the importance of Aboriginal and Torres Strait Islander representation in terms of designs, colors, images, people, organizations, and safety. Participants in the New Zealand study [29,40] expressed the need to include Māori knowledge, Whakapono (faith and spirituality), and Whakataukī (traditional proverbs), which were to be woven throughout the intervention; for example, the app depicts the completion of challenges as colored footsteps, which is analogous to the journey that the participants' tūpuna (ancestors) embarked on. There may be differences in participants' connection to culture. In Australia, up to 1 in 3 Aboriginal and Torres Strait Islander children were removed from their families during the period from the mid-1800s to the 1970s. These children are known as the Stolen Generations [39]. Of the 31 mothers in this study, 6 (19%) reported that they had family members from the Stolen Generations, whereas 13 (42%) were unsure. The effect of the Stolen Generations on the loss of culture is profound [39] and is likely reflected in the findings of this study. This intervention may, in a small way, help to promote culture through links to Aboriginal and Torres Strait Islander organizations, connection to mothers of Aboriginal and Torres Strait Islander children, and culturally safe health information.

Conclusions

An mHealth intervention that included app, SMS text messaging, and Facebook page modalities was developed based on co-design findings. The intervention incorporates health behavior change theory, evidence-based information, and the preferences of Aboriginal and Torres Strait Islander women and health professionals. The next step of this research is to assess the acceptability and feasibility of the intervention in a pilot study. The pilot study will be conducted with the Aboriginal Health Services and NSW Health sites that participated in this co-design study. Participating mothers will also be invited to participate in the pilot study. If the *Growin' Up Healthy Jarjums* intervention is shown to have adequate acceptability and feasibility, the next phase will be to measure its effectiveness in improving health knowledge and changing health behaviors. Assessing the effectiveness of this intervention will provide valuable evidence for the use of mHealth in improving the health and well-being of Aboriginal and Torres Strait Islander populations and contribute to the evidence for using co-design methodologies, both of which have been highlighted as gaps in the literature [46].

Acknowledgments

The authors would like to acknowledge and pay their respects to the Aboriginal and Torres Strait Islander women who shared their views and knowledge in the study. The authors would also like to acknowledge the Aboriginal Community Controlled Health Services that participated in the study (Armajun Aboriginal Medical Service [AMS], Galambila AMS, Awabakal AMS, Kulai Aboriginal preschool, and Muloobinba Aboriginal Corporation) as well as the New South Wales Health sites that participated (Aboriginal Maternal and Infant Health Services located in Inverell, Coffs Harbour, and Newcastle). The authors wish to thank researchers from the National Institute for Health and Innovation, Auckland University, Auckland, New Zealand, for sharing expertise on mobile health and Sam McCrabb for coding behavior change techniques.

Abstract

Background: Despite experiencing the second-highest rate of HIV incidence in the United States, pre-exposure prophylaxis (PrEP) use remains low among Black women due, in part, to a lack of patients' awareness and providers' knowledge.

Objective: Our goal was to design animated educational tools informed by patients and women's health providers to address these barriers, specifically for women at risk for HIV.

Methods: Two animation storyboards about PrEP for women were created by academic stakeholders (eg, HIV clinical experts, educators, and HIV peer counselors), one for patients and one for providers. Four focus groups with community members from Baltimore, Maryland and four with women's health providers (eg, obstetrician/gynecologists, midwives, nurse practitioners, and peer counselors) at an academic center were conducted to discuss the storyboards. Transcripts were analyzed using conventional content analysis, and themes were incorporated into the final versions of the animations.

Results: Academic stakeholders and 30 focus group participants (n=16 female community members and n=14 women's health providers) described important themes regarding PrEP. The themes most commonly discussed about the patient animation were understandability of side effects, HIV risk factors, messaging, PrEP access, and use confidence. Provider animation themes were indications for PrEP, side effects, and prescribing confidence.

Conclusions: We created two PrEP animations focused on women. Stakeholder feedback highlighted the importance of ensuring the understandability and applicability of PrEP educational materials while including necessary information to facilitate use or prescribing confidence. Both community members and women's health providers reported greater use confidence after viewing the animations.

KEYWORDS

PrEP; animations; education; HIV; prevention; women

Introduction

Black women in the United States experience the second-highest incidence of HIV behind men who have sex with men and account for over half of new HIV diagnoses among women [1]. Many population-level factors contribute to this risk, including social and economic inequities that influence sexual networks, stigma, discrimination, and inadequate access to HIV care [2,3].

Oral HIV pre-exposure prophylaxis (PrEP) with antiretroviral drugs emtricitabine and tenofovir is a Food and Drug Administration–approved medication that prevents HIV in women up to 90% when taken daily [4-6]. The Centers for Disease Control and Prevention recommends that all sexually active adolescents and adults be informed about PrEP [7]. Furthermore, the American College of Obstetrics and Gynecology recommends PrEP for women who are at substantial risk of acquiring HIV, including those who have an HIV-positive

or unknown status sexual partner, a recent sexually transmitted infection, a high number of sexual partners, report inconsistent or no condom use, participate in commercial sex work, live in a high HIV prevalent area, or inject drugs [4].

Despite the availability of PrEP, uptake has been poor among women at high risk [8,9]. Patient-level barriers to PrEP include low self-perceived risk of HIV, limited knowledge, and high perceived cost [10,11]. Provider-level barriers include poor support and infrastructure to provide PrEP, inadequate education, and underestimating patients' risk [10,11]. Additionally, few PrEP campaigns specifically target women or women's health providers [10,11].

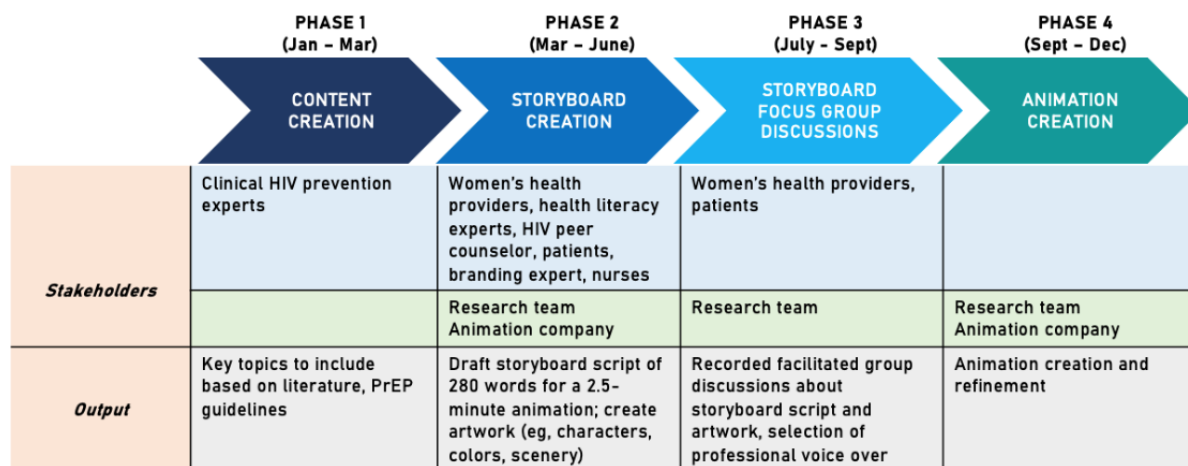

Computer-based interventions, such as animations, have been associated with decreased high-risk behaviors leading to HIV acquisition [12]. Furthermore, creating multimedia tools for health education with stakeholder involvement has been

encouraged to identify specific community needs and ensure effective dissemination [13,14]. Additionally, animations can decrease cognitive overload and increase attention retention and long-term recall [14,15]. Therefore, to address commonly cited barriers to PrEP uptake among women, we sought to create two women-centered PrEP animations, one for providers and one for patients, grounded in Mayer's [15] Cognitive Theory of Multimedia Learning that posits combined auditory text and visual pictures deepens understanding more than either alone. Below, we describe the animation development process with the participation of community members and women's health providers from Baltimore, Maryland.

Methods

Animations were created and iteratively refined in four phases between January 2020 and December 2020 (Figure 1).

Figure 1. Study phases. PrEP: pre-exposure prophylaxis.

Ethics Approval

This study was approved by the Johns Hopkins University School of Medicine Institutional Review Board (approval number: IRB00252170).

Phase 1: Animation Content Creation

Clinical HIV prevention experts (eg, obstetrician/gynecologists with fellowship training in HIV care and HIV peer counselors) created outlines for the animations based on published literature and existing animations about PrEP [11,16-18]. Proposed content included background information about HIV and PrEP among women, risk factors for HIV, indications for PrEP, side effects of PrEP, and a step-by-step guide to taking PrEP or prescribing PrEP.

Phase 2: Storyboard Creation

Two storyboards (ie, scripts and 2D slides) were created by an animation company (Science Animated, Cotswolds, United Kingdom) based on the outlines written in phase 1. The patient storyboard used simple language to aid low-health literacy populations, had relatable characters, and used positive framing. The provider storyboard assumed prior knowledge of women's sexual health and was framed for practicality using medical

terminology. In addition, we held formative discussions with our academic stakeholders (ie, lay individuals, a patient education professional, a branding director, nurses, and clinical HIV prevention experts), and storyboards were revised based on these initial discussions.

Phase 3: Focus Groups

Feedback about the storyboards from a larger audience was gathered. English-speaking women from the community and women's health providers (eg, obstetrician/gynecologists, midwives, nurse practitioners, and peer counselors) were recruited for focus groups. Fliers were placed in all general gynecology clinics, all academic specialist obstetrician/gynecologists in an academic hospital were emailed about participating, and prior research participants who had agreed to be contacted for future studies were recruited. Purposive sampling was conducted.

After obtaining written consent and collecting demographic information, the focus groups were scheduled. A trained facilitator and logistical coordinator conducted focus groups virtually using a secure videoconferencing platform (Zoom 5.5.4; Zoom Video Communications, Inc). Participants were offered the option to turn off their video and remove their names

to allow partial anonymity, as all still heard voices. There were 8 focus groups, 4 for community members and 4 for women's health providers. Each focus group contained 3 to 6 participants and lasted 60 to 90 minutes. A semistructured focus group guide was used to frame the discussions. Near the end of each focus group, participants were asked to rank 6 female-sounding professional voice-over actors who read the same script but may have had differences in inflection, cadence, pitch, or articulation. Participants received a US \$25 compensatory gift card.

Phase 4: Focus Group Analysis and Animation Creation

The focus group audio was recorded and transcribed verbatim. The transcripts were coded using ATLAS.ti 9.0.3 (ATLAS.ti Scientific Software Development GmbH), and the findings were organized and analyzed using conventional content analysis [19]. Two research team members read the transcripts twice, line-by-line, and prepared memos summarizing their preliminary findings. Next, preliminary codes were derived inductively by highlighting recurring words or statements through an iterative process. Research team members convened multiple times to discuss and compare memos, and revisit emerging themes iteratively. Discrepancies were solved by the principal investigator. Final codes were then assessed for broader concepts to generate themes through subsequent rounds of team discussion. The generation of themes was guided by an adaptation of the Model of Communication and Health Behavior Change by Kincaid [20]. The themes identified in the

storyboards (phase 2) and focus group discussions were incorporated into animation prototypes. The highest-ranked voice-over options were chosen. Finally, two 120-second 2D animations were created and iteratively refined by the research team.

Results

Storyboard Creation (Phases 1 and 2)

Themes that were presented in the initial creation of the storyboard included accurate PrEP information, ensuring an appropriate health literacy level to reflect the target population (eg, proficient level for the provider animation and basic to below basic level for patient animation) and representative graphics/artwork (eg, multicultural characters and scenery). The scripts for the storyboards and animation graphics were refined numerous times by stakeholders.

Focus Groups (Phase 3)

A total of 30 participants enrolled in the focus groups (n=16 female community members and n=14 providers, Table 1). Some themes pertained to both animations (messaging, design, background, side effects and risk factors, and perceptions of PrEP access and barriers), while others were only relevant to the patient animation (relatability and applicability of characters and storyline, and PrEP use confidence) or the provider animation (understandability of PrEP indications and prescribing confidence).

Table 1. Sociodemographic characteristics of focus group participants (N=30).

Characteristic	Community member (n=16)	Women's health provider (n=14)
Age (years), mean (SD)	26 (6)	42 (13)
Sex, n (%)		
Male	0 (0)	2 (14)
Female	16 (100)	12 (86)
Self-reported race, n (%)		
Black	12 (75)	3 (21)
Asian	0 (0)	3 (21)
White	1 (6)	7 (50)
Other	3 (19)	1 (7)
Highest education level, n (%)		
High school	7 (44)	0 (0)
College	6 (38)	1 (7)
Graduate school	2 (13)	13 (93)
Other	1 (6)	0 (0)
Marital status, n (%)		
Single	8 (50)	6 (43)
Married/union	7 (44)	7 (50)
Divorced	1 (6)	1 (7)

Provider Feedback

Providers' most common themes included prescribing confidence, indications for PrEP, and side effects. Additional themes and respective quotes are highlighted in [Multimedia Appendix 1](#).

Indications

Providers were surprised by a few of the indications for prescribing PrEP, specifically in relation to the area in which their patients were living. Several of them were surprised to learn that the HIV prevalence in a location was included in evaluating HIV risk and PrEP indications.

So, automatically living in Baltimore, it puts you at a higher risk for HIV, so really understanding that kinda stood out to me.

Side Effects

The level of details on side effects and their timing was a concern for some providers. Providers asked for more clarification on which side effects to expect and a given time frame for each to be included in the animation.

I wanna like know [...] how long is it [resolution of initial side-effects] gonna take? Are we talking about the next day? Are we talking about a month?

Prescribing Confidence

Providing a more detailed step-by-step guide applicable to the flow of a typical clinic encounter, including follow-up steps after prescribing PrEP, was recommended.

I'd first ask myself like, "Hmm, this person seems like they're high risk for HIV." And then, I would ask myself, "Do I – do I have testing that allows me to firmly confirm or deny the fact that they actually have HIV right now?" [...] And then, I would say to myself, like, "Okay, so I think if they like don't have a test on file or it's not that recent, are there any signs that I think that they're nonetheless actively infected with HIV and I need to test them for that before, you know, starting a conversation about preventing HIV."

Providers were, overall, confident in their ability to prescribe PrEP based on these steps but expressed doubt about their patient's desire and ability to comply with extensive follow-up and regular lab draws.

You're gonna have people who are not gonna wanna come in for a HIV test every three months...I mean, that's just gonna be a deterrent for people.

Community Member Feedback

Community members' most common themes were understandability of side effects and risk factors, messaging, PrEP use, PrEP access, and use confidence.

Risk Factors

Community members were surprised by the prevalence of HIV in their community and that they themselves would qualify for PrEP based on the listed risk factors.

I would say it related to me because before then, I never knew about PrEP [...] And I think that it will be not only a big eye-opener for me but for everyone else.

I didn't know that – um, that Baltimore City, HIV was as high as it is. They had shared it on the news, I think like a week or two ago, and liked it just kinda like caught me off-guard...

Side Effects

Community members were concerned about serious side effects and wanted more information about drug-drug interactions, specifically interactions between PrEP and contraceptive methods.

The stomach and the headaches, [...] that's kinda common. But like generally, kidney and bone density, that's not like average things.

Um, you said that it doesn't affect pregnancy or anything like that, but is there any risk – Like, if I'm on birth control, and I supplement with PrEP, is there any effect there, or they don't affect each other whatsoever?

PrEP Use

Community members highlighted confusing concepts, including PrEP's ability to prevent HIV and the logistics of PrEP follow-up that would need to be clarified to encourage use.

How long does it last? Is it like a shot? Well, I know it's like a pill, but like how long does it last? Like do you have to take one every day, every week, once a month?

Messaging

Overall, community members reported that the language and the messaging were appropriate for all education levels.

So, if we can clear it up that – Yeah, condoms alone do prevent HIV acquisition, but it's much more effective if you use PrEP. And if you do both together that's even better. Um, so maybe there is a way that we could kind of, like, get that message across.

PrEP Access

Community members thought use confidence would be impacted by information about PrEP access, especially insurance coverage. They wanted the animation to convey that it was easy to take PrEP via the step-by-step guide, which motivated participants to recommend PrEP to their peers.

I think the most surprising thing for me is that there is an option for people without insurance [...] I don't know how true that is. Because y'all always say that, but they'll be, like, "Yeah. There's an option. You can take off 10 percent." That's not enough.

Use Confidence

Overall, there was a potential for greater use confidence after viewing the storyboard. Community members expressed that

the storyboard motivated them to read more about PrEP and initiate a discussion with their provider.

But now, after this focus group, I'm more interested because it was kinda well-explained. I will do my own research on like the bone density and the kidneys and the side-effects, but I think after this focus group that, uh, it's something that I will have a conversation with my doctor about.

...But, yes, I would. It's very simple, it's appealing. Um, if it's 90% accurate plus on top of a condom, um, especially if you have multiple partners. Why not?

Animation Creation (Phase 4)

Stakeholder feedback from all phases led to clarifying language modifications and additional detail to describe the background, risk factors, indications, and steps for prescribing or accessing PrEP. Specifically, the provider animation was modified to clearly delineate prescribing steps. Details about side effects and interactions were added to the patient animation. The importance of evaluating HIV risk and PrEP eligibility according to risk factors, including geographic HIV prevalence, was explained better. Finally, design changes to the characters were made to make them more relatable ([Multimedia Appendixes 2 and 3](#)).

Discussion

Principal Findings

Two educational animations to facilitate learning about HIV prevention and PrEP for female patients and providers were created using a user-centered approach. There were some similar themes both community members and women's health providers wanted to highlight in the animations that included a clear demonstration about indications for PrEP, addressing barriers to PrEP use, and providing step-by-step guides to accessing or prescribing PrEP. These themes were considered the most important for both patients and providers to increase PrEP awareness and uptake among at-risk women. In addition, there was greater use confidence after viewing the storyboards.

Comparison to Prior Work

Although we did not test the "real-world" effectiveness of the final PrEP animations in this formative study, in general, animations have been found to be effective in increasing health information recall [12,16,21]. One study used a 2×2 factorial design among patients with different health literacy levels to determine which features of animations improved health

information recall and attitudes [21]. They found that spoken animation significantly improved recall of health information compared to written messages among low-literacy participants ($P=.02$). Additionally, there was no differences in health information recall between high- and low-literacy participants after exposure to spoken animation ($P=.12$). Furthermore, a meta-analysis demonstrated that technology-based HIV prevention interventions have been proven to be at least as efficacious as human-delivered interventions in reducing high-risk sexual behaviors [12].

Strengths and Limitations

A notable strength of our study is the user-centered approach with key stakeholders, which has been proven to foster stronger relationships between researchers and the community [22]. This may allow greater dissemination among at-risk women and women's health providers. However, there are limitations. First, the generalizability of these findings to other locations may be limited. We recruited providers from a single tertiary care center, who do not represent all health care providers in different settings. However, our community members reflect women most impacted by the HIV epidemic and that share similar characteristics. Second, although we collected data until we thought that theme saturation was reached, the sample of participants was small and additional themes might have been missed. Third, the animations did not provide exhaustive information and were not tested for effectiveness. However, the purpose of the animations will be to facilitate a discussion between female patients and women's health providers as an adjunct to routine sexual health care. Additionally, we do not expect our animations to be less effective than other human-delivered interventions, as existing data has shown that technological interventions are effective [12].

Conclusion

To increase the use of PrEP in women who live in communities with high HIV risk, the dissemination of information regarding its use in a relatable, accessible, and applicable way is vital for both patients and providers. Therefore, we included stakeholders in creating short educational PrEP animations. Stakeholders highlighted important issues to them, which included identifying individuals that qualified for PrEP, delineating key steps in accessing or prescribing PrEP, and addressing barriers to PrEP. As a result, there was greater use confidence for community members and women's health providers after viewing the storyboards. Future research is planned to evaluate the effectiveness of the animations to increase PrEP awareness and uptake among women who are at substantial risk for HIV.

Acknowledgments

The authors thank the focus group participants and Rosemary Ramroop, Janelle Ramroop, Gregoria Valdez, Tom Bauer, and Tanique Bennett for reviewing early versions of the focus group guides and animation storyboards.

Authors' Contributions

AMY was responsible for facilitating the focus groups, data analysis, data interpretation, modification of scripts for the animations, and drafting of all manuscript sections. TF was responsible for facilitating the focus groups, data analysis, data interpretation,

creating and modifying scripts for the animations, and drafting all manuscript sections. OO was responsible for facilitating and recording the focus groups, study coordination, participant follow-up, and editing and reviewing the manuscript. EG was responsible for analyzing and interpreting the data, modifying the animation scripts, and editing and reviewing the manuscript. JC posed the research question for this manuscript and was responsible for data interpretation, analysis, editing, and manuscript review.

Abstract

Background: The prevalence of common mental disorders (CMDs) among people living with HIV and people who inject drugs is high worldwide and in Vietnam. However, few evidence-informed CMD programs for people living with HIV who inject drugs have been adapted for use in Vietnam. We adapted the *Friendship Bench* (FB), a problem-solving therapy (PST)-based program that was successfully implemented among patients with CMDs in primary health settings in Zimbabwe and Malawi for use among people living with HIV on methadone maintenance treatment (MMT) with CMDs in Hanoi, Vietnam.

Objective: This study aimed to describe the adaptation process with a detailed presentation of 4 phases from the third (adaptation) to the sixth (integration) of the Assessment-Decision-Adaptation-Production-Topical Experts-Integration-Training-Testing (ADAPT-ITT) framework.

Methods: The adaptation phase followed a qualitative study design to explore symptoms of CMDs, facilitators, and barriers to conducting FB for people living with HIV on MMT in Vietnam, and patient, provider, and caretaker concerns about FB. In the production phase, we revised the original program manual and developed illustrated PST cases. In the topical expert and integration phases, 2 investigators (BNG and BWP) and 3 subject matter experts (RV, DC, and GML) reviewed the manual, with reviewer comments incorporated in the final, revised manual to be used in the training. The draft program will be used in the training and testing phases.

Results: The study was methodologically aligned with the ADAPT-ITT goals as we chose a proven, effective program for adaptation. Insights from the adaptation phase addressed the who, where, when, and how of FB program implementation in the

MMT clinics. The ADAPT-ITT framework guided the appropriate adaptation of the program manual while maintaining the core components of the PST of the original program throughout counseling techniques in all program sessions. The deliverable of this study was an adapted FB manual to be used for training and piloting to make a final program manual.

Conclusions: This study successfully illustrated the process of operationalizing the ADAPT-ITT framework to adapt a mental health program in Vietnam. This study selected and culturally adapted an evidence-informed PST program to improve CMDs among people living with HIV on MMT in Vietnam. This adapted program has the potential to effectively address CMDs among people living with HIV on MMT in Vietnam.

Introduction

Injection drug use is the main cause of the HIV epidemic in Vietnam, resulting in a high HIV prevalence among people who inject drugs, 15% in 2017 [1] and 12.7% in 2020 [2]. Antiretroviral therapy (ART) and methadone maintenance treatment (MMT) have been implemented in Vietnam since 2004 and 2008, respectively, and people living with HIV who inject drugs are commonly treated with simultaneous ART and MMT [3,4]. HIV and drug addiction are chronic stressors on mental health, and when combined with many other barriers related to HIV and drug addiction such as stigma and discrimination, the prevalence of common mental disorders (CMDs) among people living with HIV who inject drugs is higher than in the general population [5,6]. CMD is a collective term that refers to a range of depressive, anxiety, and stress-related disorders [7]. Depression is characterized by sadness, low self-esteem, tiredness, lack of concentration, lack of interest, and sleeping difficulties. Anxiety disorders refer to the feeling of anxiety, fear, panic including posttraumatic disorder, and social anxiety [7]. Stress is a state of physical and emotional tension caused by reactions to stressful stimuli from life and the environment [8]. The prevalence of depression and anxiety disorder among MMT clients in China in 2017 was 12.8% and 19.5% [9], compared with only 4.4% and 3.6% in the general population in 2015, respectively [7]. In a study by Levintow et al [10], people living with HIV who inject drugs in North Vietnam had a mild depression rate of 25% and moderate depression rate of 44%. Mughal et al [11] reported that people living with HIV on MMT in Hanoi had CMDs of depression and anxiety and posttrauma stress rate of 17% [11]. Prior research has demonstrated the effectiveness of behavioral and mental health programs among people living with HIV [12], including an evidence-informed program (EIP) to decrease levels of distress among people living with HIV in Thai Lan [13], an adapted life step intervention to effectively improve depression among people living with HIV in Zimbabwe [14], and an adapted CMD program for people living with HIV proved effective in 2020 in Malawi [15]. In Vietnam, we found evidence that family group counseling improved depression symptoms among people who inject drugs in 2017 [16]. Other studies have also recommended the need for CMD programs

for people who inject drugs in Vietnam [17]. Problematically, there have been no mental health programs for this population and setting.

Friendship Bench (FB), developed by Chibanda Dixon in 2006 [18], is a brief evidence-informed psychological program using problem-solving therapy (PST) and implemented by lay counselors. More than 50,000 people have received counseling in the FB program, making it the largest mental health program integrated into primary health care in Africa, supported by the government and the Ministry of Health of Zimbabwe [18]. FB has been validated through a clinical trial to reduce CMDs among community members in Zimbabwe. In this study, people receiving FB sessions had lower depression and anxiety scores on the Shona Symptoms Questionnaire (SSQ-14) than those who did not receive FB sessions (3.81 and 8.90, respectively). Moreover, the percentage of people in the intervention arm who had depression symptoms on the Patient Health Questionnaire-9 was lower than that in the control arm (13.7% in the intervention arm compared with 49.9% in the control arm) [19]. FB was used in the provision of ART adherence and depression counseling sessions to people living with HIV in Malawi. A total of 501 people living with HIV who had just started ART and had mild depression (Patient Health Questionnaire-9 scores from 5 to 9) were randomized into 2 groups: the intervention group and the control group. The study indicated that people living with HIV in the intervention group had a higher rate of adherence to ART than those in the control group [15]. Recently, FB had been adapted to reduce depression and anxiety among people living with HIV adolescents in a clinical trial in Zimbabwe. The study of this adaptation is ongoing [20]. FB is also currently being adapted for use among people living with HIV who are pregnant in Malawi [21].

FB consists of up to 6 structured 45-minute sessions, and it has been effective in treating CMDs among community members in Zimbabwe [19,22]. The sessions were conducted outside of the primary clinics. Each session followed a PST approach and included steps to determine a manageable problem, choose a problem to solve, make a plan to solve the problem, create a follow-up of plan implementation, and encourage work on new problems. After completing an individual session, participants are invited to take part in group activities, where people facing similar life challenges share their stories, spend time together,

and work on income-generating activities [22]. The original FB manual has 23 chapters, covering the topics of counseling techniques and session structure, core competencies of counselors, mental illness, HIV and mental health, substance use disorders (SUD), and PST. However, to implement this program for a new population, we first simplified and restructured the program to meet local norms [23], the new target population, and the new study settings [24] via the Assessment-Decision-Adaptation-Production-Topical Experts-Integration-Training-Testing (ADAPT-ITT) model [25].

The adaptation method ADAPT-ITT of the Centers for Disease Control and Prevention (CDC) was developed by Wingood and DiClemente in 2008 as a framework to guide the adaptation of a proven EIP to the specific goals and study participants of HIV prevention [25]. The ADAPT-ITT model has been used to adapt HIV prevention EIP for HIV key populations such as African American couples in the United States [26], people living with HIV in Zimbabwe [27], African American women in the United States [28], and men who have sex with men in Thailand [29] and to address mental and sexual health for young people living with HIV in sub-Saharan Africa [30].

This study is nested within the parent study “Adaptation of the Friendship Bench counseling programme to improve mental health and HIV care engagement outcomes among people living with HIV who inject drugs in Vietnam,” which aimed to test the feasibility, acceptability, and fidelity of the adapted FB in Vietnam [31]. This paper describes the process of FB adaptation to address CMDs among people living with HIV on MMT in some MMT clinics in Hanoi, Vietnam, in 2021, in preparation for a randomized controlled trial (RCT) following the ADAPT-ITT framework and specifically focuses on ADAPT-ITT phases 3 to 6.

Methods

Overview

The ADAPT-ITT model [25] comprises 8 sequential phases. Phase 1, the assessment, was conducted in a previous study [17]. Phase 2, the decision, was conducted by the parent study [31]. This paper describes in detail from the third to the sixth phases of the model: phase 3 (adaptation), phase 4 (production), phase 5 (topical experts), and phase 6 (integration). Phase 7 (training) and phase 8 (testing) will be presented in future papers.

Phase 1: Assessment

This phase involved needs assessment of people living with HIV on MMT for reduction in CMDs. The study conducted 28 in-depth interviews (IDIs) with people living with HIV who inject drugs (n=16, 57%), HIV and MMT providers (n=8, 29%), and health care providers (n=4, 14%) in private clinic rooms in Hanoi, Vietnam in May 2018.

Results of the study showed that both health care providers and people living with HIV who inject drugs believed that people living with HIV who inject drugs were particularly susceptible to CMDs, especially depression, and had a high need for mental health treatment. The study also recommended integrating

mental health care into MMT clinics to increase mental health access to people living with HIV on MMT [17].

Phase 2: Decision

This phase involved reviewing evidence-informed CMD programs and deciding which EIP to select for the new target population. Few programs addressing CMDs for people living with HIV exist in low- and middle-income countries, which have limited mental health resources. One of the few evidence-informed CMD counseling programs is the “FB” model, which has extensive validation in low- and middle-income countries [19]. FB helped to reduce CMDs, which was the aim of this study. In addition, FB has also been adapted for people living with HIV in Zimbabwe and Malawi [15,20,21] and may be suitable for people living with HIV on MMT in Vietnam.

Phase 3: Adaptation

In phase 3, stakeholders including people living with HIV on MMT, their family members, and health care providers reviewed the original FB content and implementation methods to answer questions related to who, when, where, and how to deliver FB in Vietnam for appropriate implementation in MMT clinics. The study conducted IDIs with 12 people living with HIV on MMT, 5 family members and caretakers of the patients, and 4 clinic directors. In all, 2 focus group discussions (FGDs) were conducted with MMT health care providers (each group had 5 people).

Inclusion criteria for patients were being aged ≥ 18 years, willing to participate in the study, and having at least one of the symptoms: depression, anxiety, stress disorders as indicated by the Depression, Anxiety, and Stress Scale-21 items (DASS-21), consisting of 21 questions and 3 items measuring levels of the emotional states of depression, anxiety, and stress. The DASS-21 is based on a dimensional conception of depression, anxiety, and stress as part of the full human experience rather than the categorical approach of either having a disorder or not (as used in the Diagnostic and Statistical Manual of Mental Disorders or International Classification of Diseases) [32]. Although FB was initially tested using the SSQ-14 to screen for CMDs, this tool has not been validated in Vietnam. The DASS-21, however, has been validated in this setting. Originally developed by Lovibond [32] in Australia in 1983 and tested to screen for CMDs in the community, the DASS-21 has been translated and successfully validated for a variety of study participants in Vietnam, including adolescents [33], rural women [34], health care workers [35], and people living with HIV on MMT [17]. The DASS-21 is aligned with the SSQ-14 in terms of screening CMDs, including depression and anxiety disorders in the general population, but is distinguished by having a stress disorder scale. Thus, the study team chose the DASS-21 as a research tool, as it has the advantages of validity in this population, brevity, ease of implementation, and measurement of depression, anxiety disorder, and stress disorder relevant to the purpose of the study. The study will also use suicide risk assessment that was effectively used in the HPTN074 study for people living with HIV who inject drugs in Vietnam [36].

Inclusion CMDs scores were at least a moderate level in which depression subscale score was ≥ 14 , anxiety subscale score was ≥ 10 , and stress subscale score was ≥ 19 . People who were aged < 18 years, did not meet the DASS-21 moderate score, had cognitive impairments, or had suicidal thoughts (exclusion, therefore, included referral for standard clinical follow-up care) were excluded from the study. Patients who met the inclusion criteria were invited to participate in an IDI. Family members and caretakers were the patients' parents, spouses, or main caretakers who already knew the patients' HIV and MMT status and who were introduced by the patients. Only family members and caretakers who had patients' consent to approach and who already knew the patients' HIV and MMT status were invited for IDIs. The inclusion criteria for health care providers were having at least two years of counseling and clinical experience with people living with HIV and people who inject drugs.

IDI and FGD guides were developed in English in accordance with previous FB interviews and the objectives of this study. The interview guides were reviewed for linguistic and cultural appropriateness. The guides were translated into Vietnamese, discussed, and revised by the research team, who had knowledge and experience on the study topic and participants. The guides were piloted among 5 patients who met the study inclusion criteria but received treatment from another MMT clinic and did not participate in the study. The IDIs and FGDs were facilitated in Vietnamese by 2 interviewers who were trained in qualitative research methods and had extensive experience working with people living with HIV who inject drugs. Each IDI had an average duration of 50 (SD 18) minutes. The average FGD duration was 1.5 (SD 25) hours. All IDIs and FGDs were conducted in Vietnamese, audio recorded, and transcribed verbatim. The interview and FGD transcriptions were deidentified and translated into English. The analysis was conducted according to the applied thematic analysis approach [37]. Thematic analysis was performed using NVivo (version 12.0; QSR International). All qualitative research was guided by the consolidated criteria for reporting qualitative studies, a 32-item checklist [38]. In all, 4 study members with experience in qualitative data analysis were involved in the data analysis process. The list of parent and child codes was developed and agreed upon by the coders. Parent and child codes and definitions were created a priori and were derived from the interview guide and literature review. Furthermore, 20% of the transcripts were double coded. Inter-coder reliability was

assessed after all coders coded the first 2 transcripts. A total of 2 meetings were held among the coders to discuss the coding results item by item. The official coding process began after all 4 coders agreed on the coding method and procedure. The codebook was refined throughout the analysis process and the findings were presented, discussed, and agreed upon by the study team.

Phase 4: Production

In all, 3 external content experts reviewed the phase 3 results. The original FB manual study procedures and content were modified according to expert comments. On the basis of the content experts' review, the manual was tailored for use by both health care providers and lay counselors. In addition, the experts' feedback informed the study team to include relevant matters regarding injecting drugs and HIV transmission in Vietnam. Finally, all the case studies were revised to make them suitable for participants in Vietnam.

Phases 5 and 6: Topical Experts and Integration

We solicited and integrated input and feedback on the first draft of the adapted FB program from 2 investigators, 2 creators of FB, and 1 topical expert on behavioral programs for people living with HIV and SUD from Hanoi Medical University (HMU). This feedback informed the development of the next draft of the FB manual. Culturally, Vietnamese illustrations were designed to replace Zimbabwean illustrations and were added to the second manual draft in English. A total of 2 translators of the study team had experience with people living with HIV who inject drugs and mental health and were responsible for translating the second draft. The Vietnamese topical expert revised the translated draft to ensure conceptual equivalency. The team then revised the translation again and agreed on the second FB manual version.

Phases 7 and 8: Training and Testing

Using the second adapted version, the creators of FB led a Training of Trainers session for 6 study team members in Vietnam and 3 people from HMU via a 5-day virtual training course. Trainers in Vietnam then provided in-person 5-day training for lay counselors and health care counselors in MMT clinics. The second draft was then piloted with 5 eligible patients to further refine the session content. The process culminated in a final version of the adapted FB manual that would be ready for formal evaluation in an RCT study (Table 1).

Table 1. The Assessment-Decision-Adaptation-Production-Topical Experts-Integration-Training-Testing (ADAPT-ITT) model [25] applied in the study.

Phase	Method	Version
1: Assessment of new study population	Assessed needs of people living with HIV on MMT ^a for CMDs ^b	Completed in 2019
2: Decision on choosing EIP ^c for adaptation	Reviewed EIPs for CMDs then decided to choose FB ^d counseling CMDs for community people of Zimbabwe to adapt for counseling CMDs for people living with HIV on MMT	Completed in 2019
3: Adaptation	Conducted IDI ^e with 12 people living with HIV on MMT, 5 family members and caretakers, 4 clinic directors, and 2 FGDs ^f with MMT health care providers (each group had 5 people); analyzed results by themes and reported results	Original manual
4: Production	Presented results of phase 3 to 2 creators of FB and 2 investigators and 1 expert in HMU ^g ; recorded and reported comments of 2 investigators and topical experts for production; reviewed original FB manual to modify per results above and received investigators' agreement on adaptation into the first draft manual	First draft
5: Topical experts	Sent the first draft manual to 3 topical experts and 2 investigators for comments and revision	First draft
6: Integration	Integrated experts' and investigators' comments to make the second draft, added Vietnamese illustrations to make the third draft in English, and sent the third draft to experts and investigators again for comments; translated the third draft to Vietnamese; sent the Vietnamese version of the third draft to a Vietnamese topical expert for revision and to ensure conceptual equivalency	Second draft
7: Training	Creators of FB trained for trainers in Vietnam; trainers trained for counselors	Third draft
8: Testing	Piloted the third draft for 5 people living with HIVs on MMT and having CMDs; revised third draft to make final manual	Final

^aMMT: methadone maintenance treatment.

^bCMD: common mental disorder.

^cEIP: evidence-informed program.

^dFB: Friendship Bench.

^eIDI: in-depth interview.

^fFGD: focus group discussion.

^gHMU: Hanoi Medical University.

Ethics Approval

The study protocol is available at ClinicalTrials.gov (NCT04790201). The study protocol, interview guides, and informed consent forms were approved by the institutional review boards at University of North Carolina at Chapel Hill on August 24, 2020 (study 20-1689), and HMU on June 19, 2020 (decision 119 ĐHYHN). All the study participants provided written informed consent in Vietnamese.

Results

Phase 3: Adaptation

Overview of the Study Participants

We approached 67 patients using purposive sampling representing people living with HIV on MMT in 4 MMT clinics in Hanoi to answer the DASS-21 questions. Less than one-third of the patients approached (19/67, 28%) met the DASS-21

threshold CMD scores. Of 19 eligible patients, 12 (63%) agreed to be interviewed. A patient was female. The average age of the patients was 44 years. In all, 83% (10/12) of the patients had symptoms of depression, 83% (10/12) had symptoms of anxiety, and 33% (4/12) had symptoms of stress at screening (Table 2).

The age of family members and caretakers ranged from 60 to 73 years. All participants were either retired or unemployed. Health care providers included 2 MMT clinic directors, 1 associate director of CDC Hanoi, and 1 deputy director of the Hanoi Department of Health. A total of 10 health care workers, including MMT physicians and nurses in MMT clinics aged 35 to 66 years, participated in 2 FGDs.

The adaptation phase in our study aimed to explore the most culturally appropriate way to adapt FB in Vietnam. Using IDIs with patients, their family members or caretakers, clinic directors, and FGDs with health care providers, we addressed the who, where, when, and how regarding the administration of the FB program in the MMT clinics.

Table 2. Demographic characteristics of participants (N=12).

Demographic characteristics	Value
Gender, n (%)	
Male	11 (92)
Female	1 (8)
Age (years), mean (SD; range)	44 (6; 35-56)
Employment, n (%)	
Unemployed	6 (50)
Working full-time or part-time	6 (50)
Marital status, n (%)	
Single	5 (42)
Married	3 (25)
Divorced or separated	4 (33)
Years on ART ^a , mean (SD)	8 (6)
Years on MMT ^b , mean (SD)	5 (2)
DASS-21^c, n (%)	
Symptom of depression	10 (83)
Symptom of anxiety	10 (83)
Symptom of stress	4 (33)
Number of types of different CMD^d symptoms, n (%)	
One symptom	3 (25)
Two symptoms	6 (50) ^e
Three symptoms	3 (25)

^aART: antiretroviral therapy.

^bMMT: methadone maintenance treatment.

^cDASS-21: Depression, Anxiety, and Stress Scale-21 items.

^dCMD: common medical disorder.

^eOverall, 5 had depression and anxiety 1 had anxiety and stress.

Who Should Deliver the Program

When being asked who (health staff person or peer) should provide the FB program for people living with HIV on MMT, the study respondents gave mixed reviews of who would be best for the FB program. Broadly, it appeared that directors and focus group respondents saw more advantages with a staff member as the program provider. Among family members, caretakers, and patient respondents, there was no distinct, overarching opinion on a preferred program provider. A total of 2 directors and 2 patient respondents shared that the professionalism of health care providers would be beneficial. A family member stressed that staff members should be purposively selected and need certain personality traits to be as effective as lay counselors, including honesty and willingness to share their experiences with patients in FB. Clinic providers noted that clinical experience with ART and MMT management are also helpful skills for a potential program provider. They shared that their mental health counseling experience may not be at the level needed for this type of program, as exemplified in focus group FGD_01:

It's certainly good. We haven't been trained in depression. We haven't had a chance to attend any depression courses. That's why we can't help our patients. We just told the patient's family to take the patient to the psychiatric clinic. Without experience, we can't support more than that. I have worked here for many years, but there has been no training course for depression.

A director emphasized key aspects to improve and that staff members as program providers may need further training and understanding, enthusiasm, and gentleness:

Knowledge is always along with skills. They must be trained in skills and knowledge, when they understand, they can do it. Their attitude and their speech towards the patients must be from their hearts. If it's a real feeling, the patients will believe in the health workers. Patients are sensitive, sometimes only a glance could affect them. [Director_IDI_D03]

For the program led by peers, participants from different groups (1 director, 4 FGD participants, 2 family members, and 7

patients) agreed that peers could understand patients very well. Peers and patients had many similarities in terms of life, health, and living conditions. Peers understood the patient's language and experienced similar things, both good and bad. In addition, formality was unnecessary between them, making it easier for patients to talk and share their opinions with peers, which could not be achieved with staff members:

I think it's feasible because they are the persons same as us, so they can understand the mindset of sick people like me, you are not sick so you cannot understand our thoughts. [Patient_IDI_102]

Moreover, peers had a better understanding of patients' health conditions from their perspectives and experiences. All of these built more trust between peers and patients, facilitating the counseling sessions. However, according to clinic providers and directors, to successfully implement the FB program, peers had to have a serious attitude and commitment to the task. In doing so, they need training on how to provide counseling and care for patients to fulfill the tasks of a counselor. In addition to their practical experience, peers should update their knowledge about the topic and improve communication skills to effectively transfer what they have learned to the patients. Only 1 clinic health care provider and 1 patient were concerned that peers might not be able to fully understand their patients' conditions. Because of their addiction and medication and their mental state, it might be difficult to find enthusiastic and suitable peers to lead the program:

Because a peer can change differently day by day, it's difficult to find an appropriate methadone peer, but it is easier to find an ART peer. In my clinic, there is a peer who also counsels other patients...But we should think carefully about selecting methadone peers, we should consider medical staff doing the programme because we don't know if they [peers] are stable or not. We may have to change to others if we choose them. [FGD_01]

In addition, although peers might receive training to do the job, they lack practical experience in caring for patients with different types of mental problems. A dominant theme among the patient respondents was the importance of the personality traits and counseling approach of the program provider. Patient respondents stressed the need for counselors who are gentle, empathetic, and understanding:

Someone like me needs affection, gentle speech, even a slightly unappropriated attitude will lead to my rejection. I need them to be considerate and gentle. [Patient_IDI_303]

Considering the insights from interviews and FGDs in the adaptation phase, the study selected health care providers and people living with HIV or community members who were trusted by the study participants to work as study counselors in the RCT.

When to Deliver the Program

All clinic directors, health care providers, family members, and 9 participants (14 references from clinic directors, 15 references from FGDs, 10 references from family members, and 46

references from patients) reported their concerns about what time to implement the FB program. They all shared that as many patients work, it might be challenging to find a suitable time for them to attend the FB program. Most of the patients suggested that the counseling sessions should be in the morning when they come to take methadone:

Because we usually take the medicine in the morning and after that, we can do activities. In the afternoon, we can't wait, at that time we have to go home, so the most convenient time is the morning. [Patient_IDI_301]

A patient shared that many patients could not sit for a long time, which would affect their participation in the counseling sessions. The patient believed that the counseling time should be arranged to suit the patient's employment and examination time, such as on weekends. For clinic directors and health care providers, apart from patients' employment, the timetable for clinic providers is very strictly scheduled; thus, time arrangement for the clinic providers to join the FB program is problematic. Providers thought that it is best to conduct FB during office hours to ensure convenience and safety for counselors and patients:

If we do it outside of office hours, we should consider the safety of people here. If something happens, we are also affected. So we should do counseling in the daytime, not nighttime because we can't control if they do something bad or not. [FGD_01]

However, it is necessary to arrange counseling time in advance so that clinic staff do not have many overlapping tasks and have enough time for counseling patients:

So if we have such a programme then we have to have a better management of our time so that we can do it. [FGD_01]

Where to Deliver the Program

All directors and most health care providers said that the place of program should be at the MMT clinic, as this is the place MMT patients visit every day. At MMT clinics, there were examination rooms; therefore, confidentiality and privacy would be ensured during the counseling sessions. Counseling outside the MMT clinic might be noticed by community members, which patients feared would cause them to be disliked. In addition, it is illegal for drug addicts to congregate in public spaces:

It's not possible to gather in the community. It is against the law, they are already drug addicts, if they gather that is against the law, and people in the community don't like that, so the methadone treatment facilities are the most suitable places. In the community, there are also a few places like that, but I only see their family come, I never see them [patients/people on treatment]. So, the medical facilities are still the best place. [Director_IDI_D03]

Half of the patients (6/12, 50%) and almost all family members (4/5, 80%) preferred to receive counseling in MMT clinics for convenience and safety for both counselors and patients,

ensuring privacy for patients and having timely and relevant health services if needed. The other respondents expressed that they needed to have a private and confidential place for counseling. They also suggested that the program only needs to designate a random room in the clinic as the counseling room and that it would be great if the room could have materials or visual aides to refer to or use.

What and How to Deliver the Program

All 4 directors mentioned that the program should be facilitated by the medical leadership. According to the directors and health care providers, to have the FB program implemented, it is crucial that the program follows all the administrative procedures of the MMT clinics before starting it. It should have a clear and detailed work plan, in which who, how, where, and when to conduct each activity are specified. Importantly, it is necessary to know about the people living with HIV on MMT and the severity of their CMD symptoms to have appropriate approaches and program sessions for them:

If the programme is implemented in the clinic, in general, in terms of administrative procedures, I also said earlier that there must be a direction. As for the implementation, first, you must have purposes and goals, then it is necessary to train staff, then find the target group we need to consult, and then plan a schedule for specific activities, jobs. [Director_IDI_01]

From the perspective of patients and their family members, though they believed that patients would benefit from a program such as FB, they thought the patients would participate in the program if they received compensation for their time and effort in participating in FB sessions (3/31, 10%) and did not have to pay or have any additional restrictions for program participation (2/31, 6%):

If only he participates without any condition from the programme, that's very good. [Family_IDI_1011]

Participants thought that not having any additional challenges related to employment (10/31, 32%), financial issues (12/31, 39%), and transportation (2/31, 6%) would facilitate participation. Patients expected the program to be new and be organized interestingly and attractively:

I can't imagine it yet, but I want new and interesting methods. We will love it and if the programme have people like you, we will join. [Patient_IDI_101]

Family members and patients discussed the following recommendations: the program materials should be easy to understand; fruits, cake, and drinks should be provided; patients who actively participated in the program activities and adhered to treatment should be rewarded and praised; and if possible, the program could assist patients with job opportunities or friend-making.

Both clinic providers and patients agreed that they preferred to delicately, rather than directly, discuss mental health to help patients feel comfortable. A health care provider suggested the use of words and language that is familiar to patients to help them feel more comfortable joining the program:

I think their language when talking together is very important, they want to release and use their language to feel comfortable but they can't do that when talking to medical staff. [FGD_01]

A patient even suggested excluding the name of the program if possible. None of the suggestions for the language surrounding FB included “mental illness” in the program name.

From the perspective of family members, words in Vietnamese that are simple and easy to understand with positive meaning were preferable, and sensitive words that might worsen patients' mental state should be avoided. A health care provider and a patient thought that the name “Friendship Bench” was beautiful and acceptable, as it did not mention the problem and had a pleasant feeling:

The Friendship bench name is also very beautiful and good. [FGD_F01]

Phase 4: Production

The results of the qualitative research in phase 3 were presented in a web-based meeting with 2 investigators, 2 creators of FB, and 1 expert from HMU to reach a consensus on the necessary adaptation of the FB manual. The original FB was adapted for use by both health care providers and lay counselors in Vietnam. Table 3 describes the details of FB adaptation. Overall, the manual illustrations of counselors were changed from Zimbabwean to Vietnamese and included both sexes. The illustrations of case studies have also been redrawn. The title “Lay Health Workers” was changed to “Counselors” to suit both groups of health care counselors and lay counselors for the study in Vietnam. The training curriculum was shortened from 8 to 5 days, and the new training program was written in a web-based format. The preface cited additional information about HIV infection and substance use patterns in Vietnam and provided a brief introduction to the adaptation of the FB manual to the study in Vietnam.

We retained the content of 8 out of the 23 chapters in the original manual. The 8 chapters included PST, counseling skills, FB cards, emotions, stabilization, strong emotional reactions, men's health-seeking behaviors, and self-care. We completely removed 6 of the 23 chapters, namely epilepsy, belief in supernatural powers, psychosis, home visits, group circle, and proverbs. We edited the contents in 8 of the 23 chapters. Key edits included using the words *Common Mental Disorders* to refer to a collective term of depression, anxiety, and stress-related disorders instead of “kufungisisa” (Zimbabwean for depression and anxiety), replacement of SSQ-14 to DASS-21, and suicide risk assessment and management procedures, which were used in the study in Vietnam. In addition, we excluded sessions on abuse of bronchodilators, alcohol and pregnancy, and information about antipsychotics, as they were not related to the study population. Information about the use of FB on tablets was removed, as the Vietnam FB program used paper forms to record counseling session information. Information on HIV transmission through injection, substance abuse disorders caused by injecting drugs, and amphetamine-type stimulants, which were common issues of people who inject drugs—the study population in the RCT—was added.

Table 3. Summary of changes in Friendship Bench (FB) manual.

^aN/A: not applicable.

^bCMD: common mental disorder.

^cSSQ: Shona Symptoms Questionnaire.

^dDASS-21: Depression, Anxiety, and Stress Scale-21 items.

^eART: antiretroviral therapy.

^fMMT: methadone maintenance treatment.

All cases were revised, and the PST case was rewritten. In the original FB, the PST case featured a common problem in the Zimbabwe community, and the main character was a person with an unknown HIV status, a person with SUD, or a woman experiencing domestic violence. The new character in the adaptation was people living with HIV who inject drugs with short-term, solvable problems about employment, family matters, finances, and relationships with neighbors.

Phase 5: Topical Experts

The first English version was sent to 2 investigators, 2 creators of FB, and 1 expert from HMU for viewing and editing. All of them are associate professors with intensive expertise in the areas of mental health, HIV or AIDS, and substance use. They have led clinical studies and trials on a global scale. Experts advised correcting cases of PST to adjust them to Vietnamese culture. They recommended not changing the in-person counseling procedures and having up to 6 individual counseling sessions for each patient. An FB creator wrote scripts for the counselors to be included in the draft. The creator also advised maintaining the PST structure, with 4 main parts in each counseling session. The 4 main parts were the following: open your mind, make a list of problems, plan to solve the problem according to the Specific, Measurable, Achievable, Realistic, and Timely method, and encourage the clients to implement the plan. The 4 main parts of the PST were implemented into 7 small steps: (1) How does the client deal with problems? (2) How to recognize a problem? (3) How to select a problem, find the goal, and define the problem? (4) How to brainstorm for solutions? (5) How to select a solution? (6) How to make a Specific, Measurable, Achievable, Realistic, and Timely action plan? and (7) Did it work?

Phase 6: Integration

On October 20, 2021, a meeting was held on the web with 3 content experts, the study team in Vietnam, and 2 investigators. The investigators agreed on continuing to revise the case example of a typical people who inject drugs who encounters common mental problems in their life. These problems should be specific, simple, and solvable within 1 week. For example, "I want to quit using drugs for the next 1 year because next

week is my son's birthday." The study team agreed to remove the group discussion portion, as it would be ineffective where MMT clinics are far from each other, without finding additional study resources. The study team then synthesized the expert revision to create the second draft in English. Illustrations of Vietnamese people were added to the second English version to make the third version which was sent to 3 content experts and 2 investigators to review and finalize. The third English version was translated into Vietnamese with the same content and images. A Vietnamese topical expert reviewed the translated third version to ensure conceptual equivalency.

Discussion

Principal Findings

This study successfully illustrates the process of operationalizing the ADAPT-ITT framework to adapt to a mental health program in Vietnam. The outcome of this study was an adapted FB manual to be used for training and piloting to create the final program manual.

We note that our study departs from the standard ADAPT-ITT framework by selecting an EIP that does not come from the CDC database of EIPs [26] and by adapting a program addressing CMDs rather than HIV prevention per the usual ADAPT-ITT goals [25]. Nevertheless, our study was methodologically aligned with the ADAPT-ITT goals, as we chose a proven, effective program for adaptation. FB improved CMDs among people living with HIV in Zimbabwe and Malawi, and we hope to use FB to address CMDs among people living with HIV on MMT in Vietnam.

The application of the ADAPT-ITT framework for the systematic adaptation of EIP can vary depending on the program, population, and resources [28,30,39]. A key strength of this study is that it used a linear approach to adapt the ADAPT-ITT framework on a small scale [28]. Results of the previous phases provided informative contributions for the next phase [40] in terms of the program procedures and content of the program manual. Other study and adaptation strengths were the translation into Vietnamese and the creation of local

illustrations to increase the clarity of the concepts while maintaining the original meaning of the English version.

The results from phase 3 informed the program procedures built upon the existing resources and administrative strength of MMT clinics [40]. As a result of adaptation, the study will choose health care providers and people living with HIV or community members who are trusted by the study participants to work as study counselors. The counselors will be trained and managed closely to ensure the quality of counseling. The counseling locations must be private and safe in MMT clinics. Counseling appointments will be scheduled between counselors and patients in parallel. Standardized criteria of counselors to deliver the program are defined as being understanding and having the trust of the patients but not necessarily having a high level of counseling techniques before training. Instead of using tools and procedures in the original FB program, the study will use questionnaires and protocols relevant to the study participants.

Regarding the content of the manual, the ADAPT-ITT framework guided the appropriate adaptation of the program while maintaining the core components of the PST of the original program throughout the counseling techniques in all program sessions [25,26]. The strength of our adaptation process was that the PST of the original FB fits the goals of reducing CMDs for people living with HIV on MMT in Vietnam; therefore, we did not have to change PST counseling as well as other chapters mentioning CMDs, HIV, and SUD in the original program that address common problems that global and Vietnamese people living with HIV and people who inject drugs encounter [41,42]. Feedback from topical experts informed the study team to alter some contents of the original program to ensure that it was suitable for Vietnamese people living with HIV on MMT and in MMT settings [27,40]. Specifically, unlike the original program conducted in Zimbabwe, we cut content that is not common in Vietnamese culture such as a church, beliefs in supernatural power, and praying together. The study also changed the illustrations from Zimbabwean to Vietnamese. Information from a qualitative study in phase 3 about common health problems faced by people living with HIV on MMT (the results are not reported within the scope of this paper) helped the study team rewrite sample PST cases to reflect typical problems in the key population. In addition, because of the new study with people living with HIV on MMT in Vietnam, we added additional guidelines on HIV, injecting drugs, and SUD to the original program to make it more culturally relevant and

relevant to the study population. As recommended by topical experts, we dropped group activities that were proven more adaptive to the Zimbabwean setting and chapters less relevant to the target population (fatherhood, alcohol and pregnancy, epilepsy, and psychosis).

Limitations

This study has some limitations, the first being that the process of adaptation and production has not yet tested the feasibility and acceptability of the adapted manual. In addition, the semistructured interviews had not presented the original manual to the study participants. Therefore, we did not have comments from them on the content of the manual. Instead, the content of the manual was reviewed and revised in detail according to the study team's revisions and experts' comments. There might be challenges such as following the structure of FB counseling sessions, applying relevant counseling skills required in FB, following PST methods for health care, and lay counselors using the adapted manual as a resource material in conducting PST counseling sessions as they first work with this approach. As such, the adapted manual will be used to train counselors and piloted with the study participants of the future RCT to receive feedback to finalize the manual. Study participants and counselors can provide their feedback during the pilot phase. Future RCTs will test the acceptability and fidelity of the finalized adapted program.

Conclusions

This initial exploratory study demonstrates a successful process of following the ADAPT-ITT to adapt a proven mental health program for people living with HIV on MMT in Vietnam. This study selected and culturally adapted an evidence-informed PST program to improve CMDs among people living with HIV on MMT in Vietnam. The adaptation of the program through qualitative interviews and discussions with stakeholders and study participants and the use of feedback to tailor the program procedures allowed us to identify and preemptively address potential barriers to implementation. The production, integration, and expert input phases were used to tailor the manual to reflect typical manageable problems that people living with HIV on MMT encounter daily. If the adapted FB manual is acceptable and feasible, it may be used in MMT clinics in Vietnam to reduce CMDs for patients on MMT, which would contribute to the effectiveness of drug treatment and ART.

Acknowledgments

The authors are grateful for the support of the leaders of the Hanoi Department of Health and the Centers of Disease Control Hanoi and the 4 methadone maintenance treatment clinics in Hanoi for the implementation of this study. The authors would like to thank interviewers Nguyen Nhu Trang and Vu Thi Thanh Nhan who conducted the interviews for this study. Finally, the authors would like to thank the participants for their invaluable contribution to this research.

Authors' Contributions

BNG and BWP obtained funding and designed the study. HVT and HTTN oversaw training and data collection. HVT collected the data. TTTT, HTTN, TRF, and KRL coded and analyzed all data. KRL created the analysis plan, reviewed the coding, and reviewed memos to measure consistency and reliability. HVT drafted the manuscript. BNG, BWP, KRL, TRF, VFG, RV, HTH,

MXN, DC, and GML commented on, reviewed, and revised the manuscript for important intellectual content. All authors contributed to and approved the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Neurofeedback training (NFT) has been shown to be effective in treating several disorders (eg, attention-deficit/hyperactivity disorder [ADHD], anxiety, and depression); however, little is currently known regarding the effectiveness of remote NFT systems.

Objective: This retrospective study provides real-world data (N=593) to assess the efficacy of app-based remote NFT in improving brain health and cognitive performance.

Methods: Improvement was measured from pre- to postintervention of in-app assessments that included validated symptom questionnaires (the 12-item General Health Questionnaire, the ADHD Rating Scale IV, the Adult ADHD Self-Report Scale, the 7-item Generalized Anxiety Disorder scale, and the 9-item Patient Health Questionnaire), a cognitive test of attention and executive functioning (ie, continuous performance task), and resting electroencephalography (EEG) markers. Clinically significant improvement was evaluated using standard approaches.

Results: The greatest improvement was reported for the anxiety questionnaire, for which 69% (68/99) of participants moved from abnormal to healthy score ranges. Overall, adult and child participants who engaged in neurofeedback to improve attention and executive functions demonstrated improved ADHD scores and enhanced performance on a cognitive (ie, response inhibition) task. Adults with ADHD additionally demonstrated elevated delta/alpha and theta/alpha ratios at baseline and a reduction in the delta/alpha ratio indicator following neurofeedback.

Conclusions: Preliminary findings suggest the efficacy of app-based remote neurofeedback in improving mental health, given the reduced symptom severity from pre- to postassessment for general psychological health, ADHD, anxiety, and depression, as well as adjusted resting EEG neural markers for individuals with symptoms of ADHD. Collectively, this supports the utility of the in-app assessment in monitoring behavioral and neural indices of mental health.

KEYWORDS

EEG biofeedback; remote care; neurofeedback; attention-deficit/hyperactivity disorder; delta/alpha ratio

Introduction

Background

Neurofeedback training (NFT) is considered a primary or supplementary treatment for a number of disorders, including

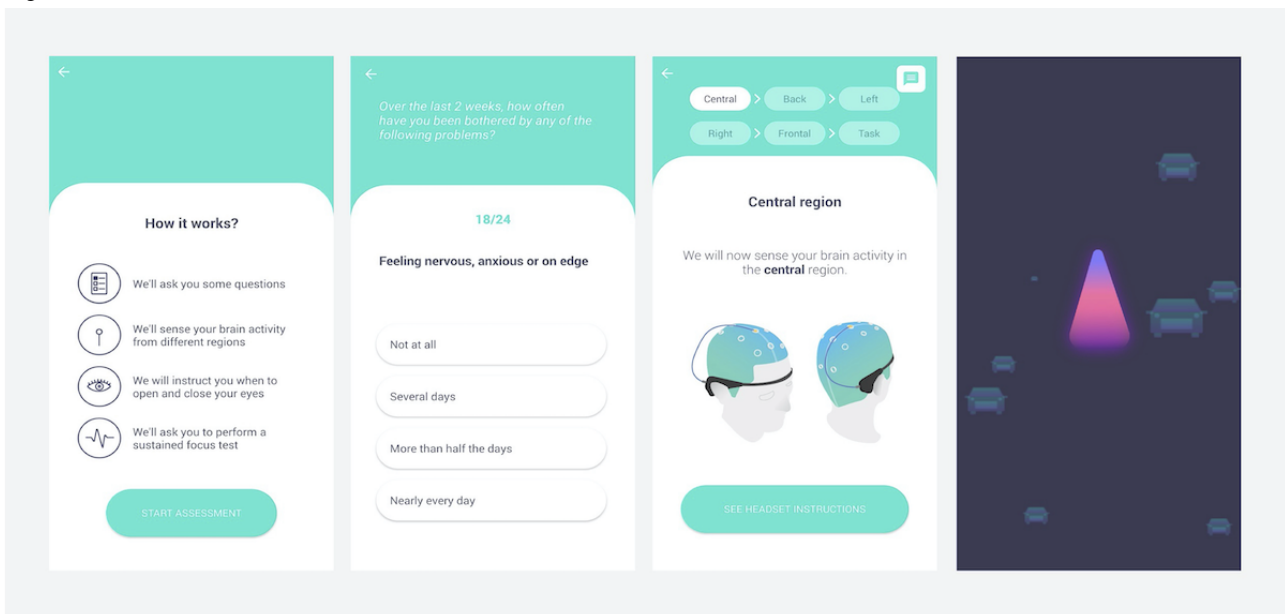

attention-deficit/hyperactivity disorder (ADHD) [1-5], anxiety [6-9], and depression [7,8,10]. The American Academy of Pediatrics [11] provided a “level 1 best support” rating of NFT as a safe and effective evidence-based therapy for childhood ADHD. Nonetheless, several significant barriers prevent patients from receiving quality neurofeedback therapeutics; for example,

electroencephalography (EEG) systems are expensive, complex, and often only accessible at health care clinics. A recent pilot study [12] provided encouraging evidence for the efficacy of therapist-guided NFT, suitable for remote home-based use. Findings showed improved ADHD symptomatology in a small cohort of children after 9 weeks of NFT. The system was designed as an affordable convenient wireless alternative to clinic-based EEG. NFT users regulate neural activity through operant conditioning, which can lead to morphological changes in the brain [13,14] and calmer, more focused cognitive, affective, and physical functioning. Currently, little is known about the effectiveness of NFT systems in the field [15]; therefore, this retrospective open-label pilot study offers real-world data supporting the efficacy of remote NFT in improving brain health.

Mental Health Improvement in Real-World Settings

Unlike standard EEG systems, Myndlift is an easy-to-use tool for patients and clinicians (Figure 1). While wearing the validated EEG headband (Muse; InteraXon [16,17]) containing four dry recording electrodes (ie, anterior frontal [AF] 7, AF8, temporal pole [TP] 9, and TP10), one ground electrode, and one auxiliary wet electrode, the patient trains with an Android or iOS app linked to the headset by Bluetooth, which delivers visual and auditory feedback during YouTube videos or specialized games. When patients' brain waves are in the desired range, positive feedback is delivered. A therapist can set or adjust the training protocol and monitor progress remotely via a cloud-based web service. The device incorporates an app-based assessment, lasting approximately 40 minutes, completed prior to NFT (ie, baseline) and periodically over the intervention period for longitudinal tracking of improvement.

Figure 1. Myndlift in-app assessment screens. From left to right: introduction, symptom questionnaires, resting electroencephalography assessment, and cognitive task.

Real-world studies provide external validity and accurately represent the heterogeneity of a patient population [18]. From the app, real-world data were collected from more than 500 participants on outcome measures, including pre- and postintervention assessments of validated symptom questionnaires, a cognitive test of attention and executive functioning (ie, continuous performance task [CPT]), and resting EEG markers. An efficacious system could serve as a reliable, cost-effective solution for users. In-clinic NFT costs approximately US \$150 to \$200 per session, with a minimum of 30 to 40 sessions typically recommended. In contrast to a cost-per-session model, remote NFT could offer monthly charges, ranging from US \$200 to \$500.

EEG Neuromarkers of ADHD

Given the success of neurofeedback for child ADHD, more adults with ADHD are turning to NFT for treatment. Currently, 6.76% of adults worldwide—translating to 366.3 million people—are affected [19]. ADHD is commonly recognized as a hypoaroused brain state [20]. In recent years, EEG measures

have provided supporting evidence for popular theoretical models of hypoactivation [21] related to core symptoms of hyperactivity, inattention, and impulsivity [22]. The hypoarousal state is best localized to frontal and posterior regions [23] (ie, neuroanatomical structures subserving attentional networks [24,25]). EEG patterns of ADHD in children are characterized by elevated low-frequency power (ie, primarily theta) and reduced *relative* high-frequency power (ie, alpha and beta) [23,26-28], or an elevated ratio of the two (ie, low to high frequency). The theta/beta ratio (TBR) is the most common form of NFT in treating ADHD [29,30]; however, inconsistencies in the literature suggest that TBR [31,32] may not be reliable as a diagnostic measure [33]. This may reflect EEG heterogeneity across ADHD-diagnosed individuals (eg, Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition [DSM-5] subtypes; psychiatric comorbidities; age; and sex) [34,35]. For instance, although theta and beta power differences are evident in child ADHD [31,36], a recent review [37] suggested that theta and alpha frequencies may be more reliable markers for adults. Notably, most adult studies

emphasize group differences in alpha power during eyes-closed conditions [38-43], while more recent work has identified elevated theta and delta power in adults with ADHD [44,45]. Given this evidence, this study investigates whether TBR versus the delta/alpha ratio (DAR) or the theta/alpha ratio (TAR) are biomarkers for adult ADHD. Overall, the study evaluates evidence for improvement in mental health via symptom questionnaires, a CPT, and hypothesized EEG markers. Findings have implications for the benefits of NFT and efficacy of a remote home-based system.

Methods

Participants

Participants, 13 years of age or older, signed up through their clinician or a clinician suggested by Myndlift and completed NFT at home or in clinic in a clinical care context. Informed consent was provided through the app, allowing participants' anonymized data to be used for research. Data were included for analysis if baseline (ie, preintervention) assessment was conducted after 7 or fewer NFT sessions (ie, attributed to in-app NFT tutorial). For analyses of improvement, postintervention sessions occurred 30 to 180 days after baseline with 20 or more NFT sessions completed [46]. An average of 1 or more NFT sessions per week was required for inclusion, given that effective neurofeedback requires consistency [47,48], irrespective of the neurofeedback protocol used. Data were collected via the app.

Ethical Considerations

Procedures were reviewed by an independent Institutional Review Board (IRB)—Pearl IRB—who permitted IRB exemption for analyses of data previously collected and deidentified, following the guidelines of the Declaration of Helsinki.

Neurofeedback Protocol

Participants performed neurofeedback protocols (Multimedia Appendix 1) that were customized by their clinicians and consistent with current literature [49].

Procedure and Outcome Measures

Symptom Questionnaires

The in-app assessment includes 14 brief standardized questionnaires commonly used to screen for mental health conditions. In this study, data were reported for the following five questionnaires completed at baseline and follow-up by at least 25 participants: the 12-item General Health Questionnaire (GHQ-12) [50], the ADHD Rating Scale IV (ADHD-RS-IV) [51], the Adult ADHD Self-Report Scale (ASRS) for DSM-5 [52], the 7-item Generalized Anxiety Disorder scale (GAD-7) [53], and the 9-item Patient Health Questionnaire (PHQ-9) [54]. For each questionnaire, participants filled out self-report measures based on frequency of symptom occurrence using a 4- or 5-point Likert-style scale. Total scores were calculated for use in improvement analyses. Participants engaging in neurofeedback for ADHD completed the ASRS [52] if they were 18 years of age or older; otherwise, they completed the ADHD-RS-IV. The GHQ-12, GAD-7, and PHQ-9 were completed by participants of all ages [55-58].

Continuous Performance Task

The assessment contained an 8-minute CPT, a behavioral test of response inhibition, in which participants are instructed to tap the screen when the target object (ie, an arrow-like shape pointing upward) is shown, but not when other stimuli appear. The interstimulus interval and presence of audiovisual distracter stimuli were varied throughout the task. Outcomes included average response time (RT) and response time variability (ie, the SD of RT [SDRT]), as well as omission and commission errors related to inattention and impulsivity, respectively [59]. This type of test is commonly used as an objective measure of attention and executive function [60-62] and has become a standard assessment tool for attentional difficulties [59,63,64].

Resting EEG

Resting EEG was recorded from 9 electrodes (ie, AF7, AF8, TP9, TP10, central [C] zero [z], frontal [F] z, F3, F4, and occipital [O] 1). The EEG assessment was divided into five sequential (ie, "sensing") phases; in each phase, the auxiliary electrode was placed at a different scalp location: central (Cz), frontal (Fz), left (F3), right (F4), and back or posterior (O1). Each phase was split into eyes-closed and eyes-open blocks. A block continued until 30 seconds of clean EEG—sampled at 256 Hz—had been recorded, which typically took up to 45 seconds.

Statistical Analysis

Symptom Questionnaires

Questionnaire results were analyzed in terms of improvement in total score from pre- to postintervention, including mean change in points, effect size (ie, Cohen *d*), and percent of users with clinically significant improvement, defined as 20% improvement [65,66]. Results are presented separately for participants scoring in healthy and abnormal ranges at baseline, as per conventional clinical cutoff values. The percent of participants who shifted from abnormal to normal (ie, healthy) ranges after the intervention is also reported. Paired-samples *t* tests (2-tailed) evaluated statistically significant improvement for each clinical measure ($P < .05$). By convention, small, medium, and large effects correspond to $d = 0.2$, $d = 0.5$, and $d = 0.8$, respectively. For symptom questionnaires, CPT, and resting EEG analyses, multiple comparisons were corrected using the Benjamini-Hochberg (BH) method [67] to maintain a family-wise error at $P = .05$, reported as BH-adjusted *P* values (P_{BH}). The Levene test assessed assumptions of equality of variance and corrected for inhomogeneities.

Continuous Performance Task

CPT results were analyzed for participants who completed child (ie, ADHD-RS-IV) or adult (ie, ASRS) ADHD questionnaires. Results are given in terms of improvement in RT and SDRT for correct responses (ie, shorter and less variable response times, respectively), commission errors, and omission errors. This includes mean change, in milliseconds or errors, and effect size. RT and SDRT scores were standardized by age to minimize age effects on performance [68]. Percent of participants demonstrating clinically significant improvement was reported, defined by a reliable change index (RCI) [69] that accounts for

practice effects [70]. Exceeding a critical value of 95% for a 1-tailed test—equivalent to 1.65 SD units on a standardized z scale—indicates a significant reliable change, similar to others [71].

Resting EEG

Participants who completed the adult ADHD questionnaire at baseline were split into groups with “healthy” and “abnormal” ranges of values based on their score. Only participants with clean EEG signals were included (see [Multimedia Appendix 2](#) for EEG preprocessing). Results were reported in terms of EEG amplitude (ie, Hz; relative power) for TAR, DAR, and TBR at baseline. Independent-samples t tests were conducted for each power ratio across groups (ie, healthy and abnormal values). Frequency bands were defined as follows: delta (1-4 Hz), theta (4-8 Hz), alpha (8-13 Hz), and beta (13-30 Hz). These were averaged across frontal electrodes (ie, F3 and F4, based on the frontal nodes of the frontoparietal network [25,72] and the

prevalence of a clean EEG signal) during the eyes-closed condition. Improvement analyses were conducted separately for each group and included the mean change in ratio amplitude from pre- to postintervention and associated effect size; paired-samples t tests were used to evaluate within-group changes.

Results

Sample Characteristics

Data from 560 participants met the criteria for inclusion in the analysis. Depending on clinical considerations determined by their therapist, subsets of participants completed each symptom questionnaire, CPT, resting EEG, or any combination of the three. [Table 1](#) gives sample characteristics for each assessment component, including the NFT protocols completed by 50% or more of each sample population ([Multimedia Appendix 1](#)).

Table 1. Sample characteristics as separated by each outcome measure and analysis.

Measure	Age (years)		Gender, n (%)		Test setting, n (%)		NFT ^a protocols used in ≥50% of sample	No. of sessions, mean (SD)	Treatment duration (days), mean (SD)	Frequency (sessions/wk), mean (SD)

Symptom Questionnaires

Results for participants who completed symptom questionnaires (n=301) were separated into groups with abnormal and healthy scores ([Table 2](#)). Most participants engaged in NFT protocols to reduce theta (227/301, 75.4%) and enhance high beta (248/301, 82.4%), while many who completed the PHQ-9 (76/134, 56.7%) and the ASRS (59/112, 52.7%) also performed enhanced alpha, whereas children who completed the ADHD-RS-IV also often included enhanced low beta (21/27,

78%) and enhanced sensorimotor rhythm (SMR; 16/27, 59%). In the groups with abnormal results, all questionnaires had large effect sizes ($d=0.99$ to 2.41), while the effect sizes for groups with healthy results were large only for child and adult ADHD questionnaires. Improvement in the groups with abnormal results was statistically significant for all questionnaires, with the majority (30/56, 54% to 7/7, 100%) of users demonstrating clinically significant change (ie, ≥20%) [65,66]. The most prominent improvement was observed in participants with abnormal baseline anxiety or child ADHD scores. Nevertheless,

ADHD-RS-IV findings are considered preliminary given the small sample size. Most participants (30/56, 54% to 7/7, 100%) in the groups with abnormal results shifted their values to healthy ranges at postintervention. Improvement of healthy

participants was statistically significant for all questionnaires, with the majority (30/66, 45% to 14/20, 70%) demonstrating clinically significant change.

Continuous Performance Task

Participants completing CPT and ADHD questionnaires performed primarily reduced theta (76/99, 77%) and enhanced high beta (81/99, 90%) protocols. Most adults also performed enhanced alpha (54/90, 60%), whereas most children also performed enhanced low beta (9/9, 100%) and enhanced SMR (7/9, 78%). Results (n=99) for average RT, SDRT, omission errors, and commission errors were divided by abnormal versus healthy scores for child and adult ADHD combined (Table 3). The greatest improvement observed, irrespective of group (ie, abnormal and healthy ADHD ranges), was in SDRT ($d=1.02$

and $d=1.24$, respectively), where nearly half of the participants (42/99, 43%) demonstrated clinically significant improvement, as indicated by the RCI. Although average RTs improved comparably (42/99, 43%), differences between pre- and postintervention were significant only for the healthy results group ($d=0.56$). At least one-third of users improved in their commission errors (35/99, 35%) and omission errors (45/99, 45%) from pre- to postintervention. Results from a group (n=104) with unknown ADHD assignment were comparable to those of groups with abnormal and healthy results (Multimedia Appendix 3).

Table 3. Improvement in CPT after ≥ 30 days of Myndlift neurofeedback (n=99) separately for healthy users that scored in the normal range for children or adults at baseline and for those in the abnormal ADHD range (per conventional clinical cutoffs).

EEG Indicators of Adult ADHD

Resting EEG Baseline

The DAR, TAR, and TBR were calculated from baseline resting EEG data (n=271) in frontal regions (ie, average of F3 and F4) with eyes closed from participants scoring in abnormal (n=125) or healthy ranges (n=146) on the adult ADHD questionnaire.

Regarding the DAR, an independent-samples *t* test demonstrated that participants in the abnormal results group (mean 1.10, SD 0.61) had significantly greater frontal DAR than healthy participants (mean 0.90, SD 0.48; $t_{235}=3.02$, $P_{BH}=.009$, $d=0.37$). The Levene test indicated unequal variances ($F=5.25$, $P=.02$), so degrees of freedom were adjusted from 269 to 235. Post hoc independent-samples *t* tests confirmed that results were driven by participants in the abnormal results group having significantly greater frontal delta power ($t_{269}=2.80$, $P_{BH}=.01$, $d=0.34$) and less frontal alpha power ($t_{269}=2.61$, $P_{BH}=.01$, $d=0.34$) than healthy participants.

Regarding the TAR, a comparable *t* test reported a significant difference for the frontal TAR ($t_{269}=2.46$, $P_{BH}=.02$, $d=0.30$), as participants with abnormal scores (mean 0.64, SD 0.30) had significantly greater ratios than those with healthy scores (mean 0.56, SD 0.26). Post hoc *t* tests confirmed that results were driven by less frontal alpha, as opposed to differences in theta ($t_{269}=1.11$, $P_{BH}=.27$, $d=0.13$).

Regarding the TBR, a final *t* test reported no significant difference between participants with abnormal scores (mean 0.66, SD 0.27) and those with healthy scores (mean 0.64, SD 0.31; $t_{269}=0.532$, $P_{BH}=.60$, $d=0.06$).

Preliminary Resting EEG Improvement

Changes in the DAR, TAR, and TBR in the frontal regions with eyes closed were reported for participants (n=41) scoring in the abnormal (n=20) or healthy ranges (n=21) of the adult ADHD questionnaire (Table 4). Most participants completed reduced theta (32/41, 78%), enhanced high beta (37/41, 90%), and enhanced alpha protocols (27/41, 66%). After correcting for multiple comparisons, significant improvement was only reported for the DAR in the abnormal results group.

Table 4. Change in resting EEG ratios from frontal (ie, average F3 and F4) electrodes during the eyes-closed condition after ≥ 30 days of Myndlift neurofeedback (n=41) for healthy users and separately for those that scored in the abnormal adult ADHD range (per conventional clinical cutoffs) at baseline.

Discussion

Principal Findings

This retrospective study offers initial evidence of therapist-guided remote neurofeedback as an effective tool for reducing subjective symptoms, improving objective cognitive performance, and adaptively modifying EEG markers. Improvements in attention were evident in children and adults with ADHD, as well as healthy participants. Findings suggest that the TBR is not a reliable marker for adult ADHD, instead demonstrating alternative elevated slow/fast power ratios [37]. Moreover, we provide preliminary evidence for improvement (ie, reduced DAR) in adults with ADHD. These findings offer a promising use for remote NFT as a low-cost alternative to clinic-based EEG.

Efficacy for Improving Mental Health Remotely

Based on real-world data, significant improvement was reported across standardized questionnaires. The greatest improvement was observed in participants with abnormal anxiety scores, where most received reduced theta, enhanced high beta, and enhanced alpha protocols. As anticipated, greater effect sizes were observed for participants with scores in the abnormal versus healthy ranges. Interestingly, healthy participants and those with ADHD, both children and adults, demonstrated significant improvement with large effect sizes after completing primarily reduced theta and enhanced high beta protocols, as well as adults who completed enhanced alpha protocols or children who completed reduced low beta and reduced SMR protocols. Consistent with the literature [33-35], our findings suggest that children and adults may benefit from unique NFT protocols to improve ADHD symptoms, although a larger sample is required to confirm preliminary ADHD-RS-IV results.

Apart from the child ADHD assessment, questionnaire analyses included large total sample numbers (ie, 112 to 263 participants), and after an average of 53 NFT sessions, 57% to 78% of the participants demonstrated significant improvement, depending

on the questionnaire. Results were particularly impressive compared to other in-app mental health therapeutics [73-76], such as mobile-enabled text psychotherapy [77] or app-based cognitive behavioral therapy [78]. The majority (61%) of participants scoring in the abnormal ranges moved to the healthy results group over an average of approximately 3 months, a time frame costing less than US \$1500 with Myndlift versus US \$6000 to \$8000 for traditional neurofeedback.

Improved Cognitive Performance for Healthy Participants and Those With ADHD

NFT led to greater consistency in response times on a response inhibition task for subjects scoring in healthy or abnormal ADHD ranges, agreeing with similar reports of subjects with ADHD [79,80]. In addition, the RCI demonstrated that approximately 50% of healthy participants improved their average response time, while similarly, participants in abnormal ranges reduced omission errors. Importantly, CPT findings agree with improved ADHD questionnaire scores, suggesting that NFT provides objective evidence of improved executive function, the primary cognitive domain impacted by attentional difficulties.

Identifying Adult ADHD Neuromarkers

Resting EEG findings demonstrated that elevated DAR and TAR were indicative of adult ADHD at baseline. This translated to significantly higher levels of delta and lower levels of alpha, as previously reported in adults with ADHD [39-42,81,82]. Notably, Liechti and colleagues [35] reported high theta to be less consistent in adults than in children, and that ADHD versus healthy control classification improved having exploratorily included delta waves in the discriminant analysis. Adults with ADHD may present slower theta waves—bordering fast delta waves—than children, although further analysis is required. Together, findings are consistent with the cortical hypoarousal theory, where low-power fast oscillations accompany reduced self-control and executive functioning [83], and high-power slow oscillations are reported with decreased subcortical motivational drive [84]. Preliminary evidence for reduced DAR

in adult ADHD from pre- to postassessment may reflect the improved ADHD symptoms and CPT measures, particularly given the success of protocols inhibiting slow oscillations and enhancing fast oscillation [1], and the high percentage of ADHD participants performing reduced theta (ie, slow) and enhanced alpha (ie, fast) protocols.

In contrast to our work and that of others, several groups reported high alpha power at baseline during eyes-closed conditions in adult ADHD populations [85,86], or rather, no difference across ADHD participants and healthy controls [87,88]. Importantly, variability across the adult ADHD literature may, in part, be due to the heterogeneity of ADHD [34,35] and differences in study designs, sample sizes, analyses, and EEG technology [89]. For example, Loo and colleagues [38] demonstrated that adults with ADHD combined-type (ie, symptoms of inattention and hyperactivity or impulsivity) present reduced alpha power globally, compared to ADHD inattentive-type or non-ADHD controls.

Limitations and Future Directions

Study results are encouraging, but conclusions should be tempered by limitations, including small subgroup sample sizes and lack of control groups. Moreover, subjects may have received alternative treatment in parallel (eg, medication) that could influence symptom improvement as well as alter neuromarkers. For example, two studies administering stimulants (ie, methylphenidate or dexamphetamine) to treat symptoms of ADHD in adults demonstrated altered delta [90,91] and theta waves [90] posttreatment. No changes in alpha or beta waves were reported. Given the evidence in this study for altered delta and alpha waves in adults with abnormal ADHD scores,

we would hypothesize that the mechanism of action for stimulants versus NFT may differ, *resulting in influence over varied frequency bands*. Moreover, as this population reflects real-world use, the likelihood of these two forms of treatment to have commenced simultaneously, for treating symptoms of depression, anxiety, and ADHD, would arguably be low. Those seeking treatment with remote neurofeedback most often do so to avoid taking pharmaceuticals [92,93] or, rather, to supplement their current treatment, which alone may not be sufficiently effective [94]. Frank H Duffy [95], a Harvard professor and pediatric neurologist, suggests that “if any medication had demonstrated such a wide spectrum of efficacy it would be universally accepted and widely used.” Further, controlled research studies will be required to facilitate comparison of neurofeedback efficacy with other interventions. Notwithstanding these limitations, the findings are essential as they reflect real-world benefits of remote neurofeedback to actual patients. Follow-up analyses will compare benefits across NFT protocols and will further evaluate the impact on resting EEG outcomes.

Conclusions

Preliminary findings from this retrospective pilot study demonstrate efficacy of remote NFT in improving mental health, particularly for individuals with symptoms of ADHD and anxiety, mainly through reduced theta, enhanced high beta, and enhanced alpha NFT protocols. Moreover, adult ADHD was distinguished from healthy individuals by elevated frontal DARs, where ratios were significantly reduced following NFT. The effectiveness of the system in a real-world population via remote use positions it as an affordable and accessible alternative to clinic-based systems.

Acknowledgments

Funding for this study was provided by McGill University, Montreal, Canada, and Myndlift Ltd. JCW received funding from McGill University for a doctoral internship.

Authors' Contributions

JCW conducted the analyses, interpreted the results, cowrote the paper, and revised the final version. RN co-designed the study, extracted the data, interpreted the results, cowrote the paper, and revised the final version. GMD designed the study, cowrote the paper, and revised the final draft. All authors reviewed and revised the results and approved the final version of the paper.

Abstract

Background: Behavior change apps have the potential to provide individual support on a population scale at low cost, but they face numerous barriers to implementation. Electronic health records (EHRs) in acute care hospitals provide a valuable resource for identifying patients at risk, who may benefit from behavior change apps. A novel, emerging implementation strategy is to use digital technologies not only for providing support to help-seeking individuals but also for signposting patients at risk to support services (also called *proactive referral* in the United States).

Objective: The OptiMine study aimed to increase the reach of behavior change apps by implementing electronic signposting for smoking cessation and alcohol reduction in a large, at-risk population that was identified through an acute care hospital EHR.

Methods: This 3-phase, mixed methods implementation study assessed the acceptability, feasibility, and reach of electronic signposting to behavior change apps by using a hospital's EHR system to identify patients who are at risk. Phase 1 explored the acceptability of the implementation strategy among the patients and staff through focus groups. Phase 2 investigated the feasibility of using the hospital EHR to identify patients with target risk behaviors and contact them via SMS text message, email, or patient portal. Phase 3 assessed the impact of SMS text messages sent to patients who were identified as smokers or risky drinkers, which signposted them to behavior change apps. The primary outcome was the proportion of participants who clicked on the embedded link in the SMS text message to access information about the apps. The acceptability of the SMS text messages among the patients who had received them was also explored in a web-based survey.

Results: Our electronic signposting strategy—using SMS text messages to promote health behavior change apps to patients at risk—was found to be acceptable and feasible and had good reach. The hospital sent 1526 SMS text messages, signposting patients to either the National Health Service Smokefree or Drink Free Days apps. A total of 13.56% (207/1526) of the patients clicked on the embedded link to the apps, which exceeded our 5% a priori success criterion. Patients and staff contributed to the SMS text message content and delivery approach, which were perceived as acceptable before and after the delivery of the SMS text

messages. The feasibility of the SMS text message format was determined and the target population was identified by mining the EHR.

Conclusions: The OptiMine study demonstrated the proof of concept for this novel implementation strategy, which used SMS text messages to signpost at-risk individuals to behavior change apps at scale. The level of reach exceeded our a priori success criterion in a non-help-seeking population of patients receiving unsolicited SMS text messages, disconnected from hospital visits.

Introduction

More than one-third of cancers are preventable by adopting a healthier lifestyle, such as stopping smoking and reducing risky drinking; tackling these health behaviors would lead to significant health benefits, minimize comorbidity, and reduce the burden on the National Health Service (NHS) [1-3]. The traditional approach to health promotion in the hospital environment is centered on health professionals providing verbal advice or information in leaflets, with or without the offer of referral to a lifestyle service. This approach relies on the clinician's knowledge, skills, and confidence; time; and the availability of health promotion literature, of which all are significant barriers to delivery [4,5]. Attempts have been made to boost health promotion activities in acute care hospitals in England. For example, (1) financial incentives have been provided for hospitals that undertake screening and brief advice for smoking and risky drinking (2018-2020) [6]; (2) brief advice on health behaviors through opportunistic day-to-day interactions between patients and health care professionals is promoted via Making Every Contact Count, an NHS initiative [7]; and (3) public health specialists are increasingly being embedded into the acute care context in recognition of the links between health behaviors and chronic illnesses, such as cancer, and the pressure this puts on the NHS. However, these interventions are typically resource-intensive or have been discontinued owing to resource constraints.

Digital interventions, such as behavior change websites or apps, have been developed to bridge the evidence-to-practice gap. They can be used as an alternative or adjunct to face-to-face delivery and have a substantial evidence base as interventions [8-12]. Digital interventions can provide effective individual support on a population scale at low cost [13]. They overcome barriers to delivering face-to-face interventions, such as removing the stigma associated with seeking help and alleviating pressure on busy health professionals to deliver brief interventions. Digital interventions for addictive behaviors are more commonly offered in higher education, primary care, and community settings (although far from routine) but rarely in the context of acute health services [8,9,14-16]. Furthermore, the implementation of effective digital interventions is often not considered and relies on the help-seeking behavior of motivated individuals. Another underused digital resource in the acute care setting is the electronic health record (EHR) for screening patients at risk. Although screening is commonplace

for promoting medication adherence, vaccine uptake, or cancer screening, systematic screening for health behaviors (such as risky alcohol consumption and tobacco smoking) for signposting to support services is in its infancy.

We developed a novel implementation strategy that uses the combined potential of three existing technologies to bridge the evidence-to-practice gap: (1) acute care hospital EHR for identifying at-risk individuals at scale, (2) health promotion apps and websites that provide behavior change support at an individual level, and (3) SMS text messages that are commonly used by health services to communicate with patients. Using electronic messages (such as SMS text message or email) to signpost (referred to as *proactive outreach* in the United States [17-19]) patients who are at risk, identified by the EHR, to health promotion apps is cheap, efficient, quick to implement using existing infrastructure, and scalable to other health behaviors and health care settings and has the potential to achieve behavior change at the population level. Although SMS text messaging has been used successfully as a treatment tool for smoking cessation [11], using it as a primary channel for outreach and enrollment to support services or treatment represents a novel application with preliminary success. Krebs et al [18] used outreach SMS text messages in a large New York health system to connect patients to quitline counseling. Furthermore, Abrams et al [20] used SMS text messaging to connect patients in the emergency department to a smoking cessation SMS text messaging program or quitline counseling.

So far, no previous studies have evaluated the ability of electronic messages to signpost patients who are not seeking help to behavior change apps, disconnected from hospital visits. The aim of this 3-phase, mixed methods implementation study (the OptiMine study) was to explore the acceptability (phase 1), feasibility (phase 2), and reach (phase 3) of electronic messages to signpost patients who smoke tobacco and drink alcohol at risky levels to behavior change apps. The primary outcome of phase 1 was a qualitative synthesis of patient-perceived attributes of signposting. The primary outcome of phase 2 was the estimated size and characteristics of the population that may be reached by the intervention. Findings from these 2 phases informed the design of phase 3, the primary outcome of which was the proportion of contacted patients who followed the signpost to access more information about the promoted behavior change apps (ie, the *click rate*). The approach and methods have been reported in our published protocol [21].

Methods

Ethics Approval

The NHS Research Ethics Committee and the Health Research Authority approved this study in June 2019. EHR data were accessed and analyzed by staff within the West Suffolk NHS Foundation Trust (WSFT) information service team. Patients at risk were identified by the WSFT information service team and received electronic messages directly from the hospital. All analyses were conducted by the WSFT information service and public health teams. The study team members had access only to anonymized, aggregated data. Authorization for using EHR data at the WSFT was provided by the Information Governance Team via Data Protection Impact Assessment (approval date: September 20, 2019) [22].

Theoretical Frameworks

We used the taxonomy of implementation outcomes by Proctor et al [23] to design this implementation study, focusing on acceptability, feasibility, and reach. Acceptability and feasibility are important precursors for effective uptake and reach of an intervention and were explored using qualitative focus groups (acceptability before implementation), a web-based survey (acceptability after implementation), and routinely collected data from the EHR (feasibility). We assessed *reach* as our measure of implementation success, operationalized as the proportion of patients who engaged with our SMS text message by clicking on an embedded link to access free apps to support health behavior change. The topic guides and survey exploring the acceptability of delivering electronic messages to patients were informed by the Perceived Attributes of eHealth Innovations [24]—an extension of the Diffusion of Innovations Theory [25], which has been applied through a validated questionnaire to test the acceptability of a digital innovation [26]. Further information on the model and its application in this study is provided in our published protocol [21].

Setting

The research was conducted between April 2019 and July 2020 within the West Suffolk Hospital, an acute NHS provider renowned for its world-leading delivery of care using digital technologies, that is, an acute Global Digital Exemplar Trust [27]. eCare (trade name: Cerner Millennium), the EHR system at the WSFT, was launched in 2016 and includes records for all outpatients and inpatients registered with the hospital. The EHR contains contact information, demographics, and health data such as chronic disease status needed for this study. Data on smoking and alcohol consumption status were collected as part of the lifestyle screening survey or the Activities of Daily Living assessment, routinely provided to patients on admission to the hospital. The hospital is situated in the rural region of West Suffolk in the East of England, where population characteristics are similar to those of the general population in England, with slightly higher proportions of individuals aged >65 years and White British residents [28].

Implementation Strategy and Behavior Change Apps

We electronically signposted patients to the NHS Smokefree and Drink Free Days apps. Public Health England has developed

the Smokefree and the Drink Free Days apps as part of their One You campaign for supporting healthy lifestyles. These apps are freely available on the web [29] and are heavily promoted in the United Kingdom mass media. The apps are theoretically informed and use evidence-based behavior change techniques, such as goal setting and self-monitoring. This mixed methods implementation study explored acceptability (phase 1) and feasibility (phase 2) as important precursors for the reach of our implementation strategy (phase 3).

Phase 1: Acceptability of Electronic Signposting (Before Implementation)

Acceptability of the implementation strategy was explored before its delivery via focus groups. Patients and staff were invited to participate in face-to-face focus groups to explore their perspectives. Patients were eligible if they were smoking or drinking alcohol regularly. Eligible staff were those (1) in senior IT management roles, (2) responsible for administering lifestyle screening, or (3) involved in EHR data management and hospital communications. Patients were identified via volunteer coordinators, a news story on the hospital website, and a recruitment stall at the main hospital entrance. Staff were recruited directly through email invitation and a weekly staff newsletter. All participants were provided with a participant information sheet and a consent form. Patient focus groups were conducted on-site at the education center at WSFT, whereas staff focus groups were conducted in meeting rooms. Focus groups were audio-recorded and transcribed verbatim by a professional transcription company, removing any identifiable data. Transcripts were coded using NVivo (QSR International). Framework analysis was used to synthesize the findings of the focus groups, based on 3 domains of the Perceived Attributes Theory: compatibility (ie, degree to which electronic messaging was consistent with patient preferences), complexity (ie, degree to which electronic messaging was difficult to understand or act on), and relative advantage (ie, degree to which electronic messaging was superior to alternative or more traditional approaches) [24]. Subthemes were focused on the pragmatic development, refinement, and delivery of the implementation strategy.

Phase 2: Feasibility of Electronic Signposting

Feasibility of using the EHR to identify patients at risk who have mobile phone numbers, email addresses, and patient portal access was explored through data mining. Patients with alcohol consumption or smoking status that had been recorded or updated within the past 13 months were included. The Activities of Daily Living and customized lifestyle screening assessments are used by the WSFT to record alcohol consumption and smoking status on admission to the hospital. The following data were extracted and aggregated from the EHR by a hospital-based information analyst: smoking status (yes or no), alcohol consumption status: Alcohol Use Disorders Identification Test–Consumption (AUDIT-C) score [30] (low risk: 0–4, at risk: 5–9, and dependent: 10–12), sex (woman or man), mobile phone number (yes or no), email address (yes or no), and patient portal access (yes or no). Frequencies and percentages of patients with valid data in each of the fields mentioned

previously were reported to the study team, who had no direct access to the underlying data.

Phase 3: Reach of Electronic Signposting

Participants

Eligible patients were adults (aged ≥18 years) recorded as smoking or drinking alcohol at risky levels within the past 13 months, with a valid mobile number. Patients were excluded if they were pregnant, were registered on the end-of-life pathway, or had opted out of communications from the hospital. As specified in the protocol, a minimum sample size of 383 per risk profile group would allow calculation of 95% CIs within a margin of -5% to +5% points, assuming a population proportion of 50% and a population size of 100,000 [21].

Procedure

SMS text messages were selected as the most acceptable and feasible electronic format based on the findings of phase 1 and phase 2. Although the protocol sought to compare 3 risk profiles (exclusive smokers, exclusive risky drinkers, and both), to reach the a priori specified minimum sample size, it was necessary to collapse to two risk profiles: (1) exclusive smokers and (2) risky drinkers regardless of smoking status. The hospital’s SMS text messaging system was used to send an initial message to all the participants, signposting to either the Smokefree or Drink Free Days apps based on risk profile, with a second reminder message sent 3 days later to any participant who had not clicked the link yet. Unique link URLs were used to identify the participants who clicked the link. Figure 1 illustrates the content and delivery schedule of the messages.

Figure 1. Flowchart of SMS text message content and delivery.

Data Collection

To determine the characteristics of patients to whom SMS text messages were sent, data were retrieved from eCare, and analyses were performed by a public health manager with the support of coauthors MSA and ZK in July 2020. The following variables were extracted from the system and categorized as follows:

1. Name (for data linkage purposes only)
2. Hospital and NHS number (for data linkage purposes only)
3. Date of birth (for data linkage purposes only)
4. Age—categorized as 18-25, 26-35, 36-45, 46-55, 56-65, and >66 years
5. Sex—woman or man
6. Ethnicity—categories were merged to increase patient numbers in less-populated groups: any White background, any other background, and not known or not stated; refer to the study protocol for individual categories [21]
7. Postcode—used to calculate index of multiple deprivation decile—grouped into quintiles
8. Date of smoking or alcohol consumption screening at the hospital—categorized as days since screening: 1-4, 4-7, 7-10, 10-13, and >13 months
9. SMS text message sent, targeting smoking cessation or alcohol reduction
10. Embedded link to apps clicked or not clicked

Indices of Multiple Deprivation

Postcodes were entered into the government multiple deprivation lookup to obtain the deciles of multiple deprivation for each patient [31], where decile 1 represents the most deprived 10% of the population and decile 10 represents the least deprived 10% of the population.

Recency of Screening

The number of days since patients were screened for smoking or alcohol consumption was calculated by subtracting the date of smoking or alcohol screening from the date on which the smoking or alcohol SMS text message was sent. This was rounded to a whole number.

Health Data

The long-term health conditions stored as structured data in eCare were audited against the whole medical record to determine its suitability for use. Auditors used inpatient, emergency department, and general practice notes to collate patients' medical history. More than half of the manually audited records found different health data than those retrieved from the patient records. Thus, the health data were considered as too incomplete and inaccurate to be included in the study. Refer to the study protocol for the list of long-term health conditions originally intended for extraction from eCare [21].

Missing Data in AUDIT-C Fields

A large proportion of the records (1424/1975, 72.1%) that documented alcohol status had missing data in the AUDIT-C fields. Scores were calculated from the available fields, imputing a value of zero for missing fields, based on information from hospital staff that fields were most likely skipped because they were not applicable (eg, erroneously left blank instead of

selecting 0). Patients with missing data and calculated AUDIT-C scores of 7 to 8 were excluded from the study because it was not possible to be confident that these patients were not dependent drinkers, for whom the intervention would be clinically inappropriate.

Statistical Modeling

We determined a priori that 5% reach, as evidenced by clicking on the embedded links to the apps, would constitute a clinically meaningful level of reach, given the low-burden and scalable nature of the interventions [21]. This success criterion was based on the rationale that reaching even this modest proportion of non-help-seeking individuals with high-risk drinking and smoking behaviors via unsolicited SMS text messages at a time disassociated with their last hospital visit could have great impact at a population health level. The number of patients who clicked the embedded link within their respective SMS text message was reported along with their baseline characteristics. The denominator for reach rate was the total number of patients with that characteristic who received an SMS text message. R software (R Foundation for Statistical Computing) was used to model the logistic regression, where we used the glm function with a Poisson distribution. To investigate potential relationships of common demographic covariates and assess any effect of screening recency, the model included all patient-level variables that were available: sex, age group, ethnicity group, index of multiple deprivation quintile, and days since screening group. Relative risks (RRs) with 95% CIs for each characteristic were derived from the model in R, using exponentiated values of the model coefficients.

Acceptability of Electronic Signposting (After Implementation)

Acceptability of the implementation strategy was also explored after its delivery via a web-based survey. Eligible patients were those to whom a signpost SMS text message was sent. Then, 6 days after the initial signpost SMS text message was sent, 2 additional SMS text messages were sent to the participants (an initial message and a reminder), inviting them to participate in a web-based survey about their views on receiving the signpost SMS text messages. Participant information sheets and consent forms were incorporated into the web-based survey. We used JISC web-based surveys, a free web-based platform designed for academic research and public sector organizations. Participants were given 15 days to complete the survey.

Results

Phase 1: Acceptability of Electronic Signposting (Before Implementation)

A total of 10 patients participated in 2 focus groups (group 1: n=3, 30% of the participants; group 2: n=6, 60% of the participants) and 1 individual interview (n=1, 10% of the participants; owing to low turnout for the focus group). A total of 14 staff members participated in 3 focus groups (group 1: n=5, 36% senior managers; group 2: n=1, 7% nurse and n=1, 7% pharmacy technician; group 3: n=7, 50% members of IT staff and communications officers). Patients' ages were collected as categories and ranged from 46 to >66 years; 60% (6/10) were

women. Most patients (7/10, 70%) were members of the hospital's volunteer group and patient portal user group, with 20% (2/10) of them being members of the public and 10% (1/10) being members of staff identified via the recruitment stall. Findings from this phase suggested that most patients found SMS text messaging as the most acceptable form of electronic message for receiving communications. A more detailed summary of the key findings under each theme and subtheme is presented in [Multimedia Appendix 1](#) (qualitative focus group findings), along with illustrative quotes and the approach that informed the development and delivery of electronic messages.

Phase 2: Feasibility of Electronic Signposting

The dynamic nature of an acute care hospital EHR database was found to be an implementation challenge. The mining of data from eCare needed to be performed on different days, owing to the size of the data queries, and with different search strategies depending on the fields required. Furthermore, the results changed depending on the date on which the queries were run (both the denominators and numerators). Queries that were intended to generate data sets that would include the whole EHR population could only be achieved by limiting the number of variables in the data set; large queries often took several hours to run and were at risk of timing out before they had completed.

The total number of adult patients in the eCare system on October 9, 2019, was 228,982, of which 1092 (0.48%) adults were recorded as smokers (smoking and drinking status data extracted on January 10, 2020). Among the 0.74% (1702/228,982) of the patients who were recorded as drinking alcohol, 23.62% (402/1702) patients were recorded as at-risk drinkers. An additional 0.55% (1249/228,982) and 0.02% (51/228,982) of the patients were reported as drinking at low risk or dependent levels, respectively. Most patients (226,784/228,982, 99.04%) had missing data in the EHR regarding their tobacco or alcohol use status. Smoking and drinking status are only recorded in a way that is retrievable when a patient has an inpatient admission. The proportion of the catchment population that is admitted each year is typically 13% [32]. The proportions of admitted patients who were screened for smoking and alcohol use in the financial year 2018 to 2019 were reported by WSFT information service staff to be 64% and 68%, respectively.

Of the 228,982 patients, 146,171 (63.84%) had mobile phone numbers, of which 707 (0.48%) were recorded as smokers and 271 (0.19%) were recorded as at-risk drinkers. Of the 228,982

patients, the total number of patients with email addresses was 32,375 (14.14%), of which 137 (0.42%) were recorded as smokers and 115 (0.36%) were recorded as at-risk drinkers. The database of patient portal users was independent of the EHR, and could not be linked to the EHR by the WSFT information service staff. The numbers of patient portal users recorded as smoking and drinking could not be determined. Therefore, the consideration of the patient portal as a form of message delivery was discontinued in this study. Combined with the findings from phase 1, these feasibility findings from phase 2 reinforced the decision to use SMS text messages as the channel for the electronic messages.

Phase 3: Reach of Electronic Signposting

Baseline Characteristics and Risk Profile Groups

On the basis of the findings in phase 2, the participant sample was mined from eCare on January 10, 2020. The sampling frame used the most recent admissions to the hospital with validated data to identify patients whose records were most likely to be up to date and accurate. A 13-month time frame (October 1, 2018, to November 30, 2019) was used to obtain a sufficiently large population of patients to meet the minimum sample size required, which was balanced against recency of the data. A total of 6521 people admitted during the time frame were aged ≥ 18 years, not on the end-of-life pathway, and not pregnant and had a mobile phone number recorded and either their smoking or alcohol status recorded. Owing to the relatively small number of patients who could be identified as exclusively consuming alcohol at risky levels but who were nonsmokers, all participants with risky drinking were combined into a single risk profile group, regardless of their smoking status. The resulting 2 risk profile groups (smoking only and risky drinking with or without smoking) represent a deviation in analysis from the protocol, which aimed to create 3 risk profile groups (smoking only, risky drinking only, and smoking and risky drinking). This deviation was necessary to meet our a priori minimum sample size of 383 participants per group, which was also specified in the protocol. The decision to collapse the risky drinking groups was based exclusively on the baseline data, before the analyses of outcomes. Ultimately, of the 1526 individuals, the selected sample included 1103 (72.28%) individuals who were recorded as smokers only, 276 (18.09%) individuals who were recorded as risky drinkers only, and 147 (9.63%) individuals who were recorded as both smokers and risky drinkers. [Table 1](#) shows the baseline characteristics of the participants.

^aGroup includes all participants recorded as smoking and not drinking alcohol at risky levels.

^bGroup includes all participants recorded as drinking alcohol at risky levels, regardless of smoking status, owing to sample size considerations. The risky drinker status is defined as an Alcohol Use Disorders Identification Test–Consumption score of 5 to 10 if 3 of its items were completed or a score of 5 to 6 if only 2 items were completed.

^cN/A: not applicable.

Reach

In January 2020, an SMS text message was sent to 1526 patients, signposting them to either the NHS Smokefree (n=1103,

72.28%) or the Drink Free Days apps (n=423, 27.72%). A total of 13.56% (207/1526) of the participants clicked on the embedded link to the apps (smokers: 26/207, 12.56% and risky drinkers: 34/207, 16.43%), which exceeded our 5% a priori

success criterion in both groups. Figure 2 shows a CONSORT (Consolidated Standards of Reporting Trials) diagram. Characteristics of patients who clicked the embedded link within the SMS text message versus the characteristics of those who did not click the embedded link are presented in Table 2. The only significant differences in baseline characteristics were observed among smokers. Among smokers, the lowest click rate was among participants aged ≥66 years (6.8%). Compared with this age group as reference, smoking participants aged 36

to 45 years (18.2%; RR=2.6; 95% CI 1.4-4.6) and those aged 56 to 65 years (13.1%; RR=1.98; 95% CI 1.05-3.73) were significantly more likely to click. Male smokers were significantly less likely to click than female smokers (10.2% vs 14.8%; RR=0.71; 95% CI 0.51-0.98). Although no significant differences by age were observed among risky drinkers, a numerically different distribution emerged, such that risky drinkers aged 56 to 65 years were the most likely to click the link (20.4%).

Figure 2. CONSORT (Consolidated Standards of Reporting Trials) diagram. *Alcohol Use Disorders Identification Test–Consumption (AUDIT-C) score of 5-10 if 3 fields populated or score of 5-6 if 2 fields populated; **AUDIT-C score<5; ***both=patients who are both smokers and risky drinkers.

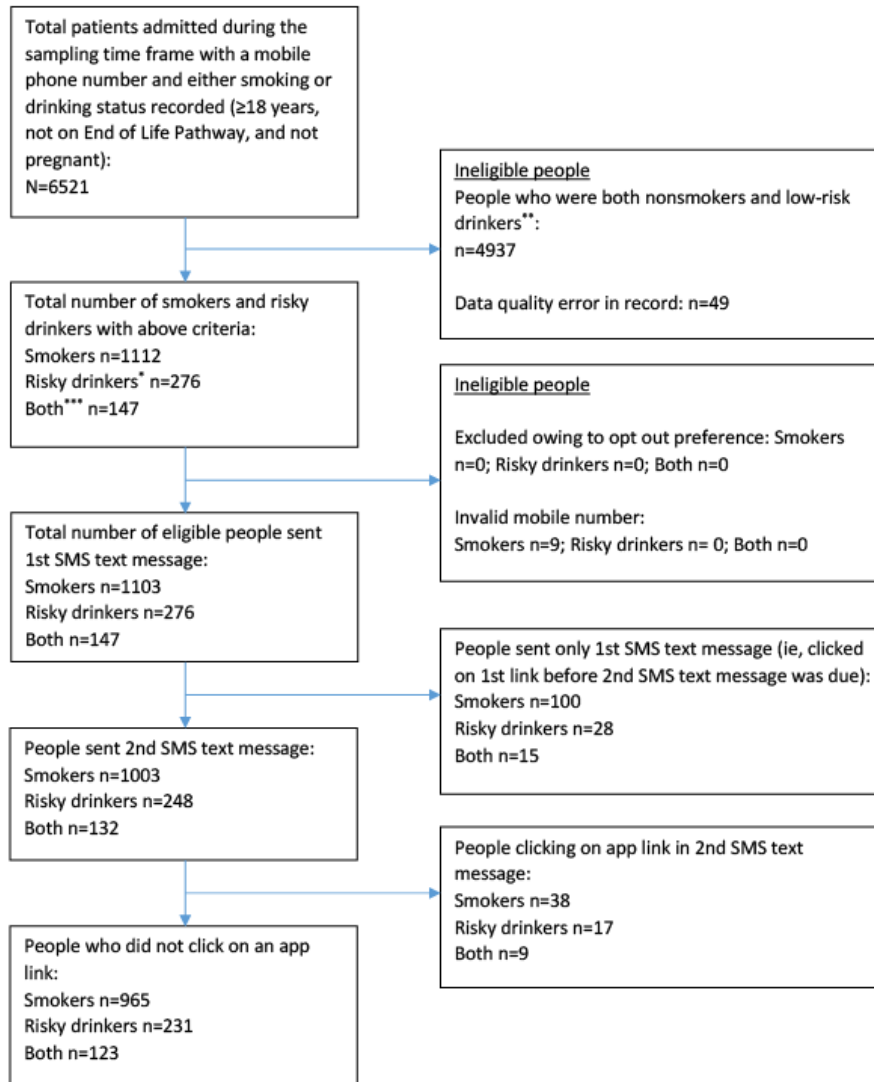

Table 2. Comparison of characteristics of patients who clicked versus those who did not click on links to apps within the SMS text message.

Acceptability (After Implementation)

The survey was completed by 3.67% (56/1526) of participants. Among the 56 survey responders, 18 (32%) participants reported that they had clicked on the link within the SMS text message and 9 (16%) participants reported that they downloaded the app. Approximately two-thirds (36/56, 64%) of the participants found the messages to be at least slightly *helpful*. The message was found to be *not at all difficult* by almost all patients (55/56,

98%). Most participants (51/56, 91%) were happy with the wording of the SMS text message. Almost half of the participants (26/56, 46%) reported that they would like the hospital to deliver this service; however, an opt-out option was also popular (21/56, 38%). Most of the respondents (42/56, 75%) submitted free-text comments. Common positive themes were that the SMS text messages were supportive (7/56, 13%), easy to understand (6/56, 11%), and brief (6/56, 11%). Common

negative themes were that the messages were irrelevant (9/56, 16%), not supportive (4/56, 7%), and unwanted or unexpected (3/56, 5%).

Discussion

Principal Findings

Our electronic signposting strategy that used SMS text messages to promote health behavior change apps to patients at risk via an acute care hospital EHR was found to be acceptable and feasible and to achieve clinically meaningful reach. The hospital sent 1526 SMS text messages signposting patients to either the NHS Smokefree or Drink Free Days apps, with 13.56% (207/1526) of the patients clicking on the embedded link to the apps. The level of reach exceeded our 5% a priori success criterion in a non-help-seeking population of patients receiving unsolicited SMS text messages, disconnected from hospital visits. The strategy was found to be acceptable both before and after implementation. The OptiMine study demonstrated the proof of concept for this novel implementation strategy, specifically signposting digital health promotion interventions at scale to at-risk individuals who are not seeking help.

A 13.56% (207/1526) click rate is promising, considering the comparable outcomes reported in the literature. For example, in a study to promote colorectal cancer screening, patients—identified from EHRs as being overdue for their colorectal screening—received an electronic message from their primary care physicians with information about their overdue status, methods to arrange a screening appointment, and a web-based risk assessment tool for colorectal cancer [33]. The intervention led to 3% of the patients requesting colorectal screening. Our 13.56% (207/1526) click rate exceeds this result. However, it is important to account for the action requested from patients, which will trigger varying levels of response, such as the 3% response rate for colorectal screenings versus the 13.56% (207/1526) click rate on our embedded link to behavioral interventions. Future research should build on this study and aim to define appropriate thresholds for e-referral interventions that correspond to different behaviors that require varying degrees of involvement from patients (eg, time and effort invested, duration of behavior, and difficulty of behavior). Furthermore, it is important to note that our SMS text messages were sent from the patients' hospital, which would be expected to foster trust in the messages and their source and increase uptake.

Using SMS text messages to signpost patients to addictive behavior apps is a scalable implementation strategy, which can provide individualized support to patients at risk. As such, cost-effectiveness increases as the strategy is scaled up. Our low-cost and low-burden strategy has the potential to reach large number of patients at high risk in a novel form (proactive referral to existing tools). Health promotion is typically delivered in primary care and community settings, but it is equally important in acute care settings, as health behaviors such as smoking and risky drinking can cause long-term health conditions and exacerbate existing health conditions. Following the success of this study, the WSFT plans to routinely deliver health promotion advice using electronic signposting.

Strengths and Limitations

The mixed methods design helped to explore multiple implementation outcomes that assess both proximal outcomes and indicators of success [23]. This was a novel and pragmatic study, facilitated by NHS staff in a busy hospital setting. Major strengths of this study included the real-world application of the strategy with patients at the hospital and readiness of the implementation context. Senior-level leadership and buy-in from a public health consultant within the digital health team were instrumental in the successful implementation of this project. Global Digital Exemplar Trusts have EHRs and in-house expertise to support the setup and delivery of SMS text message signposting. We identified the following stakeholders as pivotal to the successful setup, implementation, and evaluation of the strategy: patient representatives, information analysts (assess infrastructure and access to data), deputy chief information officer (design and oversight of message implementation), IT integration developer (implement SMS text message signposting and send messages), public health manager (in-house data analysis), communications team, volunteer coordinator, and administrative support. Although the readiness of the implementation context is considered a strength of our study, it could be seen as a limitation to broad scalability in less-ready, low-resourced contexts, which may serve more disadvantaged or underserved populations.

There were challenges in using the EHR as a research database. The data set was extracted directly from the EHR at different time points owing to the size of the EHR, time to download the data, and workload of hospital staff. Queries for different parts of the data were run on different days over a 4-month period from October 2019. Each day, the total number of EHR records changes owing to new records being created, existing records being edited, and people dying. Smoking and alcohol consumption status were not retrievable from hospital day patients, which meant that there were large amounts of missing data. Furthermore, there were difficulties in retrieving accurate health condition data, and matching to eligible patients was not possible. Health condition data rely on the population of the appropriate fields in a patient record; if the condition is listed in the wrong place or not recorded at all, it cannot be electronically retrieved. This occurs with some frequency across the EHR, and this limitation needs to be addressed before using electronically retrieved health data for similar studies in the future. As such, the full capacity of patient reach was not used owing to missing data, and the impact of long-term health conditions on the likelihood of clicking the embedded link is unknown.

Our primary outcome—whether each participant did or did not click the embedded link—directly measured the willingness to access information about behavior change apps among a non-help-seeking population. However, we did not measure the proportion of participants who actually downloaded and used the app. Although technical limitations prevented us from measuring app use, uptake should be assessed through future studies to support broader dissemination of this approach. In addition, response rates to the web-based questionnaire were low and may have been subject to response bias. This may have been owing to message fatigue, where patients had previously

received up to 2 SMS text messages signposting to the apps, followed by 2 messages inviting participation in the survey. Finally, the SMS text messages did not include instructions for opting out of future messages, which is a requirement in the United States. Future studies should examine click rates in the presence of explicit opt-out instructions.

Implications for Further Research and Practice

The WSFT views this approach as the future for routine delivery of digital interventions for health promotion within their acute care context and as an important adjunct to the opportunistic behavior change interventions that are made by health care professionals. Further refinement and evaluation are needed to optimize the SMS text message content and delivery approach. Additional studies with other populations are needed to understand the best strategy for implementation at other hospitals and institutions. The COVID-19 pandemic has highlighted the urgent need for scalable health promotion support, which can be delivered via digital technology. There is also an international call for greater access to high-quality, safe, and effective addictive behavior apps [34]. Regarding refinement and further evaluation of SMS text message signposting to apps, we propose the following ideas for further development:

1. Tailor message content to groups of people who are less likely to engage, such as older people, low socioeconomic status groups, and ethnic minority groups.

2. A timely trigger for the SMS text message, possibly in the context of a face-to-face consultation, may be more effective than sending all the messages at the same time. The SMS text messages were sent in January 2020 to optimize the click rate by taking advantage of the seasonal high demand for support, and therefore, other times of the year may be less or more likely to have high rates of engagement.
3. Use the strategy to target other health behaviors.
4. Explore other implementation outcomes, such as implementation cost and cost-effectiveness, compared with other methods for promoting lifestyle change; sustainability; and fidelity, including engagement with the app.
5. Investigate system interventions for addressing barriers identified regarding the reliability of EHR data.

Conclusions

The OptiMine study demonstrated the proof of concept for this novel implementation strategy, which used SMS text messages to signpost at-risk individuals to behavior change apps at scale. The level of reach exceeded our a priori success criterion for a non-help-seeking population of patients receiving unsolicited SMS text messages, disconnected from hospital visits. These findings suggest that electronic signposting to support is an effective method for health systems to proactively engage meaningful proportions of their at-risk populations.

Abstract

Background: The rapid extent of digital innovation for the collection of data has transformed the way in which health professionals collect, share, and analyze health information for better clinical decision-making and health care. In the last decade, there has been an increased interest in telemedicine by mental health agencies; the gap between the need for care and both diagnosis and treatment is wide, and digital technology could play an important role in filling this gap. However, there are limited data on the effectiveness of the clinical process and cost-effectiveness of most telemedicine applications.

Objective: This study examined the implementation of the first Italian online, web-based, comprehensive screening tool and described the screening and diagnostic process through the interactive web platform in a child psychopathology clinic. This is a feasibility study that aims to present the design and implementation of the best practices to improve patient experiences and clinical outcomes. Moreover, the paper evaluates the platform with qualitative and quantitative measures.

Methods: We planned, designed, and implemented a web-based system to collect, store, and manage clinical data. The platform was developed by a multidisciplinary team composed of researchers, clinicians, and informatics professionals through different steps. First, we defined the clinical information to be collected. A number of measures were chosen, tapping several clinical risk areas such as neurodevelopmental disorders and emotional and behavioral problems. The web application architecture and process were then designed. The three phases of process design are described in detail: design of the input interface, processing design, and design of the output interface. Finally, the system has been implemented and evaluated. Based on indicators recommended by the National Quality Forum and the Italian National Guidelines, we evaluated the quality of the system and used quantitative measures that were replicable and comparable over time.

Results: We present the implemented architecture and features of Medea Information and Clinical Assessment On-Line (MedicalBIT), and we provide performance measures for the data collected between October 2018 and June 2021. The measured concepts pertain to four domains: access to care, financial impact/cost, experience, and effectiveness.

Conclusions: In this study, we present the successful implementation of an innovative digital tool. The findings of this study show that the implemented web-based platform appears to be an efficient, cost-effective, and feasible way to improve digital care in the field of child psychiatry.

KEYWORDS

digital health; big data; developmental psychopathology; neurodevelopmental disorders; digital data; digital innovation; mental health; screening tool; children; psychopathology; web platform; digital intervention; clinical outcome

Introduction

Digital data collection is an emerging trend in various fields, including the medical and psychological ones. Digital innovation is changing the way health information is collected, shared, and analyzed for better clinical decision-making and health care. Digital innovation is also rapidly expanding in the medical field, significantly improving the quality of health care, reducing health care costs, and enhancing research processes [1]. The rapid evolution of technology has recently promoted web platforms for big data collection in the health care field, and related publications are exponentially increasing [2].

“Big data” refers to a voluminous collection of information taking place quickly without affecting quality, and there are several well-known definitions describing this [3-5]. Pastorino and colleagues [2] stress the importance of defining data as both smart and big because big data presents a substantial potential when it is meaningful. This implies using data for improving health conditions by searching for increasingly clearer and more accurate links between causes, diseases, therapies, and outcomes. In the Study on Big Data in Public Health, Telemedicine, and Healthcare [6], the European Commission identified four macroareas in health care for big data use: (1) early signs for detection, diagnosis, and intervention; (2) identification of risk factors for diseases to improve prevention; (3) enhancing pharmacovigilance and patient safety by communication of real-time information; and (4) improvement in outcome prediction.

All this is possible since a large amount of data is an invaluable resource for epidemiological studies, analyses of general population needs, treatment evaluation, and experimental designs on the target population. If research develops in this direction, it will enable precision medicine that will contribute to optimization of resources: the right care for the right patient at the right time. Therefore, smart use of big data can provide a possible answer to the need for care: socioeconomic and clinical sustainability. In line with this, health technology assessments aim to inform on safe, effective, patient-centered policy-making as well as determine the greatest value for it.

Against this background, telehealth [7] should be seen not only as a complement or alternative to traditional clinical practice but also as an ideal channel to collect and analyze big data. Besides rapid technological progress, COVID-19 spurred an exponential growth in telehealth, and there will be no return to the prepandemic situation according to the American Telemedicine Association [8]. There are several fields of telehealth, just like there are medical specialties. For example, investments in information technology are promoting the development of telepsychiatry. According to Allen [9] and Torous and colleagues [10] one of the most important contributions of artificial intelligence for psychiatry concerns apps, as shown by their innovative project Learn, Assess, Manage, and Prevent (MindLAMP). MindLAMP is a digital platform used both for clinic and research purposes: it receives patient input and aggregates data, it guides reflection, and it helps orient toward treatments. Through the app, patients can input data in an active way (survey, symptom registration, etc)

or in a passive way (information collected in the background even if the user is not using the app), and they can receive some advice and mindfulness resources [11]. It is evident that, in the last decade, there has been an increased interest in telemedicine by mental health agencies; the gap between the need for care and possible answers both for diagnosis and treatment is wide, and digital technology could play a fundamental role [12]. In the child and adolescence mental health services, the parents and caregivers of young patients must be involved in the clinical diagnostic process, both as powerful sources of information to be used by clinicians and to obtain a clear understanding about their child’s difficulties. This engagement should be conducted in a comfortable environment for the participants.

Telemedicine seems to be efficient both for the assessment and treatment. For example, among services for the diagnosis of autism spectrum disorder (ASD), the use of telemedicine has shown some promising results in terms of observation [13-15]. As for remote treatment, several recent studies on telemedicine and developmental disorders such as autistic spectrum disorder, specific learning disorder, specific language impairment, dyspraxia, and acquired brain injuries show encouraging results [16-20].

A review of the literature by the National Quality Forum—a no-profit organization for health care development—found a positive effect of telehealth on the quality of processes, outcomes, and costs. It also identified the medical areas where telehealth spread more extensively, with a correspondingly greater increase in scientific publications, namely, dermatology, mental health, rehabilitation, medical management, and chronic diseases. However, despite this topic being current and debated, telemedicine is relatively recent, and there is a lack of studies assessing its quality [21].

In our study, we examined the implementation of the first Italian online, web-based, comprehensive screening tool: Medea Information and Clinical Assessment On-Line (MedicalBIT) [22]. We carried out a feasibility study aimed to present the design and the implementation of the best practices to improve users’ experiences and discuss the evaluation of the platform with qualitative and quantitative measures. Additionally, we intend to describe a web-based screening and diagnostic process in a child psychopathology clinic.

Methods

Overview

This section describes the key elements of the platform implementation.

We planned, designed, and implemented a web-based system to collect, store, and manage clinical data through different steps. The whole eHealth system is composed of users (patients and clinicians), a service provider (the Association La Nostra Famiglia-IRCCS Eugenio Medea, a no-profit organization providing care and rehabilitation to children with disabilities), and a service developer (SE-GE Consulting Company).

The main purpose of the MedicalBIT platform is to support diagnostic flow by systematic data collection.

Patients can answer questionnaires comfortably from home through a user-friendly and easily accessible interface, saving time traveling to and staying in a clinic. Clinicians have access to a real-time description of individual patients' symptoms and a graphical output of possible alerts through clinically based algorithms. Clinicians then assign patients to different diagnostic paths for principal neurodevelopmental disorders (Attention-Deficit/Hyperactivity Disorder, Autism Spectrum Disorder, Specific Learning Disorders, Language Disorders) and behavioral and emotional disorders based on this output. Taking into account the international gold standard, a clinical assessment is performed for each path. The final diagnostic output may differ from the initial path assignment based on the assessment results.

Finally, the data collected can be easily exported in Excel (Microsoft Corporation) format for research analyses: researchers can use collected data for further analysis to develop predictive models.

The platform was developed by a multidisciplinary team composed of researchers, clinicians, and informatics professionals. Figure 1 provides an overview of the workflow, and Figure 2 displays some picture frames of the web platform home page. A description of each step is reported below:

1. Defining clinical information to be collected
2. Web application architecture and process design
3. System implementation and evaluation

Figure 1. The diagnostic flow on Medea Information and Clinical Assessment On-Line (MedicalBIT).

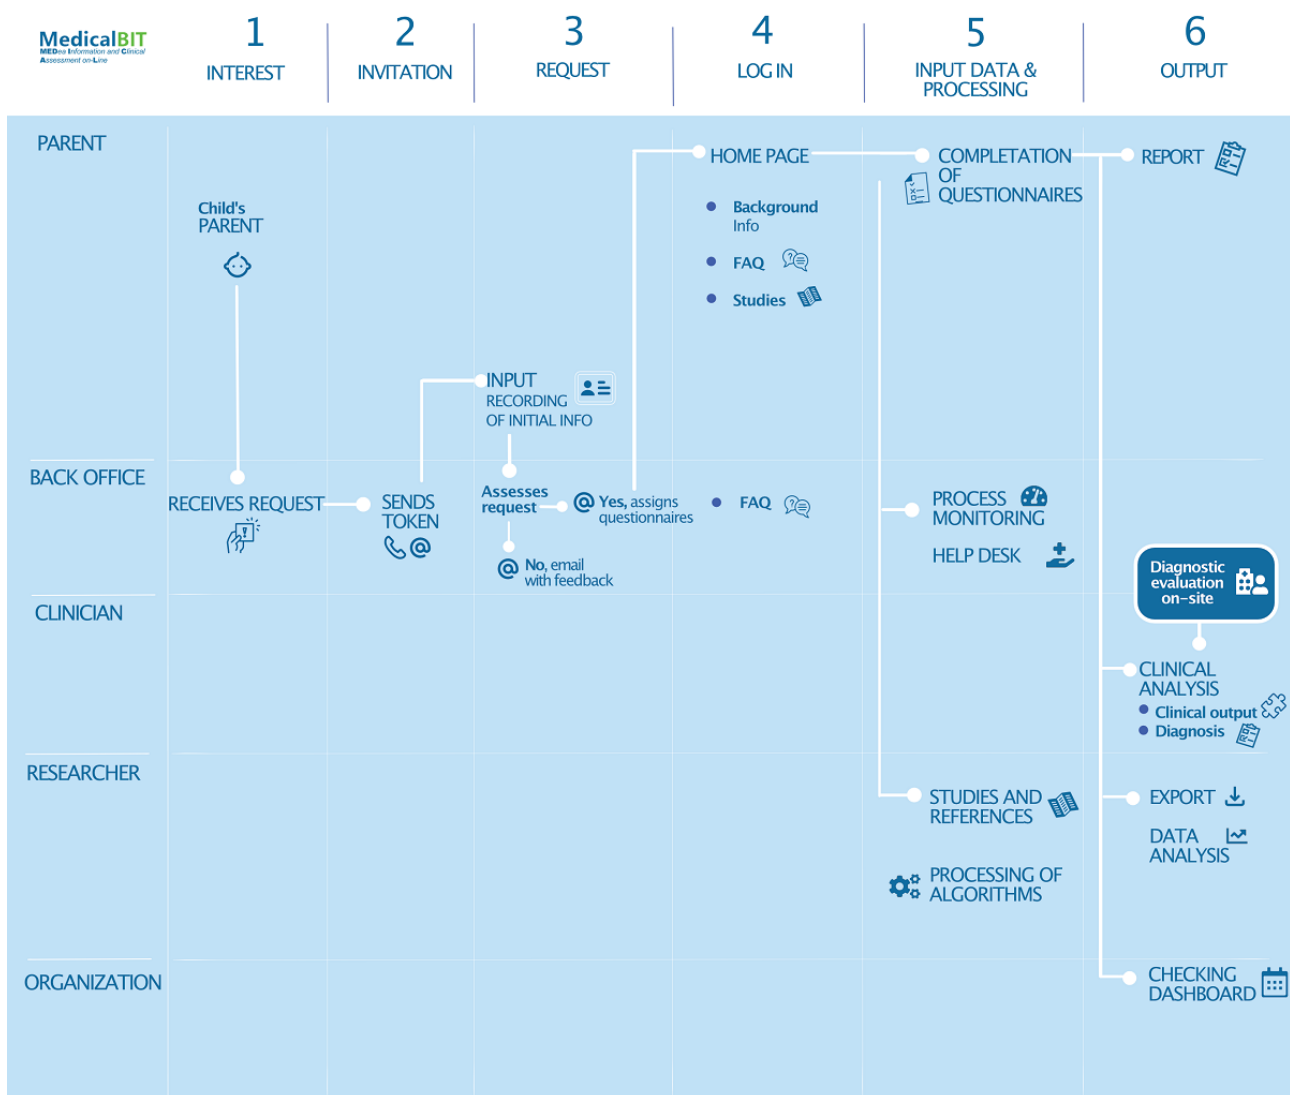

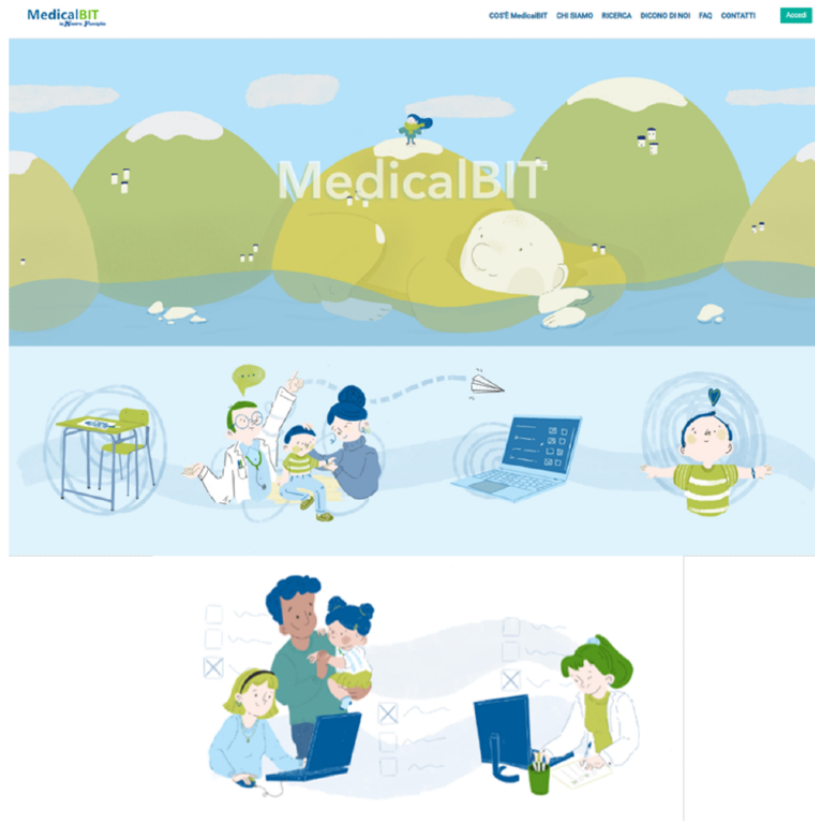

Figure 2. The main menu and some pictures of the Medea Information and Clinical Assessment On-Line (MedicalBIT) home page.

Defining Clinical Information to Be Collected

A number of measures were chosen by tapping several clinical risk areas, such as neurodevelopmental disorders and emotional and behavioral problems. Measures were selected for their feasibility in routine clinical practice (ie, brevity, free availability, validation in children and young people, and translation) and psychometric performance (ie, validity, reliability, and sensitivity to change).

The following questionnaires were selected:

- Risk factors: A questionnaire to explore biological and environmental risk factors such as family composition; presence/absence of psychiatric diseases in parents or close relatives; prenatal, perinatal, and postnatal factors; and developmental milestones.
- ASD: The Modified Checklist for Autism in Toddlers [23] and the Autism Spectrum Quotient: Children's Version [24] were used for the detection of ASD. The first is one of the most widely used ASD toddler screening instruments; it is easily accessible and low-cost. The second is a brief, parent-reported, 50-item questionnaire to quantify autistic traits in children aged 4-11 years.
- Emotional and behavioral problems: The Strengths and Difficulties Questionnaire [25] is a brief instrument widely used to assess main areas of developmental psychopathology and personal strengths. It consists of 25

items and is available in three forms depending on responders: parents, teachers, and adolescents (self-report).

- Other neurodevelopmental disorders: Ad hoc screening tools for specific language impairment and specific learning disorder were implemented by our institute's research group working on specific learning, language, and communication disorders.

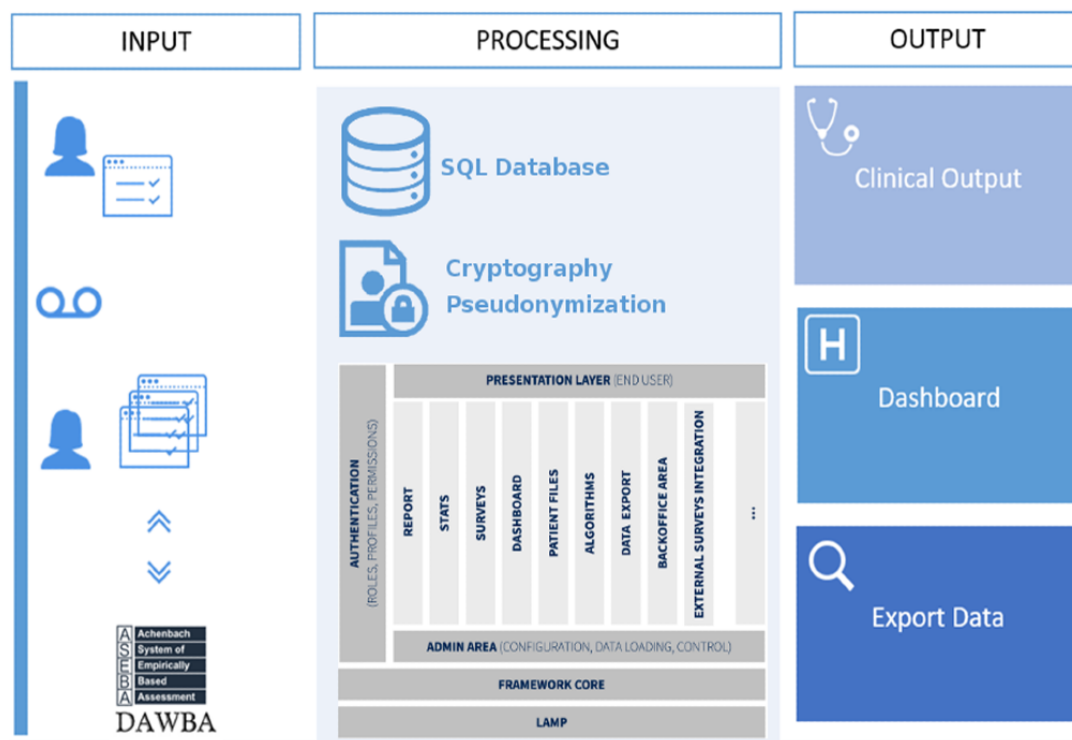

Overall, these tools cover ages ranging from 18 months to 15 years.

After this initial screening step, other standardized assessment tools can be administered too, such as the Child Behavior Checklist (CBCL) [26,27] and the Development and Well-Being Assessment (DAWBA) [28]. Through an interoperability system, links and credentials can be sent to caregivers to complete questionnaires (CBCL through ASEBA-Web) and the interview (DAWBA through Dawba.net), and results can then be imported by uploading appropriately encrypted files.

Web Application Architecture and Process Design

Figure 3 shows a high-level diagram of the platform development process. The three phases of process design are described in detail below:

- Design of the input interface
- Processing design
- Design of the output interface

Figure 3. The developed web app architecture design.

Design of the Input Interface

An easy-to-use interface was developed to support the interaction between front-end users and the web-based application; the web interface is simple to learn and easy to use, and it displays information in a consistent and progressive manner and maximizes functionalities. To be displayed properly on most mobile devices, the platform implements a responsive web design.

The system also relies on the active engagement of caregivers who send their data to the informatics system using a PC and mobile device. Patients scheduled for an appointment at the Child Psychopathology Unit (IRCCS Medea) get an email with a token for the first web app. They are then guided through a series of steps: completion of a brief form with primary clinical information, verifying of this information, and filling out of the registration form. They then receive a set of questionnaires according to their age and main characteristics, along with the link to the MedicalBIT assessment for completion.

Users are not asked to complete all forms in one session, they can resume from where they last left. After completing all the selected questionnaires, patients are scheduled for a doctor's visit.

To support the user's interaction with the platform, a user-friendly back-end interface was implemented. Through a control panel, staff can handle main functions such as administration rights, patients' lists, and support for data entry.

Processing Design: Technical Implementation of Data Storage and Automated Scoring Algorithm

At the end of each survey, the system immediately processes the caregiver's answers using artificial intelligence algorithms. Starting from scores provided for every possible answer and

relying on appropriate threshold values, alerts, and key performance indicators are generated, which are useful to health professionals not only to monitor single patients but also for statistics and research purposes.

The whole process is General Data Protection Regulation compliant. The web portal is protected with a digital certificate issued by a certification authority, implements HTTPS (the secure browsing protocol for the World Wide Web), and is hosted on a virtual server in the GARR cloud environment. GARR is the Italian ultrabroadband network for education and research.

The infrastructure provides high reliability, service continuity, and data protection. Backup takes place daily, and we rely on disaster recovery as a service in an alternative environment to ensure availability in case of downtime. We used open source solutions for easier integration with company applications and to avoid vendor lock-in. Our platform is compliant with Italian guidelines [29]: "To ensure an effective support to all company processes, it is necessary to guarantee data univocity and integrity, real-time updating, historicization and audit trail, ergonomics, standardization, integration, stability, availability, security, privacy, innovation, evolvability."

All data are unique; nothing is duplicated. Information can be accessed only by authorized users and is protected from unauthorized changes; furthermore, confidential data is safeguarded.

There are two different access levels:

- Front-end user
 - Caregivers filling out the forms can only view and download the information concerning their child. They have no access to scores generated by the automatic

scoring algorithms. Multiple patients can be associated to each caregiver (eg, in the case of siblings).

- Back-end users
 - Health care professionals viewing the answers and any alerts enter the diagnoses at the end of the diagnostic process.
 - Back-office users with full operation rights
 - The system administrator has access to additional features such as dashboard and data export (see next paragraph).

The integrity of data and documents is guaranteed by the use of appropriate logs of activity and changes. These logs are also useful from a legal point of view. All information relating to a particular patient can also be deleted by users with administrator rights. Documents saved on the server are protected by

encryption; to comply with the privacy legislation, the information stored in the database is pseudo-anonymized.

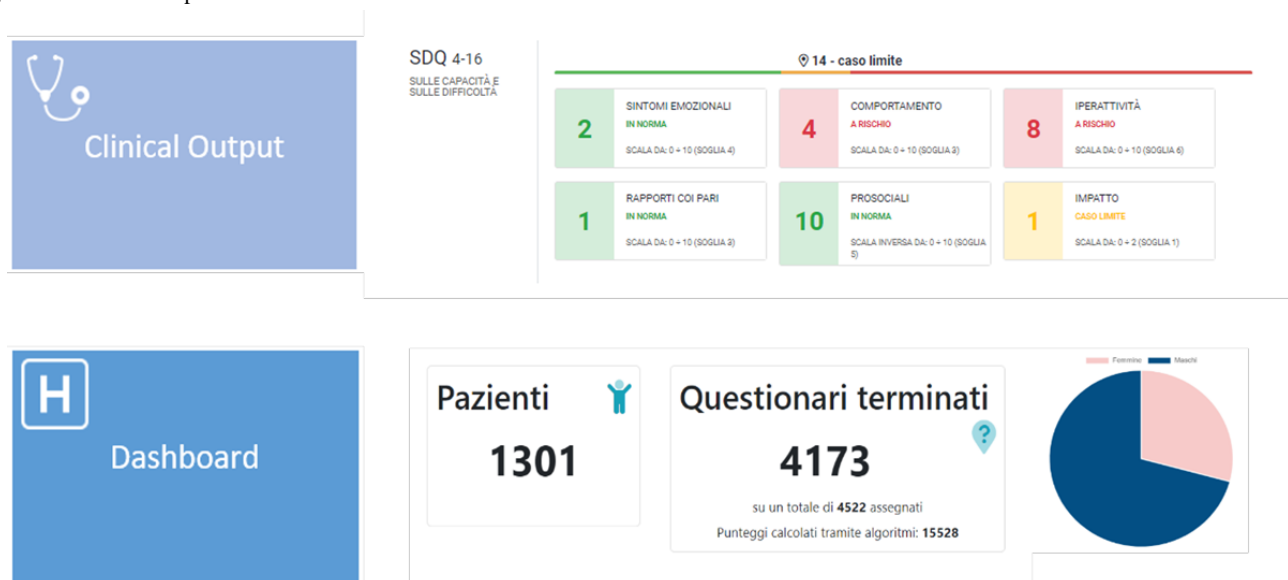

Design of the Output Interface

A real-time graphing, panel, and table interface is available only to back-end users and contains all processed data in real time. This data is also displayed in interactive dashboards available at different access levels. Two different types of reporting are created to display the collected data (Figure 4):

1. Clinical output: an individual-level output, reporting patient outcome scores
2. Dashboard: group-level data, reporting summarized data in a dashboard

All data stored in the database system can be exported in Excel format for further processing.

Figure 4. Different output levels.

System Implementation and Evaluation

This digital system has been on since October 2018 and has been used by 1301 patients (front-end users) and back-end users, including 17 clinicians, 2 back-office operators, and administration operators.

Back-end users are employed by the provider service: back-office operators are office secretaries and administration operators are psychologists and researchers who designed the

service in collaboration with the data scientist and consulting company SEGE srl.

Based on indicators recommended by the National Quality Forum [21] and the Italian National Guidelines [29], we evaluated the quality of the system and used quantitative measures that were replicable and comparable over time. As shown in Textbox 1, the selected measures pertain to four areas: access to care, financial impact/cost, experience, and effectiveness.

Textbox 1. Telehealth measurement framework domains and subdomains.

<p>Access to care</p> <ul style="list-style-type: none">• Access for parent/caregiver• Access to information <p>Effectiveness</p> <ul style="list-style-type: none">• System effectiveness• Operational effectiveness• Technical effectiveness <p>Costs</p> <ul style="list-style-type: none">• The financial impact to family/caregiver• The financial impact to care team <p>Experience</p> <ul style="list-style-type: none">• Patient, family, or caregiver experience
--

Results

According to the Italian National Guidelines [29] and the National Quality Forum [21], we provide performance measures

available for data collected between October 2018 and June 2021 (Table 1 and Figure 5). This process is a work in progress, and in the future, we aim to capture more indicators about different domains and subdomains.

Table 1. Platform performance measures.

Domains and subdomains	Qualitative measures	Quantitative measures
Access to care		
<ul style="list-style-type: none"> • Access for parent/caregiver • Access to information 	<ul style="list-style-type: none"> • The web system is responsive to different devices • Family's patient can access the system using dedicated access points in the institute • Clear instructions in the home page • Responsive technical assistance 	<ul style="list-style-type: none"> • N/A^a
Effectiveness		
<ul style="list-style-type: none"> • System effectiveness 	<ul style="list-style-type: none"> • N/A 	<ul style="list-style-type: none"> • Continuity: from October 2018 to June 2021 • Dimension: 1100 new patients accessed the telehealth system and were subsequently sorted to different diagnostic paths. For details about the accesses trend over time, see indicators in Figure 5. Each patient completed on average 4 questionnaires, for a total of 177 items. • Speed: (1) Only a few days elapsed between the initial request from family and the completion of screening questionnaires on the platform. (2) The average length between screening questionnaire completion and completion of the diagnostic process was 106 days, with a decrease over the 3-year period from 2019 to 2021 (see Figure 5e)
<ul style="list-style-type: none"> • Operational effectiveness 	<ul style="list-style-type: none"> • The system is perfectly integrated within the traditional diagnostic path. • Customized in-person visits are based on web questionnaire output. 	<ul style="list-style-type: none"> • N/A
<ul style="list-style-type: none"> • Technical effectiveness 	<ul style="list-style-type: none"> • Output dashboard for clinicians and database with collected data for researchers are automatically generated. • The system is integrated with other screening and diagnostic tools implemented on different platforms: the Development and Well-Being Assessment [28] and the Child Behavior Checklist [26,27]. 	<ul style="list-style-type: none"> • N/A
Costs		
<ul style="list-style-type: none"> • Financial impact for family/caregiver • Financial impact for care team 	<ul style="list-style-type: none"> • Decrease in the length/frequency of stay/visit to hospital • Clinician can integrate traditional work setting with smart working 	<ul style="list-style-type: none"> • N/A
Experience		
<ul style="list-style-type: none"> • Patient, family, or caregiver experience 	<ul style="list-style-type: none"> • N/A 	<ul style="list-style-type: none"> • Caregivers dropout: (1) 5.3% of registered users do not fill in any questionnaire. (2) 99.6% of caregivers that begin a questionnaire, complete it

^aN/A: not applicable.

Figure 5. (a) Number of accesses of new patients for each semester in the last 3 years: multiple accesses by 1 patient are counted once. (b) Average and SD per month of accesses by new patients in the last 3 years. (c) Dynamic dimension value = (August 2020 to July 2021) / (August 2019 to July 2020) = 560 / 410 = 1.36. This enabled us to compare differences in accesses in the last 2 years. (d) The graph shows the trend in Medea Information and Clinical Assessment On-Line (MedicalBIT) during the different phases of the pandemic. (e) Data show that the average time between the completion of questionnaires and receiving a diagnosis has clearly decreased over the 3-year period: 2019 (mean 150, SD 179.6), 2020 (mean 82, SD 77.3), and 2021 (mean 65, SD 34.9).

Discussion

Principal Results

In this study, we present the design and implementation of the MedicalBIT web platform, which allows patients to complete questionnaires comfortably from home through a user-friendly and easily accessible interface.

This work is based on the European Commission's recommendations in the Study on Big Data in Public Health, Telemedicine, and Healthcare [6] that identified four major areas in health care where big data may be used: (1) early signs for detection, diagnosis, and intervention; (2) identification of risk factors for disease to improve prevention care; (3) enhancing pharmacovigilance and patient safety by communication of real-time information; and (4) improvement in outcomes prediction.

The MedicalBIT platform, as described in this paper, allows for the timely collection of clinical data to support the diagnostic process and subsequent steps (1 and 3), and it enables the development of predictive models to improve preventive care and outcome prediction (2 and 4). A core component of the proposed model is caregivers' perspective of their child's mental health, laying the foundation for evidence-based practice and person-centered care. The MedicalBIT web platform was introduced into the clinical workflow, making patients' and caregivers' care experiences more comfortable. As mentioned, health information technology can save time and reduce costs, thereby improving the health care experience for both patients and clinicians. For this purpose, we also collected customer satisfaction feedback.

Furthermore, performance measures enable us to describe the platform with an objective measurement that allows for comparisons both within the same platform over time and between different web platforms used for similar purposes.

According to reports so far, available quantitative data shows general upward trends for platform use from 2018 to 2021 despite the apparent drop during the first months of the COVID-19 pandemic, which required a complete reorganization of care provision.

This trend is in line with research confirming the value of telepsychiatry [30,31] not only during the pandemic period but also before and, most importantly, after the emergency. As described in the Introduction, use of telemedicine in the psychiatry and developmental psychiatry fields can offer several benefits such as improved efficiency and effectiveness of mental health services: it can reach more people with fewer resources [32].

We hope that these changes will lead to filling the care gap in the field of child psychiatry, which has been appropriately defined as “one of the most difficult and crucial challenges of the next decade” [12].

Our project fits into this still uncertain and experimental scenario, with its pros and cons. Telemedicine in the child psychiatry clinical routine can help both patients and health care providers save time and provide them easy access to the care system. Furthermore, because of its fast and advantageous features, it facilitates the hospital and clinic workflow, as processing and automatic output of clinical data enables the collection of large amounts of data for research purposes. Nevertheless, there are some limitations to consider such as the impact of physical distance on human relationships and ethical and coroner issues [29].

Further studies are clearly necessary to establish evidence-based telepsychiatry-specific standards of care, following guidelines

proposed by the American Telemedicine Association [33] and the American Academy of Child and Adolescent Psychiatry [34].

Limitations and Further Development

Based on the current limitations, we are working on a customer satisfaction questionnaire for both families and clinicians to collect feedback to make users feel more engaged in this process and help us as back-office operators to improve services. Moreover, we intend to improve our platform performance measurement tools to obtain more quantitative indicators about the four domains presented in Table 1.

According to Waller and Stotler [35], one of the next steps should be the implementation of a measurement and methodology evaluation of the impact of telehealth on clinical outcomes (in our case, on the diagnostic outcome as an indicator of clinical effectiveness). Our intent is to also implement a platform-based service that could follow and provide assistance to patients after diagnosis (information, psychoeducational materials, rehabilitation tools).

Conclusions

This study describes the successful implementation of an innovative digital tool. According to our results, the web-based platform appears to be a feasible, efficient, and cost-effective method for enhancing digital care in the field of child psychiatry. It also contributes to the collection of big and smart data, in line with European guidelines. This work shows how large data sets may enhance the accuracy and timing of diagnosis, and contribute to more effective interventions based on predictive models.

Acknowledgments

The authors wish to thank clinicians and back-office staff who took part in the web platform co-design and all clinicians using Medea Information and Clinical Assessment On-Line (MedicalBIT). This work has been possible due to the patients' families, clinicians, researchers, and back-office staff who trust this innovative system.

Authors' Contributions

PC, SBC, and MM conceptualized the study. SBC gathered the resources and curated the data. SBC, SP, and PC prepared the original draft. PC, SBC, SP, and SC reviewed and edited the manuscript. MM supervised the study.

Conflicts of Interest

None declared.

Abstract

Background: Engaging adolescents and young adults (AYAs) who are at elevated risk for HIV acquisition or who are living with HIV in health care has posed a major challenge in HIV prevention and care efforts. Mobile health (mHealth) interventions are a popular and accessible strategy to support AYA engagement despite barriers to care present along the HIV care continuum. Even with progress in the field of mHealth research, expert recommendations for the process of designing, evaluating, and implementing HIV-related mHealth interventions are underdeveloped.

Objective: The aim of this study was to compile expert recommendations on the development, evaluation, and implementation of AYA-focused HIV prevention and care mHealth interventions.

Methods: Experts from adolescent mHealth HIV research networks and investigators of recently funded HIV mHealth projects and programs were identified and invited to complete a series of electronic surveys related to the design, implementation, and evaluation of HIV-related mHealth interventions. A modified Delphi method was used to ask experts to score 35 survey items on a 4-point Likert scale from not important to very important and encouraged experts to leave additional comments in textboxes. Responses were reviewed by the researchers, a team of 4 HIV mHealth intervention experts. The average importance ratings from survey responses were calculated and then categorized as retained (high importance), flagged (mid-level importance), or dropped (no/low importance). Additionally, thematic analysis of expert comments helped modify survey items for the next survey round. An evaluation of the level of agreement among experts on the most important items followed each round until consensus was reached.

Results: Of the 35 invited experts, 23 completed the first survey representing a variety of roles within a research team. Following two rounds of Delphi surveys, experts scored 24 of the 28 (86%) survey items included in round two as important to very important. The final consensus items included 24 recommendations related to the mHealth intervention design process (n=15), evaluation (n=2), and implementation (n=7). The 3 survey items with the highest average scores focused on the design process, specifically, (1) the creation of a diverse team including researchers, app software developers, and youth representation; (2) the importance of AYA-focused content; and (3) the value of an iterative process. Additionally, experts highlighted the importance of establishing the best ways to collect data and the types of data for collection during the evaluation process as well as constructing a plan for participant technology disruption when implementing an mHealth intervention.

Conclusions: The modified Delphi method was a useful tool to convene experts to determine recommendations for AYA-focused HIV prevention and care mHealth interventions. These recommendations can inform future mHealth interventions. To ensure the acceptability, feasibility, and efficacy of these AYA HIV prevention interventions, the focus must be on the specific needs of AYAs by including representation of AYAs in the process, including consistent and relevant content, ensuring appropriate data is collected, and considering technology and health accessibility barriers.

Introduction

In the United States, HIV is a major cause of morbidity, mortality, and social adversity among adolescents and young adults (AYAs) [1]. In 2019, individuals aged 13-24 years accounted for 21% of newly reported HIV infections [2]. AYAs have poor health outcomes across the HIV care continuum—diagnosis, linkage and retention in care, maintaining an antiretroviral therapy (ART) regimen, and achieving viral suppression [2]. Over 40% of youth living with HIV (YLH) in the United States are unaware of their status compared to 14% of adults [3]. Additionally, for YLH with a known HIV diagnosis, care engagement was greater than the overall population with HIV diagnosis, yet viral suppression was 60% [3], again fairing worse than their adult counterparts. Beyond age, disparities based on race, gender, and sexual orientation have created an environment where communities with the highest incidence of HIV infections have access to the fewest resources [2-4]. Young Black and Latinx gay, bisexual, other men who have sex with men (GBMSM), and transgender women are at the greatest risk of becoming infected with HIV in their lifetime [3]. Experiences of pervasive stigma and systemic racism in and outside health care systems prevent communities most vulnerable to HIV from accessing and engaging in the HIV care continuum [3,5]. High rates of sexual risk behaviors, low rates of HIV testing, and poor engagement in HIV care [2,3] have generated a high demand for culturally competent and accessible AYA-targeted HIV prevention and treatment interventions.

The US Department of Health and Human Services Ending the HIV Epidemic (EHE) initiative outlined strategies to reduce new HIV infections by 90% by 2030 [6]. Efficient implementation of HIV research into practice was an area of focus included in the National HIV/AIDS Strategy to move toward EHE, as well as prioritizing populations most affected by the HIV epidemic [7]. In 2018, more than 90% of US youth regardless of race, income, or parent's education level had access to a smartphone [8], and adolescents expressed a preference for HIV interventions on mobile technologies [9,10]. Hence, mobile health (mHealth) approaches have become increasingly common in engaging AYAs in HIV prevention and care efforts. Focus groups and usability testing studies with YLH have identified privacy, entertainment, social support, and educational content as desired features of mHealth HIV interventions [11-14]. To date, mHealth interventions have used a variety of app features to support engagement, including connecting with other YLH

via in-app forums or message boards [15], daily or weekly SMS text message reminders [16-18], and educational games [10,19]. Many mHealth projects, such as weCare, MyPEEPS, and Guy2Guy, prioritize engagement of GBMSM and transgender women with a social support network, inclusive sex education, and culturally relevant content [15,20,21]. mHealth interventions have shown some improvement in outcomes of interest including ART adherence, viral suppression, medical appointment attendance, HIV testing, and perceived social support [10,15,19,20,22]. However, few of these interventions have been tested in large-scale randomized controlled trials, and fewer have been implemented into routine clinical care or community-based settings. Further, there are no existing recommendations for developing, testing, and disseminating mHealth HIV prevention or treatment interventions for AYAs. Accordingly, this study aimed to use a modified Delphi method [23,24] to elicit expert recommendations on the design, evaluation, and implementation of AYA-focused HIV prevention and care mHealth interventions. Study design refers to the road map used to collect and analyze data based on a specific question the researchers hope to answer [25]. An evaluation reflects on how the intervention is implemented and how effective it is over time [26]. An effective evaluation will allow an intervention to adapt over time. Finally, implementation is the adaption and delivery of evidence-based research findings into real-world practice to benefit the community that the intervention was developed to benefit [27].

Methods

Overview

The Delphi method is based on the convergence of expert opinion after multiple rounds of data collection (eg, surveys with Likert scale items) with the final round occurring when agreement emerges among experts [23]. The multiple rounds of data collection and analysis in the Delphi method allow for elimination of survey items that experts agree are unimportant and refinement of the remaining items [23]. The final round leaves a consensus list of recommendations experts agree are crucial to consider. This study used a modified Delphi method [24] to reach consensus on expert recommendations for AYA HIV mHealth interventions. The modified Delphi method used in this study maintained the multiple rounds of data collection, but it omitted the expert-to-expert face-to-face discussion that would occur following data collection due to difficulties in varying schedules and time zones as well as to limit experts from influencing each other. In the absence of the expert

discussion, participants had the option to leave text comments in the survey that were later considered when designing the next survey data collection round.

Study Design

Survey Development

Survey items were generated by 4 mHealth HIV experts, who were investigators for various federally funded projects relevant to this topic. A list of common considerations when developing, evaluating, and implementing HIV mHealth interventions were compiled for the survey. The study team and the survey development group reviewed and edited the initial survey to ensure items were concise and minimized influence on expert participants' scoring.

The consensus survey for the first round included 35 Likert items sorted into five different categories: (1) design: preparation phase; (2) design: core elements; (3) evaluation: preparation and study design; (4) evaluation: data sources; and (5) implementation. Item response options ranged from not important (1) to very important (4), and each item included a "comment" textbox for experts to type in general comments (eg, why they scored an item the way they did) or revised wording suggestions. The survey was programmed in Research Electronic Data Capture (REDCap), a secure website software used for data collection and management in clinical and translational research [28,29], which was used to disseminate the survey to expert participants.

Expert Identification and Selection

The identification of experts who have knowledge of and experience with AYA mHealth HIV prevention and care interventions to participate in this study involved a review of large-scale HIV mHealth intervention networks and recently funded HIV mHealth projects and programs at the start of this study in 2019. Expert participants were identified through two different adolescent mHealth HIV-related networks, the iTech U19 of the National Institutes of Health (NIH)-funded Adolescent Medicine Trials Network [30] and the Health Resources and Services Administration's Special Projects of National Significance Initiative in Use of Social Media to Improve Engagement, Retention, and Health Outcomes along the HIV Care Continuum, 2015-2019 [31]. Additional experts were identified through a search of 2019 grantees of adolescent HIV mHealth interventions in the NIH Research Portfolio Online Reporting Tools Expenditures and Results [32] with keyword Medical Subject Headings (MeSH) [33] terms "adolescent," "HIV," and "mobile health." Expert identification and selection for survey participation aimed to encompass the involvement of a variety of cities and organizations in the United States and to include representation of principal investigators, program directors, project coordinators, protocol chairs, and project staff to capture the range of perspectives and expertise within a study team.

Survey Distribution and Data Collection

The survey was distributed via email with a weblink to participate in the REDCap survey. Experts had a 4-week window to complete the survey. After the round 1 survey window closed,

the data were deidentified and analyzed. Survey items were modified based on expert participant survey response scores and accompanying comments resulting in a subsequent round 2 survey. Given the number of invited experts and consideration of their daily responsibilities, instead of having experts review each other's responses in their entirety, experts were informed of the group's overall responses by presenting them only with retained and reworded survey items in the next round for efficiency and privacy. A subsequent round was conducted similarly until a consensus was reached by participants. Only participants from the first round were eligible to participate in the subsequent round. Ultimately, the process was completed in two survey rounds between November 2019 and April 2020. Following successful completion of participation, expert participants were compensated in the form of a US \$50 e-gift card for their time and effort in this study.

Data Analysis and Consensus Criteria

Deidentified survey Likert responses were exported from REDCap for analysis in Excel (Microsoft Corporation). Scores for each survey responses were determined based on the mean importance rating from not important (1) to very important (4) and were then categorized as retained, flagged, or dropped. Retained survey responses were those with mean scores between 3 (important) and 4 (very important), and automatically appeared on the next iteration of the survey. Flagged survey responses had a score between 2 (somewhat important) and 3 (important). For flagged survey responses, the SDs were calculated. The survey responses with an $SD > 1$ were dropped, and the other flagged survey responses were revised based on the experts' comments. Finally, survey responses with a score ≤ 2 (not at all important, 1, to somewhat important, 2) were dropped.

As part of the REDCap survey, expert comments were collected in textboxes, which provided additional information on why they chose a particular survey response, and were reviewed during analysis [34]. Comments were compiled in Word (Microsoft Word) under their survey item, and responses with similar explanations/questions were grouped together for review. Comments were used to inform revisions following round 1 and were especially helpful for reviewing the flagged items, considering where divergence reflected disagreement among experts or unclear wording. Comments were also used to assist in assessing consensus among experts. The revised recommendation list presented to experts were those assessed as "important" (3) to "very important" (4) following the round 2 survey.

Ethical Considerations

This study received an exempt determination from the Children's Hospital of Philadelphia's Institutional Review Board. The beginning of each survey included an overview of the study and consent language where moving to the next page of the survey indicated willingness to participate in the study.

Results

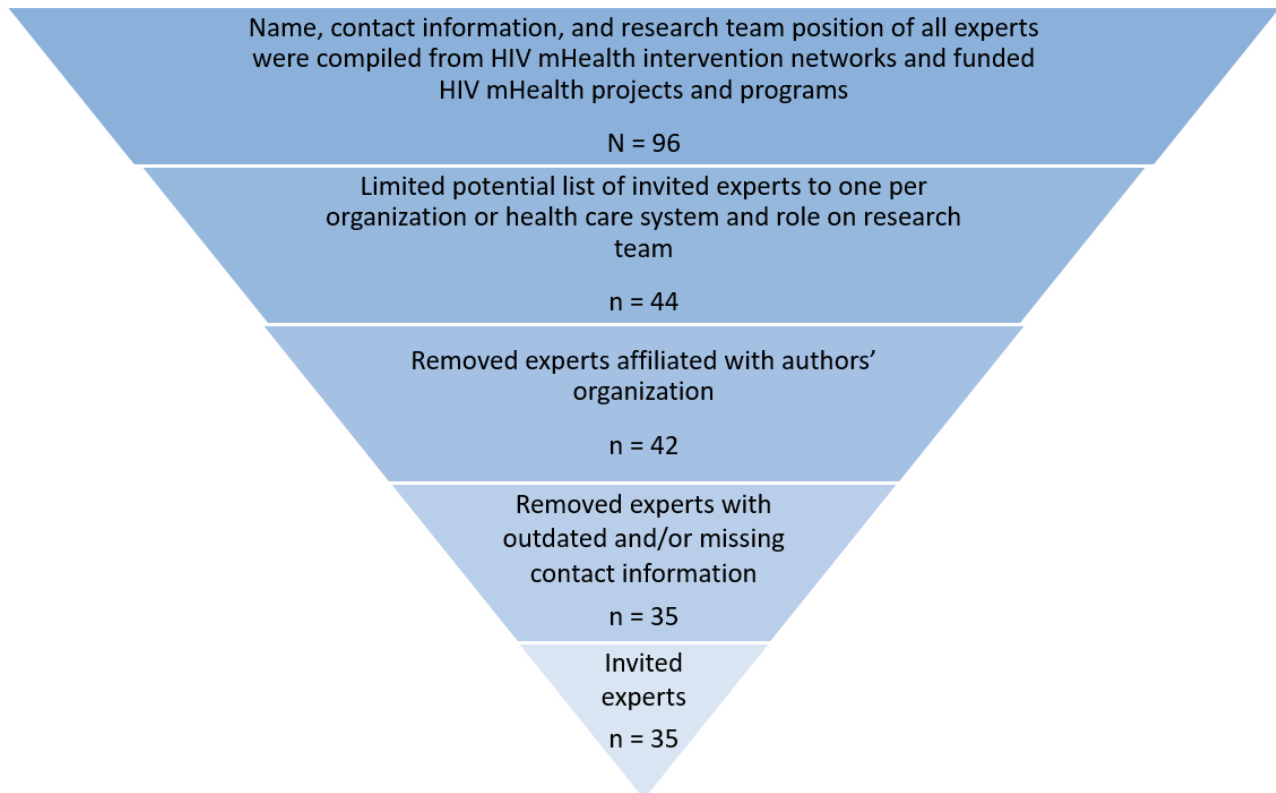

Expert Participation

Survey responses were received from 23 of the 35 (66%) invited adolescent HIV/mHealth experts for round 1 (see Figure 1)

identified using reports from HIV mHealth intervention networks and recently funded HIV mHealth projects and programs. Participating experts represented 20 research organizations across the United States. More than half were principal investigators (n=15) and the remaining experts

included various roles on a study team, including project directors (n=3), evaluators (n=2), project coordinators (n=2), and other project staff (n=1). Experts who completed the first survey were reinvited to participate in round 2 with a high response rate of 21 of 23 (91%) experts.

Figure 1. Expert identification and selection.

Round 1

Item Score Analysis

Of the 35 items asked in the round 1 survey, 86% (n=30) fit the criteria to be retained, 14% (n=5) were identified as flagged,

and none fit the dropped criteria (not important, 1, to somewhat important, 2) following the analysis of the survey responses. [Table 1](#) displays the expert responses for each section: total retained, flagged by SD, and dropped item. Of the 5 flagged items, 1 had an SD>1 and subsequently was kept for round 2.

Table 1. Consensus survey response scoring results: round 1 (R1; n=35) and round 2 (R2; n=28).

^aN/A: not applicable.

^bFlagged items with SD≤1 were dropped.

Experts' Supplemental Comments

Themes emerged within the comment section that guided the revision of the round 2 survey. Various questions by experts reflected a misunderstanding about how to rate an item's importance (eg, based on their specific projects or mHealth HIV interventions generally). For round 2, a clarifying statement was included in the instructions to correct this issue. Experts were reminded to focus on overall recommendations that are important even if they do not apply to all intervention types. Additionally, some items (n=6) were revised based on feedback that they were unclear and required further clarification.

Retained Items

After review of the quantitative and qualitative analyses, decisions were made about which items to retain for the next round. A total of 4 flagged items with a SD≤1 were dropped, and 3 others were eliminated due to feedback related to the similarities among items in the evaluation: data source section. Specific data sources such as paradata, electronic medical

records (EMRs), self-reports, and qualitative data individually were found to be less important than generally identifying an appropriate data source for evaluation of mHealth HIV interventions. Therefore, 3 data source questions were dropped and 1 was revised into a single simplified data source item. The round 2 survey included 28 survey items reduced from the original 35 survey items in the round 1 survey.

Round 2

Item Score Analysis

Experts were asked to score the importance of the revised 28-item survey. Following the same analytical process as in round 1 (see Table 1), 24 survey items were retained, 4 were flagged, and none fit the dropped criteria (see Table 1). The 4 items that scored in the flagged range (somewhat important, 2, and important, 3) in both round 1 and again in round 2 (see Table 2) were subsequently removed from the recommendation list. Over the two rounds of data collection, experts scored these flagged items consistently as less important compared to the retained items (important, 3, and very important, 4).

Table 2. Rounds 1 and 2 scores for flagged items that were dropped from expert's recommendation list.

Flagged items	Round 1, mean (SD)	Round 2, mean (SD)
Design: preparation		
Weigh the advantages and disadvantages of integration with an electronic medical record	2.83 (0.94)	2.81 (0.81)
Consider the advantages and disadvantages of an intervention that is publicly available vs offered by providers in a clinical setting	3.09 (0.73)	2.86 (1.06)
Design: core intervention elements		
Use a theoretical foundation to guide intervention development	3.00 (0.85)	2.95 (0.74)
Evaluation: preparation, study design, and data source		
Consider a study design other than traditional randomized controlled trials, such as a multiphase optimization strategy, sequential multiple assignment randomized trials, or pragmatic trials to optimize and tailor the intervention	3.13 (0.82)	2.76 (0.70)

Expert Recommendations

Overall, 86% of the items in round 2 were scored by experts as important (3) to very important (4), indicating a consensus was reached, and a third round of survey data collection was not needed. Table 3 provides the experts' final 24 recommendations for developing, evaluating, and implementing HIV prevention and care mHealth interventions.

As shown in Table 3, the majority (15/24) of the final recommendations experts assessed as the most important were related to intervention design. Design encompasses a broad range of considerations from who will be on the design team, cost, content, privacy concerns, and more. For example, expert made the following comments on the importance of design consideration:

...The intervention is not for us. It is not something fun to do with hundreds of thousands of dollars and hours. It is a product we're building with our population to make impactful and positive change in

the lives and health of our target population. [On AYA-specific content]

Having the intervention be stealth during everyday life is important. However, message content, when participants are interacting with the intervention, may need to push the privacy boundaries to make it relevant. [On importance of privacy]

When it comes to youth (and perhaps people in general), novelty is important as is continuous development. Nothing is perfect from the beginning. There will always be something that can be tweaked, added, or removed in order to better serve the users of the technology [On incorporating an iterative process]

Evaluation items made up 2 of the final recommendations. As discussed previously, data sources individually were not viewed as important as tailoring the evaluation to each intervention appropriately. Finally, there were 7 final implementation recommendations.

Table 3. Final expert recommendations and average importance scores (range 1-4: not important to very important).

	Round 1, mean (SD)	Round 2, mean (SD)
Design: preparation recommendations		
1. Have a multidisciplinary team including experts in HIV, adolescent development, software programming, user interface design, and youth	3.83 (0.39)	3.81 (0.40)
2. Include youth throughout the process to maximize engagement	3.78 (0.52)	3.71 (0.56)
3. Weigh challenges and benefits of using existing technology (platforms or apps) vs newly created technology	3.30 (0.70)	3.24 (0.83)
4. Use an iterative process (incorporating feedback and refining) in developing or adapting the intervention	3.65 (0.49)	3.81 (0.51)
5. Design with sustainability in mind	3.52 (0.79)	3.52 (0.68)
6. Consider the balance between cost and functionality	3.56 (0.59)	3.38 (0.59)
7. Develop an intervention that is accessible, for instance it is platform agnostic (ie, can be used on Android, iOS, or Windows) and available to the majority of youth (ie, those with limited cell phone plans and access to Wi-Fi)	3.74 (0.54)	3.67 (0.58)
8. Determine the appropriate level of real human engagement (eg, automated messaging vs live human coach)	3.39 (0.84)	3.38 (0.59)
9. Consider whether you want to design for youth at various points across the continuum or for a specific target audience	3.36 (1.01)	3.33 (0.66)
Design: core intervention elements recommendations		
1. Ensure that intervention content is relevant to the needs of your specific youth population	3.74 (0.54)	3.95 (0.22)
2. Consider the appropriate dose/frequency of the intervention for optimal efficacy	3.61 (0.66)	3.57 (0.60)
3. Determine the most appropriate digital health modalities (eg, SMS text messaging, social media, mobile website, e-coach, app, or telemedicine) or a combination that will allow for the maximal engagement and effectiveness of intervention	3.74 (0.54)	3.52 (0.51)
4. Consider privacy and confidentiality in design (app icon, message content, home screen)	3.78 (0.52)	3.71 (0.46)
5. Ensure content and engagement strategies are developmentally and culturally appropriate	3.78 (0.42)	3.62 (0.50)
6. Maximize engagement strategies with the intervention to address issues with attrition	3.57 (0.51)	3.38 (0.67)
Evaluation: preparation, study design, and data source recommendations		
1. Determine which intervention components are most effective across groups or individuals	3.35 (0.78)	3.19 (0.68)
2. Establish the best ways to collect data and what types of data (eg, Google analytics, paradata, self-report data, or electronic medical record)	3.35 (0.65)	3.38 (0.67)
Implementation recommendations		
1. Consider the cost and logistics of any human component	3.52 (0.67)	3.38 (0.67)
2. Plan for participant technology disruption (lost, stolen, broken phone, or plan cut off) by collecting multiple modes of contact information and making it easy to reupload or log in to a platform	3.78 (0.52)	3.52 (0.51)
3. Consider integration into routine clinical care and community-based services where appropriate	3.17 (0.83)	3.48 (0.75)
4. Seek youth input about strategies to improve engagement with the intervention	3.43 (0.67)	3.62 (0.59)
5. Plan for how intervention informational content will be updated	3.48 (0.67)	3.33 (0.66)
6. Anticipate changes in platforms or operating systems	3.26 (0.69)	3.43 (0.68)
7. Consider strategies to meet milestones of potentially different timelines of research (eg, grant) and technology partners (eg, development and revision)	3.35 (0.83)	3.10 (0.70)

Discussion

Principle Findings and Comparison With Prior Work

The modified Delphi method allowed for the rapid collection of data including the opinions of more than 20 AYA-focused mHealth HIV intervention experts with varied experience across the United States. Following two rounds of data collection, an

original list of 35 items were modified into 24 recommendations on the design, evaluation, and implementation of HIV prevention and care mHealth interventions for AYAs. These consensus items provide guidelines for future development, evaluation, and implementation of mHealth interventions as well as for prevention scientists to support the health of AYAs at risk for acquiring or living with HIV. At each stage of AYA-focused mHealth HIV research, these considerations can guide

decision-making to optimize efficacy, acceptability, and accessibility of mHealth technology to work toward ending the HIV epidemic.

The three items that experts scored as most important were related to intervention design: ensuring that intervention content is relevant to the needs of the specific youth population; having a multidisciplinary team including experts in HIV, adolescent development, software programming, user interface design, and youth; and using an iterative process (incorporating feedback and refining) in developing or adapting the intervention. These design recommendations highlight the potential value of youth involvement and using community-engaged research principles (eg, listening to your community stakeholders throughout the research process to build trust and improve health outcomes that outlast the study duration) [35,36]. These processes can ensure a strong foundation for the intervention as well as for intervention engagement and sustainability.

This study also identified that intrinsic elements of the design are critical for accessibility and privacy. The accessibility of mHealth interventions may fluctuate depending on the type of platform (eg, iOS, Android, or web applications), device's operating system version, and adolescent's access to Wi-Fi and data plan. Privacy and confidentiality of HIV-related mHealth interventions has been documented as very important to YLH [13,37,38], and AYA HIV experts in this study agreed. Preventing unwanted disclosures in fear of the stigma associated with HIV may stop adolescents from downloading or using mHealth interventions that do not protect their privacy and confidentiality [37]. Password-protected accounts, discrete app names, and limiting the access to one's health information are ways to improve privacy and confidentiality [37,38].

The key considerations for the evaluation of mHealth interventions identified included determining what intervention components were the most effective and advantageous data collection strategies. The round 1 survey analysis found experts scored recommendations on individual data collection methods such as self-report, paradata, and EMRs as less important than selecting the right one for a specific project. This suggests that a one-size-fits-all approach to mHealth intervention evaluations may not be appropriate and should rather be tailored to fit each project's goals and evolving technology. A clear understanding of the intervention's desired outcomes may help to determine the most appropriate data collection methods.

In regard to real-world implementation of interventions, experts scored seeking youth input about strategies to improve engagement highest, indicating youth input would be the most important factor. Using a multidisciplinary team, including AYA input, from the start of intervention development was regarded as most important among experts. Again, the importance of including AYA input throughout the entirety of the project was recognized as crucial to reach and engage the youth audience the intervention was designed to help. Other highlights from the implementation recommendations primary focus on technology limitations such as high costs and frequent updates to platforms, operating systems, or devices. Understanding and taking into account the challenges facing youth most affected by HIV may help plan for a more successful implementation. For example, multiple forms of contact information, like emails or social media handles, may be helpful to collect since mobile phone disruptions are common in this group [39]. Additionally, staff time for technology maintenance and initiation were highlighted as important aspects to consider for intervention implementation for clinical care teams and community health organizations.

Limitations

While not hosting a face-to-face discussion among experts allowed us to avoid scheduling challenges and reduced participant time burden, it remains a potential limitation to this study [23]. The option for experts to leave comments served as a discussion forum that allowed us to receive every expert's opinion without influence from other experts. Another limitation was the potential for bias among experts invited to participate. Additionally, demographic, employment responsibilities, or years of experience were not collected. For this reason, researchers who occupied diverse roles on research teams were intentionally invited as experts to reduce this bias and gain a more complete understanding of different perspectives of the research design, evaluation, and implementation process.

Conclusions

This study is among the first to propose expert recommendations on the development, evaluation, and implementation of mHealth interventions for HIV prevention among AYAs. With a clear focus on the role of youth in all aspects of the process, these expert opinions may not only help move forward the quality of technology-based research for adolescent HIV prevention but also ensure that successful interventions will be disseminated broadly for the most impact.

Acknowledgments

The authors would like to thank the experts for their time and efforts in the study. This research was supported by the National Institutes of Health, K23 (NIH K23MH102128, Dowshen).

Abstract

Background: Research and dissemination of smartphone apps to deliver coaching and psychological driven intervention had seen a great surge in recent years. Notably, Acceptance Commitment Therapy (ACT) protocols were shown to be uniquely effective in treating symptoms for both depression and anxiety when delivered through smartphone apps. The aim of this study is to expand on that work and test the suitability of artificial intelligence–driven interventions delivered directly through popular texting apps.

Objective: This study evaluated our hypothesis that using Kai.ai will result in improved well-being.

Methods: We performed a pragmatic retrospective analysis of 2909 users who used Kai.ai on one of the top messaging apps (iMessage, WhatsApp, Discord, Telegram, etc). Users' well-being levels were tracked using the World Health Organization-Five Well-Being Index throughout the engagement with service. A 1-tailed paired samples *t* test was used to assess well-being levels before and after usage, and hierarchical linear modeling was used to examine the change in symptoms over time.

Results: The median well-being score at the last measurement was higher (median 52) than that at the start of the intervention (median 40), indicating a significant improvement ($W=2682927$; $P<.001$). Furthermore, HLM results showed that the improvement in well-being was linearly related to the number of daily messages a user sent ($\beta=.029$; $t_{81.36}=4$; $P<.001$), as well as the interaction between the number of messages and unique number of days ($\beta=-.0003$; $t_{81.36}=-2.2$; $P=.03$).

Conclusions: Mobile-based ACT interventions are effective means to improve individuals' well-being. Our findings further demonstrate Kai.ai's great promise in helping individuals improve and maintain high levels of well-being and thus improve their daily lives.

KEYWORDS

Acceptance Commitment Therapy; well-being; WHO-5; World Health Organization-Five Well-Being Index; mHealth; mobile health; smartphone; health application; mental health; quality of life; artificial intelligence

Introduction

Psychological distress, which can be broadly understood as an emotional state of suffering from mood- and anxiety-related symptoms [1], is among the leading causes of disability in the world [2]. It has become highly prevalent; it was recently estimated that up to 50% of the world's population experiences

symptoms of psychological distress [3]. Knowing how widespread mental health issues are, it is not surprising that they were found to be a central cause for the global burden of diseases worldwide, accounting for some 56.7% of disability-adjusted life years [2]. Furthermore, a recent report estimated that in 2010, poor mental health resulted in a US \$2-\$5 trillion annual loss worldwide owing to poor health and

reduced productivity. This loss was only projected to increase, expected to approach US \$6 trillion by 2030 [4].

While the COVID-19 pandemic imposed numerous hardships on the world, the increase in prevalence and severity of mental distress symptoms reached a level where worldwide organizations declared it a global crisis that needed immediate attention [4,5]. While the number of individuals with mental illnesses has been documented in the second decade of the 21st century, there was no comparable increase in the numbers of individuals receiving treatment for these symptoms over the same period. This highlights the unmet needs for more treatment possibilities [6]. Furthermore, it was recently claimed that despite the substantial investment in the development of new medications and therapeutic protocols, they are only expected to have a limited impact over the long term. In contrast, it is argued that greater attention should be given to the development of prevention strategies and tools [7].

Recently, mobile apps and computer-based applications have become increasingly useful tools for creating and disseminating mental health prevention and treatment programs [8-10]. Mobile interventions introduce a fresh variety of possibilities, including the provision for unlimited interactions and psychological interventions. This creates opportunities to reach patients anytime and anywhere. Furthermore, this kind of platform also has the possibility to enhance efficiency by increasing the treatment intensity and integrating therapeutic strategies into daily life [11].

The use of mobile-based interventions was found to be particularly effective when it was used to deliver Acceptance Commitment Therapy (ACT) protocols [12-15]. Since ACT protocols allow for a low-intensity or high-frequency approach [12], they are a highly effective method to facilitate changes in the flexibility of the thinking process, which is one of ACT's central features [16]. ACT is a form of psychotherapy positioned within the third wave of behavioral therapies. It focuses on teaching patients how to deal with challenging experiences by reflecting on their values [16]. ACT works to develop psychological flexibility, which entails having the ability to stay in contact with the present regardless of any unpleasant thoughts, feelings, or bodily sensations. Recently, ACT was shown to be effective in treating symptoms of both depression [14] and anxiety [13].

In this pragmatic retrospective study, we report the test results of a mobile platform called Kai.ai. Kai.ai is a platform designed to provide ACT-based, artificial intelligence-driven conversational coaching that helps users build habits for healthy living and resilience. It integrates seamlessly with all the top messaging apps (iMessage, WhatsApp, Discord, Telegram, etc) allowing for ecological momentary assessment and ecological momentary interventions. The platform checks in with users throughout the day and leverages users' responses and journaling exercises to deliver tailored ACT skilled coaching. In this study, the platform was evaluated using both a pre-post and longitudinal design to assess changes in measures of well-being among users. Our hypothesis being that using Kai.ai will result in improved well-being.

Methods

Study Design

A pragmatic retrospective design was used for this study, using data collected as part of users' engagement with Kai.ai's services. All participants were located in the United States and had free access to the service, which is seamlessly integrated with all the top messaging apps (iMessage, WhatsApp, Discord, Telegram, etc). This retrospective study included data from 2909 Kai.ai users, 85% of whom were recruited from major social networks such as TikTok, and they are presented with an advertisement inviting them to test how happy they are. Clicking the advertisement would direct users to a landing page (How happy are you? - Kai), where they can complete the World Health Organization-Five Well-Being Index (WHO-5). Upon completing the questionnaire, users were asked whether they would like to continue and engage with Kai.ai in the future.

During the first engagement, users were asked to complete an electronically secured version of the WHO-5. The survey was completely optional, and users could opt to not take part in the assessment phase. As users continued using Kai.ai, they were prompted once every 6 weeks to complete an additional WHO-5 assessment.

Participants

Participants completed the WHO-5 at least twice, with the highest number of completed WHO-5 measurements being 9. All participants in this study were from the United States, but since the data set used in this study was completely anonymized before it was given to the authors, no gender- or age-related information was available.

Ethical Considerations

This report is based on a postfactum analysis, which used anonymized data gathered during users' engagement with Kai.ai's services. As such, it was determined as not being a study involving human subjects by WCG IRB (1-1504102-1).

WHO-5

The WHO-5 is a short self-report to measure well-being [17,18]. Items are rated on a 6-point Likert scale, where participants are asked to rate their experiences in the past 2 weeks from 5=all of the time to 0=at no time. Raw scores are then multiplied by 4 to transform the scale to a percentage-based scale, ranging from 0% to 100%. A transferred score of below 50% reflects poor well-being, and a 10-point change in the translated score is seen as clinically relevant [17]. Owing to its ease of use and high validity, the WHO-5 has been extensively used in mental health- and physical health-related mobile apps [19-23].

Intervention

Overview

Users can choose to interact with Kai.ai through common messaging apps. Each user's first interaction starts with an onboarding process where the WHO-5 is administered. Based on the users' responses, Kai.ai builds 3 routines for the morning, noon, and evening. Each routine includes one or more of the

service's main blocks: (1) *Reflections and Journaling* and (2) *Exercises*.

Reflections and Journaling

For *Reflections and Journaling*, users are invited to think and write about their experiences. To maintain structure and help guide users, Kai.ai uses three kinds of journaling cues: gratitude, learning, and one good thing that happened.

During the gratitude exercise, users are encouraged to identify things for which they are grateful and to list them in writing, where they can easily review this list daily—this gives room to develop flexible thinking patterns. In the learning exercise, users are asked to focus on the lessons they can learn from their experiences and, lastly, in one good thing that *Exercises* users learn to reduce stress and anxiety by focusing on a single task rather than a long to-do list and spreading themselves too thin. Adopting a routine reflection and journaling process is meant to help users achieve a more centered, grounded, joyous, and purposeful state of mind.

Exercises

Two main types of exercises are offered to users: breathing exercises and ACT training. The breathing exercises focus on teaching users how to breathe in a constructive manner; breathing through their noses, using their diaphragm, and noting their posture. These are all meant to ensure a better flow of oxygen to the body, allowing for a reduction in stress and anxiety through the operation of the parasympathetic nervous system [24].

The used ACT training is based on the mindfulness approach aimed at increasing psychological flexibility, and treating pain and discomfort as facts of life can be used for personal growth through a process of acceptance and validation [16].

User Interaction

Users have 2 main ways to interact with Kai.ai: passive and active. In the passive way, the service checks in on the user at least once and not more than 3 times a day, depending on the routine created during onboarding. The check-in prompts can include either *Reflection and Journaling* open-ended questions or closed questions where users are asked to indicate how happy they are. In addition to the passive check-ins, users can actively reach out to Kai.ai by simply texting it whenever they feel the need to.

Data Analyses

To test Kai.ai's impact on participants' well-being, 2 analytical methods were used. First, a paired samples *t* test was performed to compare participants' baseline WHO-5 scores, which were collected just before the initiation of use, and the last WHO-5 score recorded for each participant. Following the initial analysis, hierarchical linear modeling (HLM) was used to examine the change in the users' well-being over time. HLM was chosen over other repeated measures models, such as repeated measures ANOVA, owing to its unique ability to model incomplete or imbalanced data sets. In the first level, the HLM was modeled to estimate the individual linear slopes and intercepts, and in the second level, the sample's average slope and intercept were estimated.

Results

Paired Samples *t* Tests

Users' scores on the WHO-5 were compared from the first and last measurement of each user. On average, users' last measurement score was better (median 52) than their first (median 40). A Wilcoxon signed rank test indicated that this difference was significant ($W=2682927$; $P<.001$). Figure 1 shows a box plot of the median (IQR) values of change in WHO-5 scores.

Figure 1. Box plot of the median (IQR) values of change in World Health Organization-Five Well-Being Index (WHO-5) scores for users' first and last measurements.

HLMs

In addition to the paired samples *t* test that was used to compare users first and last measurement scores, an HLM was used since it is best suited to deal with incomplete data sets while still accounting for the data set's repeated measures nature [25]. This unique strength of the HLM analysis was this analysis because the number of measurements among users varied between 2 and 9. Some users used the app for only 2 months, others used it for well over a year.

Consequently, our model tested whether differences in users' WHO-5 score between any 2 consecutive measurements could be predicted by the level of engagement during the time frame.

As such, we used 2 variables as indications of engagement: the number of unique days during which the user had active interactions with Kai.ai during the specified time frame and the number of daily messages the user sent during that time. Using the R nlme package [26], the effect of the engagement variables on the difference in WHO-5 scores was first tested separately for each measurement time point (second to ninth) and then aggregated over all time points. Our results show that the difference in WHO-5 scores was linearly related to the number of daily messages a user sent ($\beta=.029$; $t_{81.36}=4$; $P<.001$) and the interaction between the number of messages and unique number of days ($\beta=-.0003$; $t_{81.36}=-2.2$; $P=.03$), but not to the unique number of days on its own (Table 1)

Table 1. Unconditional growth model for changes in the World Health Organization-Five Well-Being Index (WHO-5) scores over time.

WHO-5 score	Estimate (β)	SE	<i>t</i> test (<i>df</i>)	<i>P</i> value
Intercept	.563	1.045	0.536 (81.36)	.59
Total daily messages	.029	.007	4 (81.36)	<.001
Unique active days	-.015	.036	-0.427 (81.36)	.67
Interaction	-.0003	.0001	-2.2 (81.36)	.03

Discussion

Principal Findings

In this paper, we report the results of a pragmatic retrospective study aiming to test the effectiveness of a mobile phone-delivered, ACT-based, artificial intelligence-delivered conversational coaching platform. In the onboarding measurement, half of all participants reported a WHO-5 score of 40 or less, which is well below the cut-off point of 50, and an indicator of poor well-being. However, on the last measurement recorded for each user, half of all participants indicated a score of 52 and above, indicating a change for the better and an overall good well-being. These results highlight the great potential ACT-based mobile apps can have for improving users' daily well-being.

Limitations

This paper describes the use of a novel platform and treatment protocol using mobile messaging apps to deploy ACT-based treatment to improve the well-being of users. Our results, while highlighting Kai.ai's great potential as reflected by the pre-post results, also hints at the wealth of possibilities still left to discover. The results of our HLM model, especially those of the negative interaction between the engagement variables, indicates that further research is needed to fully understand and describe Kai.ai's potential and fit. An example of such an area,

which future research should expand on, is Kai.ai's suitability to different genders and age groups. A recent study found differences among these groups in the adaptability of mobile-based coaching tools, as females and younger age groups (18-25 years) showed higher adaptability than males and older ones, respectively [27]. To overcome these adaptability challenges, a number of key features are introduced, which are directly aimed at improving users' engagement, leveraging the motivations of choice and progression. As such, an emphasis was placed on greater choice, as users are given the option of choosing tracks that focus on different central core ideas, such as relationships, mood, and life habits. Furthermore, over time, the daily routines and exercises offered to the user are selected on the basis of past preferences. Lastly, by allowing users to review their progress, allowing users the ability to view their progress time.

Conclusions

The findings reported in this paper show Kai.ai's great promise in helping individuals improve and maintain high levels of well-being and thus improve their daily life. These findings are further emphasized by the great need for mental health interventions, while the availability of and accessibility to treatment remains limited. It seems that the use of such technology, which is found to improve mental well-being per the findings of the WHO-5, is essential, especially nowadays.

Conflicts of Interest

AF is employed by Kai.ai, receives income from Kai.ai, and has been granted equity in Kai.ai. NN and MW receive income from Kai.ai and have been granted equity in Kai.ai.

Abstract

Background: Type 1 diabetes mellitus (T1DM) is dependent on self-care to avoid short- and long-term complications. There are several problem areas in diabetes that could be addressed by psychological interventions, such as suboptimal problem-solving strategies and fear of hypoglycemia. There is empirical support for a few psychological interventions, most often cognitive behavioral therapy, with various treatment aims. However, these interventions are largely unavailable in regular diabetes health care. Online guided self-help cognitive behavioral therapy could help achieve greater outreach.

Objective: We tested a manualized treatment in the early stage for further development, with the long-term aim to increase access to care. The purpose of this report was to show the potential of this newly developed online intervention by describing 2 illustrative cases.

Methods: An online guided self-help cognitive behavioral therapy protocol featuring problem solving and exposure was developed. The treatment was administered from a secure online platform and lasted for 8 weeks. Case 1 was a male participant. He had a number of diabetes-related complications and was worried about his future. He reported that he had a general idea that he needed to change his lifestyle but found it difficult to get started. Case 2 was a female participant. She had fear of hypoglycemia and unhelpful avoidance behaviors. She kept her blood glucose levels unhealthily high in order to prevent hypoglycemic episodes. Furthermore, she avoided contact with diabetes health care.

Results: The 2 participants showed clinically significant improvements in their most relevant problem areas. In case 1, the participant's blood glucose levels reduced, and he was able to establish healthy routines, such as increase physical exercise and decrease overeating. In case 2, the participant's fear of hypoglycemia greatly decreased, and she was able to confront many of her avoided situations and increase necessary visits to her diabetes clinic. Treatment satisfaction was high, and no adverse events were reported.

Conclusions: It is possible to deliver a cognitive behavioral therapy intervention aimed at problem areas in diabetes online. Problem solving appears to help with problems in everyday routines and lifestyle choices. Exposure to aversive stimuli appears to be a plausible intervention specifically aimed at the fear of hypoglycemia. Larger and controlled studies are needed.

KEYWORDS

fear of hypoglycemia; problem solving; cognitive behavioral therapy; psychology; self-help; diabetes; type 1 diabetes mellitus; high blood glucose

Introduction**Background**

Type 1 diabetes mellitus (T1DM) is a chronic condition caused by deterioration in the ability of the pancreas to produce insulin, leading to insufficient insulin levels [1]. Lifestyle factors have not been found to increase the risk of T1DM, although, for example, diet and exercise are important to keep blood glucose stable when the disease is present [2]. Thus, patient self-care behaviors are necessary to maintain a stable and healthy blood glucose level [2]. People with T1DM are required to monitor their blood glucose levels multiple times per day and to plan and adjust insulin doses based on several factors. These factors include daily activities, food intake, exercise, ongoing infection, stress, and others, requiring well-functioning planning and problem-solving skills [3]. Fear of hypoglycemia is a fear specific to insulin-treated diabetes, which can lead to several unhelpful avoidance behaviors [4]. These behaviors generally include keeping blood glucose levels unhealthily high to try to avoid hypoglycemia, as well as avoiding places or situations viewed as potentially dangerous [5].

Psychological interventions aimed at people with T1DM have usually involved different types of cognitive behavioral therapy (CBT), often aimed at emotional coping and behavioral change [4]. One intervention that has been used for people with T1DM is problem solving, which is a technique that teaches a structured approach to solving practical and emotional problems [6]. Another CBT intervention that has been suggested is exposure, an often used and effective treatment component for anxiety disorders. This technique is used to confront feared stimuli, in order to decrease fear and to decrease avoidance of fearful situations [7]. For T1DM, exposure has mainly been proposed as an intervention for fear of hypoglycemia [4]. Exposure has previously been successfully tried for fear of hypoglycemia in a case study of face-to-face CBT [8]. Further evaluation of exposure has been proposed [4]. Exposure has been used successfully in guided self-help treatments for somatic conditions, including irritable bowel syndrome (IBS) [9], atrial fibrillation [10], and asthma [11].

Exposure may theoretically be a sound approach for people with T1DM who display avoidance behaviors and fear of symptoms, and this approach has been successful for similar chronic conditions. Regardless of the helpfulness of CBT in people with T1DM, access to psychologists with relevant knowledge of the diabetes population is severely limited [12]. Over several years,

great progress has been made with CBT over the internet. Internet-delivered CBT (internet CBT) has some advantages over traditional CBT. Internet CBT requires less time per therapist and patient, and therefore allows more people to be treated. The format also means that the treatment can be available for people living in rural areas. The effects of internet CBT have been evaluated for a large number of conditions, generally with equal effects as traditional CBT [13]. One recent meta-analysis found 25 randomized controlled trials of CBT for diabetes, although only 5 of these were aimed at type 1 diabetes. The analysis suggested that CBT is an effective intervention to improve blood glucose and quality of life. However, none of the approaches had been completely delivered via the internet, and none had exposure as the main intervention [14]. There is some evidence suggesting the effectiveness of CBT for improving blood glucose and mental health in people with T1DM [14]. Therefore, we believe it is valuable to examine if online CBT for T1DM, including exposure, can be feasible, using a case study as the first step.

Objective

The objective was to develop a manualized CBT treatment delivered online. In this study, we tested a treatment in the very early stage. The participants' course of treatment was explored to get an early indication of what might and might not be practical in this type of treatment. To illustrate this, we describe 2 cases involving 2 participants with T1DM, who completed online guided self-help CBT. The illustrative cases will be used to revise and further adapt the treatment protocol adopted.

Methods**Participants**

The details of the below 2 cases have been altered to protect the anonymity of the participants while keeping the functional similarity of the participants' behavioral analysis and the characteristics of the treatment. The participants were recruited via advertisements on social media. They had to have a self-reported T1DM diagnosis, be unsatisfied with their blood glucose, or report other psychological or behavioral problems connected to their diabetes. In telephone interviews, the participants were asked about their diabetes history. The participants were asked about problematic areas with diabetes self-care and life in general. In particular, the participants were asked about specific emotional and behavioral reactions to problematic situations. The interviews were not recorded. See [Table 1](#) for the timeline of the intervention.

Table 1. Timeline of the intervention.

Participant	Assessment	Treatment start	Treatment end
Participant 1 (Mr A)	January 25, 2018	March 06, 2018	April 27, 2018
Participant 2 (Ms B)	April 18, 2018	May 01, 2018	June 23, 2018

Case 1

Mr A was a man in his 40s with a university education. He had self-reported lifestyle problems and an increasing worry about complications. Mr A had found it difficult to engage in physical activity, which he knew was important to his health. He reported that he was very preoccupied with work and that it was challenging to fit physical activity into his schedule. He also found that he ate too much, reporting feelings of hunger even after he had eaten portions of adequate size according to the recommendations of his dietician. Mr A was already experiencing a number of diabetes-related complications (some mild and transient, and others moderately serious and permanent). He reported that he was often preoccupied with worry that the complications would deteriorate and that he would develop additional complications. He reported that it was problematic and a burden to plan the day with consideration of the disease, as well as find time and practical opportunity for self-care activities within daily life. Perfectionistic tendencies were another area that could cause problems, leading to unhelpful thoughts that if Mr A was not able to manage his diabetes perfectly, he might as well give in completely. This could lead to hopelessness and engaging in problematic behaviors, such as eating unhealthy food, reasoning that it did not matter anyway. Worry distracted him from engaging in more enjoyable activities, and could lead to a feeling of helplessness, as well as frustration and anger with the disease, or feeling overwhelmed.

Mr A reported that he had a general idea that he needed to change his behaviors and habits to improve his well-being. However, he had difficulties knowing precisely where to begin, and felt that he needed a structured way forward to fit self-care behaviors into his busy life. Previous approaches to behavioral change had also been hindered by unhelpful thoughts, worry, and perfectionism. We believed that problem solving and exposure would be helpful interventions for Mr A, as this would help him to structure what he already had in mind and help him go against unhelpful emotions to engage in behaviors he felt he needed.

Case 2

Ms B was a woman in her 30s with a university education. She reported high blood glucose levels and fear of hypoglycemia throughout several years. Her fears included worrying about losing consciousness or feeling humiliated in public, losing control, not having anyone there to help her, making serious mistakes, and becoming aggressive toward other people. A particular fear was to experience hypoglycemia during the night, which Ms B felt was a very frightening experience, sharing many characteristics of a panic attack. Furthermore, she reported that she had neglected her medical self-care to some degree when newly diagnosed in her early teens, acting as the disease would simply go away, although she knew that was not a realistic judgement. Stress was a reported problem area, which was accompanied by higher blood glucose. Ms B reported that her blood glucose level was less stable and that she did not find the time for proper self-care when under stress. This could lead to stressful thoughts about her diabetes, increasing stress in a vicious circle. A particularly unhelpful behavior was to eat to

keep the blood glucose level high, in order to avoid hypoglycemic episodes during the night. This behavior would ease the fear and anxiety in the short term. In the long run, however, this led to hyperglycemia, with its unpleasant symptoms, such as thirst and fatigue. Likewise, Ms B preferred her blood glucose level to be on the higher side in other situations, such as when attending parties and driving. Another problematic area was that Ms B was afraid of diabetic health care itself. She avoided contacting her hospital diabetes unit as much as possible and reported aversive events where she had been educated in great detail about possible complications. Although the physician had all the best intentions, Ms B reacted with fear. Further mentions of complications made her anxious, and she wished to avoid the subject altogether. Ms B had been in contact with a psychologist about her diabetes before, but she was not satisfied with the intervention, reporting that they mainly talked in general, and that she was told to practice positive thinking, rather than behavioral interventions aimed at specific targets.

Ms B reported that her situation was beginning to be difficult to handle and felt overwhelmed by her fears. Our behavioral analysis showed that her fear had led to many avoidance and safety behaviors, with a negative impact on her blood glucose and general well-being. We hypothesized that it would be useful to have a particular focus on Ms B's fear of hypoglycemia during the treatment. According to our hypothesis, if her fear of hypoglycemia was improved, it would lead to improvement overall.

Ethical Considerations

The exercises in the treatment were discussed with a consultant endocrinologist and were considered safe. All procedures in the study were in accordance with the ethical standards of the regional ethics committee and with the 1964 Helsinki Declaration and its later amendments or comparable ethical standards. It was approved on January 04, 2018, by the regional authority Etikprövningsnämnden Stockholm (2017/2278-31). An addendum was approved by the same regional authority on February 12, 2018 (2018/300-32). Another addendum was approved on April 30, 2021, by the Swedish national authority Etikprövningsmyndigheten (2021-02263). Participants provided written informed consent for participation and publication.

Measurements

This study relied on self-reported measures. The measures were filled out as online questionnaires, before and after treatment, and every week in some cases.

Blood Glucose

Glycated hemoglobin (HbA_{1c}) is a well-used biomarker for the blood glucose level over several months [2]. Participants reported their latest known HbA_{1c} value and were encouraged to get a new measurement toward the end of treatment. In what way and how often participants measured their blood glucose level as part of their regular self-care was not controlled for in this study.

Problem Areas in Diabetes

The Problem Areas in Diabetes (PAID) Scale [15] is a scale used to assess areas of diabetes a patient may need guidance for from health care, and to screen for “emotional distress” in patient with diabetes. The PAID Scale consists of 20 items on a scale from 0 (“not a problem”) to 4 (“serious problem”). The total score ranges from 0 to 100, and scores over 40 indicate “emotional distress.” According to the authors of the scale, people with a score of 40 or higher require attention from their diabetes team, and the score is expected to drop 10-15 points following medical and educational interventions. The scale has been validated and shown to be acceptable in a diabetes population [15]. This scale was measured weekly.

Fear of Hypoglycemia

The Hypoglycemia Fear Survey (HFS) [16] was developed to measure to what degree a patient with diabetes is afraid of hypoglycemia. This scale explores avoidance behaviors and worry in relation to hypoglycemia. It has 23 items with a range from 0 (“never”) to 5 (“always”). The total score is 0-92, with a mean score of 25 in a clinical sample. This scale was measured weekly.

Anxiety

Generalized Anxiety Disorder-7 (GAD-7) [17] is commonly used to measure anxiety. It consists of 7 items using a scale from 0 (“not at all”) to 3 (“nearly every day”). The total score is 0-21 points. The authors suggest cutoff scores for mild (5), moderate (10), and severe (15) anxiety. The scale has been found to be valid and reliable [17].

Depression

The Patient Health Questionnaire (PHQ-9) [18] consists of 9 items on a scale from 0 (“not at all”) to 3 (“nearly every day”), with a total score of 0-27. The authors suggest a cutoff at 5 (possible depression) and 15 (probable depression). The scale has been found to be valid and reliable [18].

Stress Reactivity

The perceived stress scale [19] consists of 14 items on a scale from 0 (“never”) to 4 (“very often”), with a total score of 0-40. The authors suggest intervals, with 0-13 indicating low stress, 14-26 indicating moderate stress, and 27-40 indicating high perceived stress. The scale has been shown to be valid and reliable [19].

Credibility/Expectancy

Participants’ perception of the credibility of the treatment and their expectation of the final result were assessed with the Credibility/Expectancy Questionnaire (CEQ) [20], using a scale from 1 to 6, with a total score of 0-50. Higher scores suggest better credibility/expectancy. The scale has been found to be valid and reliable. The scale was administered 1 week into treatment.

Treatment Satisfaction

The Client Satisfaction Questionnaire (CSQ) [21] consists of 8 items on a scale from 1 to 4, with a total score of 8-32. The score can be recalculated with a total score from 25 to 100. A higher score suggests a higher satisfaction [21].

Adverse Events

Participants answered questions about whether they had experienced any adverse events, and if so, they were told to elaborate on these experiences. The questionnaire was unpublished.

Subjective Assessment

Participants were asked about subjective blood glucose improvement, using the Subjective Assessment Questionnaire (SAQ), with a 6-point scale ranging from “much declined” to “much improved.” This type of scale is often used for other somatic conditions and has been found to be useful and valid [22].

Therapeutic Intervention

The treatment was delivered entirely via the internet, through a secure treatment platform. Participants received homework each week, answering questions about the psychoeducation and doing exercises in their everyday life. Participants received psychoeducation based on material from a previously evaluated CBT group treatment for T1DM [23] and adapted material from an internet-delivered treatment for IBS [9]. The material from the IBS treatment was general information on worry about symptoms and exposure to avoided stimuli, which was easily adapted for T1DM by changing examples. The participants had access to 5 modules of psychoeducation, each approximately corresponding to 10 written A4 pages. The active treatment consisted of established CBT interventions. The main components used were problem solving and exposure. There were also some cognitive interventions, namely information about thinking traps and basic cognitive restructuring, and additional interventions such as assertiveness training and life values. The participants read the same material and tried all interventions. After about half of the treatment, a main focus was chosen according to their specific problem in a discussion with the therapist.

Therapist and Supervisor

The therapist (DK) was a master’s student at the time of the study and was trained in CBT. His supervisor for the master’s thesis (BL) also acted as a therapy supervisor. The supervisor is a professor of psychology and a licensed psychologist specialized in CBT. The therapist could be reached through text messages in the online platform at any time throughout the treatment. The role of the therapist was to provide guidance and support, provide feedback, and answer questions. The therapist also gave access to the next module after the previous one was completed. Study participants were notified by an automatic text message each time the therapist had made contact via the online platform. If participants were inactive, they were encouraged to continue their assignments via text messages or phone calls.

CBT Model

We mainly used a general cognitive-behavioral model, where we assumed that thoughts, emotions, and behaviors interact and influence each other, which was largely influenced by an exposure-based CBT program for IBS [9]. See Figures 1 and 2 for an overview. This model also assumes that these influence

blood glucose levels directly via behaviors or indirectly via thoughts and emotions that influence behaviors. In some cases, emotions, such as stress, may influence general mood, which may directly influence blood glucose, as suggested by a CBT group treatment for T1DM [4]. Increased awareness may lead to symptom preoccupation, making a person more observant of potential symptoms [9]. We worked from an exposure-based paradigm, where we assumed that humans avoid unwanted experiences that may be aversive short term, but still are important and helpful [9]. Exposing oneself to aversive stimuli or situations decreases anxiety over time, most likely due to extinction of fear [7]. It is possible that symptoms of anxiety can overlap with symptoms of low blood glucose, thus

conflating the two [4]. Exposing oneself to feared situations in the presence of anxiety symptoms should, according to this model, decrease fear of hypoglycemic symptoms, and decrease avoidance of feared situations or situations where low blood glucose levels would be unwanted.

The intervention also contained a few approaches that were not necessarily based on this model but did not contradict it, including cognitive restructuring, assertiveness communication skills, and life values. These were components from the previously evaluated CBT group treatment on which this intervention was partially based [4]. These were kept in addition to the main exposure-based model, in order to explore if these could be useful complementary interventions.

Figure 1. General cognitive behavioral therapy model. Adapted from T Anderbro and Susanne Amsberg (unpublished data, 2004) and B Ljótsson and E Hedman-Lagerlöf (unpublished data, 2012).

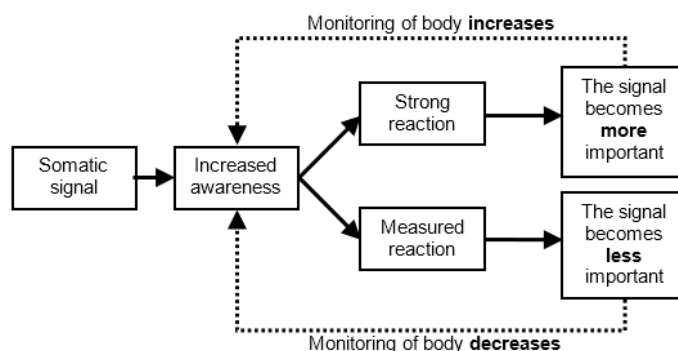

Figure 2. Suggested exposure model for fear of hypoglycemia. Adapted from B Ljótsson and E Hedman-Lagerlöf (unpublished data, 2012).

Content of Treatment Modules

Module 1

The module began with practicalities followed by general education on T1DM. The module also introduced the CBT model and education of general CBT principles. Participants were taught about our proposed interaction of thoughts, emotions, and behaviors. This, in turn, would influence self-care and blood glucose levels. Participants were introduced to the concept of functional behavioral analysis and learned how to identify what prevented them from behaving in accordance with their goals.

Module 2

The module continued the psychoeducation with a focus on stress and negative emotions. The intervention *problem solving* was introduced and presented mainly as an aid for self-care. This was presented as being particularly useful during periods of stress or negative mood, as sometimes self-care behaviors decrease in priority. The potential impacts of negative thoughts, as well as how to identify them were also taught. The participants identified any negative thoughts on their own and discussed how these might interfere with their everyday life, with a focus on diabetes.

Module 3

The module contained psychoeducation about anxiety and worry, and the roles these play in unhelpful behaviors. The participants were educated about the concept of exposure to aversive stimuli, and were provided further information on how to facilitate behavioral change. This module also introduced life values, often used in acceptance and commitment therapy [24], as an additional intervention. The participants considered the various areas in their own life where diabetes could have interfered. The participants were also encouraged to plan and work toward better integrating diabetes self-care into the life they wished to lead. As an additional skill, the participants were taught about assertiveness training.

Module 4

The module was mainly dedicated to exposure exercises. These were based on the problematic behaviors and situations participants had analyzed earlier in treatment. With the help of their therapist, the participants constructed an exposure hierarchy

and used that to plan exposure exercises. If exposure to aversive stimuli was not appropriate, the participant would continue to work with behavioral change, for instance, with the help of problem solving and other helpful skills previously taught.

Modules 5-7

There was no additional information at this point in treatment. The participants continued to practice and were guided by their therapist as earlier. If a participant had a slower pace than 1 module per week, this could be a time to catch up.

Module 8

In the final module, the participants constructed a maintenance plan, based on the skills they used the most.

Results

Overview

The overall results in the 2 cases are presented in [Table 2](#).

Table 2. Results in the 2 cases.

Variable	Participant 1 (Mr A)		Participant 2 (Ms B)	
	Pretreatment	Posttreatment	Pretreatment	Posttreatment

^kCSQ: Client Satisfaction Questionnaire.

Case 1

Problem solving was the primary intervention for Mr A. He was able to try out solutions to numerous problems. For example, he managed to fit squash into his schedule, and had a goal to play once a week with his friends and to walk 8000-12,000 steps per day, in order to get an adequate amount of daily exercise. He made a rule to only take one portion of

food for each meal, and he found it effective to go against his worry to do these physical activities, even though they reminded him of his complications. This could possibly be considered a form of exposure to aversive stimuli. Before treatment, Mr A had a score of 50 in the problem areas on the diabetes scale. After treatment, the score had dropped to 28, meaning a decrease of 22 points. Answering a postmeasurement question, Mr A stated that his blood glucose greatly improved. Another

improvement was clinically significantly decreased stress according to the perceived stress scale, with a score of 32 before treatment and 16 after treatment. Fear of hypoglycemia did not seem to be a problematic area for this participant, beginning with a low grade of 8 points compared to an average of 25 in a clinical sample [4]. The value increased somewhat to about 20 through the course of treatment, but gradually decreased again to a score of 7 after treatment. Mr A reported 75 out of 100 points in the CSQ, indicating a high satisfaction with treatment. He stated that he was very satisfied with the treatment overall. Mr A also gave feedback on the psychoeducation material, feeling that the material was too long, and he wished for it to be more concise and to the point.

After treatment, Mr A reported his long-term blood glucose levels to us, which showed a decrease in HbA_{1c} from 60 to 50 mmol/mol, which is not only a clinically significant change in the desired direction, but also within the general goal value of <52 mmol/mol in Swedish diabetes care [25]. Mr A reported that it was the best HbA_{1c} value in his clinical history and that he attributed this to the treatment. It is important to remember that a decrease in HbA_{1c} does not necessarily equal a healthier lifestyle but could be a misleading finding because of repeated hypoglycemic episodes. This was not the case for this participant, however, as neither increased frequency of hypoglycemia nor any other adverse events were reported upon questioning. There were still some hyperglycemic episodes, meaning that there was room for continued decrease in hyperglycemia, but the blood glucose levels were quite satisfactory overall, according to the Swedish guidelines.

Overall, considering Mr A's satisfaction with the treatment, the decreased problematic areas associated with his diabetes condition, and the decreased blood glucose levels, the treatment appeared to be successful.

Case 2

Ms B's treatment consisted mainly of exposure exercises aimed at her fear of hypoglycemia and associated avoidance behaviors. Another important area covered was her fear of visiting the diabetes hospital unit, which could be considered exposure to the emotion of shame, as hospital visits reminded her of her perceived failures as a patient with diabetes. She gradually approached health care, attending a lecture at her diabetes clinic about complications and their prevention. She reported that this increased her anxiety severely, but she was able to stay in the situation until it reduced. As a result of this, Ms B reported that she was able to form a better relationship with her diabetes care staff, which could prove beneficial to her future health. Another important area was the safety behavior of eating extra food before bedtime to decrease the risk of night-time hypoglycemia. Ms B gradually decreased the amount she ate and was eventually able to overcome this safety behavior, with potentially significant results for her overall blood glucose levels. Initially, she reported increased anxiety and difficulty falling asleep. She also reported waking in the middle of the night, feeling anxious, and checking her blood glucose levels. After less than a week, however, she reported that her anxiety started to subside and that she was able to sleep uninterrupted again. Eventually, she

was able to stop the safety behavior of excessive eating before bedtime.

Ms B reported a significant decrease in diabetes-specific problems, with a decrease from 92 to 53 on the PAID Scale. This is still a high number, but the decrease was much greater than the expected decrease after education only, according to the authors of the scale. Relevant to her main problems, Ms B reported a significantly lower fear of hypoglycemia of 40 points on the hypoglycemia fear scale compared with 64 points before treatment, which was a clinically significant decrease, and she rated her blood glucose levels as somewhat improved. Ms B reported a score of 100 out of 100 points on the client satisfaction scale, indicating excellent treatment satisfaction. Unfortunately, we did not know if the treatment had any effects on Ms B's blood glucose or HbA_{1c} levels, as she did not report a posttreatment HbA_{1c} value. Nevertheless, we consider the treatment successful because the treatment was able to target her fear of hypoglycemia using exposure to feared stimuli. It should be noted that her depression rating increased after the treatment, as measured by the patient health questionnaire. When asked, she did not think that this was a negative effect of the intervention but attributed her decreased mood to external factors.

Adverse Events

No adverse events or other unexpected events were reported in either of the cases.

Discussion

Summary

In this case study, the online guided self-help CBT treatment of 2 participants has been described. The aim was to test an early version of this treatment, in order to revise and improve the protocol. The 2 participants were treated using the same treatment manual, and they read every module and tried all interventions. However, they both had a personalized focus. In case 1, the participant Mr A chose to focus on problem solving in the later part of the treatment. After treatment, he showed improved blood glucose and other relevant improvements. In case 2, the participant Ms B. chose to focus on exposure in the later part of treatment. She showed a significant decrease in her fear of hypoglycemia and other relevant improvements.

Principal Findings

In the 2 cases, participants had favorable outcomes on their most relevant measurements. The participants completed all modules and were highly satisfied with their treatment. Mr A felt mainly helped by problem solving, which is logical, as this intervention was most suitable to help him accomplish the lifestyle changes desired. Conversely, Mr A found it difficult and redundant to construct exposure exercises, as he did not consider himself to be driven by fear or anxiety. Instead, he preferred to focus on structured problem solving. We believe, however, that there were some elements of exposure to other avoided emotions involved, such as worry and discomfort. Ms B focused on exposure for her fear of hypoglycemia, which was much improved, as well as her general problem areas in diabetes.

Limitations

The results from this case study must be carefully considered as there are limitations. This is a report on only 2 cases, and the participants may have had personal characteristics and environmental factors that could explain their improvements. Furthermore, we were not able to control for attention. We do not know if their improvements are due to the treatment or the fact that someone kept a watchful eye on them. In fact, Mr A stated that he partially attributed attention from the therapist as a factor for his improvement. Finally, we did not receive a report on Ms B's blood glucose level. This is significant missing data, which we have no easy way of retrieving.

Comparison With Prior Work

To our knowledge, this is the first study that tentatively explored an online CBT intervention with an exposure model for T1DM. The outcomes are consistent with those in earlier studies on CBT and T1DM, as CBT has been shown to improve blood glucose and mental health [4,12]. The experiences of these participants indicate that a CBT treatment with multiple interventions may be useful. For example, an entirely exposure-focused treatment would have been less relevant for Mr A. The results of Ms B are in line with the findings in few

previous studies that have evaluated exposure to aversive stimuli as an intervention for fear of hypoglycemia [4,8].

Conclusions

These cases provide some insights on how an online-delivered T1DM CBT program could look, and preliminarily suggest that the use of both problem solving and exposure could be useful in CBT for T1DM. In accordance with the feedback of Mr A, the treatment can be further adapted to decrease the amount of text and introduce learning exercises through examples. These changes may improve the treatment and make the information focused and relatable. Looking forward, we suggest a feasibility study with a larger group of participants, to examine the safety, acceptability, and approach of the intervention, as well as its preliminary effects.

Patient Perspective

Mr A was very satisfied with his experience overall and felt that his condition was much improved. As mentioned, he had some critique of the education material provided, but felt that the contact with the therapist made up for it. Ms B was very satisfied and felt that her condition was much improved. She especially appreciated the applied and concrete nature of CBT.

Acknowledgments

We would like to thank Susanne Amsberg, PhD and Therese Anderbro, PhD for allowing us access to their cognitive behavioral therapy-based group treatment manual for type 1 diabetes mellitus, which served as valuable inspiration for the construction of the online intervention. We also would like to thank Eva Toft, MD, PhD for excellent medical expertise.

Authors' Contributions

DK: study design, drafting of the manuscript, and analysis; BL: study design and contributions to the manuscript; MB: contributions to the design of the treatment manual and contributions to the manuscript; NL: contributions to the manuscript; MK: contributions to the manuscript.

Conflicts of Interest

BL owns shares in DahliaQomit, which specializes in online services for symptom assessment outside the submitted work, and licenses a cognitive behavioral treatment manual for irritable bowel syndrome, with royalties paid from Pear Therapeutics. The other authors have no conflicts of interest to declare.

Abstract

Background: With the aging population, family caregivers provide increasingly complex and intense care for older adults and persons with disabilities. There is growing interest in developing community-based services to support family caregivers. Caregiving occurs around the clock, and caregivers face challenges in accessing community-based services at convenient times owing to the demands of care. Web-based resources hold promise for accessible real-time support. CareNav (TM), a caregiver resource information system, is a web-based platform designed to support real-time universal caregiver assessment, a record of client encounters, development of a care plan, tailored information and resource content, access to web-based caregiver resources, the capacity to track service authorization and contracts, and secure communications. The assessment includes needs and health conditions of both the care recipient and caregiver; current resources; and priorities for support, information, and referral. In 2019, the California Department of Health Care Services funded the 11 nonprofit California Caregiver Resource Centers (CRCs) to expand and improve family caregiver services and enhance CRC information technology services. Deployment of a statewide information system offered a unique opportunity to examine structures and processes facilitating implementation, providing feedback to the sites as well as lessons learned for similar projects in the future.

Objective: The aim of this paper was to describe the statewide implementation of the comprehensive CareNav system using the Consolidated Framework for Implementation Research as an organizing structure for synthesizing the evaluation.

Methods: This mixed methods study used two major approaches to evaluate the implementation process: a survey of all staff who completed training (n=82) and in-depth qualitative interviews with 11 CRC teams and 3 key informants (n=35). We initially analyzed interview transcripts using qualitative descriptive methods and then identified subthemes and relationships among ideas, mapping the findings to the Consolidated Framework for Implementation Research.

Results: We present findings on the outer setting, inner setting, characteristics of the intervention, characteristics of the staff, and the implementation process. The critical elements for success were leadership, communication, harmonization of processes across sites, and motivation to serve clients in more accessible and convenient ways.

Conclusions: These findings have implications for technology deployment in diverse community-based agencies that aspire to enhance web-based services.

Introduction

Background

In the United States, approximately 20% of adults provide unpaid care to a family member or friend [1]. Family caregivers provide the vast majority of long-term care (valued at US \$470 billion annually), eclipsing annual governmental spending on long-term care at US \$430 billion [2]. Caregiving is often a commitment spanning years and a variety of domains including personal assistance, instrumental aid and emotional support, care coordination, and managing chronic health conditions. With shortened hospital stays, family caregivers now perform complex health care including medical or nursing tasks previously within the purview of health care professionals [3]. Despite the common experience of caregiving, few individuals are prepared for the demands of the role [4]. Many people experience strain, depression, loneliness, deterioration in their own health, and financial distress in the course of providing care [1]. Even so, most are unaware of the existing resources to support them.

Despite their vital role in optimizing function and health for older adults, caregivers are relatively invisible in health care. Caregivers provide valuable information about the person receiving care, yet rarely do health care professionals assess the capacity, readiness, or mental health of caregivers to provide care during routine health encounters [3,5].

Web-Based Supports for Caregivers

In the absence of routine caregiver assessment and support in the clinical setting, there has been growing interest in developing community-based services to support family caregivers. Caregiving occurs around the clock, and caregivers face challenges in accessing community-based services at convenient times owing to the demands of care. Web-based resources hold promise for accessible real-time support, and targeted interventions have been developed for specific audiences such as caregivers for persons with cancer [6], dementia [7-10], and other chronic conditions [11-13].

Most web-based supports emphasize one element such as psychoeducational offerings or stress management. Despite quality issues with many studies, the positive outcomes of targeted interventions have included improved self-efficacy, improved self-esteem, and less strain [14]. Missing from existing web-based interventions are a global assessment of the needs of the caregiver and care recipient and the ability to respond to the priority of the caregiver at the time, whether it is for information, referral to specific local services, or counseling.

Studies on web-based caregiver support have demonstrated 3 tendencies. First, caregivers of persons with dementia are overrepresented because of the demanding nature of caregiving related to issues with memory, thinking, and behavior. Many studies on web-based support for dementia caregivers, such as iSupport [10], focus on psychoeducational interventions that help caregivers cope with stress, anxiety, caregiving burden, quality of life, awareness of stressors and needs, and caregiving competence. Overall, studies of such psychoeducational interventions have reported improvements in the well-being

and preparedness of caregivers [15-17]. However, the effect size is medium-small even in randomized controlled trials and quasi-experimental studies [15]. Significant variations in content, structure, outcome measures, and intervention duration further prevent cogent conclusions within web-based support studies for caregivers [18].

Second, the heterogeneity of web-based support types underlies varying results. Studies on web-based support for those caring for persons with cancer [19], posttraumatic stress disorder [20], and psychosis [21,22] offer findings that reflect varied web-based support needs for different caregivers. Disease type, intervention type, dosage (amount of time spent on the web), and duration affect the effectiveness, feasibility, and quality of interventions [23]. The navigation and intuitiveness of web-based sessions may depend on the distinct needs of caregiver subgroups [22].

Third, the breadth and scope of caregiver support in the web-based modality affords subgroup-specific knowledge rather than exhaustive knowledge on implementation strengths and challenges. For example, in an implementation study of a video health technology intervention to improve self-care of caregivers of persons with heart failure, Hirschman et al [24] found adaptation challenges related to hardware, software, and network connectivity. In a behavioral intervention for dementia caregivers that had significant improvements for caregivers, Nichols et al [16] discerned as important the clinical success, leadership and staff support, and ongoing need for modifications while maintaining fidelity, linkage to the organizational context, and fiscal health. In mapping directions for research, Lindeman et al [25] underscored, among others, matters of equity, inclusion, and access; privacy and security; and the influence of political and regulatory factors on interoperability. To date, research has not examined broad-based web-based resources that include caregivers involved across different health conditions and provide a full array of supports, from information and referral to individual and group support, to legal and respite service provision. The aim of this paper was to describe the statewide implementation of the comprehensive CareNav (TM) system using the Consolidated Framework for Implementation Research (CFIR) as an organizing structure for synthesizing the evaluation.

Supporting Caregivers in California

CareNav, a caregiver resource information system, is a web-based platform designed to support interactive universal caregiver assessment, a record of client encounters, development of a care plan, tailored information and resource content, access to web-based caregiver resources, capacity to track service authorization and contracts, and secure communications. The assessment includes both care recipient and caregiver needs and health conditions; current resources; and priorities for support, information, and referral. The assessment can be self-administered on the web or administered by a staff member over the phone or in-person. After assessment, a staff consultant meets with the caregiver to prioritize and develop a care plan that might include contracting services such as respite, referral to educational offerings or a support group, or vouchers for legal aid or counseling.

The Family Caregiver Alliance (FCA), one of the 11 California Caregiver Resource Centers (CRCs; California State System of Support for Caregivers), pioneered CareNav with private funding and deployed this system across 3 CRCs that served as pilot sites. In 2019, the California Department of Health Care Services funded 11 nonprofit CRCs to expand and improve family caregiver services and enhance CRC information technology services, deploying CareNav as a common data set across the state over a 3-year period (2019-2022).

The FCA led the implementation team for CareNav in partnership with the technology developer Quality Process (QP). The FCA contracted with the University of California Davis Family Caregiving Institute to conduct an evaluation of the implementation process as well as an analysis of the statewide data to determine program effectiveness and quality improvement opportunities. The implementation began in January 2020, and the system was fully deployed by September 2020.

Organizing Framework

Implementation evaluation was guided by the health-focused CFIR [26]). The CFIR includes five domains that organize our

mapping of the results (Figure 1): the outer setting, the inner setting, the intervention characteristics, staff characteristics, and the process of implementation. The outer setting includes the social and economic context within which the statewide CRC system resides, particularly considering relationships with outside organizations, client needs, and the effects of the COVID-19 pandemic. The inner setting refers to the levels and characteristics of the organization, in this case the CRC statewide system, focusing on structural characteristics, culture, the implementation climate, networks and communications, and readiness for implementation. The intervention characteristics acknowledge the perception of the stakeholders about the key attributes of CareNav including relative advantage, adaptability, complexity, and cost. The characteristics of individuals recognize staff knowledge and attitudes toward CareNav as well as beliefs about the capabilities required for the implementation and stage of change. The implementation process considers 4 major aspects: planning, engaging, executing, and reflecting and evaluating [26].

Figure 1. The Consolidated Framework for Implementation Research model for CareNav implementation. CRC: Caregiver Resource Center; DHCS: Department of Health Care Services.

Methods

Design Overview

This mixed methods study used two major approaches to evaluate the implementation process: in-depth interviews with key informants at the CRCs, and surveys of all staff who completed training. The in-depth interviews explored all aspects of the implementation process from multiple perspectives, while the surveys were used to characterize the readiness and

self-efficacy of the staff implementing the system. This approach will enable the evaluation team to assess readiness and satisfaction over time using quantitative scores while developing a deeper understanding of the dynamics of change and appreciation of multiple perspectives afforded by qualitative interviews.

Qualitative Interviews

The evaluation team conducted focus group interviews with teams of each CRC, and individual interviews with key

informants from the implementation team. All current leaders and staff of the 11 CRCs were eligible to participate in this study. A focus group was established for each CRC to include all interested staff from the same site. The interviews elicited perspectives on implementation and training activities, including perceptions of benefits and concerns regarding CareNav. We used a semistructured interview guide for both focus groups and individual interviews asking about the implementation process, challenges and facilitators, anticipated system and client outcomes, and satisfaction with the process. Owing to the widespread implications of the COVID-19 pandemic on service delivery, we asked all participants about how the COVID-19 pandemic affected both the implementation process and experiences of their clients as caregivers. Interviews were conducted using Zoom, and audio was recorded with the consent of the participants and transcribed.

Pretraining and Posttraining Surveys

The evaluation team designed a pretraining and posttraining readiness survey to determine readiness, preparation, and confidence regarding the implementation process and to identify self-efficacy and perceived benefits and concerns before and after training. We invited all staff to complete surveys before and immediately after a full day of formal training on CareNav.

The pretraining readiness survey included 10 items rated on a 5-point scale, where 1 represents the most positive response. Cronbach α for the current sample was .83. The survey also assessed whether the participants are familiar with CareNav, know its purpose, and how to do an intake and assessment. Open-ended questions identified benefits and concerns about CareNav.

The posttraining survey reassessed participants' knowledge, preparedness for implementation, confidence, and knowing where to get help with CareNav. The posttraining survey also assessed whether the training met participants' needs and their willingness to take actions that could support CareNav implementation, such as encouraging staff or coworkers to use CareNav and ensuring new staff members are educated on how to use CareNav.

Data Analysis

The transcribed interviews were imported into the Dedoose qualitative data analysis software. Qualitative descriptive methods were used to analyze the transcripts and open-ended responses to the surveys [27,28]. Two members of the research team (HMY and TRK) reviewed the transcripts and developed initial codes and definitions. They independently coded the same transcript and then compared coding decisions, refined definitions, and arrived at a consensus about coding and documenting changes to the definitions. All the transcripts were subsequently coded into agreed-upon general categories. A second analysis (by HMY and OT) identified the subthemes and relationships among ideas, mapping the findings to the CFIR.

Quantitative data were analyzed using descriptive statistics. To enable meaningful interpretation and visualization, the 10-item readiness scale was recoded to a 5-point scale in which a higher score represents better readiness. Pretraining and posttraining scores were compared using paired 2-tailed *t* tests for continuous variables and McNemar tests for dichotomous variables. Quantitative analyses were performed using the SPSS statistical package (version 27; IBM Corporation).

Ethical Considerations

This study was determined to be exempt from ethics approval by the UC Davis institutional review board. We collected no identifying information about the participants in the survey and focus groups. Participants were informed about the purpose of the study and the voluntary nature of participation, providing assent by completing the survey or continuing with the recorded Zoom interview.

Results

Participants

Pretraining and Posttraining Readiness Surveys

In total, 86 staff members completed training, with 82 (95%) participants contributing pretraining data and 56 (65%) participants contributing posttraining data. The staff included CRC directors, family consultants who interact with caregiver clients and provide resources and support, and analysts who manage client and financial data. The surveys were anonymous, with no identifying data of the staff members. The results of readiness and self-efficacy are presented in subsequent sections within the CFIR model as characteristics of the staff.

Qualitative Interviews

Between May and August 2020, we conducted 11 focus group interviews (ranging in size from 2 to 6 participants) and 5 focused individual interviews with key informants, totaling 35 participants. Participants represented all 11 sites and the implementation team and included all roles (directors, clinical, and technical staff). To protect the privacy of the participants, we did not collect demographic data associated with these interviews.

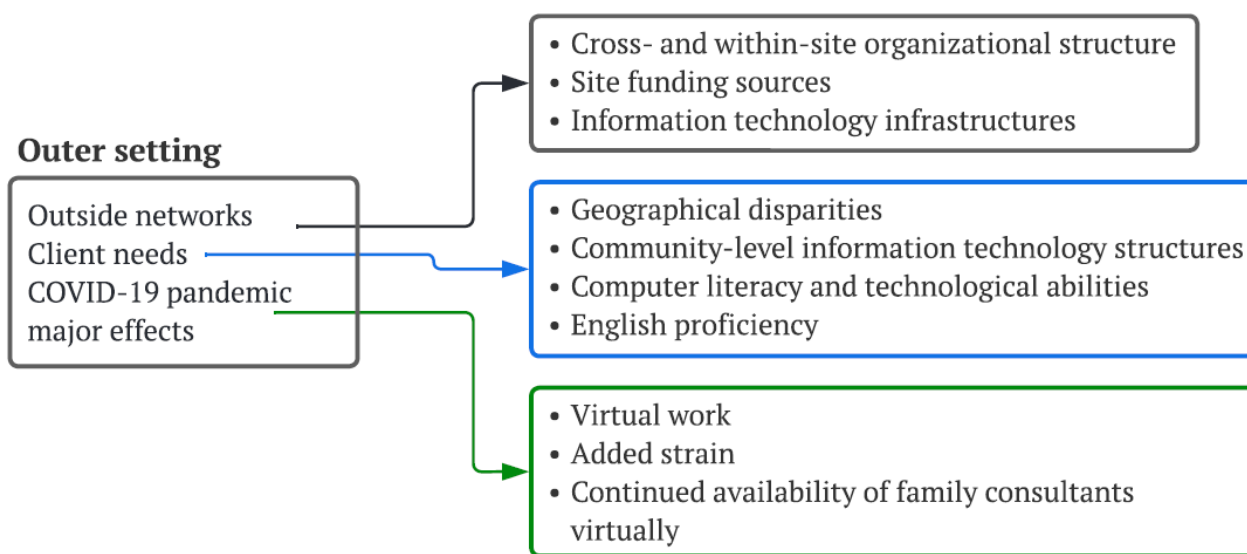

Evaluation of Implementation

We mapped the findings of this evaluation to the following CFIR domains: outer setting, inner setting, characteristics of the intervention, staff characteristics, and implementation process. The specific findings related to these domains have been expanded upon in the subsequent sections.

Outer Setting

Interviews across CRC sites revealed site-level variability and heterogeneity in relationships and networking with external organizations as well as the diversity of client characteristics and needs (Figure 2). Implementation occurred during the COVID-19 pandemic, shaping additional contextual factors.

Figure 2. Outer setting.

Outside Network

Some CRCs exist as standalone organizations. More complex sites are embedded or hosted in larger health care systems with their own information technology platforms, which requires additional efforts to integrate CareNav and to be compliant with additional health system privacy and security policies. Moreover, the funding sources and constellations of services vary between sites and influence both documentation and administrative requirements. This challenged the transition from the existing local databases to the CareNav platform. For example:

Because it's a hospital it has security really well locked down. And so, the website that I need to access to see if the data is correct in their initial upload in our system is blocked. So, I'm working within my own organization to try to get that website unblocked.

Client Needs

Geographic disparities are reflected in rural sites serving communities that lack the adequate technology structures and broadband connection necessary for reliable access to an internet platform. Clients are also diverse in their English proficiency and their capacity to use technology. Several participants mentioned low computer literacy and lack of technological and internet safety skills as barriers for older caregivers to use technology. Nonetheless, some of the staff reported being surprised by the amount of participation by clients whom they assumed would not ordinarily use technology. This observation was partially attributed to the consequences of the COVID-19 pandemic:

But I think a lot of them are open to technology. I think this pandemic has forced that issue where a lot of family caregivers are using more technology now...And I'm surprised as to the ones that I thought wouldn't know how to use technology. The ones that before COVID there were a lot that I never, never thought that they could do it as a video with me. I never thought that because I just, you generalize

people...because of age...a lot of them are facetimeing family, they are video conferencing with their family care navigator...so we just have to start thinking differently as far as how we get them used to CareNav.

COVID-19 Pandemic: Major Effects

The COVID-19 pandemic, which emerged simultaneously with the implementation kickoff, amplified the existing risks and threats to the well-being of caregivers. Family consultants reported higher levels of stress, more financial concerns, increased housing and food insecurity, job loss, and escalating costs of caregiving supplies (such as gloves and masks) among their clients. The strain was exacerbated by loss of support resources, including availability of adult day care, home help, in-person support groups, and a reluctance to consider assisted living or skilled nursing alternatives at this time as residential care facilities were widely reporting COVID-19 outbreaks and, in some cases, higher mortality rates for older persons. Many caregivers faced additional home demands, caring for multiple family members and children being schooled at home. The pandemic increased their sense of isolation, with family consultants reporting more symptoms of depression and anxiety among their clients. Finally, caregiver health was further compromised by the inability to quarantine when a family member was ill, thus increasing the exposure of the caregiver. Caregivers also expressed reluctance to access formal services owing to fear of contagion or not having the time to devote to their own health:

We've seen kind of that increased risk, I think, across the board because a lot of our support systems are not available right now. [...] I think what most impacts caregivers, or can impact their health overall and wellbeing, is what level of support they have available to them.

The pandemic created a particularly challenging climate for the implementation of a new major system. Additional strain was placed on staff members who were already facing a learning

curve to execute the new system, as well as dramatic changes in their workflow. Simultaneously, it accelerated the need for a web-based platform and rapidly demonstrated the usefulness and feasibility of the web-based environment (eg, continued availability of family consultants virtually). Interview participants highlighted how the pandemic demonstrated the benefits of CareNav:

I think the Coronavirus kind of shows how helpful it is to have everything online. There really hasn't been

too much of a disruption to the services we're able to provide our caregivers. I think that's been a huge plus to be able to see how nicely it can transition when things do happen, that we're still able to access what we need.

Inner Setting

The inner setting for CareNav implementation is the state-level CRC system and 11 individual CRCs (Figure 3).

Figure 3. Inner setting.

Structural Characteristics

California launched a CRC system in 1984 with the enactment of the Comprehensive Act for Families and Caregivers of Brain-Impaired Adults, thereby establishing a network of support for caregivers. At present, the California Department of Health Care Services (DHCS) funds 11 CRCs that provide support to family caregivers affected by chronic health conditions, including Alzheimer disease and related dementias and other degenerative diseases.

CRCs serve as a point of entry for services available to caregiving families, covering every county in California. While each center tailors its services to its geographic area, all CRCs have a core component of programs that provide uniform caregiver assessment and information, education, and support for caregivers. Individual CRCs also receive funds from county contracts, foundations, business partners, and donations to provide additional services. For over three decades, CRCs have supported caregivers in their regions, relying on staff intake interviews with caregivers and tailored referrals to relevant resources. With fluctuating funding, the programs became decentralized, and over the past decade, the 11 CRCs had been operating relatively independently. Funding to implement the statewide web-based platform provided an opportunity for new collaborations and connections.

Culture

CRCs provide services across income categories, and the original enabling legislation included middle-income families who are often overlooked and for whom few services are targeted. CRCs are united by shared values emphasizing choice,

collaboration, innovation, quality, participation, respect, and diversity.

The implementation prompted culture change in three major ways: formalizing the system of CRCs across the state by uniting loosely affiliated sites, instituting standardized assessments, and changing to a new way of delivering services to clients virtually. The funding and subsequent process fostered a shared goal among CRC directors to serve the entire state and collaborate with one another to do so. Committing to a shared technology platform involved greater discussion and information exchange among the groups as well as the recognition that the whole is greater than the sum of the parts. A welcome culture change was the comradery and mutual aid that solidified over the initial year of implementation:

I feel like just within the CRC system the genuine enthusiasm for the project. Just to embrace it, even with all this other kind of craziness [COVID-19 pandemic] going on in the world.

Implementation Climate

In-depth interviews revealed a collective positive attitude with a willingness to change, staff dedication, continued learning, and patience to follow through the stages and steps of the process. All interview participants expressed enthusiasm for the adoption of CareNav and a belief in the positive potential of this change in their practices:

I think it's been well received. We've been anticipating this for a long time. And have been very excited about it... We have some folks that were really excited and got right in there and started playing with it and

working with it. Others I think are a little bit, you know, we're learning as we go.

Participants expressed hesitation about changing to a technology platform but recognized that caregivers' needs are changing in society and that the systems must evolve to meet the changing needs.

The idea is to be innovative and for caregivers, because, as things continue our younger population is very used to being more self-directed and being online. So, it has potential for growth and change over time. We'll continue to do that with a lot of streamlining of systems.

Networks and Communication

Communication was vital at all levels, from the implementation team to the sites, from the directors to their staff, and among sites. Communication involved developing a shared vision for the process and the outcomes, as well as coordinating the logistical aspects of the implementation. The process of preparing for technology deployment revealed workflow and processes that were not initially evident or taken for granted, and these had to be addressed as technology was applied to automate processes. Communication among the teams was vital to understanding work processes and establishing new ways of operating as needed.

Communication and support from FCA and among CRC sites played a major role in successful implementation, particularly as sites faced delays or barriers and were able to benefit from lessons learned elsewhere:

Something that's new is now we are communicating and reaching out to the other CRCs, which I believe hasn't happened in years. So it's really great that if we have a question or wondering, a different way of

doing something in our program, I can just reach out and to anyone you know, in California and get their help and opinion.

Both the implementation process and the shared platform facilitated deeper collaboration among sites and the ability to elevate local issues with colleagues across the state, enhancing the strength of recommendations to address caregiver needs more comprehensively.

Readiness for Implementation

At the beginning of the implementation effort, 3 CRC sites, including FCA, were already using CareNav. The subsequent sites benefited from reliability and usability testing, as well as refinements and improvements that had been made during the initial, more limited deployment by FCA and QP.

Leadership was an essential condition for success from the implementation team and at the CRC site level. Strong leadership, reassurance, and encouragement by managers, coupled with effective communication, established the overall vision, a shared understanding of the goal, the anticipated process and outcomes, and motivated staff across the sites to engage in implementation:

I think there's been leadership behind this and a sense of vision...FCA is [a] very unique organization and that [sic] they are really sitting in this point where they're both policy wonks as well as clinical experts. And I think that this allows FCA to bring vision and be forward looking of where we're going. And I think that the other CRCs are benefiting from that.

CareNav Characteristics

Focused interviews point to CareNav attributes that both facilitate and inhibit its implementation (Figure 4).

Figure 4. CareNav characteristics.

Relative Advantage

A key factor for the intervention is its relative advantage over previous data collection tools and software used by CRC sites to gather and aggregate site-level data on the caregivers they served and the programs they administered. Using CareNav reduced paperwork, enabled easier documentation, more efficient and secure charting, and a more environment-friendly approach. Additional advantages included increased CRC capacity and round-the-clock accessibility for clients. Several participants emphasized how the design of CareNav supports the process of care:

Now when a new person starts it's...here's the computer system that we use. This is the workflow, because I think it's really laid out nicely, the toolbar at the top of care journey. There's a workflow that you follow. It's just all right there in one place and as long as you have a secure connection, you can access it, so it's going to save a lot of time. I think people are going to end up really happy that they have that information at their fingertips, and they don't have to write it down on paper or search for it, laboriously, in their client file.

Both clinicians and managers reported the advantages of CareNav for management functions. Standardization of the system across CRCs was perceived as allowing sites to collaborate for consultation, evaluation, and advocacy. Using a uniform tool supports administrative and management functions, including case data record-keeping as well as assessing the process and outcomes of the organization in real time:

For a manager being able to pull up reports without it being having to dump it into Excel and then sort through all the different things that you don't need. It looks like data collection is just going to be a lot simpler and easier...as a manager it's easier to measure staff productivity on a system like that because you can go in their notes.

Adaptability

The most frequently identified benefit and concern about CareNav implementation is related to the adaptability of CareNav to the outer-setting variability among sites and populations served. Sites varied along multiple dimensions including population served, geographic characteristics, funding sources, relationships with host organizations, and size. The ability of CareNav to provide remote access, particularly in rural areas, was perceived as a benefit even with the variability in geographic distribution of clients in several CRCs and the impact of the COVID-19 pandemic.

Nonetheless, the digital divide (the issue of equitable access to technology and broadband connection) constitutes an ongoing barrier, particularly for rural, low-income, and non-English-speaking clients. Moreover, there are some

caregivers in remote areas who value self-sufficiency and view government programs with suspicion, with reluctance to share information on the web regardless of access to broadband connection. Some communities in the catchment area do not have reliable broadband connections, and many clients may not be able to afford internet services or the associated technology. The platform is provided in English, limiting access to caregivers who do not speak English or have low literacy:

But language for me is probably my biggest concern, because we do have a big, Spanish speaking population and Vietnamese. It's a very significant group.

Complexity

Sites hosted within a larger health care and information system experienced difficulties associated with the lack of flexibility and data migration, adding complexity and increasing the time and effort demands for staff. For instance, double data entry was necessary for some CRCs to ensure timely and accurate data for fiscal reporting and reimbursement across various funding agencies.

Confidentiality presents another level of complexity. While CareNav is a secure and private system, there is a learning curve for staff to understand the inherent privacy and security protection of the care team and clients. To assure a secure environment, written direct communication with clients changed with CareNav, requiring user authentication processes to maintain clients' privacy:

In the beginning, one of the issues that I was having, for example, when I was doing intake, if I sent emails, I was sending emails through CareNav. But people were not replying back and it turns out because it would send them a message into their actual email, but it would go to Spam....People just prefer for me to directly email them to their email.

Cost

The threat of delay in funding and losing funding during the budget negotiations raised concerns about ongoing funding and support for CareNav. Several sites expressed frustration with the delays associated with state contracting and system readiness. Time-limited funding without a clear path to sustainability posed challenges for directors in their long-term planning.

Characteristics of the CRC Staff

Overview

The pretraining survey was an early opportunity to evaluate CRC staff knowledge about CareNav, self-efficacy, and readiness for change (Figure 5). Overall, the participants had very positive attitudes toward the implementation of CareNav (Table 1), with a total readiness score of 3.8 (SD 0.6) and average responses to almost all items in the positive range.

Figure 5. Characteristics of the Caregiver Resource Center (CRC) staff.

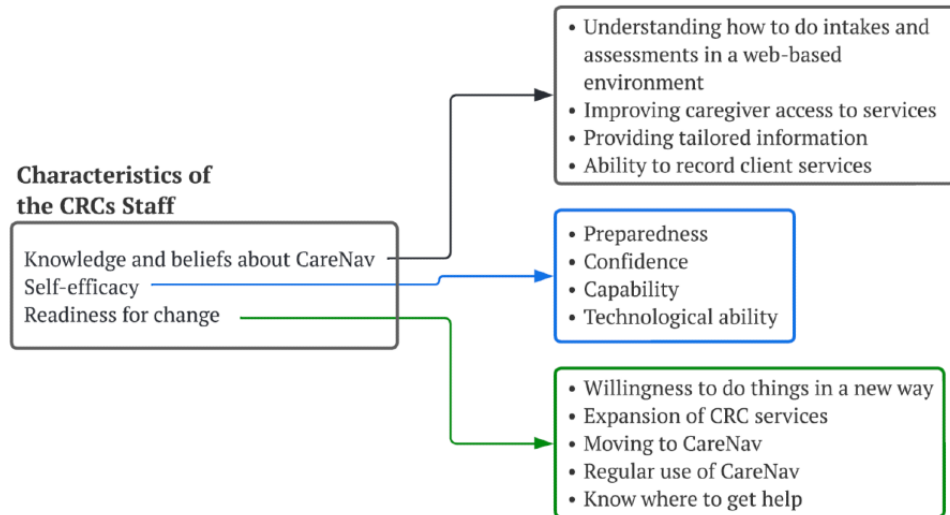

Table 1. Pretraining Readiness Survey (N=82).

Item	n (%)
Knowledge and beliefs about CareNav	
Seen or heard about CareNav ^a	73 (89)
Understand how to do an intake and assessment in CareNav ^a	30 (37)
CareNav is designed to improve caregiver access to services ^a	79 (98)
CareNav will improve the ability to record services ^b	64 (74)
CareNav provide tailored and accessible information for caregivers ^b	59 (68)
Self-efficacy	
Prepared to implement CareNav ^c	43 (49)
Confident to implement CareNav ^c	73 (84)
Capable to implement CareNav ^c	59 (68)
Readiness for change	
Positive with the expansion of CRC services ^c	71 (82)
Positive with moving to CareNav ^c	66 (76)
Willing about doing new things ^c	72 (83)
It will take time to ensure regularly use of CareNav ^b by everyone on the staff	73 (90)
Know where to obtain help ^b	47 (54)

^aStaff members reported “yes.”

^bStaff members reported “strongly agree” or “somewhat agree.”

^cStaff members reported “very positive/willing/prepared/confident/capable” or “somewhat positive/willing/prepared/confident/capable.”

Knowledge and Beliefs About CareNav

Almost 90% (73/82) of staff had seen or heard about CareNav before the training and almost all (79/82, 98%) believed that CareNav is designed to improve caregiver access to services. Before training, one-third (30/82, 37%) of the staff members reported understanding how to complete the intake and assessment in CareNav. The staff members also believed that CareNav would enable better structure and process of care

including improved ability to record services (mean 4.3, SD 0.9) and providing tailored and accessible information for caregivers (mean 4.0, SD 0.9).

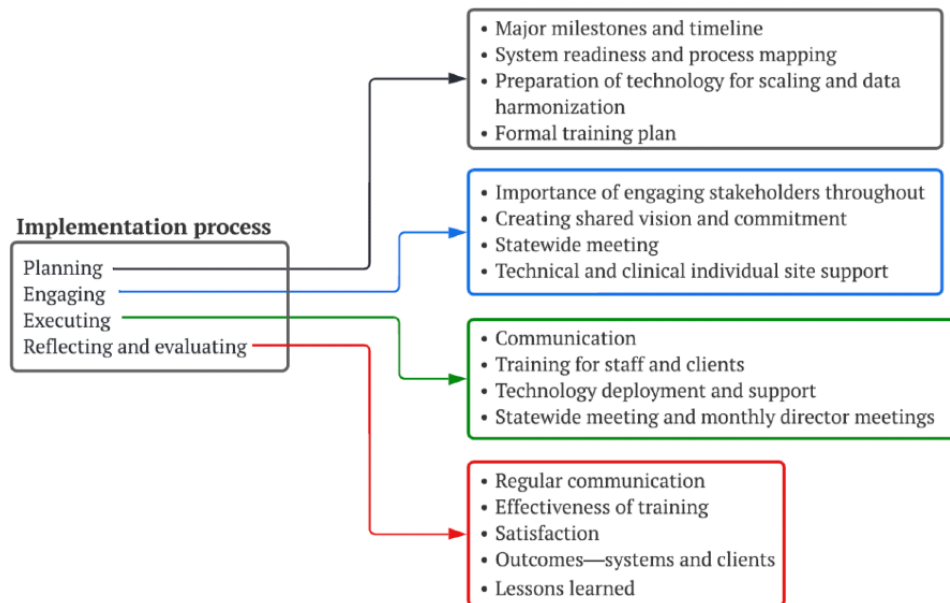

Self-efficacy

The staff expressed a high level of self-efficacy to implement CareNav in terms of feeling prepared (mean 3.3, SD 1.2), confident (mean 4.5, SD 0.9), and capable (mean 3.9, SD 1.2).

Readiness for Change

Regarding readiness for change, participants expressed a strong willingness to do new things (mean 4.5, SD 0.7) but believed that it would take time for everyone on the staff to become familiar with using CareNav (mean 1.5, SD 0.8).

Figure 6. Implementation process.

Planning

The implementation team consisting of staff from the FCA and QP developed a project management plan that addressed culture change, establishing site readiness, staff training, and technical implementation and support.

System Readiness and Process Mapping

Building on the demonstrated success and utility of CareNav in 3 sites, the implementation process involved planning for scaling the technology across 8 additional sites. As described in the inner and outer setting sections, the sites were diverse in several respects: the clients they served, the constellation of services and funding sources, and their relationship with a parent organization providing information technology. Early preparation involved assessing the requirements of each system for technology compatibility and interoperability, security, and compliance with applicable laws (eg, the Health Insurance Portability and Accountability Act). The technology team engaged with each site in mapping the data processes, identifying data sources, and reporting requirements.

Preparing the Technology for Scaling

The overall project plan involved determining major milestones along with the requisite resources and coordination to ensure progress. A major task of the technology team was to prepare the technology for scaling by harmonizing the data across the sites and mapping source data fields to the CareNav platform to assure standardization and data integrity. As the sites reviewed the CareNav software, they requested customization to fit their particular programs, funding requirements, and workflow, thus requiring site-specific revisions to the platform.

Implementation Process

The elements of implementation included developing an overall project plan, engaging stakeholders, preparing technology for scaling, general training, and providing technical expertise and support at each CRC site (Figure 6).

Engaging

The FCA team recognized the importance of engaging stakeholders throughout the process. They appreciated that scaling CareNav involved cultural change and made significant efforts to create a shared vision and commitment to engage in a new way. In a statewide kickoff meeting in January 2020, directors and staff of the CRCs came together to build relationships, develop a deeper understanding of CareNav and its deployment, and generate excitement regarding the effort. CRC sites shared best practices with one another and began to develop a stronger sense of collective resources and commitment to meet the needs of diverse caregivers across California.

General training was accomplished through an initial in-person kickoff meeting followed by statewide webinars. The webinars were widely attended and offered topics to address overarching issues, such as managing change, using telehealth and technology-enabled assessment and supports, and using data for quality improvement.

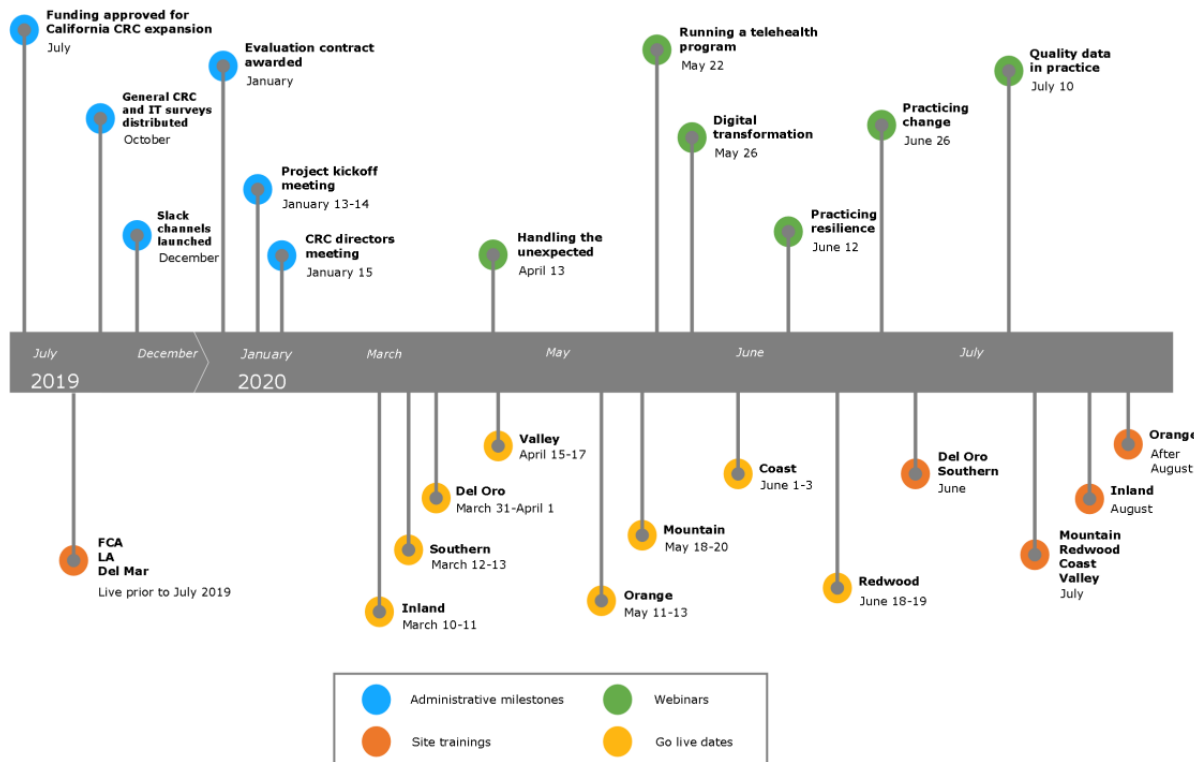

Technical and clinical support was provided by individual site-level trainings to prepare the staff for technology deployment, addressing site-specific workflow and learning needs. Starting in March 2020, these 2-day sessions included the opportunity for hands-on practice using CareNav, reviewing new work processes, creating Caregiver Action Plans and service authorizations, generating reports, and using the library of resources available within CareNav. The implementation team provided extensive individual coaching and problem solving to the sites as the implementation proceeded.

Executing

Implementation, including all activities related to training, communication, and installation of CareNav at the 8 sites began in March 2020, and the last site was onboarded in late July 2020 (see timeline in Figure 7). The initial implementation schedule was affected by delays in finalizing state contracts, fund

transfers, host agency site requirements for hiring staff, and information technology issues to enable the process to commence. In March 2020, owing to shelter-in-place and physical distancing measures to slow the spread of the COVID-19 pandemic, the sites responded by moving to remote operations with staff working from home.

Figure 7. Project timeline. CRC: Caregiver Resource Center; FCA: Family Caregiver Alliance; LA: Los Angeles.

Training and Communication

In addition to the statewide launch meeting followed by training at each individual site, regular statewide web-based training was organized to address best practices, quality improvements, and other topics of broad interest. Owing to state contracting delays, the overall implementation schedule lagged. In some cases, training occurred in March 2020, with delays occurring in technology deployment until July 2020. This necessitated refresher training and ongoing support. Overall, the training was viewed by interview participants as excellent, responsive, customized, and personal.

Technology Deployment and Support

The technology team developed and implemented a sophisticated process of CareNav deployment across sites. On the basis of the initial assessment of site-specific technology issues and requirements, they collaborated with staff members to map the data fields from existing data sources to CareNav. System-level requirements for security and interoperability with the existing information technology platform for sites hosted within health systems presented complex challenges with several levels of review and approval. For some sites, particularly those that are more rural, broadband connectivity was an issue for staff working remotely. Following the mapping process, the technology team worked with the sites to perform the data migration and verification. Throughout the process, the

implementation team provided both clinical and technical support to assist the sites in making the transition effectively and assisted local staff to become resources for peers.

All sites praised the support received from the implementation team, including their responsiveness and ability to address challenges unique to the site and to their proactive approach to problem solving. It was clear that across all the organizations, both the site directors and staff were highly committed and dedicated to making the implementation a success. Ongoing communication enabled continuous access to the evolving information and knowledge.

The long-term continuous maintenance of the system has been emphasized as a key structural component required to maintain the operational activity of CRCs:

I think it would be great to have a source to go to when things break down...And we're not gonna go in and fix the system ourselves...So someone maintaining the system is gonna be real important for us to keep it going...that's part of the whole licensing process-we're licensed to use the software and support.

Beyond staff training, several interview participants highlighted the importance of training clients on how to use the CareNav system. Currently, the staff members send information to clients about how to log on to the system but thought that this could

be enhanced to assist clients who are less experienced with the web environment or face linguistic barriers to a program provided in English. A few sites have identified the importance of marketing and outreach to assist caregivers in finding CRC services to facilitate access:

To me it's like okay so how do we sell this now and I think it's a lot it's gonna be getting them used to it. When my family care navigators schedule video zoom for family consultation...it's gonna be a lot of that education piece and getting them used to that. I think a change that we have to make internally to help the caregivers use it.

Reflecting or Evaluating

Overview

Weekly data quality meetings were held with attendance by the evaluation researchers, CareNav application developer, and the FCA Client Services Director. These meetings focused on refining definitions and operationalizing evaluation metrics, defining data filters for the evaluation, identifying and addressing data entry discrepancies overall and by CRC site, and reconciling counts of activities in the evaluation data set with those in reports generated from CareNav. Each quarter, the data quality team met with each of the 11 CRC sites individually to share activity counts and service grant data for comments and any identified data entry issues particular to the site. The team met with the CRC directors approximately 4 times each year to share progress.

Another element of reflection and evaluation is the effectiveness of the training and outcomes for clients and staff. The posttraining survey and in-depth discussions with staff at all CRCs provided insight into the effectiveness of the training, participants' satisfaction with the process of implementation, as well as early outcomes of CareNav implementation both at the system and the client levels.

Comparing pretraining and posttraining readiness for implementation survey data shows significant increase in staff beliefs about their knowledge how to use CareNav, where to obtain help if needed and their preparedness. The proportion of staff who reported that they understood how to complete an intake and assessment in CareNav significantly increased from 27% before training to 97% after training ($P < .001$ based on the McNemar test). Both before and after training, the staff believed that the system would improve caregiver access to services. Given the high proportion endorsing this survey item in the pretraining and posttraining periods, this change was not statistically significant. Paired 2-tailed t test analysis showed significant improvement in feeling prepared to implement the CareNav score (pretraining mean 3.23, SD 1.24 vs posttraining mean 3.63, SD 0.91; $P = .04$) and in knowing where to obtain help (pretraining mean 3.52, SD 1.16 vs posttraining mean 4.32, SD 0.96; $P < .001$). A nearly significant decrease in the mean confidence score was found (pretraining mean 4.39, SD 0.99 vs posttraining mean 4.11, SD 0.93; $P = .05$). It is likely that the training fostered a greater awareness of the system and recognition that it would take time to learn new ways of working and using technology.

Almost all ($n = 57$, 93%) staff reported willingness to adapt current services or provide services using CareNav. All participants will ask for support if they have questions about how to use CareNav, and 55 participants (90%) will offer support to coworkers if they have questions; 52 (85%) participants will ensure new coworkers are educated on how to use CareNav, and 50 participants (82%) will encourage coworkers to use CareNav.

Respondents found the training useful and helpful: 82% ($n = 50$) rated the training as useful, 14% ($n = 9$) were neutral, and 5% ($n = 3$) did not find the training useful. In response to a question about whether the training met their needs, 76% ($n = 46$) of the respondents agreed, 11% ($n = 7$) were neutral, and 13% ($n = 8$) did not feel that the training met their needs. Finally, almost 80% ($n = 48$) felt that they had sufficient time to practice new skills.

Satisfaction

Focused interviews explored satisfaction with the system and implementation process. Overall, the interview participants expressed a high level of satisfaction with the implementation process, affirming the vision as important for the next phase of the work of the CRCs and embracing change as a positive force. Interview participants remarked on how easy it was to learn and use the new system and how readily they could see the benefits to their workflow and clients. Many expressed surprise at how well the process had gone despite the unforeseen challenges:

I mean I think for rolling out a new platform of this magnitude, it's gone amazingly well.

It has been a pretty positive experience. So, I think it's been easy for me to navigate and I think people who are used to doing everything online appreciate that from the system.

Interview participants from the 2 sites that were the last to implement the program were less satisfied and more skeptical about the long-term benefits. Unlike other sites, these sites encountered system barriers including integration with the information system at the broader host organization and difficulty harmonizing their existing records with the new platform. Despite these frustrations and delays, the sites remained open-minded and were willing to move forward:

I think it just further kind of reaffirms that our staff is flexible and we'll just roll with it most of the time and yeah it's frustrating and that sort of thing that we're going to make the best of it, regardless of the situation and that's just kind of our attitude about most things in general.

Effectiveness of Training

The interview participants recognized that many of the features of the platform were even more relevant in the context of the pandemic and that physical distancing guidelines accelerated adoption by agencies and clients at an unexpected rate. Importantly, throughout the pandemic, CRCs continued to innovate and serve their clients who needed them more than ever:

I think what we've all learned that we've been very surprised about is we have discovered, so many new opportunities because of the pandemic. And so, our repertoire of services or our availability is expanded. My staff continue to express great satisfaction with their relationships with their clients and, and they are now having satisfying phone conversations where they're having satisfying online support groups, we're continuing to have our educational workshops and online and people are satisfied with that. So yes there are disappointments and frustrations, but at the same time we've discovered so many opportunities. And we've become empowered, and we are saying to the community, "We're here. We're open we didn't go anywhere, call us, we're here for you" and so that was a nice surprise, and my staff, myself, the entire organization, we just feel more confident now of knowing how to work remotely, knowing how to use zoom, knowing how to use our new databases, we just feel like, we got it together. I always say to my team they're rock stars they just impress me every day.

The focused interviews also explored early outcomes of the implementation of the web-based platform, both at the system and client levels. Finally, the participants shared the lessons learned during the process.

System Outcomes

The most commonly reported benefits were improved access and convenience. This was particularly salient during the pandemic with staff working from home. Interview participants cited the benefits of having a single paperless location for client data, accessible by any staff member from any location. Family consultants also valued the ability to track services more completely:

It's allowed us to work remotely, it has allowed at the time of COVID to work safely as a group and still support our caregivers. We've been able to continue to offer services. We've continued to be able to document and work together.

The directors valued the potential of the system to generate data to evaluate services, improve quality, guide program decisions, and provide evidence for advocacy. At the site level, directors anticipated using the data to guide strategic directions and identify service gaps. Statewide, they valued the potential to aggregate data to inform planning and policy. For example, data on caregivers can inform the implementation of the California Master Plan on Aging:

The other big benefit eventually will be that we will have statewide information data that is consistent across all 11 Caregiver Resource Centers. And to me that's huge because it helps with government planning and policymaking as it relates to caregiving.

A positive consequence of this initiative has been bringing the sites together, with a shared vision to serve caregivers across the entire state, learning from one another and sharing resources. Several directors shared a vision to collaborate in new ways, assuring that caregivers across the state had access to culturally and linguistically congruent resources. For example:

Could we survey our sites to see who has family consultants in different languages? In our County we have a pretty sizable Korean population. We currently don't have a Korean family consultant, but if another site did, could they serve them? And could we serve if they had a Vietnamese client? In other words, how do we leverage our statewide network around language barriers? I think there's a potential opportunity to use the statewide network differently with this common platform.

Client Outcomes

The greatest client benefit reported was having a platform that clients could access at their convenience, around the clock and from any location. In addition, the consultants found it beneficial that the platform enabled them to tailor resources for specific clients based on their assessment, which allowed for immediate delivery from the web-based library. Clients could also access information about authorized services, such as respite or counseling on the web. Several consultants voiced their advantage to clients with disabilities who find web-based navigation more accessible than other alternatives:

I have clients with disabilities, for example, I had a few who were completely deaf and—we communicated through (CareNav) and through email. So, that was a wonderful tool for her because she said in the past it was really challenging to get services.

The new platform provided an avenue for clients to connect during the COVID-19 pandemic and address social isolation in a way that had not been previously available:

One of our staff members said, "my online Spanish support group are really having a hard time with the isolation and they so appreciate being together at least once a month, but they want to meet two times. Can I do my support group two times a month?" I said of course!

Lessons Learned

The most commonly stated lesson was *patience*. All the interview participants reported resilience and flexibility as they approached and engaged in the implementation process. Many affirmed the positive nature of the change and a commitment to ongoing learning associated with this platform enhancement. They expressed heightened appreciation for the importance of communication and collaboration within sites, across sites, and in the community. For those on the clinical and technical support teams, they recognized in even greater detail the variability and diversity across the sites:

Having to realize that people really think differently, and they learn at different speeds, and they communicate differently, both individuals and as organizations, and the variability in even their data or how they store their data and how they manage their programs. Yeah, I think there was just a little bit of variability everywhere.

Discussion

Principal Findings

Our findings suggest 4 factors as essential underpinnings of successful implementation, with implications for future replication [29]. First, key informants emphasized the importance of effective leadership as a key inner-setting component. The participants cited creativity, perseverance, unwavering vision, clear communication, relevant expertise, and deep knowledge of all aspects of the intervention and the inner and outer settings. Effective leadership facilitates a positive implementation climate, which in turn enhances implementation effectiveness [30]. Beyond the inner setting, leadership was described as continually interacting and potentially affecting other CFIR domains [31]. The CareNav implementation team has long tenure in the system and a history of successful implementation of other prior initiatives across the CRC system that may have increased staff self-efficacy. The expertise of program managers, information technology staff, and site directors and staff, as well as leaders' deep knowledge of CareNav and the CRCs outside networks contributed to continuous interaction with stakeholders throughout the technology implementation process [31]. The leaders' deep understanding of unique CRC site-level structures and processes was described as particularly important for enhancing both customized and overall implementation efforts. These findings echo recent technology implementation studies in multisite settings, highlighting the lack of senior leadership endorsement as impeding successful implementation [32].

Second, the interview participants stressed the key role of training and ongoing support to increase their self-efficacy using the technology platform. Ongoing training and support were suggested as effective strategies to attract and involve key stakeholders in implementing or using the innovation [33,34]. Our results in the implementation process domain provide insight into the participants' thoughts on the ongoing training performed. The implementation leadership team gathered information about the system user experience from the training and applied the learning for system refinement and quality improvement. As reflected in both the surveys and interviews, participants appreciated the pace and cadence of the training as well as the opportunity to provide feedback. This feedback loop, in turn, improved platform usability, further inspiring staff self-efficacy. Of note, this 2-way communication for continuous improvement is ongoing with quarterly meetings of the QP development team, program evaluators, and CareNav end users to review program productivity data and share issues, concerns, and feedback—providing an open forum for problem solving in the future.

Third, CareNav represented culture change in two major ways: by bringing together decentralized sites and by introducing novel technology that provides customization, round-the-clock availability, and enhanced workflow for staff. In addition, CareNav reflects culture changes societally. In both surveys and interviews, participants expressed a high degree of willingness to change and an openness to new approaches to delivering and documenting interactions with caregivers. This

willingness to adopt technology was a key factor in the rapid and successful deployment of the platform.

Finally, the interview participants raised a critical issue of ongoing funding to support the CareNav initiative going forward. Over the last few decades, state funding for the CRC system has waxed and waned, along with the political will to support family caregivers. In the leanest years, CRCs functioned largely as independent entities, drawing on local funding and scaling back services accordingly. In the current phase of funding, state-level investment for CareNav was significant, covering the technology roll out across 11 sites and supporting the QP CareNav development team to provide ongoing technical support, system refinement, reporting capability, and building system elements that expand the functionality of the user interface of the portal through which caregivers can complete intake and assessment forms and access information around the clock. Without ongoing funds to support this vital work, the impact of this initial investment will be vastly diminished, and none of the stakeholders (caregivers, CRCs, and funders) will be able to capitalize on its full potential. Indeed, the long-term benefits of a uniform assessment, data collection, and reporting system are yet to fully materialize, with great potential to disseminate interventions to support family caregivers in the future.

Context of the COVID-19 Pandemic

This study echoes the recent implementation literature underscoring the COVID-19 pandemic as an outer-setting construct inconclusively affecting implementation [35-37]. In fact, the pandemic may have facilitated and accelerated the technology implementation process with significant effects on CareNav characteristics, the inner setting, characteristics of the CRC staff, and the outer setting. CareNav proved to be an agile system during the unexpected national and global circumstances of the COVID-19 pandemic and showed promise of helpfulness in sudden onset or unforeseen conditions, especially in California, given the likelihood of natural disasters such as earthquakes or fires and their impacts on caregivers and the caregiving role. Indeed, the vision for a shared technology platform proved to be prescient as the COVID-19 pandemic gained momentum and the CRCs were able to respond quickly to provide uninterrupted services to their clients by ramping up outreach and adapting supports for caregivers. As examples related to the inner setting, the circumstances of the pandemic may have improved the organizational will to implement by spotlighting the perceived benefits of the technology platform, given its ability to support web-based work; improved the implementation climate through increased staff enthusiasm for the platform; increased staff patience to follow through the stages and steps of the implementation process; reduced hesitation about changing to the technology platform; and increased the need for cross-site communication to best serve the needs of clients. Related to the outer setting, CRC staff members were acutely aware of the toll the pandemic took on their clients, as their needs increased and access to many services and supports—including respite care, adult day care, and institutional placement—became more limited.

At the same time, CRC staff members themselves experienced added strain, juggling their own competing demands outside work, covering for one another owing to illness, coping with staff turnover, and pivoting to remote work from home to provide web-based family consultations to their clients. These factors may have either increased or decreased the willingness of the staff to use the CareNav platform to do their work in new ways, their readiness for change, and their perceived need to expand services. Moreover, the pandemic might have slowed the ability to integrate CareNav with other systems, specifically for sites hosted within a larger health care system who were themselves focusing on care delivery priorities. Similarly, the implementation of other web-based technologies encountered significant barriers, explained by time constraints and competing priorities associated with the COVID-19 pandemic [38]. Effective leadership engagement, as demonstrated in our study, might have played a mediating role in buffering the COVID-19 pandemic slowing effect by maintaining commitment and resources to the implementation and ultimately reducing behavioral resistance to change [35,36,39]. Taken together, these factors must be considered in the interpretation of the findings of this evaluation, particularly in light of the perceived success of the implementation from the staff perspective.

Comparison With Prior Work

This implementation evaluation also offers the knowledge needed to address gaps in prior research. A systematic review of internet-based supportive interventions for caregivers of patients with dementia recommended individual tailoring of supports for the success of digital interventions for caregivers [23]. Underlying this recommendation is the heterogeneity of web-based support systems regarding intervention type, dosage (amount of time spent on the web), and duration, which affect intervention effectiveness, feasibility, and quality [23,40]. In addition, caregivers use web-based supports targeting caregiving for distinct illnesses such as cancer [41], dementia [10], posttraumatic stress disorder [20], and psychosis [21,22] suggesting illness-specific web-based support needs for caregivers. As described, CareNav enables either self-administered or staff-administered caregiver and care recipient assessment, appraisal of current resources, delineation of priority supports, and development of a care plan to contract appropriate services such as respite, educational sessions, support groups, and vouchers for legal aid or counseling across all health conditions, providing a more comprehensive resource for caregivers. These services can be individually tailored to caregivers and illness-specific caregiving needs. CareNav includes a tailored library of resources for caregivers based on the assessment, with the ability to link to resources such as the World Health Organization's iSupport site [10].

Studies in the past have shown that web-based support can increase confidence, self-efficacy, and self-esteem and reduce depression and strain among caregivers [14,23,42]. This study showed that the capacity to enhance access, convenience, and customized support for clients held a universal appeal for CRC staff. CRC sites highly valued the potential of the data collected in CareNav to provide real-time feedback on who they were serving and the effectiveness of their interventions. Future analyses should explore changes in client confidence and mental

health outcomes. As users gain expertise and competence, they will likely see greater benefits to full use of the CareNav platform features, enhancing client engagement and improving decision-making for care consultants, particularly for clients at the highest risk for negative outcomes.

Limitations

This study was an evaluation of an implementation process in established CRCs across the state. There were trade-offs in data collection and reporting to protect the anonymity of participants who could otherwise be readily identified. Therefore, this study does not provide demographic characteristics of participants nor is it able to link findings to the specific roles of staff. However, the decision to permit anonymity facilitated broader participation and a more complete perspective on implementation, as evidenced by the high participation rate of staff in both the surveys and interviews. We applied the CFIR during the data analysis stages of the implementation and did not use the framework to its full potential in guiding implementation design. This study focused on the implementation process and its immediate impact on staff and clients, and did not examine changes in caregiver health and well-being.

Conclusions

In this study, we applied the CFIR [29] to examine the implementation of a web-based platform to engage and support family caregivers across 11 regional sites in California, the most populous state in the United States. The findings identified factors that contributed to success and were relevant for future scaling and dissemination of this innovative platform designed to support global assessment, intervention, and service delivery to address the unmet needs of family caregivers. Importantly, the platform is accessible to both staff and clients regardless of geographic region or care recipient medical condition, and supports timely and local responses to caregiver priorities. Using the CFIR facilitated a more systematic understanding of the multilevel experience of technology implementation across multiple sites. Future implementation projects would benefit from using the CFIR to organize implementation strategies and identify potential blind spots in planning.

As noted, the value of long-term care provided by family caregivers eclipses that provided by government funding [2]. Caregivers have become indispensable in health care delivery. Although their contributions have remained largely invisible, CareNav elevates caregivers' contributions as part of the fabric of health care. The global assessment of the caregiver and the ability to respond to the priority of the caregiver in real time with information or referral responds to myriad health-related urgencies and imbeds caregivers as elemental in the fluid and ongoing process of care. CareNav additionally supports caregivers in the community. Studies show that the caregiver community is helpful over and above the benefits related to caregivers' coping [43]. Information gathering, reminiscing, legacy building, and giving back to the community of caregivers maintain the spirit of commitment [42,43]. Although in our study, the mechanism of culture change is primarily associated with modernizing business practices using technology, the CRC vision and long-range outcomes align with broader societal

implications of acknowledging and supporting caregivers as a crucial link in providing supports across communities.

Among the 5 bold goals of California's Master Plan on Aging for 2030 is *caregiving that works* [44]. The California CRCs took on the impressive goal to harmonize their information technology platform and implement the new platform across the state in all 11 sites in 6 months. Other state plans, such as those of New York, have similar priorities for caregivers and CRCs [45]. Future studies could compare California state data with both other states and national populations. This could produce greater knowledge of the similarities and differences in the support needs for the nation's caregivers. With the opportunity for longitudinal analysis, future studies could examine the predictive factors of intake for negative caregiver outcomes, facilitating earlier interventions. Further analysis of use and outcomes could elucidate which services are most helpful for subpopulations of caregivers.

The next phase of implementation should involve developing a deeper understanding of the rich information available through

CareNav, determining both site-specific and statewide reports that would be most helpful in evaluating adoption and dissemination of the programs into the community, effectiveness and gaps in service, quality of delivery, and the impact of the services and supports on caregiver outcomes. The data hold the power to drive individual and system changes. At the individual level, the assessment can be the basis for determining risk and matching services to caregiver needs. At the system level, the data can drive strategy for priority program development, funding, and advocacy. Future studies should evaluate the impact of the CRC system on caregiver health and well-being, as well as develop a deeper characterization of the trajectory of caregiving and how interventions can improve outcomes for caregivers and the persons in their care.

A determined and committed group of leaders and staff dedicated to improving the lives of caregivers began a journey together. They are well on their way to actualizing a vision for the future of caregivers in California.

Acknowledgments

This work is a collective effort with many dedicated individuals sharing a vision and contributing their time, energy, and effort to serve the caregivers of California. The evaluation team worked closely with the Family Caregiver Alliance team (represented by Christina Irving and KK) and the Quality Process team (represented by Brad Silen) throughout the evaluation design, data collection, and data verification process. The authors appreciate the leadership and commitment of the 11 Caregiver Resource Center directors and the dedicated staff who participated in the implementation while delivering high quality services.

The authors received funding from the California Department of Health Care Services and the Gordon and Betty Moore Foundation (Family Caregiving Institute and Heather M Young postdoctoral fellows TRK and OT).

Abstract

Background: Antibiotic resistance is a worldwide public health problem that is accelerated by the misuse and overuse of antibiotics. Studies have shown that audits and feedback enable clinicians to compare their personal clinical performance with that of their peers and are effective in reducing the inappropriate prescribing of antibiotics. However, privacy concerns make audits and feedback hard to implement in clinical settings. To solve this problem, we developed a privacy-preserving audit and feedback (A&F) system.

Objective: This study aims to evaluate a privacy-preserving A&F system in clinical settings.

Methods: A privacy-preserving A&F system was deployed at three primary care practices in Norway to generate feedback for 20 general practitioners (GPs) on their prescribing of antibiotics for selected respiratory tract infections. The GPs were asked to participate in a survey shortly after using the system.

Results: A total of 14 GPs responded to the questionnaire, representing a 70% (14/20) response rate. The participants were generally satisfied with the usefulness of the feedback and the comparisons with peers, as well as the protection of privacy. The majority of the GPs (9/14, 64%) valued the protection of their own privacy as well as that of their patients.

Conclusions: The system overcomes important privacy and scaling challenges that are commonly associated with the secondary use of electronic health record data and has the potential to improve antibiotic prescribing behavior; however, further study is required to assess its actual effect.

Introduction

Antibiotic stewardship is an issue that has recently come under scrutiny in Norway [1] and internationally [2], especially in general practices, which is where most antibiotic prescribing occurs [3]. The inappropriate use of antibiotics is thought to be an important factor in the development of antimicrobial

resistance. Although a number of guidelines define when antibiotic use is warranted, defining *appropriate use* is difficult, unless there is clear agreement on the etiology of an infection [4]. There are diverse and complex reasons for the overuse of antibiotics, and consequently, several strategies have been designed to combat this problem [5]. There have been increasing calls by government agencies, such as the US Centers for

Disease Control and Prevention, to embrace regular tracking and reporting (audits and feedback) as two of the core elements of stewardship programs [6].

Audits and feedback [7] can incorporate behavioral science elements, that is, clinical performance can be reviewed and compared among peers, and this has been widely reported as effective in reducing the inappropriate prescribing of antibiotics [1,2,8,9]. Despite strong support in the literature, there are at least two important factors that make audits and feedback hard to implement in real-life settings or make them ineffective altogether. First, without proper privacy safeguards, the risk of breaching regulatory compliance with regard to health data confidentiality increases. Additionally, underperforming general practitioners (GPs) may feel exposed and view the exercise as punitive [10]. The second factor, scalability, is important for efficiently analyzing vast amounts of distributed electronic health record (EHR) data to facilitate the regular scheduling of audit and feedback (A&F) programs. Regular scheduling is an important factor, since evidence shows that if audits and feedback are stopped, their benefits are likely to dissipate [11,12].

This study evaluates a scalable, privacy-preserving A&F system [13] in clinical settings. The system was deployed in three GP offices and used to generate feedback for 20 GPs on their antibiotic prescribing for selected respiratory tract infections (RTIs), which was viewed in comparison to the average performance of peers. The objective is to evaluate the GPs' sentiments toward (1) the privacy protections that the system offers, (2) the accuracy and appropriateness of using personal feedback as the basis for comparisons with peers, and (3) self-efficacy and the potential of the intervention to improve the prescribing of antibiotics.

Methods

Privacy-Preserving System for Audits and Feedback

The privacy-preserving system contains software components that are deployed at each health institution. The system extracts data daily from the local EHR system and transforms and loads the data into a database that conforms to a common data model [14].

A third party (denoted as a *coordinator*) aids the system without learning private information and is trusted to follow protocol specifications. This is a standard security model known as the *honest-but-curious adversarial model* [15]. In this study, the Norwegian Centre for E-health Research acted as the coordinator. The coordinator accepts queries for the aggregated performance indicators of GPs across health care institutions. The system uses privacy-preserving distributed data mining techniques [16-18] for executing statistical queries on the combined data of health care institutions without allowing any party to view the private data that health care institutions compute locally. Statistical results on the combined data of multiple health care institutions are not considered sensitive information and are therefore stored at the coordinator and retrieved through a web service.

The feedback report is generated locally by combining local personal indicators and the aggregated indicators retrieved from the coordinator. Access to the feedback report is restricted to the respective GP and is provided through a web client or email as an encrypted PDF file, and the decryption key is sent to a mobile phone. We refer interested readers to a study by Yigzaw et al [13] for an elaborated description of the system.

Study Setting

In 2019, we deployed the system in three GP offices in Norway, and 20 GPs received a single feedback report on their prescribing of antibiotics for selected RTIs. The GPs were then asked to fill out a web-based questionnaire for assessing their perceptions of the feedback received and how the feedback was presented.

Norwegian GPs are responsible for treating a set of patients and refer only those who need more specialized health services to hospitals [19]. Therefore, the 20 GPs had a total of around 19,345 patients on their lists. The number of registered patients varied during the study period because patients sometimes change their GP.

Audits and Feedback

The GPs received a single feedback report on their prescribing of antibiotics for selected RTIs for which antibiotics are generally not recommended if the patient is otherwise healthy (eg, during the first presentation of a current episode of an RTI or when the patient has no significant underlying comorbidity) [20]. Based on the *International Classification of Primary Care, Second Edition* [21], the selected RTIs were acute upper respiratory infection (R74), acute sinusitis (R75), acute laryngitis/tracheitis (R77), acute otitis media/myringitis (H71), and unspecified respiratory infections (R83). Acute bronchitis (R78) was also included because it is most often a viral infection, and the use of an antibiotic is rarely recommended.

Feedback was provided for the selected RTI cases between 2015 and 2018; both combined and separate feedback were provided for each of the diagnoses. All statistics were stratified by both year and antimicrobial spectrum (broad- and narrow-spectrum antibiotics). Based on the Anatomical Therapeutic Chemical classification system [22], narrow-spectrum antibiotics include β -lactamase-sensitive penicillins (J01CE), and broad-spectrum antibiotics include tetracyclines (J01A); β -lactam antibacterials and penicillins (J01C, excluding J01CE); other β -lactam antibacterials (J01D); sulfonamides and trimethoprim (J01E); macrolides, lincosamides, and streptogramins (J01F); and quinolone antibacterials (J01M).

The feedback report contains the number of cases that were diagnosed and treated with antibiotics. A set of performance indicators was presented as a time series graph that compares the performance indicators of a GP with the average indicators of all participating GPs. Performance indicators were based on the indicators proposed by the European Surveillance of Antimicrobial Consumption Network [23], as follows:

- The percentage of diagnosed cases treated with an antibacterial drug for systemic use

- The percentage of cases treated with narrow-spectrum antibiotics among all diagnosed cases treated with antibiotics
- The percentage of cases treated with broad-spectrum antibiotics among all diagnosed cases treated with antibiotics

Questionnaire

A panel of experts with clinical and medical informatics backgrounds developed the questionnaire. As shown in [Multimedia Appendix 1](#), the questionnaire broadly covers aspects that were derived from the following three theoretical constructs of the Theory of Planned Behavior [24]: (1) attitude toward privacy and the prescribing of antibiotics, (2) subjective norms (reflection on the accuracy and appropriateness of using feedback as the basis for comparisons with peers), and (3) self-efficacy regarding changing prescribing behavior.

Statistical Analysis

Descriptive statistics were calculated to summarize the results of the categorical questions, including age groups and years of experience.

Figure 1. Antibiotic prescribing for all participating general practitioners between 2015 and 2018.

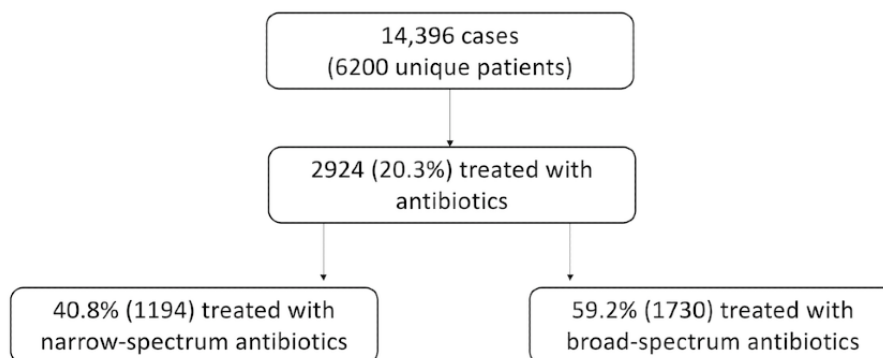

Table 1. Participant attitudes toward privacy, audits, and feedback (N=14).

	Very useful, n (%)	Useful, n (%)	Not useful, n (%)
Participant attitudes toward patients’ privacy	10 (71)	4 (28)	0 (0)
Participant attitudes toward physicians’ privacy	3 (21)	6 (42)	5 (35)
Participant attitudes toward feedback on own prescribing of antibiotics	9 (64)	4 (28)	1 (7)
Participant attitudes toward comparison with peers	6 (42)	7 (50)	1 (7)

Privacy Protection

We can observe from [Table 1](#) that the GPs were unanimous about privacy protection for their patients, and 64% (9/14) of GPs considered the protection of their own privacy to be very useful or useful.

Feedback Report

Most of the GPs (13/14, 92%) reported that feedback on their prescribing of antibiotics and the ability to compare their performance indicators with those of their peers were useful or very useful. The clinicians preferred to receive feedback at regular intervals, such as half-yearly (5/13, 38%) and yearly (7/13, 53%; 1 response was invalid). Most of the clinicians (13/14, 92%) preferred to receive an encrypted feedback report

Ethical Considerations

This study was based on an anonymous questionnaire and therefore did not require ethics review board approval, according to Norwegian regulations. However, all participants gave their informed consent to participate in this study.

Results

Participants

The retrospective data that were generated by using the A&F system show that approximately 20% (2924/14,396, 20.3%) of all cases of the selected RTIs were treated with antibiotics, as illustrated in [Figure 1](#).

A total of 14 GPs responded to the questionnaire, representing a 70% (14/20) response rate. Of these GPs, 36% (5/14) were aged 50 years or older, 57% (8/14) had more than 15 years of experience as a GP, and 79% (11/14) had a specialization in family medicine. The survey results on attitudes toward privacy, audits, and feedback are summarized in [Table 1](#).

through email rather than having it integrated into the EHR (3/14, 21%), receiving it on a secure website (1/14, 7%), or receiving it on a mobile app (0/14, 0%).

Effects of Audits and Feedback

Of the 14 GPs, 1 (7%) indicated the intention to change their antibiotic prescribing behavior based on the feedback received, 2 (14%) indicated that they did not intend to change, and the rest (n=11, 78%) were unsure of whether they would change.

Feedback Stratification

Most of the GPs (11/14, 78%) wanted their feedback to be stratified by the characteristics of their patient populations and diagnoses. Age and gender were the commonly requested patient characteristics for stratification. The clinicians also requested

stratification by chronic conditions, such as chronic obstructive pulmonary disease, asthma, cystic fibrosis, other airway comorbidities, acne, perioral dermatitis, and heart failure.

Discussion

Privacy Protection

Perhaps the major highlight of this study relates to privacy preservation, since the A&F system resolves most of the privacy concerns raised in similar studies. Our results show that the GPs value the protection of their own privacy as well as that of their patients, and this finding is in line with those of existing studies [25]. Our results appear to support our initial assumption that protecting the privacy of clinicians may increase their willingness to participate in quality improvement activities.

GPs in Norway often work in small practices with few or no peers; therefore, comparisons with peers across multiple institutions could be especially useful, and the privacy safeguards serve as further incentives for participation.

Feedback Report

Our results show that the GPs were in favor of receiving encrypted feedback reports through their emails. This contrasts with the common belief that integrating a clinical decision support system with EHR systems is an important success factor [26]. It is plausible that the GPs assumed that integration with the EHR would trigger distractive feedback alerts more frequently than those triggered by the desired half-yearly or yearly periodic feedback.

Effects of Audits and Feedback

The GPs appeared to value both seeing their antibiotic prescribing statistics and being able to compare these with those of their peers. Although this study did not measure whether the clinicians actually changed their prescribing behavior following feedback, it is likely that most of the participants had a close-to-average prescribing practice and would therefore not have an incentive to change their prescribing behavior. In a larger sample of clinicians, there would be a higher number of individuals that deviate from the mean and have an incentive to change their prescribing behavior.

Feedback Stratification

The GPs requested the stratification of feedback by patient characteristics, such as demographics and chronic diseases, of which both are known to influence the decision to prescribe antibiotics. Stratification provides important information to clinicians on whether their prescribing behavior can be justified based on patient characteristics and enables peer comparisons among clinicians with similar patient populations.

Limitations

An important limitation is that we could not evaluate GPs' responses based on their clinical performance, since the questionnaire was anonymous and access to feedback reports was limited to the respective clinician. For example, we were

not able to assess how the self-reported intention to change related to an individual's current clinical performance.

Another limitation is that the feedback reports provided to GPs were not adjusted for comorbidities and age. These two variables are known to influence the decision to prescribe antibiotics, and this may have affected their responses to the survey.

We also noted that the average performance of peers might be skewed if there are outlier clinicians who are far from the mean on 1 side. Therefore, it might be necessary to exclude outliers or provide more statistics, such as SDs and percentiles, to enable detailed comparisons with peers.

The sample size in this study can be considered small but can also be viewed as appropriate for an in-depth case analysis for a pilot implementation of this type.

Recommendations, Implications for Practice, and Impacts

The findings from this study have important implications for practice, especially implications related to quality improvement programs at health care institutions. We single out 3 elements that we recommend for improving systems that support antibiotic stewardship programs. The first and basic element is protecting the privacy of clinicians as well as that of patients. Second, scalability should be considered so as to enable comparisons among peers across multiple health care providers. Comparisons across health care providers are especially useful for small practices like GP offices, since such comparisons require a wide pool of similar patient groups and can be adjusted for comorbidities and age. Finally, human factors should be considered. For example, the frequency of feedback should be considered, since clinicians may not want distractive feedback alerts.

In terms of impact, our system offers a solution to key challenges that hamper antibiotic stewardship programs. It provides privacy guarantees to patients, clinicians, and health care institutions and provides the scalability required to ensure that long-term audits and feedback can be sustainable parts of stewardship programs.

The impact for Norway might be limited, since Norway is a small country with relatively lower antibiotic prescribing rates compared to those of other European countries [27]. For larger countries with differently organized general practices, a higher effect can be expected, since audits and feedback are the most effective in places where the baseline performance is poorer compared to that of the best general practices [7].

Conclusion

Our results show generally positive sentiments among GPs regarding the potential impact of our system, but it should be noted that this was an initial study with a relatively small number of participants. Therefore, the absolute number of clinicians with very high prescribing rates was likely to be low. In larger samples, we expect that a higher number of physicians would receive an incentive to change their practice.

Acknowledgments

We are very thankful for the general practitioners who participated in this study. We also would like to thank Peder A. Halvorsen, Torje Henriksen, Andrius Budrionis, and Luis Marco-Ruiz for their contributions to the design of the questionnaire that was used in this study. This work was supported by the European Commission's H2020 research and innovation program (project number: 826093) and the Research Council of Norway (grant 248150/O70). The funding bodies did not have any role in this study and the writing of the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: The modern management of chronic pain is largely focused on improving functional capacity (often despite ongoing pain) by using graded activation and exposure paradigms. However, many people with chronic pain find functional activation programs aversive, and dropout rates are high. Modern technologies such as virtual reality (VR) could provide a more enjoyable and less threatening way for people with chronic pain to engage in physical activity. Although VR has been successfully used for pain relief in acute and chronic pain settings, as well as to facilitate rehabilitation in conditions such as stroke and cerebral palsy, it is not known whether VR can also be used to improve functional outcomes in people with chronic pain.

Objective: This study aimed to assess the feasibility of conducting an adequately powered randomized controlled trial (RCT) to test the efficacy of VR in a chronic pain treatment center and assess the acceptability of an active VR treatment program for patients in this setting.

Methods: For this mixed methods pilot study, which was designed to test the feasibility and acceptability of the proposed study methods, 29 people seeking treatment for chronic pain were randomized to an active VR intervention or physiotherapy treatment as usual (TAU). The TAU group completed a 6-week waitlist before receiving standard treatment to act as a no-treatment control group. The VR intervention comprised twice-weekly immersive and embodied VR sessions using commercially available gaming software, which was selected to encourage movement. A total of 7 VR participants completed semistructured interviews to assess their perception of the intervention.

Results: Of the 99 patients referred to physiotherapy, 53 (54%) were eligible, 29 (29%) enrolled, and 17 (17%) completed the trial, indicating that running an adequately powered RCT in this setting would not be feasible. Despite this, those in the VR group showed greater improvements in activity levels, pain intensity, and pain interference and reported greater treatment satisfaction and perceived improvement than both the waitlist and TAU groups. Relative effect sizes were larger when VR was compared with the waitlist (range small to very large) and smaller when VR was compared with TAU (range none to medium). The qualitative analysis produced the following three themes: VR is an enjoyable alternative to traditional physiotherapy, VR has functional and psychological benefits despite continued pain, and a well-designed VR setup is important.

Conclusions: The active VR intervention in this study was highly acceptable to participants, produced favorable effects when compared with the waitlist, and showed similar outcomes as those of TAU. These findings suggest that a confirmatory RCT is warranted; however, substantial barriers to recruitment indicate that incentivizing participation and using a different treatment setting or running a multicenter trial are needed.

Introduction

Background

Chronic pain is a leading cause of disability worldwide and represents a significant burden to individuals, societies, and health care systems [1,2]. Virtual reality (VR) has been successfully used to supplement conventional care across diverse medical and rehabilitation settings, including stroke and cerebral palsy [3], and VR technologies are increasingly being used in pain treatment settings to provide pain relief and facilitate rehabilitation [4-6].

Within the field of pain, VR has been predominantly used in acute pain settings as a nonpharmacological approach to pain relief in people undergoing painful medical procedures such as needle insertion and burn care [7,8]. In addition, the past decade has seen growth in the use of VR in chronic pain settings, where studies have generally focused on using VR to provide immediate pain relief via distraction or relaxation [4,9-14]. These interventions typically involve participants being immersed in a pleasant and distracting setting in which they can interact with a simulated environment. For example, in a proof-of-principle study on 13 people with chronic pain, an immersive VR game designed to teach mindfulness-based stress reduction led to reductions in pain scores immediately after a 12-minute session [9]. In another study, 30 people with chronic pain played a VR game specifically designed for pain management, with results showing a reduction in pain scores during gameplay and from the pre- to posttreatment time points [12]. Similarly, a randomized controlled crossover study of 20 people with chronic pain found that an immersive VR game led to greater reductions in pain scores than the baseline and control conditions [10]. Despite representing a useful start, studies focusing on the application of VR for short-term pain relief have not assessed long-term outcomes. Although findings suggest that applications designed to be relaxing or distracting can provide immediate analgesia, whether this approach leads to sustained improvements in other pain outcomes is not known.

The successful management of chronic pain relies on maintaining or improving physical activity, often despite ongoing pain [15]. In addition to short-term pain relief, VR may be used as a tool to encourage healthy movement [16]. VR has been used to support functional rehabilitation for spinal cord injury [17], traumatic brain injury [18], Parkinson disease [19], stroke [20,21], and phantom limb pain [22]. In these contexts, VR has been used to help participants increase their range of movement using neuromodulation and exposure paradigms, and recent work has begun to explore whether these principles can also be applied to other chronic pain conditions. For example, in a well-designed feasibility study, 52 participants with chronic low back pain were randomized to either VR or no-treatment control [23]. The VR group played 15 minutes of virtual dodgeball, designed to gradually increase lumbar flexion

for 3 consecutive days. The results indicated that the VR group had greater increases in lumbar flexion during gameplay, with participants reporting a strong positive response to the game. Although there were no between-group differences in pain and functional outcomes 4 to 6 days after treatment, the authors attributed this to the brevity of the intervention, and a randomized controlled trial (RCT) testing the efficacy of a 9-week VR intervention is currently in progress [24].

In related work exploring whether VR can be used in chronic pain settings to encourage activity, 2 recent RCTs compared VR with physiotherapy treatment as usual (TAU) among people with chronic neck pain [25,26]. Both studies were based on 44 participants and administered VR interventions comprising 8 training sessions over 4 weeks. One of the studies used a game designed specifically to improve neck function [25], whereas the other used commercially available games [26]. Both studies reported pain-relevant outcomes immediately and at follow-up, with both reporting that the VR group showed at least equivalence to TAU across outcomes [25,26].

These studies suggest that VR can be used to encourage healthy movement using conditioning and exposure paradigms; however, to date, studies have typically focused on specific pain sites using targeted exercises [24-27], often with specifically designed health applications [23,25,28]. Although specifically designed games are appropriate in some treatment settings [28], there are also circumstances where commercially available games have advantages, which may be true for chronic pain treatment settings where people tend to present with widespread pain or pain in multiple sites. In many cases, general function and activities of daily living are more important therapeutic targets than training specific joints or muscle groups [29,30]. In these instances, commercially available VR games may be useful for supporting sustained behavior change and adherence to physical activity more broadly [31,32].

Overall, it seems likely that commercially available, immersive, and embodied games that encourage full-body movement may be a less threatening and more enjoyable way for people with diverse pain conditions to improve their general function. However, the authors are only aware of 1 pilot study that has tested this possibility. In this study, 16 veterans with chronic pain participated in daily VR sessions using commercially available VR games over a 3-week period. The authors reported improvements in kinesiophobia, pain intensity, pain catastrophizing, and pain-specific functioning in some participants [33]; however, whether this approach is also suitable for patient groups in clinical settings has not been examined. Moreover, the perspectives of end users have not been adequately assessed [28], and perceptions of whether commercially available VR games are considered an acceptable treatment option among people seeking treatment for chronic pain are not known.

Study Aims

This mixed methods pilot study aimed to test the planned methods and approach by identifying whether it would be feasible to conduct an active VR RCT in a hospital-based chronic pain treatment center and whether active VR treatment would be considered acceptable to patients in this setting. The criteria for feasibility were as follows: (1) 30 participants recruited within a 6-month time frame; (2) $\geq 70\%$ retention rate; and (3) effect sizes (ESs) for primary outcomes (pain intensity and interference) of ≥ 0.5 , indicating that a sample of approximately 60 participants per treatment arm would be sufficient to detect an effect [34]. The criteria for acceptability to patients were that (1) session rating scales for enjoyment are ≥ 6 on Likert scales ranging from 0 to 10; (2) treatment satisfaction and perceived improvement are ≥ 4 on Likert scales ranging from 0 to 7; (3) no serious adverse events or increases in pain specific to the VR treatment; (4) outcomes for VR are at least equivalent to TAU; and (5) interviews indicate that participants enjoy the VR treatment, find it beneficial, and believe that it is an acceptable and appropriate intervention for chronic pain rehabilitation.

Methods

Ethics Approval

Ethics approval was granted by the Health and Disability Ethics Committee (New Zealand Ministry of Health; HDEC ref 19/CEN/106), and locality approval was granted by the Auckland District Health Board in July 2019. The trial was registered with the Australian New Zealand Clinical Trials Registry (ACTRN12619001170112; universal trial number U1111-1234-0487). Eligible patients were given a written information sheet, an informed consent form, and instructions for accessing the study website. Those interested in participating were advised to access the study website where the information sheet and consent form were replicated, and informed consent was indicated by clicking a link at the end of the web-based consent form. This action opened the baseline questionnaire, and the completion of this questionnaire enrolled participants in the study. Eligible participants who expressed interest in the clinic but did not complete the baseline questionnaire were contacted via telephone to address any questions or concerns they may have had about the study. Participants were able to complete informed consent procedures and baseline questionnaires in the clinic in a separate appointment if they preferred.

Study Design

A mixed methods randomized pilot study was conducted with assessment points before and after 3 treatment arms to assess the feasibility and acceptability of a planned RCT, comparing an active VR intervention with a waitlist control and physiotherapy TAU.

Participants

The study took place at a hospital-based interdisciplinary chronic pain center, The Auckland Regional Pain Service (TARPS), Auckland District Health Board, New Zealand. Patients attending TARPS and referred to physiotherapy between

October 1, 2019, and November 30, 2020, were invited to participate. Inclusion criteria were having musculoskeletal pain, being aged 18 to 70 years, and being able to communicate in English. Participants were excluded if they had a severe medical or psychiatric condition, were receiving treatment for pain elsewhere, or if their health care was being funded by the Accident Compensation Corporation (New Zealand's accident compensation provider).

Procedures

Overview

Participants completed baseline questionnaires before being randomized using a web-based random number generator to either VR or waitlist followed by TAU. All participants wore activPAL activity monitors (PAL Technologies Ltd) and completed questionnaires at the start and end of each 6-week treatment period. Participants in the VR group completed session evaluations at each appointment, and 7 attended the semistructured interviews.

VR Intervention (Experimental Group)

Participants attended twice-weekly VR appointments for 6 weeks, supervised by a physiotherapist with 4 years of experience in using VR for chronic pain. The HTC Vive immersive VR system (HTC Corporation) was used with a head-mounted display and accompanying hand sensors. The VR software programs were run via a wall-mounted desktop display that allowed the physiotherapist to view the participant's visual field. Games that encouraged full-body movements were selected, and participants were guided to perform physically active tasks within the virtual environment and progressed through VR games at the discretion of the treating physiotherapist (Multimedia Appendix 1).

Waitlist

Patients assigned to TAU completed a 6-week no-intervention waitlist to act as a no-treatment control before receiving standard physiotherapy treatment. Outcome measures were completed before and after the waitlist period.

TAU Group

Following the 6-week waitlist, the participants attended 6 weeks of physiotherapy treatment with 1 of 2 physiotherapists, each with >10 years of experience working in this chronic pain treatment setting. Therapy included education related to pain neuroscience, fear avoidance, and deconditioning, and participants were given home-based exercise regimens and tailored gym-based activity programs focused on graded activation and exposure therapy.

Measures

Brief Pain Inventory

The Brief Pain Inventory (BPI) [35,36] measures pain intensity and interference on 11-point Likert scales. The BPI has adequate reliability and validity in populations with chronic pain [37] and is a recommended outcome measure for chronic pain clinical trials [38]. A 2-point reduction is considered the minimal clinically important difference (MCID) in pain intensity scores [38,39].

Kinesiophobia

The Tampa Scale of Kinesiophobia-13 (TSK-13) is a measure of fear of movement, injury, and reinjury [40,41]. Participants respond to items on 4-point Likert scales, with scores ranging from 13 to 52, with higher scores indicating greater fear of movement and (re)injury. The TSK-13 has sufficient reliability and validity in samples with chronic pain [42,43]. In this study, Cronbach α was .72, indicating adequate internal consistency. An 18% reduction in TSK-13 scores is considered an MCID [44].

Activity

Daily activity and step counts were collected using activPAL activity monitors during weeks 1 and 6 of VR, waitlist, and TAU. ActivPAL monitors have been validated in samples with chronic pain [45-46], and the average daily number of steps and activities (total minutes spent standing, walking, and cycling) were extracted.

Global Impression of Change

The Patient Global Impression of Change scale [47] is a single-item recommended pain outcome measure [38] of perceived improvement with treatment on a 7-point Likert scale ranging from 1 (*not at all improved*) to 7 (*very much improved*). Participants also indicated their satisfaction with treatment on a scale from 1 (*not at all satisfied*) to 7 (*very satisfied*).

Session Evaluation Questionnaire

Participants completed questionnaires at each VR treatment session to assess changes in pain intensity from the pre- to postsession time points, as well as the degree to which they found the VR session enjoyable and immersive, using 10-point Likert scales.

Semistructured Interviews

The qualitative component of this study was designed in accordance with the Critical Appraisal Skills Program (CASP) guidelines [48]. The first 7 participants to complete 8 VR treatment sessions attended 30 to 60-minute semistructured

interviews designed to assess their expectations and perceived usefulness of the VR intervention, changes in pain and function, and suggestions for improvement.

Data Analysis

Quantitative data were analyzed using SPSS (version 27). Baseline demographics and clinical characteristics were summarized using descriptive statistics (Table 1). Recruitment and retention rates, pain outcomes, enjoyment, and immersion scores were calculated. As this was a feasibility study, significance testing was not conducted. Instead, Hedges g relative ESs were used to estimate the necessary sample sizes for an RCT using G*Power software, with an α of .05 and power of 0.80. Ratings of pain, enjoyment, and immersion collected at the end of each VR session were averaged across the total number of attended sessions to create mean pain change, enjoyment, and immersion scores.

For qualitative data, interviews were transcribed and analyzed using reflexive thematic analysis [49,50] by a member of the research team (CW), with support from 2 additional team members (NT and DB). The 5 steps of reflexive thematic analysis were followed, where phase 1 (familiarization) involved reading and rereading the data while taking notes on features of interest. In phase 2, data were coded by applying brief unique labels to all quotes that appeared relevant to the research question. For phase 3, initial themes were generated by grouping quotes with similar codes and examining the resulting sets of quotes. In phase 4, 3 themes were developed and reviewed by looking at how each code fit with the proposed theme, the data supporting each code and theme, and the degree to which each theme helped answer the research question. Finally, in phase 5, 3 themes were named and defined. As noted earlier, qualitative analysis was conducted primarily by CW, a female physiotherapy student with training in reflexive thematic analysis. Qualitative analysis was supported by NT and DB, both of whom have PhDs in health psychology and prior experience working in an interdisciplinary pain center. Both NT and DB currently hold positions as senior research fellows, with training in reflexive thematic analysis.

Results

Quantitative Results

Recruitment and Retention

Between October 1, 2019, and November 30, 2020, a total of 99 non–Accident Compensation Corporation patients were assessed at TARPS and referred to physiotherapy. Of these 99 patients, 53 (54%) met the inclusion criteria, and 29 (29%) were enrolled in the study. Of the 29 patients, 13 withdrew ($n=5$ from the VR group, and $n=4$ from each of the waitlist and TAU groups), resulting in a final sample of 20 participants, of whom 10 were in the VR group, 10 in the waitlist group, and 6 in the TAU group. The recruitment rate of 2 participants per month, as well as the dropout rate of 45%, indicated that it would not

be feasible to recruit approximately 60 participants per trial arm in this clinical setting.

Intervention Parameters

All participants in the VR arm completed ≥ 7 appointments, and 30% (3/10) completed 12 appointments. There were no adverse events or increases in pain specific to the VR intervention. Immersion scores ranged from 8.4 to 9.6, and enjoyment scores ranged from 8.0 to 9.9, thereby meeting the acceptability criteria.

Pain Intensity and Interference (BPI)

There were medium ESs favoring VR over the waitlist for a reduction in BPI pain intensity ($ES=0.52$) and BPI pain interference ($ES=0.50$). This suggests that for an α of .05, and a power of 0.80, a sample of 60 and 64 per group would be sufficient to detect significant effects for pain intensity and interference, respectively (Table 2).

Table 2. Mean change scores and relative effect sizes for pain-relevant outcomes, perceived improvement, and satisfaction with treatment.

Outcomes	Waitlist (n=10)		TAU ^a (n=6)		VR ^b (n=10)		VR versus waitlist, effect size (95% CI)	VR versus TAU, effect size (95% CI)
	Participants, n (%) ^c	Values, mean (SD)	Participants, n (%) ^c	Values, mean (SD)	Participants, n (%) ^c	Values, mean (SD)		
Δ BPI ^d intensity	10 (100)	-0.30 (1.57)	6 (100)	-0.17 (2.32)	9 (90)	-1.00 (0.87)	-0.52 (-1.39 to 0.67)	-0.49 (-1.47 to 0.51)
Δ BPI interference	10 (100)	-1.10 (2.13)	6 (100)	-1.00 (1.39)	9 (90)	-2.06 (1.46)	-0.50 (-1.37 to 0.39)	-0.70 (-1.70 to 0.32)
Δ TSK-13 ^e	10 (100)	-2.90 (5.17)	6 (100)	-4.00 (4.56)	9 (90)	-1.56 (5.57)	0.24 (-0.63 to 1.10)	0.44 (-0.55 to 1.42)
Change in daily steps	7 (70)	212 (2394)	6 (100)	1127 (2784)	8 (80)	852 (2934)	0.22 (-0.74 to 1.18)	-0.09 (-1.08 to 0.90)
Change in daily activity (minutes)	7 (70)	2.15 (59.03)	6 (100)	-21.05 (91.49)	8 (80)	19.45 (64.50)	0.26 (-0.70 to 1.22)	0.49 (-0.52 to 1.49)

Kinesiophobia

Small ESs favored the waitlist over VR ($ES=0.24$) and TAU over VR ($ES=0.44$). None of the groups met the criteria for MCID in kinesiophobia change scores ($\geq 18\%$ reduction; Table 2) [44].

Step Counts and Activity (Minutes Spent Standing, Walking, and Cycling)

There were small ESs favoring VR over the waitlist for both step count ($ES=0.22$) and activity scores ($ES=0.26$). Both VR and TAU met the criteria for an MCID in daily step counts (≥ 600 -1100 step increase; Table 2) [51].

Treatment Satisfaction and Global Impression of Change

There were very large ESs favoring VR over the waitlist for treatment satisfaction ($ES=1.18$) and perceived improvement ($ES=1.31$) and small ESs favoring VR over TAU for treatment satisfaction ($ES=0.28$) and perceived improvement ($ES=0.24$; Table 2).

Qualitative Results

Analysis of the transcribed interviews generated three themes: (1) VR is an enjoyable alternative to traditional physiotherapy, (2) VR leads to functional and psychological benefits despite continued pain, and (3) the importance of a well-designed VR setup.

Theme 1: VR Is an Enjoyable Alternative to Traditional Physiotherapy

Participants were enthusiastic about trying VR rehabilitation and had positive expectations of treatment; for example, one of the participants said the following:

I had really high hopes...I thought it might actually take my pain away [Male, 51 years, Fijian-Indian, chest and shoulder pain]

Participants also described VR as more enjoyable, accessible, and achievable than their previous experiences of physiotherapy and described VR as *fun* and *exciting*:

It's a really good way to incorporate fun activity into your life on a regular basis. And for someone who struggles to find the mental and physical energy to do anything like that, it's a really good pull to get you up. [Female, 25 years, European, back pain]

Participants also described VR as improving activity levels by distracting them from pain. Several participants described VR as *brain training* and believed that taking part in the VR treatment changed the way that their nervous system processed pain:

By doing a movement and not having that immediate thought that it's going to hurt, it's already training my brain so that it doesn't go—nope you're not doing that!—and then sending pain signals everywhere. [Female, 23 years, European, pelvic pain]

Despite the perceived benefits, some participants expressed uncertainty about whether VR could be considered a legitimate treatment. They explained that the enjoyable nature of VR was inconsistent with their expectations of physiotherapy:

With VR you don't really feel like it's treatment...you have an expectation that when you go to [physical therapy] they give you exercises or manual treatment so when you leave it feels like you've done something. But when you're doing VR, I don't feel like I've necessarily achieved any treatment. [Female, 21 years, European, hip pain]

Overall, the participants had positive expectations about VR, the rationale for VR treatment was clear to them, and they found VR to be highly agreeable. For some participants, the enjoyable nature of VR meant that it did not feel like a legitimate treatment approach.

Theme 2: Functional and Psychological Benefits Despite Continued Pain

Participants said that they experienced pain relief during the VR sessions; however, this was not sustained after treatment. Despite ongoing pain, participants reported an overall increase in daily physical activity, improved strength, reduced stiffness, improvements in sitting and standing tolerances, and greater confidence in engaging in activities of daily living. Participants said that VR changed their perspectives of activity from something unpleasant and difficult to something that could be enjoyable:

It helped me understand that I can move and do more activity. I can go for a walk outside and enjoy it and not have to focus on being in pain all the time. So, I think it just made me realise that that was actually an option. [Female, 21 years, European, hip pain]

The participants also felt that the VR sessions improved their moods. They described feeling happier and more content following the sessions and explained that VR provided relief from daily stressors and an opportunity to do something enjoyable:

Mentality wise, it made a big difference. I looked forward to coming to the VR sessions. I'd be like—yeah, I've got this pain but at least something's happening, and I have fun when I'm there. [Female, 23 years, European, pelvic pain]

Overall, participants described the intervention as having a positive impact on their mood and function and reported increased confidence in participating in physical activities despite continued pain.

Theme 3: The Importance of a Well-Designed VR Setup

Most participants found the VR equipment easy to use and the games straightforward to understand and play. The exceptions were those whose first language was not English and who described difficulties in understanding game instructions. Participants emphasized the importance of a comfortable and adjustable headset, and the physical space was considered important, with all participants feeling constrained by the size of the room. There were a range of opinions regarding the importance of having a trained physiotherapist deliver the VR; however, all participants highlighted the importance of being supervised by someone with whom they could form a therapeutic alliance:

I think it makes you feel better that it's a trained physiotherapist. You knew they had that background and it just fills you with confidence a bit more. [Female, 64 years, European, back pain]

Overall, this theme demonstrates the importance of investing in a good-quality VR setup that participants can use easily and comfortably in a safe and supervised environment and the value of developing a strong therapeutic relationship.

Discussion

Principal Findings

This mixed methods pilot study assessed the acceptability and feasibility of a VR RCT in a hospital-based chronic pain treatment center. The findings indicated that the VR intervention was highly acceptable to patients, with session rating scores, treatment satisfaction, and perceived improvement all surpassing the a priori acceptability criteria. Those in the VR treatment showed improvements in pain intensity, pain interference, step counts, and activity scores, with preliminary findings suggesting that VR may be superior to no treatment and equivalent to TAU. Qualitative data supported the quantitative findings and indicated that participants enjoyed the VR treatment and found it beneficial.

Despite the benefits, poor recruitment and high dropout rates suggest that it would not be feasible to conduct an adequately powered RCT in this setting. ESs for primary outcomes in this study indicate that a reasonable sample size of approximately 60 per group (power=0.80) would be adequate to detect effects. These ESs are consistent with recommended ESs for motor interventions [34] and comparable with another VR RCT currently in progress [24]; however, the recruitment rate of approximately 2 participants per month means that an adequately powered RCT would not be feasible. In addition, any future RCT assessing multiple pain-relevant outcomes would need to carefully select the most relevant outcome measures and correct for the family-wise error rate. Attrition was higher than expected, with approximately 45% of enrolled participants withdrawing from the study. Similar rates of withdrawal across all treatment arms suggest that attrition was not specific to the treatment, with the most frequently cited reasons for withdrawal being (1) comorbid mental health problems, (2) inability to attend regular appointments, and (3) loss of contact following SARS-COV-2 lockdowns. High attrition is common in chronic pain settings [11], and future work may benefit from encouraging participation by offering treatment in community settings, ensuring adequate parking, and providing transportation and remuneration for attendance. Finally, although the findings suggest that the involvement of a qualified physiotherapist is important, remotely delivered VR therapies have shown promise [11], and future RCTs may benefit from adapting active VR treatments for home use.

Comparison With Prior Work

Most prior studies exploring the role of VR in chronic pain have focused on specifically designed health applications [23,25], targeted singular pain sites [26], or tested the efficacy of VR among veterans with chronic pain [33]. This is the first study to assess the feasibility of conducting an RCT that tests whether commercially available active VR games may improve outcomes among people attending a tertiary-level chronic pain treatment center. Consistent with previous studies [23], high levels of engagement and treatment satisfaction were reported, and the findings suggest that active VR may be equivalent to standard physiotherapy [25,26]. When considering potential mechanisms, it has been hypothesized that VR might improve functional outcomes by reducing kinesiophobia, and prior work has documented reductions in kinesiophobia following VR interventions [26,33,52]. However, our findings did not support this hypothesis. Instead, qualitative data suggest that increases in general well-being and pain self-efficacy are more likely mechanisms. Positive mood states may be a protective factor in chronic pain [53,54], and a previous study has shown that a VR intervention among people with fibromyalgia led to improvements in general mood state, positive emotions, motivation, and self-efficacy [55]. Future RCTs may benefit from the inclusion of measures of pain self-efficacy [56] along with positive affect, sleep, and other pain-relevant quality of life measures to identify the mechanisms by which VR interventions improve chronic pain outcomes.

When considering game design and selection, commercially available games were used for this pilot study because of their benefits in terms of access, convenience, and cost. Using

commercially available games in chronic pain rehabilitation also makes theoretical sense, as when pain is attributed to nociceptive mechanisms, the key interventional targets are general physical activity, stress reduction, and pain self-management [57] rather than focusing on specific movements, muscles, or joints. Despite the benefits of using specifically designed apps in some health settings [28,56], games that target specific pain sites, such as neck pain or back pain, would only be suitable for a subset of people attending chronic pain treatment centers, whereas commercially available games are more likely to be applicable to people with a range of pain conditions and pain sites and varying degrees of functional impairment. In addition, commercially available games appear to be at least equivalent to conventional therapy in diverse physical rehabilitation settings [32]. Overall, whether commercially available or specifically designed games are used, it is important that games are developed using fundamental design principles of reward, goals, challenge, and meaningful play [58], and it seems likely that combining active VR treatment with other established interventions such as pain neuroscience education, as well as strategies to downregulate autonomic arousal, may strengthen the positive effects of VR in chronic pain management and enhance our understanding of how VR can supplement conventional care.

Limitations

This study had several limitations. Primarily, comparing active VR with a no-treatment control and physiotherapy TAU allowed for comparisons between active VR and standard physiotherapy-led activity programs but did not provide insight into the most salient elements of VR or gaming interventions. Future work administering an active non-VR control, such as computer-based games using similar movements but without a head-mounted display, or comparing active VR with passive VR treatments that facilitate downregulation of autonomic arousal, would help to clarify the unique benefits specific to immersive, embodied, and active VR protocols over and above other VR and gaming platforms. Furthermore, this study deviates from a standard 3-arm trial design as, for practical purposes (given the small pool of participants), a single group covered 2 intervention arms (waitlist and TAU). Future work would benefit from recruiting separate groups of participants for the TAU and no-treatment arms. In addition, it is likely that patients interested in VR would have self-selected for the trial and potentially overreported the perceived benefits. Another limitation is that session rating scales were not collected in the TAU arm, meaning that between-group comparisons for session enjoyment and changes in pain scores immediately after treatment could not be made and that VR and TAU were delivered at different doses, with VR offered twice weekly and TAU delivered once weekly; thus, it is not known whether VR delivered at the same dose of TAU would have produced the benefits seen here. Finally, end users were not consulted in the study design phase, and future RCTs would benefit from engaging in a co-design process.

Conclusions

Despite these limitations, this mixed methods pilot study indicates that active VR is an acceptable treatment for patients

attending a tertiary-level chronic pain treatment center. Qualitative data suggest that participants enjoyed the VR treatment, found it beneficial, and believed that it was an acceptable component of chronic pain rehabilitation. Although outcomes for VR in this pilot study were superior to no treatment, and appeared to be at least equivalent to standard physiotherapy, these findings should only be interpreted as a basis for designing future adequately powered clinical trials. In particular, the finding that the ESs comparing VR with standard treatment were generally small suggests that there may not be clinically meaningful differences between these groups in a larger trial. Despite this, an adequately powered RCT appears justified as, if equivalence is found, then VR may be a useful

adjunct or alternative to standard treatment for some people with chronic pain. Although a future RCT is warranted, low recruitment and poor retention rates indicate that this would not be feasible in the present setting. Future RCTs would benefit from incentivizing study participation and actively reducing dropout rates while considering a broader range of outcome measures to identify likely mechanisms. VR technology is increasingly affordable and accessible and may improve chronic pain outcomes by encouraging participation in activities in a novel and enjoyable way. Adequately powered RCTs with long-term follow-ups examining the recommended pain-relevant outcomes and potential mechanisms of action are warranted.

Abstract

Background: COVID-19 vaccines are vital tools in the defense against infection and serious disease due to SARS-CoV-2. There are many challenges to implementing mass vaccination campaigns for large, diverse populations from crafting vaccine promotion messages to reaching individuals in a timely and effective manner. During this unprecedented period, with COVID-19 mass vaccination campaigns essential for protecting vulnerable patient populations and attaining herd immunity, health care systems were faced with the dual challenges of vaccine outreach and distribution.

Objective: The aim of this cross-sectional study was to assess the effectiveness of a COVID-19 vaccine text outreach approach for patients aged 65 years and older. Our goal was to determine whether this approach was successful in scheduling patients for COVID-19 vaccine appointments.

Methods: We developed SMS text messages using the Tavoca platform. These messages informed patients of their vaccine eligibility and allowed them to indicate their interest in scheduling an appointment via a specific method (email or phone) or indicate their lack of interest in the vaccine. We tracked the status of these messages and how patients responded. Messages were sent to patients aged 65 years and older (N=30,826) at a nonprofit health care system in Washington, DC. Data were collected and examined from January 14 to May 10, 2021. Data were analyzed using multivariate multinomial and binary logistic regression models in SAS (version 9.4; SAS Institute Inc).

Results: Approximately 57% of text messages were delivered to patients, but many messages received no response from patients (40%). Additionally, 42.1% (12,978/30,826) of messages were not delivered. Of the patients who expressed interest in the vaccine (2938/30,826, 9.5%), Black or African American patients preferred a phone call rather than an email for scheduling their appointment (odds ratio [OR] 1.69, 95% CI 1.29-2.21) compared to White patients. Patients aged 70-74 years were more likely to schedule an appointment (OR 1.38, 95% CI 1.01-1.89) than those aged 65-69 years, and Black or African American patients were more likely to schedule an appointment (OR 2.90, 95% CI 1.72-4.91) than White patients.

Conclusions: This study provides insights into some advantages and challenges of using a text messaging vaccine outreach for patients aged 65 years and older. Lessons learned from this vaccine campaign underscore the importance of using multiple outreach methods and sharing of patient vaccination status between health systems, along with a patient-centered approach to address vaccine hesitancy and access issues.

Introduction

Authorization of the emergency use of COVID-19 vaccines, which were developed and tested in record time, was a seminal moment in efforts to control the COVID-19 pandemic [1]. These vaccines are vital tools in the prevention of infection and serious disease from SARS-CoV-2, and COVID-19 mass vaccination campaigns have been essential for protecting vulnerable patient populations and achieving herd immunity. Launching these vaccination campaigns has been challenging for several reasons related to logistical issues of producing, storing, and transporting vaccines, and patient-level factors such as vaccine access and vaccine hesitancy [2-5]. Health care systems were starting points for vaccination campaigns given their direct access to patient populations and having the personnel and resources to store vaccines and vaccinate patients. However, the COVID-19 vaccination effort was unprecedented in its scale, and many health care systems across the United States were faced with challenges of outreach, equity, scheduling, and administration.

With no blueprint for this type of vaccination campaign, health care systems—particularly those with large diverse patient populations—had to quickly design and launch outreach efforts to patients [2]. These efforts were further complicated by ongoing challenges with patient distrust of medical institutions, vaccine hesitancy and access barriers, and interoperability of health record databases [3,6]. Outreach to patients was complicated by out-of-date or incorrect demographic information, which was necessary for determining vaccine eligibility of each patient. Other complications included the absence of coordination between adjacent health care systems, as patients had the opportunity to be vaccinated at other health

care sites, but these vaccination records were not shared among health care systems.

Reflecting on these challenges, this cross-sectional study used a not-for-profit health system as a case study to examine the intersection of health information technology and health disparities in vaccine outreach efforts. The focus of this study was on patients aged 65 years and older as they were among the first to be eligible for the COVID-19 vaccine. Additionally, patients in this age group may face additional challenges to vaccination, such as complicated medical conditions, transportation needs, and reliance on caregivers to assist with medical decision-making [7]. Findings from this study generated important lessons learned for ongoing efforts to increase COVID-19 vaccination rates among patients aged 65 years and older.

Methods

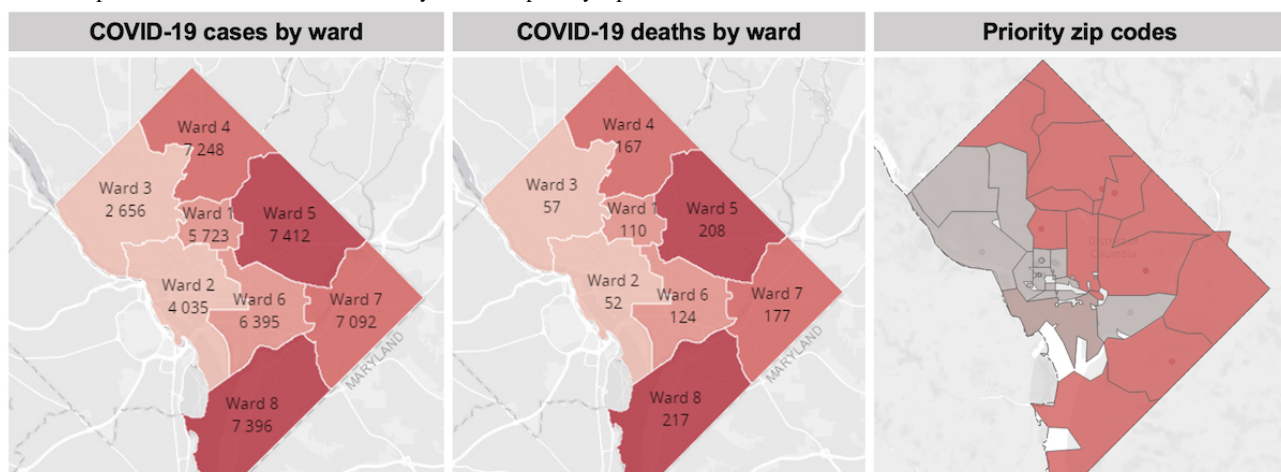

Study Site

This study took place in a not-for-profit health system with 10 hospitals, over 280 outpatient clinics, and nearly 2 million patients in the mid-Atlantic region of the United States.

Target Population

For this study, COVID-19 vaccine outreach to patients in the Washington, DC catchment area was examined. In Washington, DC, the local health department prioritized patients aged 65 years and older in the initial rollout of the vaccine to the public [8,9]. Additionally, certain zip codes were prioritized for outreach efforts based on the disproportionate impact of COVID-19 in terms of morbidity and mortality rates. A side-by-side comparison of priority zip codes with COVID-19 cases and deaths is presented in Figure 1.

Figure 1. Maps of COVID-19 cases and deaths by ward and priority zip codes for vaccination.

Similar to nationwide trends, COVID-19 cases and deaths were concentrated in areas with greater proportions of racial or ethnic minorities and low-socioeconomic-status populations in Washington, DC. Four health systems in the region, the local health department, and local community organizations (eg, faith-based and nonprofit organizations) conducted outreach to residents in priority zip codes, including virtual webinars and

door-to-door canvassing for the purpose of answering questions and concerns about the COVID-19 vaccines [10].

Study Population

The health system serves approximately 45,000 Washington, DC residents aged 65 years and older, which required a large-scale outreach operation to contact, screen, and schedule these patients for vaccination. It is important to note that local policy at the time permitted health systems to only vaccinate

patients who had previously been served by the health system. Information on whether a patient was vaccinated at a different facility was unavailable.

Inclusion and Exclusion Criteria

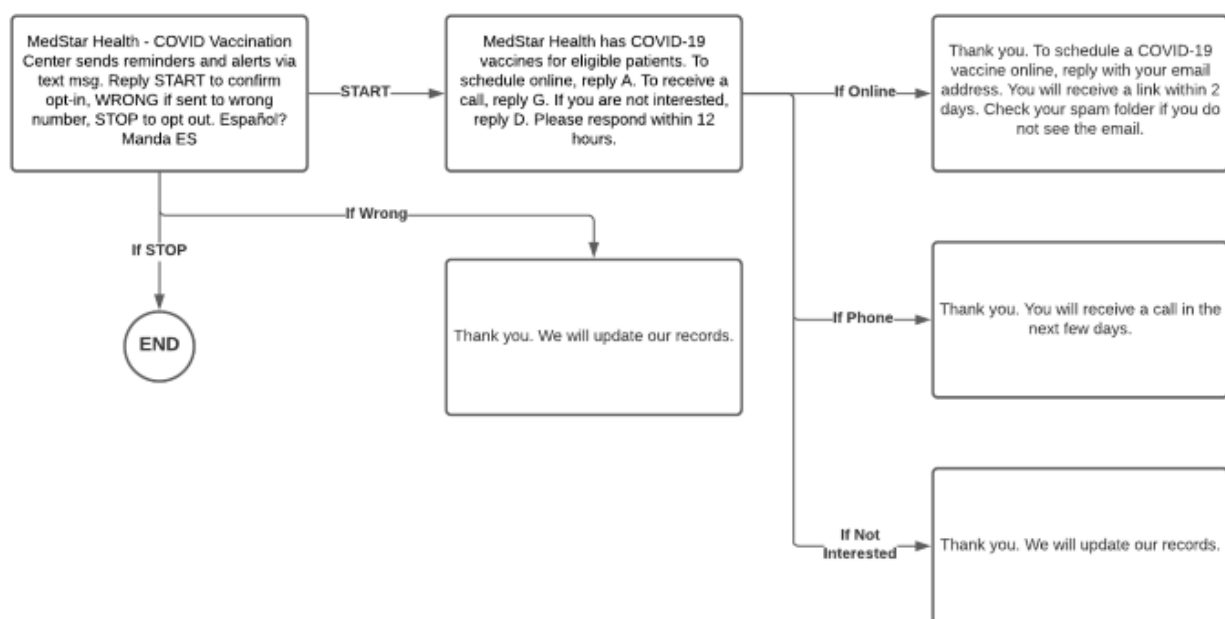

Eligibility was limited to patients aged 65 years and older with a Washington, DC address per local health department vaccination guidelines. Patients who had been seen at any of the health system facilities in the last 5 years were contacted about the COVID-19 vaccine.

Text Message Vaccine Outreach

During the initial phase of outreach, a dedicated call center contacted patients who met vaccine eligibility criteria. Operators were only able to speak to 41% (1093/2670) of patients

contacted, and only 42% (458/1093) of connected calls resulted in scheduled appointments. Thus, only 17% of total calls resulted in a scheduled appointment. Given the relatively slow pace and resource-intensiveness of this approach, a transition was made to an automated text messaging and follow-up strategy, in which patients were sent a text message informing them that they were eligible to receive the vaccine and asking if they were interested in scheduling an appointment. The text messaging platform, Tavoca, was used to create message templates informing patients of their vaccine eligibility and allowing them to indicate their interest in scheduling via a specific method (email or phone) or indicate their lack of interest in the vaccine. Text messages were drafted on the basis of character limits of the Tavoca platform, and the text sequence is shown in [Figure 2](#).

Figure 2. Text messaging flow.

Batches of text messages were sent on the basis of a prioritization algorithm that ranked patients by age and priority zip code, starting with the oldest patients in priority zip codes and then patients in nonpriority zip codes. Patients who indicated they were interested in the vaccine were asked which communication platform they preferred (phone or email), and depending on their response, they were referred to a call center or a web-based scheduling system. There was a high volume of messages not delivered owing to phone numbers no longer being in operation and some being landlines, which do not accept text messages.

Data Collection and Management

Patient information was extracted from the electronic health record and scheduling systems. Data were extracted and

analyzed from January 14 to May 10, 2021. During this stage of the vaccine rollout, only the Pfizer and Moderna COVID-19 vaccines were available to patients. For this analysis, patients who shared the same phone number ($n=14,419$) were excluded, as there was no way to accurately determine which of the multiple patients associated with one phone number responded to the text message ([Table 1](#)). Confirmed text messaging interaction data were available for 30,826 patients who had unique phone numbers, which were analyzed for this study ([Table 1](#)). The demographic characteristics of the excluded patients were similar to those of the patients included in the study sample.

Table 1. Demographic Information for excluded patients (N=14,419) and study participants (N=30,826).

Characteristics	Excluded patients, n (%)	Study participants, n (%)
Sex		
Female	8224 (57.0)	18,399 (59.7)
Male	6181 (42.8)	12,427 (40.3)

Yes	744 (5.1)	239 (0.77)
No	13,675 (94.8)	30,587 (99.2)
Dose 2 received		
Yes	643 (4.4)	232 (0.75)
No	13,776 (95.5)	30,594 (99.2)

Independent Variables

A total of 7 independent variables related to patient demographics and health system utilization in this study. Demographic variables included residing in a priority zip code (priority=1 and nonpriority=0), binary variables for each racial or ethnic group (Black or African American, Hispanic, Asian, White, and other), binary variables for each age group (65-69 years, 70-74 years, 75-79 years, 80-84 years, 85-89 years, and >90 years), and sex (male=1, female=0). Health system utilization variables included having a primary care provider (yes=1, no=0) and total visits in the past 5 years (continuous). A series of interaction variables were created for priority zip code and age and for priority zip codes and race or ethnicity.

Outcome Variables

There were 4 primary outcome variables of interest. The first outcome variable was the status of the initial text message sent to patients: 1=delivered and interested in vaccine; 2=delivered and no response; 3=delivered and not interested in the vaccine; and 4=not delivered (number belongs to a landline or is no longer in operation). Among patients who expressed interest in

the COVID-19 vaccine, the preferred communication method for scheduling the vaccine appointment (phone=1, email=0) and if an appointment was scheduled (scheduled=1, not scheduled=0) were assessed.

Statistical Analysis

First, descriptive statistics were assessed to determine sample characteristics. Next, multivariate regression models were used to assess the association between patient demographics (priority zip codes, race or ethnicity, age, and sex) and outcomes of interest. Multivariate multinomial regression models were used for the first outcome of interest (text message status) and multivariate logistic regression for the other outcomes (preferred communication method and appointment scheduled). It was not possible to analyze vaccine uptake in this study owing to sample size limitations. Data were analyzed using SAS (version 9.4; SAS Institute Inc).

Ethics Approval

This study received approval from the institutional review board of MedStar Health Research Institute (STUDY00002197).

Results

Sample Characteristics

Demographic information on study patients is detailed in [Multimedia Appendix 1](#). The majority of patients (24,211/30,826, 78.5%) live in a priority zip code, which implies that there is high COVID-19 morbidity and mortality, 59.7% (18,399/30,826) of participants are female, and 62.8% (19,372/30,826) of participants are Black or African American. Further, 57% (17,848/30,826) of text messages were delivered to patients and 42.1% (12,978/30,826) of messages were not delivered (number belongs to a landline or is no longer in operation). Of the messages that were delivered, 40% (12,333/17,848) received no response. A few patients (2,938/17,848, 9.5%) expressed interest in getting the COVID-19 vaccine. Among patients who expressed interest in the vaccine, only 253 scheduled an appointment. A majority of patients who scheduled an appointment completed their first (214/226, 87.5%) and second (207/226, 80%) vaccine doses.

Regression Models

First, differences among the 4 status options for the initial text message sent to patients were examined: interested in the vaccine, not interested in the vaccine, no response, and text message not delivered ([Table 2](#)). Notable findings include patients residing in priority zip codes who were more likely to “not respond” (odds ratio [OR] 1.19, 95% CI 1.12-1.27) than for message “not delivered” in comparison with patients living in nonpriority zip codes. In models that included age, among patients aged 70 years and older, the message was more likely to not be delivered than for there to be patient engagement with the message. Black or African American patients were less

likely to be interested rather than not having received the message in comparison to White patients. Asian and Hispanic patients were more likely to not respond rather than not having received the message in comparison to White patients. Patients with a primary care provider were more likely to be interested rather than not having received the message in comparison to patients without a primary care provider.

Next, the preferred communication platform for scheduling an appointment among patients interested in the vaccine was assessed ([Table 3](#)). Patients living in priority zip codes were more likely to prefer a phone call (OR 1.43, 95% CI 1.15-1.78) than those living in a nonpriority zip code. These results remained the same with the addition of other independent variables in the models. Preference for a phone call was more likely among patients aged 70-74 years (OR 1.33, 95% CI 1.08-1.64) and those aged 80-84 years (OR 1.82, 95% CI 1.17-2.83) than among those aged 65-69 years, and among Black or African American patients (OR 1.69, 95% CI 1.29-2.21) than among White patients. Regarding the interaction effects, patients living in priority zip codes and those aged 75-79 years were significantly less likely to prefer a phone call (OR 0.40, 95% CI 0.20-0.81) than those aged 65-69 years and living in a priority zip code.

Finally, scheduled visits among patients who expressed an interest in being vaccinated were examined ([Table 4](#)). Patients aged 70-74 years were more likely to schedule an appointment (OR 1.38, 95% CI 1.01-1.89) than those aged 65-69 years, and Black or African American patients were more likely to schedule an appointment (OR 2.90, 95% CI 1.72-4.91) than White patients. Interaction variables could not be examined in these models given the small sample size.

Discussion

Principal Findings

Our findings highlight important considerations for large health systems attempting to use text messaging for effective and efficient vaccination outreach for diverse patient populations. Many text messages were not delivered (12,978/30,826, 42.1%) and of the messages that were delivered, 40% received no response. A small percentage of patients expressed interest in the vaccine (2938/30,826, 9.5%). Among patients who expressed interest in being vaccinated, it was found that patients largely preferred a phone call over email for scheduling their vaccine appointment. Of the patients contacted to schedule an appointment, 70-74-year-old patients were more likely to schedule an appointment than 65-69-year-old patients, and Black or African American patients were more likely to schedule an appointment than White patients.

These results reflect several key challenges. The first challenge was the verification of patient information and ascertaining whether a listed number was a landline or mobile number. Given the large number of text messages not delivered (n=12,978), a mechanism to validate these numbers is needed. In addition, a mechanism to update and clearly designate a number as a mobile number in the electronic health record is critical. Second, based on the selected outreach preference (phone) by those who were successfully contacted, it is critical to leverage nontext outreach methods for effective engagement of some populations. This

finding may reflect comfort levels with technology among patients aged 65 years and older related to using a phone or computer to schedule an appointment. As patients had opportunities to be vaccinated elsewhere, it would be imprudent to draw any conclusions about why certain patient groups were more likely to schedule an appointment than others.

Comparison With Other Studies

Results from another study that examined a COVID-19 vaccination text message outreach to older patients found that reminder messages and messages that instilled ownership in patients led to increased scheduling of appointments and vaccination rates [10]. The findings from this study reflect how messaging protocols and how messages are written influence patient responsiveness to text message outreach. A study with older patient populations in Italy found that vaccine passports influenced patient receptiveness to being vaccinated, as the vaccination card allowed them to access to public spaces [11]. Policies around vaccination status may have shaped patient decision-making regarding vaccine uptake in the United States as well.

Implications of Study Findings

There are important lessons learned from this vaccination effort, which most health care systems undertook with no prior knowledge of how to execute this monumental task. The first one is the importance of accurate and updated patient contact information, particularly as it impacts effective outreach modalities. The second one is identifying patient preferences

for communication to increase the likelihood of engagement. The third one is the need for interoperability of patient health records to triangulate patient touch points with other health systems and services. This ensures patient health records are up to date, and finite outreach resources are focused on priority groups. The final lesson is establishing strong relationships with neighboring health systems and government agencies for the purpose of coordinating outreach efforts and sharing pertinent patient data with each other. The COVID-19 vaccination campaign is still underway in the United States, and health systems need to be nimble and flexible in reaching out to patients, including nondigital efforts such as provider-patient communication, and partnering with community-based organizations to reach vulnerable patients.

Limitations

There are several strengths and limitations to this study. A strength is the use of real-time patient data, which allowed capture and analysis of text outreach data linked to patient health records. This study provides critical data on digital outreach efforts as part of the COVID-19 vaccination campaign, which has important implications for local, regional, state, and national vaccination efforts. However, there are some limitations. First, 14,419 patients were excluded owing to shared phone numbers. The excluded patients had a similar demographic background as the study sample (Table 1). Second, it was not possible to verify if the patients received a COVID-19 vaccine outside of the study site.

Conclusions

The United States has made significant strides in vaccinating Americans aged 65 years and older through a combination of

digital outreach efforts, community-based vaccine clinics, and at-home visits. This study highlights the benefits and challenges of using text messaging outreach methods, specifically the ability to reach large numbers of patients quickly. While the majority of Americans aged 65 years and older have been fully vaccinated (87.1%-92.7%), younger Americans aged 18-39 years are lagging behind in vaccination rates [12,13]. Emerging data have shown disparities by geographic location with lower vaccination rates in rural areas and differences by patient demographics (eg, education level and political beliefs) [14,15]. Guidelines regarding booster vaccines to protect against new variants will require expanded and ongoing outreach efforts to eligible patients. Reaching these populations will require multiple outreach methods (eg, texting, email, phone calls, and community vaccine clinics) designed to address vaccine hesitancy and access issues. These last 2 points necessitate partnering with trusted figures in the community to encourage vaccination (eg, faith-based and community leaders), providers respectfully and empathetically answering patient questions about the vaccine, health care systems and medical institutions building relationships with community members, and making it easy and simple to get vaccinated through expanded vaccination locations with flexible operating hours [4]. Furthermore, sharing of patients' vaccination statuses among health systems is integral to ensuring that outreach efforts are focused on unvaccinated individuals and individuals eligible for a booster. Coordination among health care systems, partnerships with and input from community leaders and members, and persistence are key elements to increasing COVID-19 vaccine uptake.

Abstract

Background: Early childhood is a critical period for supporting the development of healthy eating habits, which may affect lifelong health. Childcare services are important settings for promoting early childhood nutrition; however, food provision in childcare frequently does not align with dietary guidelines. Web-based menu planning tools are well suited to support healthy food provision in childcare, although little is known about their use. Research is needed to understand how web-based menu planning tools are used in the childcare setting and how they can effectively support healthy menu planning and food provision for children in childcare.

Objective: We aimed to explore the use of a web-based menu planning tool called *FoodChecker*, which is available to childcare services in Victoria, Australia. We also aimed to gain insights and perspectives from childcare staff involved in menu planning about their use of the tool to plan healthy menus and guide healthy food provision for children.

Methods: We conducted a qualitative descriptive study using a cross-sectional web-based survey completed by the staff involved in menu planning in childcare services. Thematic analysis was performed using NVivo software. Emergent themes were mapped against constructs of the Technology Acceptance Model regarding perceived usefulness, perceived ease of use, and external variables influencing perceptions and use.

Results: The participants included 30 cooks and 34 directors from 53 childcare services. Participants perceived the web-based menu planning tool as useful for supporting child nutrition and health, improving organizational processes, and aiding the menu planner role. Perceptions regarding ease of use were mixed. External variables influencing perceptions and use included awareness of the tool, perceived need, time, resources, organizational support, and the food budget. Participants made recommendations to improve the tool, particularly the need to integrate functionality to make it easier and faster to use or to include more links to resources to support healthy menu planning.

Conclusions: The web-based menu planning tool was perceived as useful for cooks and directors in childcare services. Areas for improvement were identified; for example, the need for integrated digital features to make the tool easier and faster to use. As the first qualitative study to explore childcare staff experiences with a web-based menu planning tool, these findings inform future research and development of such tools to aid scalable and sustainable support for healthier food provision in the childcare sector.

Introduction

Background

Early childhood (commonly defined as 0-5 years) is a critical period for supporting the development of healthy eating habits that may track into later life [1]. An unhealthy diet during childhood is associated with both undernutrition and overweight and obesity [2]. As such, an unhealthy diet is a risk factor for nutrient deficiencies, impaired growth and development, and adverse chronic disease outcomes that can influence lifelong health [2-4]. Internationally, health [5] and government [6,7] authorities have established dietary guidelines outlining the types and amounts of foods children and adults are recommended to eat to support good health. However, population surveys demonstrate that globally, compliance with dietary guidelines is low across age groups and that children's diets are suboptimal (eg, diets low in vegetables and high in energy-dense, nutrient-poor foods are prevalent) [8-11].

Setting-based health promotion, where health is created and lived by people within the settings of their everyday life [12], is widely advocated as evidence-based best practice [13]. Early childhood education and care settings have been identified in systematic reviews as opportune places to promote early childhood nutrition [14,15]. Long day care or center-based care (herein referred to as childcare) is the most common form of early childhood education and care setting in Australia, with almost 800,000 children attending for an average of 30.5 hours (approximately 3 days) per week [16]. Similarly high patterns of childcare attendance are observed across other high-income countries, for example, in European countries [17], the United States [18], and the United Kingdom [19], reflecting changes in family workforce patterns, including increased female participation and shared caring responsibilities [20].

In Australia, half of childcare services operate as private, for-profit organizations, while 35% are private and not-for-profit. The remainder are managed by state or local governments (11%) or nongovernment schools (4%) [21]. Families accessing childcare services are supported by a means-tested national government subsidy, whereby families with lower income are eligible for a greater subsidy amount [22]. However, this does not guarantee affordability for everyone, and access to childcare is unequally distributed across Australia, with regional, remote, and disadvantaged areas more likely to experience low provision or absence of childcare [23].

Childcare services commonly provide meals and snacks for attending children, contributing up to two-thirds of their daily food intake [24]. As such, they have an important opportunity to support early childhood nutrition, and fundamental to this is planning a healthy childcare menu [25]. Recognizing this, leading health [26-28] and childcare [29,30] authorities around the world have established recommendations for healthy menu planning and food provision in the childcare setting. For example, the World Health Organization Commission on Ending

Childhood Obesity advocates mandatory childcare nutrition standards [26], and the Australian National Quality Standard [29] requires childcare services to ensure "healthy eating... [is] promoted and appropriate for each child" (Element 2.1.3). However, a broad, international evidence base indicates that childcare menus do not meet dietary guidelines and are suboptimal for both food [25,31-33] and nutrient [34,35] provision.

Several barriers to healthy food provision in childcare have been identified in the literature, including insufficient menu planning tools and support resources, lack of time, and limited nutrition and dietary guideline knowledge [36]. Although limited in number, small randomized controlled trials (RCTs) have shown that some intervention strategies, including menu auditing and feedback [37,38], provision of menu planning resources [37-39], and expert implementation support [37,39], can improve childcare food provision. However, implementation models have traditionally relied on in-person support [40] and ongoing resourcing [41], limiting the scalability and sustainability of intervention strategies to date.

Web-based menu planning tools are emerging as a novel strategy for improving childcare food provision [42,43]. Given that almost all childcare services have access to computers and the internet [44], web-based tools may provide a mechanism for delivering scalable and sustainable menu planning support across the childcare sector, including in geographically dispersed locations. Such tools can be embedded into existing web-based childcare management systems [43] and completed at a time, location, and pace convenient for end users, with modest financial and staff resourcing requirements compared with other mechanisms [15]. Using digitalized systems, web-based menu planning tools can integrate user-engagement features, such as automated calculations of food groups on menus, comparisons with dietary guidelines, provision of instant feedback reports, and direct links to easily accessible and relevant web-based support resources [42,43].

To our knowledge, only two published RCTs have considered the impact of childcare programs that incorporate web-based tools to support healthy menu planning and food provision: (1) a pilot RCT (n=31) of the *Go-NAPSACC* (Nutrition and Physical Activity Self-Assessment for Child Care) program in the United States [42] and (2) an Australian RCT (n=54) of the *feedAustralia* menu planning tool in the state of New South Wales [43]. Although both tools were shown to improve healthy food choices on childcare menus, neither resulted in significant increases in menu compliance with sector food provision guidelines [42,43]. Authors from both studies called for future research to identify factors that influence the implementation of web-based menu planning tools in the childcare setting and exploration of strategies to inform their widespread use across the sector [42,43].

The implementation and effectiveness of web-based health promotion tools in achieving public health impact is largely

determined by end-user engagement [45]. In the childcare setting, users of web-based menu planning tools are most likely to be staff members who plan, prepare, and provide food for children—namely childcare cooks and directors [25,46]. However, little is known about how these users engage with web-based menu planning tools to support healthy food provision. From the limited evidence base, user acceptance of such programs is reportedly high, although studies to date have considered feedback from directors only [42,43] or captured only quantitative data [43]. This indicates that existing evidence may not reflect the nuanced perspectives of all stakeholders, including cooks and directors, who are likely to use web-based menu planning programs in practice.

In the Australian state of Victoria, the Victorian government has invested in the development and implementation of a

web-based menu planning tool called *FoodChecker* [47]. Delivered by Nutrition Australia Victorian Division (NAV), *FoodChecker* is freely available to all Victorian childcare services to support menu alignment with sector dietary recommendations [48]. *FoodChecker* has been used by a third of Victorian childcare services since its inception in 2017 (NAV Program Manager, personal communication, December 14, 2021). The flow of the *FoodChecker* website, including the home page, menu data input template, and a sample automated report of menu alignment with dietary guidelines, is shown in Figures 1-3 [47]. The rollout of *FoodChecker* provides an opportunity to explore the use of web-based menu planning tools for providing equitable, scalable, and sustainable menu planning support in the childcare sector.

Objectives

Despite the potential of web-based menu planning tools to improve childcare food provision, to date, there are no published qualitative studies on the ways menu planning staff have engaged with these tools. The primary aim of this study was to explore the use of the web-based menu planning tool *FoodChecker* in Victorian childcare services. In particular, we aimed to gain insights and perspectives from menu planning

staff members, in their own words, about their use of the web-based tool to plan healthy menus and guide healthy food provision for children in childcare.

Methods

Ethics Approval

This study was part of a broader research project on healthy eating and physical activity in childcare, with ethics approval

from the Deakin University Human Ethics Advisory Group (HEAG-H91_2021). All participants provided voluntary and informed consent to participate and received an Aus \$20 (US \$13.94) gift card in appreciation of their time.

Design and Setting

A qualitative descriptive study was conducted to explore participants' perspectives about their use of a web-based menu planning tool in the childcare setting. Although all research team members held nutrition qualifications, they sought to learn from the experience and expertise of the childcare staff. The researchers held an ontological position that embraced subjectivity, focusing on participants' personal experiences, insights, and opinions as opposed to seeking an *absolute truth*. The methods and results of this study were reported in accordance with the Standards for Reporting Qualitative Research checklist [49].

A cross-sectional survey of childcare staff members involved in planning childcare menus was conducted between July and September 2021 in Victoria, Australia. The survey explored the use of the web-based menu planning tool *FoodChecker*. Participant perceptions of *FoodChecker* were captured using a web-based qualitative survey, a data collection method recognized as beneficial for harnessing nuanced accounts of participant experiences within the qualitative descriptive paradigm [50].

Participants

Childcare services were identified from the Australian Children's Education and Care Quality Authority National Register [51] in July 2021. Eligible services were required to (1) be located in Victoria, Australia; (2) be open for at least 8 hours each weekday; (3) operate for at least 48 weeks annually; and (4) prepare and provide lunch, morning tea, and afternoon tea for attending children on each weekday. Services that did not provide food for children (eg, where meals were provided by parents) were ineligible because of differing meal planning requirements and because these represent a minority of childcare services in Victoria [52]. As childcare cooks and directors frequently share menu planning responsibilities [25,46], data were collected from both staff groups. A target sample size was not predetermined because of the inductive nature of the investigation and the desire to capture as broad a range of responses as possible from those with experiential expertise in childcare menu planning. Given that there are no published data on the proportion of childcare services in Victoria that provide food to children, the size of the target population was unknown. As such, data collection continued until no further responses were received.

Recruitment

An email invitation was sent to directors of all Victorian childcare services on the Australian Children's Education and Care Quality Authority National Register in July 2021 (N=1726) with a link to a voluntary self-administered *director survey* on the secure REDCap (Research Electronic Data Capture; Vanderbilt University) platform [53]. Directors providing consent responded to a screening question (within the *director survey*) regarding *FoodChecker* use (yes, no, or unsure).

Directors who nominated that *FoodChecker* was or may have been used at their service were sent a link to a *FoodChecker survey*, which included individual consent. This could be forwarded to the cook responsible for planning the service's menu or completed by the director if they were involved in menu planning. One reminder email was sent to directors who did not respond to the initial recruitment email after 2 weeks. To maximize cooks' participation in the *FoodChecker survey*, the study was advertised to cooks in September 2021 via a post on a social media webpage commonly accessed by the target population.

Data Collection and Measures

Childcare Service and Participant Characteristics

Similar to previous research within the Australian childcare setting [43], participants reported their childcare service postcode and type of management (private or community), as well as their role in the service, years of employment, educational attainment, and whether they had received nutrition training. Participants also reported whether their service had ever used *FoodChecker* for menu planning (yes, no, or unsure).

FoodChecker Survey Design

As this is the first study, to the best of our knowledge, focusing on the qualitative exploration of a web-based childcare menu planning tool, a set of questions about *FoodChecker* use was purpose-designed by the research team. Previous international studies on user experiences with digital health tools have identified the need to capture information in the domains of user attitudes, experiences and expectations, and resultant changes in confidence, learning, and behavior [54,55]. To ensure that the study needs were addressed, additional domains were included to capture information about the frequency and purpose of use of *FoodChecker* and barriers and enablers influencing use (Table 1).

Topic-based qualitative questions were designed to be open and as succinct, clear, and unambiguous as possible, using the guidance for designing qualitative survey questions provided by Braun et al [50]. To contribute to internal generalizability and to support the interpretation of findings within the qualitative analysis [56], 5 quantitative questions using a nominal (yes or no) scale were added. Questions were then tested for face validity by 7 researchers (including JVK, ACS, PL, and KAB) with expertise in early childhood nutrition, 3 NAV staff members (including MR), 1 user experience design professional, and 1 previous childcare cook, with feedback incorporated into the final survey questions. Readability scores for the final set of *FoodChecker* questions (n=16 questions; Table 1) were 69.8 on the Flesch Reading Ease Test (desirable range 60-70) and 5.9 on the Flesch-Kincaid Grade Level Test, indicating that the content could likely be understood by a person approaching sixth grade in the United States [57].

The *FoodChecker survey* included the complete set of *FoodChecker* questions. Four of these questions were included in the *director survey*. This approach preempted the expectation that most participants responding to the *FoodChecker survey* would be cooks but that it was also important to seek insights from directors who often play a role in menu planning [25,46].

For both surveys, the number of questions included was within the range of 4 to 16, which is commonly observed in the literature for qualitative survey analyses focusing on lived experiences [50].

Table 1. Domains and questions in the *FoodChecker* question set^a.

Domain	Question
Frequency of use	<ul style="list-style-type: none"> Q1. How often do you use <i>FoodChecker</i>?
Purpose of use	<ul style="list-style-type: none"> Q2a. Please briefly state why you use or have used <i>FoodChecker</i>.^b or Q2b. Please explain why your center does not use <i>FoodChecker</i> for menu planning.^b
User experiences	<ul style="list-style-type: none"> Q3. What is the first thing that comes to mind about your experience with using <i>FoodChecker</i>?
User attitudes	<ul style="list-style-type: none"> Q4. What do you like the most about using <i>FoodChecker</i>? Q5. What do you like the least about using <i>FoodChecker</i>? Q6. Do you think that online menu planning tools like <i>FoodChecker</i> are useful for your role? (yes/no) Please tell us why/why not. Q7. Do you think that online menu planning tools like <i>FoodChecker</i> are useful for childcare centers? (yes/no) Please tell us why/why not.^b
Enablers to use	<ul style="list-style-type: none"> Q8. Have you accessed any support to help you use <i>FoodChecker</i>? Q9. What organizational support do you receive (if any) to use <i>FoodChecker</i>?
Barriers to use	<ul style="list-style-type: none"> Q10. What challenges do you face (if any) regarding the use of <i>FoodChecker</i>?
Changes in confidence, learning and behavior	<ul style="list-style-type: none"> Q11. What do you think has changed for you or your center as a result of using <i>FoodChecker</i>?^b Q12. As a result of using <i>FoodChecker</i>, has your confidence about planning healthy menus improved? (yes/no) Q13. As a result of using <i>FoodChecker</i>, have you learnt something? (yes/no) What have you learnt? Q14. As a result of using <i>FoodChecker</i>, has your center's menu changed? (yes/no) What has changed?
User expectations	<ul style="list-style-type: none"> Q15. If <i>FoodChecker</i> was being updated, is there anything that you would like to see in an "ideal" online menu planning tool?
Other	<ul style="list-style-type: none"> Q16. Is there anything else that you think is important for us to know about <i>FoodChecker</i>?

^aAll questions were included in the *FoodChecker* survey.

^bQuestions included in *director* survey with the additional question, "Who has used *FoodChecker* in your center?"

Data Analysis

Survey response files were downloaded from REDCap, deidentified, and uploaded to NVivo (version 20; QSR International), a secure web-based data analysis platform [58].

Statistical Analysis

Postcode to remoteness area matching using the Australian Statistical Geography Standard [59] was used to classify each childcare service's geographic location as metropolitan or regional, based on proximity to a major city. Area-level socioeconomic position (SEP) for each childcare service was determined using the Index of Relative Socioeconomic Advantage and Disadvantage [60]. Each service was allocated a decile score based on its postcode to determine the relative level of advantage and disadvantage (1=greatest disadvantage and 10=greatest advantage) in the local area. Descriptive statistics were generated for the following: (1) childcare service characteristics including location (metropolitan or regional), type of management (private or community), area-level low SEP (score of 1-3), middle SEP (score of 4-7), or high SEP (score of 8-10) and *FoodChecker* use (yes, no, or unsure); (2) participant characteristics including role (director or cook), years of employment, educational attainment, and nutrition

training; and (3) nominal (yes or no) data about *FoodChecker* usefulness and changes in confidence, learning, and the childcare menu.

Thematic Analysis

The Braun and Clarke [61] approach to inductive thematic analysis was used to explore menu planner perceptions of *FoodChecker*, as is consistent with the qualitative descriptive methodology [62]. Through an iterative process, an open coding technique was used to assign previously undefined codes to raw data extracts using NVivo. To minimize the risk of bias, a 10% sample of survey response files (n=6) was independently analyzed by 2 researchers (JVK and ACS), each of whom developed a preliminary coding framework. Differences in the coding frameworks were discussed until a consensus was reached. This verification process has been previously used in inductive thematic analysis of qualitative descriptive research [63]. Data extracted from the remaining survey response files were coded by 1 researcher (JVK). The codes were systematically categorized to determine common themes and their trends, patterns, and relationships. Through ongoing iteration and analysis, themes were reviewed and discussed with the research team, refined and named, and then rechecked to

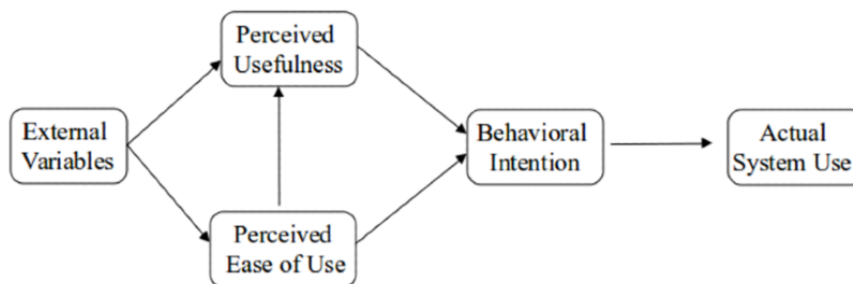

ensure that they accurately reflected coded extracts and raw data.

Application of Theory

Constructs of the Technology Acceptance Model (TAM) were used to report themes identified from the inductive analysis related to the degree to which participants perceived *FoodChecker* would be useful and easy to use, and external variables specific to the individual or organization influencing

perceptions and use (Figure 4 [64]). The TAM is a validated, widely used, and highly predictive model of information technology use [65], which posits that acceptance of a technology is directed by the degree to which users perceive the system to be useful (or enhance their job performance) and easy to use (or free from effort) [66]. It has been significantly associated with the intention to use a digital menu planning tool in the childcare sector [44].

Figure 4. Technology Acceptance Model (Venkatesh and Davis [64]).

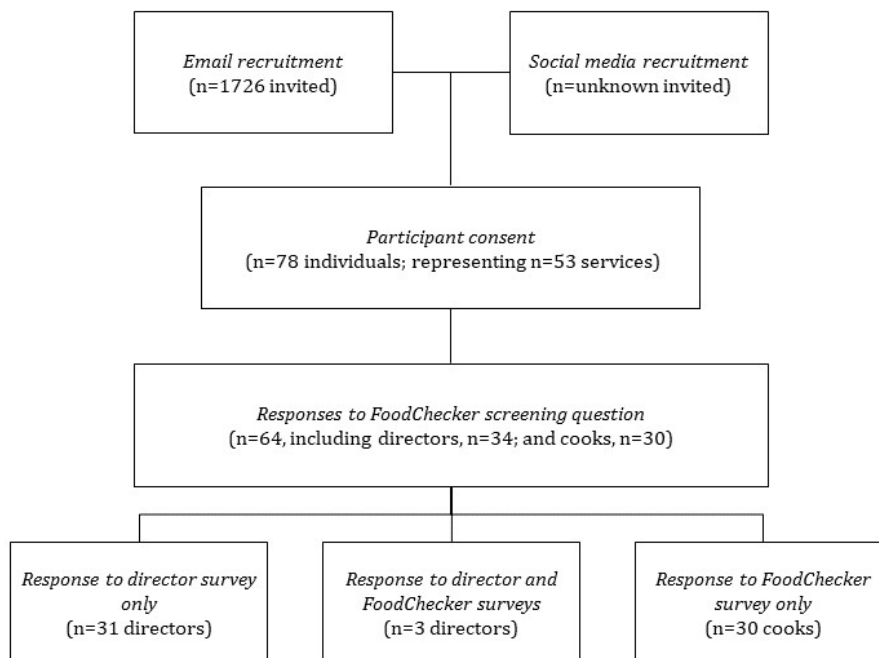

Results

Participants

A total of 64 participants (comprising 34 directors and 30 cooks) from 53 childcare services participated in this study (Figure 5);

52% (33/64; n=30 cooks and 3 directors) responded to the *FoodChecker* survey. The remaining participants (31/64, 48% directors) responded to the *director* survey only.

Figure 5. Childcare service and participant recruitment and survey respondents.

Childcare Service and Participant Characteristics

Childcare service and participant characteristics are presented in Table 2. Most services were located in metropolitan areas of Victoria (47/53, 89%) and privately owned (40/53, 75%). Half of the services (n=27) were located in regions classified as high

SEP. Furthermore, 60% (32/53) of services reported using *FoodChecker* for menu planning. Most commonly, *FoodChecker* was used monthly or when menus were updated. Most participants had a minimum of certificate- or diploma-level qualification (55/64, 86%). Fewer than half (26/64, 41%) of the participants reported receiving nutrition training.

FoodChecker Usefulness and Changes in Confidence, Learning, and Menus

Participant responses to quantitative questions about *FoodChecker* are presented in Table 3. A total of 79% (26/33) of participants responded to quantitative questions about

FoodChecker. Of these, the majority agreed *FoodChecker* was useful for their role (22/24, 92%) or childcare services (23/25, 92%). Furthermore, most participants agreed that due to using *FoodChecker*, their confidence about planning healthy menus had improved (20/26, 77%), they had learned something (17/24, 71%) and that their service's menu had changed (17/25, 68%).

Table 3. Participant reports of *FoodChecker* usefulness and changes in confidence, learning, and menus (n=33)^a.

Question	Response rate, n (%)	Yes, n (%)	No, n (%)
Do you think that online menu planning tools like <i>FoodChecker</i> are useful for childcare centers?	25 (76)	23 (92)	2 (8)

FoodChecker Themes

Overview

From the thematic analysis, 10 common themes were constructed about *FoodChecker* use, which were reported according to TAM constructs (Table 4).

Table 4. Overview of 10 themes constructed from thematic analysis and organized under constructs of the Technology Acceptance Model (TAM).

TAM construct	Theme
Perceived usefulness	<ul style="list-style-type: none"> • Theme 1: Supporting child nutrition and health • Theme 2: Improving organizational processes <ul style="list-style-type: none"> • Quality improvement and accountability • Meeting food provision recommendations and standards • Improving menu planning processes • Improving menu quality • Engaging families • Theme 3: Aiding the menu planner <ul style="list-style-type: none"> • Increasing confidence and learning • Reducing workload • Theme 4: Ways to improve usefulness
Perceived ease of use	<ul style="list-style-type: none"> • Theme 5: Mixed perceptions about ease of use • Theme 6: Ways to improve ease of use
External variables	<ul style="list-style-type: none"> • Theme 7: Awareness and perceived need • Theme 8: Time and resources • Theme 9: Organizational support • Theme 10: Food budget

TAM Construct: Perceived Usefulness

Almost all participants, including directors and cooks, described *FoodChecker* as useful in their role or for the childcare sector, particularly for supporting child nutrition and health, improving organizational processes, and aiding the menu planner role.

Theme 1: Supporting Child Nutrition and Health

Child health was a priority for directors and cooks, who commonly discussed health motivations when describing the usefulness of *FoodChecker* in their role. This was demonstrated

by one director who explained that the tool “changed the way we think about health” (director-34). Several cooks drew links between using *FoodChecker* and supporting children's health. One explained that it helped their service provide “nutritious food to reduce illness” (cook-6) and another specified a “healthy diet has direct benefits to students' mental health” (cook-13). Another drew a further link to children's learning, stating that the web-based tool was useful “especially for us: Strong Foundations! Healthy eating and healthy bodies = learning!” (cook-3). Participants acknowledged that food provided at their

service influenced children's health and discussed using *FoodChecker* to ensure that menus met children's nutrition and dietary needs. One cook stated, "it's a part of the program we use to ensure our children have a balanced, nutritional diet" (cook-8). A director emphasized this was particularly important given "many children receive most of [their] meals/snacks at the service" (director-25).

Theme 2: Improving Organizational Processes

The overview of this theme has been described as follows:

1. *Quality improvement and accountability*: quality improvement was important for participants, as evidenced by a director who explained "anything that assists us in continuous improvement has great value" (director-20). Cooks and directors alike described the need for childcare services and staff to be accountable for food provision practices. For example, a director described using *FoodChecker* to "ensure menu planning is on track and give accountability to the chef" (director-23), while a cook discussed using it "to keep services accountable for what they feed their children. There are still far to[o] many services with terrible budgets and menus that are not well balanced" (cook-24).
2. *Meeting food provision recommendations and standards*: *FoodChecker* was considered useful for supporting services to meet food provision recommendations. For example, a cook described using the web-based system to ensure "best-practice nutritional guidelines for children are being met in daily menus...and make sure we are meeting all healthy eating standards for children" (cook-3). Another referred to national childcare standards, stating that meeting children's daily nutrition needs is "required for rating and assessment" (cook-24). In some services, *FoodChecker* was used to meet food provision benchmarks within government-funded and endorsed health promotion initiatives. Indeed, one director stated, "As a part of the Achievement Program [67], we use *FoodChecker* to make sure our menus meet the daily intake of required foods and is healthy for all" (director-17).
3. *Improving menu planning processes*: several cooks expressed *FoodChecker* was valuable for improving menu planning processes. For example, they explained that *FoodChecker* "makes it easier and quicker to plan the menu" (cook-29) or "helps in the planning of meals, as it serves as a reference for appropriate quantities, number of serves, variety of food from the five food groups, and portion size... [it] also helps in wastage control, budgeting and ordering" (cook-5). *FoodChecker* was reported to offer further menu planning guidance through links to web-based resources including "healthy ingredient swaps and shopping tips" (cook-15) and ways "to deal with challenges such as allergies and budgeting" (cook-12).
4. *Improving menu quality*: most participants (17/25, 68%) who responded to the question about whether their childcare menu had changed because of using *FoodChecker* reported that menu changes had occurred owing to using the web-based program (Table 3). When describing these changes, some provided general information, explaining that they felt their menus were better, healthier, or more

varied. For example, a director explained "we have a season[al] menu now where before it was a fortnightly menu which didn't change" (director-17). Others described specific changes, such as adapting portion sizes or food provision (eg, providing more dairy, vegetables or grains, or less fatty, salty, or sweet foods). One cook explained that they had rearranged the menu so it was now "designed and implemented based on the recommendations available on the system" (cook-5). Some respondents also thought that menu changes had resulted in dietary changes, as one cook stated, "we eat and enjoy more nutritional foods" (cook-8).

5. *Engaging families*: for some participants, *FoodChecker* provided a platform for accessing recipes, information, and guidelines to share with families and support their engagement in menu planning. Indeed, a director explained "children have more input and... parents are asking for a copy of recipes... parents are using the menus at home" (director-17).

Theme 3: Aiding the Menu Planner

The overview of this theme is described as follows:

1. *Increasing confidence and learning*: most participants who responded to questions about whether *FoodChecker* had impacted their confidence and learning reported that using the web-based tool had helped them build confidence in menu planning (20/26, 77%) and learn information relevant to their role (17/24, 71%; Table 3). Several cooks explained that from the web-based system they "learned how to cook" (cook-21) or "how to plan food for the kids" (cook-20). One stated that they "learned a lot of nutrition knowledge, which is very useful" (cook-15).
2. *Reducing workload*: several cooks reported *FoodChecker* made it "easier and quicker" (cook-8) to plan menus and that using the web-based tool reduced their workload. Some explained "it lightened a lot of work and made me more relaxed" (cook-14) or "it lightens my workload. I'm very satisfied that I can do other things" (cook-16).

Theme 4: Ways to Improve Usefulness

Although there was agreement about the usefulness of *FoodChecker*, the participants described updates that would further improve its value. For example, a cook recommended "Keep improving the tool... Provide us with accreditation evidence (a tick) so that families can see that our menus meet *FoodChecker* standards" (cook-3). Others suggested that the tool should provide information about food suppliers. Further recommendations were provided regarding additional resources that could be made available through the platform, such as sample menus, ingredient substitutions, nutrition information, allergy resources, and a greater variety of recipes. One cook noted the need for the digital system to ensure confidentiality, stating "I also need to know my recipes are private and won't be used in any way without my authorization" (cook-24).

TAM Construct: Perceived Ease of Use

Theme 5: Mixed Perceptions About Ease of Use

Perceptions about the ease of use of *FoodChecker* were mixed. Some participants reported that the tool was “easy to use” (director-23) or noted specific elements such as an “easy checklist to ensure a balanced weekly menu” (cook-3). Conversely, some described the web-based functionality as “not very easy to navigate” (director-13) or “a little too complicated in some ways” (cook-21). One cook stated it was “...too confusing, I needed help...computers are tricky for me... I don’t like to use [it]” (cook-7).

Theme 6: Ways to Improve Ease of Use

Some participants stated that updates to navigation and functionality within the tool would make it easier to use. One cook, who described *FoodChecker* to be useful in their role, also stated “I just hope they work on the navigation of the site” (cook-17). Others discussed the need to integrate strategies to reduce data input time, explaining that “data input is quite time-consuming” (cook-5) or suggested the need for functionality to easily fix errors in data input, for example, “not having to start the entire menu over for small incorrect servings” (cook-4).

TAM Construct: External Variables

Participants identified several variables that influenced their perceptions of *FoodChecker* and their use of the tool.

Theme 7: Awareness and Perceived Need

Some participants had not used *FoodChecker* because they were unaware of the tool. One cook explained “I didn’t know about it until now. I have registered and will look at it from now on” (cook-2). Others who did not use *FoodChecker* perceived their service as having adequate processes in place to ensure healthy menu planning. This included the presence of cooks and directors believed to be adequately skilled in healthy menu planning, as well as input from staff, parents, and children. One director explained “we are a small private center with a self-managed system in place that works well” (director-21). Others accessed support from external consultants or used “the alternative [menu planning tool] from *feedAustralia*” (director-5).

Theme 8: Time and Resources

Time was described as an important factor related to *FoodChecker* use. Participants commonly stated that inputting menu data into the program was “very time consuming” (director-13). The short turnaround times for planning new menu cycles and the need to reassess menus with each change presented challenges. For example, participants explained that they “normally allow two weeks to complete [a] new season menu” (director-17) and “each time we change a menu, we need to food check again” (cook-3).

Lack of time was a reported barrier to *FoodChecker* use, as a director explained, “the cook is aware of *FoodChecker* but is limited on time to use this service” (director-14). For one cook, lack of time was exacerbated by a lack of technological resources, as they explained, “there is no computer or iPad in

the kitchen” (cook-24). They further described the challenge of competing priorities within their role, stating they:

Get menu planning time, [b]ut it is also documentation time, cleaning, and food safety plan time. As well as newsletters and posting on story park. So [I] need to prioritize the work and FoodChecker is sometimes last. [Cook-24]

Others reported that dedicated “paid time for menu planning” (cook-4) within their role enabled them to use *FoodChecker*.

Theme 9: Organizational Support

Cooks reported that management support and leadership facilitated their use of *FoodChecker*. One cook expressed they received “encouragement, time and practical support from management to use *FoodChecker*” (cook-3) and another explained, “the director and teachers of our center are very satisfied and give us the greatest support” (cook-15). In some services, using the web-based system was perceived to be a directive from management. Cooks discussed using *FoodChecker* at the “request of the business to ensure that we meet (and exceed) the nutritional requirements of the children” (cook-5) or that it was “part of our policy...to use *FoodChecker*” (cook-29).

Theme 10: Food Budget

The food budget was an important factor for cooks, as reported by one participant who stated, “cost control is our biggest headache” (cook-15). While some reported *FoodChecker* provided links to web-based resources that supported their service with budgeting, others explained that recommendations made by the *FoodChecker* system presented challenges for the food budget. For example, they explained that when using *FoodChecker* they were “unable to control costs” (cook-12) or that it was “easy to exceed our budget and buy food materials” (cook-16).

Discussion

Principal Findings

In this novel study, we aimed to explore the use of a web-based menu planning tool for childcare services. Among the first of its kind, the study sought insights and perspectives from childcare cooks and directors, in their own words, about their use of a web-based tool to plan menus and guide food provision for children in childcare. The study found that cooks and directors alike considered the web-based tool to be useful in their roles, although use was influenced by a variety of factors including awareness, perceived need, time, resources, organizational support, and budgetary considerations. Participants made recommendations to improve the web-based tool, including the need to update navigation and functionality, integrate strategies to reduce data input time, and provide more links to relevant web-based resources to support healthy menu planning.

Comparison With Prior Work

To the best of our knowledge, this is the first study to consider insights from both cooks and directors about their use of a web-based childcare menu planning tool, with limited previous

analyses focusing on acceptance by childcare directors only [42,43]. As such, this study offers an end-user perspective most likely to represent insights from both staff groups involved in menu planning. Participants described a variety of motivations important for menu planning, particularly the need to support children's health and nutrition, improve food provision and menu planning processes, and aid the menu planner role. Similar motivations have been reported in previous analyses of childcare menu planners [68,69]. However, this is the first study to document the usefulness of a web-based menu planning tool for integrating these motivations into practice.

In this study, directors and cooks emphasized the value of a web-based menu planning tool for both the childcare sector and within their specific role. Comparatively, in limited prior evidence, reports on the perceived value of web-based menu planning tools in childcare settings have been mixed. For instance, while directors have previously reported high intentions to use a web-based menu planning tool and high levels of computer access [44], cooks have reported not using or requiring web-based menu planning tools and having limited computer literacy and access [68]. This discordance could indicate differing needs, levels of computer access, or perceived levels of computer literacy between cooks and directors in childcare settings. Indeed, in this study, one cook reported low levels of digital literacy, and another indicated that a lack of technology in the kitchen was a barrier to using a web-based menu planning tool. These challenges were not reported by the directors.

In this study, the web-based menu planning tool was considered valuable for supporting engagement with families, particularly for sharing menus and recipes. This is important, given that family engagement is widely recommended to increase the impact of childcare-based healthy eating interventions [70]. Most childcare services use web-based platforms to communicate with families [44], indicating the potential to extend the use and reach of web-based menu planning tools to the family and home environment. Indeed, this is demonstrated in the *feedAustralia* intervention where parents can use a mobile app to view daily food offerings and access sample menus and recipes that they can recreate at home [71].

Despite the consensus about the usefulness of the web-based menu planning tool in this study, there were mixed reports from both directors and cooks about how easy it was to use the tool in practice. It stands to reason that user training may improve ease of use, as reported in the *Go-NAPSACC* trial [42]. However, the participants in this study did not discuss the need for *FoodChecker* training but rather the need to update navigation and functionality within the web-based tool to make it easier to use. Given that up to 80% of health technologies have limited success owing to a lack of end-user adoption or sustained use [45], understanding and integrating user preferences within web-based systems is necessary to increase their use and impact [72]. Future developments of web-based childcare menu planning tools should therefore consider strategies to improve user engagement (such as simpler site navigation or functionality to facilitate faster data input), to amplify their adoption, for sustained use over time, and for public health impact. This indicates the importance of directing funding toward the ongoing

development of web-based menu planning tools for the childcare sector to meet user expectations, particularly in the current era of rapid technological advancement.

The limited evidence available has demonstrated that, even when the acceptability of a web-based menu planning program in the childcare sector is high, use may still be variable [42,43]. This indicates that factors external to the system itself (eg, individual or organizational factors) may influence use. Exploration of such factors was novel to this study, with participants reporting that awareness, perceived need, time, management support, and the food budget were important variables relevant to their uptake of the web-based menu planning tool.

Several participants were unaware of the tool and, as such, had not used it. Others who were aware of the tool but did not use it perceived that childcare staff had adequate nutrition knowledge and skills to plan a healthy menu. Given the scope of this study did not include a menu assessment component, it was not possible to triangulate staff perceptions about their knowledge and skills in healthy menu planning and the degree to which childcare menus complied with food provision guidelines. This is an important direction for future research. Despite this, there were multiple instances in which both cooks and directors demonstrated good knowledge of the scientific evidence related to their roles. For example, participants discussed the need to provide optimum nutrition to children who received most of their meals and snacks in childcare or links between healthier eating and children's health outcomes, as evidenced in the literature [1,24]. Although these examples of accurate nutrition knowledge are reassuring, it cannot be inferred that this knowledge is consistent or accurately translated into menu planning practices, indicating the need for healthy menu planning support in the sector.

Although support in the form of nutrition training has been shown to improve menu quality, such training is not routine [25]. Indeed, less than half of the participants in this study reported having received nutrition training. This is similar to previous studies where childcare staff reported low levels of nutrition training despite their responsibility to plan a healthy menu that meets food provision guidelines [25]. This indicates that there is scope for the design and implementation of interventions, such as web-based menu planning tools that offer accessible, evidence-based guidance that can be integrated into menu planning practices, even in the absence of formal staff nutrition training.

Some participants who stated that they did not use the web-based menu planning tool reported using an external consultant to support healthy menu planning in their service. Such consultancy may increase the financial burden of healthy menu planning, and may not be viable for all childcare services. However, it may also present a sensible approach to ensure accuracy in menu compliance with dietary guideline recommendations, if such support is available at a feasible cost.

Time was an important factor in this study, with mixed perceptions among the participants. Staff members who received dedicated and paid time within their role to use the web-based menu planning tool reported that this facilitated its use.

Moreover, some participants who used the tool reported that it was time saving and reduced their workload. However, as in previous studies [73], most participants did not report receiving paid time for menu planning within their roles. Furthermore, the use of the tool was commonly perceived to be time consuming, even by participants who had never used it before. As such, perceptions about time were a deterrent to initial adoption. This indicates that there is scope to (1) integrate user-engagement features within childcare menu planning systems to improve time efficiency and (2) establish strategies to shift user perceptions about such systems from being *time consuming* to being *time saving*. These are important areas for future development, particularly given that childcare staff members are known to be a time-poor population group [36].

In addition to dedicated time, service management support and leadership were reported to facilitate the uptake of the web-based menu planning tool. Interestingly, one cook who did not want to use the program had used it on instruction from their manager to ensure menu compliance with dietary guidelines. This indicates that despite the presence of management support, menu planner resistance may exist and could be a potential barrier to ongoing use of the web-based menu planning tool.

The food budget and cost control were important considerations for participants who described budgeting resources linked to the web-based menu planning tool as useful. However, several cooks reported that specific food recommendations generated by the web-based system exceeded their allocated food budget. This is a novel finding, indicating the need for dietary guidelines and recommendations embedded within such systems to consider food budgets and financial constraints. It may also suggest the need to investigate the capacity of childcare food budgets to adequately provide optimal nutrition for children. There is scope for web-based childcare menu planning systems to integrate strategies to support services in establishing and managing food budgets, which is an area for future research and development.

Although the services in this study were located in areas of varying levels of advantage and disadvantage, half were located in regions classified by postcode as high SEP. This is consistent with data indicating that, in Victoria, there is a higher provision of childcare services in areas experiencing greater levels of advantage [23]. However, as the study achieved a modest sample size, it was not possible to determine whether area-level SEP was associated with the acceptance of the web-based menu planning tool or the degree to which the tool supported healthy food provision in childcare services. Given that area-level disadvantage is associated with poorer diet quality [74], and given that services in low SEP areas were least represented in this study, there is a need for future research to better understand the use of web-based childcare menu planning tools in lower SEP areas.

Strengths and Limitations

The strengths of this study warrant discussion. As this study captured perspectives from cooks and directors, the findings

are likely to represent the perspectives of both staff groups involved in menu planning. The study's qualitative descriptive underpinning provided scope to capture participant-generated data on menu planner experiences in their own words. Insights generated from spontaneous reporting were likely to reflect motivations and perspectives that are most important to users when compared with quantitative analyses using predefined, researcher-generated items and response scales [62]. The use of the validated TAM contributed to the study's underlying theoretical foundation. In line with emerging methodology-focused evidence, a web-based qualitative survey facilitated data collection from a time-poor and varied, dispersed, and geographically heterogeneous population with the potential to reduce social desirability bias [50]. A further strength of this study was that it analyzed the use of a real-world web-based tool in current practice, to which real-time refinements are possible. As such, the exploration brought together research, reflection, and practical solutions as part of an action research approach.

Given that the *FoodChecker* tool is only freely available in Victoria, the scope of this study was purposely delimited to Victorian childcare services. A modest study sample was achieved, as observed in previous studies on food provision in childcare settings [68]. Furthermore, given that childcare staff are known to be a time-poor population group, the perspectives of those who have particularly limited time to engage with a web-based menu planning tool, and as such, to participate in this research, may not have been captured. This may impact the ability to generalize the findings to the broader childcare sector. However, as the analysis explored participant perceptions and insights that are subjective by nature, the findings may be indicative of childcare menu planner experiences more broadly. This should be further investigated in larger studies exploring the use of web-based menu planning tools to support healthy food provision in childcare. It was beyond the scope of this study to include a quantitative analysis of the impact of the web-based menu planning tool on menu compliance with dietary guidelines, food provision, or children's dietary intake. These are important areas for future research.

Conclusions

This novel qualitative descriptive study demonstrates the usefulness of a web-based tool to support healthy menu planning in childcare services. Use of the tool was impacted by its internal functionality as well as external organizational factors. Recommendations were made to improve the web-based menu planning system.

Further research is needed to better understand how web-based menu planning tools can improve food provision and children's consumption in the childcare setting. In particular, studies should investigate and evaluate strategies to improve user engagement with web-based menu planning tools in childcare to increase their adoption, use, and public health impact.

Authors' Contributions

JVK, ACS, PL, and KAB contributed to the conception and design of the study and data acquisition. JVK, ACS, and PL contributed to data analysis and interpretation, and JVK conducted the data analysis. PL led the acquisition of data. MR oversaw the development of the *FoodChecker* intervention. JVK drafted the manuscript. All authors took part in revising the manuscript, gave approval for this version to be published, and agreed to be accountable for all aspects of the work.

Conflicts of Interest

JVK is a previous employee of NAV, which delivers *FoodChecker*. JVK currently holds no contractual or financial relationship with NAV. MR is an employee of NAV. Individual members of the research team had no prior relationship with the participants. Participants may have interacted with NAV as an organization.

Abstract

Background: Most efforts to identify caregivers for research use passive approaches such as self-nomination. We describe an approach in which electronic health records (EHRs) can help identify, recruit, and increase diverse representations of family and other unpaid caregivers.

Objective: Few health systems have implemented systematic processes for identifying caregivers. This study aimed to develop and evaluate an EHR-driven process for identifying veterans likely to have unpaid caregivers in a caregiver survey study. We additionally examined whether there were EHR-derived veteran characteristics associated with veterans having unpaid caregivers.

Methods: We selected EHR home- and community-based referrals suggestive of veterans' need for supportive care from friends or family. We identified veterans with these referrals across the 8 US Department of Veteran Affairs medical centers enrolled in our study. Phone calls to a subset of these veterans confirmed whether they had a caregiver, specifically an unpaid caregiver. We calculated the screening contact rate for unpaid caregivers of veterans using attempted phone screening and for those who completed phone screening. The veteran characteristics from the EHR were compared across referral and screening groups using descriptive statistics, and logistic regression was used to compare the likelihood of having an unpaid caregiver among veterans who completed phone screening.

Results: During the study period, our EHR-driven process identified 12,212 veterans with home- and community-based referrals; 2134 (17.47%) veteran households were called for phone screening. Among the 2134 veterans called, 1367 (64.06%) answered the call, and 813 (38.1%) veterans had a caregiver based on self-report of the veteran, their caregiver, or another person in the household. The unpaid caregiver identification rate was 38.1% and 59.5% among those with an attempted phone screening and completed phone screening, respectively. Veterans had increased odds of having an unpaid caregiver if they were married (adjusted odds ratio [OR] 2.69, 95% CI 1.68-4.34), had respite care (adjusted OR 2.17, 95% CI 1.41-3.41), or had adult day health care (adjusted OR 3.69, 95% CI 1.60-10.00). Veterans with a dementia diagnosis (adjusted OR 1.37, 95% CI 1.00-1.89) or

veteran-directed care referral (adjusted OR 1.95, 95% CI 0.97-4.20) were also suggestive of an association with having an unpaid caregiver.

Conclusions: The EHR-driven process to identify veterans likely to have unpaid caregivers is systematic and resource intensive. Approximately 60% (813/1367) of veterans who were successfully screened had unpaid caregivers. In the absence of discrete fields in the EHR, our EHR-driven process can be used to identify unpaid caregivers; however, incorporating caregiver identification fields into the EHR would support a more efficient and systematic identification of caregivers.

KEYWORDS

veterans; caregivers; electronic health record

Introduction

In the United States, approximately 26.4 million people provide unpaid care to adults aged >50 years [1]. Family and other unpaid caregivers (hereafter called unpaid caregivers) are people who provide volunteer care to a loved one [2]. The care provided by unpaid caregivers is associated with reduced hospital readmissions and increased time at home for patients [3-5]. At the same time, unpaid caregivers are at risk of negative impacts on their physical, social, emotional, and financial well-being. Most unpaid caregivers provide care with little or no training or support [6-11]. Furthermore, unless present for appointments or enrolled in caregiver programs, caregivers are not easily identified within the health systems.

To address the unmet needs of unpaid caregivers, outreach is a critical step. However, there is no systematic method of identifying caregivers for supportive services or research interventions. Prior caregiver research studies relied on caregivers to respond to advertisements or through existing caregiver programs [12-16]. Past approaches may not be ideal for overburdened caregivers, especially for those who are not already involved in these programs, and could result in underwhelming caregiver response and participation. Moreover, passive approaches can decrease representativeness and bias toward caregivers already engaged in these interventions or those already empowered to actively seek help or services [17].

Given the need to improve the representation and systematic identification of unpaid caregivers for caregiving research and supportive services, a systematic, reliable, and proactive process to identify caregivers is needed to increase engagement, expand participation, and reduce sample bias. The electronic health record (EHR) provides an important standardized method of identifying and reaching potential caregivers for research and interventions. The aim of this paper was to evaluate an EHR-driven process used to identify unpaid caregivers for a caregiver survey study in the US Department of Veteran Affairs (VA) cluster-randomized, multisite, stepped-wedge, pragmatic trial—implementation of Helping Invested Families Improve Veteran Experiences Study (iHI-FIVES) [18]. We describe the patient-focused EHR-driven process, its caregiver identification capabilities, and veteran characteristics across the initial EHR and screening groups.

Methods

This study specifically analyzed caregiver identification through patient EHRs for a caregiver survey from the overarching iHI-FIVES study [19].

Setting

iHI-FIVES was conducted at 8 VA medical centers from April 2018 to October 2020 using a type III hybrid implementation effectiveness stepped-wedge, cluster-randomized trial design as part of the Optimizing Function and Independence Quality Enhancement Research Initiative program. The study evaluated the implementation of an unpaid caregiver program designed to promote the function and independence of veterans through caregiver group training aimed at improving caregiver coping, support seeking, and health system navigation skills [18,20]. Eligible caregivers were friends or family members who assisted a patient at home because of ongoing health problems (eg, helping them get around the house, bathe, or pay bills) [19]. This study focused on the identification of caregivers for a caregiver survey that was administered at all sites to assess secondary outcomes (caregiver burden, depression, and satisfaction with VA care).

Ethics Approval

The iHI-FIVES study was approved by the Durham VA Health Care System institutional review board (02040) and registered at ClinicalTrials.gov (NCT03474380).

EHR-Driven Process

As there is no standardized method in EHRs for identifying patients with unpaid caregivers, we evaluated an EHR-driven process to identify unpaid caregivers and patient characteristics (eg, age, race, ethnicity, sex, and comorbidities) associated with having an unpaid caregiver.

We identified 5 relevant VA home and community-based services as these 5 referral types represent an increased need for care in the veteran's home and are likely to indicate the presence of caregivers [21]. These 5 referral types included homemaker home health care, home-based primary care, adult day health care, respite care, and veteran-directed care. Homemaker home health care provides assistance in daily activities (eg, eating, getting dressed, grooming, bathing, and going to the bathroom) through an aide from a home health care agency. Adult day health care is a full- or half-day program for

veterans to be supervised for daily activities during the weekday. Home-based primary care provides veterans who have difficulty traveling to clinic visits to their illness with primary care, social work, and rehabilitation visits at home. Respite care provides home or nursing home care when a caregiver is unavailable. Veteran-directed care assists veterans in connecting to community care services for daily activities [21].

There is no uniform referral naming convention for these 5 categories of home and community-based services in the VA; therefore, we purposively selected related keywords in the text of EHR referral (eg, %home%, %respit%, %grec%, %adult%, %adhc%, %hbpc%, %vd hcbs%, and %veteran directed%). The study team reviewed referral titles identified by the keywords and then applied exclusionary conditions to the programmed code to weed out inappropriate referrals garnered by the broad search. The culled list of referral titles was also confirmed by clinical experts (physicians and caregiver support coordinators) and VA EHR programmers (Multimedia Appendix 1). Some enrolled sites requested expansion beyond these 5 referral types because of the high likelihood of having an active unpaid caregiver present (eg, skilled home health referrals). We subsequently included all these referrals, as well as one additional (respiratory therapy for chronic obstructive pulmonary disease inpatient home transition program) referral in our EHR-driven process, classifying them as *other referrals*.

Screening

We used the EHR-driven process to identify all veterans in our study window who had these qualifying referral types. The study team identified veteran patients with a qualifying referral by using VA EHR data stored in the VA Corporate Data Warehouse. Patients with referrals to hospice care were excluded [19].

Owing to the limited contact with veterans and an option to opt out, waivers of informed consent and Health Insurance Portability and Accountability Act documentation were approved for research contact with patients in this study. As the study focused on caregivers and institutional review board approval, the study team could directly confirm and seek nonveterans' participation in the screening process and study. In addition, veterans' treating clinicians were not involved in the identification process.

Identified veterans were stratified by site, sorted by the earliest qualifying referral date, and selected for recruitment over a 30-month study period. Those with the earliest dates were mailed a recruitment letter with an opt-out telephone number. The letter described that if a family member or friend helps the veteran with their ongoing health problem, they may qualify for a caregiver study. As the goal of the iHI-FIVES caregiver survey study was to enroll and collect baseline surveys for approximately 450 caregiver surveys, the study staff conducted phone screening until caregiver recruitment goals were met at each site.

For the telephone screening, the study staff used the veteran's phone number and assessed the presence of a caregiver based on information provided by the veteran, the caregiver, or another person(s) who answered the phone if neither the veteran nor the

caregiver was available at the time of the call. As it is not always the case that veterans or caregivers recognize the term *caregiver* or do not identify as having or being a caregiver, the screener was written to identify assistance. Specifically, veterans were asked, "Do you have a family member or friend who helps care for you because of your ongoing health problems (for example, helping you get around the house, bathe, or pay bills?)." If nonveterans answered the phone, a similar screening question was asked, starting with "Does the Veteran..." The screening script distinguished between paid, formally trained caregivers such as home health aides and caregivers who were not paid typically and for whom the veteran had an established personal relationship (eg, friends, family). The script also asked if the veteran did not have a caregiver and whether they needed help with their care.

The study team used 2 call attempts to contact veterans after sending the letter to determine if they had a caregiver. For phone messages, the study team used a general Health Insurance Portability and Accountability Act-compliant script describing a VA research study on friends or family who help care for a veteran and a follow-up phone call attempt.

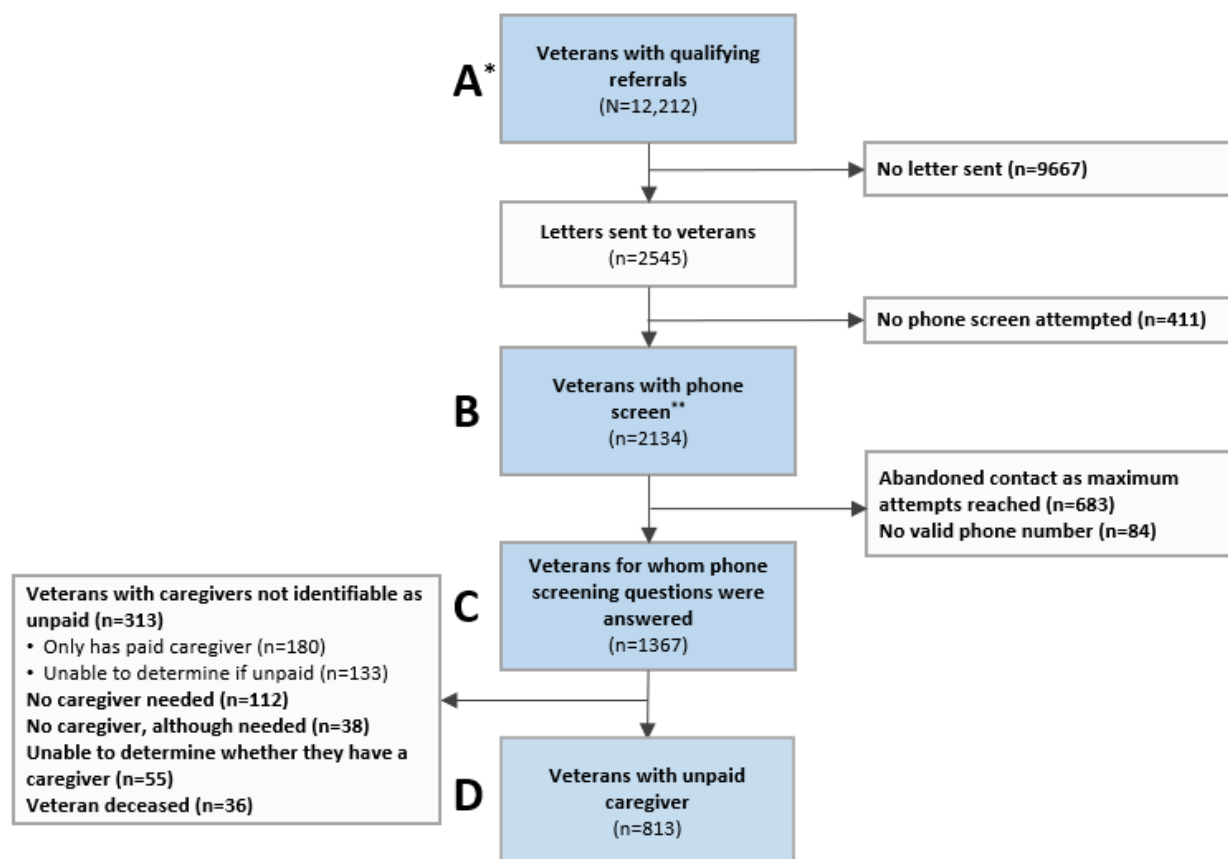

The study team used DatStat Illume (version 6.1) [22] to administer and store phone screens and baseline and 3-month survey data. In the event of a highly distressed caregiver respondent, the study staff was trained in administering a harm protocol.

EHR Data and Measures

This study also evaluated whether particular veteran characteristics were associated with veterans having an unpaid caregiver. To examine these questions, we compared four patient groups: (1) patients with a referral to home- and community-based services, (2) patients contacted for a phone screen, (3) patients with a completed phone screen, and (4) patients confirmed through screening to have an unpaid caregiver (we label these groups as boxes A-D in the CONSORT [Consolidated Standards of Reporting Trials] diagram, Figure 1).

The study identified the following patient data from the VA Corporate Data Warehouse: demographics (age, race, ethnicity, marital status, and rural residence), VA health care eligibility (measured by service connection), outpatient International Classification of Diseases–10th Revision (ICD-10) codes in the prior year, chronic health condition risk score measuring expected health care costs compared with the average patient (Nosos [23]), and home- and community-based care referrals. We used ICD-10 codes to group patient comorbidities by Quan Deyo diagnosis categories [24] to identify patients with dementia and calculate the Charlson Comorbidity Index (CCI) [24,25]. We only included dementia, as patients with dementia have known increased caregiver needs [26]. Nosos risk scores were centered around 1, representing the national expected average cost of VA patients. A risk score >1 represents a higher than expected cost for the patient, whereas a score of 3 represents a patient with an expected cost 3 times higher than the average patient [23,27]. VA service connection indicates a medical condition associated with a veteran's military service, for which the VA completely subsidizes all health care costs [28].

Figure 1. CONSORT (Consolidated Standards of Reporting Trials) diagram for the iHI-FIVES (implementation of Helping Invested Families Improve Veteran Experiences Study). *The blue callouts (letters A to D) indicate the columns listed in Table 1. **The phone screen may have involved speaking to only the veteran, only the caregiver, or both the veteran and the caregiver, which may have occurred during only one call or across multiple calls.

Statistical Analyses

We calculated the screening contact rate based on the study by Slattery et al [29]. In addition, we calculated the unpaid caregiver identification rates. The screening contact rate is the percentage of veterans for whom our study staff was able to talk to a person (veteran, their caregiver, or another person(s)) when we called the veterans' phone number of record, out of all phone screening calls attempted by research staff (see box B in the CONSORT diagram in Figure 1). The unpaid caregiver identification rate is the number of veterans positively identified to have an unpaid caregiver divided by the denominator of interest (phone screen attempted [box B] and phone screen questions completed [box C]; see the CONSORT diagram in Figure 1).

Descriptive statistics for the veteran characteristics are presented for the 4 subgroups described previously. Descriptive statistics were calculated for dichotomous (sex, ethnicity, rural residence, service connectedness, and dementia by ICD-10 codes), categorical (race, marital status, rural residence, highest level of education, and qualifying referral type), and continuous (age, CCI, and Nosos score) variables. Percentages were calculated for dichotomous and categorical data and means and SDs or medians and IQRs for continuous variables.

Simple logistic regression models were fit to estimate the association (odds ratio [OR] and 95% CI) between having an

unpaid caregiver (vs not having one; among veterans with a completed phone screen) for each demographic and clinical variable defined previously. A multivariable logistic model was then fit with the same dependent variable but with all demographic and clinical variables examined independently in the simple models into one model to examine adjusted associations. Complete EHR data were used for the veteran factors in the analyses. The reference groups for the analyses were age (<55 years), sex (female), race (White), ethnicity (not Hispanic), marital status (never married), rural residence (urban), service connected (not service connected), dementia (absence of dementia diagnosis), CCI (score of ≤ 2), Nosos (score of ≤ 1), and referral qualification (homemaker home health care). The purpose of these models was to determine whether any veteran demographics, disease burden, health care cost risk scores, or referral types were associated with having an unpaid character with the idea that if such associations exist, they might inform attempts to recruit caregivers into training or research studies.

Analyses were performed using R (version 4.0.3) [30].

Results

Descriptives of Veteran Groups

A total of 12,212 veterans (box A in Figure 1) were identified through the EHR-driven process of 5 home- and community-based service referrals. A subset of veterans (2545/12,212, 20.84%) was sent a letter describing the study,

followed by attempts to call in order of earliest qualifying referral. Only one-fifth were sent letters and screened by phone because of recruitment goals and resource limitations. Of the 2545 veterans who were sent a letter, 2134 (83.94%; box B in [Figure 1](#)) had an attempted phone screening. Of the 2545 veterans, no phone call was attempted for 411 (16.15%); 34 of those opted out of the study prior to a phone call attempt. Of the 2134 veterans contacted for phone screening, 1367 (64.06%; box C in [Figure 1](#)) veterans were reached, and 767 (35.94%) were unable to be reached. Therefore, the screening contact rate for initial veteran screening for unpaid caregivers was 64.06% (1367/2134).

Of the 1367 veterans who completed the screening questions, 1126 (82.37%) had a caregiver; 813 (59.47%; box D in [Figure](#)

1) had an unpaid caregiver, and 180 (13.17%) were paid. We were unable to determine whether 11.81% (133/1126) of caregivers were unpaid or paid. The identification rates of unpaid caregivers were 38.10% (813/2134) and 59.47% (813/1367) among veterans with attempted phone screens and veterans with completed phone screens, respectively.

Descriptive Comparisons Between Veteran Groups

The veteran characteristics were similar among the 4 groups, including age, sex, race, urban residence, CCI, and Nosos score. The most common type of referral for veterans across all subgroups of interest was a homemaker home health care referral ([Table 1](#)). In addition, as of July 7, 2021, 38 months after the start of the study, one-third (4089/12,212, 33.48%) of the identified veterans had died.

Table 1. Electronic health record–based demographic characteristics of veterans by study milestone^a (N=12,212).

Veteran characteristic	Veterans with qualifying referral (box A ^b ; N=12,212)	Veterans with attempted phone screen (box B; n=2134)	Veterans with completed phone screen (box C; n=1367)	Veterans with unpaid caregiver (box D; n=813)

^aVeterans were identified by first home or community referral placed during the study time frame.

^bBoxes on the CONSORT (Consolidated Standards of Reporting Trials) diagram (Figure 1).

^cCCI: Charlson Comorbidity Index.

^dSome enrolled sites requested the addition of specific referral types (eg, skilled home health, nursing home, and specialty home care) because of the high probability of an unpaid caregiver being present when these referrals occur. We subsequently included all these referrals, as well as one additional (respiratory therapy for chronic obstructive pulmonary disease inpatient home transition program) referral, in our electronic health record–driven process, classifying them as *other*.

Certain characteristics were different among the groups. Compared with veterans with a qualifying referral (box A in [Figure 1](#)) and those contacted for phone screen (box B in [Figure 1](#)), veterans who answered phone screening (box C in [Figure 1](#)) had higher proportions of veterans who were aged 75 to 84 years (396/1367, 28.97%), married (741/1367, 54.21%), and referred for respite care (159/1367, 11.63%). Veterans with unpaid caregivers (813/12,212, 6.66%; box D in [Figure 1](#)) had higher proportions of initial referrals for respite (122/813, 15%), adult day care (45/813, 5.5%), and veteran-directed care (35/813, 4.3%) than those of the other groups.

Modeled Associations Between Veteran Characteristics and Presence of an Unpaid Caregiver

Among veterans for whom screening questions were answered and were without missing data (1261/12,212, 10.22%), the odds

of having an unpaid caregiver were higher among married veterans (unadjusted OR 2.90, 95% CI 1.88-4.50) than among unmarried veterans and veterans with dementia (unadjusted OR 2.06, 95% CI 1.55-2.75) than those without dementia. Similarly, the odds of having an unpaid caregiver were higher among veterans referred for respite services (unadjusted OR 2.64, 95% CI 1.76-4.06), adult day health care (unadjusted OR 4.82, 95% CI 2.17-12.80), and veteran-directed care (unadjusted OR 2.07, 95% CI 1.05-4.38) than for veterans referred to homemaker home health care. In addition to dementia diagnosis and veteran-directed care, adjusted ORs for the associations between having an unpaid caregiver and marital status, as well as health care referral type, were similar to the unadjusted results ([Table 2](#)).

Table 2. ORs^a and 95% CIs from simple logistic regression models (unadjusted) and multiple logistic regression models (adjusted) for the association between veterans having unpaid caregivers among veterans with a completed phone screen and without missing data (N=1261)^b and veteran electronic health record characteristics.

Discussion

Principal Findings

We describe an approach to systematically identify family and other unpaid caregivers in a caregiver study using the VA EHR. This EHR process was effective in identifying caregivers through EHR home- and community-based referrals.

We identified >12,000 veterans with relevant home- and community-based referrals. We called >2000 veterans for screening. Among the 1367 veterans who answered the phone screening, 813 (59.47%) had a family or other unpaid caregivers. Through the EHR-driven process, we found that veteran characteristics were similar among all 4 identified groups (veterans with qualifying referrals, attempted phone screening, completed phone screen, and unpaid caregivers); some notable exceptions included marital status, dementia, and referral type. Veterans with unpaid caregivers were more likely to be married and have a referral for adult day health care or respite care. Although not statistically significant in the adjusted analysis, dementia diagnosis and veteran-directed care referral were also suggestive of an association with having an unpaid caregiver.

Comparison With Prior Work

This study is unique in that there are currently few replicable or standardized EHR methods for identifying veterans with unpaid caregivers. Using the EHR to identify veterans with unpaid caregivers can uniquely position the VA to identify caregivers interested in participating in research studies and increase the representation of caregivers that may not be identified through traditional avenues [31-34]. However, although EHRs can be useful for identifying patient participants through standardized fields for patient demographic, laboratory, medication, and diagnostic data, caregiver identification through EHRs can be difficult because it is rare to have a discrete caregiver field in EHRs [35].

As there is no discrete caregiver field in the VA EHR, we used selected home- and community-based referrals to define a patient population that may have an unpaid caregiver. Although this EHR-driven process was able to identify caregivers independent of their participation or nonparticipation in existing VA caregiver support and services, the process was resource

intensive. To meet the goal of 450 caregiver surveys, 4 research staff members would spend approximately 8 to 16 hours every week during active data collection screening veterans or caregivers; screening approximately one-fifth of the identified EHR referral population resulted in the reaching of survey goals.

Therefore, although the EHR-driven process is a helpful approach to identifying caregivers not already directly linked to services in a health care system (and to be clear, most health systems do not have large-scale programs of caregiver support such as seen in VA), potential future improvements to the EHR should consider a discrete caregiver field to improve efficiency in identifying caregivers for research studies and interventions. VA is currently making investments to link caregiver records to veteran EHR records, beginning with those caregivers already engaged in the VA Caregiver Support Program support and services. This will allow the examination of program impacts on the outcomes of the enrolled caregivers and veterans over time.

Importantly, these caregiver EHR fields should be assessed using an activity-based brief screening question based on the types of assistance received in the home because of a patient's health problems rather than whether a patient *has* a caregiver. The term caregiver is problematic for many older adults; many patients do not recognize that they have a caregiver, and many family members and friends do not identify themselves as caregivers [36].

This study identified several veteran characteristics associated with having an unpaid caregiver. First, we found that being married was positively associated with a veteran having an unpaid caregiver. Although marital status is rarely a variable in other EHRs or insurance claims (ie, Medicaid or Medicare) data, marital status could be a useful target for the identification of caregivers within the VA and potentially in other health systems, with certain caveats. Specifically, marital status alone may not be sufficient to determine the presence of a caregiver as the marital status may be out of date in the EHR and dependent on individual sites and personnel to update this discrete field.

Second, in the unadjusted analysis, veterans with dementia were more likely to have unpaid caregivers. The OR and 95% CI for this association were 1.37 (1.00-1.89) in the adjusted analysis,

suggesting a moderate and likely clinically meaningful association. A dementia diagnosis is more likely to be in the medical record and may identify additional unpaid caregivers in the absence of information about the home care network in the EHR.

Third, focusing on homemaker home health care, respite care referrals, and veteran-directed care may also identify unpaid caregivers. Although most (494/813, 60.8%) of veterans with an unpaid caregiver had a homemaker home health care referral, veterans with respite, adult day health care, and veteran-directed care referrals were more likely to have an unpaid caregiver (122/813, 15%; 45/813, 5.5%; and 35/813, 4.3%, respectively) than veterans identified by the initial EHR pool (929/12,212, 7.61%; 440/12,212, 3.60%; and 358/12,212, 2.93%, respectively). This is likely because respite care, adult day health care, and veteran-directed care programs are specifically designed to assist unpaid caregivers who need time separate from the veterans [37,38]. As such, depending on the purpose of the study, future VA EHR-driven approaches may want to narrow the types of home- and community-based services from which to recruit unpaid caregivers, focusing on respite care, adult day health care, and veteran-directed care.

Strengths and Limitations

A strength of this study is the creation of a systematic approach to screening a large number of veterans across multiple VA sites in the United States. Compared with a prior study at a VA medical center where 89% of patients referred to home- and community-based services reported having an unpaid caregiver, the systematic approach taken here at multiple sites with more geographic representation found that 59.47% (813/1367) of veterans had an unpaid caregiver [39]. Moreover, the percentage of unpaid caregivers may be larger, as we were unable to determine the caregiver status for 16.39% (224/1367) of the patients screened. Using geographically diverse sites, this study provides a more generalizable estimate using EHR-based, home- and community-based referrals to identify unpaid caregivers.

There are several limitations to consider. First, this analysis was limited to examining the associations between veteran characteristics and the presence of unpaid caregivers. We did not have caregiver information for veterans who were not screened or who had unpaid caregiver characteristics.

Second, the generalizability of this study outside the VA health system may be limited, as this study uses VA home- and community-based referrals that may not be available in non-VA settings. Despite this limitation, this was a multisite study, and veterans identified in the EHR were from VAs of various sizes in both urban and rural settings across many regions of the United States. Although the application of this process to identify caregivers may be limited to VA, the process described in this study may be applicable to many VA settings across the country looking to identify caregivers for research studies or for caregiver interventions. Other health care systems in the private sector with a unified EHR system that uses home- and community-based referrals could also use our approach to identify unpaid caregivers.

Finally, because of the resource-intensive process, we screened one-fifth of the veterans identified in the EHR-driven process. Even so, >1000 veterans answered phone screenings for unpaid caregivers. Even if the exact count of unpaid caregivers among all veterans identified is unattainable, a large number of veterans were successfully screened, and there was similarity in veteran characteristics across veterans with a qualifying referral and phone screen; therefore, our results may suggest a similar percentage of unpaid caregivers among veterans who were not contacted for the study.

Conclusions

We present a systematic process for the identification of unpaid caregivers using veteran referrals and additional EHR factors for a caregiver survey study. Using this EHR-driven process, we were able to positively identify the presence of unpaid caregivers for approximately 60% (813/1367) of veterans whose households responded to phone screening calls. In the setting of a resource-intensive process, additional research is needed to increase the efficiency and effectiveness of caregiver identification efforts in EHRs for caregiver interventions and research. Potential future steps may include the incorporation of a discrete caregiver field into the EHR. This type of field would not only improve the efficiency of identifying caregivers within the EHR but also the clinical care for patients in recognizing and including the primary caregiver in the health care team.

Acknowledgments

This work was funded by the US Department of Veterans Affairs (VA) Quality Enhancement Research Initiative (QUE-16-170) and by the Center of Innovation to Accelerate Discovery and Practice Transformation (CIN 13-410) of the Durham VA Health Care System. The efforts of JEM were supported by the US Department of VA Office of Academic Affiliations postdoctoral fellowship (TPH 21-000) and the Durham VA Center of Innovation to Accelerate Discovery and Practice Transformation (CIN 13-410). MSB was supported by the US Department of VA, Veterans Health Administration, Office of Research and Development, and United States Department of VA Health Services Research and Development (HSR&D) Career Development Award (CDA 17-006). The funding agencies had no role in the design or conduct of the study; collection, analysis, or interpretation of the data; or the preparation, review, or approval of the manuscript. The contents do not represent the views of the US Department of VA or the US Government. iHI-FIVES (implementation of Helping Invested Families Improve Veteran Experiences Study) was implemented at the participating sites as a clinical program; evaluation was approved as human subjects research by the Durham VA institutional review board (protocol #02040). The authors thank the caregivers who participated in the study. The authors

would also like to thank additional members of the research team who supported the iHI-FIVES administration and data collection: Elizabeth Mahanna, Katina Morris, Nadya Majette Elliott, Matthew Tucker, Cassie Meyer, and Rebecca Bruening.

Authors' Contributions

JEM, CHVH, and JG were involved in the study conceptualization. SNH, KDA, CHVH, and VW were involved in the funding acquisition. KD, JD, and CS were involved in project coordination and data collection. JEM, JG, CJC, CHVH, VW, and KD wrote the original article. JEM, JG, CJC, CHVH, VW, NRS, MSB, KD, CS, and JD reviewed and edited the article. All authors read and approved the final manuscript.

Abstract

Background: Acute blood glucose (BG) decompensations (hypoglycemia and hyperglycemia) represent a frequent and significant risk for inpatients and adversely affect patient outcomes and safety. The increasing need for BG management in inpatients poses a high demand on clinical staff and health care systems in addition.

Objective: This study aimed to generate a broadly applicable multiclass classification model for predicting BG decompensation events from patients' electronic health records to indicate where adjustments in patient monitoring and therapeutic interventions are required. This should allow for taking proactive measures before BG levels are derailed.

Methods: A retrospective cohort study was conducted on patients who were hospitalized at a tertiary hospital in Bern, Switzerland. Using patient details and routine data from electronic health records, a multiclass prediction model for BG decompensation events (<3.9 mmol/L [hypoglycemia] or >10, >13.9, or >16.7 mmol/L [representing different degrees of hyperglycemia]) was generated based on a second-level ensemble of gradient-boosted binary trees.

Results: A total of 63,579 hospital admissions of 38,250 patients were included in this study. The multiclass prediction model reached specificities of 93.7%, 98.9%, and 93.9% and sensitivities of 67.1%, 59%, and 63.6% for the main categories of interest, which were nondecompensated cases, hypoglycemia, or hyperglycemia, respectively. The median prediction horizon was 7 hours and 4 hours for hypoglycemia and hyperglycemia, respectively.

Conclusions: Electronic health records have the potential to reliably predict all types of BG decompensation. Readily available patient details and routine laboratory data can support the decisions for proactive interventions and thus help to reduce the detrimental health effects of hypoglycemia and hyperglycemia.

KEYWORDS

diabetes; blood glucose decompensation; multiclass prediction model; dysglycemia; hyperglycemia; hypoglycemia

Introduction

Blood Glucose Decompensations Are Associated With Poor Outcomes in Inpatients

Diabetes is one of the most common lifestyle diseases worldwide (affecting approximately 537 million people in 2021), particularly among older adults (aged >65 years), with numbers on the rise [1,2]. Consequently, the number of inpatients with diabetes is also increasing, with currently approximately every sixth hospital bed being used by patients with diabetes [3,4].

The hallmark of diabetes is loss of control over blood glucose (BG) levels. Failure to maintain BG levels within the ranges normally set by functional glucose homeostasis in nondiabetic people manifests as hyper- and hypoglycemia, where BG levels decompensate, that is, exceed or fall below a critical threshold, respectively.

Both hypoglycemia and hyperglycemia have been associated with numerous complications in inpatients. This includes an increased length of stay [5], diabetic ketoacidosis or hyperglycemic hyperosmolar state in the case of hyperglycemia [6], increased risk of infection [7,8], admission to intensive care units (ICUs) [9], and an overall increase in mortality [10-12]. The association between hypoglycemia and hyperglycemia and poor outcomes in inpatients who are critically and noncritically ill calls for a rigorous inpatient management approach toward reducing dysglycemia [13,14].

Challenges of Inpatient Dysglycemia Management

The environment of inpatients (ie, a hospital setting) is usually well-controlled; nevertheless, the maintenance of BG levels in a normoglycemic range is demanding. It is complicated by the fragile health status of the inpatient, stress (including postoperative stress), prolonged fasting, changes in diet and meal timings, and inadequate dosing of or changes in the type of antidiabetic drugs administered to name a few main troubles [14,15]. Standard diabetes therapy using adjusted subcutaneous insulin injections (sliding-scale insulin) combined with insufficient glucose monitoring is another issue and a potential risk factor for hypoglycemia [16], aggravated by the frequent shortage of nursing staff in hospitals.

The combination of continuous glucose monitoring (CGM) systems and subcutaneous insulin pumps with automated insulin delivery (closed-loop) systems is a recent promising development [17-19], which may reduce the workload of clinical staff in addition to benefiting patients.

Prediction of BG Decompensation

An alternative approach to continuous BG measurements is the prevention of BG decompensation by the detection of early signs or patterns associated with it, thereby avoiding the immediate and long-term adverse effects of hypoglycemia and hyperglycemia [20]. To date, studies have primarily assessed the prediction of hypoglycemia [20] based on, for instance, laboratory data [21,22] or data from electrocardiograms [23], or they required subcutaneous glucose readings from CGM systems [24].

Aim of This Study

This study investigated whether readily available standard laboratory results and patient information could be used to reliably predict both hypoglycemia and hyperglycemia in inpatients with a clinically relevant prediction horizon.

Methods

Patient Cohort

The data set contained anonymized hospital admission data collected during the routine management of adult (aged ≥ 18 years) inpatients of the 6 hospitals of the Insel-Gruppe (Bern, Switzerland) from January 1, 2014, to December 5, 2019. Data were retrieved as is; that is, no extra data were collected for this retrospective cohort study. Data of patients whose BG levels had been assessed at least once were included if they met ≥ 1 of the following inclusion criteria:

Diagnosis of diabetes or diabetes-related syndromes (codes as specified in the 10th revision of the International Statistical Classification of Diseases and Related Health Problems of the World Health Organization [25]), including E10 to E14, E16, E66 to E68, G59, G63, H28, H36, K77.8, K85, M14.2, N08.3, O24, R73, and R81

Administration of an antidiabetic drug falling into code category A10 (or subcategories thereof) of the Anatomical Therapeutic Chemical Classification System

Extreme BG levels regardless of any formal diagnosis of diabetes, including a BG level of <4.0 or ≥ 11.1 mmol/L measured at any time, a fasting venous BG level of ≥ 7.0 mmol/L, a 2-hour value of ≥ 11.1 mmol/L during an oral glucose tolerance test, or an HbA_{1c} value of ≥ 48.0 mmol/mol (International Federation of Clinical Chemistry) or $\geq 6.5\%$ (Diabetes Control and Complications Trial and National Glycohemoglobin Standardization Program)

The rationale behind these 3 inclusion criteria was to include a broad range of patients with potential indications of dysglycemia. The fact that BG level tests belong to the routine panel of laboratory tests in inpatients further helped reduce potential cohort bias. The unfiltered inclusion of all patients' BG measurement data was not possible because of the limitations set by the Swiss Human Research Act.

In total, the patient cohort comprised 38,250 patients ($n=16,842$, 44.03% women and $n=21,408$, 55.97% men) who had undergone 63,579 hospital admissions (cases), during which at least 1 laboratory analysis of 52 parameters was performed (Multimedia Appendix 1).

Definition of Dysglycemia

The types of BG decompensation are defined by BG levels of <3.9 mmol/L (<70 mg/dL; hypoglycemia) [26] or >10 , >13.9 , or >16.7 mmol/L (representing different degrees of hyperglycemia; >180 , >250 , and >300 mg/dL, respectively) [26,27]. A second level of hypoglycemia (BG <3.0 mmol/L [<54 mg/dL]) [26] was not considered specifically as both BG levels of <3.0 or <3.9 mmol/L may lead to an "altered mental and/or physical status requiring assistance" [26]; that is, a BG

level that is <3.9 mmol/L may already pose a significant risk for a patient.

BG level intervals were assigned category numbers of 0 to 4, with category 0 representing cases not showing BG

decompensation (Table 1). These categories were selected on the basis of clinical relevance, intuition in interpretation, and clinicians' decision-making and were aligned with clinical practice guidelines [26,27].

Table 1. Category assignment of blood glucose decompensation types.

Blood glucose level interval (mmol/L)	Category	Decompensation type
≥ 3.9 to ≤ 10	0	Nondecompensated
< 3.9	1	Hypoglycemia (level 1)
> 10 to ≤ 13.9	2	Mild hyperglycemia
> 13.9 to ≤ 16.7	3	Moderate hyperglycemia
> 16.7	4	Severe hyperglycemia

Data Preprocessing

Before use, the data sets were cleaned and preprocessed to remove erroneous entries and unreasonable, unlikely, or even impossible values.

For patient variables, values outside the following (reasonable) limits were set to "N/A" (whereas all other values of the respective patient were retained) as they are most likely the result of errors during data input: ages 18 to 130 years, body height 100 to 250 cm, and weight 25 to 400 kg. For laboratory measurements, negative values were removed (apart from the measurements of base excess, which allowed negative results). Values generally *incompatible with human life* were published only for a relatively small number of analytes [28], and measurements outside the following limits were excluded on the basis of such published limits for chloride (<65 or >138 mmol/L) [29], plasma pH (<6.8 or >7.8) [30,31], potassium (<1.3 or >9.0 mmol/L) [29], and sodium (<100 or >191 mmol/L) [29].

Other putative outliers were identified using the *Isolation Forest* algorithm [32] (implemented in the Python *sklearn.ensemble.IsolationForest* module; version 0.21.3) and were flagged. These binary outlier flags were used as additional variables to label potentially severe cases.

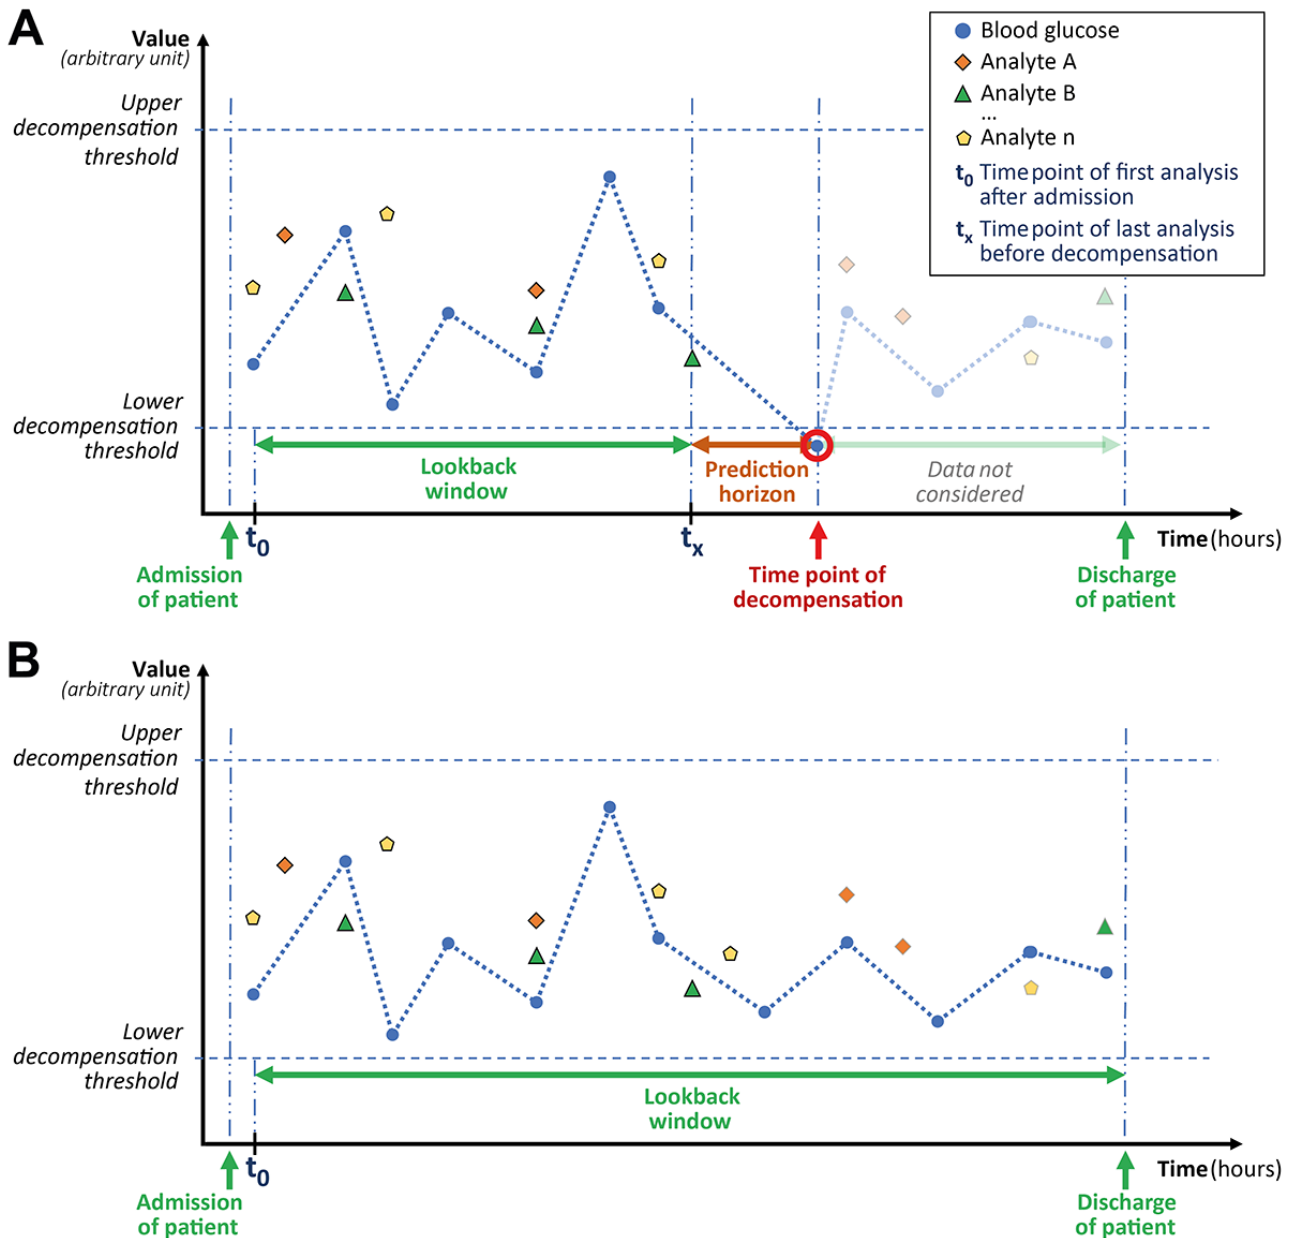

Predictors and Outcomes

Decompensation events corresponding to the different decompensation categories specified in Table 1 were identified in the data for each admission case. If an event corresponding

to a decompensation category was present, all data collected before the decompensation event (look-back window; see Figure 1 for a fictive case with [Figure 1A] and without [Figure 1B] a decompensation event) were used to form derived variables for each laboratory analyte (descriptive statistics: mean, SD, IQR, total range, recent trend, most extreme and most recent value, and analysis count). These derived variables are supposed to reflect the current overall status of a patient, mimicking a physician's assessment of the information present in a patient's health record. Only the first decompensation event was considered for each category. If a decompensation event was detected with the first measurements of a case, it was not considered at all in the corresponding decompensation categories. If no decompensation event of a specific category occurred within a case, the data collected at all its time points were used to create the derived variables (Figure 1B). The time span from the last piece of data of at least 1 predictor variable in the electronic health record (EHR) before the decompensation event of interest was considered the prediction horizon for the respective category (Figure 1A).

Analyte statistics were subsequently combined with patient demographics (age, sex, weight, height, language, and civil status), information on the previous and current administration of antidiabetic drugs, previous incidents of BG decompensation, history of diagnoses, and stay in ICU (complete variable list is provided in Multimedia Appendix 2). The data points were hashed, duplicates were removed, and a final data table was generated for the development and evaluation of the prediction models.

Figure 1. Look-back window and prediction horizon (A: decompensated case; B: nondecompensated case).

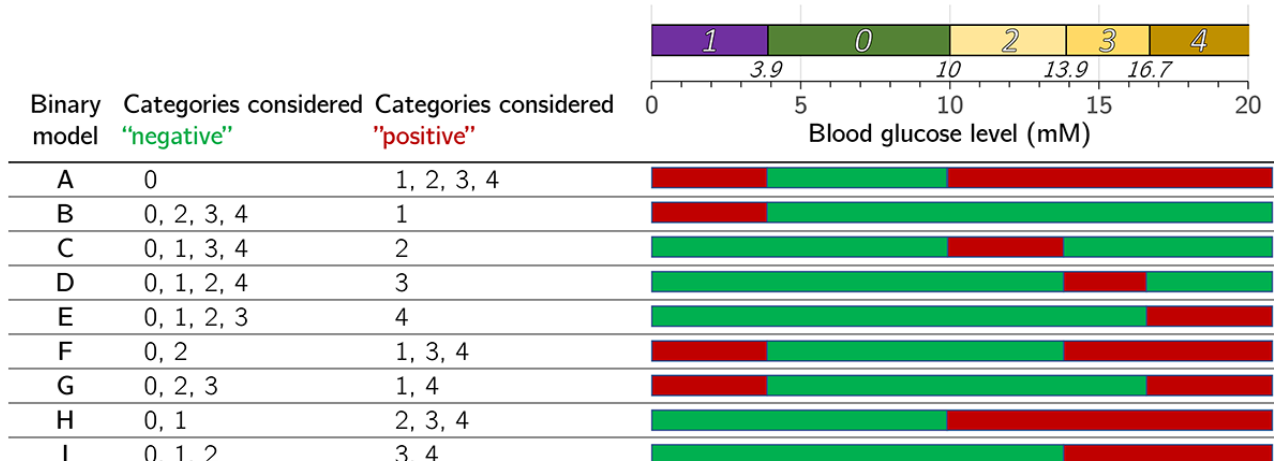

Prediction Models and Second-Level Ensemble

Binary prediction models were set up to distinguish clinically relevant combinations of decompensation categories (Figure 2). To this end, decision tree-based classification models using extreme gradient boosting (XGBoost; XGBoost package [33]; version 1.0.0.2) were trained. XGBoost models do not make

any assumptions about the distribution of the data and can deal with incomplete data sets. This is particularly useful for clinical data where the time points and types of analyses are specific for each individual patient. XGBoost uses a sparsity-aware split-finding algorithm that assigns a default direction to each node [33]. If a feature value is missing, the default direction along the corresponding node is taken [33,34].

Figure 2. Binary models detecting clinically relevant combinations of blood glucose decompensation types.

The data of cases falling into several categories were used to train each of the relevant prediction models. For each binary model, cases that did not meet the respective decompensation criterion were used as controls. The resulting categorizations may be puzzling for the human observer at first glance; for example, a binary hypoglycemia model using the data of a hyperglycemic case as *control*.

The model parameters were optimized over a wide parameter space using a stochastic grid search approach covering 2000 to 4000 parameter combinations. Data were split 70/30; that is, 70% of the cases were used for iterative training and the withheld 30% for model testing.

To counter the imbalance in the data sets, each sample was assigned a weight corresponding to the inverse frequency of its class during model training.

The best models with respect to precision (positive predictive value), sensitivity (recall), area under the curve of the receiver operating characteristic curve (AUC ROC), and informedness were retained. The *importance* of each variable (feature importance), which is a score indicating how influential each variable was during the construction of the tree ensemble, was determined during model training [33]. The selection of variables in advance was not required for the XGBoost models. Feature importance was calculated for each separate decision tree and node as the amount by which splitting on that particular node reduces the loss function, weighted by the number of leaf assignments to which the node contributes. Therefore, features affecting more decisions and decisions with higher significance will have higher relative importance. For the final assignment, the importance was averaged across the entire ensemble for each variable [33,35].

Subsequently, multiple binary models were assembled into a second-level ensemble to build a multiclass classifier. The composition of this second-level ensemble was optimized for

average precision using a genetic algorithm [36,37], as the number of possibilities for combining binary models into an ensemble grows exponentially.

Each multiclass is described by a (theoretical) combination of predictions of all binary classifiers (class-specific bit strings, ie, *ideal results*). For multiclass classification, a case-specific bit string for the votes of all binary classifiers of the second-level ensemble was created. The label of the *ideal* class-specific bit string with the minimal Hamming distance to the predicted case-specific bit string was chosen as the predicted case label.

In the case of a tie between ≥ 2 classes, they were prioritized according to clinical relevance (severity): hypoglycemia>severe hyperglycemia>moderate hyperglycemia>nondecompensated case>mild hyperglycemia. Mild hyperglycemia was assigned the lowest priority to reduce false alarms.

Ethics Approval

This study was approved by the Bernese cantonal ethics committee (Kantonale Ethikkommission, KEK) and registered with the Business Administration System for Ethics Committees of the canton of Bern (KEK/NZE file number: Req-2018-00335).

Results

Patient Cohort Characteristics

For this study, we analyzed clinical data from 38,250 inpatients who had undergone 63,579 hospital admissions between January 1, 2014, and December 5, 2019, during which at least 1 laboratory analysis was performed. Of the 38,250 patients, 16,842 (44.03%) were women (age: mean 62.6, SD 19.6 years), and 21,408 (55.97%) were men (age: mean 65.9, SD 14.4 years). Specific details for the different categories of dysglycemia (based on clinical relevance; compare with the *Methods* section) are summarized in Table 2.

Table 2. Patient cohort characteristics at baseline.

	Category				
	0: nondecompensated	1: hypoglycemia	2: mild hyperglycemia	3: moderate hyperglycemia	4: severe hyperglycemia
Characteristics					
Number of cases ^a	24,330	8164	26,788	10,419	8484

Antidiabetic drugs (administered before hospital admission), n (%)	8046 (33.1)	1975 (24.2)	8396 (31.3)	3829 (36.8)	3291 (38.8)
Previous BG ^c decompensation, n (%)	6801 (28)	4238 (51.9)	10,820 (40.4)	7885 (75.7)	6415 (75.6)
Decompensation level (mM), median (IQR)	N/A ^d	3.6 (3.2-3.7)	11.4 (10.6-12.3)	14.9 (14.4-15.7)	18.6 (17.4-20.8)
Time point of decompensation (hours; time after hospital admission), median (IQR)	N/A	34 (4-115)	16 (1-43)	25 (3-70)	22 (1-74)

^aNumbers sum up beyond the total number of hospital admissions (63,579), as cases occasionally fell into multiple categories if different decompensation events occurred within a case (Figure 3).

^bICU: intensive care unit.

^cBG: blood glucose.

^dN/A: not applicable.

Men represented approximately two-thirds of the patients showing a hyperglycemic decompensation event (Table 2), whereas nondecompensated and hypoglycemic cases mirrored the overall gender distribution of the cohort.

The patients showing hypoglycemia included significantly younger patients compared with other categories, and similarly, patients presenting with hypoglycemia were less obese (ANOVA [type II] using subjects as blocking factors, followed by the Games-Howell post hoc test 95% confidence level; $P < .001$). The likelihood that patients with some form of BG decompensation were admitted to the ICU increased approximately 5-fold.

An overview of the baseline characteristics of the patient cohort is provided in Table 2.

In a subset of cases, the patients showed multiple episodes or categories of decompensation events during admission (Figure 3). This included opposing decompensation types (hypo- and hyperglycemia) during the same admission in approximately 10.16% (3987/39,249) of decompensated cases. The inclusion criteria of the cohort favored a high prevalence of decompensation events (eg, patients with a formal diagnosis of diabetes or diabetes-associated comorbidities); hence, the prevalence of cases without any kind of BG decompensation was appreciably low (Table 2).

Figure 3. Types of decompensation events.

Multiclass Classifier Performance

Several binary models were assembled into a second-level ensemble to create a multiclass classifier. For k classes, a minimum of $\log_2 k$ binary classifiers are required to represent all classes, (ie, a minimum of 3 classifiers for 5 classes). Adding additional binary classifiers (beyond $\log_2 k$) is, in principle, redundant; however, additional bits can act as error-correcting codes (eg, the study by Berger [38]).

As the number of potential ensembles built from binary models grows exponentially, their composition was optimized using a genetic algorithm [36,37], assessing different combinations of the best binary models with respect to precision, sensitivity (recall), AUC ROC, and informedness. Average precision served as a readout (*fitness value*) during the optimization process.

The multiclass classifier ensemble with the best performance comprised binary model types A, B, G, H, and I (compare Figure

2; ie, of models trained to recognize all types of decompensations, only hypoglycemia, hypoglycemia and severe hyperglycemia, all types of hyperglycemia, and moderate and severe hyperglycemia, respectively). The mean AUC ROCs of the contributing binary models were 0.925 (SD 0.001), 0.960 (SD 0.002), 0.867 (SD 0.002), 0.914 (SD 0.001), and 0.863 (SD 0.003), respectively (5-fold cross-validation).

An overview of the true decompensation categories versus the model predictions (confusion matrix) is shown in Figure 4. Our multiclass classifier correctly predicted nondecompensated, hypoglycemic, and hyperglycemic cases in 93.66% (28,042/29,941), 58.99% (1093/1853), and 63.56% (6240/9817) of cases, respectively, in relation to the true category.

The performance metrics for each class are summarized in Table 3. All types of dysglycemia were predicted reasonably but somewhat conservatively.

Figure 4. Classification by multiclass classifier for nondecompensated cases (control), hypoglycemia, and hyperglycemia (confusion matrix; percentages relative to true class; number of cases in parentheses).

Table 3. Performance of multiclass classifier by class (5-fold cross-validation).

Performance metric	Performance (%), mean (SD)		
	Control	Hypoglycemia	Hyperglycemia
Sensitivity	67.1 (2.3)	59.0 (5.7)	63.6 (1.1)
Specificity	93.7 (0.9)	98.8 (0.5)	93.9 (0.6)
Precision	80.6 (1.9)	71.8 (8.6)	76.3 (1.6)
Balanced accuracy	80.4 (0.7)	78.9 (2.6)	78.7 (0.4)

When the different types of hyperglycemia were considered separately, mild, moderate, and severe hyperglycemia were correctly predicted in 46.69% (2411/5164), 31.22% (797/2553), and 36.87% (774/2099) of the cases in relation to the true category, respectively (Figure 5). For each type of

hyperglycemia (mild, moderate, and severe), an additional 20% to 30% of the classifications fell into other categories of hyperglycemia, meaning that the overall state of hyperglycemia was detected in those cases as well.

Figure 5. Classification by multiclass classifier (confusion matrix; percentages relative to true class; case numbers in parentheses).

Nondecompensated cases or cases showing hypoglycemia and severe hyperglycemia were predicted reasonably, albeit fairly conservatively, with lower sensitivity. The correct distinction between hyperglycemia types was more challenging. From a clinical perspective, this is understandable as these cases form a continuum. Nevertheless, a warning of any kind of hyperglycemia makes no difference in terms of the measures taken; hence, a classification of hyperglycemia was assumed to be sufficient, as long as this is indeed the underlying condition.

The median look-back window was 4.4 (IQR 1.8-9) days, 1.9 (IQR 0.4-5.7) days, 1.0 (IQR 0.3-2.4) days, 1.5 (IQR 0.6-3.7) days, and 1.8 (IQR 0.7-4.4) days for control class, hypoglycemia, and mild, moderate, and severe hyperglycemia, respectively. The median prediction horizon was 7 (IQR 3-15) hours for hypoglycemia and 4 (IQR 3-7, 3-6, and 3-6 for mild, moderate, and severe hyperglycemia, respectively) hours for all hyperglycemia types. In a clinical setting, such a prediction horizon would allow sufficient time for proactive interventions before BG decompensation occurs.

If the multiclass classifier is converted (reduced) to a binary classifier, it correctly predicts 67.12% (7833/11,670) of decompensated and 93.66% (28,042/29,941) of nondecompensated cases, corresponding to sensitivity (recall) and specificity (selectivity), respectively. In terms of precision (positive predictive value) and balanced accuracy, the model achieved 80.5% and 80.5%, respectively.

Notably, across all predictions, a relatively small set of variables had a comparably large impact on the individual binary models constituting the multiclass classifier (Figure 6). Although the contributions of the variables (feature importance; see the *Methods* section for details) varied slightly across models, they all pointed in the same direction. A set of 12 variables encompassed the 10 most important variables for all 5 binary models. Not unexpectedly, quantitative readouts of glucose measurements had the highest importance; however, *soft* variables, such as information on recent decompensation events or time since admission, were also critical.

Figure 6. Variable importance (population level) of binary models comprising the multiclass classifier (top 10 shown). ADD: antidiabetic drug; all: all types of; decomp: decompensation; hyper: hyperglycemia; hypo: hypoglycemia.

Discussion

Principal Findings

In this study, we set up a prediction model for hypo- and hyperglycemia from routine inpatient clinical data. We used anonymized EHRs of 63,579 hospital admissions of 38,250 patients between January 2014 and December 2019 to derive variables from measurements of common laboratory analytes, as well as patient information, drug administration, and diagnosis history. The data were characterized by a high degree of missingness, particularly for many of the variables originating from less common laboratory tests. To address this issue, we created a second-level ensemble comprising binary decision tree models that could deal with incomplete data. With respect to the overall main categories of interest (nondecompensated cases and hypo- or hyperglycemia), our classifier achieved 93.7% (28,042/29,941), 59% (1093/1853), and 63.6% (6240/9817) correct predictions, respectively. When converted to a binary classifier, it reached correct classification rates of 93.7% (28,042/29,941) and 67.1% (7833/11,670) for decompensated and nondecompensated cases, respectively. The median prediction horizon was 7 and 4 hours for hypo- and hyperglycemia, respectively.

Strengths and Limitations

In our modeling approach, the variables were derived rather than directly taken from the EHRs. This increases the effort in

an applied clinical setting as the variables need to be updated when new measurements are added to a patient's EHR. This concerns both the summary statistics of each analyte and variables related to patient history (eg, application of antidiabetic drugs or previous decompensation events), which may change during hospitalization. However, an automatic update from clinical data warehouses should solve this issue. The ultimate aim should be to allow integration into a real-time alert system.

Data were not specifically collected for our retrospective study; hence, our data set may show a potential bias in terms of the timing of blood sampling; for example, hours during the day with higher staffing levels or before meals may be somewhat overrepresented. Hypoglycemia, in particular, may occur at night or in the early morning hours when no measurements are performed. Despite this potential bias in the training data, our model featured a promising prediction horizon. With 7 and 4 hours for hypo- and hyperglycemia, respectively, it provided sufficient time to initiate measures and prevent BG decompensation and its adverse effects. The difference between hypo- and hyperglycemia may be explained by more deliberate monitoring of BG levels in potential hypoglycemic patients by clinical staff.

The main strength of our model's performance lies in the distinction between the extreme ends of the decompensation scale (nondecompensated cases, hypoglycemia, and severe hyperglycemia). However, the discrimination rate of different

types of hyperglycemia, was rather moderate, particularly the rate of correct classification of moderate hyperglycemia (31.2%). In part, this may be because the categorization of different types of hyperglycemia, and the overall distinction into 5 categories in our model, had a clinical relevance rather than a computational one. Different types of hyperglycemia are defined by clinical practice guidelines [26,27] and form a continuum in the daily routine.

This does not affect the model's usefulness drastically when taking into account the intention behind a model like ours, namely serving as decision support for adjustments of patient monitoring or therapeutic strategies (not triggering any treatment such as administration of insulin or glucose). Regarding the potential consequences of misclassification for a patient, mix-ups of hyperglycemia types are clinically irrelevant, and similarly, confusion of hypoglycemia and hyperglycemia has no drastic consequences—they would all *trigger* a BG test by clinical staff. False positives cause an extra workload for clinical staff but are also noncritical for a patient and occurred at a low rate (6.3%). False-negative predictions are more problematic as they may possibly result in the noninitiation of a BG test or countermeasures for BG decompensation. The false-negative rate of our model (32.9%) is suboptimal, meaning that it classifies too conservatively and misses too many decompensated cases. However, in light of these cases being missed completely without decision support, this is a step in the right direction.

Despite having a common denominator—diabetes or diabetes-related comorbidities—patients in our cohort were diagnosed with various primary and secondary diagnoses. Consequently, a plethora of different analyses have been conducted, with some tests done routinely; for example, the assessment of blood count, and other, more specific ones, were missing in most cases, such as analyses related to iron metabolism. Our prediction model, a second-level ensemble using derived variables, deals well with this sparse data (shown in the *Methods* section), in contrast to other popular methods such as logistic regression, support vector machines, and neural networks, which require complete data sets.

Akin to other studies [22], the patient cohort underlying our model features a certain bias toward patients with potential indications of dysglycemia (see the *Methods* section). However, this is not necessarily disadvantageous. A cohort without preselection may lead to trivial models calling for the (nondecompensated) group with an overwhelming frequency, yielding a low overall classification error but limited clinical utility [39]. The actual performance, clinical applicability, and performance for specific patient subgroups (eg, dysglycemia risk patients) must be assessed in broader follow-up studies, as for every model.

Notably, our model uses routine clinical data from standard laboratory tests and patient information, all of which are readily available in hospital settings. This is beneficial as these variables—assuming a proper in-house information flow—are available for free, both in terms of cost (no additional testing required) and effort (once the information is entered). However, such data collected during routine management usually do not

feature fixed sampling times or a common set of analyses, which complicates alignment between cases. Given the absence of periodicity in the data, our approach was to mimic a physician's intuitive assessment of the information present across a patient's health record (eg, average and extreme values, trends, and most recent values) rather than individual data points.

This could ensure broad applicability, for example, in contrast to models based on expensive specialized tests [22] or even data from sensor implants [24]. Without a doubt, CGM devices offering frequent subcutaneous glucose measurements are ideal for a narrow set of patients, such as those with type 1 diabetes. However, their wider use in the general context of inpatients is neither practical nor cost-effective. In times of tight budgets for health care systems, the frugality of a model relying only on pre-existing data is of additional value. Our model does not require data sampled at specific time points; it takes whatever data are available. The identification of high-risk patients at no extra cost may lead to a reduction in workload for clinical staff and less frequent blood sampling for average patients. Overalerting should be taken into account as well—it would reduce the benefit of correct predictions; hence, the rather conservative nature of our multiclass classifier may actually not be such a drawback. A model is always an approximation of reality and should serve its purpose in the first place (“All models are wrong but some are useful.” [40]).

Comparison With Prior Work

An increasing number of prediction studies are using the growing amount of patient data available in EHRs (for review, see the studies by Woldaregay et al [20], Roca et al [41], and Torkamani et al [42]). Diabetes is a popular and promising target of prediction studies [20] because of both its high prevalence in an aging population and the associated economic burden. The growing number of inpatients with deficiencies in controlling their BG levels calls for a refinement of the existing inpatient dysglycemia management [12-14,43].

Models for predicting a single type of BG decompensation as diabetes-associated complications have been established previously, mainly for hypoglycemia [20-22,44,45]. Few studies only have been published for hyperglycemic events [20].

To the best of our knowledge, this is the first general multiclass prediction model for BG decompensation to date (ie, both hypo- and hyperglycemia). A multiclass model offers the advantage of overcoming the vagueness associated with a binary model in a setting of >2 classes. For example, the prediction of *nonhypoglycemic* by a hypoglycemia model is ambiguous as the affected patient could be *nondecompensated* or *hyperglycemic*, where the latter would require action by the patient or clinical staff. A multiclass model such as ours resolves this conflict by differentiating between nondecompensated and multiple types of decompensated cases.

Notably, our model performed reasonably well when reverted to a binary model. Although it may be counterintuitive to first build a multiclass classifier and then revert it to a binary classifier, this approach takes advantage of the fact that ensembles tend to outperform individual models [46] and can benefit from error correction [38].

Future Directions

In the next step, it would be interesting to assess the multiclass classifier in a follow-up retrospective cohort study for validation purposes using an independent data set. Optimizing the sensitivity and reducing the false-negative rate should be an additional focus to make the model more applicable for clinical use. Further down the road, the incorporation of the model into an alert system or even actionable artificial intelligence [17-19] could be tested. This would allow the evaluation of its real-time effectiveness, ideally leading to a reduction in the incidence of BG decompensations in inpatients.

Conclusions

Our multiclass prediction model based on derived variables can classify both hypo- and hyperglycemia with reasonable sensitivity.

Given the serious adverse health effects of hypo- and hyperglycemia and the associated poor outcome of BG decompensation in inpatients, it is important to prevent dysglycemia whenever possible. Prediction models such as ours may support clinicians in inpatient management by proactively pointing out the necessity for adjustment of patient monitoring or therapeutic strategies. Therefore, this study may serve as a step toward a real-time alarm system and actionable artificial intelligence, which may aid in reducing BG decompensation in inpatients.

Acknowledgments

The authors are indebted to all patients who gave general consent for using their data for research; the Bernese Cantonal Ethics Committee (*Kantonale Ethikkommission*) for approving this study; David Herzig for discussions; Tobias Blatter for input on data processing; and the team at Insel Data Science Center, in particular Jeremy Koch and Noel Frey, for extracting the data set.

Abstract

Background: University students are susceptible to excessive stress. A web-based stress management intervention holds promise to improve stress but is still at a novel stage in Indonesia.

Objective: The aim of this paper was to report the feasibility of the intervention we developed—Rileks—among university students in Indonesia in terms of acceptability and usability, and to propose recommendations for future improvements.

Methods: A single-group pretest and posttest design was used. Participants with scores of 15 or higher on the stress subscale of the 42-item Depression Anxiety Stress Scales were given access to the intervention (N=68). The main outcome measures were the 8-item Client Satisfaction Questionnaire (CSQ-8) score, the System Usability Scale (SUS) score, and intervention uptake. Participants' experience in each session was evaluated using closed- and open-ended questions for future improvements. Descriptive statistics were used to examine primary outcome and qualitative session evaluations. Participants' responses to each topic of the open questions were summarized.

Results: The intervention was evaluated as being satisfactory (CSQ-8 mean score 21.89, SD 8.72; range 8-32). However, the intervention's usability was still below expectation (SUS mean score 62.8, SD 14.74; range 0-100). The core modules were completed by 10 out of 68 participants (15%), and the study dropout rate was 63% (43/68) at postassessment. In general, the module content was rated positively, with some notes for improvement covering content and technical aspects.

Conclusions: This study indicates that Rileks is potentially feasible for Indonesian university students. In order to be optimally applied in such a context and before scaling up web-based interventions in Indonesia, in general, further development and refinement are needed.

Introduction

Globally, an increasing number of university students experience stress [1-3]. To a certain extent, stress can be advantageous in stimulating human thriving [4]. However, ongoing high levels of stress may lead to negative outcomes, such as psychological distress, anxiety, depression, physical illness, substance abuse, and impaired work-related and academic performance [4-6]. The prevalence varies across studies and among countries, but overall, studies suggest that 20% to 25% of university students around the globe from various fields of study [7] suffer from psychological distress [3]. However, most of them do not receive support in reducing their high stress levels [5,8]. This is due to various reasons, including fear of stigma for seeking help for mental health problems [5] and limited availability of skilled mental health professionals within universities [5,9]. This has also been reported by university students in Indonesia [10], despite considerable need for psychological support (eg, two-thirds of Indonesian nursing and medical students experience moderate to severe levels of stress) [11,12].

Web-based interventions may overcome some of the issues related to this treatment gap. They may provide an accessible and potentially less stigmatizing alternative compared with face-to-face treatment, because clients can use web-based interventions privately [13,14]. Studies have shown that a web-based intervention can be a stand-alone intervention or can be an adjunct in a psychological intervention, which is known as a blended strategy [15,16]. A blended strategy offers some benefits, such as increasing an intervention's acceptability [17], lowering dropout rates, and increasing the clinician's efficiency [16]. However, implementing a blended strategy requires an adequate infrastructure and a mental health system that promotes the use of telemental health. In Indonesia, where an internet- or web-based intervention is still a novel approach and mental health service is still limited, a blended strategy might require more time to develop. Thus, as an initial step, we focused on a web-based intervention, as this would be more suitable for the current circumstances in Indonesia. Web-based interventions could be especially suitable for a university student population [18], since younger, well-educated individuals already tend to seek information and help for emotional and mental health problems through the internet [19-21]. A meta-analysis reported that web-based and computer-delivered stress management interventions can effectively diminish university students' stress, with an effect size of 0.73 (95% CI -1.27 to -0.19, $P=0.008$) [22]. A web-based stress management intervention culturally adapted for Indonesian university students might be feasible because of the increasing availability of the internet in Indonesia [23]; consequently, there would be greater internet access at their universities and, to a lesser extent, at home.

Several web-based stress management interventions for university students have been developed in high-income countries [22]. GET.ON Stress has been investigated in several randomized controlled trials [24-26], is based on the

transactional model by Lazarus and Folkman [27], and consists of problem-focused and emotion-focused coping strategies. It was originally developed for German employees, has been adapted for German-speaking university students, and has been renamed StudiCare Stress [28]. As part of this project, the GET.ON Stress intervention was culturally adapted to the Indonesian context, using the integrative cultural adaptation model by Barrera et al [29] as a guideline. The first two steps of the adaptation process, which have been previously reported [30], have led to the Rileks intervention; Rileks means relax, and means calm in the Indonesian language.

Due to the novelty of this kind of intervention in Indonesia, instead of a pilot study, a feasibility study was conducted as the third step with an emphasis on the process of developing, implementing, and assessing preliminary responses of participants to the new intervention [31,32]. Furthermore, a feasibility study helps to evaluate components (ie, participant recruitment, accuracy of the intervention protocol, and ability to execute the new intervention) necessary for the next large-scale study [33,34]. This paper reports on the third step of the model by Barrera et al [29], which is the feasibility study of the preliminary version of Rileks.

The primary aim of this study was to investigate the feasibility of Rileks among university students in Indonesia in terms of acceptability, usability, and intervention uptake. The secondary aim was to investigate stress, anxiety, and depression reduction and improvement of quality of life, as well as to generate feedback for further refinement of Rileks.

Methods

Participants and Sample Size

Inclusion criteria were for participants to have scored 15 (ie, low stress level) or higher on the 42-item Depression Anxiety Stress Scales (DASS-42) [32], to be enrolled in a university in Indonesia, to be 19 years of age or older, to have access to the internet, and to be able to speak Bahasa Indonesia fluently. Participants were recruited between October 10 and 19, 2018. Information about our study and website was disseminated through social media platforms, such as Facebook, Instagram, and WhatsApp groups, and through presentations by the principal investigator (DJ) at events at two universities in Indonesia: YARSI University and the Indonesian State College of Accountancy.

A formal calculation of sample size used for effectiveness trials is not suitable for a feasibility study [35]. In our study, we intended to include at least 50 participants, with a saturation of 75 participants to ensure sufficiently reliable estimates of our main study parameters. We based this estimate on a systematic study analyzing sample sizes in pilot and feasibility studies in the United Kingdom, which reported a median of 36 participants for a feasibility study sample size [35].

Study Design and Procedure

A single-group pretest and posttest design was used. Interested university students who signed up on our website subsequently received a link to the screening measurement, the DASS-42 stress scale. Eligible university students then had to submit their signed electronic informed consent form before completing the baseline measurements (ie, pretest). All included participants received log-in credentials for the intervention, and only those who logged in received posttreatment measurements (ie, posttest) 10 weeks after the pretest. A duration of 10 weeks was chosen as the postmeasurement time point, as we considered this to be sufficient time for participants to complete the intervention. All measures were self-reported and administered online.

Ethics Approval

The study was reviewed and approved by the Indonesian ethics committee at YARSI University (project No. 193/KEP-UY/BIA/VIII/2017).

Intervention

Rileks consists of six sessions and an optional booster session provided 4 weeks after intervention completion. The first session comprises psychoeducational information about stress, based on the emotion-focused and problem-focused coping strategies by Lazarus and Folkman [27]. The second session comprises the six-step problem-solving method based on problem-solving therapy [36,37]. In the second session, participants work on their problem-solving skills by applying the method to their individual problem. In sessions 3 to 5, participants are introduced to emotional regulation techniques based on affect regulation training [37,38]. The techniques include muscle and breathing relaxation, acceptance and tolerance of emotions, and self-support in difficult situations. These techniques are explained one by one in each session, respectively. In the last session, participants are asked to reassess their goals for the training and to identify their personal warning signs for stress. Furthermore, participants are asked to write a letter to themselves about how they imagined their life would be after applying the methods and techniques they had been taught. In addition, a booster session may be given as an option to evaluate the letter they had written to themselves in the last session, reassess their goals, and make plans to continue applying what they had learned from Rileks.

Each session contains general information, examples related to the exercises, exercises guided by electronic coaches (e-coaches), quizzes, slideshows encompassing explanations related to stress management methods and techniques, audio files, and downloadable material, which were all presented on a secure platform. Access to the platform was given to the participants based on their email addresses and self-designated passwords. Participants were advised to log in once or twice per week. A reminder was sent to the participants if they did not log in within 7 days. Within 48 hours after completion of each session, four trained psychologists acting as e-coaches gave personalized written feedback on the exercises. The e-coaches followed guidelines about the feedback process that

are defined according to the standardized manual on feedback writing for the intervention.

Primary Outcome Measures

Acceptability was measured by assessing clients' satisfaction with Rileks using the translated version of the 8-item Client Satisfaction Questionnaire (CSQ-8) [39-41]. The scale consists of eight questions answered using 4-point Likert scales (scored from 1 to 4), with total scores ranging from 8 ("great dissatisfaction") to 32 ("great satisfaction"). We set an average score of above 20 (20 is the median total score) as the criterion for acceptable satisfaction. The CSQ-8 has good reliability, as it has been reported to have a Cronbach α of .92 [42].

The Indonesian version of the System Usability Scale (SUS) [43] was used to assess the usability of Rileks in terms of user friendliness [44,45]. The scale comprises 10 statements scored on a 5-point Likert scale, ranging from 1 ("strongly disagree") to 5 ("strongly agree"). The total scores were then transformed into a scale with scores ranging from 0 to 100, with higher scores representing higher usability. A score of 70 or more was considered adequate as a feasibility criterion [45]. The Cronbach α of the Indonesian version has been reported as .84 [43], which indicates good reliability. Both the CSQ-8 and the SUS were only administered at postintervention.

Intervention uptake was measured by assessing the number of participants who completed the core online sessions (ie, sessions 1 to 5), where participants learn the basic principles of problem solving and emotion regulation. The criterion for acceptable adherence was set at 60% or more participants who completed the core sessions [30]. The 60% threshold was based on previous meta-analyses on adherence to internet-based cognitive behavioral therapy (CBT) for depression, which found that 65.1% of participants completed the entire internet-based CBT sessions [46].

Secondary Outcome Measures

The severities of stress, anxiety, and depression were measured using the Indonesian version of the DASS-42 [47]. The scale consists of 42 items divided into three subscales—depression, anxiety, and stress—where each subscale contains 14 items ranging from 0 to 3 and a higher score indicates a greater degree of severity [48]. The Indonesian version of the DASS-42 shows excellent overall reliability, with a Cronbach α of .95, and high internal consistency in the separate depression, anxiety, and stress subscales (α = .91, .85, and .88, respectively) [47].

Quality of life was measured by the Indonesian version of the brief version of the World Health Organization Quality of Life instrument (WHOQOL-BREF) [49]. It consists of two items that measure overall quality of life and general health, and 24 items that measure how the respondent felt in the last 2 weeks across four domains: physical health, psychological health, social relationships, and environmental health [49,50]. Among the Indonesian population, the WHOQOL-BREF has been reported as having internal consistencies, or Cronbach α values, of .41 to .77 in the four domains, respectively [51], and reliability with intraclass correlation coefficients of 0.70 to 0.79 in the four domains, respectively [49]. The DASS-42 and the WHOQOL-BREF were assessed both at pretest and posttest.

Other Measurements

Demographic variables were collected to describe the characteristics of the study population. Cultural-related aspects of the Rileks modules were evaluated within the aspects of language, case examples, and visual presentation. With regard to language use, we asked whether the participants could understand the words in each session. To evaluate case examples and visual presentation, the participants were asked whether the case examples and pictures used in the sessions represented the Indonesian university student context. Participants' experience with e-coaches was evaluated using six questions concerning participants' satisfaction with contact with their e-coaches. Some of the questions were adapted from another study that assessed participants' satisfaction with online therapeutic contact [52]. A selection of responses was provided for each question. An open question asked for participants' recommendations for future improvement of the e-coaches.

Furthermore, by the end of each session on the intervention platform, participants gave an evaluation about their experience in each session. The participants assessed general aspects of each session (eg, usefulness, easiness, and time needed to complete the module) using a Likert scale ranging from 1 (eg, "very useful" or "very easy") to 5 (eg, "not useful at all" or "very difficult"). They also assessed specific aspects of the sessions (eg, the structure of the module) using a Likert scale ranging from 1 ("positive judgement") to 7 ("negative judgement") and answered some open questions (eg, "What did you like and not like about this session?" and "How might you have benefitted from it?").

Statistical Analyses

Descriptive statistics were used to examine primary outcomes, demographic data, and session evaluations. Participants' satisfaction, using the CSQ-8, and system usability, using the SUS, as feasibility parameters were summarized using means and SDs. Intervention uptake was summarized with frequency of participants who logged in or completed each session. Differences in demographic characteristics between participants who logged in and those who did not were tested using a chi-square test in terms of sex, level of education, field of study, and university location. Independent-sample *t* tests were used to assess differences in mean age, DASS-42 scores, and WHOQOL-BREF scores.

Secondary outcomes were analyzed using 2-tailed paired-samples *t* tests with a level of significance of $P=.05$. A normality test at each time point was conducted beforehand, using the Shapiro-Wilk test. As the distributions significantly differed from normal ($P<.05$), a sensitivity analysis using nonparametric tests (eg, the Wilcoxon signed-rank test) was conducted. Furthermore, within-group effect sizes (Cohen *d*) were calculated. SPSS software (version 26; IBM Corp) was used for the analysis.

In order to understand the participants' experience and provide recommendations relevant to future refinement, participants' responses to the open questions for each topic were summarized by categorizing responses with similar themes. Categorization was done by the principal investigator (DJ) and one of the Indonesian team members as a second rater. The summary was finalized by consensus between the two.

Results

Enrollment and Participant Characteristics

A total of 191 university students registered and completed the screening on the study website. Most of the participants ($n=169$, 88.5%) learned about the study through social media (eg, Facebook, Instagram, and WhatsApp groups). A small proportion ($n=22$, 11.5%) were informed through presentations by the principal investigator (DJ) at two universities. Of the 191 registered university students, 40 (20.9%) scored lower than 15 on the DASS-42 stress scale, which can be considered as normal stress, and 151 (79.1%) were eligible for inclusion. See [Figure 1](#) for study flowchart.

Baseline questionnaires were completed by 121 out of 151 (80.1%) participants. The majority were female ($n=103$, 85.1%), had a bachelor's degree ($n=94$, 77.7%) in social and behavioral sciences ($n=83$, 68.6%), and studied on the island of Java ($n=79$, 65.3%). The average DASS-42 stress score at baseline was 23.11 (SD 5.8), indicating moderate stress. One-third of the participants ($n=41$, 33.9%) fell into the severe stress category (ie, score 26-33). Those who logged in mostly studied in Java and scored lower on psychological quality of life compared to those who did not log in. See [Table 1](#) for all participants' characteristics at baseline.

Figure 1. Study flowchart.

Table 1. Characteristics of participants at baseline and comparisons between those who did not log in and those who did.

Characteristic	Baseline (n=121)	Participants who did not log in (n=53)	Participants who logged in (N=68)	<i>P</i> value ^a
Age (years)

^a*P* values are based on the difference between those who logged in and those who did not.

^bN/A: not applicable; the *P* value was not calculated for these values.

^cDASS-42: 42-item Depression Anxiety Stress Scales; scores range from 0 to 42 for each subscale, where a higher score indicates increased severity.

^dWHOQOL-BREF: brief version of the World Health Organization Quality of Life instrument. Scores range from 1 to 5 for each item in each domain; the total score for each domain was then transformed linearly to a scale ranging from 0 to 100, where a higher score indicates increased quality of life.

Primary Outcomes

A total of 10 weeks after the pretest, posttreatment questionnaires were sent to the 68 participants who had logged in. Questionnaires were completed by 25 participants; thus, the

study dropout rate was 63% (43/68). The CSQ-8 mean score was 21.89 (SD 8.72), which met our acceptable satisfaction criterion of a mean score of above 20. Table 2 provides the mean scores of the CSQ-8 items.

Table 2. Scores for all items of the 8-item Client Satisfaction Questionnaire for Rileks (n=25).

Item	Score, mean (SD) ^a
How would you rate the quality of service you have received from Rileks?	3.20 (0.71)
Did you get the kind of service you wanted?	2.92 (0.70)
To what extent has Rileks met your needs?	2.72 (0.61)
If a friend were in need of similar help, would you recommend Rileks to him or her?	3.24 (0.59)
How satisfied are you with the amount of messages you have received from Rileks?	3.16 (0.55)
Has Rileks helped you to deal more effectively with your problems?	3.28 (0.74)
In an overall general sense, how satisfied are you with the help you have received from Rileks?	2.96 (0.73)
If you were to seek help again, would you use Rileks again?	3.04 (0.68)

^aItems were rated on a 4-point Likert scale, ranging from 1 to 4, where higher scores indicate increased satisfaction.

The SUS mean score was 62.80 (SD 14.74), with the lowest score for the learnability item (Table 3). With regard to intervention uptake, all 121 enrolled participants received log-in credentials for Rileks by email. Of those participants who enrolled, 68 (56.2%) logged in. These 68 participants did not differ from those who never logged in (n=53, 43.8%) on any of the baseline characteristics, with the exception of university location ($\chi^2_{26}=21.2$, $P=.04$) and psychological quality of life ($t_{113}=2.14$, $P=.02$; Table 1). Of the 68 participants who logged

in, the core sessions were completed by 10 (15%) participants. This number is below our acceptable uptake criterion of 60%. Reasons for nonadherence were mostly unknown because those participants could not be reached. The known reasons for nonadherence or withdrawal included time management problems, rare use of email so they missed notifications, unexpected events (eg, internship to a remote village with limited internet coverage), and technical problems, such as unfamiliarity with the log-in system. Table 4 outlines the number of completed sessions in Rileks.

Table 3. Scores for all items of the System Usability Scale for Rileks (n=25).

Item	Score, mean (SD) ^a
I think that I would like to use Rileks frequently.	3.48 (0.82)
I found Rileks unnecessarily complex. ^b	3.40 (1.04)
I thought Rileks was easy to use.	3.56 (0.96)
I think that I would need the support of a technical person to be able to use Rileks. ^b	3.88 (1.01)
I found that the various functions in Rileks were well integrated.	3.72 (0.89)
I thought there was too much inconsistency in Rileks. ^b	3.56 (0.77)
I would imagine that most people would learn to use Rileks very quickly.	3.88 (0.73)
I found Rileks very cumbersome to use. ^b	3.44 (1.01)
I felt very confident using Rileks.	3.32 (0.85)
I needed to learn a lot of things before I could get going with Rileks. ^b	2.88 (1.27)

^aItems were rated on a 5-point Likert scale, ranging from 1 to 5, where higher scores indicate increased usability.

^bThe scores for this item were reversed.

Table 4. Rileks sessions completed by participants.

Step	Participants (N=68), n (%)
Logged in	68 (100)
Completed module 1	40 (59)
Completed module 2	26 (38)
Completed module 3	16 (24)
Completed module 4	12 (18)
Completed module 5	10 (15)
Completed all 6 modules	9 (13)

Secondary Outcomes

At posttest, out of 25 participants who completed the CSQ-8 and the SUS, the DASS-42 stress scale and the WHOQOL-BREF were completed by 23 (92%) participants, consisting of the core session completers and noncompleters. At posttest, participants reported significantly lower levels of stress (mean -10.04 , 95% CI 5.36-14.72), depression (mean -6.85 , 95% CI 1.37-12.32), and anxiety (mean -6.45 , 95% CI 1.56-11.34), with a high effect size on stress and moderate effect

sizes on anxiety and depression. Participants also reported significantly improved quality of life in terms of physical health (mean -21.25 , 95% CI -29.05 to -13.44), psychological health (mean -12.50 , 95% CI -20.25 to -4.75), overall quality of life (mean -0.55 , 95% CI -0.96 to -0.13), and overall health (mean -0.70 , 95% CI -1.31 to -0.09). However, we did not find significant differences in the social relationship and environmental health aspects of quality of life (Table 5). Wilcoxon signed-rank tests for nonparametric distributions yielded the same results.

Table 5. DASS-42 and WHOQOL-BREF scores at baseline and posttreatment (n=23).

Measure	Baseline score, mean (SD)	Postassessment score, mean (SD)	<i>P</i> value	Cohen <i>d</i>
DASS-42^a subscales				
Stress	24.74 (6.33)	14.70 (11.41)	<.001	0.93
Anxiety	17.95 (8.35)	11.50 (8.34)	.01	0.62
Depression	17.10 (10.74)	10.25 (11.39)	.02	0.58
WHOQOL-BREF^b domains				
Physical health	42.30 (8.28)	63.55 (13.95)	<.001	1.25
Psychological health	43.85 (17.74)	56.35 (20.14)	.003	0.78
Social relationship	49.40 (17.99)	54.35 (19.64)	.45	0.19
Environmental health	54.55 (13.32)	50.60 (15.14)	.13	0.41
Overall quality of life	2.70 (1.08)	3.25 (1.07)	.01	0.62
Overall health	2.70 (1.03)	3.40 (0.94)	.03	0.54

^aDASS-42: 42-item Depression Anxiety Stress Scales; scores range from 0 to 42 for each subscale, where a higher score indicates increased severity.

^bWHOQOL-BREF: brief version of the World Health Organization Quality of Life instrument. Scores range from 1 to 5 for each item in each domain; the total score for each domain was then transformed linearly to a scale ranging from 0 to 100, where a higher score indicates increased quality of life.

Feedback for Future Refinement

Module and Session Evaluation

In general, participants rated the individual modules positively (Table 6). The response summary of the open questions (Multimedia Appendix 1) indicated that, in general, participants were in favor of the clear examples given in the modules and the case examples, to which they felt they could relate. Furthermore, participants suggested that the module content had provided them with new and comprehensive information as well as exercises that could help them manage their stress in

terms of recognition, being more reflective and accepting of oneself, learning how to examine problems, and thinking of positive activities that could help them manage their stress. Moreover, Rileks was considered to be a medium where participants were able to express their problems openly without feeling ashamed.

Participants also mentioned things they did not like, mostly technical problems, such as unfamiliarity with the system, poor audio quality, and some files being too large to download, as well as some repeated questions and confusion about how to do the exercises, despite the given examples.

Table 6. Module evaluation.

Evaluation criteria	Evaluations by module					
	Module 1 (n=40)	Module 2 (n=26)	Module 3 (n=16)	Module 4 (n=12)	Module 5 (n=10)	Module 6 (n=9)
General usefulness	Useful	Useful	Useful	Very useful	Useful	Very useful
Easy to complete	Easy	Easy	Easy	Easy	Easy	Very easy
How long did it take? (minutes)	30-60	30-60	30-60	30-60	60-90	30-60
Clarity	Undecided	Clear	Clear	Clear	Clear	Very clear
Subcontent usefulness	Undecided	Useful	Useful	Useful	Useful	Very useful
Pleasantness	Undecided	Pleasant	Undecided	Pleasant	Pleasant	Very pleasant
Comprehensibility	Undecided	Comprehensible	Comprehensible	Comprehensible	Comprehensible	Very comprehensible

Suggestions for improvements included the following: adding interactive functions for communication with the e-coach or other professionals to get direct help, such as live chat, especially in parts where participants need to remember and deal with negative events they had; making the intervention simpler and shorter; adding links to music and video guidance, especially for relaxation; providing downloadable materials; and developing a better display for those accessing Rileks from a mobile phone.

Cultural and Technical Aspects

At posttest, all participants (n=23) could understand the language used in the Rileks modules, including idioms and metaphors. Most participants (n=20, 87%) thought that Rileks used suitable media, such as audio guidance for relaxation or a slide show to explain theory. Case examples in Rileks were considered to represent the Indonesian university student context (n=22, 96%). Furthermore, one participant suggested adding a case example that speaks for university students who come from a family with a low economic background.

e-Coach Evaluation

Of the 23 participants at posttest, 13 (57%) said they missed face-to-face communication and 7 (30%) had hoped for more support. The quality of support was generally considered positive. The e-coach support helped participants gain insight into managing their problems and go through the modules with confidence and motivation. Moreover, the presence of e-coaches made them feel understood and less lonely.

Open questions about suggestions for future refinement were responded to by 22 (96%) participants. Suggestions for refinement from the open questions can be summarized as follows. Firstly, the feedback process could be more interactive and personal (n=3, 13%). Participants hoped that they would be able to ask further questions by replying to the feedback they had received. Secondly, some participants suggested the use of a medium other than email to deliver feedback (eg, using chat; n=2, 9%). Thirdly, they would like the possibility of maintaining a future connection with the e-coaches for further counseling after the intervention had ended (n=2, 9%). Lastly, there was a suggestion to combine offline and online treatment to meet the needs of a participant who felt that they could not fully express themselves to the e-coach through written text (n=1, 4%).

Discussion

Principal Findings

The main aim of this study was to evaluate the feasibility of Rileks as part of an adaptation process of a web-based stress management intervention among university students in Indonesia. Rileks was reported as being acceptable, even though its usability and intervention uptake were still below our expected criteria levels. Study findings showed that participants' stress level and quality of life improved at posttest. The intervention was appreciated by participants in terms of content usefulness, easiness to complete, comprehensibility, suitability for the Indonesian university student context, and the quality of e-coach support, with more e-coach interaction being desired.

Primary Outcomes

Rileks was rated as generally satisfactory, which indicates that the intervention was acceptable. The most satisfying aspect of Rileks as perceived by the participants was that the intervention helped them deal with their problems effectively and that they would recommend it to their friends. With regard to usability, Rileks received a lower than expected threshold score, with the learnability aspect as a main challenge. As reported, participants needed to learn and become familiar with a number of new technical aspects related to the system before they could engage with the intervention. We considered this to be due to the fact that a web-based intervention was relatively new in Indonesia, hence, participants did not have much prior experience in using such an intervention, which may have affected their perception of its usability [53]. Another possible explanation is that the user interface of the system is not user friendly enough. Even though learnability was a challenge, participants felt positive about being able to learn it in a relatively short period of time.

Usability issues were also found in internet-delivered mental health treatments in developed countries [54]. While usability is an essential part of system development, assessing usability of a web-based intervention system is still challenging. As usability is closely connected with interaction design, we are challenged with human-computer interaction issues that are still poorly understood. Furthermore, studies also revealed the need for a guideline for testing the usability of internet-delivered treatment systems [54] and a standardized usability questionnaire for such interventions [55].

The study findings revealed that the uptake of the intervention's core modules was below our criterion level. However, the number of participants who completed the core modules in our study still fell within the range of the reported number of module completers in a systematic review on computerized CBT (12%-100%) [56]. Moreover, a systematic review reported that only 30% of patients adhered to treatment until the third session of face-to-face interventions [57], making an uptake of 24% for module 3 sufficient, considering that computerized CBT is more likely to have a lower adherence rate [56]. Thus, we consider that Rileks still has potential, even though it did not yet meet the uptake criterion level.

Compared to the GET.ON Stress and StudiCare Stress interventions, Rileks' adherence rate of 15% for its core modules still falls behind. Studies of the GET.ON Stress intervention revealed an adherence rate range of 41.9% to 71.8% for its modules [24-26,58,59]. While the StudiCare Stress adherence rate was reported to be high, on average, the participants completed 74.7% of the intervention [60]. The findings seem in line with participants' overall satisfaction with the intervention. Based on the CSQ-8, the StudiCare Stress intervention had a very high satisfaction rate [60], and the GET.ON Stress intervention had high to very high satisfaction rates in its studies [24-26]. Rileks itself had an acceptable overall satisfaction level. Participants perceived that the intervention had helped them to deal more effectively with their problems, but they still considered Rileks to be suboptimal in meeting their needs or to be the kind of service they wanted.

A few reported reasons for nonadherence included time management issues (eg, being too busy), having competing activities, and technical problems, such as unfamiliarity with the log-in system. This is supported by a systematic review that argued that unfamiliarity with computers or the internet and feeling too busy to complete treatment may contribute to dropout from internet-based treatment [61,62]. Other reasons for intervention dropout in our study were that participants missed notifications because they seldom used or checked their email. This implies the need for future studies to use means other than email to send reminders to participants in order to boost intervention uptake, such as personal messages via preferred platforms (eg, instant chat messaging). Furthermore, problems with internet connections in rural areas were also experienced, which indicate that other forms of communication or channels, such as a mobile phone apps, may also be explored as potential options, as the use of mobile apps does not always require constant internet connectivity.

Furthermore, nearly 50% of participants dropped out by the end of module 1, which was the largest number of dropouts compared to other modules. Among all modules, module 1 also received the most "undecided" responses in the evaluation categories of clarity, subcontent usefulness, pleasantness, and comprehensibility. This result may be due to several possibilities. One possibility is that those who dropped out after module 1 were interested in and curious about the intervention at first, but found out that a module-based intervention was not suitable for them after finishing module 1. Another possibility is that participants' experience was suboptimal during module 1 due to a delivery method of psychoeducational content that

was less than ideal for university students. This is in line with a systematic review that reported that young people tend to perceive educational material as unengaging, which caused dropout [63]. Further investigation on how to deliver psychoeducational material in engaging ways for university students in Indonesia is needed for future refinement.

Interestingly, it was found that stress severity level was associated with adherence, as those who logged in and engaged tended to have higher stress levels and significantly poorer psychological quality of life compared to those who did not log in. This is supported by other studies that confirmed that participants with less severe problems and difficulties may be less motivated and are subsequently more likely to drop out of internet-based treatment [61,64].

Secondary Outcomes

Participants' stress levels at the posttreatment assessment were significantly lower than at the pretreatment assessment. In addition, the levels of anxiety and depression were also significantly lower among participants at postintervention. This finding is in line with a previous meta-analysis that reported that face-to-face and internet-based interventions do reduce stress levels as well as symptoms of anxiety and depression among university students [22,65,66]. Furthermore, participants' overall quality of life as well as their health and psychological quality of life were better at posttreatment compared with pretreatment. Our study findings may give initial implications for the clinical impact of Rileks, but should be interpreted with caution due to our study design and small sample size.

Future Web-Based Intervention Studies and Rileks Refinements

Our findings demonstrate that web-based intervention studies targeting university students in Indonesia may be feasible. We reached 191 potential participants from several islands in Indonesia in 10 days, with 80.1% (121/151) of invited participants giving their consent and filling in baseline questionnaires. This indicates that university students in Indonesia were interested in our study. The use of the internet, social media, and particularly WhatsApp groups play an important role in the process of reaching targeted potential participants. These strategies allowed us to reach potential participants from many different cities, islands, and fields of study with relatively little effort. Furthermore, taking part in activities involving the target group was also useful in disseminating information on the study. Such activities allowed face-to-face interaction between the principal investigator (DJ) and the target group, where the principal investigator could give information on stress and our study, thus increasing university students' awareness of stress and the credibility of our study. However, our study had a relatively high dropout rate (63%), which is commonly found in other internet-based interventions [56]. It is unfortunate that we did not have sufficient data to explain the reasons for dropout due to the unresponsiveness of our participants. This may be because we approached the participants who dropped out via email, which was not the most convenient medium for them. Thus, for future studies, we recommend using other ways to approach study participants

(eg, sending a short survey about reasons for dropout through any of their preferred devices or platforms).

Participants' feedback for improving future versions of Rileks related to both content (eg, scope of case examples and wording) and technical aspects (eg, suggesting a medium other than email to send notifications and a better display on the mobile phone version). Involvement of relevant stakeholders in the process of refining the content and technical aspects would be valuable for the purpose of achieving an optimal form of Rileks. One highlight of our findings was the request for the availability of interactive communication with the e-coach. This suggested that even though university students in Indonesia are open to the use of internet-based interventions, face-to-face or interactive communication is still preferred. This outcome is in line with other research that suggests that face-to-face interaction is still considered an essential and significant element of mental health services [64,67,68]. According to the latter study, Indonesian people in general would still prefer face-to-face contact, especially when they can access it nearby. This condition may make the use of a web-based intervention to overcome the mental health gap in Indonesia seem challenging. One alternative is to use lay counselors (eg, psychology students trained as e-coaches). Furthermore, reaching out and involving local community health centers to support interventions may be a possible means for future dissemination and implementation of web-based interventions in Indonesia [69]. Another alternative is using a blended strategy by combining modules and instant chat or video conference for more interactive communication between the client and the e-coach.

Our findings indicate that a web-based psychological intervention such as Rileks is acceptable among Indonesian university students and has the potential benefit of clinical effectiveness. Thus, it may provide a good opportunity for university students to have psychological support when there is a mental health service gap within universities and stigma for seeking mental health care. A refinement incorporating all input from participants to overcome challenges of usability and dropout rates is needed. In order to incorporate all input related to the content, technical aspects, and e-coach support into the intervention, involvement and collaboration of relevant stakeholders will be very important (eg, university students, clinicians, lay counselors, software developers, and user interface and user experience experts). Input from participants

that we highlight from this study is their desire to have more interactive e-coach support. Further study should make sure that the amount and type of e-coach support that is needed throughout the intervention is provided (eg, chat, video call, email, time of support, and duration). Another shortcoming that we need to tackle is optimizing participants' experience while they are going through the modules, especially the psychoeducational module. Future studies may experiment to find the most engaging way to deliver psychoeducational content to university students in Indonesia.

Strengths and Limitations

To the best of our knowledge, Rileks is the first web-based intervention to provide stress management in the Indonesian university student context. Furthermore, it is among the first web-based psychological interventions being culturally adapted from Western culture to Asian culture. In addition, other than quantitative assessment, our study also considered qualitative data from open questions to give more insight into participants' experience in working with the Rileks modules and system, including e-coaches. However, our study also has a number of limitations. The dropout rate from the enrollment stage to postassessment was relatively high. The data obtained at the postassessment only came from 37% of the participants who were logged in to the intervention and, thus, did not equally represent all participants. Furthermore, 85.1% of the participants were female and, thus, not likely to represent the real university student population, which consists of 56.1% female students and 43.9% male students [70].

Conclusions

Rileks shows potential feasibility for Indonesian university students. However, our findings also underscore the need for further development of this kind of intervention in order to optimize the experience for Indonesian university students. Further refinements are needed regarding content and technical aspects. Despite the potential of web-based interventions and telemental health, in general, to minimize the mental health gap among the Indonesian population, our study implies that more work needs to be done before we can scale up this kind of intervention in Indonesia. In sum, the intervention has potential, but it needs refinement before it can be optimally applied in this setting.

Abstract

Background: Many researchers have aimed to develop chronic health surveillance systems to assist in public health decision-making. Several digital health solutions created lack the ability to explain their decisions and actions to human users.

Objective: This study sought to (1) expand our existing Urban Population Health Observatory (UPHO) system by incorporating a semantics layer; (2) cohesively employ machine learning and semantic/logical inference to provide measurable evidence and detect pathways leading to undesirable health outcomes; (3) provide clinical use case scenarios and design case studies to identify socioenvironmental determinants of health associated with the prevalence of obesity, and (4) design a dashboard that demonstrates the use of UPHO in the context of obesity surveillance using the provided scenarios.

Methods: The system design includes a knowledge graph generation component that provides contextual knowledge from relevant domains of interest. This system leverages semantics using concepts, properties, and axioms from existing ontologies. In addition, we used the publicly available US Centers for Disease Control and Prevention 500 Cities data set to perform multivariate analysis. A cohesive approach that employs machine learning and semantic/logical inference reveals pathways leading to diseases.

Results: In this study, we present 2 clinical case scenarios and a proof-of-concept prototype design of a dashboard that provides warnings, recommendations, and explanations and demonstrates the use of UPHO in the context of obesity surveillance, treatment, and prevention. While exploring the case scenarios using a support vector regression machine learning model, we found that poverty, lack of physical activity, education, and unemployment were the most important predictive variables that contribute to obesity in Memphis, TN.

Conclusions: The application of UPHO could help reduce health disparities and improve urban population health. The expanded UPHO feature incorporates an additional level of interpretable knowledge to enhance physicians, researchers, and health officials' informed decision-making at both patient and community levels.

Introduction

Background

Enhanced health surveillance systems for chronic disease support could mitigate factors that contribute to the incline of morbidity and mortality of diseases such as obesity. Obesity is linked to increased overall mortality and has reached pandemic proportions, being responsible for approximately 2.8 million deaths annually [1,2]. Obesity represents an excessive and abnormal accumulation of body fat, which leads to adverse health effects that impose a health and financial toll on individuals and society [2]. More than half of the US population has at least one chronic condition, and 27% are living with multimorbidity [3]. These conditions cause more than 1.7 million deaths per year in the United States, where obesity is associated with the top leading causes of death (eg, diabetes, heart disease, stroke, and cancer) [4].

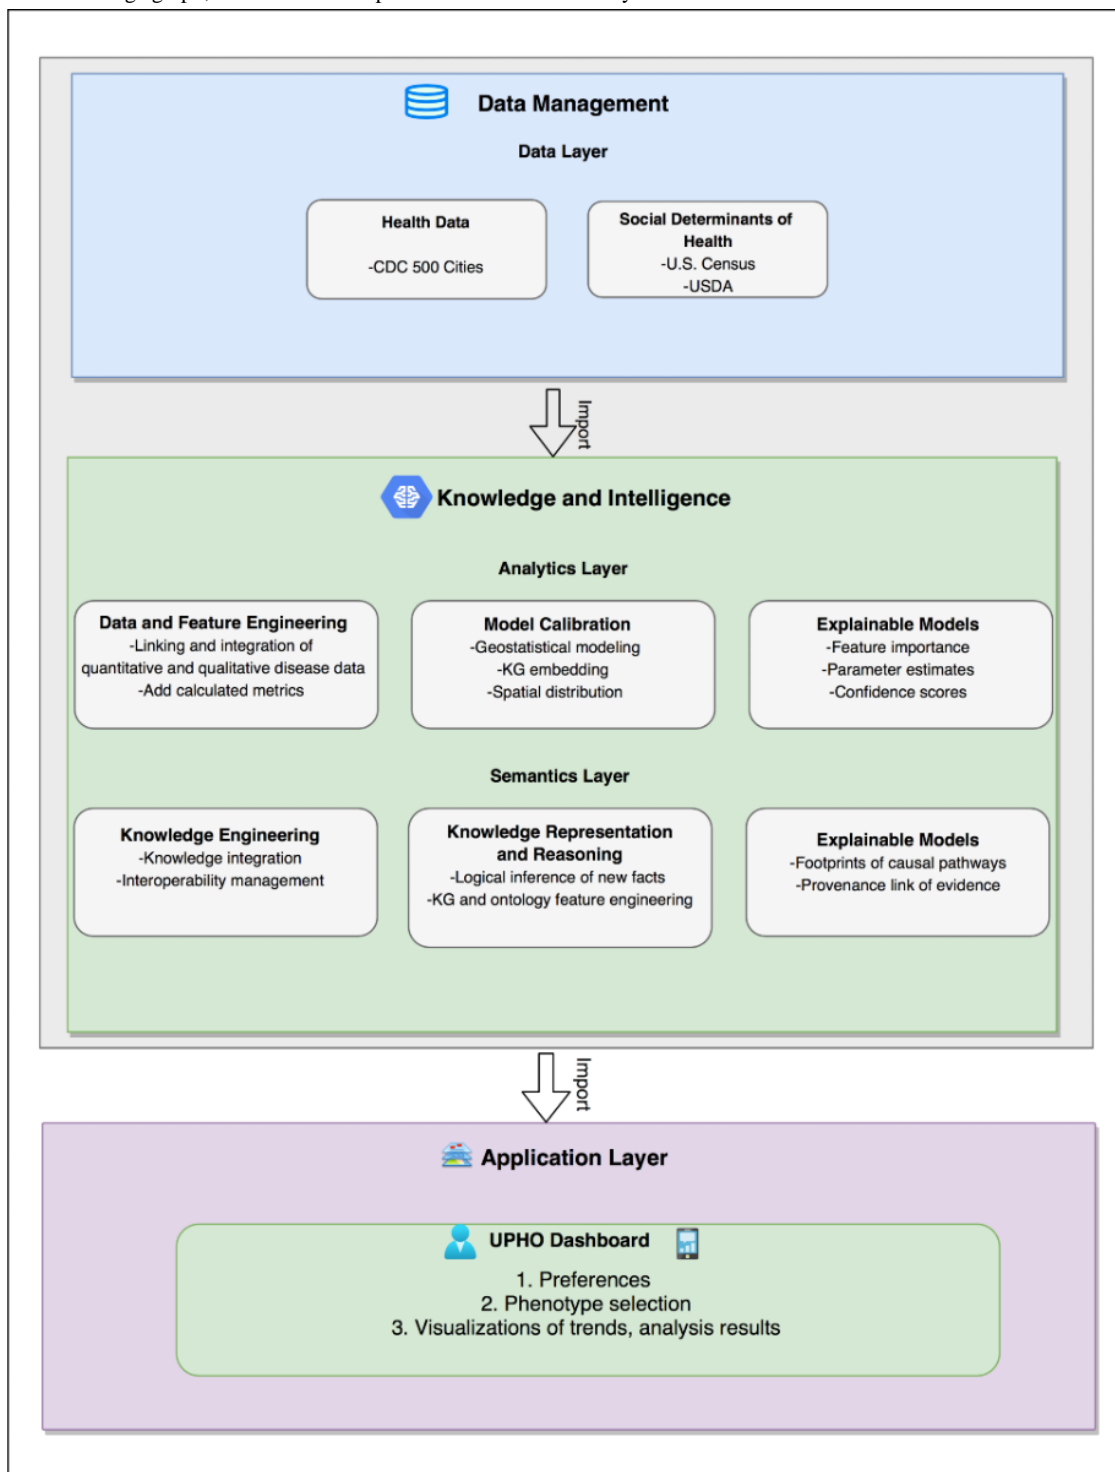

Neighborhood factors such as socioenvironmental determinants of health (SDoH) significantly contribute to these statistics [5-8]. Implementation of an intelligent health surveillance platform that incorporates SDoH can improve preparedness, prevention, and management of this obesity pandemic by assisting in the implementation of effective treatment and interventions.

Health surveillance involves the “ongoing systematic collection, analysis, and interpretation of data essential to the planning, implementation, and evaluation of public health practice, closely integrated with the timely dissemination of these data to those who need to know” [9]. Researchers have aimed to develop chronic health surveillance systems to assist in chronic health decision-making [10-16]. The World Health Organization (WHO) developed a conceptual framework for an Urban Public Health Observatory (UPHO) comprised of 3 domains: mission, governance, and knowledge and intelligence, the latter of which incorporates a data management component [17]. This framework from WHO therefore provides a strategic model for health surveillance.

Many current digital health solutions and electronic health record (EHR) systems lack the ability to incorporate machine learning algorithms into their decision-making process, and even if they do, the algorithms used do not have appropriate capabilities to explain the suggested decisions and actions to human users [18]. Machine learning approaches, so-called black-box statistics, should be trustworthy, transparent, interpretable, and explainable when making decisions in the clinical or health science setting [18-20]. A system’s explanation constitutes its interpretability [18,20-22]. Explainable AI (XAI) increases the intelligence delivered to the user by providing explanations, thereby enhancing the interpretability of outcomes and findings. Researcher efforts have been shifting toward applying algorithms that can aid in explaining the results of machine learning models. For instance, the SHAP (Shapley Additive Explanations) analysis [23] is an approach that assigns each model feature an importance score for making a particular prediction. Compared to traditional feature importance analyses, the novelty of SHAP lies in its ability to assess importance at the individual patient level. In this paper, we propose a novel approach to explainability that uses knowledge graphs as a semantic infrastructure explainable by design and enriches those graphs with results from machine learning algorithms as metrics and scores. The semantic causal relationships on the graph provide contextual knowledge around a population, and the metrics support those relationships, which provides 2 levels of evidence: knowledge level and statistical level.

We implement a UPHO platform as a knowledge-based surveillance system that provides better insight to improve decision-making by incorporating SDoH and providing XAI and interpretability functions [24]. Our UPHO consists of 3 layers: data, analytics, and application. In this work, we refine the initial design by incorporating data management, knowledge, and intelligence domains (Figure 1) that are in alignment with the conceptual model by WHO and a focus on the semantics layer.

Figure 1. Expanded Urban Population Health Observatory framework. CDC: US Centers for Control and Prevention; USDA: US Department of Agriculture; KG: knowledge graph; UPHO: Urban Population Health Observatory.

Objectives

The objectives of this article are to (1) expand UPHO by incorporating a semantics layer, (2) cohesively employ machine learning and semantic/logical inference to provide measurable evidence and detect pathways that lead to undesirable health outcomes, (3) provide clinical case scenarios and design case studies on identifying SDoH associated with obesity prevalence, and (4) provide a dashboard design that demonstrates the use of UPHO in the context of obesity, using the provided case scenario.

Methods

UPHO Expansion

Figure 1 shows the expansion of the UPHO to incorporate the semantics layer. In the following section, we provide a detailed description of the UPHO platform expansion design.

Data Management Domain

The data management domain comprises the data layer. The UPHO collects population-level health and SDoH data and

individual-level clinical and demographic data from EHRs through regional registries.

Data Layer

To obtain population-level health data, we used the US Centers for Control and Prevention (CDC) 500 Cities Behavior Risk Factors Surveillance System, which includes data regarding chronic diseases and their behavioral risk factors [25]. These variables are model-based estimates of crude prevalence among adults aged ≥18 years in 2018. We extracted variables pertaining to obesity, lack of physical activity, lack of insurance, and diabetes mellitus at the census tract level.

We extracted population-level SDoH variables that pertain to food insecurity, transportation, and socioeconomic stability at zip code, census tract, census block, and census block group levels from the US Census Bureau 2018 American Community Survey [26] and the US Department of Agriculture Research Atlas [27].

Knowledge and Intelligence Domain

Analytics Layer

The analytics layer pulls raw data from different sources in the data layer and analyzes it to classify it, predict new relations, conduct spatial pattern detection, and calculate new metrics. The analytics layer also performs feature engineering by deriving new metrics and using them to enrich the original data sets.

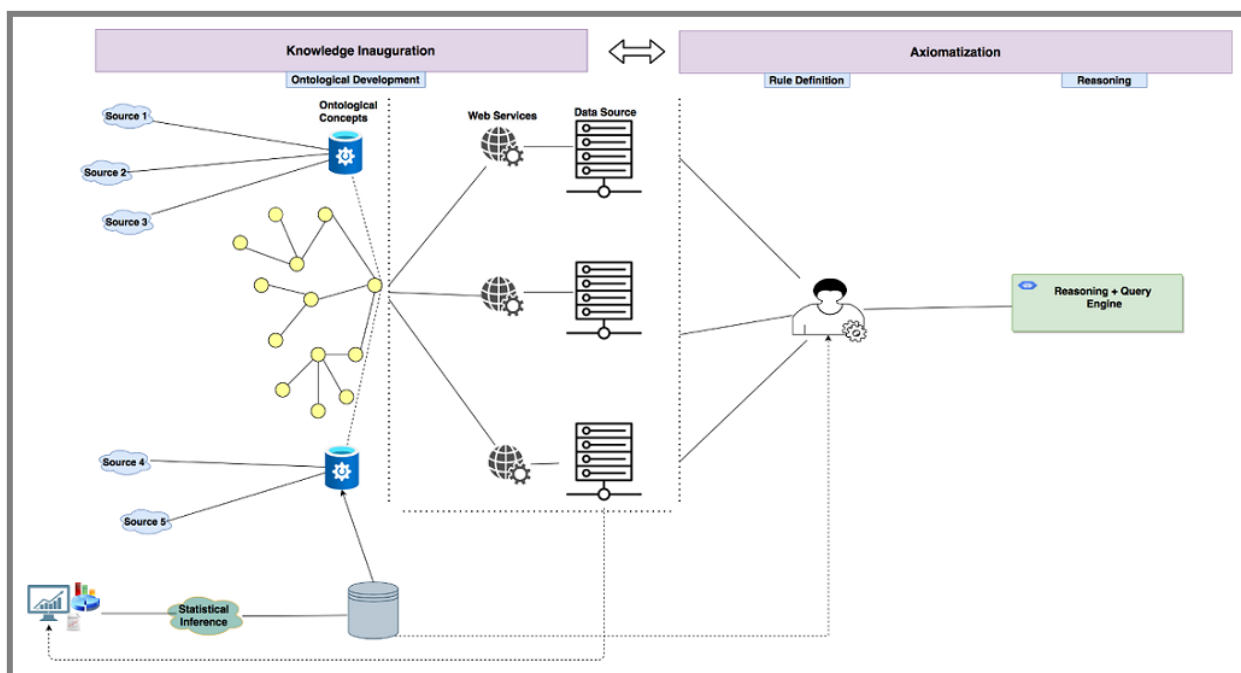

Semantics Layer

The stages of the UPHO semantics layer are shown in Figure 2. In the knowledge representation and axiomatization stages, we use semantic web technologies to develop several domain and application ontologies from relevant domains of interest to provide necessary contextual knowledge. Ontologies are

systematic representations of knowledge that can be used to integrate and analyze large amounts of heterogeneous data, thereby allowing classification of knowledge [28]. In those ontologies, we define concept hierarchies and rule axioms by using existing domain knowledge, such as the WHO/CDC guidelines, and federal and local sources. We develop new ontologies by reusing several existing domain ontologies. For this study, we adopted concepts, properties, and axioms from 5 different ontologies that we used in our prior work [29-32], specifically (1) disease ontology (DO) [31] (eg, obesity, diabetes); (2) the Childhood Obesity Prevention (Knowledge) Enterprise (COPE) ontology [29] that defines SDoH concepts such as socioeconomic issues (eg, food deserts, income) and behavioral issues (eg, lack of physical activity, purchasing preference); (3) geographical information system ontology (GISO) [32] (eg, zip code, census tract); (4) health indicators ontology (HIO) [32]; and (5) the adverse childhood experiences (ACEs) ontology (ACESO), which defines concepts related to ACEs, health outcomes (eg, mental and physical health), interventions, and SDoH, including axioms that define issues like lack of transportation (eg, limited access to a vehicle and limited access to public transit) and food and how they affect routine follow-up activities (eg, missing medical appointments) [30].

We start our semantic analysis using concepts defined in our ontologies and web services to align concepts to actual data resources, allowing us to construct a population knowledge graph structure that abides by an ontology and contains both data and concepts [33]. We enrich that knowledge graph using a logical reasoner that uses facts derived from existing knowledge, new knowledge extracted from the analytics layer, and the generic rule axioms defined in the domain ontologies that trigger specific actions under certain conditions.

Figure 2. Urban Population Health Observatory semantic layer framework.

Explainable AI

An effective explainable system accounts for the target user group (eg, physician, researcher). Knowledge of the end user is very important for the delivery of decisions, recommendations, and actions. Each analytics and semantics layer contains an explainability component that can be leveraged in the uppermost health applications layer. To maintain features such as data integration, XAI, and interpretability, we must achieve interoperability by using semantics and ontologies. Explanations adaptable to the user can decrease errors in interpretation by enhancing the interpretability of outcomes and findings.

Application Domain

The UPHO platform can be used as a basis to develop several applications, some of which we have already developed, including dashboards [24], mobile health (mHealth) apps [34], digital assistants, and recommender systems [35]. In this article, we leverage the UPHO to implement a dashboard for real-time surveillance. By accessing dynamic knowledge discovered through the UPHO, the dashboard can provide real-time early warnings that are based both on content and context. The platform is accessible to policymakers, physicians, researchers, public health officials, and the public.

Clinical Scenarios

The following sections present 2 clinical case scenarios that focus on a physician and a researcher as users to demonstrate the methodology used in the knowledge and intelligence domain layers and the corresponding dashboard design in the application.

Scenario 1: A physician seeks an effective intervention for an adult African American patient diagnosed with obesity. The physician focuses on how SDoH in the patient's neighborhood can influence the doctor's management plans.

Scenario 2: A researcher investigating the impact of SDoH on obesity seeks an effective intervention for the adult obese populations in Memphis, TN.

Analytics Layer: Machine Learning Model Development

We trained a machine learning–based support vector regression (SVR) machine model [36,37]. We linked CDC 500 Cities population-level obesity and behavior data [25] to the population-level social DoH [26,27] data set at the census tract level in Memphis, TN. We analyzed 8 features and used a Spearman rank test to assess the positive or negative relationship between each feature. We used a variance inflation factor (VIF) to detect multicollinearity between features. To examine patient neighborhood-level exposure, we used SHAP analysis. Table 1 shows the summary statistics for features considered for this study. We trained our support vector model on the 85% of randomly selected training data and tested the model on the 15% of remaining data to ensure the generalizability of the model, and we applied the linear kernel function. We scaled our data to have a mean of zero and standard deviation of one. We applied the grid search optimization method to seek optimal hyperparameters to improve model performance using the Caret package in R software (R Foundation for Statistical Computing) [38]. In addition, to avoid overfitting 5-fold cross-validation was applied to the training data set. We used root mean square error (RMSE) and R^2 to evaluate the performance of the model.

Table 1. Summary statistics for obesity and related risk factors in Memphis, TN, census tract (n=178 census tracts).

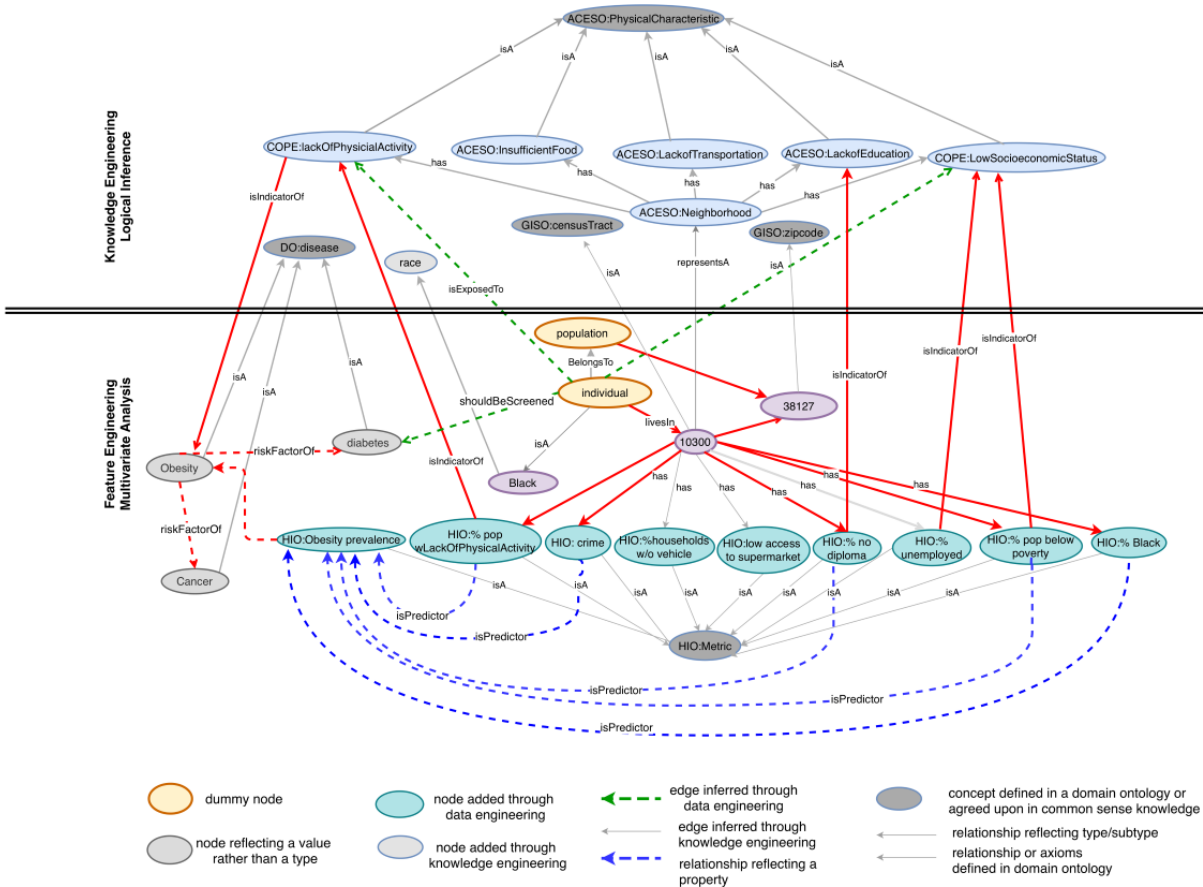

Features	Operationalization	Original, mean (SD)	Training, mean (SD)	Test, mean (SD)
Obesity	Model-based estimate for crude prevalence of obesity among adults aged ≥ 18 years, 2018	37.50 (7.84)	37.42 (7.54)	37.97 (6.95)
Low access to supermarket	Count of low income population more than half mile from a supermarket in the census tract	1382.20 (108.37)	1345.68 (967.83)	1616.17 (1120.23)
Black	Percentage of population that is Black or African American	63.17 (32.70)	62.22 (33.04)	63.72 (31.88)
Poverty	Percentage of population living below the federal poverty line	28.65 (16.28)	28.27 (16.18)	31.06 (17.06)
Unemployment	Percentage of unemployed population	15.73 (9.31)	15.97 (9.67)	14.16 (6.52)
High school diploma	Percentage of population 25 years or older without high school diploma	10.38 (6.59)	10.23 (6.70)	11.35 (5.89)
Lack of physical activity	Model-based estimate for crude prevalence of lack of physical activity among adults aged ≥ 18 years, 2018	36.16 (9.80)	35.97 (9.79)	37.34 (9.99)
Crime	Crime rate per thousand people	350.20 (126.26)	160.99 (337.65)	111.93 (80.40)
Lack of access to insurance	Model-based estimate for crude prevalence of lack of insurance among adults aged ≥ 18 years, 2018	20.21 (6.78)	20.10 (6.81)	20.88 (6.67)

Semantics Layer: Knowledge Graph Generation

We followed the following ordered steps to generate the semantics layer knowledge graph from concepts defined in our domain ontologies.

1. We use concepts, relations, and axioms from domain ontologies to construct a preliminary population knowledge graph. For our scenario, we start by adding a dummy node that represents either a patient or a population (Figure 3). We begin connecting that node to concepts like disease, risk factors, physical characteristics, etc. For example, obesity falls into the disease type represented by the *isA* relation in Figure 3, where *isA* reflects a subtype. For instance, SDoH *isA RiskFactor*, and *lackOfTransportation* is an SDoH subtype. These different hierarchies are encoded in the ACESO ontology. We also add a prefix before each type to reflect the namespace where that concept is defined (eg, the term DO:Disease reflects that the concept disease is defined in the DO). Relations can also reflect the properties of a node. For example, a patient *livesIn* 38127, which *isA* zip code, and that zip code has 8 census tracts of the type *CensusTract*, defined in the GISO ontology.
2. We populate the generated graph structure with evidence from the data layer. For instance, our data set contains a variable that shows the prevalence of obesity as a percentage metric in specific neighborhoods. We use that information to add edges to our graph that link obesity (as a disease) to prevalence (as a metric).
3. We further enrich and refine the initial graph by performing knowledge engineering using the logical reasoner (Figure 2) and feature engineering using the results from the analytics layer. The logical reasoner uses a set of rule axioms to perform logical inference on concepts already existing in the graph. For instance, our COPE ontology encodes epidemiological causal axioms that link SDoH to negative health outcomes. Textbox 1 shows how we encode the generic axioms R1-R3. When we combine those generic rule axioms with facts about a specific census tract, we can infer all the risk factors associated with living in that census tract, eg, knowing the facts F1 can tell us that the population living in that area may be exposed to risk factors that lead to obesity.
4. After performing the logical inference on the initial graph structure, we incorporate new nodes and edges in the graph corresponding to new concepts (eg, the *lackOfPhysicalActivity* concept from the COPE ontology) or new relations (eg, *isExposedTo*). The knowledge graph refinement is an iterative process, so we can repeat step 2 until we reach a stable state of the graph after which we can populate the graph with more evidence from our engineered data that we pull from the analytics layer. For that purpose, we use the population-level data about SDoH risk factors collected from US Census, CDC, and USDA. For instance, to capture the lack of physical activity we use the CDC 500 Cities data set. The machine learning analysis performed by the analytics layer provides edges that pertain to prediction (eg, *isPredictorOf*, Figure 3). The final knowledge graph is shown in Figure 3, which provides a generic view of all possible assumptions we can make about this patient or population.
5. To gather the most important information from this graph, a user can trace a specific pathway based on both logical inference and machine learning results. The red arrows in Figure 3 reflect the pathway in our scenario.

Figure 3. Knowledge graph that links concepts defined in domain ontologies (eg, GISO: CensusTract) to data resources stored in databases (eg, percentage Black population) or those derived from the analytics layer. The upper part of the figure shows the nodes and edges produced through semantic inference during the knowledge engineering phase. The lower part of the figure shows the nodes and edges added through ML analysis during the feature engineering phase. GISO: geographical information system ontology; HIO: health indicators ontology; ACESO: adverse childhood experiences ontology; COPE: Childhood Obesity Prevention (Knowledge) Enterprise; DO: disease ontology.

Textbox 1. Encoding axioms as general rules, initial facts, or new facts derived from feature engineering or logical reasoning.

Generic rule axioms

- COPE:lackOfPhysicalActivity *leadsTo* DO:Obesity (R1)
- %ObesityPrevalence:Metric *isHealthIndicatorFor* DO:Obesity (R2)
- Obesity:Disease *isRiskFactorOf* Diabetes:Disease (R3)

Facts

- individual:Patient *livesIn* "10300":CensusTract (F1)
- "10300":CensusTract *has* "49":%PopWLackOfPhysicalActivity (F2)
- "10300":CensusTract *has* "21":%PopNoHighSchoolDiploma (F3)

- individual:Patient *shouldBeScreenedFor* Diabetes:Disease [using R1, R2, R3, F6, F7]

Ethics Approval

No ethics review board assessment was required for this study because we used publicly available data.

Results

Machine Learning Analysis

The significant Spearman rank coefficient and VIF of the 7 features included in this study are shown in Table 2. Any feature exhibiting a VIF of greater than 10 was removed. For the SVR model results, we obtained an RMSE of 0.312 for the training set and 0.203 for the test set, while the R^2 for the training set was 0.91 and that for the testing data set was 0.95. Since the model provides similar results for training and test data sets, the proposed model does not overfit. The SVR feature importance results range on a scale of 0 to 100, and the greater the score, the most important the feature (Table 3). We found that the percentage of the population lacking physical activity, percentage of population below poverty level, percentage of

population without high school diploma, percentage of population unemployed, and percentage of Black population were the most important variables when predicting obesity prevalence in Memphis, TN.

Figure 4 shows SHAP's value plot of feature contribution at the patient neighborhood level (census tract: 10300), which indicates the most important features such as the percentage of the population that lack physical activity and the percentage of population below the poverty level, from the point of view of the prediction of obesity prevalence in the patient neighborhood. The lack of physical activity and poverty had the largest positive (increased) contributions to obesity prevalence. On the other hand, the population of low income and more than a half-mile from the supermarket showed a negative (decreased) contribution but was the least important variable when predicting the patient neighborhood obesity prevalence. The knowledge extracted from our analysis will be used to detect the obesity prevalence pathways, which are defined by the top 5 most important features.

Table 2. Spearman rank coefficient and variance inflation factor for each feature.

Features	Spearman rank coefficient	VIF ^a
Low access to supermarket	0.37	1.70
Black	0.77	2.80
Poverty	0.83	3.66
Unemployment	0.73	3.02
No high school diploma	0.81	3.55
Lack of physical activity	0.92	8.82
Crime	0.37	1.68

^aVIF: variance inflation factor.

Table 3. Support vector regression data set-level feature importance score.

Features	SVR ^a feature importance
Low access to supermarket	4.39
Black	68.20
Poverty	78.60
Unemployment	70.16
No high school diploma	73.41
Lack of physical activity	100
Crime	0

^aSVR: support vector regression.

Figure 4. The Shapley Additive Explanations (SHAP) value plot of the feature contribution (unscaled) for the patient's neighborhood (census tract:10300). The x-axis represents the SHAP's value, and the y-axis represents the features. The lack of physical activity and poverty had the largest positive (increase) contributions to obesity prevalence in the patient's neighborhood.

UPHO: Dashboard Design

Use Case Scenarios

In this section, we describe the semantics feature provided by UPHO through a proof-of-concept prototype that will display the different features of the expanded system by implementing the clinical scenarios described in the previous section.

First, the user will sign into the UPHO platform dashboard, which will determine their specific role and establish the proper access permissions. The user will make the selections from the following menu items:

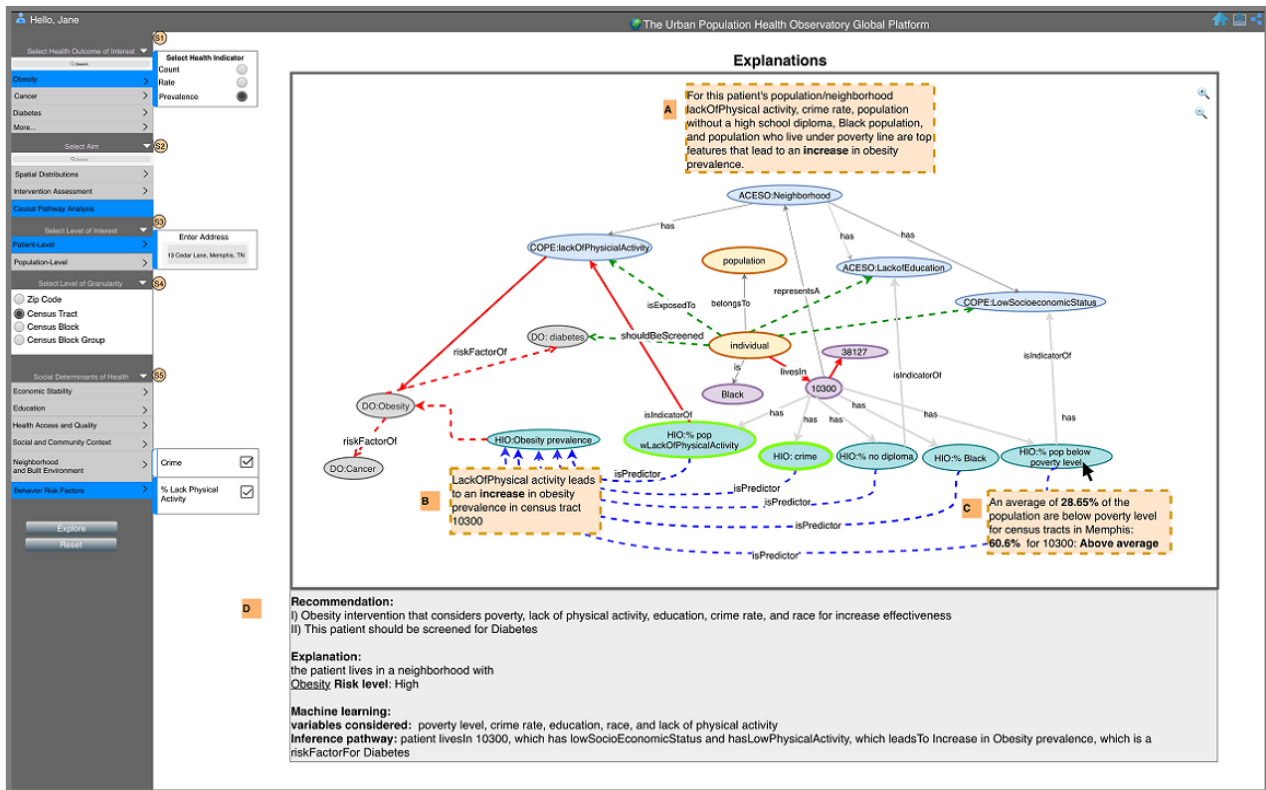

- S1. Select an outcome of interest (eg, obesity prevalence, cancer,)
- S2. Select analytics aim
- S3. Select level of analysis and enter address/location (patient's address [patient-level], city, county, or state [population-level])
- S4. Select geographical level of granularity (eg, zip code, census tract)
- S5. Select SDoH domain-specific risk factors

After making these selections, the system will present on-demand explanations of risk level calculations, based on the selected level of geographic granularity.

Scenario 1

The physician selects "obesity prevalence" as the outcome of interest (S1), and "causal pathway analysis" (S2) as the analytics aim, "patient-level" as the level of interest (entering patient's address, S3), and "census tract" as the geographical level of granularity (S4). The system provides risk-level calculations and descriptive statistics based on the census tract of the patient's address. The physician also has the option to select a particular SDoH of interest in S5, in which case the system will highlight these nodes in the graph. Finally, the user selects "Explore" to generate the results and a corresponding knowledge graph. These results are tailored to the user's interest in patient-level analysis and provide an explanative overview of the analysis results (Figure 5A). The system also allows the user to hover over pathways and nodes to explore explanative knowledge (Figure 5B, 5C) and offers a summary of recommendations and knowledge (Figure 5D).

Figure 5. The dashboard of the Urban Population Health Observatory displays a physician user interested in obesity prevalence in her patient’s neighborhood with an overview of analysis results (A), explanations displayed when user hovers over a particular pathway (B), knowledge displayed when user hovers over a particular node (C), and summary of recommendations and knowledge (D). ACESO: adverse childhood experiences ontology; GISO: geographical information system ontology; DO: disease ontology; HIO: health indicators ontology.

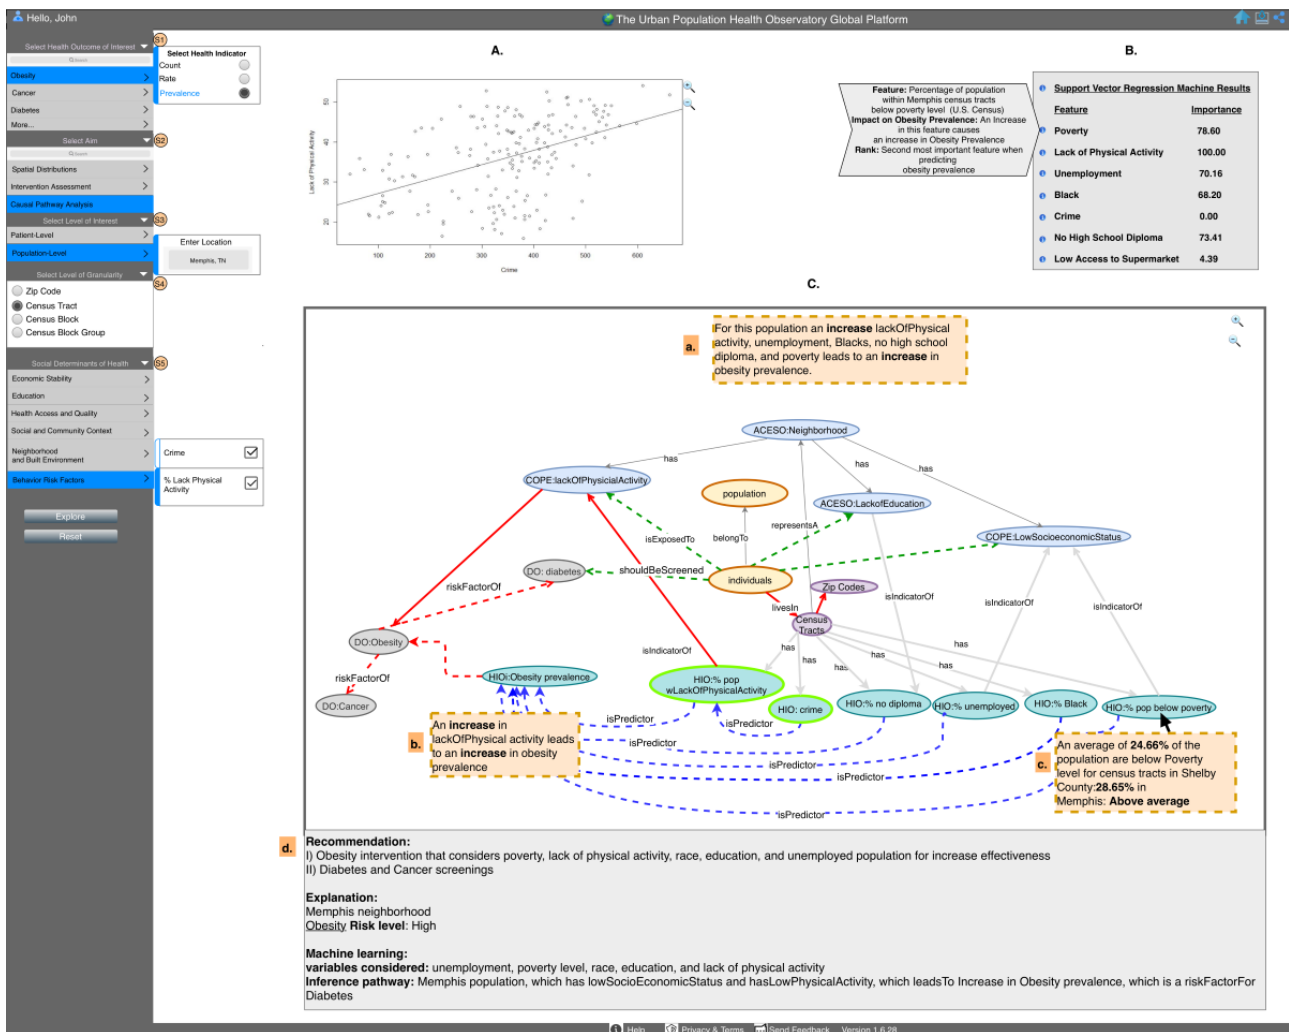

Scenario 2

Here the researcher has access to more features. The researcher explores the causal pathway analysis aim in a population-level analysis and enters Memphis, TN, as a location of interest at the census tract-level (S1-S3), as shown in Figure 6, and the system provides risk-level calculations for the city of Memphis, TN. The researcher also has access to regression plots (Figure 6, A), which reflect the selection in S5. In section B, the system

reports the results from the SVR machine model and provides explanations for each feature included in the model (Figure 6, B). In section C, the explanation pane presents a knowledge graph showing results tailored to the user’s interest in population-level analysis (Figure 6, C). The researcher can also hover over pathways and nodes for knowledge (Figure 6, C, a, b, and c), like the physician in scenario 1. The system also offers the researcher a summary of recommendations and knowledge (Figure 6, C, d).

Figure 6. The dashboard of the Urban Population Health Observatory displays a researcher as the user interested in obesity prevalence in Memphis, TN, with univariate regression plot (A), multivariate analysis (B), and (C) which contains an overview of analysis results (a), explanations displayed when user hovers over a particular pathway (b), knowledge displayed when user hovers over a particular node (c), and summary of recommendations and knowledge (d). ACESO: adverse childhood experiences ontology; GISO: geographical information system ontology; DO: disease ontology; HIO: health indicators ontology.

Explanations

The graph part of the dashboard can serve as a tool for researchers and physicians to semantically explain the recommendations that we made about a specific patient or population. The current version of the graph provides 2 different visual cues, as follows.

- Tracing pathways on the graph provides visual cues. The red arrows in Figure 3 show the edges that are part of a causal pathway that leads from risk factors to negative health outcomes for the specific patient, zip code, or census tract. While this path is specific to the selected patient or population, it can be used as a generic metapath. For example, Individual *livesIn* CensusTract → *representsA* Neighborhood → *hasPhysicalCharacteristic* → *RiskFactorFor* Disease. Depending on the level of sophistication desired, the user can trace paths on the graph and click on certain nodes or edges to obtain more insights, including statistically derived evidence or semantically inferred knowledge. They can also track the sources of that knowledge including the ontologies used.

- Clicking on a node or edge on the graph displays analysis results or knowledge. The user can hover over a certain edge (eg, lackOfPhysicalActivity isPredictorOf ObesityPrevalence; Figure 5B) to obtain an explanation of the data that show lackOfPhysical activity in the patient’s census tract leads to an increase in the prevalence of obesity. Similarly, the user can hover over a metric node (eg, percentage of the population below the poverty line, Figure 5C) to explain that this patient lives in a neighborhood in which nearly 61% of the population lives below the poverty line, compared to the average in their city, county, or state.

UPHO’s metrics can be implemented into the backend of EHR systems (eg, Epic), and the results of those metrics can be rendered on the EHR interface in the form of risk scores on dashboards with severity indicators based on thresholds. Physicians can examine these metrics at the population level or individual patient level. UPHO can alternatively be used in a standalone approach by allowing a physician to extract more details about a single patient by providing the patient’s address or a population of patients by providing their city, state, or

county. The input is coded to a geographical level of granularity that can be aligned with the population-level data to gain insights into the patient's environment.

Discussion

Principal Findings

Previous studies provided evidence that socially disadvantaged communities are disproportionately affected by chronic diseases such as obesity [5-8], which is a risk factor for developing diabetes, heart disease, and cancer. The significance of UPHO lies in its ability to provide a multifaceted surveillance system design that serves as an apparatus for actualizing effective interventions, addressing concerns in health disparities, providing awareness to the public, and equipping health officials with a surveillance system that will improve population health decision-making and planning [24]. Using the semantics layer, the UPHO platform provides contextual knowledge by reusing several ontologies focusing on public health (eg, diseases, transportation, geography).

The incorporation of semantics provides the user with an additional layer of explainability and interpretability, which could decrease errors in intervention or treatment due to misinterpretation or misunderstanding. The semantics layer can also use ontologies to overcome the challenge of scattered data sources, thereby assisting in the achievement of interoperability, which will be used to maintain features such as data integration, XAI, and interpretability. We apply logical reasoners to extract and supply knowledge despite limited data.

Similar chronic disease surveillance systems [10-16] have offered approaches to assist in the efforts of improving chronic disease surveillance. Several published systems do not incorporate SDoH data [10-14]. One did not provide an implementation of the systematic framework [16] and several of them did not include XAI as a feature.

We followed the conceptual framework for UPHOs [17] and sought to improve the quality of disease surveillance by incorporating advances in AI and Big Data, including interactive dashboard design, explainability, data integration, and interoperability, and incorporation of multimodal SDoH data.

Developing a multidimensional scalable surveillance system to monitor and detect trends and deliver rapid early warnings and recommendations could assist health officials, physicians, and researchers in mitigating a health crisis such as the ongoing COVID-19 pandemic [24].

Limitations

One of the major limitations of UPHO is that it collects population data so that neighborhood or population assumptions are made for an individual in a clinical setting. For instance, individuals or patients who live in a particular population or neighborhood might not have the same characteristics as other individuals residing in the same neighborhood or population. However, our platform provides an end-to-end approach to examining the environment one resides and incorporates information that is important for the implementation of effective interventions for a given disease.

The future work will be focusing on the further development of the UPHO platform, so it can enable timely, insight-driven decisions and inform immediate or long-term health policy responses [15] to current and future public health crises.

Conclusions

This study leveraged semantic technology and presented a proof-of-concept prototype design for our knowledge-based surveillance system, UPHO, which aims to reduce health disparities and improve population health. The expanded feature incorporates another level of interpretable knowledge needed to inform physicians, researchers, and health officials' decision-making process at the community level. Incorporating XAI helps with the explainability and interpretability of the relevant data, information, and knowledge. Users who are not equipped with domain knowledge could extract common sense knowledge from a system that incorporates XAI [35]. We as humans need a clear visualization and understanding of relationships between parameters in a system to make informed decisions. The lack of understandability and explainability in the health care and public health domains often leads to poor transparency, lack of accountability, and ultimately lower quality of care and biased health policies [39]. Thus, the incorporation of semantics and XAI can improve fairness, accountability, transparency, and trust in health care and public health.

Abstract

Background: Adolescents' consumption of healthy foods is suboptimal in low- and middle-income countries. Adolescents' fondness for games and social media and the increasing access to smartphones make apps suitable for collecting dietary data and influencing their food choices. Little is known about how adolescents use phones to track and shape their food choices.

Objective: This study aimed to examine the acceptability, usability, and likability of a mobile phone app prototype developed to collect dietary data using artificial intelligence–based image recognition of foods, provide feedback, and motivate users to make healthier food choices. The findings were used to improve the design of the app.

Methods: A total of 4 focus group discussions (n=32 girls, aged 15-17 years) were conducted in Vietnam. Qualitative data were collected and analyzed by grouping ideas into common themes based on content analysis and ground theory.

Results: Adolescents accepted most of the individual- and team-based dietary goals presented in the app prototype to help them make healthier food choices. They deemed the overall app wireframes, interface, and graphic design as acceptable, likable, and usable but suggested the following modifications: tailored feedback based on users' medical history, anthropometric characteristics, and fitness goals; new language on dietary goals; provision of information about each of the food group dietary goals; wider camera frame to fit the whole family food tray, as meals are shared in Vietnam; possibility of digitally separating food consumption on shared meals; and more appealing graphic design, including unique badge designs for each food group. Participants also liked the app's feedback on food choices in the form of badges, notifications, and statistics. A new version of the app was designed incorporating adolescent's feedback to improve its acceptability, usability, and likability.

Conclusions: A phone app prototype designed to track food choice and help adolescent girls from low- and middle-income countries make healthier food choices was found to be acceptable, likable, and usable. Further research is needed to examine the feasibility of using this technology at scale.

Introduction

Background

The consumption of healthy foods and nutrients is suboptimal worldwide, particularly in low- and middle-income countries. Although the daily intake of unhealthy foods (such as red and processed meats and sugar-sweetened beverages) exceeds the optimal consumption level, the daily intake of healthy foods (such as fruits, vegetables, grains, nuts, seeds, and fiber) is far below the recommended levels globally [1]. The importance of diets rich in fruits, vegetables, and whole grains should not be underestimated [2]. Plant-based diets prevent cancers [3] and cardiovascular diseases [4], and the consumption of fruits and vegetables has been associated with increased happiness, life satisfaction, and psychological well-being [5-7]. In contrast, sugar-sweetened beverage consumption is associated with increased adiposity, long-term weight gain, and a higher risk of diabetes [8-11]. The population of Southeast Asia has a low consumption of grains, legumes, fruits, vegetables, nuts, and seeds and a high consumption of processed meat, sugar-sweetened beverages, trans fats, and sodium [1]. Adolescents in this region have especially low consumption of fruits and vegetables [12].

Interventions intended to improve adolescents' knowledge of nutrition and health behaviors can take advantage of new technology to self-monitor diets with feedback on performance [13,14]. Young people are early adopters of mobile phone apps, games, and social media and are highly influenced by peer norms [13,15,16]. Mobile phones and computers are now widely used by adolescents from countries with all income levels [17-19]. The implementation of nutrition interventions based on apps holds great potential to improve the dietary quality of this population, but its impact is yet to be demonstrated [17].

Prior Work

Vietnam is a country in nutrition transition, with great changes in food supply, food prices, household expenditure, diet, and nutrition outcomes [20]. We previously reviewed the apps available in the Vietnamese market that could serve as tools for nutrition interventions [18]. Most of the apps found focused on tracking and changing food choices with the ultimate goal of losing weight [18]. Food consumption is usually tracked by searching for and selecting each food and beverage separately from a dropdown menu and their portion sizes [18]. This was considered so time consuming that even adolescents from Vietnam interested in changing their diets stopped using these apps [18]. There is a lack of free, user-friendly apps that focused on changing dietary quality [18]. We also conducted a literature review for detailed descriptions of eHealth and mobile health technologies used in nutrition interventions [18]. Intervention studies to promote healthy diets in adolescence often ignore techniques to keep participants engaged, leading to low participation and high drop-offs [18]. Adherence to these interventions is poorly reported in the literature [18].

Research Objectives

Our goal was to develop a new app with artificial intelligence (AI) technology to recognize images of foods that can be used to track and influence the quality of food choices of adolescent girls in Vietnam using gamified nudges. Previous apps based on image recognition of foods have successfully estimated the carbohydrate content of meals with higher accuracy than individuals, predicted glycemic dynamics, and helped improve diabetes self-management [21-23]. First, we prepared a food database and an image library by (1) developing a food inventory with priority foods; (2) preparing, cooking, and taking graduated pictures of foods; and (3) annotating pictures and linking them to the food database. Second, we used annotated pictures to train a semantic segmentation model to recognize foods and estimate portion sizes (details of the AI model development are under review elsewhere). Third, we developed the *Food Recognition Assistance and Nudging Insights* (FRANI) app, which included (1) conducting formative research (2 rounds of focus group discussions [FGDs]) with users to develop its interface; (2) validating the image recognition AI technology against the 2 gold standard forms of dietary data collection: 24-hour recalls and weigh food records; and (3) integrating the validated AI technology with the user interface. The app was developed by engineers from our team.

This study aimed to examine the acceptability, usability, and likability of the FRANI prototype. Our three specific objectives were to obtain qualitative inputs on (1) the acceptability of its daily individual- and team-based dietary goals to motivate healthier food choices, (2) the usability and likability of the image capturing feature and the likability of the feedback to users (badges, notifications, and statistics), and (3) to use the inputs of participants to improve the user interface design and functionality. We hypothesized that FRANI would be acceptable, usable, and likable.

Methods

Study Design, Participants, and Setting

We conducted 2 rounds of FGDs with 32 adolescent girls aged 15 to 17 years in Thai Nguyen, Vietnam. The first round of FGDs was aimed at developing the FRANI prototype, and the second aim was to understand its acceptability, usability, and likability and make changes so as to improve its dietary goals, camera, and feedback (badges, notifications, and statistics). We purposely selected an urban public high school because of its good relationship with the research team. All 12th graders were excluded, because they would graduate within a few months from the recruitment period, which could undermine follow-up studies. A total of 2 classes from each of the remaining 2 grades (10th and 11th) were randomly selected, and 8 (25%) girls were randomly selected from each of the 4 classes.

They were approached by the school teachers and divided into 4 FGDs with 8 participants, each according to their school year and specialization (social science and language vs natural and

biological sciences). Two of the girls initially selected did not participate because their parents thought that the study would take time and interfere with their studies. A total of 2 additional adolescents were randomly selected and replaced those who refused to participate. Randomization led to a sample of participants that varied in scholastic performance and

socioeconomic characteristics as described in [Table 1](#). The study design and reporting of findings were based on content analysis, ground theory, and the consolidated criteria for reporting qualitative research, which includes a 32-item checklist for interviews and FGDs [24].

^aExcellent school performance was defined as an average grade of ≥ 9 out of 10.

Research Team, Data Collection, and Analysis

A total of 2 researchers designed a semistructured questionnaire based on an analysis of the content of themes that emerged from previous FGDs [18]. The questionnaire was pilot-tested and changed according to the feedback of the pilot participants. FGDs were then facilitated in Vietnamese by a female senior researcher with a PhD degree and experience in qualitative methods from the National Institute of Nutrition of Vietnam. Moreover, 2 female researchers from the Preventive Medicine Department of the Thai Nguyen University of Pharmacy and Medicine assisted in taking notes, recording the audio, and keeping the time. The researchers did not know the participants before the FGDs. Each FGD took approximately 2 hours, and all interviews were completed in November 2020. Another researcher coded the data.

The researchers presented the wireframes of the FRANI prototype (Figures 1A-1I, Multimedia Appendix 1) along with short instructions to guide the participants to explore the core functionality of their project-provided smartphones. Participants were guided to choose individual-based dietary goals and discussed the acceptability of each goal option. These goals for 3 food groups (vegetables, whole grains, and proteins) were selected from the lists described in Textbox 1. After selecting goals, participants took and uploaded pictures of foods using

the camera tool in the FRANI prototype and then received feedback from the FRANI prototype. The facilitator asked questions on acceptability, usability, and likability, as described in Textbox 2. The FGDs were conducted in the school participants' study.

All FGDs were tape recorded and transcribed nonverbatim. Field notes and interviewers' observations were also incorporated into transcripts. Transcribed data from the early interviews were reviewed and discussed by the team to identify gaps in data exploration, which could be further investigated during subsequent interviews. No new information was generated in the fourth FGD, suggesting theoretical saturation. All transcripts were translated into English and randomly checked by a senior researcher who is proficient in English and Vietnamese.

Patterns within and across FGDs were reviewed and organized into the most important common themes using NVivo (version 11; QSR International) software [25]. These themes were acceptability of FRANI prototype's individual- and team-based dietary goals; usability and likability of the FRANI prototype's camera; likability of the feedback, including badges, notifications, and statistics; and likability of the graphic design. Transcripts did not return to the participants for comments and corrections, and interviews with the same group were not repeated. Each FGD lasted approximately 2 hours.

Figure 1. Examples of the Food Recognition Assistance and Nudging Insights wireframes presented for focus groups participants. (A) Home screen, which represents the individual- and team-based scores. The denominators were mistakenly presented in the focus group discussions (FGDs) as 8 and 15 instead of 10 and 14 signifying the food groups for the Dietary Diversity Score (DDS) and subgroups Sustainable Healthy Diet Score (SHDS), respectively. (B) All food groups for which participants could choose goals during the FGDs. (C) All possible goals for vegetables. (D) Camera frame. (E) Confirmation screen with a golden badge for completing 3 goals. (F) Activity screen in which participants can react to what other users posted. (G) Team-based badge. (H) Progress bars for team-based goals (bottom of home screen [A]). (I) Summary of daily statistics. The wireframes presented in the FGDs were written in Vietnamese.

Textbox 1. List of the Food Recognition Assistance and Nudging Insights (FRANI) individual-based dietary goals that were shown to participants and discussed during the focus group discussions. The FRANI includes other food groups, but only those mentioned in this textbox were discussed with the participants.

Vegetables

- Start the day with vegetables
- Snack with vegetables
- Have a vegetable with dinner
- Have a vegetable with lunch
- Eat some vegetables today
- Have a dark green vegetable
- Have a salad with 3 different vegetables

Proteins

- Start the day with proteins
- Snack with proteins
- Have proteins with dinner
- Have proteins with lunch
- Eat some protein today
- Vary your protein routine with beans and peas
- Have a protein food with another food group
- Bake, roast, or grill a protein food

Whole grains

- Start the day with whole grain
- Snack with whole grain
- Have whole grain with dinner
- Have whole grain with lunch
- Eat some whole grain today
- Try a new whole grain
- Have whole grain with another food group

Textbox 2. Questions asked during the focus group discussions.

Acceptability

- What do you think about the dietary goals?
- What do you think about the process of setting dietary goals?
- How does having goals related to food groups help you achieve your personal goals (eg, getting in shape or being healthier)?
- How do you like having team-based goals?
- What do you think about the team-based goals?
- Would you change or improve the way the team-based goals are presented on the home screen?
- On the activity feed, how do you like seeing the combined progress of your team (“A total of 22% of your team has met the goal...”)?
- Do you like how much information can be shared on the activity feed?
- How does FRANI compare with other apps you already used to improve your habits in general, and what you eat specifically?
- How was FRANI’s information relevant for you to understand the basic principles of a healthy diet?

Likability and usability

- How do you like the tool for taking pictures of your meals?
- How would you change or improve the design of the confirmation screens (the immediate feedback after taking the photo)?
- How do you like the way the feedback on what you ate was provided?
- In general, how do you like the idea of receiving feedback each time right after you logged food?
- How do you like the idea of receiving medals (badges) each time you reach a goal?
- How do you like the design of the medals (badges)?
- How do you like the idea of having daily statistics about what you eat?
- How do you like the way the 3 different scores are presented on the statistics screen?
- Is the progress bar clear?
- Should the layout of that screen be changed or improved?
- Do you like using the app? Why?
- What features do you like best? Why?
- What features do you like least? Why?
- What kind of problems do you see with using the app as it’s currently designed?
- What other features do you miss in this app?
- What kind of benefits do you see resulting from using this app?
- What kind of problems do you see resulting from using this app?

Ethics Approval

Methods and materials for the FGDs were approved by the institutional review boards of the International Food Policy Research Institute (protocol code 00007490) and Thai Nguyen National Hospital (protocol code 274/ĐĐĐ-BVTWTN). All participants assented to participate, and their parents consented to their participation. The participants were paid \$50,000 Vietnamese dong (US \$2.14). All procedures were performed in accordance with the Declaration of Helsinki.

Results

Acceptability of the Individual-Based Goals

Acceptability of the Vegetable Goals

Participants generally considered the FRANI dietary goals listed in [Textbox 2](#) achievable and suitable for a variety of people because of numerous alternatives. Respondents were confident that they could eat vegetables every day but not in all meals. All alternatives for vegetable goals are shown in [Figure 1C \(Multimedia Appendix 1\)](#). The goal *Eat some vegetables today* was considered easy to achieve, whereas *Eat vegetable for a snack* and *Start the day with vegetables* were considered hard to achieve. *Have a salad with 3 different types of vegetables* was seen as part of a *Western diet*, unsuited for the Vietnamese culture, because they understood a salad to be exclusively

composed of leafy greens. When informed that root vegetables could be part of the salad group, they suggested the goal of having 2 vegetables, because 3 were an uncommonly high variety of vegetables for 1 meal. A group of participants suggested changing the goal *Have a salad with 3 different types of vegetables* for *eat n m*, meaning *a mix of vegetables* in a local dialect, although the term may not be understood in other regions of Vietnam. The goal of *Having a dark green vegetable* was seen as meaningless, because they did not comprehend how the color of food could impact nutrition and had difficulty distinguishing dark green from light green vegetables. There were also concerns about intoxication from pesticide residues in the vegetables.

Acceptability of the Protein Goals

Respondents were unclear about what constitutes a plant-based protein. The facilitators explained that the objective of the *Vary your protein routine with beans and peas* goal was to facilitate the replacement of animal proteins with plant proteins, for example, with soybeans, peas, or tofu. Some participants held that FRANI should show examples of plant-based proteins to facilitate comprehension; others suggested changing the guidance to *Eat plant-based proteins instead of animal-based protein*. This goal and *Snack with protein* were seen as difficult to achieve, because adolescents mostly eat pastries, cakes, or candies as snacks. The healthfulness of the cooking methods of the goal *Bake, roast, or grill protein-rich foods* divided opinions. Some asked to include an explanation in FRANI about why proteins should be roasted, grilled, or baked. Others proposed boiling, air frying, and steaming, noting that well-known health influencers used these cooking methods.

Acceptability of the Whole-Grain Goals

Whole grains, including rice, wheat, corn, and others [26], were widely mistaken for packaged breakfast cereals:

I thought that [whole grain] was a packaged cereal.
[FGD 1]

Others thought whole grains were a synonym for unprocessed food or snacks:

I think that whole grains are foods that have not undergone many preparations and are pre-processed.
[FGD 3]

[A whole grain] is everything that is considered a snack, for example, bread, or milk. [FGD 1]

Most whole-grain goals were either achievable or redundant after the leads explained their meaning. The only exception was the goal *Start the day with a whole grain*, which was perceived as difficult to achieve for those who did not eat breakfast. Participants thought that the goal *Try a new whole grain every day* required too much cooking time and creativity. To avoid misunderstanding, it was suggested that *whole grains* should be renamed.

The Relationship Among the Dietary, Health, and Fitness Goals

Overall, participants were interested in healthy eating but felt rightly unequipped to make healthy food choices. All participants said that the FRANI should ask for weight and

height, medical history, and fitness and health goals. On the basis of this information, personalized, suitable dietary goals that consider both the quality and quantity of food groups should be suggested:

There must be a complete set of information. It [FRANI] cannot help us with anything if it's too vague. When people have filled out all the information [weight, height, medical history, and health condition], the app should make personalized suggestions so people can pay attention to what they eat. [FGD 3]

Most participants would only use an app that could help them achieve fitness goals, so there was a high demand for a feature to set goals such as weight gain or loss and building muscle mass. They said that FRANI should suggest what dietary goal users should set to achieve their health and fitness goals and indicate what and how many food groups, nutrients, and calories were missing from each meal:

The app's purpose is to promote healthy eating, [...] but I still don't know [after choosing dietary goals on FRANI] if the way I eat is right or wrong, if it's nutritionally inappropriate... The app has to give me advice so I can follow it. [FGD 3]

Choosing goals should not be based on "users' opinions." [FGD 4]

Other comments suggested difficulty in deciding among multiple goals, and some said that FRANI should choose their dietary goals. They also stated that FRANI should provide information about what foods are contained within each food group to avoid misunderstanding. FRANI was interpreted as an app better suited for helping with weight gain than weight loss, because receiving rewards for achieving multiple goals was associated with eating more.

Acceptability of the Team-Based Dietary Goals and Competition

The team-based goals included *eat fruit*, *eat vegetables*, and *drink 6 glasses of water*. At the bottom of the home screen, there was a progress bar for active goals, with 1 box for each day of the week (Figure 1H, Multimedia Appendix 1). Individual members of a team would have their boxes checked if they met the goal that day. For example, if a user chose to opt in to a team-based goal of having fruits every day, they would be grouped with other users who opted in to the same goal. If the individual user achieved that team goal for that day, they would have the box checked, turning it green, or leave it red if they did not. The participants liked the idea of competing in teams. Some participants suggested adding a search engine to find users by their names, inviting contacts to join FRANI, and receiving friendship suggestions so that they could have friends as teammates.

Some participants were more excited about team-based than individual-based goals, saying that competition could trigger motivation, create connections, and foster social support. They wanted more options for team-based goals, because the team-based goals available were seen as easy to achieve:

The team-based goals are easy to achieve because these are foods that we eat every day and that are essential. [FGD 1]

They would like to see team members individually ranked, with the lowest achievers at the bottom and highest achievers at the top:

Here [home screen] it must have a specific team name, and when I click on the team name, I see what goals people have achieved today and the rankings of the team members below. [FGD 3]

Many claimed that underachievement would make them try harder and that they were not worried about peer pressure.

Usability and Likability of the Image Capture Camera

Many participants said that families would support the use of FRANI as long as it helped improve the quality of their diet. However, several challenges were raised. The first perceived usability barrier of the FRANI was the size of the FRANI camera window, which is considered too small to capture images of whole family food trays (Figure 1D, Multimedia Appendix 1), because meals are typically served and eaten communally in Vietnam. Another perceived barrier to usability was the inconvenience for family members in waiting for the process of taking pictures completely before starting to eat their meals. Furthermore, separating what they eat from the rest of the family meal would be seen as disrespectful by most families, especially in the presence of older adults, house guests, and in restaurants:

If there are many people of my family [during mealtime], including the elders, it would be strange for me to separate my food from everyone else. [FGD 3]

An additional usability limitation was that participants did not know how much they ate during the shared family meals:

When eating with others, we share food so it [food consumption attributed by FRANI to user] can't be accurate. It's complicated when many people are eating at once. [FGD 3]

Similarly, after taking and uploading photos, they may consume additional servings. Thus, participants requested a wider camera frame and feature to digitally separate what users ate. Finally, participants were concerned about how much the picture could illustrate the food:

There are many things in a sandwich, but the app won't know all the ingredients unless I take it apart. [FGD 2]

They also talked about the difficulty of taking pictures of foods that come inside packages, such as potato chips. They suggested that FRANI recognizes food packages. They also wanted the ability to upload food pictures to the app after meals to avoid the inconvenience of waiting for other family members or in case there was no internet access. They would prefer to log the same picture for multiple similar meals to save time and phone memory.

Likability of the Feedback, Including Notifications, Badges, and Statistics

Participants said they would like FRANI to give immediate feedback on the quantity and quality of foods eaten, including indications on which foods are unhealthy so as to help them make healthier choices for their next meal:

It [FRANI] should provide an immediate response so that I can learn from the previous experience for the next meal. [FGD 4]

Some said they would rather receive a brief notification reminding them what they still have to eat to achieve individual-based dietary goals, than to get a daily report at night with a summary of what was eaten. They said that FRANI should also notify users about dietary goals that were not met at the end of each day and remind them to take pictures at the time of their meals. Others would like to choose the time of day to receive notifications.

Badges, or visual representations of individual- and team-based dietary goal achievements (Figure 1E, Multimedia Appendix 1), are a form of feedback that can be shared with FRANI friends on an activity screen (Figure 1F, Multimedia Appendix 1). The badge system ranges from bronze to silver to gold and streak badges praise for high dietary diversity multiple days in a row. They liked the badge system but preferred to receive only one badge per day:

I think there should only be one badge a day. This means that if you accomplished all three goals very well, you'll get a gold badge, if you did not do too well [...] you would get a silver badge. If you didn't accomplish any goals, you will not get a badge. [FGD 3]

Participants liked the fact that friends could react (send *hearts*) when they shared their badges in the feed and agreed that comments should not be allowed to avoid cyberbullying (Figure 1F, Multimedia Appendix 1).

Participants were also presented with statistics on food intake using simple charts designed to minimize cognitive load [27]. Most participants understood the 3 different dietary scores calculated by the FRANI prototype, as explained in Multimedia Appendix 2 [28,29]. Participants liked daily statistics on dietary scores for individual goals (Figure 1I, Multimedia Appendix 1). They suggested diagrams to show if users met goals, including how much was eaten from each food item and how much they would still need to eat to achieve the goals. They would like to have a history of daily statistics permanently saved in the FRANI.

Likability of the Graphic Design

Participants wanted the graphic design of the FRANI prototype to be more colorful and the icons to be brighter. The graphic design of the badges was considered unattractive (Figure 1E and 1G, Multimedia Appendix 1). Any food logged by participants during the FGDs showed a watermelon icon as a badge (Figure 1G, Multimedia Appendix 1); therefore, they thought the FRANI prototype did not recognize the foods correctly. This was not a recognition mistake but an unclear

graphic design. They suggested that each food item should have its own differentiated badge. They also stated that graphic design should be more intuitive. The plus (+) icon used to take pictures on the home screen (Figure 1A, Multimedia Appendix 1) should be replaced by a camera icon.

Discussion

Principal Findings

This formative study investigated the acceptability, usability, and likability of an AI-based, gamified mobile phone app prototype to track and improve the nutritional quality of food choices of adolescent girls in Vietnam. The FRANI prototype was designed to self-monitor and influence food choices by considering the capabilities of and opportunities for potential users [30]. We included game elements, such as setting dietary goals and giving feedback on performance, including a badge system, notifications, and statistics, to motivate app use [31-35]. We also added elements of social media, such as sharing information with other users, a newsfeed, and the possibility to react positively to what others posted [34]. Participants of the 4 FGDs provided feedback on the app prototype, informing platform designers of their expectations [36].

Acceptability of the Individual-Based Goals

Most participants had previously tried using various nutrition and health apps to track physical activity, diet, and health. However, they deleted these apps within a few weeks after downloading, owing to excessive battery consumption (ie, for counting steps) and time spent to complete the required tasks (ie, for logging food consumption). Adolescents preferred apps focused on behavior changes that would help them achieve immediate, potentially unhealthy fitness goals (ie, losing weight quickly) rather than focusing on health benefits (ie, improving dietary diversity). This is in line with the idea of *young invincibles* described in the literature: adolescents tend to make unhealthy food choices because of their low likelihood of developing diseases at their life stage [37]. The FRANI was

carefully designed to avoid reinforcing this tendency. We opted to inspire continued use of the app by reinforcing the comprehension of the goals [34] and by increasing the saliency of healthy food choices.

Participants accepted most of the FRANI dietary goals related to vegetable, protein, and whole-grain consumption. The dietary goals that were not understood had their language changed in the updated version of the FRANI (Figure 2, Multimedia Appendix 3). Some participants preferred FRANI to assign goals based on medical history and anthropometric characteristics, instead of choosing dietary goals themselves. This is because they rightly did not feel knowledgeable about nutrition to make choices that would optimize health and fitness. Despite their lack of confidence in setting appropriate dietary goals, FRANI was designed with the expectation that achieving the goal set would improve dietary quality, as long as the dietary goals are changed daily, and goals are achieved [18]. Furthermore, the advantages of fostering habit formation by setting specific goals [38] could be undermined by automatizing this process. Therefore, the updated version of the FRANI does not suggest dietary goals for users. This was an example of incongruity between what users said they wanted and research objectives and theory, a problem that has been previously described in the literature [39].

Following the participants' suggestions, the updated version of FRANI's image recognition software estimated the weight of foods and beverages and provided feedback on quantities. However, goal setting was purely qualitative because maintaining simplicity may be important to the user's experience. The updated version of the FRANI also includes information pages with infographics and detailed explanations for food groups, goals, scores, and health implications of achieving goals. The incorporation of user goals and expectations should lead to higher motivation to use this technology and more effective future digital interventions [40,41].

Figure 2. Examples of the Food Recognition Assistance and Nudging Insights (FRANI) wireframes after changes based on feedback from the focus groups participants. (A) Home screen, which represents the individual- and team-based scores with brighter colors and the right denominators for the Dietary Diversity Score (DDS) and Sustainable Healthy Diet Score (SHDS). (B) Three of the food groups for which users will be able to choose goals (they can also choose goals for dairy and meat when scrolling down). (C) Wider camera frame. (D) Slide bars to digitally indicate how much users ate from foods recognized. (E) The confirmation screen with a bronze badge. (F) Completed goals, badges, and quantities. (G) Activity screen. (H) Individual-based badges. (I) Team-based badges with 1 design for each type of food. (J) The FRANI daily report sent at night for users so they can include complete or correct information uploaded throughout the day. There are English and Vietnamese options for FRANI.

Acceptability of Team-Based Dietary Goals and Competition

Team-based challenges were widely accepted, as they were seen as a means of self-improvement driven by competition. Participants suggested a form of within-team competition: FRANI should show individual achievement information to all team members and rank them accordingly. However, the updated version does not do so, because we want to avoid excessive peer pressure, given that changes in the brain and increased

testosterone during this life stage have been associated with a greater sensitivity to social evaluation and influence [42].

Usability and Likability of the Camera

The updated version of FRANI has a wider camera frame that fits the whole family food tray and has a function to digitally separate the food portions eaten by users from the rest of the family meal. Concerning the difficulty of capturing the multiple ingredients of foods (eg, a sandwich) and foods inside packages, FRANI now also recognizes images of packages, and it is possible to manually log the ingredients that were not captured

by AI technology from the picture. The manual log-in of ingredients is not only more time consuming than taking pictures of foods but also increases the overall accuracy of the app.

Likability of the Feedback, Including Notifications, Badges, and Statistics

FRANI provides personally relevant feedback using credible nutrition information in the form of notifications, badges, and statistics. Participants demonstrated extensive interest in receiving personalized feedback from FRANI, which is important to keep users motivated and engaged [40,43], and it works better than *one size fits all* feedback [41,44]. Receiving feedback has been shown to have the potential to break undesired habits [45,46]. However, some adolescents wanted to receive negative feedback when recording unhealthy food.

In accordance with the desire of participants, the updated version of FRANI sends *just-in-time* notifications reminding users to take pictures at breakfast and lunchtime, which can lead to behavior change [47-49] and habit formation [50]. Notifications can now be turned on and off, but it is not yet possible to choose the time of the day and length of the notifications received. We chose not to send feedback disapproving unhealthy food choices or suggesting substitution for healthy foods, because it can be counterproductive and encourage unhealthy food consumption [51]. Adolescents are also particularly prone to eating disorders

[52,53]; therefore, we tried to minimize the stress generated by negative feedback.

Study participants saw badges as an effective way to support behavior change, but the effects of badges, although promising, have not yet been teased out from other incentives in the nutrition behavior literature [31]. Using badges as rewards can be effective in encouraging positive responses, such as supporting desirable studying practices [33], increasing participation and engagement in schooling [54], supporting professional development [55], and stimulating voluntary contributions in web-based communities [56]. The participants were interested in self-monitoring through daily statistics and suggested that the FRANI should save historical dietary data. The updated version of the FRANI displays the dietary records.

Likability of the Graphic Design

In line with the ground theory, participants showed a preference for a simple interface with an appealing design [18,57-59]. The extent of the engagement benefits of eHealth and mobile health depends on the appropriate design that should be persuasive and personally relevant [60]. The updated interface was simple and visually appealing. The badges sent to praise achievements related to any food group during the FGDs had a watermelon design, which was confusing for the participants. The updated version of FRANI has badges with distinctive designs for accomplishments based on each food group (Figure 3).

Figure 3. Design of new badges based on remarks from the focus group discussions. Colors are brighter than in previous badge versions, food groups have different badges, and users are leveled up from bronze to silver to gold depending on what they achieved.

Strengths and Limitations

The main strength of this study was the in-depth qualitative assessment of the FRANI prototype. Although this assessment was based on the presentation of the prototype during the FGDs and not on real user experience, the process we describe herein can help other researchers build acceptable, usable, and likable tools for interventions. This may increase participation and adherence to future studies. As our study had a small sample

size from a limited geographic location, the findings cannot be generalized to other countries, cultures, genders, and age groups.

Conclusions

Participants accepted FRANI and deemed it usable and likable conditionally on the following modifications: (1) tailored feedback based on users' medical history, anthropometric characteristics, and fitness goals; (2) new language on dietary goals; (3) provision of information about each of the food group's dietary goals; (4) wider camera frame to fit the whole

family food tray, as meals are shared in Vietnam; (5) possibility of digitally separating food consumption on shared meals; and (6) more appealing graphic design, including unique badge designs for each food group.

The findings on FGDs served as a guide to improve the FRANI prototype, which may also help other researchers design tools for different interventions. The acceptability, usability, and likability of the new version of FRANI, along with an assessment of the effects of using FRANI to improve food

choices and dietary quality, will be quantitatively examined in a randomized controlled pilot study. To the best of our knowledge, FRANI is the first AI-based gamified self-monitoring app focused on improving the diets of adolescents in low- and middle-income countries. If successful, this tool will help to improve female adolescents' diets and will make high-frequency data collection on food consumption possible, minimize errors, decrease long-term research costs, and help fill the gap in adolescents' food consumption data collection [61].

Acknowledgments

This research was supported by a Fondation Botnar grant (REG 19-018) and by the Consultative Group for International Agricultural Research (CGIAR) program on Agriculture, Nutrition, and Health (A4NH). BCB is a PhD candidate supported by the Friedman Nutrition and Citizenship Fellowship from the Friedman School of Nutrition Science and Policy at Tufts University. The authors would like to thank Alexei Stulikov and Rohit Gangupantulu for their support in designing this prototype. The sponsors were not involved in the study design or in the collection, analysis, and interpretation of data or in the writing of the report and its submission to publication.

Data Availability

The data are available on request from the authors. Thus, a formal data sharing agreement is required. The lead author has full access to the data reported in this manuscript.

Authors' Contributions

AG, BCB, and N-LA designed this study. AG, BCB, BK, DH, and PM provided inputs for the wireframe design and prototype of the Food Recognition Assistance and Nudging Insights. FD programmed the prototype. AG, BCB, and BK wrote the focus group discussion (FGD) scripts. BCB and BK designed the discussion guide. GF designed the code book. PHN, LT, NH, and PH recruited the participants and ran the FGDs. BCB coded and analyzed the FGD transcripts. BCB wrote the manuscript. PNH, N-LA, BK, and AG revised the manuscript. All the authors have read and approved the final version of the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Alcohol use and sexual assault are common on college campuses in the United States, and the rates of occurrence differ based on gender identity and sexual orientation.

Objective: We aimed to provide an assessment of the usability and preliminary outcomes of *Positive Change (+Change)*, a program that provides integrated personalized feedback to target alcohol use, sexual assault victimization, sexual assault perpetration, and bystander intervention among cisgender heterosexual men, cisgender heterosexual women, and sexual minority men and women.

Methods: Participants included 24 undergraduate students from a large university in the Southwestern United States aged between 18 and 25 years who engaged in heavy episodic drinking in the past month. All procedures were conducted on the web, and participants completed a baseline survey, *+Change*, and a follow-up survey immediately after completing *+Change*.

Results: Our findings indicated that *+Change* was acceptable and usable among all participants, despite gender identity or sexual orientation. Furthermore, there were preliminary outcomes indicating the benefit for efficacy testing of *+Change*.

Conclusions: Importantly, *+Change* is the first program to target alcohol use, sexual assault victimization, sexual assault perpetration, and bystander intervention within the same program and to provide personalized content based on gender identity and sexual orientation.

Trial Registration: ClinicalTrials.gov NCT04089137; <https://clinicaltrials.gov/ct2/show/NCT04089137>

KEYWORDS

sexual assault prevention; alcohol; college students; sexual and gender minorities

Introduction

Background

Alcohol use and sexual assault are widespread problems on college campuses in the United States [1,2], and the rates of occurrence differ based on gender identity and sexual orientation [3,4]. A total of 52.5% of college students used alcohol in the past month, and 33% engaged in heavy episodic drinking (>4 drinks for females and >5 drinks for males in <2 hours) [1,5]. Individuals who identify as a sexual or gender minority (lesbian, gay, bisexual, trans, queer or questioning [LGBTQ]) engage in alcohol misuse at higher rates than their heterosexual and cisgender counterparts [3]. Similarly, sexual assault is common among college students, with students who identify as cisgender heterosexual women and LGBTQ both experiencing the highest rates of sexual assault [4]. Despite alcohol interfering with sexual assault victimization risk perception, sexual assault victimization resistance [6] and bystander behavior [7], as well as increasing the risk for sexual assault perpetration [8], no intervention has targeted alcohol use and sexual assault victimization, perpetration, and bystander intervention in a single intervention. This is problematic, given that sexual assault is a multifaceted issue, and providing prevention for one component of sexual assault (victimization, perpetration, or bystander intervention) cannot address the full scope of sexual assault. Furthermore, providing one prevention component to men (ie, perpetration prevention) may send the message that men are not victims of assault or that it is not necessary to address all 3 components. Targeting multiple, related health issues, such as alcohol and sexual assault, is more effective than targeting them separately [9,10]. Furthermore, no program has provided tailored feedback for cisgender heterosexual men, cisgender heterosexual women, and LGBTQ students, despite their differential risk and differential risk factors. Therefore, this study presents the usability of a novel social norms-based intervention, *Positive Change (+Change)*, which targets alcohol and sexual assault (victimization, perpetration, and bystander intervention) and is tailored based on gender identity and sexual orientation.

Alcohol Use and Sexual Assault Among LGBTQ Individuals

Individuals who identify as LGBTQ are not a homogeneous group, and the drinking patterns of the LGBTQ community are, on average, equal to or greater than their cisgender heterosexual peers [11-15]. For example, one national study in the United States found that individuals who identify as lesbian or bisexual women and gay or bisexual men were 3.81 and 1.76 times more likely, respectively, to engage in high-intensity drinking (>12 drinks in a single drinking episode), compared with those who identify as heterosexual [3]. Another study indicated that women who identify as lesbian and bisexual were 10.7 times more likely to drink compared with women who identify as heterosexual [16]. This discrepancy in drinking behavior has been replicated in college students who identify as LGBTQ [14,17]. Drinking to cope with minority stress [18,19] and social norms of bar culture among individuals who identify as LGBTQ may explain the disparities in alcohol use among LGBTQ men and women

[12,13,20]. According to the minority stress model [18,19], individuals who identify as LGBTQ experience daily heterosexual and transphobic aggressions and microaggressions that cause compounded stress over time. According to the negative reinforcement model, alcohol can be used to cope with stress. Therefore, drinking to cope with minority stress and LGBTQ-specific drinking norms are essential to address in interventions targeting alcohol use for LGBTQ individuals.

Lifetime rates of sexual assault victimization among LGBTQ individuals are higher than their cisgender heterosexual counterparts, with 63% of LGBTQ individuals experiencing sexual assault victimization [21]. Lesbian and bisexual women experience sexual assault victimization at higher rates and experience more mental health symptoms after sexual assault victimization, including higher rates of posttraumatic stress disorder and depression [22,23] compared with their heterosexual counterparts. Gay and bisexual men have also reported high rates of sexual assault victimization. A recent study found that 67% of gay and bisexual men reported an adult sexual assault victimization experience, and 67% of those sexual assaults involved alcohol [24]. This rate of sexual assault victimization is higher than that when examining national data sets of men in the United States. For example, the National Intimate Partner and Sexual Violence Survey found that 24.8% of men experienced sexual assault victimization in their lifetime [25]. LGBTQ populations may be uniquely targeted for sexual assault because of heterosexism. Furthermore, perceived normative behaviors related to resisting sexual assault may differ based on gender and sexual orientation. For example, as LGBTQ populations are disproportionately targeted for violence, they may believe that their peers would not support them if they used active resistance strategies when targeted for sexual assault. Little is known about bystander behaviors among students who identify as LGBTQ, but it is anticipated that there may be unique barriers to engaging in bystander intervention as a member of the LGBTQ community, mostly because LGBTQ populations are disproportionately targeted for violence.

Despite the heightened risk for heavy episodic drinking and sexual assault victimization [24,26-29], men and women who identify as LGBTQ are often overlooked in heavy episodic drinking and sexual assault prevention programs. One exception is an assessment of an in-person bystander intervention, *Green Dot*, which has been tested in high schools, and secondary data analyses examined whether the program was effective for individuals who identified as a sexual minority [30]. This program was not specifically adapted to the unique needs of LGBTQ students; however, it was found that there were reductions in victimization and perpetration among heterosexual youth but not sexual minority youth. Therefore, it is essential to adapt interventions made to prevent sexual assault to LGBTQ populations. Furthermore, it is essential to address this large gap by including alcohol use and sexual assault victimization risk reduction content specific to students who identify as LGBTQ and this study presents an initial step toward this needed effort.

Integrated Personalized Normative Feedback Interventions

The National Institute on Alcohol Abuse and Alcoholism Alcohol Intervention Matrix [31] recommends both personalized normative feedback and skills training as evidence-based interventions with low cost, high effectiveness, and high reach potential. Personalized normative feedback interventions target perceptions of normative drinking, which is the strongest predictor of alcohol use [32,33]. Specifically, personalized normative feedback interventions correct misperceptions of peer alcohol use by comparing one's own use with actual peer use as well as comparing one's perceptions of peer use with actual peer use. In a systematic review, 64% (25/39) of the trials found support for descriptive drinking norms as a mechanism of change in alcohol use interventions [34]. However, current approaches do not account for the unique drinking patterns of cisgender heterosexual women, cisgender heterosexual men, and LGBTQ men and women.

Social norms approaches for prevention allow for the prevention of cross-cutting behavior in an integrated manner as targeting social norms for multiple risk behaviors can be done within one theoretical framework. Furthermore, given that alcohol is associated with an increased risk for sexual assault victimization and perpetration and a decreased likelihood of engaging in a potential sexual assault situation as a bystander [7,8,35], it is essential to target alcohol use, sexual assault victimization, perpetration, and bystander intervention within 1 integrated program. This study included preliminary testing of *Positive Change (+Change)*, a multipronged personalized normative feedback intervention targeting alcohol use and sexual assault (victimization, perpetration, and bystander intervention) within 1 prevention program.

Sexual assault is still widely prevalent, and prevention efforts have not resulted in 0 perpetration rates; thus, feminist scholars emphasize harm reduction behaviors to reduce sexual assault risk while still placing the responsibility of the sexual assault solely with the perpetrator [36,37]. Theoretical models for sexual assault victimization risk reduction focus on providing skills for sexual assault risk perception and empowerment to resist sexual assault [37,38]. As social and psychological barriers can interfere with using active sexual assault resistance strategies, a social norms approach can be used to correct misperceptions of peer disapproval of using active resistance strategies [9]. Similarly, perpetration prevention can use a social norms approach [39,40] by targeting perceptions of peer rape supportive attitudes, beliefs, and behaviors that foster sexual assault perpetration [41]. This approach can also be used to target bystander intervention behaviors. Bystander intervention training encourages bystanders to engage in interventions when witnessing potential sexual assault situations. These programs are based heavily on the Social Norms Theory, as sexual assault perpetrators overestimate supportive peer attitudes toward sexual assault [42]. A recent meta-analysis of sexual assault bystander programs indicated that students who participated in these programs engaged in more bystander behaviors and had more prosocial attitudes, compared with those who did not [42]. Thus, a social norms approach combined with skills training can be a useful approach to address alcohol use and sexual assault

prevention (victimization, perpetration, and bystander intervention) within 1 multipronged, comprehensive program.

Researchers have integrated sexual assault victimization risk, perpetration, and bystander intervention programs as a multipronged approach to prevent sexual assault on college campuses [43]; however, this integrated approach has not yet been implemented or tested. Furthermore, no program to date has targeted sexual assault prevention using this multipronged approach with integrated alcohol content. There are several advantages to addressing the needs of all college students within 1 program. First, it is costly for universities and time-consuming for students to provide 4 separate prevention programs. Second, excluding LGBTQ students from prevention programming is a form of heterosexism and may contribute to the continuing higher rates of alcohol and sexual assault among this population. Third, integrated intervention programming is more effective than providing separate interventions for related health behaviors [9].

This Study

This study assessed the usability and acceptability of *+Change*, a multipronged program targeting alcohol misuse, sexual assault victimization risk, sexual assault perpetration, and bystander intervention among cisgender heterosexual men, cisgender heterosexual women, and LGBTQ men and women. It was hypothesized that *+Change* would have high usability and acceptability ratings. Furthermore, although the study was not powered or designed to detect differences in outcomes related to indicators of alcohol use, sexual assault victimization, sexual assault perpetration, and bystander intervention, these indicators were examined to determine whether there was a decrease in alcohol use risk and sexual assault risk after *+Change*.

Methods

Participants

A total of 30 participants consented to and were enrolled in the study, and 24 (80%) participants fully viewed the content and postintervention questionnaire and were included in the analyses for this manuscript. The final sample included 24 undergraduate students aged between 18 and 25 years who engaged in heavy episodic drinking in the past month. Participants were recruited from a large university in the Southwestern United States.

Measures

Demographics

Participants completed items assessing age, race or ethnicity identity, year in college, and relationship status.

Gender Identity and Sexual Orientation

To assess gender identity, participants were asked the following question: "Understanding gender identity can be complex, which one category best describes your gender identity now?" Prior research has validated the use of this item to assess gender identity [44]. Responses included the following options: (1) female, (2) male, (3) transgender (female-to-male), (4) transgender (male-to-female), and (5) other. To assess sexual orientation, participants responded to the following question:

“Understanding that sexual identity can be complex, which one category best describes your sexual identity now?” This item has been used in previous research among sexual minority individuals [45]. Response options included the following: (1) lesbian, (2) gay, (3) bisexual, (4) queer, (5) two-spirit, (6) straight or heterosexual, (7) questioning, (8) other, and (9) prefer not to answer. Participants responding that they identified as male and straight were placed into the cisgender heterosexual male group. Participants who responded that they were female and straight were placed in the cisgender heterosexual female group. Finally, participants who responded that their sexual orientation was any response other than straight or heterosexual or that their gender was anything other than male or female were labeled in this study as LGBTQ (no participants in the sample identified as transgender or other).

Usability and Acceptability

Participants were asked 2 questions about intervention helpfulness for themselves (“How helpful did you find the intervention content?”) and their peers (“How helpful do you think the intervention content would be for students at [your university]?”) and one question about how distressed they were by the intervention (“How distressing did you find the intervention content?”). Participants rated these items on a scale from 1 (very unhelpful or not at all distressing) to 7 (very helpful or very distressing). Participants also responded to 2 instruments assessing the intervention’s usability and functionality. To assess usability, participants responded to the Post-Study System Usability Questionnaire [46]. This 18-item instrument uses a Likert-type scale with response options ranging from 1 (strongly disagree) to 7 (strongly agree), where participants indicated their agreement with items such as “it was comfortable using this web-based intervention” and “it was easy to find the information I needed.” The Post-Study System Usability Questionnaire includes subscale scores assessing system usefulness, information quality, and interface quality.

Alcohol Use

The Daily Drinking Questionnaire [47] was used to assess participants’ alcohol consumption during a typical week. Participants were asked how many standard drinks they typically consume on each day of the week and then queried on the amount of time (ie, in hours) they typically consume that amount of alcohol. The Drinking Norms Rating Form [48] was used to assess normative perceptions of alcohol use among peers. This instrument assessed the perceived amount to which other students at their university in a particular group consume alcohol during a specific time frame for each day of the typical week. The peer groups assessed in this study included cisgender heterosexual women, cisgender heterosexual men, and LGBTQ, intersex, and asexual (LGBTQIA+) students at their university. The Injunctive Drinking Behaviors Scale [49] is a 15-item scale that was used to assess injunctive norms regarding the acceptability of drinking-related behaviors. Example items include rating how acceptable the typical student thinks it is to “drink shots” or to “drink alcohol every weekend.” Participants responded using a Likert-type scale, where they rated each behavior from 1 (unacceptable) to 7 (acceptable), with higher scores indicating increased levels of acceptability for each

behavior. The contemplation ladder [50] assesses stages of change for alcohol use on a 0 (I have no thoughts of changing my drinking now) to 10 (I’m taking action to change [ie, cutting down]) scale.

Sexual Assault Victimization Risk

To assess the perceived risk of sexual assault victimization while intoxicated, participants were asked how likely they would be incapacitated by alcohol while engaging in unwanted sex. Participants responded using a 7-point Likert-type scale, with response options ranging from 1 (very unlikely) to 7 (very likely). Participants were also asked to estimate the percentage (0 to 100) of each group (cisgender heterosexual men, cisgender heterosexual women, and LGBTQIA+ students at their university) who have experienced sexual assault victimization since entering college.

Sexual Assault Perpetration Risk

The Stages of Change Scale [51-53] assessed the participants’ perceptions of sexual assault prevention efforts on campus. This instrument contains 8 items such as “I don’t think sexual assault is a big problem on campus” and “I am actively involved in projects to deal with sexual assault on campus.” The response options ranged from 1 (strongly disagree) to 4 (strongly agree), with higher scores indicating greater agreement with each item. The Illinois Rape Myth Acceptance Scale [54] was used to accept participant endorsement of 8 common rape myths on a Likert-type scale, with response options ranging from 1 (strongly disagree) to 4 (strongly agree), with high scores indicating greater agreement for each item. To assess the perceived risk for sexual assault perpetration, participants were asked how likely they would be to ask for verbal consent during sexual activity while drinking. To estimate the percentage of false reports at their university, participants were asked “What percent of sexual assaults are falsely reported at [your university]?” Participants were also asked how likely they would be to decide not to engage in sexual activity with someone who is drunk on a 6-point Likert-type scale, with response options ranging from 1 (not at all likely) to 6 (very likely).

Bystander Intervention

The Bystander Efficacy Scale [53] assessed participants’ confidence in performing prosocial behaviors related to the prevention of sexual violence. Specifically, the Bystander Efficacy Scale is an 18-item measure, which contains items where participants rate their confidence in performing behaviors such as “ask a friend/stranger if they need to be walked home from a party” and “speak up to someone who is making excuses for forcing someone to have sex with them.” Participants rated each of the 18 behaviors on a 0% (can’t do) to 100% (very certain) scale as to their confidence in performing the corresponding behavior, with high scores indicating greater levels of confidence.

Procedure

Participants aged 18 to 25 years, who engaged in heavy episodic drinking in the past month, were recruited from a large university in the Southwestern United States using a random sample of students from the registrar by email. From a list of over 6000 students, 468 (7.8%) prospective participants were

randomly selected to receive an email inviting them to participate in this study. Of those 468 invited to participate in the screening survey, 41 (88%) participants were eligible, and 30 (6.4%) participants were enrolled in the open pilot trial. Of these 30 participants, 24 (80%) completed the study procedures. The participants were capped to ensure equal recruitment of cisgender heterosexual women, cisgender heterosexual men, and LGBTQIA+ students. Participants completed consent procedures, a baseline survey, a social norms-based personalized feedback intervention (+*Change*), and a postintervention survey. All study procedures were performed on the web. They were compensated with US \$25 for their participation.

Ethics Approval

All study procedures were approved by the Georgia State University's institutional review board (H2006) and participants consented to all study procedures before participating in the study.

+Change Program Content

+*Change* included content from an integrated alcohol and sexual assault risk reduction program for women [9] and a web-based adaptation of a brief motivational interviewing personalized feedback protocol integrated with the men's workshop for sexual assault perpetration and bystander intervention for men [41,55]. Given that the previous interventions included separate content for men and women and did not address the needs of LGBTQ men and women, new content was created for men's victimization risk, women's perpetration risk, and women's bystander intervention skills training. Furthermore, content was created for the LGBTQ students. The intervention content underwent a rigorous process of intervention development where mockups were provided to college students (equal numbers of cisgender heterosexual men, cisgender heterosexual women, and sexual or gender minorities) and administrators for extensive feedback in interviews and focus groups, and iterative changes were made based on the feedback.

Participants received personalized feedback based on their answers to the baseline survey compared with a larger sample of college students at their university. Feedback was tailored by gender and sexual orientation (cisgender heterosexual men, cisgender heterosexual women, and LGBTQ individuals).

+*Change* targeted heavy episodic drinking and sexual assault by integrating existing, theoretically driven [9,56-58], and evidence-based prevention initiatives delivered via a web-based platform: (1) social norms approach to reduce or prevent alcohol misuse, (2) programming to reduce sexual assault perpetration, (3) bystander intervention to all students tailored by gender and sexual orientation, and (4) sexual assault risk reduction programming tailored by gender and sexual orientation (Multimedia Appendix 1 [9,56-58]).

Analytic Plan

Independent 2-tailed *t* tests were used to examine preintervention and postintervention differences. Given the small sample size, we examined both the trends ($P < .10$ and $P > .05$) and significance ($P < .05$). Separate *t* tests were conducted for variables in the full sample and for each group examined (cisgender heterosexual men, cisgender heterosexual women, and sexual minority men and women).

Results

Demographics

Of the 24 participants, 8 (33%) identified as cisgender heterosexual men, 9 (38%) as cisgender heterosexual women, and 7 (29%) as LGBTQ (1 [4%] identified as gay, 4 [17%] as bisexual, 1 [4%] as queer, and 1 [4%] as questioning). Of the 7 participants who identified as LGBTQ, 6 (86%) identified as female and 1 (14%) identified as male. The mean age of participants was 19.63 (SD 0.97) years, and most were in their second year of school. Most participants identified as White (16/24, 59%), non-Hispanic, or non-Latinx (15/24, 63%), and reported being in a long-term monogamous relationship lasting at least 6 months (10/24, 42%). Participants reported engaging in 2.08 (SD 2.04) episodes of heavy episodic drinking (≥ 4 drinks for individuals assigned female at birth; ≥ 5 drinks for individuals assigned male at birth) per month on average. Furthermore, participants reported drinking 4.75 (SD 4.87) drinks per week on average. Sample characteristics are presented in Table 1. Of the 30 initially enrolled, 2 (7%) cisgender heterosexual men, 1 (3%) cisgender heterosexual woman, and 3 (10%) LGBTQ participants did not fully complete the study procedures and were excluded from the analyses.

Table 1. Demographic characteristics of participants in open pilot.

Demographics	Cisgender heterosexual men (n=8)	Cisgender heterosexual women (n=9)	LGBTQ ^a individuals (n=7)	Total sample (N=24)

^aLGBTQ: lesbian, gay, bisexual, trans, queer or questioning.

Usability and Acceptability of +Change

On average, participants took 17.52 (SD 11.75) minutes to complete +Change. Overall, the participants were satisfied with the information quality (mean 5.52, SD 1.19), interface quality (mean 5.98, SD 1.05), and system usefulness (mean 5.74, SD 1.05) of +Change. In terms of +Change's helpfulness, participants reported they found the intervention content helpful

(mean 5.22, SD 1.51) and believed their peers would as well (mean 5.17, SD 1.47).

Alcohol Misuse

Results of *t* test analyses indicated that participants reported significant pre-post decreases in drinking norms, but did not report significant pre-post differences in injunctive drinking norms or in stages of change (Table 2).

Table 2. Changes in pre-post alcohol and sexual assault variables in open pilot.

Sexual Assault Victimization Risk

Results of the *t* test analyses indicated that there was no significant pre-post difference in participants' estimations of the risk of experiencing incapacitated sexual assault victimization themselves while in college (Table 2). However, all participants significantly increased their estimation of how

many LGBTQIA+ students had experienced sexual assault since entering college significantly after +*Change* (Table 2).

Sexual Assault Perpetration Risk

Results of the *t* test analyses indicated that after +*Change*, participants were significantly more aware of the problem of sexual assault on their campus (ie, less precontemplative) and

had greater intentions to make changes to prevent sexual assault perpetration (ie, more contemplative; Table 2). Participants reported significant reductions in pre-post rape myths and increases in deciding not to have sex with someone who was drunk (Table 2). In relation to false reports, participants at baseline estimated that, on average, 15.76% (SD 17.83%) of sexual assaults at their university were false reports. After participating in +Change, participants estimated that, on average, 7.94% (SD 7.39%) of sexual assaults at their university were false reports. This decrease in estimated false reports was a trend that did not reach significance ($P=.052$).

Bystander Intentions

Results of the *t* test analyses indicated that participants reported a significant preintervention to postintervention increase in the likelihood to intervene when witnessing sexual assault and nonsignificant increases in bystander efficacy following +Change (Table 2).

Discussion

Overview

This is the first program to provide personalized normative feedback to students who identify as LGBTQ and integrate multiple components of alcohol-related sexual assault prevention including victimization risk reduction, perpetration prevention, and bystander intervention training. Although a larger clinical trial to examine +Change's efficacy is needed, these findings provide initial evidence that a comprehensive alcohol and sexual assault prevention program can be used among college students of varied genders and sexual orientations. Given the high rates of alcohol use and sexual assault among women and LGBTQ individuals, the rates of men as victims, and differences in perpetration rates, tailored content based on gender and sexual orientation are needed to move the prevention field forward.

Principal Findings

The results supported the usability and acceptability hypotheses such that +Change had high usability and acceptability ratings among cisgender heterosexual women, cisgender heterosexual men, and LGBTQ college students. Furthermore, despite the relatively low power to test for significant differences, there were some significant initial indicators suggesting that +Change may be helpful.

The findings from this study suggest that +Change may be an acceptable strategy to target alcohol and sexual assault among cisgender heterosexual men, cisgender heterosexual women, and LGBTQ college students. Overall, participants rated +Change to be acceptable across several usability domains including information quality, interface quality, and system usefulness. Furthermore, participants indicated that +Change was helpful for themselves and believed it would be helpful for their peers. This may be because of the brief duration of the prevention program and the user-friendly format of the web-based personalized feedback intervention.

There was a significant decrease in descriptive drinking norms after participating in +Change. Although differences between cisgender heterosexual men, cisgender heterosexual women,

and LGBTQ individuals were not examined because of the small sample size, mean values suggest that the largest changes may have occurred within cisgender heterosexual men and cisgender heterosexual women. Although there were no significant changes in injunctive drinking norms or in stages of change in drinking, an examination of the means before and after +Change suggests that there were small changes in the direction toward lower injunctive drinking norms and higher motivations for change. These findings are similar to other social norms interventions targeting drinking among college students [34] and suggest that targeting descriptive drinking norms is a viable strategy when targeting both alcohol and sexual assault among college students.

There were significant increases in the awareness of sexual assault victimization risk among LGBTQ students during college. Specifically, participants estimated that more LGBTQ students experienced sexual assault during college at their university after +Change than before +Change. This is an important finding because awareness of sexual assault perpetrated against LGBTQ students could encourage bystander intervention behavior if a potential sexual assault is witnessed against an LGBTQ peer. This is also important because 17 years is the median age at which LGBTQ individuals begin to identify as LGBTQ (Pew Research Center [59]). Therefore, although individuals are identified as cisgender and heterosexual at the time of the intervention, their identity may change later in life. There was also a similar nonsignificant trend among female students. Although group comparisons were not assessed, an examination of the means suggested that LGBTQ students estimated that all college students experienced sexual assault during college more than other groups. This may be because LGBTQ students themselves have higher rates of sexual assault [21] and therefore, may be more aware of the risk for all college students. Nonetheless, the findings suggest that providing current rates of risk based on gender identity and sexual orientation can change one's perceived risk of experiencing sexual assault on a particular college campus.

Importantly, there were some indicators that +Change may have the potential to reduce sexual assault perpetration. Specifically, participants reported significantly less precontemplation and significantly more contemplation in terms of readiness to change sexual assault on their college campuses. In addition, participants reported decreased endorsement of rape myths and decreased estimate of how many sexual assault reports are false reports. Interestingly, before +Change, cisgender men and women believed that approximately one-fourth of reported sexual assaults at their university were false reports. This finding suggests that work is needed to change perceptions, given that only 5.9% of assaults are false accusations, the same rate as other crimes [60]. Furthermore, participants indicated increases in deciding not to have sex with someone who is drunk while they are drinking. This is an important behavioral intention indicator as it suggests that +Change may be helpful in reducing incapacitated sexual assault perpetration.

In terms of bystander intentions and attitudes, participants reported a significant increase in the likelihood to intervene when witnessing sexual assault and nonsignificant increases in

bystander efficacy. These results are promising, especially in light of the theory suggesting that intentions to perform a behavior are the closest cognitive antecedent of behavioral performance [61,62]. Furthermore, both longitudinal [63] and experimental [64] studies have found that bystander intentions predict subsequent bystander behavior for sexual assault.

Comparison With Prior Work

+*Change* is the first program to tailor content based on gender identity and sexual orientation. It is also the first program to integrate sexual assault victimization risk reduction, perpetration prevention, and bystander intervention training within one program. Therefore, this work extends previous research indicating that alcohol and sexual assault risks differ based on gender and sexual orientation [1-4], and previous calls for integrated programs for victimization risk reduction, perpetration prevention, and bystander intervention training [43]. Previous work has tested nontailored interventions of one component of sexual assault, such as the *Green Dot* which focuses on bystander intervention training, among sexual minority high-school students and found that the bystander content was not effective at reducing sexual assault among sexual minority youth [30]. Therefore, this study provides promising initial findings for an intervention that may address this large gap in prevention literature.

Limitations

This study had several limitations including the fact that it was an open pilot study of a small sample of college students at one university. Therefore, conclusions on the initial outcomes are only preliminary and a large-scale randomized clinical trial across multiple universities is needed. In addition, as no participants identified as gender-diverse, future research is needed to assess the efficacy of +*Change* among gender-diverse students. As the assessments were conducted on the same day, before and after +*Change*, they were not able to capture any behavioral changes. Future efficacy trials should examine whether +*Change* is effective at reducing alcohol use, sexual assault victimization, perpetration, and increasing bystander intervention behaviors to determine efficacy. This study assessed potential helpfulness and distress in assessing acceptability.

Future research should use more in-depth acceptability measures. Future research is needed to understand Black, Indigenous, and People of Color students and LGBTQ Black, Indigenous, and People of Color students, as their experiences may differ and they could benefit from tailored interventions. LGBTQ students were included within one group rather than including different intervention components for the LGBTQ subgroups. This is problematic as LGBTQ students are not a heterogeneous group. However, this is a necessary first step in tailoring the programs for LGBTQ students. Although it appears in this sample that the LGBTQ participants did not engage in more alcohol use than their cisgender heterosexual peers, which is likely because all participants enrolled in this study engaged in heavy episodic drinking at least once in the past month. Research findings that LGBTQ men and women engage in drinking at higher levels than their cisgender heterosexual peers do not include a restricted sample as in this study and this sample likely has a ceiling effect because of the inclusion criteria. Although this study is limited to the United States, research indicates that sexual assault in higher education occurs at high rates across the globe [65]. Furthermore, alcohol-involved sexual assault is a global problem [66]. Future research should focus on the development of integrated prevention programs for alcohol use and sexual assault using culturally appropriate content worldwide.

Conclusions

+*Change* is the first program to integrate sexual assault victimization risk reduction, perpetration prevention, and bystander intervention training into one program. This is important to reduce both university costs and student time. It is also the first program to provide tailored content for LGBTQ students. This is important to acknowledge and address the unique risks of LGBTQ students as ignoring their needs may be a form of heterosexism embedded within the university prevention programming. Finally, it harnesses the strength of previous works [9,41]. The findings from this study suggest that +*Change* has high acceptability and usability among college students. Furthermore, there were several pre-post differences in outcomes related to alcohol use and sexual assault suggesting the need for a large randomized clinical trial.

Abstract

Background: After the Great East Japan Earthquake in 2011, backup systems for clinical information were launched in Japan. The system in Miyagi Prefecture called the Miyagi Medical and Welfare Information Network (MMWIN) is used as a health information exchange network to share clinical information among various medical facilities for patients who have opted in. Hospitals and clinics specializing in chronic renal failure require patients' data and records during hemodialysis to facilitate communication in daily clinical activity and preparedness for disasters.

Objective: This study aimed to facilitate the sharing of clinical data of patients undergoing hemodialysis among different hemodialysis facilities.

Methods: We introduced a document-sharing system to make hemodialysis reports available on the MMWIN. We also recruited hospitals and clinics to share the hemodialysis reports of their patients and promoted the development of a network between emergency and dialysis clinics.

Results: In addition to basic patient information as well as information on diagnosis, prescription, laboratory data, hospitalization, allergy, and image data from different facilities, specific information about hemodialysis is available, as well as a backup of indispensable information in preparation for disasters. As of June 1, 2021, 12 clinics and 10 hospitals of 68 dialysis facilities in Miyagi participated in the MMWIN. The number of patients who underwent hemodialysis in Miyagi increased by more than 40%.

Conclusions: Our backup system successfully developed a network of hemodialysis facilities. We have accumulated data that are beneficial to prevent the fragmentation of patient information and would be helpful in transferring patients efficiently during unpredictable disasters.

Introduction

Patients undergoing hemodialysis (HD) require collaborative team care, not only because their renal function is poor but also because they are vulnerable to various comorbidities [1,2]. Since an increase in the number of comorbidities makes care for patients more complex, multiple medical facilities may need to share patient information, and diverse specialist expertise may be required for patient management. However, sharing clinical information among different facilities is not an easy task because most dialysis clinics and hospitals do not have the same electronic health record (EHR) or do not have a health information exchange (HIE). Furthermore, the EHR and HD systems are rarely integrated. Such fragmentation of clinical information becomes a more serious concern during natural disasters such as earthquakes, tsunamis, and hurricanes. In 2011, the Great East Japan Earthquake (GEJE) hit Miyagi Prefecture [3,4] and damaged many facilities, including HD clinics and hospitals, resulting in the transfer of patients undergoing HD from Miyagi to other distant places [5]. At that time, the importance of patient information was recognized through experience. In addition, Katrina, a hurricane that hit the United States in 2005, caused similar situations in which many patients could not receive optimal dialysis treatments at alternate dialysis institutions because of a lack of medical records and information about their dialysis regimen [6]. Thus, sharing patient information is critical for disaster preparedness.

After the GEJE, backup systems of clinical data were developed in many places in Japan, and Miyagi Prefecture launched the Miyagi Medical and Welfare Information Network (MMWIN), which saves patient clinical information obtained from medical facilities, including hospitals, clinics, pharmacies, and nursing homes [7]. Moreover, the MMWIN is now used as an HIE to share clinical information, such as patients' basic information, history of diagnosis, prescription data, laboratory test data, and hospitalization data, among more than 800 facilities in Miyagi Prefecture [8]. This study aimed to facilitate the sharing of clinical data of patients undergoing HD among HD facilities.

Methods

The MMWIN System and Data Storage

The system used in MMWIN was explained in detail in our previous paper [7]. Briefly, the main system of the MMWIN consists of backup storage, a portal server to manage patients' ID registration information, the gateway that receives clinical data from facilities and stores them in the storage, and viewer applications. A standard storage format, Standardized Structured

Medical Information eXchange version 2 (SS-MIX2), which is authorized by the Ministry of Health, Labour and Welfare of the Japanese government, enables the collection of clinical information from different vendor systems and is commonly used in several national projects to store and use large amounts of clinical data in Japan [9-12]. The storage format is divided into two categories. The first is the standardized storage, including standard clinical data in a standard form (Health Level 7 [HL7] v2.5), such as basic patient data, prescriptions, and laboratory data. The second is the extension storage that includes the remaining data not stored in the standard storage [12].

Computers in the MMWIN-affiliated facilities are connected to the MMWIN server via a virtual private network (MMWIN secure network). Clinical data from the hospital information system (HIS; or other information systems available in clinics, pharmacies, or nursing care homes) are transferred to SS-MIX2-formatted XML/HL7 files via gateways.

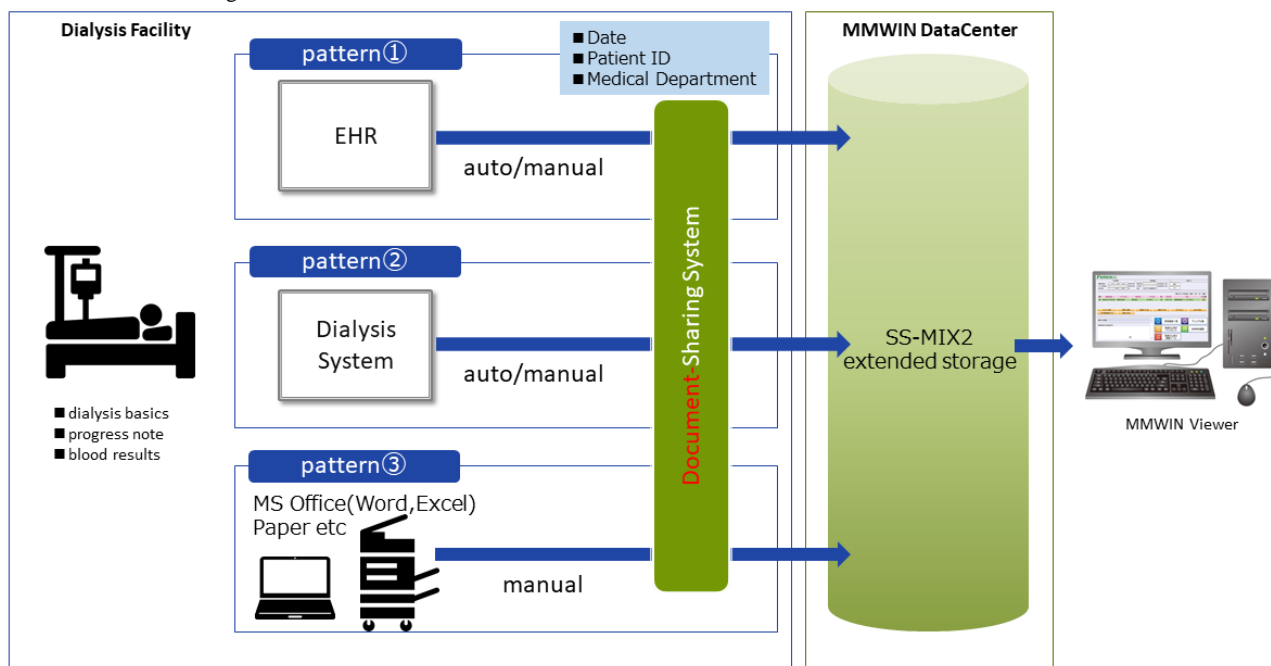

Opt-in for patients to register with the MMWIN includes a unique MMWIN ID number, which is connected to a different ID number in each facility, thereby permitting the sharing of patient information. Finally, these data are available through a browser-based SS-MIX2 viewer application, Human Bridge (Fujitsu). Thus, in each facility, the clinical information of all patients in the facility can be seen on MMWIN, which allows clinicians to check clinical data even when their own information system is out of order.

Data Transfer of HD Reports

Since there is no standard format for HD reports, we started storing the reports in extension storage using Docuworks (FUJIFILM Business Innovation Corp.), which enables the transfer of HD reports from the facilities to the MMWIN center. Figure 1 shows the scheme of the system for sharing HD reports between the MMWIN and facilities.

There are three ways to transfer HD information from facilities. First, HD reports could be integrated into the HIS and automatically or manually transferred to the SS-MIX2 center in the MMWIN. Second, HD reports could be released from the dialysis system and automatically or manually transferred to the SS-MIX2 center in the MMWIN. Third, a facility that still uses a paper record of HD or the original format using Word or Excel (Microsoft Corporation) can transfer the data manually via our document-sharing system. Through Docuworks, these files with additional necessary patient information, such as patient ID and labels as HD reports, are converted to SS-MIX2 format and are transferred to the SS-MIX2 extension storage in MMWIN through the facility's gateway and MMWIN secure network.

Figure 1. A scheme of connection between the MMWIN data center and the hemodialysis (HD) report in each facility. Three sources of HD information from facilities are shown: HD reports integrated with the hospital information system and transferred to the SS-MIX2 center in the MMWIN; HD reports released from the dialysis system and transferred to the SS-MIX2 center in the MMWIN; and a manual transfer of HD data via our document-sharing system. EHR: electronic health record; MMWIN: Miyagi Medical and Welfare Information Network; MS: Microsoft; SS-MIX2: Standardized Structured Medical Information eXchange version 2.

Ethics Approval

The project was approved by the administrative boards of MMWIN on December 25, 2015.

System Promotion

To promote the use of the system, we tried to encourage the development of a network within the clinical communities of HD clinics and hospitals. We asked nephrologists in Miyagi Prefecture to use this system and explained the benefits, such as being paperless and reducing the work burden of medical staff in HD facilities, through information brochures, personal meetings, and seminars since 2016. We also encouraged patients undergoing HD to provide consent to share their clinical information including prescription, laboratory data, and HD reports with the other HD facilities.

Statistical Analysis

A chi-square test and the Welch *t* test were used for statistical analysis using R 3.6.0 (R Foundation for Statistical Computing). Two-sided *P* values <.05 were considered significant.

Results

We introduced a document-sharing system to make HD reports available on the MMWIN. Figure 2 shows a screenshot of the HD report on the MMWIN. MMWIN users can refer to data regarding HD as well as a variety of information, such as basic

patient information, diagnosis, prescription, laboratory data, hospitalization, allergy information, and image data from different facilities. When a user clicks the icon, detailed information is obtained. Next, we compared the amount of information available on the MMWIN to the items that were required during a disaster, as recommended in previous reports [13,14]. Table 1 shows that 39 items are available in the MMWIN, and these covered 92% (23/25) of recommendation 1 [13] and 100% (19/19) of recommendation 2 [14].

According to the network linkage of patient transfer between core hospitals and HD facilities, we recruited hospitals and clinics sharing HD reports and promoted the development of a network between emergency hospitals and dialysis clinics. As of June 1, 2021, 12 clinics and 10 hospitals of the 68 dialysis facilities in Miyagi participated in the MMWIN. The basic characteristics of the facilities with or without HD are shown in Table 2. There were no significant differences among them, except for the number of beds in clinics, with a smaller number of beds in the facilities using the MMWIN-HD system ($P=.02$). We also asked patients for their consent to share clinical information among facilities. Figure 3 shows the rate of opt-in patients (line chart) and the total number of all patients undergoing HD in Miyagi Prefecture (bar chart). The number of opt-in patients increased to more than 40% of all patients who underwent HD in Miyagi Prefecture after we began recruitment.

Figure 2. A screenshot of the Miyagi Medical and Welfare Information Network viewer and hemodialysis report. Users can access information on dialysis regimen, the latest body weight, and vital signs by this view.

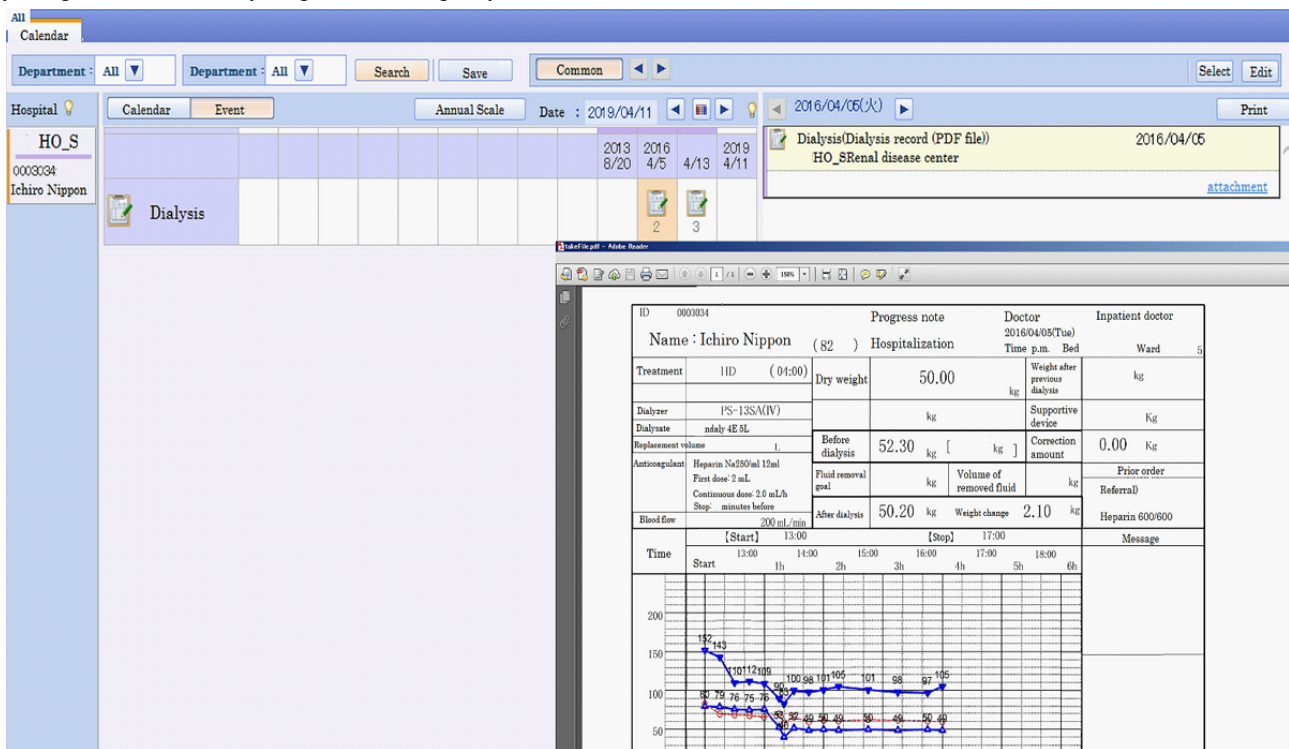

Table 1. Available information about dialysis in the MMWIN and recommended data items for disaster preparation.

^aMMWIN: Miyagi Medical and Welfare Information Network.

^bIndicates this item is present in the recommendations or MMWIN.

^cHD: hemodialysis.

^dCAPD: continuous ambulatory peritoneal dialysis.

^eCCPD: continuous cycling peritoneal dialysis.

^fHDF: hemodiafiltration.

^gBP: blood pressure.

^hReuse is not allowed in Japan

ⁱHBsAg: hepatitis B surface antigen.

Table 2. The characteristics of hemodialysis facilities participating in the Miyagi Medical and Welfare Information Network.

Facility	Attending (n=22), n		Not attending (n=46), n	
	Clinic	Hospital	Clinic	Hospital
Fund				
Public	0	5	0	9
Private	12	5	26	11
Area				
Coast	1	2	3	3
North	3	1	6	7
South	4	1	3	2
Central	4	6	14	8
Beds, mean (SD)	1.6 (5.3)	279.3 (320.4)	7.7 (9.1)	306.8 (182.3)
Beds for HD ^a , mean (SD)	51.8 (22.1)	40.1 (19.2)	37.4 (13.0)	28.8 (17.3)
Doctors, mean (SD)	2.1 (1.1)	155.1 (396.1)	2.0 (1.1)	67.8 (68.7)
HD patients, mean (SD)	118.0 (66.5)	95.9 (55.7)	87.9 (51.1)	70.8 (55.5)

^aHD: hemodialysis.

Figure 3. The rate of opt-in patients undergoing hemodialysis in the Miyagi Medical and Welfare Information Network and the number of patients undergoing hemodialysis in Miyagi Prefecture. The bars show the total number of patients undergoing hemodialysis in Miyagi. The line chart represents the ratio of opt-in patients to all patients undergoing hemodialysis in Miyagi.

Discussion

Principal Results

We developed a system for sharing HD reports and other clinical information among medical facilities and enhancing their connection networks. This would be helpful when the condition of patients undergoing HD is aggravated and when they need to be transferred to other hospitals. It would also be effective for the improvement of medical staff members' work burden in the view of a paperless environment where they do not have to send HD reports by fax or mail to other facilities. Another merit is that patient information can be made available during a disaster, resulting in prompt extraction of patient information even in a chaotic situation. Lastly, sharing patient information would be very helpful for collaborative care, especially among general care practitioners and specialists, including nephrologists. An HIE can be a good tool to support clinical decision-making and ensure continuity of care, especially for complex medical problems.

In catastrophic situations, like the GEJE in 2011, the clinical information on MMWIN can be accessed from different facilities to acquire patient clinical data when needed. Since the MMWIN system is independent of the HIS in each facility, the information can be accessed even if the HIS is unavailable. Medical staff members can refer to medication and laboratory results and input clinical notes on the MMWIN system. Therefore, even when an HIS is down, medical staff can conduct HD as usual according to patient records on MMWIN.

Comparison With Prior Work

Access to prior clinical data from different facilities is important for continuing appropriate treatment in the community. A fully interoperable EHR or HIE would also be helpful in maintaining the flow of critical patient information. In particular, for the care of patients undergoing HD, the information would reduce the risks of HD and prevent aggravation of renal function. In our system, we introduced a document management system for several measures to transfer HD reports from an EHR, dialysis systems, or original documents. Although specific information systems were launched elsewhere [15,16], we successfully integrated the sharing of HD reports into the main HIE system without the high cost of additional implementation. This system is based on document sharing. As the next step, digital data transfer is desirable for using clinical data, such as copying and pasting to avoid tedious record keeping by medical staff in daily clinical activity or for research purposes when researchers obtain informed consent from patients for secondary use. In addition to HD, since our document-sharing system is used in various situations, such as reference letters when a patient is transferred, notes to doctors from pharmacists when patients have questions regarding medication at the pharmacy, and sharing documents between care workers and doctors, this system can be used in different fields as a digital transformation tool.

The future of interoperability may lie in using novel standards to transfer clinical data more easily between an HIS and mobile devices, such as personal health records (PHRs). One such standard may be based on the Fast Healthcare Interoperability Resource (FHIR) [17]. We have already attempted to transmit

clinical data using the FHIR for PHRs [18]. It could also be applied to HD reports soon. In addition, this system is used for care coordination between primary care physicians (PCPs) and nephrologists to manage the associated complex chronic conditions of patients undergoing HD. This could improve the management of patients with end-stage renal disease [19]. Our previous study revealed that an HIE is a good tool to improve patient prognosis, with collaboration between PCPs and specialists [8].

One of our major concerns in patient management is preparedness for disasters. During a disaster, HD facilities sometimes cannot supply the usual HD environment, resulting in HD at alternate dialysis locations without patients' medical records or information about their dialysis regimen being available. Therefore, we checked whether the available information on the MMWIN could cover the necessary data items during a disaster for dialysis-specific disaster preparedness [13,14,20]. Thus, as shown in Table 1, we covered almost all the recommendations. Available data provided in MMWIN include the latest body weight and vital sign on regular HD, which are essential information for optimal and secure dialysis management. Although it is recommended that the patients themselves always have basic information of their own for disaster preparedness, this is not easy because older people comprise two-thirds of patients undergoing dialysis in Japan [21].

Limitations

This study had some limitations. First, we did not include all HD facilities in Miyagi. Although we managed to enroll 22 HD facilities joining the MMWIN and more than 40% of patients undergoing HD in Miyagi were registered, HD records from dialysis facilities cannot be shared with other dialysis facilities that do not have access to the MMWIN. It would be difficult for small facilities to implement the system without the support of public budgets. Encouragement by the local government through stronger incentives to both facilities and EHR vendors is needed to implement the MMWIN system. There were no significant differences among facilities, except for the number of beds in clinics, with fewer beds in the facilities within the MMWIN system ($P=.02$; Table 2). In the survey, most clinics with fewer beds were HD-specific facilities that did not have admission beds for inpatients, only for outpatients with HD. Table 2 shows that the HD-specific facilities favored MMWIN systems over other facilities, mainly because of our document-sharing system for patients undergoing HD. This indicates that the HD-specific clinics for only HD outpatients favored using the MMWIN-HD system to share patient information with hospitals, which would accept patients when their condition worsened. In addition to HD reports, the document systems are available for sharing reference letters or notes among hospitals, between hospitals and clinics, between doctors and pharmacists, and between hospitals and nursing care homes. As well as HD facilities, we believe that all health care facilities should make an effort to share patient information across all care settings. Another potential benefit for such a network may be its use to guide medical decisions based on individual patient characteristics (personalized medicine) rather than averages over a whole population. Personalized medicine

in patients with kidney disease is lagging behind the other medical disciplines as most randomized controlled trials are currently excluding patients with kidney disease. Second, we have not encountered a disaster that requires HD records to be shared among facilities. This is fortunate, but there is a requirement to test the system with more practical simulations for possible disasters.

Additionally, we did not have a wide range of training exercises among different facilities to simulate large disasters. Support from patients and many facilities throughout the prefecture would be practical. A plan for a wide range of training exercises

is needed in the near future. However, the staff members in facilities attending MMWIN have already implemented daily use of this system in clinical activities. This habit can be helpful, even during disaster situations.

Conclusions

In conclusion, our backup system successfully developed a network of HD facilities. We have accumulated data that are beneficial to prevent the fragmentation of patient information and would be useful to transfer patients efficiently as preparedness for unpredictable disasters.

Acknowledgments

We thank Ms Mikiko Sato, Ms Misaki Arakawa, and Miyagi Medical and Welfare Information Network members for their technical support.

Abstract

Background: There is a growing bottleneck in mental health care, as the demand for services has outpaced the availability of mental health professionals. Consequently, many health systems have shifted to teletherapy as a scalable approach to increasing accessibility to care. Within these care models, various treatment modalities (eg, coaching and clinical care) are used to deliver support for anxiety and depression. However, more research is needed to better understand the differences in treatment responses.

Objective: The purpose of this study was to examine the association between different care modalities and the levels of use with symptom score changes for members seeking virtual care services.

Methods: We conducted an observational study of 4219 members who accessed Ginger, an on-demand mental health service, between September 2020 and September 2021. Using a mobile app, members can access text-based behavioral health coaching and virtual clinical services. This study focused on members with clinically elevated depression or anxiety levels at baseline. Logistic regressions were used to assess the association between care modalities and the levels of use with treatment response in depression and anxiety, using the Patient Health Questionnaire and Generalized Anxiety Disorder Assessment, respectively.

Results: Of the 4219 members, 1623 (38.47%) demonstrated a full response to depression, and 1684 (39.91%) demonstrated a full response to anxiety. Members who completed care (ie, text-based coaching, virtual clinical therapy, hybrid of coaching, and clinical care) beyond the introductory session showed significantly increased odds of a full response compared with those who completed only limited care. Members who completed a hybrid of care had the highest odds of improvement; the odds of showing a full response in depression were 2.31 times higher (95% CI 1.91-2.80; $P<.001$) and in anxiety were 2.23 times higher (95% CI 1.84-2.70; $P<.001$) compared with members who completed limited care. For members who completed only coaching or clinical care, the largest effects were observed among those with high use. For members who completed a hybrid care program, we observed similar treatment responses across all levels of use.

Conclusions: Our real-world study found that members who completed text-based coaching achieved full treatment responses at similar rates compared with members who completed virtual clinical care and members who completed a hybrid of care. There were no significant differences in the predicted probabilities of full treatment response between coaching and clinical care. Generally, the odds for a full response were highest among members with high use within each care modality; however, there were no differences in full-response treatment odds across levels of use with hybrid care. The results support the utility of digital behavioral health interventions and further highlight text-based coaching protocols as an accessible and suitable option when considering virtual care for treating anxiety and depression.

Introduction

Background

Before the current pandemic, the prevalence of mental health illness in the United States was more than 1 in 5 adults (20.6%) [1]. Anxiety and depression result in an estimated global economic cost of US \$1 trillion each year for lost productivity, absenteeism, and medical costs [2]. The confluence of physical health risks, financial stressors, social isolation, and disruption of daily activities during the COVID-19 pandemic has had a profound impact on the number of individuals with clinical depression and anxiety [3]. In fact, the Centers for Disease Control and Prevention reported that between August 2020 and February 2021, the percentage of adults with recent symptoms of anxiety or depression increased from 36% to 42%, and the percentage of those reporting an unmet mental health care need increased from 9% to 12% [4]. Despite the urgent need for mental health care, individuals still face many barriers in accessing effective treatment services, including high out-of-pocket expenses and transportation challenges [5,6]. In addition, there has been a long-standing care delivery bottleneck for mental health care as the demand for care has outpaced the availability of qualified mental health professionals. Long waitlists have only worsened during the pandemic and underscore the urgency to identify innovative new models to increase access to effective mental health care.

To address the pressing need for services, many health systems and organizations have shifted to teletherapy and other digital interventions as scalable approaches to increasing accessibility to mental health care [7]. Within these care models, various treatment modalities (eg, self-guided content, coaching, and teletherapy) are used to deliver support for anxiety and depression. The efficacy of virtual teletherapy for the treatment of mood and anxiety disorders has been well established, with outcomes similar to face-to-face visits and greater efficacy compared with treatment as usual or placebo [8-11].

Although virtual care can increase access and reach to care, some approaches still rely on the limited supply of highly trained mental health specialists (eg, clinical psychologists). A promising and increasingly popular method of care is behavioral health coaching, which can serve as a lower-intensity alternative to care. Although this type of care may not be suitable for all types of patients (eg, those with suicidal ideation, substance use disorder, or repeated hospitalizations), behavioral health coaching has demonstrated improvements in both the physical and mental health status of patients [12-14]. Care can be delivered by bachelor's or master's level providers and represents a more scalable solution that does not overly rely on the limited supply of mental health specialists with advanced training (eg, doctoral degree). Coaching uses methods similar to traditional psychotherapy and can address anxiety and depression through techniques derived from interventions such as mindfulness, solution-oriented focus, and positive psychology [15]. With the rapidly shifting landscape of care models, traditional coaching models have adapted to digital methods, such as text-, video-, or telephone-based coaching. One of the benefits of text-based coaching in particular is that it requires

less coaching time and allows for both synchronous and asynchronous support for members, which may be more suitable for the on-the-go lifestyle of those seeking care [16]. Several recent studies using text-based coaching have demonstrated treatment outcomes equivalent to those of in-person and telephone-based care [16-19]. These treatment modalities can serve as scalable solutions to address the growing demand for mental health services; however, more research is needed to better understand the differences in treatment responses for depression and anxiety.

This Study

The purpose of this study was to examine the association between different care modalities and different levels of use with clinical symptom score changes in members seeking services in a virtual care model. As such, we have two hypotheses: (1) members who completed text-based coaching, clinical sessions, or a hybrid of coaching and clinical care would demonstrate higher odds of a full treatment response ($\geq 50\%$ reduction in symptom scores) for anxiety and depression compared with members who only completed limited care and (2) members who used more sessions would demonstrate higher odds of a full treatment response.

Methods

Overview

We conducted a retrospective observational study of members who accessed Ginger, an on-demand mental health service, between September 2020 and September 2021. This is a secondary analysis of pre-existing deidentified data. The study team did not have access to participants' identifying information and did not intend to recontact the participants.

Ethics Approval

Ginger's research protocols and supporting policies were reviewed and approved by Advarra's institutional review board (Pro00046797) in accordance with the US Department of Health and Human Services regulations at Title 45 Code of Federal Regulations Part 46 [20].

Participants

Study participants had access to Ginger services as part of their employment or health plan benefits. Internal clinical protocols include exclusionary criteria where self-directed telehealth is likely not appropriate and where more specialized and urgent psychiatric services are required (eg, active suicide ideation and active high-risk self-harm behavior) [21]. This study included Ginger members aged ≥ 18 years who screened positive on either the Patient Health Questionnaire-9 (PHQ-9) or Generalized Anxiety Disorder-7 (GAD-7) at baseline (ie, score ≥ 10).

Procedures

The Ginger platform provides members with access to text-based behavioral health coaching, virtual clinical services, and self-guided content and assessments primarily via a mobile app platform. Examples of self-guided content include mindfulness meditation activity cards and stress-management exercises. After downloading the mobile app, members can start texting

with a behavioral health coach within minutes of requesting connection. During the coaching sessions, members and coaches work together to set goals and work plans to achieve those goals. Goals can range anywhere, from career goals and relationship goals to other personal goals that the member or coach identifies as a source of anxiety or depression. Members typically begin with text-based coaching sessions and many members remain solely at this level of care. Some members will request clinical care (teletherapy or telepsychiatry), and some will require treatment escalation if the coaches identify a clinical need. Clinical severity was ultimately determined by clinicians using the PHQ-9 and GAD-7, in addition to other assessments that gauge the risk and urgency for clinical care. Examples of situations that require escalation include individuals with chronic mental illness and severe trauma, the potential to harm oneself or others, and significant mental instability (eg, hallucinations, delusions, and extreme mood swings). Members who met certain risk thresholds were advised to escalate to therapy or psychiatry. When members are escalated to therapy or psychiatry, they may continue working with a coach, provided they seek additional specialized care concurrently. Members who did not meet these thresholds were recommended to continue coaching unless they had a specific preference for clinical care.

Ginger coaches are full-time employees who have an advanced degree in a field related to mental health or have accredited coach certification (as approved by the National Board for Health and Wellness Coaching). Coaches are also required to have at least 2 years of relevant experience, of which 6 months must have occurred with direct supervision under a qualified, credentialed, or licensed supervisor. To ensure ongoing quality in the delivery of care, Ginger coaches are trained for at least 200 hours each year on up-to-date effective methodologies (eg, motivational interviewing and goal setting). Ginger clinicians are full-time employees who have completed a minimum master's degree in psychology, social work, counseling, marriage and family therapy, or a related field. They are licensed to practice (eg, licensed clinical social worker, licensed marriage and family therapist, or licensed psychologist) and undergo quarterly training on protocols, evidence-based care, and best practices in telehealth. Additional details regarding the Ginger care model and providers can be found in previous publications [3,21].

To help providers assist with personalized care, members can track changes in depression and anxiety symptoms during their care journey. Members were prompted to complete the PHQ-9 and GAD-7 through the platform when they began using Ginger services to measure their baseline symptom scores. Symptom surveys were administered every 2 weeks to members who scored above the clinical threshold (≥ 10) at baseline. The most recent survey response that fell within a 6- to 16-week window following a member's baseline was considered their follow-up and used for analyses in this study.

Measures

The PHQ-9 is a 9-item self-report questionnaire based on the Diagnostic and Statistical Manual of Mental Disorders, 4th edition, that assesses the frequency and severity of depression symptoms over the previous 2 weeks [22]. Each of the 9 items

is scored on a scale from 0 (not at all) to 3 (nearly every day). Total scores range from 0 to 27, with higher scores indicating more depressive symptoms. A score of 10 is often used as the clinical threshold [22]. Scores of 10 to 14, 15 to 19, and >20 represent moderate, moderately severe, and severe depression, respectively [22]. On the basis of the literature, a reduction in PHQ-9 score of $>50\%$ is considered a *full response* [23]. This approach to calculate treatment response better accounts for the variation in baseline severity and, as such, enables a more unbiased measure of symptom improvement.

The GAD-7 is a self-report questionnaire based on the Diagnostic and Statistical Manual of Mental Disorders, 4th edition, diagnostic criteria to assess the frequency and severity of anxious thoughts and behaviors over the past 2 weeks [24]. Each of the 7 items is scored on a scale from 0 (not at all) to 3 (nearly every day), with total scores ranging from 0 to 21. Consistent with the existing literature, a score of 10 was used as the clinical threshold for this study [25]. Scores of 10 to 14 and >15 represent moderate and severe anxiety, respectively [24]. Similar to the threshold used for the PHQ-9, a reduction in the GAD-7 score of $>50\%$ was considered a *full response* to treatment.

Care Modality and Levels of Use

We calculated the use based on product user behavior data. Coaching sessions were operationalized as the number of unique days on which members and coaches exchanged at least five text messages. We decided on this threshold because we learned from the internal provider feedback that the first few messages are generally characterized as introductory and administrative-related messages with minimal therapeutic intervention. By definition, it is not possible to have more than one coach session per day. Clinical sessions were operationalized as the number of completed video sessions with a clinician and scheduled on a need basis. Each video session was typically an hour long. We further categorized use based on member use of different platform care modalities (ie, text-based coaching and clinical sessions) and the number of times they used these modalities (ie, minimum, low, moderate, and high). This study considered 4 different care modalities. Members who did not complete any coaching or clinical sessions and members who only completed one coaching or one clinical session or one of both were categorized in the *Limited Care* cohort. We included members who completed one coaching or one clinical session or one of both in the *Limited Care* cohort, because, generally, these first sessions are considered introductory, where providers introduce themselves and delineate the structure and plan for the member's care journey. Members who completed more than one text-based coaching session and either none or one clinical session were categorized as the *Coaching Only* cohort. Members who completed more than one clinical teletherapy session and either none or one coaching session were categorized as the *Clinical Only* cohort. Finally, members who completed more than one coaching and more than one clinical session were categorized as the *Hybrid Care* cohort.

Previous literature has not yet established an optimal threshold for on-demand text-based care. As such, we adopted a

data-driven approach to operationalize the levels of use. Different levels of use were determined for the care modalities, Coaching Only, Clinical Only, and Hybrid Care, based on quartiles of completed sessions within each care modality cohort (25th, 50th, and 75th percentiles). Members who fell below the 25th percentile for their respective cohort were categorized as

Minimal Use. Members who fell between the 25th percentile and the 50th percentile median were categorized as *Low Use*. Members who fell between the 50th and 75th percentiles were categorized as *Moderate Use* and members who scored above the 75th percentile were categorized as *High Use*. The exact number of sessions for each group is shown in [Table 1](#).

Table 1. Description of levels of use by care modality cohort (N=4219; Limited Care n=1072).

Level of use	Definition by quarter percentiles, sessions	Participants, n (%)
Coaching Only (n=1354)		
Minimal	≤2	329 (7.79)
Low	3 to 4	345 (8.18)
Moderate	5 to 7	332 (7.86)
High	≥8	348 (8.25)
Clinical Only (n=941)		
Minimal	≤3	363 (8.6)
Low	4	169 (4.01)
Moderate	5 to 6	212 (5.03)
High	≥7	197 (4.67)
Hybrid Care (n=852)		
Minimal	≤7	260 (6.16)
Low	8 to 9	173 (4.1)
Moderate	10 to 13	231 (5.48)
High	≥14	188 (4.46)

Data Management and Analysis

Analyses were conducted using R Studio (version 1.4.1717; RStudio). Data were first screened for outliers and normality. Separate ANOVA models were used to evaluate whether members varied in their baseline depression and anxiety scores. Given the binary nature of our dependent outcome variable (*full response vs no full response*), we used logistic regression modeling, a common statistical method for quantifying the relationship between various factors and a binary clinical outcome. In our first set of analyses, 2 binary logistic regression models were used to explore the association between care modality and the likelihood of demonstrating a full response in depressive and anxiety symptoms. These logistic regression models produce estimates of the probability of demonstrating reductions in depressive and anxiety symptoms when a member is in a particular group that represents a modality of care. The likelihood of each modality group demonstrating a full response relative to the reference group is shown by odds ratios. In addition, 6 logistic regression models were used to explore the association between levels of use within each care modality and treatment response for depression and anxiety symptoms. Members' depression and anxiety symptom scores at baseline were included as covariates in all models to account for

variations in the baseline symptom scores. The performance of the logistic regression models was evaluated using the Hosmer-Lemeshow test to measure model fit, and odds ratios and 95% CIs were calculated to show associations with improvements in depression and anxiety. The models were constructed using complete case analyses.

Results

Participant Demographics and Characteristics

A total of 6466 members participated in this study. Of those 6466 members, 4219 (65.25%) screened positive for depression or anxiety (ie, PHQ-9 or GAD-7 symptom scores ≥10). This study focused only on members who screened positive at baseline (N=4219), which will be subsequently referred to as the analytical sample. The complete descriptive statistics are reported in [Table 2](#). Of the 4219 members in the analytical sample, 1645 (38.99%) members were identified as female, 689 (16.33%) as male, 142 (3.37%) as other, and 1743 (41.31%) did not have gender identity information available. Of the 4219 members, a total of 1613 (38.23%) members were aged <35 years, 1264 (29.96%) members were ≥35 years, and 1342 (31.81%) members did not have their age reported.

Table 2. Characteristics of the analytical sample (N=4219)^{a,b}.

Characteristics	Analytical sample
Age (years), n (%)	
18 to 34	1613 (38.23)
>35	1264 (29.96)
No response	1342 (31.81)
Gender, n (%)	
Female	1645 (38.99)
Male	689 (16.33)
Other	142 (3.37)
No response	1743 (41.31)
Care modality, n (%)	
Limited Care	1072 (25.41)
Coaching Only	1354 (32.09)
Clinical Only	941 (22.3)
Hybrid Care	852 (20.19)
GAD-7 ^c baseline score, mean (SD)	12.7 (4.54)
PHQ-9 ^d baseline score, mean (SD)	13.7 (5.04)

^aCounts and percentages were reported for categorical variables.

^bMean and SDs were reported for continuous variables.

^cGAD-7: Generalized Anxiety Disorder-7.

^dPHQ-9: Patient Health Questionnaire-9.

On average, members completed 3.53 (SD 3.81) text-based coaching sessions and 2.32 (SD 2.85) clinical sessions. Of the total number of members in the analytical sample, 25.41% (1072/4219) received limited care, 32.09% (1354/4219) completed only text-based coaching, 22.3% (941/4219) completed only clinical care, and 20.19% (852/4219) completed a hybrid of coaching and clinical care.

The average baseline scores on the PHQ-9 and GAD-7 were 13.7 (SD 5.04) and 12.7 (SD 4.54), respectively. A total of 75.07% (3167/4219) of the participants demonstrated at least one unit of improvement in their PHQ-9 score from baseline to follow-up, with an average unit decrease in symptom scores of 4.43 units (SD 6.27). On the GAD-7, 72.05% (3040/4219) of members demonstrated at least one unit of improvement in anxiety scores from baseline to follow-up and the average unit decrease in scores was 4.08 (SD 5.82). With regard to treatment response, 38.47% (1623/4219) demonstrated a full response on the PHQ-9 and 39.91% (1684/4219) demonstrated a full response on the GAD-7.

Separate ANOVA models were used to evaluate the differences in PHQ-9 and GAD-7 baseline scores between the care modality

cohorts. The results revealed a significant difference between cohorts for both baseline PHQ-9 scores ($F_{3,4215}=12.5$; $P<.001$) and baseline GAD-7 scores ($F_{3,4215}=2.99$; $P=.03$). Tukey post hoc tests revealed that members who completed a hybrid of care had significantly higher baseline PHQ-9 scores than those who completed limited care ($Mean_{Hybrid}=14.5$, $Mean_{Limited}=13.5$; $P<.001$). Members who completed only text-based coaching sessions had significantly lower baseline PHQ-9 scores than those who completed only clinical sessions ($Mean_{Coaching}=13.2$, $Mean_{Clinical}=14.0$; $P<.001$) or members who completed a hybrid of care ($Mean_{Hybrid}=14.5$; $P<.001$). In addition, members who completed only coaching sessions had significantly lower baseline GAD-7 scores than those who completed only clinical sessions ($Mean_{Coaching}=12.5$, $Mean_{Clinical}=12.8$; $P=.02$). These differences were expected because of the nature of our triaging system used to direct members to the correct level of care. It is also important to point out that the magnitude of these mean differences is small (≤ 1 point; Table 3). However, owing to significant differences in baseline scores, as indicated by F tests, we included both PHQ-9 and GAD-7 baseline scores as covariates in all regression models.

Table 3. Descriptive statistics for the Patient Health Questionnaire-9 (PHQ-9) and Generalized Anxiety Disorder-9 (GAD-7) scores at baseline and follow-up, by care modality (N=4219).

	<i>F</i> statistic (<i>df</i>)	<i>P</i> value	Limited care (n=1072), mean (SD)	Coaching Only (n=1354), mean (SD)	Clinical Only (n=941), mean (SD)	Hybrid Care (n=852), mean (SD)
Baseline PHQ-9	12.51 (3,4215)	<.001	13.5 (4.89)	13.2 (4.97)	14.0 (5.14)	14.5 (5.14)
Follow-up PHQ-9	33.5 (3,4215)	<.001	10.8 (6.26)	9.25 (6.28)	8.54 (5.31)	8.39 (5.52)
Baseline GAD-7	2.99 (3,4215)	.03	12.7 (4.61)	12.5 (4.43)	13.0 (4.48)	12.8 (4.65)
Follow-up GAD-7	39.2 (3,4215)	<.001	10.1 (5.84)	8.56 (5.71)	7.97 (5.10)	7.67 (5.37)

Depression: Full Response by Care Modality

We used a logistic regression model to investigate the association between care modality and full response in depression symptom scores. A Hosmer-Lemeshow test failed to reject the null hypothesis, indicating goodness of fit ($\chi^2_8=6.8$; $P=.56$). All modalities showed increased odds of symptom improvement compared with members who completed limited care, but the strongest odds were observed for members who engaged with a hybrid of coaching and clinical care; the odds of showing a full response were 2.31 times higher (95% CI

1.91-2.80; $P<.001$) for those who engaged with hybrid care compared with members who completed limited care. Of note, overlapping CIs among Coaching Only (95% CI 1.41-1.99), Clinical Only (95% CI 1.64-2.38), and Hybrid Care (95% CI 1.91-2.79) cohorts suggest that members in these groups did not differ significantly from one another when predicting depression symptom improvement. Full model coefficients are presented in Table 4. These results are further shown graphically as the predicted probability of a full response in depression scores by care modality and levels of baseline severity (Figure 1).

Table 4. Coefficients from the logistic regression model predicting a full response in depression (Patient Health Questionnaire-9 [PHQ-9]) and a full response in anxiety (Generalized Anxiety Disorder-7 [GAD-7]) across care modalities^a, while controlling for scores at baseline (N=4219).

	Odds ratio (95% CI)	Percentage change (%)	<i>P</i> value
Dependent variable:^b full response in PHQ-9			
Intercept	0.29 (0.23-0.37)	-243	<.001
Coaching Only	1.67 (1.41-1.99)	67	<.001
Clinical Only	1.98 (1.64-2.38)	97	<.001
Hybrid Care	2.31 (1.91-2.80)	131	<.001

GAD-7 score at baseline	1.06 (1.05-1.08)	6	<.001

^aReference group for care modality: limited care.

^bDependent variable: coded full response=1; no full response=0.

Figure 1. Probability of a full treatment response for depression by care modality and level of baseline severity. PHQ-9: Patient Health Questionnaire-9.

Anxiety: Full Response by Care Modality

We used another logistic regression model to investigate the association between care modality and full response in anxiety symptom scores. A Hosmer-Lemeshow test failed to reject the null hypothesis, indicating goodness of fit ($\chi^2_8=4.4$; $P=.82$). All care modalities showed increased odds of symptom improvement compared with limited care, but the strongest odds were observed for members who completed a hybrid of coaching and clinical care; the odds of showing a full response in anxiety symptom scores were 2.23 times higher (95% CI 1.84-2.70;

$P<.001$) for members who completed a hybrid of both clinical and coaching care compared with members who completed limited care. Of note, overlapping CIs among Coaching Only (95% CI 1.42-2.01), Clinical Only (95% CI 1.83-2.66), and Hybrid Care (95% CI 1.84-2.70) cohorts suggest that members in these groups did not differ significantly from one another when predicting full treatment response in anxiety symptoms. Full model coefficients are presented in Table 4. These results are shown graphically as the predicted probability of a full response in anxiety by care modality and levels of baseline severity (Figure 2).

Figure 2. Probability of a full treatment response for anxiety by care modality and level of baseline severity. GAD-7: Generalized Anxiety Disorder-7.

Coaching Only Cohort: Full Response by Levels of Use

Members in the Coaching Only cohort completed, on average, 5.53 (SD 3.65) coaching sessions. Within this modality, we estimated two logistic regression models examining (1) the association between levels of use of text-based coaching and a full response on the PHQ-9 and (2) the association between levels of use of text-based coaching and a full response on the GAD-7. Hosmer-Lemeshow tests failed to reject the null hypothesis, indicating goodness of fit (PHQ-9: $\chi^2_8=9.7$; $P=.29$ and GAD-7: $\chi^2_8=5.9$; $P=.66$). Full coefficients for both models are presented in Table 5. Compared with members with minimal use, members with moderate and high levels of use had

significantly increased odds of treatment response in depression. Specifically, the odds of showing a full response in depression were 2.44 times higher (95% CI 1.77-3.37; $P<.001$) for members with high use compared with members with minimal use. Similar patterns were observed for the model predicting a full response in anxiety. Compared with members with minimal use, all other levels of use had significantly increased odds of treatment response for anxiety. The odds of showing a full response in anxiety were 1.99 times higher (95% CI 1.44-2.74; $P<.001$) for members with high use compared with members with minimal use. The association remained after adjusting for baseline anxiety and depression symptom scores. These results are shown graphically as the predicted probability of a full response by coaching use and baseline severity in Figure 3 and Figure 4 for depression and anxiety, respectively.

Table 5. Coefficients from the logistic regression model with the Coaching Only cohort predicting a full response in depression (Patient Health Questionnaire-9 [PHQ-9]) and a full response in anxiety (Generalized Anxiety Disorder-7 [GAD-7]) across levels of use^a, while controlling for scores at baseline (N=1354).

	Odds ratio (95% CI)	Percentage change (%)	P value
Dependent variable:^b full response in PHQ-9

Clinical Only Cohort: Full Response by Levels of Use

The Clinical Only cohort of members completed, on average, 4.69 (SD 2.43) clinical sessions. We estimated two logistic regression models examining (1) the association between levels of use in clinical care and full response on the PHQ-9 and (2) the association between levels of use in clinical care and full response on the GAD-7. Hosmer-Lemeshow tests failed to reject the null hypothesis, indicating goodness of fit (PHQ-9: $\chi^2_8=4.4$; $P=.82$ and GAD-7: $\chi^2_8=6.3$; $P=.62$). Full coefficients for both models are presented in Table 6. Compared with members with minimal use, all other levels of use had significantly increased odds of treatment response for depression. The odds of showing

a full response in depression were 2.06 times higher (95% CI 1.44-2.95; $P<.001$) for members with high use compared with members with minimal use. Different patterns were observed for the model predicting a full response in anxiety. Compared with members with minimal use, only members who had high levels of use had significantly increased odds of treatment response for anxiety. The odds of showing a full response in anxiety were 1.43 times higher (95% CI 1.00-2.04; $P<.001$) for members with high use compared with members with minimal use. The association remained after adjusting for baseline depression and anxiety scores. These results are shown graphically as the probability of a full response by clinical use and baseline severity in Figure 5 and Figure 6 for depression and anxiety, respectively.

Hybrid Care (Coaching+Clinical) Cohort: Full Response by Levels of Use

The Hybrid Care cohort of members completed, on average, 10.5 sessions (5.70 coaching sessions; 4.79 clinical sessions). We estimated two logistic regression models examining (1) the association between levels of use and full response on the PHQ-9 and (2) the association between levels of use and full response on the GAD-7 for members who completed a hybrid of coaching and clinical care. Hosmer-Lemeshow tests failed

to reject the null hypothesis, indicating goodness of fit (PHQ-9: $\chi^2_8=5.6$; $P=.70$ and GAD-7: $\chi^2_8=6.1$; $P=.64$). Full coefficients for the models are presented in Table 7. Members with minimal use had similar odds of improvement compared with all other levels of use for both depression and anxiety. The association remained after adjusting for depression and anxiety baseline scores. These results are shown graphically as the probability of a full response by Hybrid Care use and baseline severity in Figure 7 and Figure 8 for depression and anxiety, respectively.

Table 7. Discussion

Principal Findings

This study examined differences in depression and anxiety treatment response by care modality (ie, limited care, text-based Coaching Only, Clinical Only, and Hybrid Care), as well as by levels of use within each care modality (ie, minimal, low, moderate, and high) in members with moderate to severe baseline anxiety or depression. Overall, nearly 2 out of 5 members demonstrated a full response on the PHQ-9 (1623/4219, 38.47%) and GAD-7 (1684/4219, 39.91%). Our logistic regression models examining the association between care modalities and treatment response found significantly greater odds of full-treatment response in depression and anxiety for members who completed text-based coaching, clinical care, and hybrid care compared with members who completed limited care. The probability of treatment response did not differ significantly between text-based coaching, clinical care, and hybrid care, as indexed by the overlapping 95% CIs, with all 3 modalities estimating a probability of response >35%. In addition to differences by care modality, we also examined treatment responses by levels of use within each care modality cohort. Our data suggest that although all care modalities (ie, Coaching Only, Clinical Only, and Hybrid Care) appeared to offer comparable benefits in managing depression and anxiety above limited care, the treatment responses within each care modality cohort differed among levels of use. The possible explanations for these findings are discussed further.

Members who completed limited care had significantly lower odds of demonstrating a full response on both the PHQ-9 and GAD-7. Given that our analytical sample included only members with a baseline score on the GAD-7 or PHQ-9 ≥ 10 , the

established threshold for clinical severity, members likely needed more than limited care (0-1 coaching, 0-1 clinical sessions) to reduce their symptomatology. Members in the Limited Care cohort did not sufficiently interact with a provider, but some could have used self-guided content, although the latter was not explicitly investigated in this study. Our results suggest that interaction with a provider, above and beyond the initial introduction session, offers added benefits in addressing depression and anxiety symptoms. A systematic review of internet interventions for depression found a linear effect on the role of clinician contact, such that between-group Cohen d effect size was 0.21, if there was no contact with a clinician either before or during treatment, an effect size of Cohen $d=0.58$ if there was contact with a clinician during treatment, and an effect size of Cohen $d=0.76$ if there was therapist contact before and during treatment [26]. Trends from this study further highlight the importance of offering convenient and accessible telehealth care. In addition, the Ginger model is based on a continuum of care that provides seamless integration and escalation across different levels of care. As such, our findings offer early evidence that members are being properly directed to the correct type of care based on their mental health needs and goals. However, this is speculative and outside the scope of this study; therefore, additional research is required.

We observed similar outcomes in those who completed text-based coaching sessions and clinical care. This result supports prior work suggesting that coaching can be a suitable option for addressing anxiety and depression [12-15], which supplements the literature by investigating text messaging as a viable delivery medium for coaching. The principles of text-based coaching are consistent with how individuals engage with text messaging in their daily routines, and on-demand text-based coaching offers added convenience in terms of not

requiring scheduled appointments [16]. Given the scalability of text-based coaching, in which coaches can have simultaneous conversations, this type of care may be a more cost-effective alternative to traditional psychotherapy.

When focusing on the levels of use within care modality cohorts, our results revealed nuanced patterns. For members who completed only coaching or clinical care, the largest effects were observed among those with high use (above the 75th percentile), estimating a probability of response of >45% for both depression and anxiety. Interestingly, for members who completed a hybrid of coaching and clinical care, we saw similar treatment responses across all levels of use (ie, minimal, low, moderate, and high use), with all levels estimating a probability of response similar to the probability of response for members with high use in the Coaching Only and Clinical Only cohorts (approximately 45% for depression and anxiety). Taken together, our results suggest that typically higher use with care would yield better outcomes; however, this was not true for the members in our Hybrid Care cohort, where all levels of use had similar odds of a full treatment response for both depression and anxiety. This is likely owing to the members of the Hybrid Care cohort that used more sessions. On average, members in the Hybrid Care cohort (mean 10.5) completed approximately twice the number of sessions than members in either the Clinical Only cohort (mean 4.69 sessions) or in the Coaching Only cohort (mean 5.53 sessions) within the study period. In addition, members with minimal use in the Hybrid Care cohort completed a similar number of sessions compared with members with high use in the Coaching Only and Clinical Only cohorts. However, the use of more sessions within the Hybrid Care cohort did not demonstrate increased odds of a full treatment response. These findings suggest that more sessions do not always yield better treatment responses, and future research evaluating care should consider nonlinear patterns.

In addition, across all care modality cohorts, the odds of demonstrating a full response were higher for depression than for anxiety. We have considered a couple of reasons to explain these patterns: (1) the Ginger care model demonstrates more support for treating depression within the study time frame than for treating anxiety and (2) the study time frame we assessed (6-16 weeks following baseline) might be a sufficient amount of time to address depressive symptoms, but more time is needed to address anxiety symptoms. These explanations are speculative, and additional research is needed to specifically test these hypotheses.

Limitations and Future Studies

This study has several limitations. The data set used for this study was limited to people who had access to Ginger services, who had completed the PHQ-9 and GAD-7 survey measures, and whose baseline scores were ≥ 10 . As such, the results are

not generalizable to those who do not have access to the system or to those who may have discontinued treatment. A large percentage of members did not have age (1342/4219, 31.81%) or gender (1743/4219, 41.31%) reported, and we also had limited access to other demographic information due to lack of reporting by employers (eg, race and ethnicity, socioeconomic status, and previous mental health treatment). Thus, we were not able to examine the association between these factors and treatment response or stratify the analyses by age or gender. These additional analyses can provide valuable insights into those who may best benefit from virtual care. However, because the Ginger platform is offered through employers, we know that the survey respondents are working-age adults, suggesting that these findings may be generalized to the professional workforce and those enrolled in health benefits through their employer. In addition, we acknowledge that some members could be taking medication, which might affect their responses to care. We do not currently have medication use reported by our members. Thus, our results cannot conclude that the responses to care were not driven by the medication used in combination with therapy. Finally, because this was a retrospective observational study, we lacked a control group to infer the causality of the levels of engagement in treatment response.

The findings of this study generate additional research topics for future studies. Given that the aim of this study was to examine the impact of provider care, we did not specifically evaluate how different levels of use of our self-guided content would impact outcomes. Future research should focus on the impact of self-guided content independent of provider care. In addition, text-based coaching protocols can vary significantly, and some use highly templated messages that facilitate a more efficient coach workflow [16]. A content analysis of coaching messages could provide additional insights into the underlying mechanisms driving symptom improvement in on-demand care.

Conclusions

Our real-world observational study found that members who completed text-based coaching achieved full treatment responses at similar rates compared with members who completed clinical care and members who completed a hybrid of coaching and clinical care. There were no significant differences in the predicted probabilities of a full treatment response for both anxiety and depression between text-based coaching and clinical care. The highest level of use within each care modality cohort generally had increased odds of treatment response compared with minimal use, with the exception of the Hybrid Care cohort. The results support the utility of digital behavioral health interventions and further highlight text-based coaching protocols as an accessible and suitable option when considering virtual care for treating anxiety and depressive symptoms. Future studies should investigate optimal levels of use.

Acknowledgments

The authors are grateful for the participation of the members who completed the surveys, as well as the hard work and dedication of Ginger coaches and clinicians.

Conflicts of Interest

ES, SK, and GG were paid employees of Ginger/Headspace Health.

Abstract

Background: Children with asthma can decrease the impact of their disease by improving their physical activity (PA). However, health care providers lack interventions for children with asthma that effectively increase their PA levels and achieve behavior change. A technology-supported approach can positively influence PA and physical functioning in children.

Objective: The aims of this study were to develop a technology-supported intervention that facilitates health care providers in promoting PA for children (aged 8 to 12 years) with asthma and to systematically describe this developmental process.

Methods: Intervention mapping (IM) was applied to develop a blended and technology-supported intervention in cocreation with children with asthma, their parents, and health care providers. In accordance with the IM framework, the following steps were performed: conduct a needs assessment; define the intervention outcome, performance objectives, and change objectives; select theory-based intervention methods and strategies; create components of the intervention and conduct pilot tests; create an implementation plan; and create an evaluation plan.

Results: We developed the blended intervention *Foxfit* that consists of an app with a PA monitor for children (aged 8 to 12 years) with asthma and a web-based dashboard for their health care provider. The intervention focuses on PA in everyday life to improve social participation. *Foxfit* contains components based on behavior change principles and gamification, including goal setting, rewards, action planning, monitoring, shaping knowledge, a gamified story, personal coaching and feedback, and a tailored approach. An evaluation plan was created to assess the intervention's usability and feasibility for both children and health care providers.

Conclusions: The IM framework was very useful for systematically developing a technology-supported intervention and for describing the translational process from scientific evidence, the needs and wishes of future users, and behavior change principles into this intervention. This has led to the technology-supported intervention *Foxfit* that facilitates health care providers in promoting PA in children with asthma. The structured description of the development process and functional components shows the way behavior change techniques are incorporated in the intervention.

Introduction

Background

Physical activity (PA) is important for children with a chronic disease [1,2]. Asthma is the most frequently diagnosed medical condition in children [3]. For children with asthma, PA can positively affect their asthma control by improving their physical fitness. This can reduce the threshold of triggers causing asthma symptoms, which in turn may lead to decreased use of medication and increased quality of life [1,4-6]. Besides the positive effects of PA regarding physical fitness, stimulation of PA in children with asthma is also important for their psychosocial functioning, because PA is often intertwined with social life. Children with physical disabilities are less involved in social activities compared to their healthy peers, and children with asthma often feel left out of the group [7-9]. Despite all benefits of PA, children with asthma—especially girls—seem to be less physically active than their healthy peers [10-13].

In the Netherlands, children are treated for asthma according to the *Dutch Pediatric Society* guidelines for asthma in children [14]. This treatment includes taking medication, receiving information, and having regular check-ups. Children with asthma who are inactive are referred to health care providers, such as pulmonary nurse practitioners and pediatric physical therapists. They provide health education, encourage children to increase their PA levels, and pay attention to social participation and children's self-confidence regarding PA. Moreover, they educate them on how to cope with exercise barriers and provide exercise training. Such training interventions, which include, for instance, swimming and aerobic exercises, are shown to be effective in increasing cardiovascular fitness and in improving pulmonary function of children with asthma [6,15-19]. However, health care providers indicate that they lack interventions that result in maintenance of improved PA levels. This is because existing training programs do not aim to achieve behavior change in children with asthma [15,17,20].

This raises the question as to how PA levels can be both increased and maintained in children with asthma who are inactive. Various studies and reviews show that effectiveness of PA stimulating programs can be increased by technology-supported interventions [21-29]. Although most studies focus on adults, several studies show that a technology-supported approach can have positive effects on PA and physical functioning in children and adolescents as well [30,31].

Features of technology-supported interventions, especially behavior change interventions, are often inadequately described [23,24]. Therefore, it is difficult to compare interventions and their effects. To ease and improve this comparison, it is

important to describe the design process and the developed components of an intervention [32,33]. Several frameworks are already used to describe interventions that stimulate PA, such as the MRC (Medical Research Council) framework to stimulate PA in older adults, the IDEAS (Integrate, Design, Assess, and Share) framework to promote PA in adults, the CeHReS (Centre for eHealth Research) framework to promote PA in people with depression, and the intervention mapping (IM) model to stimulate PA in patients with heart failure [33-40]. For our intervention, we chose the IM model, because it explicitly differentiates between personal and environmental factors affecting PA, and it takes into account creating an implementation and evaluation plan. Moreover, IM was already successfully applied for developing health interventions for children [41-43]. The framework enables systematic development of evidence-based interventions and enhances adoption, implementation, and maintenance of the developed intervention [39].

Objectives

As part of a project that aims to promote PA in children (aged 8 to 12 years) with asthma, we attempted to develop an intervention that supports health care providers in stimulating PA in children with asthma using the IM model. In a preliminary study, we explored promoting factors for PA in children with asthma according to children with asthma themselves, their parents, and their health care providers [44]. In this study, we applied the IM model to develop a technology-supported intervention that incorporates both these promoting factors and behavior change principles that were discovered. We aimed to transparently report the development process and the final components of the intervention using IM to meet the demand of sufficiently describing technology-supported interventions [32,33]. We answered the following research question: "How can scientific evidence on stimulation of PA, the needs and wishes of future users, and behavior change principles be translated into features of an intervention that facilitates health care providers in promoting PA in children with asthma?"

By systematically describing the translation from requirements to functional components and our specific design and implementation choices, we give insight into the background of our intervention and ease comparisons with other interventions. In addition, we report the contribution of future users, because the intervention was developed in cocreation with children with asthma, their parents, and health care providers.

Methods

IM Model

The IM protocol includes six steps: (1) conduct a needs assessment in which a distinction is made between personal and environmental determinants; (2) define the intervention outcome, performance objectives, and change objectives; (3) select theory-based intervention methods and strategies; (4) create components of the intervention and conduct pilot tests; (5) create an implementation plan; and (6) create an evaluation plan.

Step 1: Needs Assessment

To assess the health problem, background information and scientific evidence regarding children with asthma, the impact of low levels of PA, and available interventions had to be gathered according to the IM model. In our preliminary study, 3 stakeholder groups were questioned to explore promoting factors of PA in children with asthma. To do so, concept-mapping sessions were held with 25 children with asthma (aged 8 to 12 years), 17 parents of children with asthma, and 21 health care providers of children with asthma. The health care providers were lung nurse practitioners and pediatric physiotherapists, experienced in behavior change and supporting PA in children with asthma. The resulting factors were labeled as either personal or environmental factors according to the Physical Activity for People with a Disability model [45]. More details regarding the needs assessment can be found in our preliminary study [44]. On the basis of this needs assessment, we defined the aim of the intervention. The reported factors will be used in subsequent steps of the IM framework, such as designing the program's requirements and functional components.

Step 2: Intervention Outcome, Performance Objectives, and Change Objectives

To examine the target behavior, we created a logic model of change according to the IM framework. First, we defined the program outcomes based on the stakeholders' reported clusters in the needs assessment. They describe the desired changes in the behavior and the environmental conditions that are required to reach the goal of the intervention [39]. Second, we translated the program outcomes in performance objects based on the stakeholders' reported supporting ideas in the needs assessment. Those indicate the required behavior to reach the goal of the intervention. On the basis of these performance objectives, change objectives were defined which indicate the necessary behavior to accomplish the required behavior change and environmental conditions.

Step 3: Selecting Theory-Based Intervention Methods and Strategies

On the basis of the needs assessment and the logic model of change thus created, we selected several methods and strategies that were translated into design considerations for the intervention. This was performed in a stakeholder session with a pediatric pulmonologist, a pediatric physiotherapist, and researchers specialized in exercise behavior in children, behavioral change, health technology, and game development. The final selection was a product of mutual agreement.

Step 4: Creating and Pilot-testing the Intervention's Components

On the basis of the needs assessment, logic model of change, and the design considerations, we formulated several requirements for the intervention to be developed. With a multidisciplinary team involving health care providers, data scientists, game designers, and software developers, we translated the requirements into functional components. This translation was performed in 2 sessions and the final list of requirements was a product of mutual agreement. To develop those components, we performed an agile method consisting of several design and develop iterations. Each iteration lasted for 2 weeks, and there were 10 iterations in total.

In the first 3 iterations, we created story lines, mock-ups, and user journeys resulting in a prototype. In a stakeholder session, this product was tested by children with asthma and their health care providers. Children who participated in the needs assessment were asked whether they wanted to participate in this stakeholder session as well. Children who were diagnosed with asthma and aged between 8 and 12 years could be included. The 3 participating children were aged, on average, 9.3 (SD 1.5) years, and 2 of them were female. One of the children was diagnosed with severe asthma, one of them had mild asthma symptoms, and one of them had moderate asthma symptoms. The 4 participating health care providers were all pediatric physiotherapists with >5 years of work experience with children with asthma. In the stakeholder session, the participants individually tested the prototype and shared their experiences with the researchers. The children were asked to focus on the app's functionalities, the story line, and the usability of the PA monitor, whereas the health care providers were asked to focus on the dashboard's functionalities and the clarity of the graphs showing the children's PA. Afterward, the researchers compared the experiences of the participants and translated them into requirements for improvement of the prototype. In the remaining 7 iterations, these improvements were made, and the prototype was further developed into a usable product.

Step 5: Creating an Implementation Plan

In a stakeholder session with a pediatric physiotherapist, a pediatric pulmonologist, and a lung nurse practitioner, we examined the health care provider's daily practice and the current health care situation for children with asthma who are inactive receiving care regarding PA. We explored the available time and skills of the health care providers, to support children with asthma who might benefit from PA with an intervention.

Step 6: Creating an Evaluation Plan

For a blended intervention, it is important to evaluate the usability and feasibility in children's everyday life and in their health care provider's daily practice. Therefore, we selected methods to evaluate user experiences, adherence, and usability of both children and health care providers. In addition, to evaluate the possible impact of the intervention on children, we selected methods to look into the self-perception of PA among children, their social participation, and their enjoyment of PA.

Ethics Approval

The Amsterdam University Medical Center Medical Ethical Committee approved the research protocol with trial number METC 2017 191. The study was registered in the International Clinical Trial Registry Platform with trial number NTR6658 on August 21, 2017.

Results

Step 1: Needs Assessment

Several studies show that children with asthma benefit from PA. Increased levels of PA are related to both improved cardiovascular fitness and quality of life [4-6,16,19]. However, children with asthma experience limitations in PA and social activities because of their disease [7-10,46]. Reported explanations for these experienced limitations are, for instance, inaccurate symptom perception of airflow limitation, misinterpreting healthy exercise-induced shortness of breath as an asthma attack, and low self-efficacy in relation to PA [47,48].

Parents endorse the limitations that children experience and report parental fear for exercise-induced asthma, challenges with asthma management, and lack of trust in teachers or sport coaches as parental barriers [49,50]. Increasing self-esteem and improving knowledge about PA in relation to asthma and medication are reported as strategies to reduce children's perceived limitations in PA [51,52].

Figure 1 shows differences and similarities among all reported factors of the 3 stakeholder groups. Factors that were rated as very important were getting positive feelings of PA, playing together, being stimulated and motivated by relatives, good asthma control, making PA enjoyable, rewarding PA, tailored PA, playing outside more often, setting realistic goals, relatives of child have sufficient knowledge about asthma in relation to PA, child itself has sufficient knowledge about asthma in relation to PA, digital interventions for PA, increasing extrinsic motivation, positive attitude of child, scheduling PA together with child, and variation in PA.

Figure 1. Venn diagram in which the reported factors of all stakeholders are combined. The circles indicate the stakeholder groups. The factors are listed in random order (reprinted from Brons et al [44] with permission from the author). PA: physical activity.

The aim of the intervention was defined as follows: the intervention needs to support health care providers in improving PA levels in children with asthma who might benefit from increased levels of PA. The intervention will be developed for children who are inactive, with mild to moderate asthma symptoms, who are referred to a health care provider, either a

lung nurse practitioner or a pediatric physiotherapist, to improve their PA levels.

Step 2: Intervention Outcome, Performance Objectives, and Change Objectives

All program outcomes, along with their corresponding performance and change objectives, are shown in Table 1.

Table 1. Logic model of change: program outcomes with their corresponding performance objectives and change objectives^a.

Program outcomes and performance objectives	Change objectives
Increase PA^b participation	
Use active transport instead of motorized transport	<ul style="list-style-type: none"> • Walk or cycle more often
Participate in sports activities at school	<ul style="list-style-type: none"> • Communicate about willing to join sports activities • Inform school about the disease to create a safe environment
Participate in social activities with PA elements	<ul style="list-style-type: none"> • Register for social PAs, even when having some doubts • Find a trusted buddy that can help when needed
Participate in sports activities	<ul style="list-style-type: none"> • Register for sport activity that fits capabilities • Inform the coach about the disease to create a safe environment
Resist sedentary behavior	<ul style="list-style-type: none"> • Search for enjoyable alternatives for sedentary time • Screen time should be reduced (by parents)^c
Improve knowledge about asthma and medication in relation to PA	
Gain knowledge about impact of PA and medication on asthma control	<ul style="list-style-type: none"> • Information about asthma and medication in relation to PA should be provided by health care provider or parents^c
Gain knowledge about PA possibilities despite having asthma	<ul style="list-style-type: none"> • Information about PA possibilities when having asthma should be provided by health care provider^c
Increase asthma control	
Good medication adherence	<ul style="list-style-type: none"> • Take medication as prescribed
Increase self-esteem regarding PA	
Experience positive PA feelings	<ul style="list-style-type: none"> • Learn individual capabilities and limitations
Increase perceived joy during PA	
Play together	<ul style="list-style-type: none"> • Ask friends or family to participate in PA together • Schedule PA in family agenda
Include competition element	<ul style="list-style-type: none"> • Add competitive elements to PA • PAs with competitive elements should be available^c
Introduce variation in PA	<ul style="list-style-type: none"> • A variety of PAs should be accessible^c

Learn to set realistic goals	
Set PA goals	<ul style="list-style-type: none"> • Think about own PA behavior and formulate a goal to improve the current behavior • Obtain insights into one's own PA behavior • Coaching regarding setting realistic goals should be provided by health care provider or parents^c

^aChange objectives regarding personal factors (shown in all cells unless otherwise indicated by footnote c).

^bPA: physical activity.

^cChange objectives regarding environmental conditions.

Step 3: Selecting Theory-Based Intervention Methods and Strategies

The following three design considerations were formulated: (1) support behavior change, (2) blended technology, and (3) integration in everyday life.

To start with, the intervention should support behavior change regarding PA. Gamification is frequently used in the improvement of health and well-being and has shown to be particularly effective in behavior change regarding PA [53]. Gamification is defined as “the use of game design elements in non-game contexts” [54]. Conceptually, gamification combines design elements for behavior change techniques from persuasive technologies, intrinsically motivating qualities from serious games, and methods for tracking individual behavior from personal informatics [53,55-59]. However, in practice, most gamified eHealth applications merely implement short-term engagement through extrinsic rewards [60]. For children with a chronic disease specifically, the nonsignificant results of several serious games aiming to increase PA might be explained by the lack of incorporating behavior change theories in the game [61]. To reach the full potential of gamification, it is necessary to design tools based on theories that support the overall goal, behavior change, and the effects of game mechanics [60].

To maintain improved levels of PA, children must develop new habits. An important factor in habit formation is rewarding the required behavior [62]. Rewarding increases positive feelings in relation to the behavior, in our case performing PA [63]. To develop intrinsic motivation, such positive feelings are important [64]. Increasing self-efficacy is also shown to be effective, for instance, through action planning and shaping knowledge [65-67]. Moreover, goal setting, monitoring and feedback are shown to be effective persuasive methods for improving PA behavior [67-69]. Personal coaching from health care providers, for instance, with the widely used motivational interviewing technique, might enhance the behavior change process [70,71].

Second, the intervention should use blended technology, meaning that individual use of digital technology is combined with face-to-face interaction with a health care provider. Digital technology was shown to be valuable for improving health in children and supporting behavior change [30,72]. However, the results of such digital technologies can be optimized by offering them in combination with personal coaching [30]. Personal coaching is important to provide feedback and support goal setting, which are both identified as success factors when behavior change is aimed [67-69]. Moreover, personal coaching by health care providers reinforces a tailored approach, which was also identified as a success factor of eHealth interventions that induce health behavior change [73-76]. Both a tailored approach and support of a health care provider are important supporting factors of shaping knowledge, which is a frequently used technique in supporting healthy behaviors [67]. Children with asthma specifically need to learn more about the positive

relation between PA and asthma control, how to properly take asthma medication, and the difference between healthy shortness of breath and an asthma attack [47]. Moreover, feedback and knowledge regarding accurate symptom perception is important for perceived exercise limitations. Some children report substantial discomfort when there is limited bronchoconstriction, whereas others report no symptoms even if severe obstruction is present [48].

Finally, it is important that use of the intervention and performing PA could be integrated in everyday life of the users. Although participation in everyday activities is a vital part of children’s development, children with physical disabilities or chronic diseases are less involved in such social activities than their healthy peers [8,58,77,78]. Children with asthma report that they often feel left out of the group [9]. Integration in everyday life is therefore important from 2 perspectives. On the one hand, we have to prevent that using the intervention creates a special situation as this might reinforce children’s feeling of being different and excluded. On the other hand, PA is often intertwined with social life. By focusing on PA in everyday life situations instead of sports specifically, children might experience better social participation.

Step 4: Creating and Pilot-testing the Intervention’s Components

Requirements of the Intervention

The requirements of the intervention are as follows:

1. Facilitate behavior change regarding PA by supporting goal setting, action planning, behavior execution, self-monitoring, and evaluation.
2. Monitor children’s PA so that both children and their parents can obtain insights into their PA behavior.
3. Connect the technology used by the children with the technology used by the health care providers. That way, health care providers can obtain insights into children’s PA behavior and can provide feedback. However, participating children should not see PA behavior of other children to prevent them from comparing themselves with each other. Children’s PA possibilities vary by the severity of their asthma symptoms, and their motivation might be lowered when they see other children achieving PA goals that are not achievable for themselves.
4. Promote PA in everyday life to increase social participation instead of focusing on sports activities.
5. Include learning elements to improve children’s knowledge about asthma in relation to PA. This should be presented in an attractive and stimulating way, because children with asthma themselves did not report improving their knowledge as an important stimulating factor.
6. Reward both exhibited PA and the effort undertaken to extrinsically motivate children. Although intrinsic motivation is preferred over extrinsic motivation to achieve behavior change, extrinsically motivated PA can yield positive feelings such as experiencing fun and feeling

- competent. Those positive experiences are in itself important factors to become intrinsically motivated.
7. Include adaptive components for a tailored approach such as personalized goal setting, planning, and education. Personalized goals are important to adapt to children's specific situation.
 8. Minimize required screen time for the intervention. There should only be functional screen time, because screen time induces sedentary behavior and therefore defeats the purpose of the intervention.

Functional Components of the Intervention

Structure

The final intervention, named *Foxfit*, consists of 3 technical elements that meet all the requirements: (1) a PA tracker that

monitors children's performed PA time and intensity, (2) the *Foxfit* app on the child's smartphone, and (3) the *Foxfit* web-based dashboard for health care providers. Because the intervention is blended, children receive personal coaching and feedback from their health care provider every week during a coaching moment. In the gamified story, the children are a fox that wants to travel from the moon to a planet. The child can do so by gaining points by performing PA.

In the following description of functional components, it is explicitly stated when components were added or changed because of feedback on the tested prototypes. To emphasize the evidence-based components, [Table 2](#) shows the mapping from methods regarding the design consideration, such as behavior change principles, to the final functional components.

Table 2. Translation from methods in the 3 design considerations to functional components of the intervention.

Design consideration and method	Functional component of the intervention
Support behavior change	
Monitoring	<ul style="list-style-type: none"> • Activity monitor that shows PA^a • Points in the app that represent PA levels and bonus activities • Overview of performed activities over the last week
Gamified story	<ul style="list-style-type: none"> • PA behavior, goals, and rewards are translated to an attractive story
Rewards	<ul style="list-style-type: none"> • Points for PA behavior based on activity tracker • Bonus points for being aware of PA behavior • Trophies from the health care provider for effort and positive attitude
Action planning	<ul style="list-style-type: none"> • Personal daily and weekly schedule with PAs
Shaping knowledge	<ul style="list-style-type: none"> • Tips and information as attractive drawings with supporting text • Tips and information from the health care provider during the weekly meetings
Goal setting	<ul style="list-style-type: none"> • Personal daily and weekly goals in the form of PA points • Personal PA goal for the entire duration of the intervention
Blended technology	
Personal coaching and feedback	<ul style="list-style-type: none"> • Weekly meeting with health care provider
Tailored approach	<ul style="list-style-type: none"> • Goals, activity schedules, suggestions for PA, and tips and information are tailored
Integration in everyday life	
Include all PAs	<ul style="list-style-type: none"> • Suggestions for PAs • Activity tracker monitors both general PA and specific sports activities
No special situation	<ul style="list-style-type: none"> • Usable without having the app with you (synchronize afterward)

^aPA: physical activity.

Goal Setting

A total of 4 PA goals can be listed up on the dashboard and the most important one can be marked as the main goal, such as being able to play as a hockey field player instead of goal keeper for half a match. Moreover, a weekly goal can be set. Children can see both their main and weekly goals on the home screen of the app anytime.

Rewards

On the basis of the measurements of the activity tracker, children receive points for their performed PA. Children also receive rewards for their effort, because children that tested a pilot version indicated that they did not only want to be rewarded for actual performed and measured PA but also for a positive attitude and for trying without sufficient results. Therefore, their shown effort is rewarded by their health care providers with either a bronze, silver, or golden trophy.

Self-monitoring

The activity tracker facilitates self-monitoring of PA. The app shows the received points visualized as the location of the fox on its way to the planet. In addition to self-monitoring, the child's PA behavior is visualized in graphs on the health care provider's dashboard. As requested by health care providers who tested the prototype, these graphs are easy to interpret, because they do not have much time to prepare. Moreover, at the request of health care providers, the graphs also show the relation between PA behavior and the asthma symptoms that children report every day. Because the graphs are too complicated for children aged <12 years to interpret on their own, they are shown only on the health care providers' dashboard and not in children's smartphone app.

Awareness of PA and Symptoms

Children are rewarded for the combination of filling out that they are going to be physically active and actually doing so. Moreover, the activities that are registered by the children become visible in an overview of performed activities in their app. Health care providers who tested a prototype indicated that children must learn to recognize their asthma symptoms and the relation among their asthma symptoms, PA, and medication. Therefore, the children's asthma symptoms are monitored by reporting how they feel every morning and evening. On the health care provider's dashboard, these scores are combined with the children's PA behavior.

Suggestions for PA

In the needs assessment, children indicated that they often have motivation to become physically active, but they simply do not know what to do. Therefore, the app has a button that randomly shows suggestions from a list of PAs. The list contains both personalized and general ideas based on input of children participating in the needs assessment and testing the prototype.

The personalized items can be added and adjusted every coaching moment with the health care provider.

Tips and Information

According to the needs assessment, health care providers and parents find it important that children learn more about the relation among their asthma symptoms, PA, and medication. Information regarding these topics are shown in informative and attractive drawings together with short supporting texts with practical tips for everyday life. These drawings pop up after children fill out that they are going to perform a PA in their app.

Schedule PA

A weekly schedule is visible in the app and the current day's schedule is shown every morning.

Personal Coaching of Health Care Provider

Every week, children speak to their health care provider either in person or via a video call. On the basis of the visualizations on the health care providers' dashboard, they discuss the child's PA behavior of the past week, including the relation between the performed PA and the registered asthma symptoms. Moreover, the health care provider can adjust the personalized items in the dashboard such as the child's PA goals, the informational topics, and the PA schedule.

Step 5: Creating an Implementation Plan

Technical Structure

The three elements of *Foxfit* (the activity tracker, smartphone app for children, and web-based dashboard for health care providers) must communicate with each other to synchronize. [Figure 2](#) shows an overview of the connections among all technical elements.

Figure 2. Overview of all technical elements. The arrows indicate data traffic between elements. PA: physical activity; PAM: physical activity monitor.

PA Tracker

Children wear an activity tracker that monitors their PA levels. After comparing several activity trackers, we chose the PA monitor (PAM) “PAM AM300” [79]. This instrument is shown to be valid for adults [80]. Although there is no information on the validity of the PAM for children, we expected the tracker to be applicable because in our intervention the PAM is primarily used to measure progress and relative differences. Moreover, the instrument met several important criteria for our intervention. The instrument gave the opportunity to send data to our private research database instead of a commercial organization, had positive reviews from young study participants, is reasonably priced, and is extremely easy to use, because it does not require charging and synchronizes automatically [81,82].

Children wear the PAM on their hip, where it is clipped on their waistband. The PAM measures their activity in 2 ways. First, their activity is represented as a PAM score indicating the ratio of energy expended through PA to resting metabolism [83]. Second, their daily activity is represented as active minutes per day. Those active minutes are classified based on the metabolic equivalent of task (MET) as either low intense (MET: 1.8-3), middle intense (MET: 3-7), or high intense (MET: >7). On the basis of this, bonus points are given: (1) 5 points for either 60 minutes of low intense activity or 90 minutes of middle activity (the health care provider chooses which rule fits the child best),

(2) 5 points for at least 15 minutes of high intense activity, and (3) 5 points in case children registered an activity and their PAM tracks at least five middle or high intense activity minutes. Children’s total daily score is the sum of this PAM score and the gained bonus points.

To synchronize the smartphone app for children and the web-based dashboard for health care providers, the data collected from the PAM must be stored in a database. Therefore, children have a Raspberry Pi (Raspberry Pi Foundation) with a Bluetooth and 4G dongle at home. When the PAM is near the Raspberry Pi, it automatically sends the collected data to a database on a secured remote server via a secured Secure Shell (SSH) connection. The collected data are not shared with other parties, no personal data are stored, and the collected activity data are stored pseudonymized.

Web-Based Dashboard for Health Care Providers

Health care providers visit a web-based dashboard via their internet browser to see visualizations of the collected activity data and to personalize the intervention. Every health care provider has their own ID number and password to access the dashboard. These ID numbers and corresponding hashed passwords are stored in the database on the remote server. ID numbers of health care providers are only matched to ID numbers of children that they treat at the moment to ensure they do not have access to children who are treated by other health

care providers. [Figure 3](#) shows the pages of the dashboard where health care providers log in and select the child's ID.

When a health care provider signs in to the dashboard and selects a child's ID, the child's activity data are sent via a secured SSH connection from the database on the remote server to the web-based dashboard. There, visualizations of the child's PA

behavior are shown. [Figure 4](#) shows such visualizations on the health care provider's dashboard. Health care providers also use the dashboard to tailor the intervention. [Figure 5](#) shows pages of the dashboard in which the health care provider can fill out personalized data. When they add information or fill out choices, this is again sent via a secured SSH connection from the web-based dashboard to the database on the remote server.

Figure 3. Start pages of the health care providers' web-based dashboard. Log in to dashboard (top); select the ID of the child (bottom).

Figure 4. Visualization pages of the health care providers' web-based dashboard. Graphs regarding the physical activity (PA) behavior of the child are shown. From top to bottom: PA behavior of the baseline week (“Week 0”); PA behavior of the fifth week using the app (“Week 5”). In both graphs, the date is shown on the x-axis (“datum”), the y-axis represents the amount of PA minutes (“minuten”), and the intensity of PA (“intensiteit”) is represented by the color—low (“licht”); middle (“middel”); high (“zwaar”). In the bottom graph, the smiley faces indicate whether the child has achieved their daily goal, and the number between 1 and 10 indicates the experienced asthma symptoms in the morning (1=feeling very bad; 10=feeling very well).

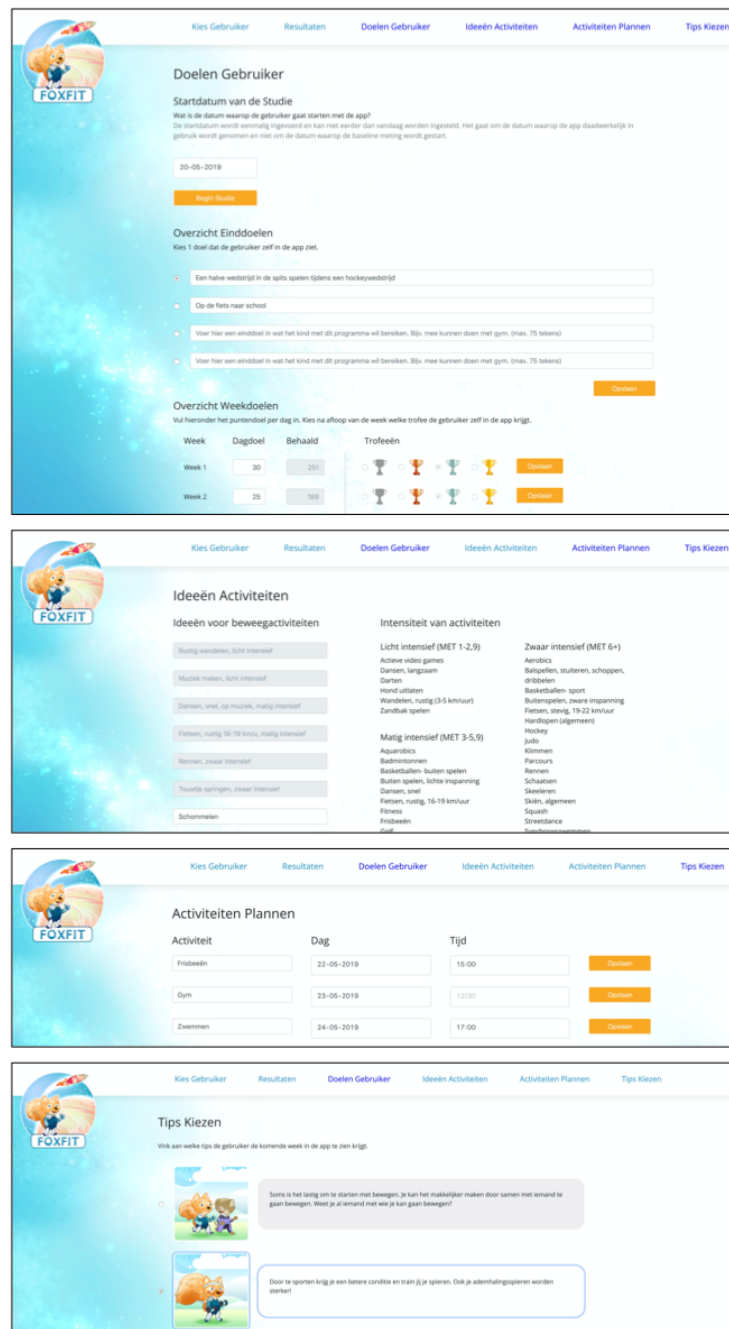

Figure 5. Personalization pages of the health care providers' web-based dashboard. From top to bottom: personal goals and trophies; physical activity (PA) suggestions; scheduling PAs; choosing relevant tips.

Smartphone App for Children

Because the *Foxfit* app is built only for Android, and because we wanted to prevent from privacy and installation problems, children receive a smartphone on which the *Foxfit* app is already installed. To see the collected activity data as a gamified story, children use the app. Figure 6 shows the pages of the child's smartphone app. Children have their own ID number and password to access the app and the app is connected with the internet through Wi-Fi or 4G. On the remote server, no personal

data of the child are stored. Only the ID number and corresponding hashed password are stored. When a child opens the app, activity data from the PAM that were automatically synchronized via the Raspberry Pi at home are sent from the remote server to the smartphone app through a secured SSH connection. When children add information or fill out choices in the app, this is also sent via a secured SSH connection from the smartphone app to the remote server. The home screen contains a help button that provides contact information to handle technical problems.

Figure 6. Pages of the smartphone app for the children. From left to right and from top to bottom: home screen; starting the day and filling out symptoms experienced in the morning; filling out physical activity (PA); overview of PAs of the current week; ending the day and filling out symptoms experienced during the day; earned trophies.

Implementation in the Health Care System

The intervention takes 7 weeks in total. Health care providers have a coaching moment with the child every week. The first 2 meetings, the midterm meeting, and the last meeting are in-person sessions and take 30 minutes. The remaining meetings are digital, to diminish the time investment and take 15 minutes. Before starting the intervention, children wear the PAM for a week without having access to the app. In this “week 0,” their

baseline PA behavior is discovered. In the following 6 weeks, the full intervention including the smartphone app is used by the child. The health care provider can access the web-based dashboard at any time in the 7 weeks. At the start of a coaching meeting, the health care provider signs in into the web-based dashboard with their own credentials and selects the ID number of the child that the meeting is with. The dashboard is designed in such a way that the health care provider is guided through all steps to be taken. All steps and tasks to be performed by the

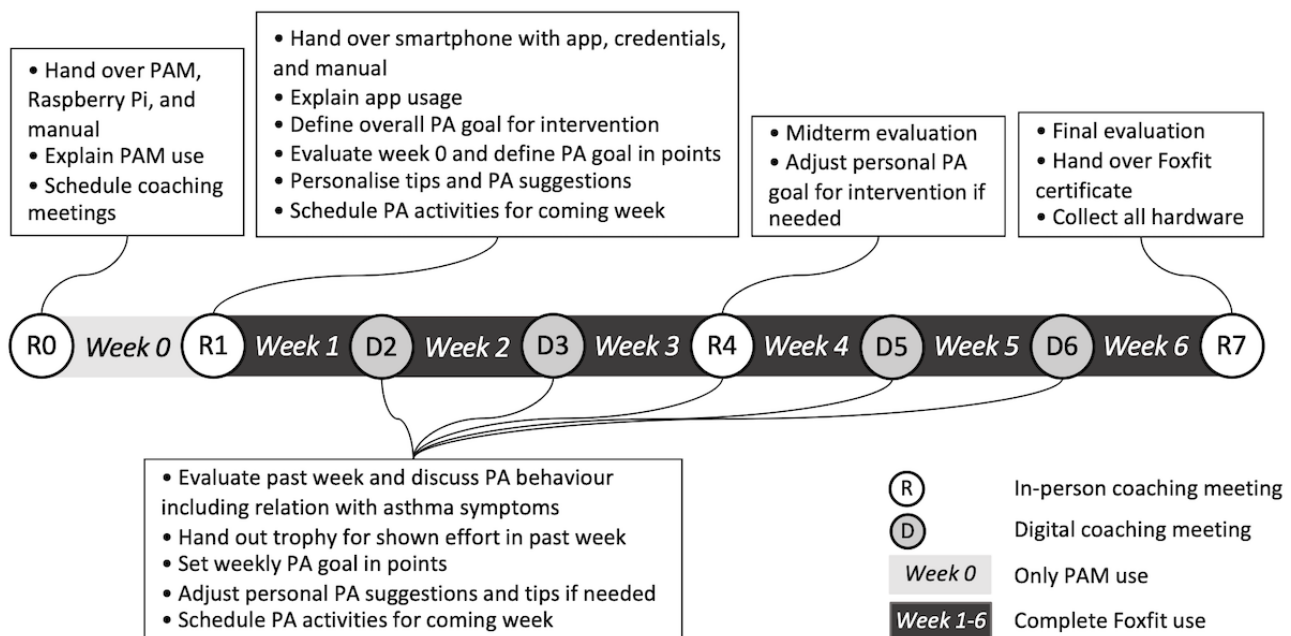

health care provider are described in a manual as well. Figure 7 shows a timeline of the *Foxfit* intervention from the health care provider’s perspective.

In the first meeting, health care providers hand over the PAM, Raspberry Pi, and a manual to the child. They introduce the intervention and explain the PAM use to the child and their parents. Moreover, they schedule coaching moments for the coming weeks. After the baseline week is complete, health care providers hand over a smartphone on which the *Foxfit* app is installed, along with the child’s credentials and a manual. They explain the intervention to the child and their parents. Together with the child, a personal PA goal for the entire intervention is set as well as a weekly goal in the form of activity points. These goals are filled out in the dashboard. Moreover, personal tips and suggestions for PAs are chosen, and PAs for the coming week are scheduled.

In the digital coaching meetings, health care providers evaluate the PA behavior of the child over the past week, based on the PA graphs on their dashboard. They also discuss the relation between the child’s PA levels and their asthma symptoms. For the child’s shown effort in the past week, they hand out a trophy. Together with the child, the health care providers set a new weekly PA goal formulated as activity points and schedule PAs for the coming week. If needed, PA suggestions and personal tips can be adjusted in the dashboard as well.

The coaching meeting after 3 weeks of using the app is conducted in real life, instead of being conducted digitally. Then, health care providers conduct a midterm evaluation in addition to the general items covered during a coaching moment. If needed, they can adjust the child’s PA goal. In the last meeting, health care providers conduct a final evaluation in which they discuss the child’s progress achieved during the intervention. In addition, they hand out a *Foxfit* certificate to the child and they collect all hardware.

Figure 7. Timeline of the *Foxfit* intervention in the daily practice of the health care providers. PA: physical activity; PAM: physical activity monitor.

Implementation in Children’s Everyday Life

After the baseline week in which children’s baseline PA behavior is discovered with the PAM, children also use a smartphone with the *Foxfit* app. Children need not carry around their smartphone all the time. To minimize screen time, the app is not required to track PAs, because the PAM automatically tracks their PA levels. When they are near the Raspberry Pi at home, data are automatically sent to the database on the remote server. Figure 8 shows a timeline of the *Foxfit* intervention in children’s everyday life.

In the morning, children attach their PAM to their waistband to track their activity during the day. After that, they open the smartphone app which shows the menu and their personal PA goal. Then, they fill out how they feel that morning to track

their asthma symptoms. When they are finished, their PA schedule of the day is shown, and they can start their day.

Although the app is not required to track PA behavior, children can use the app at any moment to register their PAs to become more aware of their own PA behavior. To do so, they open the app and fill out the activity they intend to perform at that moment. After registering, they receive a tip or information on subjects applicable to them. Children can use the app at any moment to look up their personal goal, received points, PA schedule, performed activities, or awarded trophies as well.

Around bedtime, children finish the *Foxfit* day by taking off the PAM and by gaining their daily points. When they open the app, they see the points received during the day. Their spaceship travels from the moon toward the planet based on the received PA points. Similar to the morning routine, children fill out how they felt during the day to track their asthma symptoms.

Figure 8. Timeline of the *Foxfit* intervention in the everyday life of the children. The arrows indicate flows between elements. PA: physical activity; PAM: physical activity monitor.

Step 6: Creating an Evaluation Plan

The developed intervention *Foxfit* will be tested by approximately 15 children (aged 8 to 12 years) with asthma who are inactive. They will all be treated in a hospital in the Netherlands, specialized in pediatric asthma. During the evaluation study, the intervention will be provided by pediatric lung nurse practitioners and functional exercise therapists from those hospitals.

To evaluate the usability and feasibility in children's everyday life and in health care providers' daily practice, both children and health care providers will be interviewed halfway and at the end of their participation about their user experience, adherence, and suggestions for improvement. In addition to the qualitative interviews, they also fill in the System Usability Scale, which measures the usability of the developed intervention [84,85].

To obtain insights into the effect of the intervention, children will fill out several questionnaires at the start and end of the intervention. Those questionnaires regard asthma control, PA participation, enjoyment of PA, and self-perceptions with, respectively the Asthma Control Questionnaire, Activity Questionnaire for Adults and Adolescents, PA enjoyment scale, and the self-perception profile for children (competentie-belevingsschaal voor kinderen) [86-91]. Regarding children's physical fitness and endurance, they perform a 6-minute walk test. In addition, activity data, collected with the PAM, of all participants will be analyzed. We will compare activity levels of the baseline week with activity levels of the last intervention week.

A detailed description of the evaluation together with its corresponding analyses and results will be published separately.

Discussion

Principal Findings

This study illustrated the way IM was used to translate theory and stakeholder experiences into design requirements and functional components and finally develop a complete blended and technology-supported intervention. IM was useful for describing the translation and development in a structured way. The needs and wishes of children with asthma, their parents, and health care providers were combined with scientific evidence regarding behavior change techniques and gamification in a technology-supported intervention. This resulted in the blended intervention *Foxfit* that consists of an activity tracker, a smartphone app for children (aged 8 to 12 years), and a web-based dashboard for health care providers. It focuses on PA in everyday life to improve social participation and contains behavior change elements such as goal setting, rewards, action planning, monitoring, shaping knowledge, a tailored approach, personal coaching and feedback, and a gamified story. Because of the cocreation with future users, the support of the resulting product has been strengthened among children with asthma, their parents, and health care providers. The structured description of the development process ensures that *Foxfit* can be compared easily with other interventions.

Strengths, Limitations, and Future Work

The participation of stakeholders in this project was very strong, because the intervention was not only created for the target group but together with them. Consistent with other studies that

applied IM to develop health interventions for children, we experienced that the process of IM is very time consuming, but the systematic approach improves clarity and analysis of the intervention [41,42]. The theoretical foundation increases the potential of the intervention to realize the desired outcome of supporting PA, because it tends to provoke more significant effects on PA [30,65,92,93]. Moreover, clarity and analysis of the intervention is important, because many gamified interventions for children with chronic disease lack a detailed description of the final intervention [61].

Because of the structured approach, it is relatively easy to apply this approach to other situations. On the one hand, the current gamified story and integrated behavior change techniques can be applied for children with other chronic diseases. Only the content of the knowledge components and the specific questions about asthma symptoms should be adjusted to the new disease. On the other hand, the integrated behavior change techniques can be applied for children in older age groups in case the gamified story is adjusted to their interests and experiences. Because children should be able to handle a smartphone with the *Foxfit* app themselves and understand why they need to wear the activity tracker, we do not think that the intervention is suitable for children younger than the current minimum age of 8 years.

An important factor of *Foxfit* is the support of the health care provider. Because of the blended approach, children receive personal feedback, and the intervention can be tailored. These components are success factors when behavior change is aimed for and requires considerable time from both children and health care providers [67-69]. The intervention takes 7 weeks, which will not be long enough to reach lasting behavior change. However, 7 weeks of monitoring and coaching can lead to positive PA experiences and therefore, improved PA levels. Extended use of the intervention, possibly with decreasing involvement of the health care provider, can help maintain these improved PA levels and form new habits. In the evaluation study we will obtain an indication of the effect of the intervention on improved PA levels.

Time is scarce and expensive for the health care providers. Therefore, we tried to diminish the coaching time by enabling web-based coaching meetings and by minimalizing health care providers' preparation time. Despite these optimizations, it might be difficult to structurally implement the *Foxfit* intervention in the health care system. Because of the advantages of personal feedback from health care providers on children's motivation, we would not recommend to completely omit this. However, the investment time of health care providers might be further diminished through the use of artificial intelligence (AI) for automatically personalizing the intervention. Such a technical system might, for instance, suggest health care providers weekly activity goals based on activity data of the past weeks. This approach takes the attitude of both patients and health care providers toward AI into account. Patients appreciate the human factor of health care providers and might have a negative attitude toward medical AI because of the absence of this humanistic care factor [94]. Moreover, health care providers appreciate AI systems to make the process more efficient or support them by giving suggestions, but ultimately,

they want to make their own choices [95]. By giving AI-based suggestions for weekly PA goals, there still is clinical expertise and personal feedback, but the health care providers are supported in their decisions and the process is made more efficient.

Although coaching from the health care provider is an important component of the intervention, it would be interesting to study whether the intervention can be used as standalone app for children as well. Although the intervention was designed for children with asthma who are inactive, there are also several children who already have moderate PA levels but who may still be able to diminish the impact of their disease when their PA levels are improved. A stand-alone app might, for instance, be helpful for them as well as for children who completed the entire blended *Foxfit* intervention previously and now need a repetition. To examine the possibilities of a standalone app, we should study whether some of the health care provider's tasks and dashboard functionalities can be implemented in the smartphone app. Moreover, in some cases, highly educated parents could possibly take over the coaching role of the health care provider when they receive proper instruction.

Regarding the hardware, the PAM that children must wear is extremely easy to use and safe in terms of personal data. No personal data are stored, and the activity data are not shared with a commercial organization. The PAM does not require charging during the intervention and it synchronizes automatically. Thus, the impact on children's everyday life is minimal. However, this system requires Raspberry Pi with Bluetooth and 4G dongle at home. This takes up space, requires an electrical outlet, and comprises of small components, which might be inconvenient when having very young children at home.

Although a large group of children participated in the needs assessment, it was challenging to include children with low PA levels for our pilot test. In the end, more children with sufficient PA levels than children with low PA levels pilot-tested our prototype than children with low PA levels. This might have influenced the feedback of the prototype and therefore the choices made for the final intervention. For example, in the needs assessment, children suggested that competitive elements would help them become physically more active, whereas participants of the stakeholder sessions indicated that competition is not desired, because children's motivation might be reduced when they compete against children having better PA possibilities. A solution might be to compete against each other based on children's personalized goals. In the feasibility and usability tests, user experiences and suggestions for improvement of a larger group of children with asthma who are inactive will be explored.

According to the Fogg Behavior Model, someone will not automatically perform the desired behavior when the opportunity, capability, and motivation are sufficient, but there will be a moment of opportunity in which someone can be persuaded to perform the desired behavior in case he receives a trigger [96,97]. In technology-supported interventions, providing such an external trigger at the moment of opportunity is called a just-in-time notification. Although such notifications

might have reinforced children's motivation, we did not choose to implement them, because one of our requirements was that the intervention should be usable without the children having to carry the smartphone with them all day. The PAM did not technically support such notifications, but incorporating these just-in-time notifications might strengthen the motivational aspect of our intervention in the future.

Conclusions

IM was useful to structure the development of the blended and technology-supported intervention *Foxfit*, and to describe this

development process. *Foxfit* facilitates health care providers in promoting PA in children with asthma. The intervention consists of an activity tracker, smartphone app for children, and web-based dashboard for health care providers. Important behavior change elements of the intervention are goal setting, rewards, action planning, monitoring, shaping knowledge, a gamified story, personal coaching and feedback, and a tailored approach. Not only is the intervention based on behavior change techniques, it also meets the needs and wishes of its users because it was cocreated with children with asthma, their parents, and their health care providers.

Acknowledgments

The authors thank all the children, parents, and health care providers who participated in this study. They also thank Rutger van Teutem for his helpful input regarding the design of the intervention and Gainplay Studio for their valuable contribution to the development of the intervention. This study is part of the research project SIMBA, which is funded by the directing body SIA—a part of the Dutch Organization for Scientific Research (Nederlandse Organisatie voor Wetenschappelijk Onderzoek)—under grant HW/Raak PUB 03.047.

Abstract

Background: Preoperative medical evaluation serves to identify risk factors and optimize patients before surgery. Providing a telehealth option in the perioperative setting has played a significant role in reducing barriers to quality perioperative health care.

Objective: We aimed to evaluate how telemedicine preoperative evaluations using Clinical Video Telehealth (CVT) impact hospital length of stay.

Methods: We performed a retrospective chart review between 2016 and 2017 of adult patients who underwent evaluations in our hospitalist-run preoperative medicine clinic. Patients seen in our preoperative CVT program were compared to patients seen in person to evaluate the association of visit type (preoperative CVT versus in-person evaluation) with hospital length of stay, defined as hospital stay from postoperative day 0 to discharge. There were 62 patients included in this retrospective study.

Results: The adjusted incidence rate ratio (IRR) for hospital length of stay was significantly shorter in patients who underwent preoperative CVT compared to an in-person visit (IRR 0.52, 95% CI 0.29-0.92, $P=.02$).

Conclusions: After adjusting for age and comorbidities, we show that preoperative telemedicine in the perioperative setting is associated with a shorter hospital length of stay compared to in-person visits. This suggests that telemedicine can play a viable role in this clinical setting.

Introduction

For the almost 50 million surgeries and procedures performed annually in the United States, preoperative medical evaluation serves to identify and optimize perioperative risk to decrease adverse outcomes and to prevent same-day cancellations of surgery [1]. Traditionally, preoperative evaluations are performed face-to-face in the clinic. Starting in July 2014, given

its large catchment area, the Veterans Affairs Greater Los Angeles Healthcare System implemented a telemedicine preoperative medicine clinic using Clinical Video Telehealth (CVT). CVT is a technology that Veterans Affairs (VA) providers have used since the early 2000s. With CVT, clinicians can gather relevant history and conduct a limited physical exam using a camera and digital stethoscope. Since adoption, CVT has found increasing rates of use, especially for patients living

in rural areas, who face significant barriers to completing in-person visits. In the wake of the COVID-19 pandemic, the importance of providing a telehealth option in outpatient care has become even more apparent [2].

Several studies in non-VA settings have demonstrated that preoperative evaluations done via telemedicine are associated with high patient/provider satisfaction, cost savings, and a lower rate of same-day cancellation when compared to in-person evaluations [3-6]. However, the potential limitations of telemedicine preoperative evaluation (eg, not performing a comprehensive physical exam may preclude clinical diagnoses) may lead to subsequent case-cancellation complications. Thus, our project aimed to evaluate how telemedicine preoperative evaluations using CVT impact hospital length of stay.

Methods

Overview

This manuscript follows the Strengthening the Reporting of Observational Studies in Epidemiology (STROBE) Statement guidelines for reporting observational studies. All data used in this study were extracted from electronic medical records.

We performed a retrospective chart review of adult patients who underwent evaluations in our hospitalist-run preoperative medicine clinic. Patients seen in our preoperative CVT program, which started in July 2014, were compared to patients who had in-person visits to evaluate the association of visit type (preoperative CVT versus in-person) with hospital length of stay, defined as hospital stay from postoperative day 0 to discharge. We extracted data from 2016 to 2017. Preoperative CVT involves a thorough history and a full airway exam. Exclusion criteria for the CVT preoperative program were defined at the program's start as American Society of Anesthesiologists (ASA) class 4, or ASA class 3 and uncontrolled blood pressure (>180/100 mm Hg) and/or diabetes

(glycated hemoglobin [HbA_{1c}] >9%). The patients needed to meet all criteria to be recommended for an in-person visit and therefore be excluded from CVT. These patients were recommended for in-person evaluation due to comorbidity burden and importance of taking a complete history and conducting a physical exam.

Data Analysis

Statistical analysis was performed using R (version 3.6.1; R Foundation for Statistical Computing). To measure the differences in hospital length of stay among those who received CVT versus face-to-face consultation, chi-square and student *t* tests were used. Multivariable negative binomial regressions were performed, adjusting for age, gender, ASA score, surgery type (major or minor), and Elixhauser comorbidity index. The incidence rate ratio (IRR), 95% CIs, and *P* value were calculated for each estimate.

Ethical Considerations

Our study was reviewed by the Institutional Review Board of the West Los Angeles Veterans Administration Medical Center and was granted an "exempt" status.

Results

There were 62 patients included in this retrospective study. The cancellation rate was 1.74% for CVT versus 3.48% for in-person. Table 1 outlines the distribution of patient characteristics stratified by preoperative visit type. In this unadjusted analysis, there were no significant differences between the cohorts.

Table 2 outlines the negative binomial regression for the association of visit type with hospital length of stay. The age- and Elixhauser score-adjusted incidence rate for hospital length of stay was significantly shorter in patients who underwent preoperative CVT compared to an in-person visit (IRR 0.52, 95% CI 0.29-0.92, *P*=.02).

Discussion

In summary, we show that preoperative CVT, while holding age and the Elixhauser comorbidity score constant in the model, has an IRR for hospital length of stay that is 0.52 times lower compared to in-person visits. This study found a significant

difference in the IRR of postoperative length of stay between patients receiving telehealth versus in-person preoperative evaluations. This suggests that telemedicine can play a viable role in this clinical setting. Telemedicine has the potential to increase care access across all specialties and health care systems. Our findings had several limitations including that the

study was retrospective, was conducted at a single center, and had a low sample size, leading to an increased risk of type II error. Length of stay may be affected by many factors. In the VA patient population, social reasons may affect length of stay more than the typical patient population. There likely is selection bias between those patients who were willing to do CVT versus those who wanted an in-person evaluation.

In our patient population, several patients were more interested in telemedicine compared to in-person visits and we hope to expand to other locations. We plan to apply biomedical informatics to the electronic medical records to extract granular patient data including but not limited to (1) demographic data

(age, race, socioeconomic status, and zip code), (2) comorbidities and severity of each comorbidity, (3) postoperative complications, (4) telemedicine-specific data (cancellation rates, missed appointments, and scheduling delays), and (5) patient perceptions and experiences. We hope this research design will help us to identify the benefits and potential disadvantages of telemedicine in the perioperative period. Future studies should be prospective and adequately powered to limit type II error. In addition, future studies should explore how to appropriately triage patients as being “telehealth-appropriate” in the preoperative setting, as well as investigate the effects of preoperative telehealth on other patient-centered outcomes.

Abstract

Background: Existing mental health treatments are insufficient for addressing mental health needs at scale, particularly for teenagers, who now seek mental health information and support on the web. Single-session interventions (SSIs) may be particularly well suited for dissemination as embedded web-based support options that are easily accessible on popular social platforms.

Objective: We aimed to evaluate the acceptability and effectiveness of three SSIs, each with a duration of 5 to 8 minutes (Project Action Brings Change, Project Stop Adolescent Violence Everywhere, and REFRAME)—embedded as Koko *minicourses* on Tumblr—to improve three key mental health outcomes: hopelessness, self-hate, and the desire to stop self-harm behavior.

Methods: We used quantitative data (ie, star ratings and SSI completion rates) to evaluate acceptability and short-term utility of all 3 SSIs. Paired 2-tailed *t* tests were used to assess changes in hopelessness, self-hate, and the desire to stop future self-harm from before to after the SSI. Where demographic information was available, the analyses were restricted to teenagers (13-19 years). Examples of positive and negative qualitative user feedback (ie, written text responses) were provided for each program.

Results: The SSIs were completed 6179 times between March 2021 and February 2022. All 3 SSIs generated high star ratings (>4 out of 5 stars), with high completion rates (approximately 25%-57%) relative to real-world completion rates among other digital self-help interventions. Paired 2-tailed *t* tests detected significant pre-post reductions in hopelessness for those who completed Project Action Brings Change ($P<.001$, Cohen $d_z=-0.81$, 95% CI -0.85 to -0.77) and REFRAME ($P<.001$, Cohen $d_z=-0.88$, 95% CI -0.96 to -0.80). Self-hate significantly decreased ($P<.001$, Cohen $d_z=-0.67$, 95% CI -0.74 to -0.60), and the desire to stop self-harm significantly increased ($P<.001$, Cohen $d_z=0.40$, 95% CI 0.33 to 0.47) from before to after the completion of Project Stop Adolescent Violence Everywhere. The results remained consistent across sensitivity analyses and after correcting for multiple tests. Examples of positive and negative qualitative user feedback point toward future directions for SSI research.

Conclusions: Very brief SSIs, when embedded within popular social platforms, are one promising and acceptable method for providing free, scalable, and potentially helpful mental health support on the web. Considering the unique barriers to mental health treatment access that many teenagers face, this approach may be especially useful for teenagers without access to other mental health supports.

KEYWORDS

web-based intervention; internet intervention; digital intervention; single-session intervention; mental health

Introduction

Limited Accessibility of Existing Mental Health Treatments

Existing mental health treatments have long been inaccessible due to well-established structural (eg, cost, transportation, and time) and individual (eg, stigma and distrust of providers) barriers [1-3]. Furthermore, people experiencing suicidal thoughts or engaging in self-harm often fear the negative consequences of disclosing these experiences (eg, involuntary hospitalization) [4,5], creating additional barriers to treatment among those who may need it most. This is particularly true for teenagers whose caregivers often serve as gatekeepers for their own mental health care [6-8] and who often fear the involvement of a caregiver without their consent [5].

To fill the gap between the *need* for support and *access* to it, many teenagers seek and receive mental health support on the web [9,10]. Specifically, a majority (61%-85%) of teens and young adults have sought information or help for their mental health on the web [10-12]. Teenagers report using web-based mental health resources as a way to obtain free, easily accessible, or anonymous support [12,13], and web-based communities via social platforms (eg, forums and discussion boards) offer a space to share one's experiences with others who have faced similar challenges [14-17]. Youth facing greater psychological distress are also more likely to search for and discuss topics related to their mental health on the web [15]. Thus, these web-based communities in social platforms represent a unique, underexplored avenue for reaching teenagers in need of mental health support.

Offering Mental Health Support via Web-Based Social Platforms

Initial efforts suggest that it is *possible* to provide mental health supports that are integrated into existing web-based social platforms. Koko, a nonprofit, web-based mental health platform, provides on-demand peer support [18,19], crisis triage [20], and self-guided interventions on topics such as body image, self-harm, and stress management. People can access Koko services on various messenger apps (eg, Telegram, Facebook Messenger, and Kik) or via direct message channels of certain social networking platforms (eg, Tumblr); in recent studies, a portion of Koko users were directly referred from a social media integration [20]. However, no previous evaluation of Koko's services has focused entirely on investigating the acceptability and effectiveness of embedding mental health supports within a social networking platform.

Single-Session Interventions as Embedded Web-Based Support

Single-session interventions (SSIs)—brief, targeted interventions designed to be completed within 1 sitting or clinical interaction—provide an especially promising intervention format for reaching young people on the web [21]. Multiple large-scale studies have indicated that SSIs can create meaningful changes for key mental health outcomes. In a recent randomized controlled trial of adolescents (N=2452), a 20- to 30-minute web-based behavioral activation SSI (Project Action Brings

Change [ABC]) outperformed a supportive therapy control program at reducing postintervention hopelessness and depressive symptoms 3 months later [22]. Another trial (N=565) found Project Stop Adolescent Violence Everywhere (SAVE), a web-based 30-minute SSI targeting self-injurious thoughts and behaviors in teenagers, improved postintervention self-hatred, and desires to stop future self-harm, relative to an active control [23]. Taken together, substantive evidence suggests the efficacy of web-based SSIs in improving mental health outcomes among young people.

Despite the great *potential* of SSIs to increase access to mental health supports, little large-scale research has evaluated their acceptability and effectiveness when disseminated in web-based settings that young people already routinely access. One study evaluated the acceptability and preliminary utility of a free, open-access platform offering 3 web-based SSIs for youth [24]. After viewing paid advertisements on a social media platform (ie, Instagram), nearly 700 youths clicked on the advertisement and viewed the web-based platform within 6 months. The youths rated all 3 SSIs as acceptable, and analyses indicated significant pre- to postintervention reductions in hopelessness and self-hate among 187 SSI completers. However, to complete an SSI program, the youth had to be (1) aware of the open-access platform and (2) motivated to visit the platform on a separate, unfamiliar website and finish a 30-minute activity. Reducing friction (ie, points of difficulty) between individuals and their technology during key help-seeking thresholds may be particularly important for encouraging greater access to mental health supports on the web [25]. Rather than relying on individuals' ability and motivation to seek external mental health resources in moments of heightened distress (eg, standalone web-based resources, crisis hotlines, and text lines), SSIs could provide accessible, in-the-moment anonymous supports for young people who are *already embedded* in popular social platforms.

Considerations for Intervention Design

SSIs designed for these web-based, embedded contexts should be streamlined to improve engagement while retaining their therapeutic value. Once disseminated in the real world, digital interventions often encounter issues with user engagement (ie, low uptake and low completion) [26-28]. Substantially reducing the time and effort required to complete web-based SSIs (eg, condensing content and reducing the number of writing prompts) may improve user engagement, particularly for SSIs delivered as in-the-moment supports at times of elevated distress. Determining which elements of SSIs to condense versus preserve presents a particular design challenge for the creation of SSIs embedded on the web.

Several intervention design principles, drawn from basic research in social psychology, education, and marketing [29], have been theorized to support the use of web-based SSIs for mental health: (1) using neuroscientific evidence to normalize youths' experiences and boost message credibility; (2) centering youths' expertise in their own lived experiences; (3) asking youths to share what they have learned with others, using their own words; and (4) providing testimonials from others experiencing similar and relevant challenges [21]. These core

principles have been featured in much of the existing research evaluating web-based SSIs [22-24]. However, limited research to date has evaluated whether very brief, streamlined SSIs (ie, SSIs much shorter than 30 minutes) that retain these core principles may still provide some benefit as quick, free mental health supports embedded on the web.

This Study

As a majority of existing mental health treatments remain inaccessible, many young people seek mental health support via social platforms on the web. SSIs are uniquely well positioned for integration within web-based social platforms, providing free, brief, and anonymous mental health support options at scale. However, little research has formally evaluated the acceptability and effectiveness of very brief SSIs designed for this context. This study adapted 3 web-based SSIs (5-8 minutes) that were offered as Koko minicourses on Tumblr, a microblogging and social networking website with 135 million active users monthly [30]. The aims of this study were 2-fold: (1) to evaluate the *acceptability* of SSIs in this context via user data and acceptability ratings and (2) to assess *short-term effectiveness* of all 3 SSIs in improving key mental health outcomes (ie, hopelessness, self-hate, desire to discontinue self-harm) from before to after the SSI. Given the unique barriers to mental health treatment access faced by teenagers, the analyses were restricted to teenagers (ages 13-19 years) where possible. The results may inform continued efforts to increase access to free, anonymous, and timely mental health support options.

Methods

Ethical Considerations

For this study, we collected anonymous data exclusively from individuals on Tumblr—all of whom were introduced to the service by either (1) clicking on a featured advertisement from Tumblr (eg, “take control by taking this mood-boosting minicourse”) or (2) direct referral from the platform. As all data were part of a completely anonymous program evaluation, this study was deemed as nonhuman subjects research in consultation with the institutional review board at Stony Brook University. In addition, Koko’s privacy policy and terms of service acknowledge that anonymized data may be shared for research purposes.

Recruitment and Procedure

The direct referral pathway for each of the 3 SSIs was similar. Users who searched for mental health topics on Tumblr were shown an in-app overlay with links to various resources, such as The National Suicide Prevention Lifeline. A set of over 1300 keywords and their derivations were used to detect terms such as “self-harm” or “depression” as well as slang and obfuscations, such as “sewer-slide” and “s3lf h@rm.” In addition to links to crisis lines, users were also sent a direct message from Koko through the Tumblr direct message channel. Specifically, they were sent the following automated message from a chatbot called “Kokobot”:

Hi! I'm Kokobot [wave emoji]. I'm working with Tumblr to connect people who are interested in mental health topics. Type “hi” to get started...

Next, users were onboarded to the service and asked to describe a recent negative situation that they have been facing, along with any associated negative thoughts. From there, a set of text-based classifiers for mental health [20,31] categorized the user’s posts and directed them to one of several resources, including peer support, crisis lines, and SSIs. Users could also access any of these services from a main menu at any point while using the platform. Users whose text descriptions were flagged by a crisis model were asked to specify whether their current struggles were related to suicidal thoughts, abuse, eating disorders, or self-harm. If a user disclosed that they were struggling with self-harm, they were shown crisis lines from around the world as well as a link to Project SAVE.

The 3 SSIs were initially introduced as Koko minicourses at 3 separate times: March 2021 (Project ABC), June 2021 (REFRAME), and July 2021 (Project SAVE). Across all 3 SSIs, the data for this study were collected through February 2022. Preintervention data were collected immediately before beginning each SSI (ie, each Koko minicourse), and postintervention data were collected immediately following the completion of a program.

SSI Programs

Project ABC Single-Session Intervention

Project ABC minicourse was a briefer 5- to 8-minute version of the original 20- to 30-minute Project ABC SSI evaluated in earlier randomized trial research [22]. As with the full-length program, the abbreviated Project ABC SSI used principles of behavioral activation, encouraging individuals to “take action” and engage in pleasurable behaviors that align with personal values to boost mood and build self-efficacy. Similar to the original SSI, the brief minicourse involved the following components: (1) psychoeducation, describing how taking values-based *actions* can boost *mood* over time; (2) values assessment, where individuals identify a top value for them (eg, academics, friendships, hobbies, family, or staying active); (3) “action plan” exercise, where individuals develop a personalized plan for engaging in meaningful activities of their choice; (4) roadblock exercise designed to identify real-life obstacles and how to address them; and (5) writing prompts, where individuals can share what they have learned with other Koko users. This shortened version of the Project ABC SSI contained condensed intervention content, fewer writing prompts, and greater emphasis on multiple-choice, interactive options, relative to the original 30-minute program.

Project SAVE Single-Session Intervention

Before disseminating as a Koko minicourse, an abbreviated (8-minute) version of the Project SAVE SSI was adapted from an original 30-minute program [32]. Project SAVE was designed to reduce the use of self-harm behaviors to cope with high emotional distress, especially in the context of self-hatred or desires to punish oneself [33]. Similar to the original SSI, the 8-minute version of Project SAVE included evidence-based techniques that are common in cognitive behavior therapies (eg,

psychoeducation and secondary distress tolerance skills). Specifically, Project SAVE included four key components: (1) information about how changing *actions* (eg, reducing self-harm behavior, being kinder to yourself) can change *feelings* and *thoughts* for the better; (2) statistics and testimonials from other teenagers with lived experiences of coping with self-hatred or self-harm; (3) alternative coping strategies to use in place of self-harm; and (4) offering advice to others using Koko based on what they learned. Compared with the original, the shortened Project SAVE SSI contained condensed material, fewer writing exercises, and more multiple-choice, interactive options.

The REFRAME Single-Session Intervention

The REFRAME SSI (5 minutes) teaches cognitive reappraisal, an emotion regulatory strategy that involves modifying one's interpretation of stressful situations [34]. A recent multicountry study with 21,644 individuals found that a brief web-based training on cognitive reappraisal reduced negative emotions and increased positive emotions about COVID-19-related stressors [35]. The REFRAME SSI on Koko included similar components, but it did not specifically target COVID-19-related stressors and it did not distinguish between multiple reappraisal strategies (eg, reconstrual vs repurposing). It included (1) a brief introduction to cognitive reappraisal; (2) a simplified description of its neural correlates; (3) practice examples with vignettes taken from the Koko peer support platform; and (4) a set of brief prompts to help users engage positive reappraisals in their own lives (eg, "This could get better because..."; "This isn't 100% my fault because..."). Users were also taught how to practice this skill on the Koko peer support platform and that helping others reappraise may confer positive psychological outcomes [36,37].

Measures

Demographics

Demographic information (age, gender, and race and ethnicity) was collected as part of the preintervention measures for individuals completing Project SAVE.

Hopelessness

The Beck Hopelessness Scale-4 is a brief and reliable measure used to assess hopelessness in young people [38,39]. At pre- and postintervention time points for the Project ABC and REFRAME SSIs, responders indicated their agreement "right now, in the present moment" with each of 4 statements (eg, "I feel that my future is hopeless and things will not improve") on a 4-point Likert scale (1="absolutely disagree"; 4="absolutely agree"). Hopelessness scores for each person (4-item average) ranged from 1 to 4, with higher values indicating greater hopelessness. Internal consistency was Cronbach $\alpha=.84$ and Cronbach $\alpha=.89$ for pre- and post-Project ABC time points, and $\alpha=.81$ and Cronbach $\alpha=.87$ for pre- and post-REFRAME SSI time points, respectively.

Self-hate

The Self-Hate Scale is a reliable 7-item measure used to assess self-hatred in young people [24,40]. At pre- and postintervention time points for the Project SAVE SSI, responders indicated how true each statement (eg, "I hate myself") is for them, "right

now, in the present moment," on a 7-point Likert scale (1="not at all true for me"; 4="somewhat true for me"; 7="true for me"). The self-hate scores for each person (7-item average) ranged from 1 to 7, with higher values indicating greater self-hate. Internal consistency was Cronbach $\alpha=.90$ and Cronbach $\alpha=.94$ for pre- and post-Project SAVE SSI time points, respectively.

Desire to Discontinue Self-harm

Desire to discontinue self-harm behavior was indexed using a single item adapted from the Self-Injurious Thoughts and Behaviors Interview-Revised [23,41]. Individuals were asked, "How much do you want to stop purposefully hurting yourself without wanting to die?" and told to rate their answer on a 5-point Likert scale (1="I don't want to stop at all"; 5="I definitely want to stop"). A sixth option (eg, "I have stopped engaging in these behaviors") was available for individuals not currently engaging in self-harm behaviors. Data for these individuals were not included in the analyses evaluating pre- to post-SSI changes in this outcome.

SSI Feedback

After completing all 3 SSIs, users were prompted to provide a quantitative "star rating" of the program, from 1 to 5 stars, where higher star values indicate higher ratings or more positive feedback. In addition, after the intervention, all individuals were asked if they would like to provide qualitative feedback via an optional writing prompt (eg, "Do you have any feedback for us?").

Statistical Analysis

Power

Previous web-based SSI research suggests small to large within-group effect sizes for key outcomes (including hopelessness and self-hatred) using more naturalistic study designs (ie, not randomized controlled trials) [24]. Thus, we estimated our statistical power to detect a small within-group effect (Cohen $d=0.20$) using a paired 2-tailed t test in the smallest of the 3 samples (ie, REFRAME, $n=768$ pairs).

Data Exclusion

We assessed the total number of views, starts, and completions for each SSI, as well as item-level drop-off data within each SSI, to describe broad usage patterns without excluding any data. Demographic and outcome data were only recorded and made available once individuals advanced through to the end of a program and clicked "submit." All pre-post analyses, star ratings, and qualitative data were therefore conducted and reported within program "completers" (ie, individuals who completed an SSI). In addition, where demographic data were available (Project SAVE SSI data), we restricted our analysis to teenagers (ie, excluding individuals who reported ages outside of 13-19 years). As Project SAVE was designed for teenagers engaging in self-harm, only individuals who self-disclosed recently engaging in self-harm (via the Koko onboarding pathways described earlier in this section) were directed to complete this program.

Usage Patterns and SSI Feedback

For each SSI, we evaluated usage patterns and feedback, including the number of people who viewed (ie, opened the first page of the program), started (ie, advanced past the first page), completed (ie, advanced through the entire program and beyond the questions), and provided “star ratings” (ie, quantitative ranking of 1-5 stars, with higher stars reflecting a higher rating) for each SSI. In addition, we calculated the program completion rates (percentage completed out of those who started) and average star ratings for each SSI. To illustrate the types of qualitative feedback each SSI received, we extracted specific examples of positive and negative feedback (see the Results section).

Aggregate-level data were available for views and user dropout, for every page within each SSI, among the entire sample (ie, without focusing solely on program completers). We reported these results by plotting the percentage dropout from the number of views for each page within each SSI.

Evaluating Pre-Post Changes

We evaluated pre- to postintervention changes for 4 outcomes: hopelessness (via two separate tests, 1 for Project ABC and 1 for REFRAME) as well as self-hate and desire to discontinue self-harm (Project SAVE only). After checking appropriate assumptions (ie, verifying that pre-post difference scores for each outcome were approximately normally distributed) [42], we performed 2-tailed, paired *t* tests across all outcomes for all programs. We calculated Cohen d_z for paired *t* tests using *t* values, sample sizes, and the Measure of the Effect package in R (version 4.0.0) [43] to evaluate the magnitude of within-group changes for each outcome. For outcomes where difference scores were not normally distributed, we completed an additional sensitivity analysis using the nonparametric Wilcoxon

signed-rank test to evaluate within-group changes from before to after the intervention [44]. We applied a false discovery rate correction to all 4 *P* values to reduce the likelihood of false positives [45]. Thus, we interpreted the results for each outcome as significant if the false discovery rate–corrected *P* values were $<.05$. All analysis code and deidentified data for this study have been made publicly available [46].

Results

Sample Characteristics

As Koko provides anonymous mental health support, individuals are not required to provide potentially identifiable demographic information (eg, age, gender, and race and ethnicity) to complete minicourses. Specific demographic information for this study (age, gender, and race and ethnicity) was only available for the Project SAVE SSI, as this minicourse was introduced to Koko *after* Project ABC and REFRAME SSIs had been introduced. For the Project SAVE minicourse, individuals were given the option (but were not required) to report demographic information about themselves.

The Project SAVE analyses excluded individuals who were not teenagers between the ages of 13 and 19 years, resulting in a final sample of 1194 individuals (72.28% of the total Project SAVE data). Among this group, the average age of the individuals who completed Project SAVE was 15.71 (SD 1.83) years. The top three most commonly endorsed gender identities were female (419/1194, 35.09%), nonbinary (189/1194, 15.83%), and not sure (98/1194, 8.21%). The top three most commonly endorsed racial or ethnic identities were White (607/1194, 50.84%); Asian (172/1194, 14.41%); and Hispanic or Latinx (112/1194, 9.38%). Table 1 presents complete details on participant demographics.

Table 1. Gender identity and race and ethnicity for Project Stop Adolescent Violence Everywhere (N=1194).

Demographics	Values, n (%)
Gender	
Agender	35 (2.93)
Androgynous	13 (1.09)
Female	419 (35.09)
Female to male transgender	74 (6.20)
Gender expansive	15 (1.26)
Gender identity not listed	18 (1.51)
Gender information missing	219 (18.34)
Intersex	3 (0.25)
Male	27 (2.26)
Male to female transgender	2 (0.17)
Nonbinary	189 (15.83)
Not sure	98 (8.21)
Prefer not to say	26 (2.18)
Transfeminine gender	2 (0.17)
Trans man	10 (0.84)
Transmasculine gender	44 (3.69)
Transgender	15 (1.26)
Two-spirited	2 (0.17)
Race and ethnicity^a	
Asian	172 (14.41)
Black or African American	66 (5.53)
Hispanic or Latinx	112 (9.38)
Native American or Alaska Native	23 (1.93)
Native Hawaiian or other Pacific Islander	12 (1.01)
White	607 (50.84)
Prefer not to answer	125 (10.47)

^aIndividuals could select multiple racial and ethnic identities.

Statistical Analysis

Power

Power analyses indicated that we had 99% power to detect a small effect size (Cohen $d=0.20$) using a 2-tailed paired t test in the smallest of the 3 current samples (REFRAME, $n=768$ pairs).

Usage Patterns and SSI Feedback

Project ABC

Project ABC was viewed 17,620 times, started 14,434 times, and completed 3679 times—with a 25.49% (3679/14,434) completion rate among starters across the 12-month study period. Among the Project ABC completers, 3412 (92.74%)

provided a star rating with an average star rating of 4.27 (SD 0.94; median 5) stars. In total, 1217 (33.08%) provided qualitative feedback on Project ABC (see Table 2 for examples of user feedback). The dropout percent of the number of views for each page for all 3 SSIs is plotted in Figure 1. Notably, high levels of dropout (relative to page views, 7%-13%) consistently occurred on pages where Project ABC users were asked to respond to a writing prompt.

Finally, Project ABC received far more views, starts, and completions than either of the other two SSI programs (4065 and 2174 views for Project SAVE and REFRAME, respectively), as Tumblr advertised the Project ABC SSI as a featured minicourse between December 2021 and February 2022, resulting in higher traffic to this SSI.

Table 2. Examples of positive and critical feedback for all single-session interventions (SSIs).

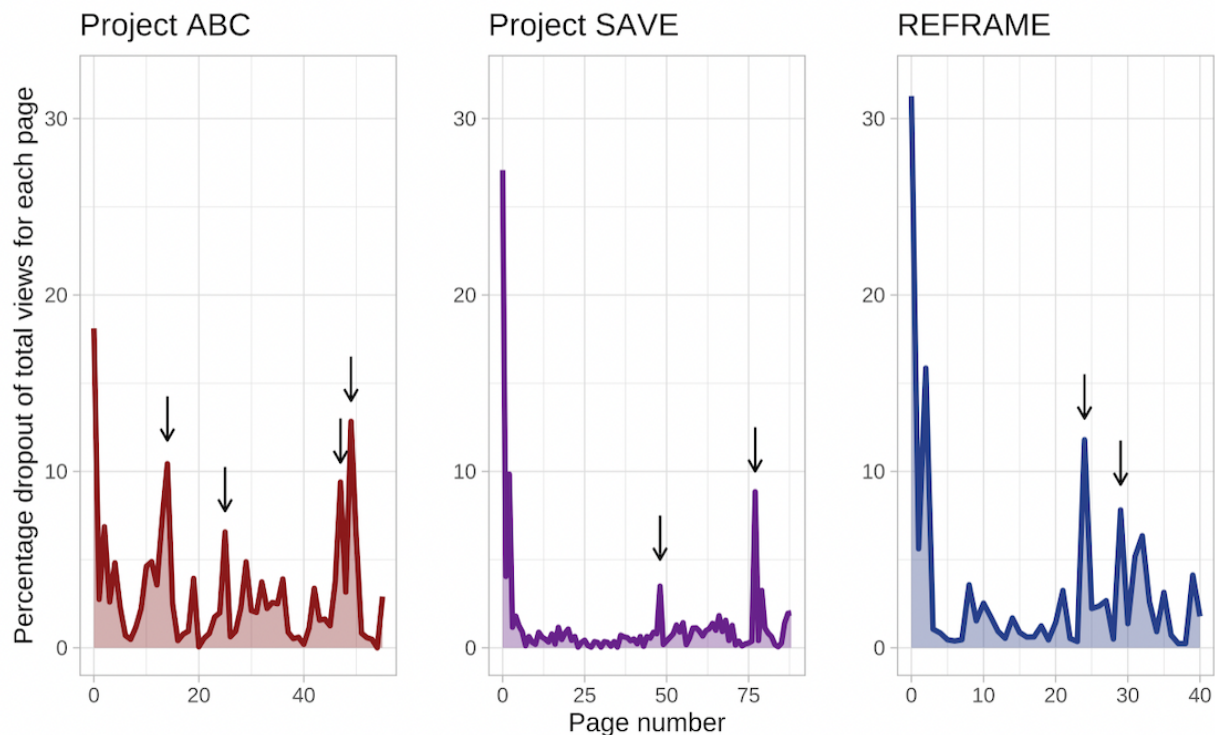

SSI	Positive feedback	Critical feedback
ABC ^a	<p>“Thanks y’all! been dealing w some serious mental health issues and having places to remind me of my agency and joy is really helpful.”</p> <p>“this was really really helpful and i’m seriously going to try my goal/plan. I also feel awake and motivated enough to study. I’d love to see more in the future.”</p> <p>“Hey, this was surprisingly well done. I went in expecting it would be terrible. But you’re making mental health a really approachable topic for people. Thanks for working on reaching out to others. I’d love to see you continue with these mini-courses.”</p>	<p>“Despite the great intentions and work I think there is situations that are very complicated and having this intermediate bot, very few info of the person you are helping it’s too simplistic.”</p> <p>“This helped me see get through my rain cloud but now I kinda feel stressed.”</p> <p>“This is a good idea, but only works for the things one has control over. If you are terminally ill, just lost a loved one or in another uncontrollable challenge, none of these can help.”</p>
REFRAME ^b	<p>“This is such a great way to de-stress, I mean re-frame your stress, it’s definitely a bit helpful.”</p> <p>“I decided to pick up my phone and do this while I was procrastinating. It’s so crazy how this seemingly small task changed my perspective.”</p> <p>“I love this so much!! It actually made me feel better, which I didn’t think it would! Thank you <3.”</p>	<p>“Less simplification”</p> <p>“i think that one of the problems i see is that this requires people to be more specific and there isn’t a sense of connection.”</p> <p>“Please include physical stress reducers, as well. It is difficult to focus on reducing stress when I can’t properly string thoughts together.”</p>
SAVE ^c	<p>“This is amazing. My thoughts of self-harm faded a bit, and prompted me to do the things alternative to when I have self-hate thoughts.”</p> <p>“This is the most convincing thing I’ve ever heard as to why not to self harm. Thank you so much this is so helpful.”</p> <p>“Thank you. This course has definitely calmed me down when I was having a breakdown and thinking of hurting myself.”</p>	<p>“It would’ve been more helpful if reasons for self-harm outside of self-hatred were explored. I’m currently dealing with external circumstances that are overwhelming me and my response is to harm myself. It feels like the only way to release my emotions.”</p> <p>“I have dealt with this so long that there wasn’t really anything new to me, so it really didn’t help.”</p> <p>“Talk about slowly building up to recovery instead of just jumping right in. Talk about how to deal with intense emotions and more.”</p>

^aProject Action Brings Change (ABC) SSI.

^bREFRAME SSI.

^cProject Stop Adolescent Violence Everywhere (SAVE) SSI.

Figure 1. Percentage dropout on each page of all 3 single-session interventions (SSIs), out of the number of individuals who viewed that page. Arrows reflect points where writing prompts were introduced, in each of the 3 SSIs. Spikes in dropout tended to occur after initially opening each SSI, as well as on pages requesting written responses. ABC: Action Brings Change; REFRAME; SAVE: Stop Adolescent Violence Everywhere.

Project SAVE

In 12 months, Project SAVE was viewed 4065 times, started 2961 times, and completed 1652 times; 55.79% (1652/2961) of those who started Project SAVE completed it. After excluding individuals with ages outside our desired range (13-19 years), 1194 observations remained for analysis. Among those who completed the minicourse, 954 (79.90%) provided a star rating for Project SAVE, with an average rating of 4.22 (SD 0.97; median 5) stars. A total of 209 (17.50%) participants provided qualitative feedback on Project SAVE (Table 2). Similar to the Project ABC SSI, Project SAVE observed higher dropout rates (relative to page views, 3%-9%) on pages where users were asked to enter a written response (Figure 1).

REFRAME

REFRAME was viewed 2174 times, started 1498 times, and completed 848 times within 12 months (848/1498, 56.60% completion rate among the starters). Among REFRAME

completers, 732 (86.32%) provided a star rating for the REFRAME SSI, with an average rating of 4.31 (SD 0.93; median 5) stars; 246 (29.01%) provided qualitative feedback on the REFRAME minicourse (Table 2). Consistent with dropout patterns for the other 2 SSIs, REFRAME observed higher dropout rates (relative to page views, 8%-12%) on pages requesting writing from users.

Evaluating Pre-Post Changes

Among individuals who completed Project ABC, hopelessness significantly decreased from before to after the SSI ($t_{3,565}=-48.48, P<.001$). Similarly, individuals who completed the REFRAME SSI reported significant reductions in hopelessness from before to after the intervention ($t_{767}=-24.41, P<.001$). Project SAVE completers reported significant pre- to postintervention reductions in self-hate ($t_{1,007}=-21.30, P<.001$) and an increase in desire to discontinue self-harm ($t_{839}=11.48, P<.001$). All the means, SDs, and within-group effect sizes are listed in Table 3.

Table 3. Means, SDs, and effect sizes for all single-session intervention (SSI) outcomes.

Outcome and SSI	Before the SSI, mean (SD)	After the SSI, mean (SD)	Cohen d_z (95% CI)
Hopelessness			
ABC ^a	2.60 (0.78)	2.16 (0.80)	-0.81 (-0.85 to -0.77)
REFRAME ^b	2.86 (0.74)	2.31 (0.78)	-0.88 (-0.96 to -0.80)
Self-hate			
SAVE ^c	5.69 (1.27)	5.07 (1.64)	-0.67 (-0.74 to -0.60)
Desire to stop harm^d			
SAVE	2.63 (1.20)	2.97 (1.32)	0.40 (0.33 to 0.47)

^aProject Action Brings Change (ABC) SSI.

^bREFRAME SSI.

^cProject Stop Adolescent Violence Everywhere (SAVE) SSI.

^dDesire to discontinue self-harm behavior.

In addition, Wilcoxon signed-rank tests were performed as sensitivity analyses for all outcomes due to the relatively nonnormal distributions of difference scores. For all outcomes, results were consistent with *t* test analyses, indicating significant pre-post reductions in hopelessness ($P<.001$; Project ABC and

REFRAME) and self-hate ($P<.001$; Project SAVE), as well as a significant increase in desire to discontinue self-harm ($P<.001$; Project SAVE) from before to after the intervention. Distributions for all outcomes at pre- and post-SSI time points are shown in Figures 2 and 3.

Figure 2. Hopelessness ratings before and after the Project Action Brings Change (ABC) single-session intervention (SSI; left) and before and after the REFRAME SSI (right). Higher scores reflect higher levels of hopelessness.

Figure 3. Self-hate ratings before and after the Project Stop Adolescent Violence Everywhere single-session intervention (left), where higher scores reflect higher levels of self-hatred. (Right) Desire to stop future self-harm behavior, where higher scores reflect higher desire to stop future self-harm.

Discussion

Principal Findings

Within 12 months, 3 very brief (5-8 minutes) web-based SSIs were viewed >18,800 times and completed >6100 times. Offered as Koko minicourses and embedded within a popular social platform, all 3 SSIs received high-quality ratings (average ratings >4 out of 5 stars). Of the participants who started an SSI, between 25% and 57% of them completed one. Among those who completed Project ABC and REFRAME minicourses, individuals reported a decrease in hopelessness from before to after the SSI. For those who completed Project SAVE, individuals reported decreased self-hatred and increased desire to stop future self-harm behavior from before to after the intervention. This study represents a real-world evaluation of the acceptability and short-term utility of web-based SSIs as very brief, anonymous, “in-the-moment” mental health supports that can be integrated within major social platforms such as Tumblr.

Comparison With Prior Work

Consistent with existing research on web-based SSIs [24], all 3 interventions were (1) rated as acceptable by users and (2) associated with improvements across primary outcomes. Furthermore, despite reducing intervention length by *nearly* 75%, effect sizes for these 5- to 8-minute SSIs were remarkably similar to effect sizes for SSIs designed to last 30 minutes (Cohen $d_z=0.71$ vs 0.81 (hopelessness) and Cohen $d_z=0.61$ vs 0.67 (self-hate) for full and abbreviated SSIs, respectively) [24]. These results support a growing body of evidence that suggests even extremely brief digital interventions may improve clinically relevant outcomes [20,47].

One possible reason for the relative similarity of postintervention effect sizes observed in this study (5-8-minute SSIs) versus within-group effects in earlier randomized trials (30-minute

SSIs) [22,23] might be the shared design features and principles across the “brief” and “very brief” versions of these interventions. Given that these core principles have been featured in all versions of these SSIs to date, it is possible that these common principles are more important than the exact length of the SSI. Future research should formally evaluate this possibility in a head-to-head trial by comparing SSIs of various lengths.

Our results may also indicate the *real-world utility* of these very brief web-based SSIs. Naturalistic study designs similar to that used in this study are crucial for evaluating acceptability and utility among web-based SSIs, as randomized trials overestimate user engagement levels for unguided, digital mental health interventions—often producing usage rates that are *4 times* greater than rates observed in real-world settings [27]. Once these interventions are disseminated outside of randomized trials, a small minority of individuals (0.5%-28.6%) complete all content [28]. Therefore, relative to real-world completion rates of other digital self-help interventions for mental health, completion rates for the 3 SSIs tested in this study (25%-57%) were extraordinarily high.

Low real-world completion rates for self-help digital interventions, especially relative to guided digital supports [26,48,49], are unsurprising; unguided supports require substantial emotional and mental bandwidth (eg, energy, sustained attention, and motivation) to find and engage with an unguided mental health support tool at the very moments when these capacities may be at their lowest (eg, when experiencing elevated distress). Our study sought to minimize the bandwidth necessary to engage with 3 single-session, unguided supports by (1) dramatically reducing their length and (2) bringing these interventions to web-based spaces where people already are. Future research should explicitly assess whether these strategies improve completion rates across other unguided digital mental health supports.

Embedding SSIs within a popular social platform (Tumblr) also likely increased the *visibility* and uptake of these SSIs. For example, after 6 months of recruitment using paid advertising and leveraging substantial media coverage, 1 study found that 700 youths viewed an open-access, web-based mental health platform featuring 3 SSIs [24]. The 3 SSIs in this study received a combined $\geq 18,800$ views within 12 months—nearly 6240 of which were views of interventions that were never featured in a Tumblr-based advertisement (Project SAVE and REFRAME). These numbers suggest considerable interest in accessible, anonymous, “in-the-moment” support options, as well as the potential to *sustainably* offer these supports at high scale and relatively low cost.

Notably, existing research identifies safety as a primary ethical concern for researchers and stakeholders interested in using digital mental health tools among youth [50]; many digital resources lack evidence or clinical validation and others may not provide sufficient protection for sensitive user data. By using SSIs that have previously been evaluated in rigorous randomized trial research [22,23] and by collecting anonymous pre- and post-SSI user data, in this study, we aimed to mitigate these common concerns. Thus, calls for clearer guidelines for safety and quality in mental health apps [51] should also be accompanied by clearer guidelines, both for academic- and industry-based program developers and researchers, on how to responsibly and ethically disseminate mental health resources via partnerships with social networking platforms.

Strengths and Limitations

This study has several strengths. Although randomized trial research overestimates user engagement for digital interventions [27], it constitutes much of the existing research on web-based SSIs to date [22,23,52]. Therefore, the naturalistic design of this study provides a valuable, more accurate estimate of the potential for web-based SSIs to offer mental health supports at scale. Koko’s partnership with Tumblr also made it possible to offer anonymous, “in-the-moment” support for people seeking mental health–related content within the platform, rather than requiring individuals to search for external resources. Finally, we conducted a fine-grained analysis of usage data (ie, dropout) going item by item for each SSI. It was especially valuable to recognize high levels of user dropout relative to page views (3%–13%) on pages requesting written responses. Further studies should seek to understand patterns in user dropout and how they may inform digital intervention design. In addition, future evaluations may also want to expand upon this study by conducting smaller-scale usability testing [53] and research explicitly designed for the in-depth analysis of rich qualitative user feedback [54].

In addition to the aforementioned strengths, this study has some limitations. First, demographic information was not available for all individuals included in this study. Demographic information that *was* available from 1 of the 3 SSIs indicated substantial missing data (several users reported skipping demographic items to ensure they could not be identified). Black, Hispanic, and Asian youths consistently access mental

health treatment at lower rates than their non-Hispanic White peers [55,56], yet up to 90% of youths in mental health clinical trials are White [57,58]. Digital interventions provide one possible avenue toward reducing disparities in access to mental health resources among racial and ethnic minority populations [59,60]; a vast majority of adolescents in the United States have internet access via either smartphones or desktops or laptops (88% and 95%, respectively) [61]. While there are disparities in broadband access by socioeconomic status, geographic region, educational attainment, and race and ethnicity, some evidence suggests that these gaps in access may be decreasing [62]. Should SSIs hope to provide truly *accessible* and *equitable* mental health supports, they must be accompanied with consistent evaluations of who has access to them, with researchers actively working to prevent further (or exacerbated) inequity via a new treatment modality [60].

In addition, as is often the case in web-based mental health support research [24,63,64], cisgender boys were underrepresented in this sample. Given unique barriers to seeking mental health treatments faced by cisgender boys and young men (eg, internalized masculine gender norms, such as “toughness”; elevated mental health stigma) [65,66], future mixed methods research may want to evaluate whether boys view SSIs as a less stigmatizing or more approachable mental health support option.

Finally, given that this study represents an unmasked evaluation of within-group intervention effects in a completers-only sample, our ability to draw causal inferences was limited. For example, those who completed an SSI may have provided more positive star ratings for the programs than those who exited before finishing the program. However, 2 of the 3 SSIs featured in this study have demonstrated positive effects on identical outcomes in large-scale, triple-masked, and randomized research [22,23]. SSIs have shown considerable promise in multiple studies and study designs.

Conclusions

Very brief SSIs (5–8 minutes) can be embedded within web-based social platforms as anonymous, in-the-moment mental health supports capable of reaching many individuals within months. Among those who complete these SSIs, individuals generally rate them as acceptable, and pre-post evaluations suggest that they may be helpful in reducing hopelessness and self-hate as well as in increasing the desire to stop self-harm. These pre-post findings, combined with results of earlier randomized trial research, suggest that SSIs delivered in this context may be a sustainable approach for providing the much-needed mental health resources, particularly for teenagers who may not have access to other mental health supports. Considering the substantial unmet need for mental health care among teenagers in the United States [67], SSIs may provide a valuable and complementary source of mental health support among a broader ecosystem of mental health treatment options (eg, school- and community-based programs, mental health screening, and gatekeeper training), all of which are necessary for reducing mental illness at scale.

Acknowledgments

JLS received funding from the National Institute of Health Office of the Director (DP5OD028123), National Institute of Mental Health (R43MH128075), National Science Foundation (2141710), Health Research and Services Association (U3NHP45406-01-00), Upswing Fund for Adolescent Mental Health, Society for Clinical Child and Adolescent Psychology, and the Klingenstein Third Generation Foundation.

MLD received funding from the Graduate Council Fellowship at Stony Brook University and has previously received research funding from the Psi Chi International Honors Society and the University of Denver Faculty Research Fund.

Authors' Contributions

JLS, RM, and MLD conceptualized the project, contributed to the study design, and developed the original versions of the single-session interventions. RM adapted the original intervention materials for integration into the Koko. MLD performed data analyses and wrote the initial draft of the manuscript. All the authors contributed to the review and editing of the final manuscript.

Conflicts of Interest

MLD receives book royalties from New Harbinger and funding from the Graduate Council Fellowship at Stony Brook University. She has previously received research funding from Psi Chi International Honors Society and University of Denver Faculty Research Fund. RM is the cofounder and chief executive officer of Koko, a nonprofit organization that receives financial aid from industry partners, private donors, and Hopelab Ventures. He also serves as a scientific advisor for Homecoming, a digital platform to help support psychedelic-assisted psychotherapy. JLS serves on the Scientific Advisory Board for Walden Wise and the Clinical Advisory Board for Koko; is the cofounder and codirector of Single Session Support Solutions, Inc.

Abstract

Background: Women in midlife are vulnerable to developing cardiovascular disease, particularly those who have conditions such as hypertension. Physical activity (PA) can reduce risk, but efforts to promote PA in this population have been only modestly effective. More attention to social influences on PA behavior may be useful, particularly social support and social comparison processes. Activating these processes with digital tools can provide easy access that is flexible to the needs of women in midlife.

Objective: This paper describes the user-centered design processes of developing and conducting initial evaluation of a personalized and adaptive web application, tailored to the social needs of women in midlife. The goal was to gather feedback from the population of interest, before and during the design process.

Methods: This study was conducted in 4 stages. The first and second authors (DA and AFL) developed technical specifications, informed by their experience with the population of interest. We collected feedback on potential content for the web application with women in midlife using both interviews (5/10, 50%; mean age 47.4, SD 6.66 years; mean BMI 35.3, SD 9.55 kg/m²) and surveys (5/10, 50%; mean age 51, SD 6.60 years; mean BMI 32.7, SD 8.39 kg/m²). We used their feedback to inform support messages and peer profiles (ie, sources of social comparison information). Nine members of the behavioral science team and 3 testers unfamiliar with the web application completed internal testing. We conducted naturalistic functionality testing with a different group of women in midlife (n=5; mean age 50, SD 6.26 years; mean BMI 30.1, SD 5.83 kg/m²), who used the web application as intended for 4 days and provided feedback at the end of this period.

Results: Iterative storyboard development resulted in programming specifications for a prototype of the web application. We used content feedback to select and refine the support messages and peer profiles to be added. The following 2 rounds of internal testing identified bugs and other problems regarding the web application's functioning and full data collection procedure. Problems were addressed or logged for future consideration. Naturalistic functionality testing revealed minimal further problems; findings showed preliminary acceptability of the web application and suggested that women may select different social content across days.

Conclusions: A multidisciplinary and user-centered design approach led to a personalized and adaptive web application, tailored to the social needs of women in midlife. Findings from testing with this population demonstrated the feasibility and acceptability of the new application and supported further development toward its use in daily life. We describe several potential uses of the

web application and next steps for its development. We also discuss the lessons learned and offer recommendations for future collaborations between behavioral and computer scientists to develop similar tools.

Introduction

Background

Cardiovascular disease (CVD) remains the leading cause of mortality worldwide, and its public health burden continues to grow [1-3]. Risk for CVD increases with age, with the increased prevalence of risk conditions such as type 2 diabetes and hypertension [4]. Women in midlife (aged 40-60 years [5]) with these conditions are particularly vulnerable; their risk is already heightened by the processes of aging [6], associated weight gain [7] and menopause transition [4,8]. Engaging in regular physical activity (PA) substantially reduces their risk for CVD [9] and has many other physical and mental health benefits for women [10]. However, the gender disparity in PA engagement that favors men across the life span widens during midlife [11], and less than half of the women in the United States in this age range meet US national PA guidelines [12]. Consequently, promoting PA among women in midlife with elevated CVD risk has received considerable empirical and clinical attention as a key pathway for improving cardiovascular health in this population [4,13].

Behavior change techniques such as goal setting, intention formation, and self-monitoring show positive effects on PA adoption and maintenance, at least in the short term (ie, 6 months to 1 year [14,15]). However, these techniques are not widely effective for increasing PA among women in midlife [16]. In addition to widespread challenges such as low motivation [17], many women in midlife face barriers to prioritizing their own health in daily life. Women in this group often serve a variety of caretaking roles in addition to other personal and professional responsibilities [18], and many perceive that taking time for their own PA is selfish [19]. Thus, there is a clear need for novel, low-burden PA resources that are tailored specifically for this population. This paper describes a user-centered design (UCD) approach to address the PA needs and preferences of women in midlife, with a tailored digital tool.

Social Influences on PA Among Women in Midlife

Great attention to *social influences on PA* in interventions may be particularly useful for women in midlife, as women in this age range often cite lack of social support for PA as a key barrier to engagement [19]. Social support for behavior change is a multifaceted construct that involves various types of behavior or communication from others. For example, informational support involves providing resources or suggestions (eg, reasons or ways to change a behavior), whereas emotional support involves demonstrating compassion (eg, encouragement or validation). Individuals differ in the type or types of support they prefer and find helpful [20], and their preferences and

responses may fluctuate across days or weeks (eg, based on mood or perceived barriers [21]). A simple way to provide support in digital interventions for health behavior change is via text-based messages, which can be assigned by the system or self-selected by users to meet their immediate needs. Common categories of support in such interventions include information (ie, advice and tips for ways to change health behaviors), encouragement (ie, motivational messages to reinforce and promote health behavior efforts or success), and accountability (ie, tips for increasing commitment to health behavior goals or plans [22]).

Similarly, social comparisons, or self-evaluations relative to others [23], show influence on PA among women in midlife. This group expresses desire for and positive subjective response to PA role models, particularly those who are similar to them (eg, regarding demographic background, caregiving responsibilities, and workload [24,25]). A range of PA-based comparisons can have positive effects. Comparing one's own PA behavior with that of someone who engages in more PA (eg, steps or minutes of aerobic exercise per day), or *upward comparison*, can provide inspiration, motivation, and guidance to achieve a similar outcome [26]. Comparing one's own PA behavior with that of someone with the same level of PA engagement, or *lateral comparison*, can provide assurance of *keeping up* to a relevant standard [27]. Comparing one's own PA behavior with that of someone who engages in less PA, or *downward comparison*, can prompt satisfaction with one's own PA behavior and motivation to continue PA efforts to stay ahead of others [28]. Importantly, both upward and downward comparisons can have the opposite effects: upward comparisons can lead to dejection and disappointment (particularly when there is a very large or consistent discrepancy between one's own and the target's PA [29,30]), and downward comparisons can confirm that one's own PA situation is bad (or likely to become so [31]), and lead to decreased PA. Lateral comparisons are least likely to prompt negative responses; however, the range of their effects is currently unclear. The consequences of all 3 types of comparisons for PA also differ between people and fluctuate within the same person over time [32-36].

Some existing studies have attempted to activate social support and comparison processes during group interventions to promote PA among women in midlife [37,38]. Others have matched intervention participants with one another to create PA partnerships that foster support and comparison, with matching based on demographic characteristics [39,40]. Findings from these studies suggest that women in midlife will engage in discussions that offer mutual support for PA between participants and will respond to social comparison opportunities (eg, by indicating that they are motivated to keep up with others

in the program or use them as role models). Importantly, however, a subset of these studies show that women differ in their responses to opportunities for support or comparison and that these opportunities can result in decreased PA motivation or behavior [39,40]. A reason for this heterogeneity in response is that existing approaches do little to ensure that opportunities for support or comparison are those that match individual preferences. Furthermore, users' preferences may not be most effective for fostering PA adoption or maintenance [41]. In addition to facilitating on-demand PA resources, digital tools that allow self-selection of support and comparison prompts can provide useful information about alignment between preferences and needs and inform improvements to intervention approaches (for women in midlife and more broadly).

Digital PA Support: Personalization, Adaptation, and UCD

Historically, evidence-based interventions to promote health behaviors such as PA have been fixed, such that all participants receive the same intervention content over time [42]. Digital tools have the potential to account for individual differences in participants' responses to intervention content. *Personalization*, or the use of specific content for its alignment with individual characteristics of the user, is intended to increase users' attention by signaling that information is meant specifically for them. Personalized content is expected to be more relevant than generic content, and thus, increase the power of communication [43]. Common personalization strategies in digital PA interventions include individualized feedback, such as customizing messages to users based on their baseline PA level, and user targeting, which adapts content based on user demographics (eg, gender and BMI [44]).

However, even personalized interventions can be insufficient, as they do not account for changes or natural fluctuations in users' needs and preferences. This is a key issue for digital behavior change tools; personalization may only address who a user was in the past, rather than who they currently are, or may not meet a user's needs in the moment [45]. *Adaptation* is a more advanced form of personalization, whereby application content is adjusted based on recent or immediate context [44]. This ensures that digital tools communicate information to users as it is currently relevant, rather than relying on data collected when the user adopts the tool initially. For example, a digital tool may account for a user's recent daily steps when delivering feedback in an intervention for PA, so that the feedback is relevant to that day's PA behavior. Digital platforms may be most effective when they are both personalized and adaptive [46,47]. As noted, there are individual differences and time-related and context-related variations in individuals' preferences for and behavioral responses to social support and comparison, both generally [36,48,49] and specifically among women in midlife who have elevated CVD risk [32,50].

Effectively personalizing and adapting digital platforms require a detailed understanding of the target population. *UCD*, which encompasses several principles and methods aimed at deeply understanding intended end users [51], is widely used in industry settings (eg, product or service development) and is steadily gaining attention in academic research as the demand for

engaging digital health platforms and services grows. UCD is iterative—new insights are used to drive and refine development throughout the process (eg, user testing informs design modifications). UCD methods have been used to develop digital health tools for many health behaviors and outcomes, including weight control and binge eating (via digital diaries and personas [52]), medication adherence (via interviews, needs assessments, and focus groups [53]), and chronic obstructive pulmonary disease (via background analysis, prototyping, and usability testing [54]). With respect to digital PA tools, UCD methods have been used to personalize apps for walking among breast cancer survivors (via needs assessment, prototyping, and usability testing [44]), sitting time reduction among office workers (via usability testing and user interviews [55]), and leisure time PA among adults living in close proximity to parks (via needs assessment and user evaluation [56]). Few existing studies, if any, have used UCD principles to develop resources for women in midlife, and no existing study has developed a digital PA tool specifically for this population.

Aims of This Study

There is a clear need for more effective PA promotion resources for women in midlife, and digital tools are appealing because of their flexibility and ease of access. To address this need, our team of behavioral and computer scientists developed a personalized and adaptive web application that is tailored to the needs of this population. This tool is accessed via a web browser and allows users to self-select PA-related social support and social comparison opportunities, which are intended to bolster PA self-efficacy and motivation. Other behavior change techniques activated by the web application include PA self-monitoring, goal setting, and intention formation or planning [26,57]. Social support is provided via short, text-based messages, and comparisons are prompted via exposure to the profile of a peer. As described in the following sections, personalization occurs with respect to the user's age and racial and ethnic identification, and the application adapts to the user's level of PA behavior at each use. Of note, the web application is designed for brief, repeated use—specifically, 10 minutes per day for multiple consecutive days—on days when users wear a PA monitor (eg, pedometer or Fitbit). This allows for the assessment of variability in selections and responses, including subjective perception of selected content and objective PA behavior on a given day.

The overarching goal of this paper was to describe the UCD process of developing and conducting the initial evaluation of the web application prototype, including the results of feasibility, acceptability, and functionality testing with real end users from the target population of women in midlife with elevated CVD risk. We also note some of the lessons learned and present recommendations for future collaborations between behavioral and computer scientists to develop similar digital tools. This study was conducted in four stages: (1) initial application development, (2) feedback on the potential content of the web application (ie, content of peer profiles and messages) from the population of interest, (3) internal functionality testing, and (4) functionality testing with a different set of participants from the population of interest. [Table 1](#) provides a summary of the goals, users, and methods for each stage.

Table 1. Summary of the 4 stages of web application development and testing.

Stage	Goal	Users	Methods
Initial development	Final storyboard and specifications to guide prototype programming	N/A ^a	Discussions between investigators, iterative storyboard generation, and feedback
Content feedback	Selection of profile images, formats, and messages in response to end users' input	A total of 10 women in midlife, with ≥ 1 CVD ^b risk conditions	In total, 5 qualitative interviews and 5 survey responses
Internal testing			
Round 1	Identification of bugs or other problems to address with respect to web application functioning	A total of 9 behavioral science trainees (clinical psychology and health behavior) who were familiar with the web application	Totally, 9 sets of positive and negative testing
Round 2	Identification of bugs or other problems to address with respect to full data collection procedure	A total of 3 behavioral science trainees (clinical psychology) who were not familiar with the web application	In total, 3 in vivo tests, each over 3 days (morning web application use, pedometer wear, and end-of-day survey)
Naturalistic functionality testing	Identification of bugs or other problems to address with respect to full data collection procedure and obtaining end-user feedback	A total of 5 women in midlife, with ≥ 1 CVD risk conditions	In total, 5 in vivo tests, each over 4 days (morning web application use, pedometer wear, and end-of-day survey)

^aN/A: not applicable.

^bCVD: cardiovascular disease.

Methods

Description of Web Application Content and Use Flow

Each user was provided a study identifier and unique link to the web application. Their researcher-created profile included their age and racial or ethnic identification, for personalization (see next paragraph); the web application does not collect any identifying information during use. The initial page of the application reminds users about the content they will encounter and instructions for optimal use of the application (eg, allocate approximately 10 minutes to engage with it via a web browser each morning). Then, the users are guided to report their step and active minute goals for the day from their PA monitors and reflect on their satisfaction with their PA behavior from the previous day.

Next, social comparisons are prompted by exposure to a peer profile, which shows an image of a fictitious peer and brief text with this peer's characteristics (ie, another woman who appears to be between 40 and 60 years of age, who is interested in increasing her PA; refer to [Figure 1](#) for an example). Each profile text lists the peer's average number of steps and active minutes per week, their favorite way to be physically active, their biggest challenge to being active, and their social context (ie, work situation, family, and caregiving responsibilities). Users can select one of four options: a highly active peer (upward target), a moderately active peer (lateral target), a

not-so-active peer (downward target), or *no preference*. In the latter case, the system randomly selects an upward, lateral, or downward target with equal probability.

For the first peer shown at each daily use, personalization is achieved by showing images of peers whose age and racial or ethnic background align with those of the user; users who do not provide a racial or ethnic identification are indicated as race or ethnicity unspecified and view a peer image whose identification is randomly selected at each use. Each image is tagged with 2 relevant age ranges and 2 relevant racial or ethnic identifiers. Within these specifications, the application randomly selects an image and peer text from a database for each profile, ensuring that a user is not shown the same image or text on 2 consecutive profiles. Adaptation occurs by anchoring the peers' average daily steps and active minutes to the user's reported PA behavior from the previous day, and peers' PA metrics are updated every day in response to changes in the user's PA behavior. Specifically, highly active peers' steps and active minutes are 130% of that of the user from the previous day, moderately active peers' PA is 95% to 105% of that of the user from the previous day, and not-very-active peers' PA is 68% of that of the user from the previous day. If PA behavior data are unavailable for the previous day, these adaptations are made using prespecified ranges. Users review the provided peer profile and then respond to a series of questions about their perceptions of the peer described.

Figure 1. Web application screens that facilitate selection for peer profiles (social comparison targets) and messages (social support sources).

Peer Profile Selection

You have the opportunity to learn more about one of your peers and their progress toward their physical activity goals. Who would you like to learn about today?

- Peer #1: very active
- Peer #2: somewhat active
- Peer #3: not very active
- No preference - choose for me

Message Selection

Which type of physical activity message would you like to see now?

- Encouragement to help me stay on track
- More information on someone else's progress
- Tips for being more active
- Holding myself accountable
- No preference - choose for me

Following peer profile reflections, social support is provided via exposure to a brief support message. Users are able to select one of four options for message category: encouragement, tips (ie, suggestions for ways to be more active and information about the benefits of activity for women), accountability (ie, suggestions for holding yourself accountable to your PA goals), or *no preference*. In the latter case, the system selects the user's least-recently-used message category. Then, the system randomly selects encouragement, tips, or accountability message from a database (Figure 1). The system ensures that a user is not shown the same text on 2 consecutive messages. Users review the provided message and respond to a series of questions about their perceptions of the message, including how helpful they found it to be.

After completing these items, users are asked whether they would like to see a third message (yes or no). Those who select

no are directed to the last set of questions for the day, which prompts PA intention formation via text entry. Those who select *yes* are offered a new set of options: encouragement, tips, accountability, another peer, or no preference. Users who attempt to select the same message category twice in the same use episode are prompted to *keep things interesting—select another type of message*, and the system does not allow them to move forward until they select a different category. Users who select to view a second peer for the day are not able to choose the type; they are randomized to a profile using the rules described previously for a *no preference* selection. After viewing the third message, the user responds to a series of questions about their perceptions and then is prompted to form PA intentions or plans via text entry, as described previously. [Textbox 1](#) lists all the behavior change techniques activated by web application use.

Textbox 1. Physical activity (PA) behavior change techniques activated by the new web application.

<p>Self-monitoring</p> <ul style="list-style-type: none"> • Use of pedometer, which is worn on days of web application use • Reflection on the previous day's PA progress <p>Goal setting</p> <ul style="list-style-type: none"> • Identification of step and active minute goals for the day <p>Social support</p> <ul style="list-style-type: none"> • Selection of support message type to support PA motivation and behavior • Reflection on message content and application <p>Social comparison</p> <ul style="list-style-type: none"> • Selection of comparison type (peer profile) to support PA motivation and behavior, personalized to match user's age and racial or ethnic identification and based on user's recent PA behavior (adapted to steps and active minutes) • Reflection on response <p>Planning or intention formation</p> <ul style="list-style-type: none"> • Open-ended response to the following prompt: "Please describe your plan for reaching your activity goals today. How will you get your steps or active minutes in today?"
--

Recruitment and Participants

Initial Application Development

PhD-level researchers in clinical health psychology (DA) and computer science (AFL) met regularly throughout 2019 and 2020 to develop the purpose, functions, and technical specifications of the web application (described in detail in the *Procedures* section). Both investigators were women; 50% (1/2) of them identified as White and 50% (1/2) identified as Latina.

Content Feedback From the Population of Interest

Women from the target population were recruited for 90-minute feedback interviews conducted via Zoom (Zoom Technologies, Inc). Eligibility criteria required that women be aged between 40 and 60 years (inclusive), with ≥ 1 risk conditions for CVD (ie, hypertension or prehypertension, prediabetes or type 2 diabetes, hyperlipidemia or hypercholesterolemia, metabolic syndrome, current smoker, or quit smoking in the past 3 months); that they were not currently pregnant; and that they had access to Zoom for the interview. Recruitment was conducted via electronic advertisements posted to the supporting institution's announcement service and social media sites such as Twitter. Interviews were conducted in January 2021. Of the 6 women who were initially contacted about their interest, 5 (83%) enrolled and completed the interview. The average participant's age was 47.4 (SD 6.66) years and BMI was 35.3 (SD 9.55) kg/m^2 . As all but one of these participants (4/5, 80%) identified as White, 5 additional participants were recruited to provide feedback via electronic survey, to ensure representation of perspectives of women from a range of backgrounds. For this group, the average participant's age was 51 (SD 6.60) years and their BMI was 32.7 (SD 8.39) kg/m^2 . Of the 5 participants who completed the survey, 2 (40%) identified as Black, 2 (40%) identified as Latina, and 1 (20%) identified as East Asian.

Internal Functionality Testing

Investigators familiarized their team members (ie, not users from the target population) with the application's purpose and previous stages of development. Then, the entire team conducted internal testing to confirm that the application functioned as intended. A total of 9 testers were included in the first round, of which 3 (33%) were doctoral students, 4 (44%) were undergraduate students in psychology, 1 (11%) was PhD-level program manager, and 1 (11%) was PhD-level investigator in clinical health psychology. All of them have backgrounds in digital health research. Of these 9 testers, 5 (56%) were women and 7 (78%) identified as White. In the second round, testers were 3 doctoral students in clinical psychology, without familiarity with the web application. All of them (3/3, 100%) were women aged 25 to 30 years; 67% (2/3) of them identified as White and 33% (1/3) identified as Black.

Feasibility, Acceptability, and Functionality Testing With the Population of Interest

Women were recruited using electronic advertisements posted to the supporting institution's announcement service and social media sites (eg, Twitter), to engage in 4-day naturalistic functionality testing. In addition to the eligibility criteria described for content feedback, eligibility required that women did not have an active injury or illness that impeded their PA. A total of 11 women expressed interest in participating, and 5 (45%) women enrolled and completed these tests in June 2021. The average participants' mean age was 50 (SD 6.26) years and BMI was 30.1 (SD 5.83) kg/m^2 . Of the 5 participants, 2 (40%) identified as Black, 1 (20%) identified as Latina, and 2 (40%) identified as White. None of these women (0/5, 0%) participated in the earlier phases of this study and thus, were naïve to the content of the web application. These users tested the application each morning for 4 consecutive days. They also wore either their personal PA monitors or a study-provided pedometer,

completed end-of-day surveys on each day, and engaged in a brief exit interview at the end of data collection.

Measures

Content Ratings (Initial Feedback)

Qualitative responses were noted for participants' impressions of peers' ages, racial or ethnic backgrounds, and professional circumstances for each image shown and for preferences regarding peer profile content. Participants who engaged in the initial interviews were asked to rate each PA message on a scale of 1 (*not at all*) to 10 (*extremely*), regarding (1) how much they liked each message and (2) how helpful they thought it would be for supporting their PA behavior. Participants were asked to briefly articulate their reasons for these ratings.

PA Monitors and End-of-Day Surveys (Second Phase of Internal Testing as Well as Feasibility and Naturalistic Functionality Testing)

Women who participated in the second phase of internal testing (3 trainees; 3 days each) and in feasibility/naturalistic functionality testing (5 women in midlife; 4 days each) wore a PA monitoring device during each test day. These participants used either their own personal device (eg, Fitbit or Apple Watch; worn on the wrist) or a study-provided Accusplit AX2720MV pedometer (worn on the waist or hip). These devices captured steps and active minutes (ie, high-intensity activity) throughout the day, and participants reported their totals from these devices at the start and end of each day. Participants reported their starting PA at the start of web application use each morning and daily totals in end-of-day surveys (sent via SMS text message or email).

Web Application Use and Technical Problems (Second Phase of Internal Testing as Well as Feasibility and Naturalistic Functionality Testing)

We determined the feasibility of web application use as intended by the percentage of times the application was accessed successfully and returned no errors (or other noteworthy problems), relative to the number of expected uses. Additional relevant data were related to devices and browsers used to access the web application, nature and replicability of reported errors, and application navigation information (eg, peer and message category selections).

Exit Interview (Feasibility/Acceptability/Naturalistic Functionality Testing Only)

Women in midlife who completed feasibility/naturalistic functionality testing engaged in a brief exit interview after the end of their tests, conducted via Zoom (15-30 minutes). Participants were asked about their overall experience with the web application, each component of the application, and whether they would be interested in future use. Given the complexity and lack of consensus regarding measuring acceptability in digital health research [58], responses in these domains were used to informally summarize participants' views of acceptability (as described in the following sections).

Procedures

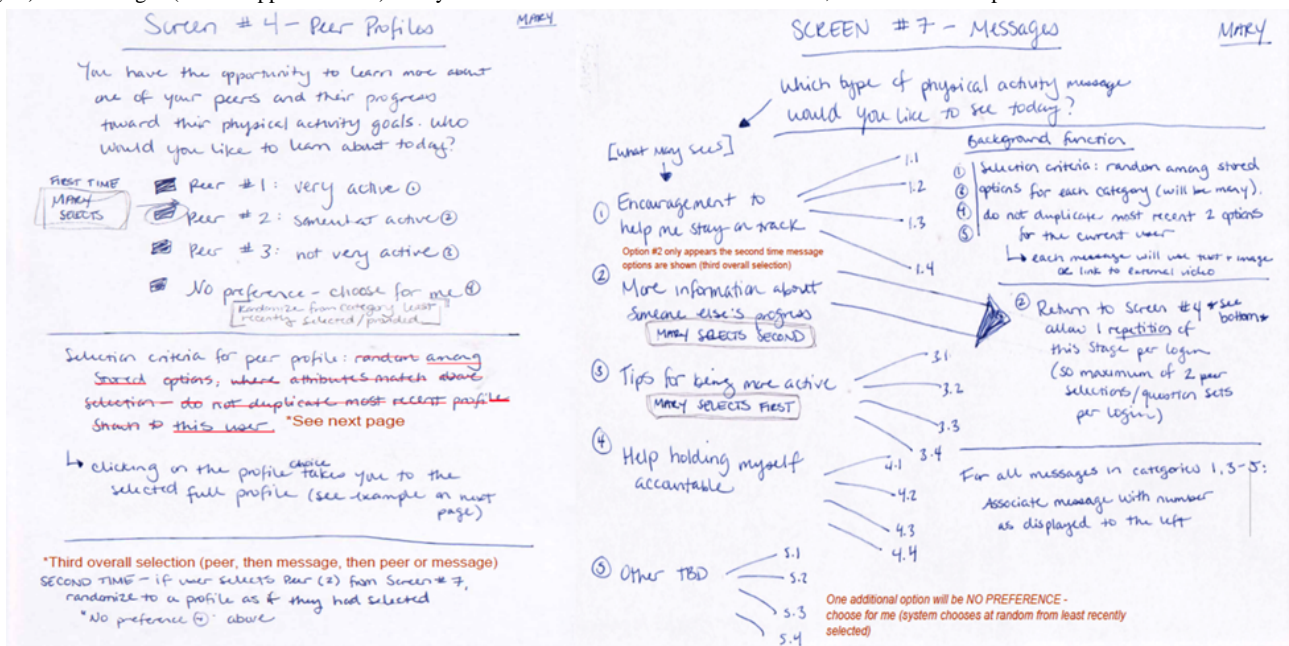

Initial Development

Collaboration began in 2018, with support from internal and external funding provided to the first author (DA). Investigators met regularly in 2019 and 2020 to discuss the goals of a new tool, how it may be tailored to the needs of women in midlife with elevated CVD risk, and the process of identifying technical specifications. Although we considered a stand-alone mobile app as the outcome, we selected a web application owing to its versatility and ease of access across devices and platforms. During this time, the first author built on her previous studies with the population of interest [37,39,59] by conducting additional observational and qualitative studies [32,33,60,61] and collecting preliminary data to assess their needs and preferences. Insights from previous studies, discussions between investigators, and new participant responses informed the refinement of the goals of the new tool.

In the spring and summer of 2020, investigators developed storyboards to specify the requirements of the web application. We developed a total of 7 storyboard drafts using an interactive process, which was led by the first author (DA) and modified with questions and input from the computer science expert (second author [AFL]). Figure 2 shows screenshots of the final storyboard, illustrating some of the important steps of the user experience with the web application. This resource included 37 sheets describing the intended progress through 15 pages of the application, including descriptions of progress for 2 fictional users and skeleton of a database that would house participants' selections and responses as they used the application. The storyboarding process led to the creation of a penultimate set of technical specifications, which the computer scientist (AFL) used to develop the code for the initial draft of the application.

Development of the application occurred during the summer and fall of 2020. We chose the Django framework for its integration of front-end and back-end development and its secure superuser view that allows team members to edit the database entries for peer texts and support messages. The application was deployed on an Amazon Web Services ec2 instance using the SQLite database. During this time, the first author (DA) and trainees in behavioral science created a preliminary set of peer profiles and support messages. This included images, profile text, and message text. Images of women who appeared to be aged between 40 and 60 years were selected from open-access web-based databases [62] to represent a range of racial or ethnic and professional backgrounds. Profile text was generated based on the investigators' knowledge of and experience with prompting PA-based social comparisons, creating 5 versions of the same 2 profiles that offered different levels of detail. Finally, 18 support messages (6 each for encouragement, tips, and accountability) were generated based on those used in previous studies [63-65], with modifications to address the needs of women in midlife and attention to the possibility of limited access to fitness facilities during the COVID-19 pandemic (eg, exercises that are easy to do at home, without equipment).

Figure 2. Pages from the final version of the web application storyboard, describing content and function for selection of peer profiles (social comparison targets) and messages (social support sources). Mary refers to the selections of a fictitious user, to indicate the expected flow.

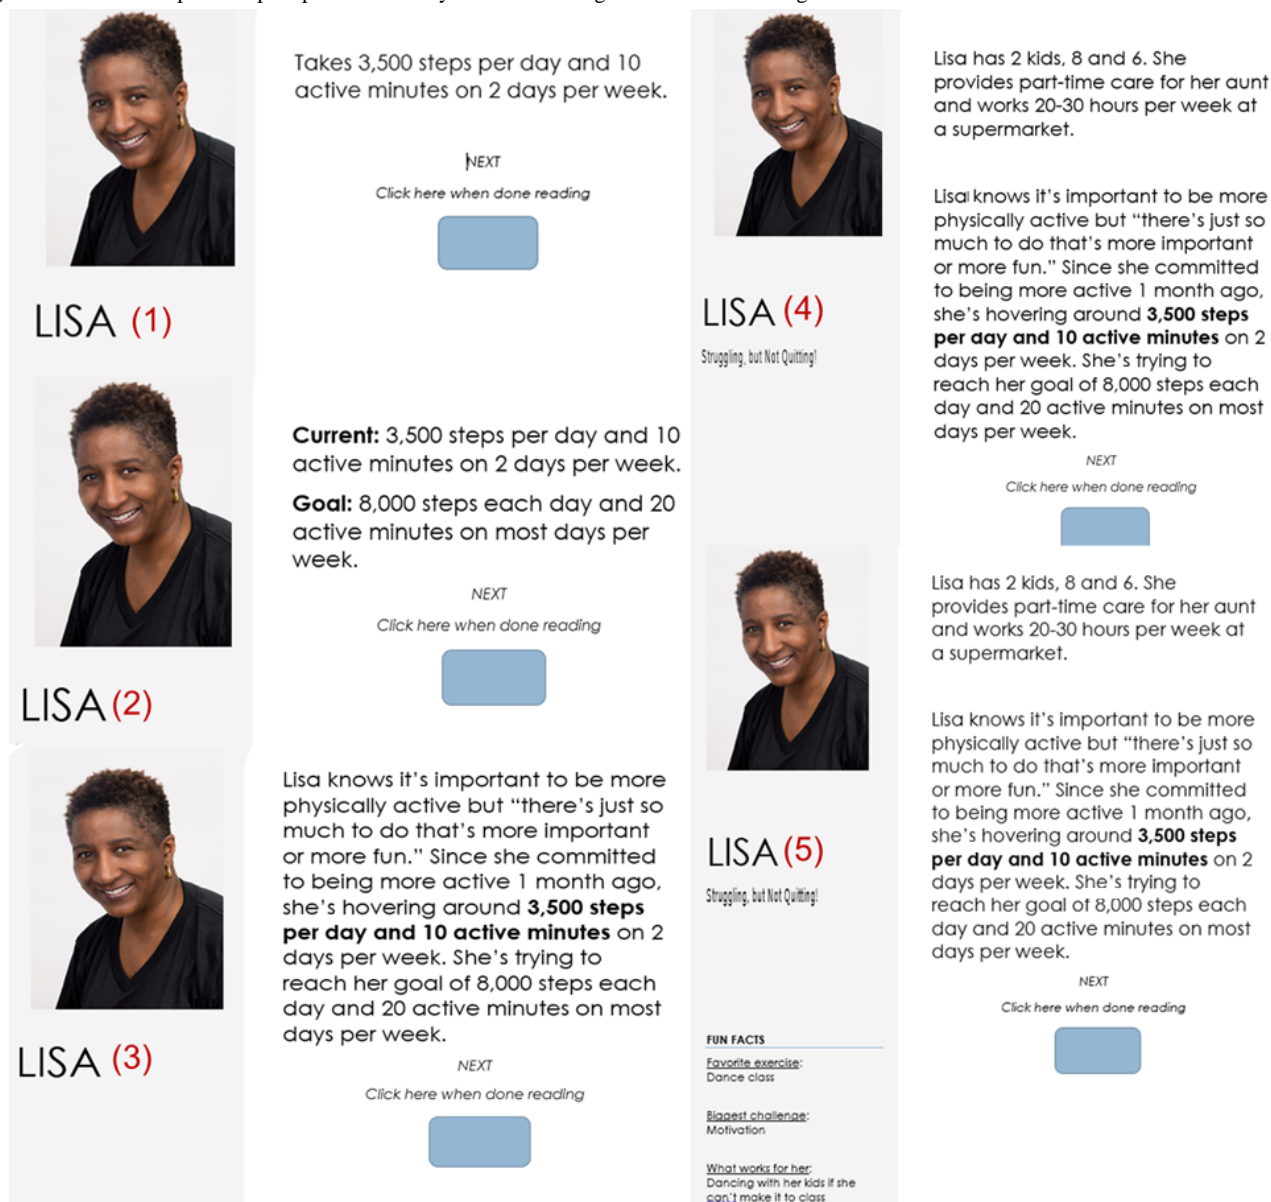

Content Feedback With the Population of Interest

Procedures were approved by the supporting institutional review boards (IRBs), and the participants provided written informed consent via Adobe electronic signature (5/10, 50%). Participants met with the first author (DA) for individual, 90-minute interviews via Zoom. These interviews focused on gathering women’s perceptions, preferences, and suggestions for improvements to sample peer images, profile text, and messages. After initial overview of the session and introduction to the purpose of the web application, participants were asked to view a series of peer images and indicate their perceptions of the woman’s age, racial or ethnic identification, and profession. Then, they viewed 5 versions of each of the 2 peer profiles and were asked to verbally evaluate each version (ie, strong vs weak preference for each, relative to the previous version, and their reasons). These profiles showed minimal information initially and increased in the number of facts presented in each version (Figure 3). Next, participants were asked to read each of the 18 messages and rate each one on the scales described previously.

Finally, they were asked to rate their interest in using the web application to support their PA efforts in the future on a scale of 1 (not at all interested) to 5 (extremely interested). Women who provided feedback via electronic survey (5/10, 50%) provided informed consent by clicking a button to verify that they consented to proceeding with the survey; they were given a brief explanation of the web application and asked to respond to a subset of the stimuli described previously.

The interviewer (first author [DA]) took detailed notes during the Zoom feedback sessions to capture numeric ratings, narrative explanations for these ratings, and other suggestions from participants. Then, the interviewer and another member of the behavioral science team reviewed and synthesized these notes and responses from the participants who completed the survey. They identified common themes and recommendations for changes, which were implemented as described in the following sections. A third member of the behavioral science team was consulted for input on messages that received a wide range of responses, and disagreements about changes were resolved by consensus.

Figure 3. Versions of possible peer profiles rated by end users during content feedback stage.

Internal Functionality Testing

In the first phase, research team members were randomly assigned to user accounts representing women in the target age range, from varying racial or ethnic backgrounds, and asked to conduct a series of tests of the web application. First, they completed a round of positive testing (using valid data entry) to verify that the application worked as expected. Then, they completed a round of negative testing (using invalid or improper data entry) to check for unexpected conditions. Each user conducted between 5 and 20 tests over the course of 4 months, with application updates occurring between each round of tests (February 2021 to May 2021). A subset of team members (5/9, 56%) also exported data files for recent use episodes to check for errors in recording the use variables in the database.

Users in the second phase of testing received instructions via email for testing the application between 8 AM and 9 AM each day for 3 consecutive days, wearing their personal PA monitors, and completing end-of-day surveys on each day. Of the 3 users,

1 (33%) user tested as a woman with racial or ethnic identification the same as her own (Black), and 2 (67%) tested as women not matched to their racial or ethnic identification (the White trainee users tested as a Latina woman and as a woman whose identification was unspecified, respectively). End-of-day surveys were sent via SMS text messages at 9 PM each night and were completed via mobile device by 9:45 PM. Before users accessed the web application on the following day, members of the research team entered their step and active minute totals to the application, to enable adaptation of the PA levels shown in peer profiles. The investigators were available during the application test window each morning (8 AM to 9 AM) to receive and address reports of errors and access difficulties.

Feasibility, Acceptability, and Functionality Testing With the Population of Interest

All procedures were approved by the relevant IRBs, and participants provided written informed consent via Adobe electronic signature (5/5, 100%). Each participant met with the

first author (DA) via Zoom for introduction to the web application and study procedures, during which the first author used screen share to show participants an episode of web application use in real time. Participants who requested to use a study pedometer (3/5, 60%) received these devices and printed instructions in the mail before this meeting (with prepaid postage for the return mailing) and were invited to ask questions about intended use for data collection. Next, participants received an overview of the end-of-day survey content and procedures and engaged in a live test of receiving surveys via SMS text messages. The interviewer collected information about participants' wake and sleep times and discussed their preferred time for using the application and receiving end-of-day surveys, according to their wake and sleep times. Specifically, participants were asked to use the web application within 2 hours of waking up and to complete the end-of-day survey within 1 hour before going to sleep. The investigators were available during the application test windows each morning to receive and address any reports of errors or access difficulties. Finally, before participants accessed the web application on the following day, the first author entered the step and active minute totals to the application, to enable adaptation of the PA levels shown in peer profiles. Following the procedures outlined previously, the interviewer (first author) took detailed notes during the Zoom exit interviews to capture participants' views of acceptability. The interviewer and another member of the behavioral science team reviewed and synthesized these notes to generate a summary of the acceptability feedback.

Ethics Approval

The IRB at Rowan University approved this study (PRO-2020-163).

Results

Development

Refinement of the initial idea for the web application occurred over a period of 1 year. This period involved regular discussions among investigators, storyboarding, identifying technical specifications, and designing a database. Investigators created 7 drafts of the web application storyboard using a process of iterative feedback. At each stage, discussions generated questions to be answered and functions to be refined, which would allow for individual user personalization and day-to-day adaptation. The initial version of the storyboard used 8 pages to describe the 9 distinct screens needed to achieve a full-use episode. The final version used 37 pages to specify back-end decision points, 15 distinct screens needed to achieve a full-use episode, and full examples of 2 different users' experiences of a full-use episode. Separate files illustrated the database (where users' selections, entries, time spent in using the application, and end-of-day data are collected and stored), administration pages (for creating users, entering end-of-day data, and downloading database files), and a penultimate set of technical specifications. The software implementation, deployment, testing, and support tasks required approximately 3 months of effort from the computer science expert (second author [AFL]). Finally, we deployed and tested the web application as described previously.

Content Feedback

Gathering feedback on potential web application content occurred during the later stages of programming, over a 4-week period. Participants who engaged in 90-minute interviews via Zoom (5/10, 50%) reported strong overall interest in using the web tool under development to support their PA efforts (mean score 4.5 out of 5). Regarding peer images, there was high agreement regarding perceived age (87%), racial or ethnic background (88%), and types of careers (85%). A total of 2 images were perceived as depicting women aged between 40 and 46 years, 3 images as women aged between 45 and 52 years, and 2 images as women aged between 52 and 60 years. A total of 3 images were perceived as depicting Black women (or multiracial with Black as an identification), 4 as Latina women (or multiethnic with Latina as an identification), 2 as White women (or multiracial with White as an identification), and 1 as Middle Eastern or South Asian (Indian or multiracial with one of these as an identification). A total of 3 images were described as portraying women with administratively focused jobs (eg, office assistants and business managers), 2 as teachers, and 3 as other (eg, coaches and retired). All images were deemed acceptable for the stated purpose, and participants indicated that some variety across images (eg, in types of clothing) may make the peer profiles relatable to a wide range of women in midlife.

A total of 2 images were perceived as *intimidating* by ≥ 1 participant. The first image was described as projecting a "no nonsense" attitude (however, still moderately welcoming), whereas the second appeared to "have it all" (ie, fit, affluent, and carefree). These happened to be the 2 images used for the next set of prompts related to the amount and types of information that participants perceived as useful for inclusion in peer profiles. For this set of prompts, the participants viewed 5 different versions of each woman's profile, each increasing the amount of information presented. For both profiles, participants indicated that the middle version provided the optimal amount of information (ie, version 3 in [Figure 3](#)). Although 60% (3/5) of the participants specifically expressed interest in the addition of *fun facts* in each profile (as these made the profiled women seem more *relatable*), they indicated that the short versions were the best for providing useful information efficiently.

Participants' overall recommendations for PA messages were to keep them short; however, there was considerable heterogeneity in the subjective response to each message. Consider the following message: "We're often told how important physical activity is to our health. But why is it important to you? Remind yourself of YOUR reasons to be more active." This message received a score of 0 from one participant (regarding how much she liked the message and found it helpful); she indicated that the message implied that PA "must not be important if I'm not doing it," which was not motivating. However, the same message received a score of 10 from another participant (who said it was "thought-provoking and affirming"), and the average ratings for liking and helpfulness were 6.2.

Examples of the highest-rated and lowest-rated messages are listed in [Table 2](#). The lowest-rated messages were removed or

substantially revised; all other messages received minor adjustments to wording or formatting (eg, whether parts of the text were underlined or bulleted), based on participant feedback.

Table 2. Sample messages and ratings and comments by end users, obtained during the content feedback stage.

Messages	Ratings (1-10 scale)		Comments
	Liking, mean (SD); range	Helpfulness, mean (SD); range	
Do you schedule meetings and appointments on your calendar, and usually show up to them? Could you do the same for physical activity? Make it easy – add time to be active on your calendar, and make it a point to show up like you would with any other obligation!	4.1 (1.67); 3.5-7	4.3 (2.11); 3.5-7	<ul style="list-style-type: none"> “I agree that this could work but it causes me stress - I have too many appointments already.” “This is a good suggestion, but reword it so that it’s not asking so many questions.”
Do you have responsibilities such as childcare, or taking care of others you care about? Lack of time or energy due to these responsibilities can make physical activity difficult, but it doesn’t mean that you can’t be more physically active. Try going for walks, light stretching, or standing while watching TV. You can do all this with your loved ones, or try it during short windows when you have a moment to yourself.	5.4 (2.97); 2-10	5.3 (1.99); 2-7	<ul style="list-style-type: none"> “This one is really long and it’s not personal - seems too general.” “Too long but it’s a good reminder.”
You don’t have to work on your physical activity goals alone! Support from family and friends can help you to achieve your goals. Let someone close to you know about your goals, so they can provide you with support and help hold you to them!	8 (2.12); 5-10	7.8 (1.92); 5-10	<ul style="list-style-type: none"> “This is good advice. It helps hold you accountable to tell someone else.” “If I were going to do this I would have done it already.”
When setting physical activity goals each week, try to make them clear and measurable. Instead of a goal of “walking more,” try: walking 3 times this week for 10 minutes each time. This will help you stay on task and make it easier to know when you’ve met your goal. Then you get a sense of accomplishment when you know you’ve met your goal!	8.3 (1.20); 7-10	8.1 (1.34); 7-10	<ul style="list-style-type: none"> “I like this a lot. It’s clear and actionable.” “I agree! Great suggestion.”

Internal Testing

Round 1

Of the 25 positive tests conducted, 2 (8%) resulted in initial errors, and they were resolved. A further 16% (4/25) of the tests revealed bugs, including failing to offer a second message and repeating the same content twice in 1 use episode. Both of these problems were resolved after the conclusion of round 1 testing. Negative testing (involving 20 use episodes) identified two application navigation pitfalls: using the back button allowed for many selections in the same use episode and entering spaces or other non-language-based text was accepted as valid responses to the open-ended questions. Across both types of tests, several team members also indicated that certain details of peer profiles did not match their intended ages. For example, a subset of photos of women in their late fifties was paired with profiles describing them as having very young children.

At the end of round 1, the investigators consulted and agreed that the application should insist that the user proceed strictly in the order described previously, irrespective of the user’s attempts to use their browser’s back button. The second author (AFL) made system modifications such that the user is required to complete a day’s survey on a single device and browser, and the user’s attempt to use their browser’s back button redirects them to the next screen. These updates were completed before the functionality testing with end users. The application specifications did not include procedures for preventing

nonlanguage text responses to the open-ended questions. In contrast, the peer profiles were intended to be tagged with age indicators (similar to peer images), but this step was skipped in the build process. As the latter two issues were deemed substantial revisions, they were noted and postponed until a future round of substantive updates.

Round 2

Across 3 testers and 3 days of use episodes (total of 9 episodes), 11% (1/9) of the test uses of the web application resulted in an error. The error for the assigned client could not be resolved and the tester was assigned a new client ID. After this substitution, all use episodes were successful, and all end-of-day surveys were completed as intended. Of the 3 testers, 1 (33%) tester noted that she received the same message twice in the same use episode, despite choosing different message categories, and this error was logged for correction. All testers (3/3, 100%) expressed their perception that the web application would be useful for supporting women’s PA efforts and indicated that the web application’s personalization and adaptation features were effective for tailoring their experience of peer profiles. Testers also offered additional feedback on the wording of peer profiles, messages, and end-of-day surveys to clarify the specific experiences of interest (eg, a missing text box for entering details if the *other* response to a multiple-choice item was selected).

Feasibility, Acceptability, and Naturalistic Functionality Testing

Testing with a different group of women from the target population was conducted over 4 weeks. All the participants (5/5, 100%) were able to access the web application on their personal devices. This included the use of desktop and laptop computers, tablets, and smartphones, across Chrome and Safari browsers. A total of 60% (3/5) of the participants did not encounter any errors or problems with access on any of their days of participation. Of the 5 participants, 1 (20%) participant received an error after starting use (ie, getting to the starting page without entering any data), closing her browser, and attempting to restart later. As the application allows only 1 use per client per day, this difficulty demonstrated correct functionality. The participant was able to access the application on the same day after her first attempt was deleted by the research staff. The final participant received error messages for attempts to access the web application on her smartphone but encountered no problems when she switched to her laptop computer the following day. The initial problem could not be duplicated by the research staff but was noted in case of repeated difficulties. Thus, of the 20 expected use episodes (5 participants; 4 days each), 18 (90%) were completed and resulted in use data without incident and the remaining 2 (10%)

were missing, owing to access difficulties described previously. In total, 85% (17/20) of the episodes were informed by previous end-of-day step and active minute totals.

Participants' peer profile and message selections are summarized in Table 3. Across participants and use episodes, initial peer type selections were most frequently lateral or downward targets (6/18, 33% each). Upward targets and *no preference—choose for me* were selected during 17% (3/18) of episodes each, by a different participant each time; *no preference* was selected on different days of use each time, whereas 67% (2/3) of the selections of upward targets were on the last days of use. All of the participants (5/5, 100%) selected at least two different peer options. Of the peers actually displayed, lateral or downward targets were seen in 39% (7/18) of episodes each, and upward targets were seen in 22% (4/18) of episodes. As noted, these directions were relative to participant's PA behavior on the previous day. Initial message type selections were predominantly those providing accountability (7/18, 39%), followed by encouragement (6/18, 33%) and tips (3/18, 17%). *No preference—choose for me* was selected only twice, by a different participant and on a different day of observation each time. A second peer and an encouragement message were chosen twice each; a tip message and *no preference* were selected once.

Table 3. Summary of peer profile and message selection types during end-user functionality testing stage (5 users; 4 days each).

Categories	Selections of episodes (n=18), n (%)
Upward peer	3 (17)
Lateral peer	6 (33)
Downward peer	6 (33)
No preference for peer	3 (17)
Encouragement message	6 (33)
Tips message	3 (17)
Accountability message	7 (39)
No preference for message	2 (11)

During the exit interviews, all participants (5/5, 100%) indicated that their overall experience with the web application was positive; 80% (4/5) of them indicated that they found the application very helpful in setting a positive tone for their PA for the day and reminding them to be more active. For example, a participant stated that she noticed herself walking her dog more often as a way to increase her PA. The final participant reported that she found the web application acceptable. As she was previously very active and used several of the application's suggested approaches at that time, the content was "not new" to her. However, she reported an expectation that it would be useful for someone just starting an effort to be more active. All participants (5/5, 100%) indicated that they would be interested in using an expanded version of the web application to support their ongoing PA efforts, with 60% (3/5) of them specifying that use would be most beneficial in conjunction with PA coaching (ie, additional, formal guidance to build behavioral and psychological skills).

Discussion

Principal Findings

Women in midlife—particularly those who have health conditions that exacerbate their increasing risk for CVD—would benefit from PA-specific resources that address their social preferences and needs. This paper describes a multidisciplinary, iterative, UCD approach for developing a personalized, adaptive web application for this purpose. Our approach involved four stages: initial design and building, gathering content feedback, internal testing, and naturalistic functionality testing with end users. Changes were made to the application's content, function, and navigation in response to feedback at each stage, which resulted in a prototype that showed evidence of feasibility and acceptability among the target population.

Our initial findings also suggest the possibility of heterogeneity in the PA preferences and experiences of women in midlife. Some social content was consistently rated as favorable, whereas other content generated wide ranges of favorability, and women

showed noteworthy variability in their support message and peer (comparison target) selections in their daily lives. Some of this variability may be due to curiosity and desire to explore the available options [66,67]. The content that women in midlife want or believe will be most helpful also likely varies from day to day (eg, with mood and other contextual factors). An important next step is to conduct studies with long test periods and large samples to determine the extent of stability versus ongoing variability in women's selections and responses. Incorporating UCD principles and methods throughout the development process provided insight into the needs and preferences of our target population. By taking an iterative approach, we identified issues early, which allowed for refinement before further testing. This process was made easy by regular, planned discussions between the behavioral science and computer science teams and ensured a shared vision and scope for the project.

Uses and Future Directions for a New PA Web Tool
