There are multiple potential uses for our new web application, and our future studies will investigate the utility of the tool for each purpose. First, as suggested by members of the target population, this tool may be used as an adjunct to and extension of more traditional PA coaching. Individual or group-based coaching, which often occurs via live interaction (in person or through phone calls or video calls), can provide a range of psychological and behavioral skills for adopting or maintaining regular PA routines (eg, intention formation and planning [68]). The web application, available daily, can supplement these interactions by providing content that reinforces skills and guides actions on demand in women's daily lives. Similarly, the web application can serve as a low-intensity introduction to some basic PA skills (eg, goal setting) and help women to determine the types of support or behaviors that may work best for their goals. Given its low intensity, the web application is unlikely to be widely effective as a stand-alone intervention for PA adoption. However, there may be a subset of women in midlife who benefit from the minimal, noninvasive, personalized, and adaptive support that it offers, either for initial PA adoption or for reinitiation of previous PA routines (eg, as women recover from PA changes owing to the COVID-19 pandemic [69,70]).

We also see potential for more innovative uses of the web application, beyond traditional PA support. For example, as noted, what users want and what works for prompting behavior change in daily life do not always align [41]. When combined with objective PA monitoring, data from the new tool can facilitate the assessment of alignment between a user's social PA content preference (selection), their subjective response to this content (liking or perceived helpfulness), and their daily PA behavior. This can be informative in 2 ways. First, from a basic science perspective, such assessment on a large scale will indicate the prevalence and distinct types of misalignments. This can inform our understanding of phenomena such as cognitive biases that interfere with PA, including strong preferences for and liking of content that is self-enhancing (eg, downward comparison targets [71]), despite the behavioral benefit of exposure to less-enhancing contact, such as upward comparison targets [72]. Second, from an intervention

perspective, information about any observed misalignment of preferences and behavioral responses can be offered as feedback (eg, from PA coaches). This can enable women to gain insight into patterns that facilitate or inhibit their PA behavior change.

A final potential use of the new web application is for assessing the alignment of preferences and responses between users, which also has implications for PA interventions. Specifically, the procedures described in the naturalistic functionality testing phase can be used to generate a profile or type for each user. Content selections and both subjective and behavioral responses can determine the *optimal* social support and comparison exposures for promoting a user's engagement with the tool and PA behavior [45]. At the same time, responses to survey items and PA behavior data can determine the type or types of support and comparison targets that the user would offer to other women in midlife. Then, this profile of optimal social input and likely output can be matched with a complementary profile to create PA partner dyads that are likely to meet each other's social needs. This process can maximize the power of the social environment of PA interventions to promote PA among women in midlife.

The present set of studies represents only the formative steps in a long process to fully develop and test a new digital health tool. Consistent with many of the existing UCD studies, we used both quantitative and qualitative methods with modest sample sizes [73]. Each of these potential uses of the web application will require the noted substantive revisions to the tool (which are currently underway) and large-scale testing with large and more diverse samples of women in midlife.

Lessons Learned and Recommendations for Future Digital Health Collaborations

The present series of studies and the creation of a new digital health tool resulted from close collaboration between behavioral and computer scientists. This type of collaboration is becoming more common and desirable to ensure that the development of a tool to support health behavior change is informed by a range of relevant expertise [74]. Such partnerships can be extremely fruitful but are not without challenges. For example, the fields of behavioral and computer science prioritize different methods and often share little common language. In this study, although we developed the storyboard and specifications for the web application over several months and a series of iterations, potentially important navigation rules were left unspecified (ie, use of the web browser's back button, entry of spaces, or nonlanguage text as open-ended responses). These and similar oversights may be owing to behavioral scientists' implicit assumptions and lack of familiarity with the problems that such errors can cause, and thus, failing to specify all desired rules ahead of time. To avoid the need for major changes after the initial tool is built—particularly if funding for such changes is limited or uncertain—there is additional pressure on computer science team members to foresee all types of possible pitfalls. In an academic setting, where funding for the development of digital tools may be scarce, early discussions about how and when substantive, unforeseen changes will be handled are critical.

Behavioral scientists also tend to focus, from the beginning, on a process of human subjects research that involves regulatory oversight, informed consent discussions, certain types of documentation (eg, test user feedback), and multiple attempts to secure additional (limited) funding. This process is intentionally methodical and can be quite slow as a result [74]. Computer scientists may not be familiar with the IRB processes, training required to participate in studies with human participants, and delays that these may cause. Computer scientists may prefer agile and iterative software development methods with multiple rounds of user feedback, but may not realize, at the beginning, the time and effort required to obtain IRB approvals and recruit participants. For this collaboration, although we were aware of the potential regulatory challenges from the beginning, we encountered difficulties regarding questions about permissions for server housing and IRB questions about the collection of protected health information via the new web application. The web application was designed to protect users' identities and does not collect protected health information; however, the process of effectively communicating this to the IRB and securing permission to house the web application on a commercial server was lengthy and involved. This was one of the several delays in the large process of web application development and testing that contributed to the extension of the project time line. The onset of the COVID-19 pandemic was the cause of another delay, as part of the investigators' research time was redirected to other professional and personal responsibilities [75].

Strengths, Limitations, and Conclusions

Despite these delays, this study had several strengths, including a base of foundational work with the population of interest [32,37,60,61,69], adherence to widely recommended UCD principles [51,73], emphasis on recruiting women from racial or ethnic minority backgrounds to maximize diversity in small samples, and collaboration between flexible researchers who

are committed to the project. This process also benefited from multiple phases of internal testing, including a range of testers who were familiar with and those who were naïve to the web application specifications and phases of both positive and negative testing. There were also noteworthy limitations to our study. For example, all data collection processes and feedback sessions with women in midlife were conducted by the first author (DA), who is the principal investigator of the project. This was intentional to ensure consistency in interview style and optimal synthesis of findings across study stages, particularly for the small samples recruited and the resources available. However, knowing that they were speaking to the project director may have heightened the participants' social desirability or self-presentation behaviors. The first author's direct involvement can also enable confirmation bias regarding the conclusions drawn (eg, from interview feedback). Interview scripts were designed to probe dislikes or nonpreferred content to limit this concern, and additional team members were consulted to provide an additional perspective, but it remains a possibility. This may be particularly relevant for the assessment of acceptability, which was performed informally in this study. In future studies, it would be ideal to record interviews and have multiple raters use a standard set of guidelines [76].

However, it is important to note that these procedures may not be possible at formative study stages owing to limited financial support to protect team members' time for such activities. Relative to the resources available for later stages of the process, such as efficacy testing for an existing digital health tool, research funding for the formative stages of tool development is often much more modest. Consequently, creative thinking, patience, and persistence are critical to the early success of such a venture. Together, this series of studies provides a useful example of how to approach these formative stages to gain necessary insights from the population of interest and to identify pitfalls and the next steps for future studies.

Acknowledgments

These studies were supported by the National Institutes of Health (NHLBI K23136657; principal investigator: DA). The authors would like to thank Megan M Brown for her assistance with data collection and Laura Travers, Ahmad Hussein, Leah Schumacher, Daija Jackson, Samuel Hart, Heather Mulvenna, Bernard Kwiatek, and Kristen Edwards for their assistance with internal testing.

Abstract

Background: There is growing evidence of the benefits of mobile health technology, which include symptom tracking apps for research, surveillance, and prevention. No study has yet addressed arbovirus symptom tracking in pregnancy.

Objective: This study aimed to evaluate the use of a smartphone app (*ZIKApp*) to self-report arbovirus symptoms and pregnancy complications and to assess compliance with daily symptom diaries during pregnancy in a cohort of women in an arbovirus-endemic, subtropical, middle-income country (Jamaica).

Methods: Pregnant women aged ≥ 16 years, having a smartphone, and planning on giving birth at the recruiting center were enrolled between February 2020 and July 2020. *ZIKApp* comprised a daily symptom diary based on algorithms to identify potential episodes of arbovirus infection and pregnancy complications. Sociodemographic, epidemiological, and obstetric information was collected at enrollment, with additional review of medical records, and users' perception was collected through an exit survey. Descriptive analyses and logistic regression analysis of possible factors associated with diary adherence were performed.

Results: Of the 173 women enrolled, 157 (90.8%) used *ZIKApp* for a median duration of 155 (IQR 127-173) days until pregnancy end, 6 (3.5%) used the app for < 7 days, and 10 (5.8%) exited the study early. For each successive 30-day period from enrollment up to 150 days after enrollment, of these 157 women, 121 (77.1%) to 129 (82.2%) completed their daily symptom diary; 50 (31.8%) to 56 (35.7%) did so on the same day. Overall, 31.8% (50/157) of the women had *good adherence* to diary reporting (ie, they completed the task on the same day or 2 to 3 days later for $\geq 80\%$ of the days enrolled). There were 3-fold higher odds of good adherence for participants aged > 34 years versus those aged 25 to 29 years (adjusted odds ratio 3.14, 95% CI 1.10-8.98) and 2-fold higher odds for women with tertiary versus secondary education (adjusted odds ratio 2.26, 95% CI 1.06-4.83). Of the 161 women who ever made a diary entry, 5454 individual symptom reports were made (median 17 per woman; IQR 4-42; range

0-278); 9 (5.6%) women reported symptom combinations triggering a *potential arbovirus episode* (none had an adverse pregnancy outcome) and 55 (34.2%) reported painful uterine contractions or vaginal bleeding, mainly in the month before delivery. Overall, 51.8% (71/137) of the women rated the app as an excellent experience and were less likely to be poor diary adherers ($P=.04$) and 99.3% (138/139) reported that the app was easy to understand and use.

Conclusions: This pilot found a high adherence to ZIKApp. It demonstrated the feasibility and usability of the app in an arbovirus-endemic region, supporting its future development to contribute to surveillance and diagnosis of arbovirus infections in pregnancy and to optimize maternal care.

Introduction

Background

Zika virus (ZIKV), chikungunya virus (CHIKV), and dengue virus (DENV) are arboviruses transmitted primarily by the *Aedes aegypti* mosquito that have caused multiple epidemics in recent years, notably the explosive epidemic of CHIKV in Latin America and the Caribbean that started in 2013, followed by the re-emergence of ZIKV a year later [1,2]. These arboviruses are of major public health concern and have been associated with significant morbidity alongside substantial economic impacts [3-5]. Although ZIKV outbreaks in particular have been highlighted with respect to maternal and infant health, owing to the causal link between ZIKV and microcephaly and other fetal and infant abnormalities [6], CHIKV and DENV are also both vertically transmitted, and all 3 viruses have been associated with adverse pregnancy outcomes (eg, preterm delivery, miscarriage, and stillbirth) and infant sequelae in the context of congenital infection [7-10].

Jamaica has experienced several DENV outbreaks of increasing intensity, severity, and magnitude in recent years (2010, 2012, and 2018-2019), with increased attributable morbidity and mortality in the very young, including reported cases of neonatal microcephaly [11-14]. Jamaica also experienced an explosive CHIKV epidemic in 2014 [3,15-18]: >80% of the general and antenatal populations were affected, with significant perinatal (maternal and newborn) illnesses, increased attributable neonatal morbidity and mortality [3,16,19], and >2500 deaths during the epidemic year nationally [18].

The ZIKV epidemic in Jamaica occurred in 2016-2017 [20-23]. National hospital-based surveillance revealed increased annual rates of severe microcephaly from 23.6 per 100,000 live births in 2010 (during the period of DENV outbreaks) to 41.7 per 100,000 live births in 2017 in association with the ZIKV epidemic [14], alongside surveillance reports of the congenital syndrome associated with ZIKV and related fetal brain disruption sequences temporally and spatially related to reported ZIKV cases [14]. The congenital syndrome was also being recognized simultaneously in 0.8% to 2.2% of the newborns in 3 urban public maternity hospitals [23], with a 15.6% ZIKV immunoglobulin G antibody seroprevalence in pregnancy reported [19]. Other complications included Guillain-Barré

syndrome and varied neurological presentations in children and adults [21,22].

The COVID-19 pandemic has seen a growing number of symptom tracker mobile phone apps that have helped to develop an understanding of an emerging infection and its associated clinical manifestations [24-27]. Before the emergence of SARS-CoV-2, there was already an increasing body of research demonstrating the benefits of mobile health (mHealth) technology for remote monitoring of symptoms, public health surveillance, education, and prevention [28], including for arboviruses [29-32]. With respect to pregnancy, mHealth apps have been used for multiple interventions, including to optimize gestational weight gain, to increase intake of vegetables and fruit, for smoking cessation, to identify specific symptoms of pre-eclampsia, for drug safety monitoring, and to support health care delivery for prevention of asthma and infections [33-38]. However, there is limited literature on the levels of adherence to mHealth apps for daily reporting of symptoms during pregnancy. This is a significant gap in evidence because the requirement for daily reporting could be an important factor potentially limiting long-term adherence.

Objectives

This pilot study aimed to evaluate the use of ZIKApp by pregnant women to report symptoms indicative of an arbovirus infection and pregnancy complications, including evaluating adherence with daily symptom diary reporting up to the end of pregnancy. The study setting was Jamaica, an example of an arbovirus-endemic, subtropical, middle-income country with high levels of smartphone penetration.

Methods

Recruitment

This pilot study was conducted at the University Hospital of the West Indies (UHWI), a university teaching hospital that performed approximately 1500 deliveries in 2016, as part of research conducted by the ZIKAction consortium, which conducts maternal and child health-focused research on ZIKV and other arboviruses in Latin America and the Caribbean. Participants were recruited between February 2020 and July 2020 from the antenatal care service by research nurses. This pilot study sought to enroll approximately 200 participants who met the following eligibility criteria: pregnant women aged ≥ 16

years who planned to give birth at the UHWI and had access to a smartphone compatible with the mobile app. Following these criteria, the research nurses orally explained the study, invited these pregnant women in the waiting room of this antenatal clinic on their first medical clinic visit (when the general educational talks are delivered) to take part in the study, and enrolled those interested. Furthermore, some of the participants also told other pregnant women about the study and recommended their participation, after which these women would also individually approach the research nurses, who would follow-up with the standard enrollment procedures. Names and contact details were stored locally by the research nurses, but all study questionnaires were pseudonymized with the use of unique study identifiers. Enrollment visit procedures are presented in the *Study Implementation* section.

The ZIKApp Intervention

ZIKApp was developed by the University Medical Center Utrecht in partnership with Your Research, a company based in the Netherlands. ZIKApp is compatible with both Android and iOS platforms. The app included a daily symptom diary for reporting presence or absence of symptoms and provided users with information on potential symptoms. In addition, the app provided information about the study itself and included a *Frequently Asked Questions* section (Figure 1A).

The app was designed to provide regular informative messages related to the pregnancy such as “Your baby is now the size of a pear,” similar to content provided by commercial pregnancy tracking apps (Figure 1B). This was to provide an additional incentive for women to adhere to app use.

Participants were sent daily reminders by email to complete their symptom diary. The daily diary entry could be completed on the same day or with a lag period of up to 7 days, after which it was no longer accessible. The symptoms included in the app and the start and end of arbovirus episode triggers are presented in [Multimedia Appendix 1](#) and were selected to identify symptoms suggestive of arbovirus infection as well as 2 specific pregnancy complications (painful uterine contractions and vaginal bleeding). The app also included some short periodic questionnaires; for example, the first questionnaire requested information on the woman’s last menstrual period date (to allow the app to send gestation-appropriate messages). Data recorded in the app were stored on a secure cloud-based portal (ResearchFollowApp portal). The portal also provided a user-friendly dashboard for the research nurses with an authorized log-in to monitor in real time the symptoms reported by participants.

Figure 1. ZIKApp screenshots. (A) Diary and symptom information. (B) Example of an informative message regarding pregnancy: "...your baby at week 19. The top of your womb (uterus) now reaches your belly button and will grow about a centimetre higher than this each week. Your baby measures up to 15.3 cm (6 in) from head to bottom (crown to rump) and weighs about 240 g (8.5 oz). He's the size of a big tomato...".

Study Implementation

A standard operating procedure (SOP) was developed to guide the research nurses, and in-person training was conducted at the UHWI in January 2020. The SOP detailed the different tasks that research nurses should fulfill during the recruitment once informed consent was obtained. It explained the process of setting up an account for the participant through the portal, assisting her in downloading the app from the Google Play Store or Apple App Store, guiding the initial app log-in, instructing her about the different app functions and notifications that she could receive (*potential arbovirus episode* or *possible pregnancy complication*), and guiding her to complete her first diary entry. Likewise, the SOP detailed the process to report any app or network issues to the coordinating University College London and University Medical Center Utrecht teams to resolve them and thus avoid early exits by participants and to improve app functionality.

At recruitment, a standardized form was used to collect additional sociodemographic, obstetric, and clinical information regarding the participant extracted from the medical chart. Data were entered and managed using REDCap (Research Electronic

Data Capture; Vanderbilt University) hosted at Penta Foundation ONLUS [39,40]. REDCap is a secure, web-based software platform designed to support data capture for research studies. The ResearchFollowApp portal was also designed to facilitate the follow-up of participants by the research nurses and to send automatic emails and notifications. The research nurses implemented the use of WhatsApp messages to inform participants about their office hours and to advise those who received notifications of *potential arbovirus episode* or *possible pregnancy complication* to contact the health services using a provided list of phone numbers. All participants received monthly phone credits to enable internet access to allow the app to transmit the data collected to the portal.

Study participation ended when the participant gave birth or when the pregnancy came to an end for other reasons (eg, miscarriage), although the women could withdraw from the study at any time. At study exit, the research nurses guided participants to uninstall ZIKApp and invited them to complete an exit survey that included questions on their experience of using the app. In addition, a standardized questionnaire was used to collect data regarding the delivery as well as details of the newborn, which were entered in the study REDCap database.

A case note review was conducted for women with potential arbovirus triggers to identify any maternal diagnoses (eg, from the laboratory information systems). During the pilot study, surveillance for SARS-CoV-2 among the pregnant women was implemented at the UHWI, and a case note review was also carried out for enrolled women with positive SARS-CoV-2 tests.

Statistical Analysis

App data stored on the ResearchFollowApp portal was downloaded and merged with data from the REDCap database using unique study identifiers before analysis. Descriptive analyses of participant characteristics were conducted. Univariable comparisons of categorical variables were assessed using chi-square or Fisher exact tests. To assess participants' adherence to completing the daily symptom diary, every diary day for each woman (ie, for the total time they used the app) was coded into 1 of 4 categories: diary completed on the same day, 2 to 3 days later, 4 to 7 days later, and >7 days elapsed without diary entry (ie, not completed). Next, for each woman, 2 binary variables (0 and 1) were created: for *good adherence* and *poor adherence* for their entire period of enrollment. *Good adherence* was where a participant had completed her diary on the same day or 2 to 3 days later for at least 80% of the time between enrollment and pregnancy end. *Poor adherence* was where there was an uncompleted diary (ie, >7 days had elapsed without diary entry) 30% of the time.

Potential factors associated with *good* and *poor* adherence were assessed using logistic regression analysis to obtain the odds ratios with 95% CIs: participant age, education, number of children, having an income, previous adverse pregnancy

outcome, comorbidities and chronic diseases, duration of app use, and whether a potential arbovirus episode was reported. Several factors were considered when selecting the final multivariable models: first, all variables that were significant with a *P* value of <.10 in univariable analysis were considered for inclusion; second, a backward stepwise selection approach was used to determine the final adjusted model. Stata software (version 16.1; StataCorp LLC) was used to conduct the analyses.

Ethics Approval

The protocol for this study was reviewed and approved by the University College London Research Committee on 27 September 2021 (Project ID 3715/005) and by the University of the West Indies Mona Campus Research Ethics Committee (project ID ECP 47, 19/20). All participants signed an informed consent form during the enrollment.

Results

Overview

A total of 173 pregnant women were enrolled in the study (Figure 2), with the last delivery occurring on January 5, 2021. Of these 173 women, 5 (2.9%) had no data recorded in the app portal, indicating that they never used the app (although, of these 5 women, for 2, 40%, this may have been a technical or connection issue as both reported completing the diary in their exit survey) and 1 (0.6%) had <1 week of study participation owing to a miscarriage 6 days after enrollment. These women were excluded from further analyses. Of the remaining 167 women, 157 (94%) used the app until they gave birth or the end of their pregnancy, whereas 10 (6%) chose to exit the study before they gave birth.

Figure 2. Study participant flow chart.

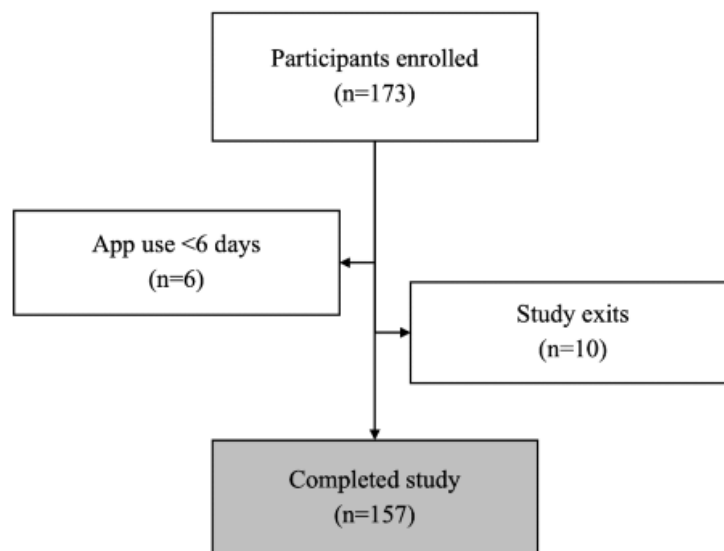

Table 1 presents the participants' baseline characteristics, stratified by study completion and study exit status. Overall, of the 167 women, 166 (99.4%) were born in Jamaica and 1 (0.6%) was born in the United Kingdom; most (137/167, 82%) of the women were enrolled in the second trimester of pregnancy. Of the 10 women who exited the study, 6 (60%) gave phone-related reasons for their study exit (eg, no longer having a smartphone

or having changed their phone), 2 (20%) changed their mind about study participation, and 2 (20%) cited problems with phone credit reimbursement. There were no statistically significant differences between the women who exited the study and those who remained and used the app until they gave birth with respect to sociodemographic characteristics and comorbidities (data not shown).

Daily Symptom Diary Reporting and Factors Associated With Good and Poor Adherence

Overall, 78.68% (17,833/22,664) of the daily diaries were completed over the study period. The timing of symptom diary

completion (ie, same day, 2-3 days later, 4-7 days later, or not completed) per successive 30-day periods between enrollment and pregnancy end is presented in [Figure 3](#) and [Multimedia Appendix 2](#). For each of these periods (up to 150 days), of these 157 women, between 121 (77.1%) and 129 (82.2%) completed

their daily symptom diary, with the proportion of diaries completed on the same day per 30-day period (up to 150 days) staying roughly constant at one-third (Figure 3; Multimedia Appendix 2).

The proportion of noncompleted diaries (ie, >7 days elapsed without diary completion) increased from the fifth month of app use. From day 181 onwards, the 7-day period within which a participant could complete her symptom diary retrospectively would have likely encompassed the date of delivery. Considering only diary days that were completed, there was also evidence of a reduced timeliness of reporting with increasing enrollment duration, with 41.69% (1024/2456), 37.67% (440/1168), and 32.4% (56/173) of the diaries completed on the same day at days 121-150, 151-180, and 181-210, respectively ($P<.001$).

To understand whether external events (eg, the Christmas holiday season) had an impact on the timeliness of diary completion, we compared the period from December 19, 2020, to January 2, 2021, and the period from December 1, 2020, to December 15, 2020, and found that the proportion of diaries completed on the same day was higher in the earlier period than during the Christmas period at 33.5% (190/568) versus 23.1% (78/337), respectively, although the proportion of noncompleted diaries was lower at 24.6% (140/568) versus 29.4% (99/337; $P=.01$), respectively.

Among the 157 women who used the app until the end of their pregnancy, there were 50 (31.9%) classified as having good adherence to diary completion (ie, completed same day or 2-3 days later at least 80% of the days). In univariable analysis (Table 2), women in the oldest age group (women aged >34 years vs those aged 25-29 years) and with tertiary education level (vs secondary education level) had higher odds of good adherence, although there was no association between good adherence and history of adverse pregnancy outcome, having a regular income, number of children, chronic disease status, duration of app use, or report of symptoms of arbovirus infection through the app. In the adjusted model (which included age and education only), both variables remained independently associated with good adherence, with the odds of good adherence being 3-fold higher for participants aged >34 years compared with those aged 25 to 29 years and 2-fold higher for women with a tertiary education compared with those who received a secondary education (Table 2).

In total, 24.8% (39/157) of the participants were classified as poor adherers to the symptom diary. Consistent with findings for good adherence, older women (those aged >34 years) had a significantly lower odds (adjusted odds ratio 0.10, 95% CI 0.01-0.80) of being poor adherers than participants aged 25 to 29 years. In addition, a short duration of app use (ie, <90 days) was associated with poor adherence (adjusted odds ratio 2.71, 95% CI 1.06-6.93).

Figure 3. Timing of symptom diary completion, by 30 day period from initiation of app use (n=157). The raw data corresponding to the percentages, and the number of women contributing to each 30 day period, are shown in Multimedia Appendix 2.

Table 2. Factors associated with good adherence to symptom diary reporting (N=157).

Reporting of Symptoms Overall

Overall, across the 17,883 completed diaries, there were 5454 (30.5%) individual reports of symptoms (n=5320, 29.75%, if vaginal bleeding and painful uterine contractions were excluded), including symptoms that may have been reported on the same day (eg, a headache and cold or cough). The most

commonly reported symptoms were headache and feeling unwell or less fit (Figure 4). Of the 161 women who ever made a symptom diary entry (including n=4, 2.5%, who exited the study early), the median number of symptoms reported per woman was 17 (IQR 4-42; range 0-278); 17 (10.6%) women never reported a symptom.

Figure 4. Count of total reports of symptoms (excluding pregnancy complications).

Potential Arbovirus Infection Symptom Episodes

In total, 5.6% (9/161) of the participants reported a combination of symptoms that triggered a *potential arbovirus episode*, with 1 episode each at a median 26 (range 13-36) gestational weeks. The distribution of symptoms for these women, including those reported just before and after the episode, is presented in [Multimedia Appendix 3](#). Of these 9 women, 4 (44%) reported some symptoms (headache, joint pain, or rash) the day before the notification of a potential arbovirus episode was triggered. In addition, of the 9 women, 2 (22%) had patterns of symptoms that resulted in both type 1 and 2 triggers and both reported additional symptoms (vomiting and cold symptoms or cough). Of the remaining 7 women, 5 (71%) reported one or more symptoms in the episode in addition to the relevant trigger symptoms, with cold symptoms or cough being the most common (reported by n=3, 43%; [Multimedia Appendix 3](#)).

No diagnosis of an arbovirus-related illness in relation to these episodes was made for any of the women (n=7) where detailed chart reviews were conducted. The women kept their regular antenatal appointments and had abdominopelvic ultrasound scans (anomaly scan and usually one more) to evaluate maternofetal health throughout pregnancy (which is the policy for evaluating any complications of arbovirus-related illness). Many (6/7, 86%) of the women had intercurrent illnesses in pregnancy, including cholestasis, urinary tract infections (several), ligamentous pain, otitis media, gastroesophageal reflux disease, and pre-eclampsia. All the women (n=9) delivered live births. None had SARS-CoV-2 detected in surveillance swabs.

COVID-19 Diagnoses

Of the 157 participants, 3 (1.9%) had laboratory-confirmed SARS-CoV-2 infection (nasopharyngeal swab positive for SARS-CoV-2 by polymerase chain reaction; all gave birth in late September and mid-October 2020). Of these 3 women, 1 (33%) reported headache over a 3-day period through the app, starting 8 days before the diagnosis; the case note review indicated additional symptoms not reported in the symptom diary (fever and cough), including anosmia and ageusia (not possible to report through the app); 1 (33%) reported headache on the day of the SARS-CoV-2 diagnosis and then 3 separate episodes of joint pain in the 10 days after the diagnosis; there was no record of these symptoms in her medical notes; and 1 (33%) reported feeling unwell or less fit for a 2-day period

starting 4 days before the SARS-CoV-2 positive result; no symptoms were recorded in her medical notes.

Potential Pregnancy Complication Episodes

Of the 157 participants, 55 (35%) reported 114 pregnancy complication symptoms (painful uterine contractions or vaginal bleeding) up to, and including, the day of delivery or the end of pregnancy. Delivery occurred at term in 85% (47/55) of the women, at 34 to 36 weeks' gestation in 7% (4/55), and before 34 weeks in 4% (2/55). Of the 55 women, 2 (4%), miscarried. Among the 114 pregnancy complication symptoms, there were 59 (51.8%) reports of painful uterine contractions, which occurred at a median of 36 (IQR 5-108; range 0-199) days before delivery, and 39 (34.2%) reports of vaginal bleeding, which occurred at a median of 64 (IQR 6-127; range 0-174) days before delivery. Nearly a third of these symptom reports occurred within 7 days before delivery (35/114, 30.7%, for both). There were 8 episodes where both these symptoms were reported on the same day, in all cases in the 3 days before delivery.

Adverse Pregnancy Outcomes and Symptom Reporting

Of the 5 participants whose pregnancy ended in miscarriage or stillbirth, 2 (40%) did not complete their diary in the 2 weeks before the end of the pregnancy. Of the remaining 3 participants, 2 (67%) reported pregnancy complications during this period; in addition, all (3/3, 100%) reported one or more of the following symptoms: unwell or less fit, rash, headache, red eyes, muscle ache, cold symptoms or cough, and diarrhea (but without activating the potential arbovirus trigger).

Participants' Perceptions of the App

Of the 157 participants who used the app until delivery or the end of their pregnancy, 139 (89%) participated in the exit survey. Regarding their experience of participating in the study, 51.8% (71/137) rated it as excellent (5 on a scale of 1-5), with 35.8% (49/137), 11.7% (16/137), and 0% (0/137) giving ratings of 4, 3, and 2, respectively. Of the 137 respondents, only 1 (0.7%) reported her experience as disappointing (rating of 1). The women who reported an *excellent* experience were less likely to be poor adherers to symptom diary completion than other women, with 18% (13/71) having poor adherence compared with 33% (22/66) who had good adherence ($P=.04$).

Of the 139 respondents, 138 (99.3%) reported that the app was easy to understand and use. Overall, 52.5% (73/139) of the

women reported experiencing technical difficulties while using the app (ie, difficulties accessing Wi-Fi to complete their diary, difficulties accessing the internet on their mobile phone, and app freezing). However, experiencing technical difficulties was not associated with poor adherence ($P=.90$) or good adherence ($P=.60$; data not shown).

Of the 10 women who exited the study before delivery, 5 (50%) participated in the exit survey. With respect to their experience as participants in the study, of the 5 respondents, 2 (40%) rated their experience as excellent, 2 (40%) gave a rating of 4, and 1 (20%) gave a rating of 2. Of these 5 women, 5 (100%) reported that the app was easy to understand and 4 (80%) reported that it was easy to use. In addition, of the 4 women who answered the section on technical difficulties, 2 (50%) reported experiencing them while using the app.

Discussion

Principal Findings

This pilot study enrolled 173 pregnant women attending antenatal care at a university hospital clinic in Jamaica to evaluate their longitudinal engagement with a smartphone app to report symptoms potentially associated with arbovirus infections and pregnancy complications. Specifically, we wanted to understand whether it was feasible for pregnant women to report through the app the presence or absence of symptoms as well as symptom type on a daily basis over a prolonged period (from the second trimester to delivery).

This 1-year pilot study achieved a larger sample than pilot studies of other apps in pregnancy, for example, monitoring weight gain (2 studies recruiting ≤ 100 women [34,41]) or on reducing stress (29 women) [42], which is noteworthy given that our pilot overlapped with the beginning of the COVID-19 pandemic that forced many countries to stop or reduce ambulatory health care. We found that very few (10/173, 5.8%) women exited the study early and only 3.5% (6/173) never used the app after enrollment. This compares favorably with a study in Germany, which involved monthly web-based visits and surveys to digitally assess pregnancy-related symptoms and complications (including physical symptoms, depression, and anxiety), in which 7% of the women formally exited the study and 55% overall stopped using the app and made no further contact with the study team [43]. Thus, initial concerns that there might be a high rate of attrition because of the perceived burden of symptom reporting were not borne out in our pilot study.

ZIKApp was designed to *tolerate* delayed reporting of symptoms (ie, up to 7 days later), with the rationale that this cutoff would maximize reporting over the remainder of pregnancy while minimizing recall bias and allowing for any temporary problems with internet access. Adherence to symptom reporting through the app was good, with 79% (17,905/22,664) of all diaries completed. As shown in our figure of timing of symptom diary completion (Figure 3), overall patterns were fairly consistent with increasing duration of app use (considering successive 30-day periods) over the first 20 weeks after enrollment, with approximately a third of the diaries completed on the same day

during this period (Multimedia Appendix 2). For the first 5 months of enrollment, only approximately 20% of the daily diaries were not completed at all (Multimedia Appendix 2).

However, patterns after 150 days of enrollment showed a decrease in diary completion overall, which may partly reflect women giving birth while they were within the 7-day window for daily diary completion. However, considering only those women who completed a diary, we showed that, as the duration of enrollment increased, there was a significant decline in the proportion completing their diary on the same day. The challenge of long-term adherence as a potential drawback of self-monitoring of symptoms through e-diaries has also been confirmed in other studies in pregnant and nonpregnant women that have reported less frequent diary reporting over calendar time [43-50].

A possible explanation for the good engagement of our participants could be the push notifications and reminders that were sent through our app as well as through email that could have been essential cues to action that encouraged our participants to complete their diaries or communicate with health care providers. This would be consistent with findings from a trial evaluating an mHealth intervention for healthy weight gain in pregnancy, which had good engagement in the intervention arm (only 9% attrition overall) in which SMS text messaging was a central feature [34]. The provision of phone credits in our study is also likely to have contributed because poor socioeconomic status has been associated with low engagement with an app for pregnant women elsewhere [51].

We found that older women (those aged >34 years) and women who had been to college or university were more likely to be good adherers to symptom diary reporting than younger women and those with less education, respectively. This finding supports other studies that have shown social variables such as older age and higher educational level to be significantly associated with sustained app use, including symptom diaries [43,44,47,52]. Other variables such as having a regular income, number of children, history of adverse pregnancy outcome, having a chronic condition, duration of app use, and reporting arbovirus infection symptoms were not found to be associated with good adherence in our study in contrast to others [44]. It was interesting to note that, although there was lower diary reporting overall and reduced timeliness of symptom reporting over the Christmas period (consistent with competing priorities during the busy holiday season), there was no association between other external factors such as technical difficulties using the app (eg, internet access and wireless connectivity) and adherence. In Jamaica, because the Christmas period is known to be a period of increased deliveries (including preterm births), the significant association with decreased app use is an important observation that should be considered for future implementation.

Of the 161 women who ever made a diary entry, 145 (90.1%) reported at least one symptom over a median of 22 weeks of app use. There was substantial heterogeneity in symptom reporting, with 1 in 10 women reporting no symptoms, whereas some (5/161, 3.1%) reported >200 symptoms. A potential challenge of using symptom diaries in pregnancy to identify signals of potential infections is the *noise* generated as a result

of common pregnancy-related symptoms. Triggers were selected to try to differentiate between *noise* and signals of true infections, but the pilot was not designed to evaluate the diagnostic performance of these triggers, which would require a different type of study to include diagnostic follow-up of all women with and without episode triggers. The most common symptoms reported in our study were headache, feeling unwell or less fit, and muscle ache, whereas the relatively low frequency of vomiting may reflect the fact that the first quartile of gestational age at enrollment was 15 weeks. It should also be noted that 45.5% (76/167) of the participants had at least one chronic condition, although participation in the study per se could have meant that the women were more sensitized to any physical symptoms they were experiencing and reported accordingly, whereas the normal ailments of pregnancy may have been exaggerated in other women, especially in light of the ongoing COVID-19 pandemic, potentially creating additional stressors for the pregnant woman.

This pilot study coincided with the start of the COVID-19 pandemic in Jamaica and as the study progressed, national surveillance for SARS-CoV-2 moved from passive to active surveillance, with pregnant women screened for symptomatic illness and asymptomatic involvement. Simultaneously, an unlinked serosurvey was performed in this antenatal population, which showed increasing SARS-CoV-2 seroprevalence, from 6.9% in September 2020 to 16.9% in October 2020 and 24% in November 2020; of the 37 pregnant women who tested SARS-CoV-2 immunoglobulin G antibody positive, only 3 were symptomatic [53]. The app development predated the emergence of SARS-CoV-2 but did capture some symptoms commonly reported with COVID-19. It was interesting to note that of the 3 pregnant women diagnosed with SARS-CoV-2, 2 (67%) reported symptoms approximately at the time of infection through the app that were not reported in the medical notes, whereas 1 (33%) did not report the fever and cough she experienced through the app (but delivered preterm within 4 days of experiencing symptoms and 2 days of testing positive).

The findings of this pilot suggest that despite most arbovirus infections being asymptomatic, screening pregnant women for relevant symptoms can improve case detection among those who are symptomatic [54], and that was part of the rationale for the development of ZIKApp. Our perspective is supported by recent evidence showing that a simple score based on clinical data and laboratory results provides a useful tool to help diagnose arbovirus infections [55].

To improve the usefulness of the app, it would possibly be more valuable to implement it during an epidemic period, rather than during a period of low prevalence of circulating arboviruses in the community, which was the case during this study. We also incorporated 2 symptoms (painful vaginal contractions and vaginal bleeding) that could signal important pregnancy complications (depending on timing).

We obtained feedback from participants about their experience of using the app in the exit survey, which had a high participation (139/157, 88.5%). More than half (71/137, 51.8%) of the responding women stated that their experience in the study was excellent and, consistently, they were less likely to

be poor adherers to diary completion. Almost all (138/139, 99.3%) reported that the app was easy understand and use, despite a relatively high proportion experiencing technical difficulties at some point. This finding differs from a study in pregnant women with gestational diabetes that found that technological problems with the app had a negative impact on user satisfaction [56]. Overall, our exit survey results corroborate other mHealth intervention results that show ease of use and simplicity [33,44,56] and ease of navigation and ease of understanding [57,58] are key features of apps that can influence sustained adherence. Furthermore, our findings support previous evidence about the role of the perception of the product on intended app use by women [59].

Our finding of *long and strong* adherence to symptom diary reporting in pregnant women in this Jamaican setting provides important evidence to inform the potential applications of apps where symptom diaries and self-monitoring may be used as a tool for research (eg, to develop a better understanding of patient-reported outcomes), for surveillance and participatory epidemiology (eg, as seen for tracking COVID-19 or influenza), or for clinical purposes (eg, for remote health monitoring of low-risk pregnancies, the importance of which was highlighted by the disruption of traditional pathways for health care during the COVID-19 pandemic). Our experience in this pilot study showed that future implementation of this intervention for clinical use will require women to be linked directly to clinical care providers in different health services (eg, antenatal clinic, labor ward, emergency department, high-risk obstetric ward, and newborn services) rather than through research nurses to allow interpretation of symptoms and provision of appropriate clinical care in real time.

Limitations

We were unable to conduct the planned qualitative aspects of this study (ie, focus discussion groups with a sample of participants and staff) because of COVID-19–related restrictions, although we were able to obtain data on user perceptions through the exit survey. We were therefore unable to explore other potential facilitators (eg, the generic pregnancy-related messages embedded in the app, acceptability of answering questionnaires through the app, the role of the research nurses, and the perceived role of the app in the context of the COVID-19 pandemic) as well as barriers to app engagement (eg, whether feeling unwell had an impact on the timeliness of diary completion) or cues to action regarding health-seeking behaviors. Questions relating to facilitators and barriers to prolonged engagement with health-monitoring apps in pregnancy as well as linked health-related behaviors therefore require future research (eg, with mixed methods approaches).

Other limitations of this pilot study include the possibility of selection bias because only pregnant women who approached the nurses after the initial information provision in the clinic waiting room were recruited into the study. Consequently, our participants likely represent pregnant women using this antenatal clinic who were willing to take part in an mHealth intervention study. Likewise, women who were willing to participate were potentially more likely to adhere to diary reporting than nonparticipants, potentially resulting in social desirability

response bias, particularly with respect to the exit survey. In addition, the results of this pilot study may not be generalizable to all pregnant women in Jamaica because of potential sociodemographic differences between our study population and the general antenatal population; for example, there were higher proportions of women who were nulliparous and who had received tertiary education in our study than in another ZIKAction consortium study that enrolled pregnant women from across the Kingston, Jamaica, metropolitan area [60]. Further research could recruit women from community-based antenatal clinics to capture a more socioeconomically diverse sample.

Conclusions

We have demonstrated the feasibility and usability of ZIKApp in an arbovirus-endemic region, showing that most pregnant women were able to adhere to symptom reporting through the app for a prolonged period and supporting its future development to contribute to surveillance and diagnosis of, and communication about, arbovirus infections in pregnancy. The findings also indicate that such an app shows promise for future development and implementation by direct treatment and care teams to optimize obstetric care. For any of these potential uses, further research will be required, for example, to explore how app use could be linked to sampling (including self-sampling) and testing within a surveillance program while adapting the mobile app interface, features, and messages to the appropriate cultural context.

Acknowledgments

The authors thank all the women and their families who, the authors hope, would have benefited positively and holistically by their active participation in this study. The authors are also thankful to all the staff of the antenatal clinics, labor ward, and postnatal wards, as well as the medical records office, who were very helpful in implementing all aspects of this study, and Ms ShreeAnn Simon, the ZIKApp study administrator. Similarly, the authors want to acknowledge and express gratitude to Francesca Viero, Giorgia Dalla Valle, Rachel Knowles, Peter Tanghe, Andrea Oletto, Thomas Byrne, Jacqueline McLean, and Trudy-Ann Blair-Wallace. This work was supported by the European Union's Horizon 2020 research and innovation program (734857; ZIKAction).

The ZIKAction Consortium collaborators are as follows: Tiziana Grossele, Francesca Viero, Giorgia Dalla Valle, Andrea Oletto, Rebecca Lundin, Daniel Lang, Andrea Garbutt, Roxanne Melbourne-Chambers, Orville Morgan, Alexander Onyonyor, Paul Mitchell, Leroy Campbell, Marissa Mayne, Karen Webster-Kerr, Joshua Anzinger, Georgiana Gordon-Strachan, Sheree Mair, Keisha Francis, Yakima Phillips, Chadwic Mears, Tracia James-Powell, Yanique Brown, Clayton Kelly, Lizette Mowatt, Judy Tapper, Amanda Rousseau, Brittiana Brown, Sofier Scott, Marlyn Grindley, Donna Kamicka, John Lindo, ShreeAnn Simon, Thomas Byrne, Moira Spyer, Eleni Nastouli, AE Ades, Fabiana Gordon, J Glenn Morris Jr., Rigan Louis, Valery E M Beau De Rochars, John Lednicky, Maha Elbadry, Derek Adam Cummings, Cyrus Saleem, Mahbubul Alam, Jean Claude Cadet, Chamblain Richard, Sonese Chavannes, Medjina Syndic, Mathieu Kern, Merisier Delson, Maureen Long, Erika Schwarz, Ana Bispo, David Brown, Patricia Brasil, Antoni Soriano-Arandes, Ana Alarcón, Elena Sulleiro, Isadora Siqueira, Rosa Bologna, Griselda Berberian, Greta Mino, Francesco Bonfante, Eva Mazzetto, Federico Martinon-Torres, Irene Rivero Calle, Trudie Lang, Bonnie Baker, Liam Boggs, Marco Safadi, Flavia Almeda, Daniel Jarovsky, and Alessandra Soriano.

Abstract

Background: Older adults are a high priority for telemedicine given their elevated COVID-19 risk and need for frequent provider contact to manage chronic illnesses. It seems that many older adults now use smartphones but few studies have examined their overall readiness for telemedicine.

Objective: The aim of this study is to survey older primary care patients about their telemedicine preparedness, including internet usage, internet-capable devices, telemedicine experiences and concerns, and perceived barriers. Results were used to inform a telemedicine preparedness training program.

Methods: Community-dwelling older adult patients (aged 65-81 years; N=30) with a chronic health condition that could be managed remotely who were present at a family medicine clinic that primarily serves an urban African American population for a prescheduled in-person appointment were asked to complete a brief survey written for this study. Data were collected February-June 2021 at a large, urban, Midwestern hospital. To minimize patient burden, the survey was limited to 10 questions, focused on the most critical topics.

Results: Most participants (21/30, 70%) reported having a device that could be used for telemedicine and using the internet. However, about half had only a single connected device, and messaging and video calling were the most commonly used applications. Few used email and none used online shopping or banking. Only 7 patients had had telemedicine appointments. Telemedicine users were younger than nonusers and used more internet functions than nonusers. Only 2 people reported problems with their telemedicine visits (technology and privacy). Nearly all respondents recognized avoiding travel and COVID-19 exposure as telemedicine benefits. The most common concerns were loss of the doctor-patient connection and inability to be examined.

Conclusions: Most older adults reported having devices that could be used for telemedicine, but their internet use patterns did not confirm the adequacy of their devices or skills for telemedicine. Doctor-patient conversations could be helpful in addressing telemedicine concerns but device and skill gaps must be addressed as well.

Introduction

Background

Since the COVID-19 pandemic began, telemedicine appointments have replaced many in-person health care visits [1,2]. However, older people are less likely to participate in telemedicine, preferring in-person care or foregoing care altogether [3-6]. With a high prevalence of chronic conditions and vulnerability to COVID-19 morbidity and mortality through exposure to others in health care environments [1-4], promoting telemedicine use among older adults should be a high priority.

Older Adults' Barriers to Telemedicine

Older adults face significant barriers to participation in telemedicine, including limited access to the internet and devices suitable for telemedicine [7]. Older adults may also lack digital skills or have visual, auditory, and tactile difficulties with telemedicine, or be uncertain about whether or when to use it. To inform our plans for offering telemedicine training to older adults presenting to an outpatient family medicine teaching clinic that serves predominantly African American, economically disadvantaged adults with chronic illness in Cleveland, Ohio, we administered a survey to learn about their telemedicine readiness, and telemedicine barriers and facilitators.

Methods

Participants

We sought to recruit 30 participants, the minimum recommended sample size for estimating univariate averages, and a number thought adequate to identify common patient journeys that would guide our plans for telemedicine training [8,9]. Participants were recommended to this convenience sample by primary care providers who were familiar with their medical history and the study criteria. Inclusion criteria included age ≥ 65 years and having a chronic health condition (diabetes, hypertension, arthritis, etc) that could be managed remotely. Patients with known dementia, residence in a long-term care facility, and presenting with an acute condition requiring in-person care (eg, fall or chronic obstructive pulmonary disease exacerbation) were ineligible.

Survey Instrument

Because existing surveys tend to lack the specificity needed to determine the adequacy of devices and skills for telemedicine,

we designed and pretested a new survey instrument based on a review of the literature, and input from our primary care providers and a digital equity expert (Multimedia Appendix 1). Because we were not offering compensation, we minimized patient burden by limiting the survey to 10 questions. Topics included demographics, experience using telemedicine, problems and perceived barriers, ownership of telemedicine-ready devices(s), and use of various internet functions.

Procedures

Patients present at an in-person primary care visit for issues that could be accomplished remotely were approached by a research assistant to complete the survey between February and June 2021. Data were collected on paper, with a research assistant available to read the survey questions and record responses if needed. The research assistant entered anonymous responses into a REDCap database to protect patient privacy. Descriptive statistics were calculated to inform our telemedicine readiness training plans. Chi-square tests were used to test for statistical significance, $\alpha=.05$.

Ethical Considerations

University Hospitals' Institutional Review Board determined the study (2021611) to be no more than minimal risk and granted expedited approval. Written informed consent was not required but prior to beginning the study, participants received written information informing them that they were invited to participate in a voluntary research study and were free to decline participation.

Results

Devices and Internet Usage

Of 30 respondents, 25 (83%) said they had devices that could be used for a telemedicine visit and that they went on the internet, but just 7 of 30 (23%) had had telemedicine visits. However, few patients had advanced devices (iPhones, desktops, laptops, or tablets) that are best suited to telemedicine. In addition, 14 of 30 respondents (47%) had only a single device that was not an iOS-based mobile device (Table 1) and may have had limited videoconferencing ability. All participants with devices said they used them for "messaging on the internet," but this was the only function used by 12 of 30 respondents (40%). No one used the internet for banking or shopping, and few used internet functions commonly needed for telemedicine (email: 7 respondents, 23%; video calling: 9 respondents, 30%) (Table 1).

Table 1. Survey participant demographics and telemedicine readiness.

Demographics and telemedicine readiness	Participants, n	Participants, %

Lack of privacy	7	23
Other disadvantage	3	10

^aMean age 70.8 (SD 4.3) years; range 65-81 years.

Telemedicine Experiences and Perceptions

Of 30 respondents, 7 (23%) had had a telemedicine appointment. Participants who owned a computer or iPhone were more likely to have had a telemedicine visit than others (Figure 1A; $\chi^2_1=9.5$; $P=.002$), as were participants who had used the internet for email or functions other than messaging (Figure 1B; $\chi^2_1=11.9$; $P<.001$). All but one respondent who had a telemedicine visit had an iPhone or a computer and used internet functions other than messaging. Participants with iPhones or computers used their devices for a broader range of tasks (Table 2; $\chi^2_3=18.0$; $P<.001$), endorsed fewer telemedicine disadvantages ($\chi^2_3=11.9$; $P=.008$), and were more likely to indicate interest in future

telemedicine visits ($\chi^2_1=5.7$; $P=.02$) than were patients with other types of mobile devices or no devices at all. Telemedicine attitudes of patients who used email or other internet functions were similar to those with advanced devices. Loss of connection with their doctor was the most commonly endorsed telemedicine disadvantage (10/30, 33%) followed by concerns about exam privacy and quality (7/30, 23%). Patients who were aged 65-70 years were more likely to have an iPhone or other computer ($\chi^2_1=10.5$; $P=.001$; Figure 2A), and were more likely to have had a telemedicine visit ($\chi^2_1=6.7$; $P=.01$; Figure 2B) and to have used internet functions other than messaging ($\chi^2_1=15.9$; $P<.001$; Figure 2C) compared with patients aged 70 years and older.

Figure 1. Comparisons of likelihood to have had a telemedicine visit by device ownership and device usage.

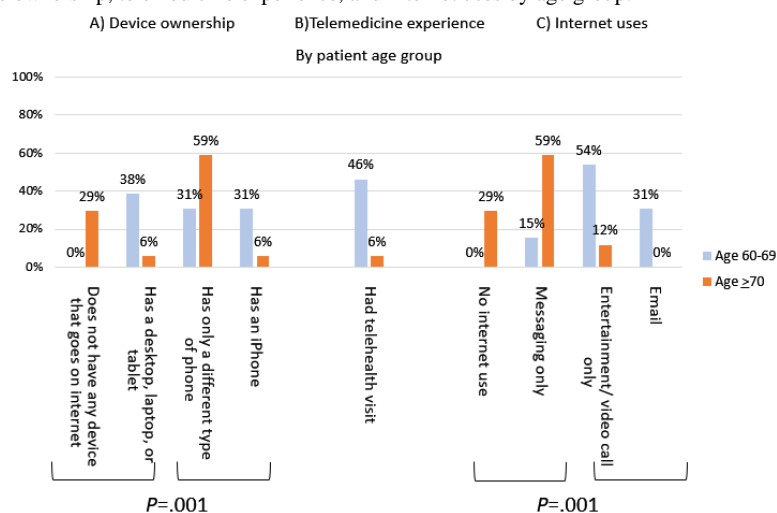

Table 2. Internet uses and telemedicine attitudes by device type.

Devices and functions used	Internet uses		Telemedicine attitudes	
	Mean number of ways participants use the internet	Messaging only, n (%)	Mean number of telemedicine disadvantages	Interest in future telemedicine visit, n (%)
Type of device				
iPhone	2.4	0 (0)	0.4	5 (100)
iPad or computer	2.3	1 (8)	0.7	4 (67)
Other mobile only	1.2	11 (92)	1.4	6 (43)

Used messaging only	N/A	N/A	1.4	4 (33.3)
No internet use	N/A	N/A	1.2	1 (20)

^aN/A: not applicable.

Figure 2. Comparison of device ownership, telemedicine experience, and internet uses by age group.

Discussion

Principal Findings

This small survey revealed significant gaps in telemedicine readiness among older adults who said they had devices that could be used for telemedicine and that they went online. No patients used key internet functions needed for staying safe during the COVID-19 pandemic, and few used internet applications that required the skills needed for accessing telemedicine. Few patients had devices that are optimal for older adults using telemedicine. Patients with more advanced devices used more internet functions and had more telemedicine experience and more favorable attitudes than others. Our results confirm previous studies [10-12] showing generally lower technological proficiency among older adults and some concerns about participating in telemedicine. However, our study is novel in pointing to subtle dimensions of telemedicine readiness that warrant further study—device capacity and use of internet in ways that build skills needed for telemedicine such as email and video calling. Before training older adults to use

telemedicine, it is important to ensure that they have the devices, basic digital skills, and connectivity needed for telemedicine. Screening for readiness may require nuanced assessment regarding specific device capacity and skills.

Limitations and Future Directions

Because of the survey's limited nature, other important topics, such as home internet access and interest in digital skills training, could not be addressed. Results may not be generalizable to other contexts, such as specialty clinics or rural areas. Participants present in the clinic may be different from those not seeking care, which could bias our results. Larger studies are needed to confirm our results and apply multivariate analysis to understand the relationships among age, device quality, internet skills, and telemedicine attitudes. Development of validated scales of telemedicine readiness as well as telemedicine training to complement in-person care can help health systems offer precision-matched interventions to address barriers, facilitate increased adoption, and generally improve patients' overall access to primary care and engagement with their primary care provider.

Acknowledgments

The authors would like to thank the Family Medicine department staff and our patients for their assistance with completion of this project.

Conflicts of Interest

The Case Western Reserve University Department of Family Medicine provided funds to AS for expert consultation around digital health equity. The other authors declared no other conflicts of interest to report.

Abstract

Background: Owing to the impact of the COVID-19 pandemic, work environments and systems, as well as occupational health measures or activities that fall within our research field, are constantly changing. It is necessary to assess the impact of these changes on the physical and mental health of workers.

Objective: To assess how occupational health measures affect the health of workers, we conducted a baseline, longitudinal internet-based survey among Japanese workers in October 2021 and additionally scheduled 2 follow-up surveys for 2022 and 2023. We describe the details of the protocol of the work systems and health internet research (WSHIR) study, provide an overview of the results of the baseline survey, and discuss the study procedures and data used in the study.

Methods: This prospective cohort study was conducted online among internet monitors. The baseline survey was conducted from October 1 to 7, 2021. This study targeted those who were working and between the ages of 20 and 69 years. A total of 5111 respondents who passed the screening survey and proceeded to the main survey were enrolled according to collection units organized by sex and age. For the screening and main surveys, the questionnaire consisted of 9 and 33 items with 9 and 55 questions, respectively. Consistency and completeness checks were performed after the questionnaires were submitted. We compared basic characteristics, such as sex, age group, educational background, and marital status, among all participants, including those who withdrew from the analysis.

Results: Of the 5111 initial survey respondents, 571 (11.2%) were considered fraudulent. The data of the remaining 4540 (88.8%) participants (2273, 50.1%, males; 2267, 49.9%, females) included in the analysis were well balanced across participant sex and age groups according to the sampling plan because there was no significant difference by sex and age group using the chi-square test for checking the distribution bias of the participants ($P=.84$). Compared to female participants, male participants tended to be more likely to be managers and supervisors (323, 14.2%, males; 86, 3.8%, females), to work in a secondary industry (742, 32.6%, males; 357, 15.7%, females), and to have an annual income of ≥ 5 million yen (976, 42.9%, males; 429, 18.9%, females). For the evaluation of a psychological indicator, Kessler 6 (K6) score, by sex and age group, the characteristics of the score distribution of the included participants were similar to those reported in previous studies.

Conclusions: This study presents a protocol and overview of the results of an internet-based occupational health survey of workers. Using the results of this survey, we hope to evaluate the changes in occupational health activities and their impact on workers' health while controlling for the COVID-19 pandemic.

Japan; occupational health; worker; internet surveys; questionnaires; cohort study; COVID-19; mental health; online health

Introduction

The global outbreak of COVID-19 in 2020 had a profound impact on the economy, daily and working life, and medical practice in Japan [1-3]. The Japanese government repeatedly announced a state of emergency, asking the public to exercise voluntary restraint, such as refraining from going out and traveling to distant places, curtailing corporate business activities, and refraining from dinners and other socializing opportunities [4]. In the occupational field, several COVID-19 infection control guidelines were developed by various industries and organizations [5]. The introduction of telecommuting [6] and the implementation of COVID-19 vaccination or antigen testing in workplaces have also been recommended. These changes brought about by the COVID-19 pandemic have resulted in dramatic changes in the work environment, work systems, and occupational health activities [7,8].

In Japan, the occupational health system is defined using occupational safety and health laws, and occupational health services are implemented in many companies [9,10]. Companies with 50 or more employees are required to appoint at least 1 industrial physician and 1 health manager [9]. Occupational physicians have been among the leaders in promoting infection and prevention measures in workplaces during the COVID-19 pandemic [5]. Occupational physicians have often played a central role in workplace COVID-19 vaccination programs as well as in awareness-raising activities for countermeasures against the COVID-19 pandemic in occupational fields. They provide health support for employees affected by COVID-19 and health management for all employees in view of the ever-changing landscape and the impact of the COVID-19 pandemic. We believe that the COVID-19 pandemic brought a more vivid focus on occupational physicians by the public and that it served as the turning point for the promotion of occupational health activities.

In Japan, since the lifting of the government's emergency restrictions at the end of October 1, 2021, until now (end of June 2022), no restrictions have been in place, and more than 60% of the population has completed the third vaccination against COVID-19. It is possible that COVID-19 will once again become prevalent in Japan and that countermeasures will have to be taken on a case-by-case basis. However, it is unlikely that the situation will change as dramatically as it did between early 2020 and September 2021. Looking ahead to the post-COVID-19 pandemic era, it is important to monitor future occupational health activities and assess how they will affect the work environment and systems or the health of workers.

We consider it necessary to focus on future challenges and issues regarding occupational health fields by looking ahead at the post-COVID-19 pandemic period. Such future challenges and issues include cooperation between health management and practice; workers' health management, including annual health

checkups, countermeasures against communicable diseases in the workplace, and fitness to work; and the actual status of occupational health services and occupational physician activities, in addition to longitudinally assessing how these affect the health of workers. Therefore, we conducted a longitudinal study, that is, a work systems and health internet research (WSHIR) study, among workers from October 2021. In addition, we scheduled 2 follow-up surveys for 2022 and 2023.

The aim of this paper is to present details of the WSHIR study protocol. Moreover, it provides an overview of the results of the baseline survey and includes a discussion of the study procedures and improvements to the quality of the data used in the study. We plan to use the data from this study to inform various research themes focused on occupational health issues, such as the impact of occupational health services and activities on workers, changes, and new challenges for occupational health in the workplace in the post-COVID-19 state.

Methods

Study Design

This survey was a prospective cohort study conducted online among internet monitors registered with Cross Marketing Inc. (Tokyo, Japan), which is a Japanese internet research contractor with 4.7 million registered monitors. We sent participation information to the registered monitors, so this was not an open survey.

The baseline survey was conducted from October 1 to 7, 2021. Two follow-up surveys are scheduled for 2022 and 2023. The study targeted those who were working and between the ages of 20 and 69 years in the baseline survey.

A document describing the time required to complete the survey, storage location, period of the survey data, the investigator, and the purpose of the study are available on the website of the Department of Work System and Health, Institute of Industrial Ecological Sciences, University of Occupational and Environmental Health, Japan (in Japanese).

Ethical Considerations

All participants provided informed consent online to participate in this study. The study was approved by the ethics committee of the University of Occupational and Environmental Health, Japan (reference no. R3-037).

Sample Size

The statistical method was not determined, because this study was mainly exploratory. However, the sample size was calculated by adapting the following conditions, which are most likely to be assumed: in sectional or cohort studies, 2-sided significance level ($1 - \alpha$)=95; power ($1 - \beta$, percentage chance of detecting)=80; ratio of sample size, unexposed/exposed=1; percentage of unexposed with the outcome=5; odds ratio=1.5;

risk/prevalence ratio=1.5; and risk/prevalence difference=2.3. Under these conditions, the required total sample size was calculated to be 3380 [11]. Hence, we set the sample size to 5000 to account for data exclusion.

Sampling Plan

Only people registered with Cross Marketing Inc. (Tokyo, Japan) could complete the survey. First, the questionnaire for the screening survey confirmed informed consent to participate in the study; the respondents were regular workers, we excluded temporary and part-time workers, and the age was ≥ 20 years. Only respondents who met these conditions proceeded to the main survey, which consisted of 10 collection units organized by both sex and age group, with 500 respondents per collection unit, for a total sample size of 5000. Third, each collection unit was designed to be closed once it reached 520 respondents; thereafter, respondents could not proceed from the screening stage to the main survey stage.

Personal information was not collected from a series of surveys. The respondents were contracted according to the privacy policy of Cross Marketing, Inc.

Recruitment Process for Participants

As instructed, Cross Marketing Inc. sent emails that included a link to the website, along with an introduction to the survey and an entry to the questionnaire page. There is an automatic method for capturing the responses on a website. Completion of this survey was voluntary, and as an incentive to complete the survey, the respondents earned points that could be exchanged for various products.

We counted the number of participants in this survey by counting the monitor IDs assigned to the respondents when they accessed the survey system. For the first survey, participation invitations were sent via email to approximately 59,000 monitors randomly selected by Cross Marketing Inc. from among more than 5 million registered monitors. This survey was started on October 1, 2021, and all sample collections were completed on October 5, 2021.

Measurements

For the screening and main surveys, the questionnaire consisted of 9 and 33 items with 9 and 55 questions, respectively. The questionnaire consisted of 33 pages, with 1 item per page. The survey consisted of the following 3 major categories: basic and socioeconomic characteristics and health status, a psychological questionnaire that was already validated, and questions pertaining to occupational medicine and health.

Questions relating to basic and socioeconomic characteristics included sex, age, marital status, income, educational background, area of residence, and work-related factors, such as occupation, number of employees at workplaces (branches, factories, and sales offices), type of industry where the participants worked, and average working hours. In addition, single items regarding the participants' health status included present medical history, presence of current physical and psychological problems and their causes, and the number of days of sick leave absence.

The psychological questionnaires included the Brief Job Stress Questionnaire [12], the Japanese version of the 3-item Utrecht Work Engagement Scale [13,14], and Quantity and Quality [15] as an evaluation index of presenteeism. Other psychological questionnaires were the Patient Health Questionnaire-2 [16] and the Kessler 6 (K6) score [17,18]. The reliability and validity of these questionnaires on psychological scales have been confirmed in previous studies. The Japanese versions of these psychological scales were used without modification.

For questions related to occupational medicine and health, we surveyed the perceived workplace health support [19], the actual state of health management for workers (eg, health checkups, countermeasures for return to work), fitness to work, countermeasures against communicable diseases in the workplace, provision of occupational health services, health consultation services, and management of workers' health information. Each question consisted of 1 or 2 original items and was not evaluated by calculating the scale scores.

All the aforementioned questionnaires were created or selected by 3 experts certified by senior occupational health physicians, who were certified by the Japan Society for Occupational Health, the body that discusses current issues regarding occupational health in Japan. After generating the questionnaires, we requested 3 other occupational physicians to respond and review the drafts.

Additionally, we verified that these questions could be answered without any problems on a web-based system before conducting the main survey. We also checked for inappropriate expressions, ease of answering, typographical errors, and other issues that were used to revise the questionnaires.

Completeness Check

Consistency and completeness checks were performed after the questionnaires were submitted. We detected fraudulent respondents based on the 3 types of algorithms designed in this survey:

- Respondents who failed to correctly answer 2 basic knowledge questions unrelated to the survey. Specifically, one was to correctly select odd numbers among five 2-digit numbers, and the other was to correctly select multiples of 3 out of five 2-digit numbers.
- Respondents who provided contradictory answers to the 3 predetermined questions (the 3 questions were likely to be contradictory if the respondents did not answer them carefully). Specifically, we designed a 2-option (yes/no) question on whether the respondent had undergone a health checkup within the past year, followed by a 6-option question on how to obtain, store, and use the results of the health checkup. In 1 instance, the respondent answered, "I had not had a health checkup within a year," but the respondent also answered, "I kept the results of the health checkup within a year."
- Respondents whose response time was < 3 minutes. To exclude questionnaires submitted too soon, we excluded those with a response time of less than 3 minutes. We set these cut-off points based on our actual response time to the questionnaires and the fact that Fujino et al [20] set the

cut-off points at 6 minutes for the questionnaire consisting of 55 items and 160 questions in their study.

Respondents who met the exclusion criteria based on these consistency or completeness checks were considered withdrawn; otherwise, they were considered enrolled.

Statistical Analysis

We compared basic characteristics, such as sex, age group, educational background, and marital status, between enrolled and withdrawn participants in the analysis using the chi-square test. In addition, we used the chi-square test to compare the characteristics between respondents who provided contradictory answers to the 3 questions and those who did not and between those whose response time was <3 minutes and those whose response time was ≥3 minutes. The comparisons between those who answered the 2 basic knowledge questions correctly and incorrectly were not analyzed because of incorrect answers.

We analyzed the educational background, marital status, occupation, industrial classification, number of employees in the business unit where the participants worked, number of employees in the company where the participants worked, and annual income (yen) by sex or age group (20-29, 30-39, 40-49, 50-59, and 60-69 years) using the chi-square test. We analyzed the K6 score by sex using the Mann-Whitney *U* test or by age group using the Kruskal-Wallis test.

Results

Participant Details

As shown in [Figure 1](#), the survey invitation was sent to approximately 59,000 registrants, and 7300 (12.4%) responded to the screening survey. A total of 2189 (30%) respondents were excluded from the screening survey stage, and 5111 (70%) completed the main survey (completion rate=ratio of users who completed the survey to users who agreed to participate). The distribution of the enrolled participants by sex and age group (ie, by 10 collection units) is shown in [Table 1](#). The number of enrolled participants by sex and age group was evaluated using the chi-square test to check for distribution bias; there was no significant difference ($P=.99$). Of the 5111 respondents, 571 (11.2%) withdrew. Of those with duplication, 434 (8.5%) provided contradictory answers to the 3 questions, 161 (3.2%) had a response time of less than 3 minutes, and none had incorrect answers to the 2 basic knowledge questions. The final number of participants enrolled in the analysis was 4540 ([Figure 1](#)). The number of enrolled participants by sex and age group was evaluated using the chi-square test to check for distribution bias; there were no significant differences ($P=.84$).

According to residence (prefecture), the 4540 participants were distributed across all 47 prefectures in Japan. The highest and lowest proportion of respondents per 100,000 population was 5.4 (Tokyo) and 1.5 (Miyazaki Prefecture), with a 47-prefecture median (quartile) of 3.0 (2.5-3.6). Among 9 (19.1%) of the 47

prefectures, with a population of more than 5 million per prefecture, 7 (77.8%) were among the top 10 with the highest proportion of respondents per 100,000 population.

We compared the basic characteristics of the enrolled and withdrawn participants ([Table 2](#)). There were no significant differences in sex, educational background, or marital status among groups. However, a higher proportion of younger participants withdrew.

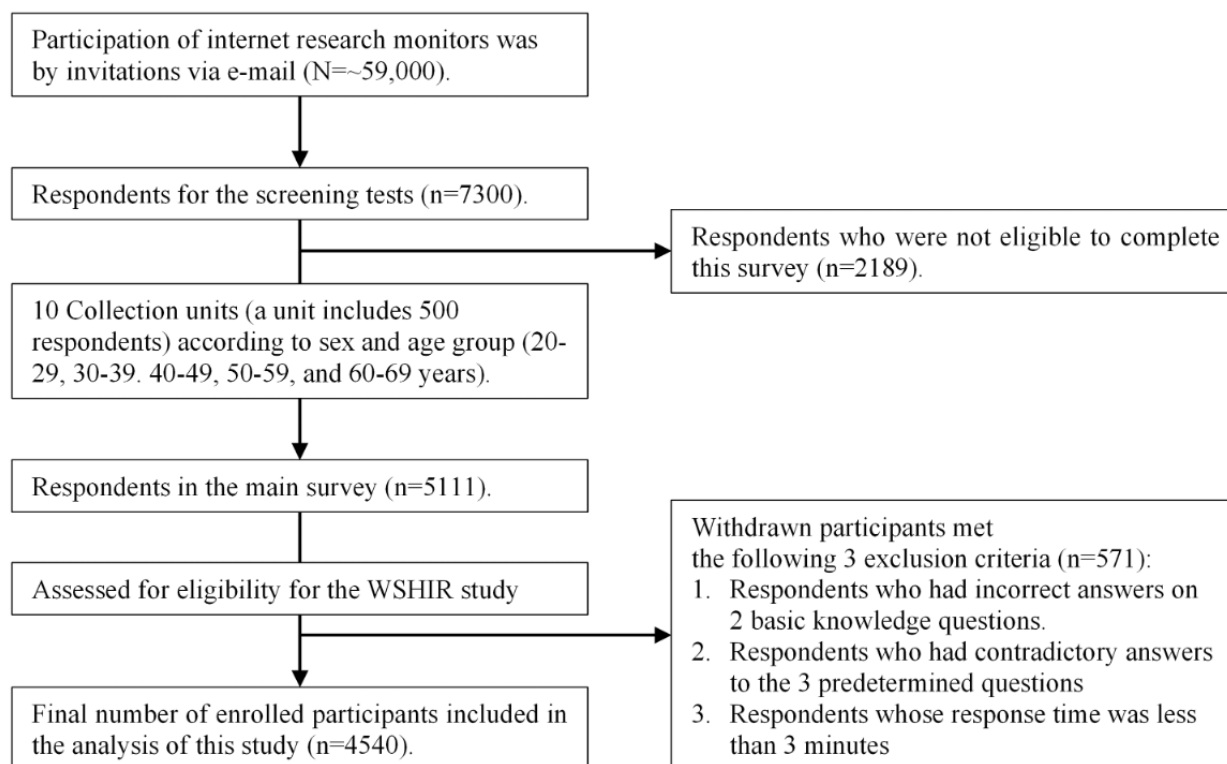

We also compared the basic characteristics of the respondents who provided contradictory answers to the 3 questions ([Table 2](#)). The number of respondents who provided contradictory answers was 434 (8.5%) of 5111. They tended to be younger and less educated, and 24 (5.5%) had a response time of <3 minutes; in addition, they were significantly more in number ($n=434$, 8.5%) than those who provided no contradictory responses ($n=137$, 2.9%).

Next, we compared the basic characteristics of respondents whose response times were ≥3 and <3 minutes ([Table 3](#)). The number of respondents with a response time of <3 minutes was 161 (3.2%). The median, 25th, and 75th percentiles were 6 minutes 49 seconds, 4 minutes 56 seconds, and 9 minutes 50 seconds, respectively. Those with a response time of <3 minutes tended to be younger, better educated, and unmarried. Of those with a response time of <3 minutes, those with contradictory answers were significantly more in number ($n=24$, 14.9%) than those with a response time of ≥3 minutes ($n=410$, 8.3%).

We compared the basic and work-related characteristics of the enrolled participants between the sexes and among the 5 age groups ([Tables 4](#) and [5](#)). Male participants tended to be more likely to be married and have a university or graduate school degree than female participants. In terms of work-related characteristics, male participants tended to be more likely to be managers and supervisors, work in a secondary industry or in large-size workplaces or enterprises, and have an annual income of ≥5 million yen (US \$36,183.51) than the female participants. Female participants were significantly more likely to be in a third industry, to work in small workplaces or enterprises, and to have an annual income of <2.99 million yen (US \$20,986.44) than the male participants.

The 20-29-year age group tended to be less likely to be married compared to those in other age groups. Regarding educational background, younger participants tended to be more likely to have a university or graduate school degree, be regular employees, and be employed in large workplaces or enterprises. With the increasing age of the respondents, an increased proportion was found among those who were engaged in workplaces or enterprises (49 employees or fewer), as well as those who were engaged in the secondary industry.

The K6 score was higher in female participants than in male participants; in addition, the K6 score tended to be higher in those aged 20-39 years ([Table 6](#)).

Discussion

Principal Findings

In October 2021, after the fifth wave of the COVID-19 pandemic had subsided in Japan, we conducted an internet-based occupational health survey among workers. Internet surveys have become more common in recent years in the fields of public health and epidemiology, health care services, and even medicine because of the potential to collect relatively large amounts of data in a short period [21]. Compared to conventional population and workplace surveys, internet surveys have the advantages of making it easier to achieve the target sample size, incorporating many conditions, surveying in a short period, and making it easier to conduct surveys targeting workers. We believe that our data obtained using the WSHIR study will be valuable for future research on the working conditions and health status of workers post-COVID-19.

One of the problems with internet surveys is that respondents may provide fraudulent answers [22,23]. Many private internet survey companies set up incentives, such as points that can be exchanged for products, to increase the number of registrants and encourage them to completely respond to various surveys. There is a possibility that some respondents may answer the questionnaires inappropriately without understanding the aims of the survey or the questionnaire just to obtain these incentives. Therefore, internet surveys must be designed to detect fraudulent respondents.

In this study, we used 3 algorithms to detect fraudulent respondents. The first was the setting of 2 basic knowledge questions that were not related to the main survey. However, all the respondents answered these questions correctly. It is possible that in many surveys, questions have already been prepared to detect fraudulent respondents or that many respondents are aware that the questions are designed to detect fraudulent practices; thus, respondents decide to respond correctly. However, we speculate that ensuring that the respondents are aware that the questionnaire contains algorithms to detect fraudulent respondents may have a deterrent effect on fraudulent responses.

Second, the way the 3 predetermined questions were set could lead to contradictory answers if they were not answered carefully. This algorithm is complicated because the respondent must be consistent among the 3 predetermined questions. In fact, 434 of 5111 respondents provided contradictory answers, and all were treated as fraudulent respondents.

Finally, the cut-off points were set to exclude premature response times to the questionnaire, which were recorded using a questionnaire system by Cross Marketing Inc. In this survey, the median, 25th, 75th, and 5th percentiles were 6 minutes 49 seconds, 4 minutes 56 seconds, 9 minutes 50 seconds, and 3 minutes 16 seconds, respectively. Therefore, we believe it was reasonable to exclude 161 respondents whose answers were within 3 minutes. Regarding the 2 conditions for detecting fraudulent respondents, we found that those who met one of the conditions were significantly more likely to meet the other condition.

This study found that respondents with extremely short response times tend to provide contradictory responses. In addition, this tendency was observed in younger participants. We speculate that 1 of the reasons for this is the possibility that there are a certain number of internet monitors who are only interested in obtaining incentives. When conducting a questionnaire survey with slightly more difficult content via the internet, as in this study regarding occupational health fields, the researchers propose that a procedure is needed to validate the data set provided by internet research contractors.

In this survey, the respondents' residences were not added to the collection unit. However, we could enroll participants from all 47 prefectures in Japan, although the proportion of respondents tended to be higher in metropolitan areas. In a conventional occupational health survey, where the researcher directly asks for research cooperation from companies, it is almost impossible to adjust for this kind of regional distribution of participants, and we believe that the data are well balanced.

By examining the relationships among the variables, we confirmed the authenticity of the data. For example, compared to female participants, male participants had a higher proportion of managers and those engaged in the secondary industry as well as a higher annual income. In addition, regarding

psychological indicators, it has been reported that the K6 scores of women are higher than those of men [24,25], and a similar trend was observed in this study. Regarding age groups, the younger age group was more likely to be unmarried, and the proportion of managers was higher in the 40-49- and 50-59-year age groups and lower in the 60-69-year age group. In Japan, most companies have a mandatory retirement age of 60 years, and those aged ≥ 60 years are often rehired without job positions, on contract, or in fixed-term employment. As for psychological indicators, previous studies have reported that K6 scores tend to be higher in younger persons, and similar results were observed in this study [26].

Selection bias is unavoidable in internet surveys. For example, those who use the internet and are willing to answer the questionnaire will inevitably be selected. Respondents were simply those who were registered with an internet research company and did not represent a particular population. *Measurement error* refers to errors caused by differences in the approach used in responding, even by the same respondent, depending on whether the answers are recorded using other methods (eg, by telephone or interview) or are self-recorded (eg, by the respondent self-completing individually) and whether the answers are shown once the questionnaire paper has been filled out or shown on an internet screen [22,27,28]. To improve the validity of this study, we adhered to the Checklist for Reporting Results of Internet E-Surveys (CHERRIES) statement [21]. In addition, it is important to clarify the characteristics of the survey population by comparing various factors with those in previous studies. This study focused on occupational health, and we confirmed work-related factors, such as occupation, industry classification, size of the workplaces or enterprises where the participants worked, annual income, working hours, occupational health system, and activity status in as much detail as possible. We also examined several health-related factors of workers and psychosocial indicators related to work that have been used in many previous studies, which can be compared to the results of this study.

This study is intended to be conducted over a 3-year period, starting in October 2021, when several people in Japan have been vaccinated against COVID-19, with the number of infected people remaining low even after the government lifted the state of emergency. Of course, there is a possibility of a recurrent epidemic in the future. However, the government and the Japan Federation of Economic Organizations (Nippon Keidanren) are making efforts to resume or strengthen economic activities, since the situation may be approaching a possible control of the

COVID-19 pandemic [21,22]. Once controlled, this study could provide an overview of changes in occupational health in Japan and how COVID-19 has affected workers.

Limitations

We mentioned some research limitations before, but there are several other limitations to this study. First, the sampling plan was not specifically designed to consider the unit of workplace characteristics, such as workplace size, location, and type of industry. Therefore, it should be noted that the results of this study generalize to the whole working population in Japan. Second, some of the participants belonged to the same workplace. According to the Statistics Bureau of the Ministry of Internal Affairs and Communications, the number of workplaces in Japan is approximately 578,000. The likelihood that all participants had different workplaces was approximately 16.8% by a simple calculation. Because of the possibility that participants may belong to the same workplace, we need to be careful when analyzing and evaluating the study data. However, as we plan to continue this study in the future, we believe that the quality of the data can be improved by obtaining data such as the zip codes of the workplaces in a follow-up survey. Third, all data in this survey were based on parameters self-reported by individual workers. Respondents of this study might be unaware of or might not correctly understand the health-related measures implemented in their workplaces, depending on their position or status. In addition, this study did not use objective indicators of mental or physical health. Such research should utilize many indicators that have been commonly used in previous studies and should be examined with reference to previous studies.

Conclusion

We commenced an internet-based occupational health survey focusing on occupational health activities and workers' health in October 2021 when approximately 80% of the population aged ≥ 12 years had been vaccinated and the fifth wave of the COVID-19 pandemic was under control in Japan. This paper presents the protocol of this study and provides an overview of the data from the baseline survey, the study procedures, and the quality of the data in this survey. Using the data of this survey, we aimed to evaluate the changes in occupational health activities and their impact on workers' health after the COVID-19 pandemic was controlled. We plan to analyze the data from multiple perspectives and present new findings regarding occupational health fields sequentially.

Acknowledgments

We thank Cross Marketing Inc. (Tokyo, Japan) for conducting this internet survey and Editage for English language editing.

Abstract

Background: Social media–delivered lifestyle interventions have shown promising outcomes, often generating modest but significant weight loss. Participant engagement appears to be an important predictor of weight loss outcomes; however, engagement generally declines over time and is highly variable both within and across studies. Research on factors that influence participant engagement remains scant in the context of social media–delivered lifestyle interventions.

Objective: This study aimed to identify predictors of participant engagement from the content generated during a social media–delivered lifestyle intervention, including characteristics of the posts, the conversation that followed the post, and participants' previous engagement patterns.

Methods: We performed secondary analyses using data from a pilot randomized trial that delivered 2 lifestyle interventions via Facebook. We analyzed 80 participants' engagement data over a 16-week intervention period and linked them to predictors, including characteristics of the posts, conversations that followed the post, and participants' previous engagement, using a mixed-effects model. We also performed machine learning–based classification to confirm the importance of the significant predictors previously identified and explore how well these measures can predict whether participants will engage with a specific post.

Results: The probability of participants' engagement with each post decreased by 0.28% each week ($P < .001$; 95% CI 0.16%–0.4%). The probability of participants engaging with posts generated by interventionists was 6.3% ($P < .001$; 95% CI 5.1%–7.5%) higher than posts generated by other participants. Participants also had a 6.5% ($P < .001$; 95% CI 4.9%–8.1%) and 6.1% ($P < .001$; 95% CI 4.1%–8.1%) higher probability of engaging with posts that directly mentioned weight and goals, respectively, than other types of posts. Participants were 44.8% ($P < .001$; 95% CI 42.8%–46.9%) and 46% ($P < .001$; 95% CI 44.1%–48.0%) more likely to engage with a post when they were replied to by other participants and by interventionists, respectively. A 1 SD decrease in the sentiment of the conversation on a specific post was associated with a 5.4% ($P < .001$; 95% CI 4.9%–5.9%) increase in the probability of participants' subsequent engagement with the post. Participants' engagement in previous posts was also a predictor of engagement in subsequent posts ($P < .001$; 95% CI 0.74%–0.79%). Moreover, using a machine learning approach, we confirmed the importance of the predictors previously identified and achieved an accuracy of 90.9% in terms of predicting participants' engagement using a balanced testing sample with 1600 observations.

Conclusions: Findings revealed several predictors of engagement derived from the content generated by interventionists and other participants. Results have implications for increasing engagement in asynchronous, remotely delivered lifestyle interventions,

which could improve outcomes. Our results also point to the potential of data science and natural language processing to analyze microlevel conversational data and identify factors influencing participant engagement. Future studies should validate these results in larger trials.

weight loss; social media intervention; engagement; data science; natural language processing; NLP; social media; lifestyle; machine learning; mobile phone

Introduction

Background

Obesity is prevalent in the United States and is a known risk factor for cardiovascular disease, type 2 diabetes [1,2], and cancer. Although lifestyle interventions are effective for weight loss and diabetes prevention [3], they require numerous clinic visits for up to a year, which is burdensome for many people. Technology-delivered lifestyle interventions, by not requiring visits, are less burdensome for participants and have shown promising weight loss outcomes [4]. Some technology-based interventions use popular commercial social media platforms such as Facebook in an effort to meet people where they are [5,6]. Many social media users already use these platforms to discuss their health experiences [7,8]. Community-building features on social media platforms, such as private groups [9,10], make them particularly amenable to delivering group-based lifestyle interventions.

Systematic reviews and meta-analyses show support for the efficacy of social media-delivered lifestyle interventions [4,11]; however, this area of research is still nascent. Participant engagement, defined as posts in the group, replies to posts, “likes,” and votes in polls, appears to be an important predictor of outcomes [12-15]. For example, a study found that every 10 posts by participants corresponded to -0.5% weight loss [16]. Another study found only certain types of engagement predicted weight loss [17]. Interestingly, the degree of participant engagement reported in studies of social media-delivered interventions is highly variable, ranging from an average of once during the entire intervention period to 11 times per week [17-19]. Engagement also generally declines over time in these programs [16]. Our understanding of the factors that influence participant engagement in these interventions is limited. Emerging evidence in the web-based communication literature shows the importance of multilevel factors influencing participant engagement, such as the characteristics of posts (eg, post length and topic and popularity of the poster), characteristics of the conversation thread in response to the post (eg, sentiment and reciprocity behavior), and participant characteristics (eg, motivation and habits) [14,20-27]. However, research is scant in the context of social media-delivered behavioral interventions [28]. Furthermore, characteristics of the conversation thread (ie, other peoples’ replies and comments) preceding each participant’s engagement is often ignored, which could be valuable in terms of providing microlevel contextual data that influences each participant’s decision to engage.

A promising approach to increase our understanding of the factors influencing participants’ engagement in social media-based behavioral interventions is to study the content and interactions generated by the interventionists and participants during the intervention using natural language processing (NLP). Data collected directly from web-based platforms (eg, Facebook) can provide detailed, real-time behavioral information over the course of intervention programs. NLP can handle a large quantity of text, generate reliable qualitative coding [29], be leveraged to derive various real-time microlevel insights concerning the characteristics of the posts (eg, topics) and conversations that followed the posts (eg, sentiment), and understand how they affect participants’ decisions of engagement independently and aggregately. This has potential implications for the design and implementation of future interventions to increase participant engagement, which could lead to more favorable weight loss outcomes.

Objective

Using data from a 16-week pilot feasibility randomized weight loss trial that delivered lifestyle interventions via Facebook, drawing on multilevel factors influencing participant engagement identified by previous web-based communication literature, we derived various factors from the content generated by participants and interventionists over the course of the intervention, including characteristics of the posts (eg, poster, time, and topic), conversations that followed the post (eg, sentiment and receiving replies), and participants’ previous engagement behaviors, and assessed how well these factors predict participant engagement individually and all together in the context of a social media-delivered lifestyle intervention.

Methods

Study Design, Settings, and Participants

In a pilot feasibility randomized trial, we randomized 80 participants who were overweight or obese into 1 of 2 remotely delivered lifestyle interventions. We recruited people interested in losing weight via web-based advertisements at the University of Connecticut on ResearchMatch and in yard sale or neighborhood Facebook groups in 37 states across the United States between June and October of 2019. Inclusion criteria included BMI between 27 and 45 kg/m², smartphone ownership, active Facebook user (ie, comments or posts more than once a week), aged 18 to 65 years, and having daily internet access. Exclusion criteria included pregnancy or planning to become pregnant during the study, bariatric surgery or plans for bariatric surgery during the study, ≥5% weight loss in the past 3 months,

pre-existing conditions that preclude physical activity or dietary changes, taking medications affecting weight, incapable of walking one-fourth of a mile unaided without stopping, type 1 or type 2 diabetes, and participation in prior weight loss studies under the principal investigator.

Participants completed an orientation webinar before randomization to learn more about the study, and those still interested in participating were mailed a Wi-Fi scale (FitBit Aria, FitBit Inc) and asked to provide the staff with their log-in information for the scale so that weights could be recorded for the assessments. We randomized 80 participants to the 2 conditions.

Intervention Conditions

Overview

Participants were randomized to either a Facebook group in which new participants were continually enrolled during weeks 1 to 8 (open enrollment) or a Facebook group that included only the original 40 randomized participants (closed enrollment). In the open enrollment condition, 54 additional participants were enrolled between weeks 1 to 8 for a final group size of 94. However, we only included the original 80 randomized participants in this study to ensure all participants had an equal amount of time to engage in all 16 weeks of the intervention.

Facebook-Delivered Lifestyle Intervention

Both conditions received the identical 16-week lifestyle intervention based on the Diabetes Prevention Program (DPP) but modified to be delivered in a private Facebook group where twice-daily posts guided participants through the program, which was led by a dietitian (counselor) who was assisted by a student counselor. We adapted the DPP content to be appropriate for a web-based setting, as described elsewhere [30]. We gave each participant an individualized calorie goal that would facilitate a 1 lbs to 2 lbs weight loss weekly and asked them to use MyFitnessPal to track their calories daily. In addition, we asked participants to have the counselor review at least 2 weeks of their MyFitnessPal records, although they could request more as needed. The Facebook group was private such that only those invited by the study team could join the group and view the intervention content. We gave participants diet and exercise goals for the week each Monday and asked them to report progress on their goals in a conversation thread on Sunday and report their weight change for the week in a conversation thread

each Friday. In between, intervention posts addressed the learning objectives of each module of the DPP. The dietitian leading the group was instructed to reply to all participant posts and comments that merited a reply and otherwise hit a reaction (eg, like and laugh) button to acknowledge the participants' comments. Participants were encouraged to post to the group and reply to each other. The details of the intervention, study procedures, and primary study results can be found elsewhere [31].

Ethics Approval

This pilot feasibility randomized trial was approved by the University of Connecticut Institutional Review Board (H17-215) in October 2017.

Measures

Overview

We included all posts and comments or replies within posts from interventionists and randomized and nonrandomized participants to construct the measures. Posts without text (approximately 6% of the posts were excluded) and polls were excluded, which resulted in 761 posts and 9396 comments or replies across the 2 intervention arms.

The outcome of interest was on the postparticipant pair level; that is, whether each participant had engaged with (ie, commented or replied to) a post in the Facebook group (1 if yes and 0 if no). Comments are in response to the original post, whereas replies are responses to comments made by others on a post. We focused on comments and replies as these activities are active forms of engagement rather than passive types of engagement such as views and reactions (eg, "likes") and have been shown to positively predict weight loss [16,32,33]. We extracted engagement data from the private Facebook groups using the Grytics app [34]. The Grytics app allowed us to download all the content posted in each Facebook group into Microsoft Excel sheets along with its unique Facebook ID number (post ID, comment ID, and parent comment ID), time stamp, reaction data, and author. Participants were asked to allow the Grytics app to access their Facebook account name so that the content from the group was identified (ie, post or comment author name was included in export).

Post Characteristics

The post characteristics described in [Textbox 1](#) were included.

Textbox 1. Post characteristics.**Original poster**

- We used a binary variable to indicate whether the focal post was created by the interventionist (1) or participant (0).

Post length

- We measured the number of words in each post.

Content sentiment

- We measured the average sentiment (text polarity) of each post's content. Text polarity measures the valence and emotion in the text and ranges on a continuous spectrum from negative (lower value) to positive (higher value). We standardized the measure of sentiment for the analysis. Sentiment analysis was performed using the *sentimentr* package in R (version 3.6.1).

Topics

- We used natural language processing to identify the topics that appeared in each post, comment, and reply. The content was preprocessed to remove emojis and non-English characters. Topics were detected using *Top2Vec* in Python 3.10.0, a deep learning-based sentence embedding algorithm that detects topics in the documents. It detected 117 unique topics along with their top words (see [Multimedia Appendix 1](#) for a random sample of 35 topics with their top 8 words) from 10,157 pieces of content (posts, comments, and replies), which were further consolidated and coded under 7 topics based on the top 20 words of each original topic: exercise, diet, weight, MyFitnessPal app use, expressing emotion, sleep, and goals or plans. Here we focused on the topics of each post and created 7 binary variables to represent whether each post involves each of the aforementioned topics. Each post could include multiple topics; for example, a post mentioning a specific dietary goal would be categorized under both diet and goals or plans.

Time of the post

- We collected the time (number of days from day 1 of the intervention) and day of the week when the post was created.

Reply or Comment Characteristics

We constructed a series of variables representing the characteristics of replies or comments on each post. To reflect the content of conversations before each participant's engagement, if the participant engaged with the post, we

calculated these variables based on all previous comments or replies under the post before their engagement for each unique postparticipant pair; if the participant did not engage with the post, we calculated these measures based on all the comments or replies under the post. The characteristics are described in [Textbox 2](#).

Textbox 2. Reply or comment characteristics.**Tags or mentions**

- We created two binary variables to represent whether each participant had been tagged or mentioned by (1) interventionists or (2) other participants in the previous replies or comments within the same post. It is worth mentioning that most tags or mentions in our data were generated automatically by Facebook (eg, when participant A comments or replies to participant B's content, Facebook automatically generates a tag on B in A's reply or comment). Thus, most tags or mentions in our data represent reply or comment relationships. In very few instances, interventionists deliberately tagged previously disengaged participants; however, the sample size was too small to test their effects separately.

Reply or comment content sentiment

- We measured the average sentiment of all replies or comments for each postparticipant pair. The measure was standardized for the analysis.

Participants' Characteristics

The included participant characteristics were as follows:

- Percentage of previous posts commented or replied: For each post, we calculated the percentage of previous posts each participant has commented or replied to.
- Baseline and sociodemographic characteristics: Although these variables were not the focus of our analysis, we included baseline characteristics for each participant, including treatment condition (open vs closed), baseline weight, BMI, age, race, sex, education, marital status, number of people in the household, and employment status, as covariates in the analyses.

Statistical Analysis

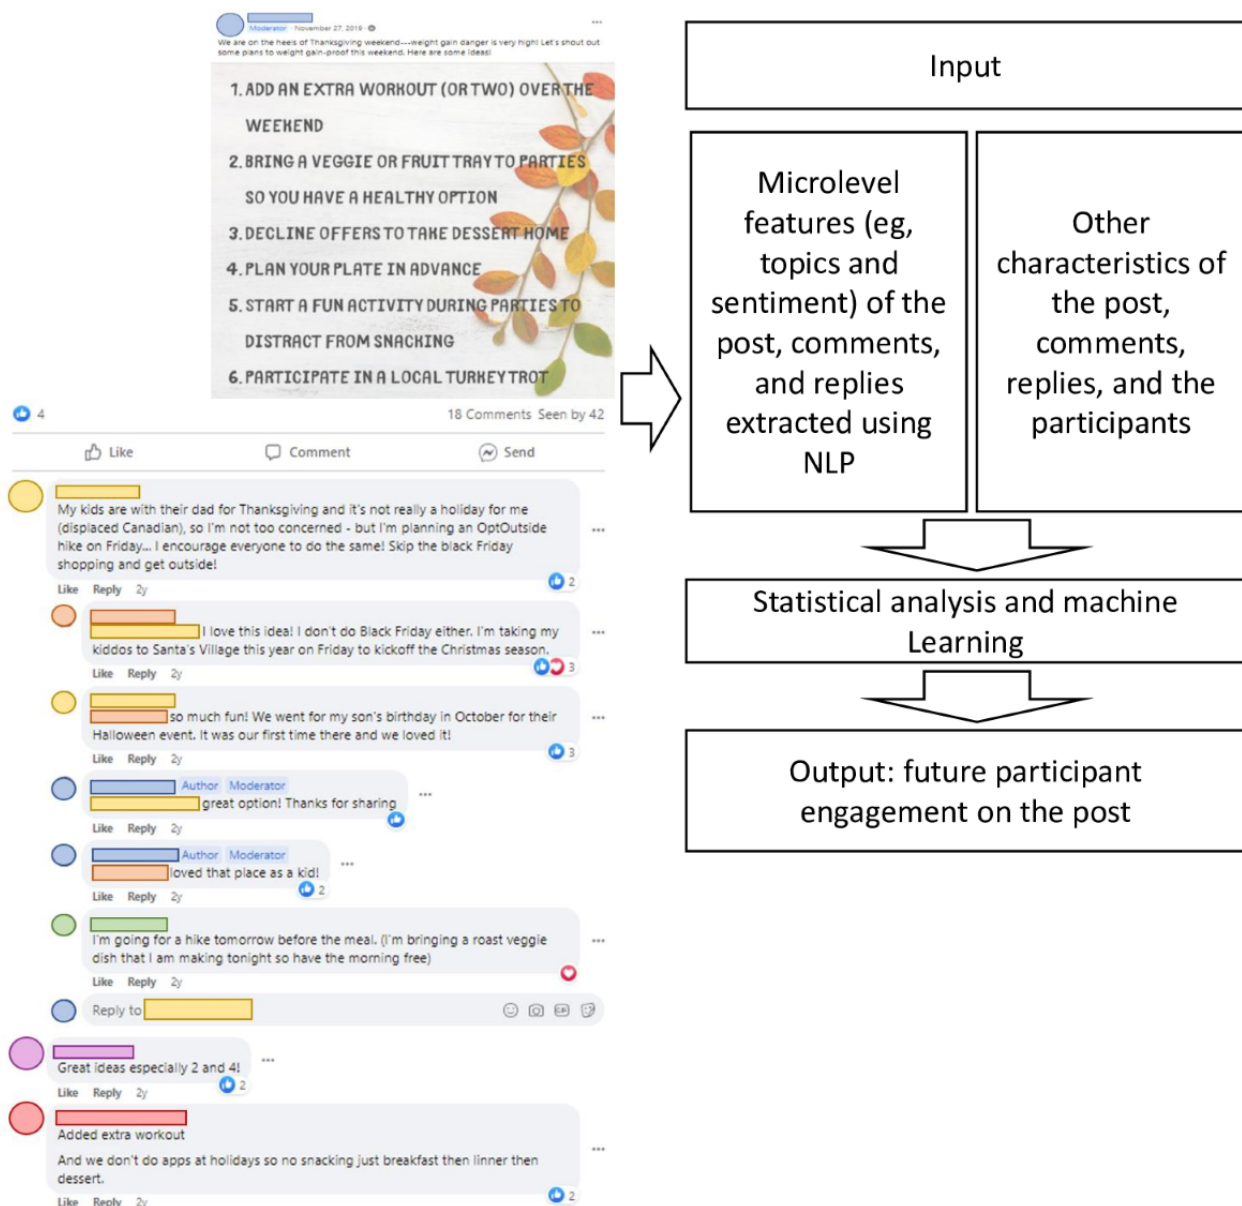

We focused our analysis on whether each randomized participant (N=80) had engaged with each post, as randomized participants had access to the Facebook group the entire length of the intervention (it should be noted that each post was only available in a particular treatment arm and, thus, can only be seen by 40 randomized participants). To examine what predicts participant engagement with each post, analyses were performed on the postparticipant pair level (ie, whether each participant engaged with each post). This allowed us to construct measures that accurately reflect the content (ie, posts and conversations) before each participant's engagement. We included all possible engagements (ie, instances where participants engaged and instances where they did not engage) from the 80 randomized

participants with each of the 761 posts, which resulted in a final sample of 31,968 observations (participants engaged in 4462 instances and did not engage in 27,506 instances) for our analysis.

The overall analysis framework is depicted in Figure 1. Data were screened for deviations from assumptions required for the used statistical analyses. We calculated descriptive statistics for the outcome and key independent variables for each treatment condition. To account for the fact that engagement was nested within each post, we performed a mixed-effects regression with postlevel random effects using participants' engagement as the primary outcome, along with all aforementioned key predictors

(ie, characteristics of the post, reply or comment, and the participants' previous engagement behavior) as independent variables, with participants' baseline and sociodemographic characteristics as covariates. We also included participant-level fixed effects as an alternative specification to account for possible omitted variable bias. As a robustness check, we also conducted a mixed-effects logistic regression with the same variables (Multimedia Appendix 1). To identify the important predictors of participant engagement, we reported the coefficient, 95% CI, and the associated *P* value for each predictor. All analyses were performed in STATA standard edition (version 16).

Figure 1. Analysis framework to identify important predictors of participant engagement. Left panel: an example of the intervention post and the comments or replies following it. Right panel: flow chart of the analysis. NLP: natural language processing.

Although regression analyses are useful to identify the statistical significance of linear relationships, some of the relationships might be much more complex (eg, nonlinear or moderated by other variables). To confirm the importance of significant predictors that we previously identified and to investigate how well these variables as a whole can predict participants'

engagement with a particular post, we included all aforementioned predictors in machine learning algorithms, including gradient boosting machines, deep learning models, and an ensemble of them [35,36], and examined the performance of these models by calculating key metrics, including (1) area under the curve (ranging from 0.5 to 1, with 1 being the best)

using a 5-fold cross-validation, (2) variable importance across different models, and (3) out-of-sample prediction accuracies on a balanced sample with 1600 observations (800 random observations with engagement and 800 observations without). In the machine learning model, variable importance was determined by calculating the relative influence of each variable: in the tree-based model, it was calculated based on whether that variable was selected or included during the tree-building process and how much it improves the model fit. In other non-tree-based models, it was calculated as the magnitude of the weight or coefficient connecting a specific input or variable to the output [37]. We also evaluated the variable importance using an alternative approach called Shapley Additive Explanations contribution in one of the top performing models, which measures how much the average model prediction would change with and without a specific feature or variable [38], as shown in [Multimedia Appendix 1](#). All the analyses were performed using the *h2o* package [39] in R (R Foundation for Statistical Computing; version 3.6.1).

Results

Table 1 presents the sociodemographic characteristics and key measures of engagement for the participants (N=80). The mean age of participants was 40.2 (SD 11.2) years with a mean baseline BMI of 34.4 (SD 5.0) kg/m². Participants were predominantly female (68/80, 85%) and mostly White (72/80,

90%) White, with most (58/80, 73%) reporting completing college or graduate school. The baseline characteristics of the participants in the 2 treatment conditions were similar, and we did not observe significant differences in these variables between the groups. Over the 16-week intervention, participants in the closed group commented or replied to 9.9% (37/374; SD 10.4%) of the posts on average, whereas participants in the open group commented or replied to 8.8% (34/387; SD 9.7%) of the posts on average.

Table 2 presents the key characteristics of the posts and comments or replies generated over the 16-week intervention across the 2 treatment arms. Post length was 33.4 words on average (SD 23.81) and 57.3% (436/761) of the posts were created by the interventionists. It should be noted participants in the 2 groups were exposed to identical program posts (whereas the number of self-generated posts by interventionists could be different). Topic modeling results showed that diet was the most popular topic across all posts (310/761, 40.7%), followed by exercise (163/761, 21.4%), goal or plan (152/761, 19.9%), and weight (138/761, 18.1%). We did not observe significant differences in post or comment or reply characteristics across groups, except that the percentage of replies or comments directed at randomized participants was significantly higher in the closed group than the open group ($P<.001$), possibly because there were 54 nonrandomized participants in the open group.

Table 1. Participant characteristics (N=80).

Table 3 shows the results from mixed-effects regression models on how well each variable predicted participants' engagement with a specific post. Regarding post characteristics, we found that the overall probability of participants' engagement with each post decreased by 0.04% each day ($P < .001$; 95% CI 0.02%-0.06%). Participants had a 6.3% ($P < .001$; 95% CI 5.1%-7.5%) higher probability of engaging with posts generated by the interventionists than with posts created by other participants. Post length also mattered—one additional word in a post's content was associated with a 0.05% ($P < .001$; 95% CI 0.03%-0.08%) increase in participants' probability of engagement. Participants also had a 6.5% ($P < .001$; 95% CI 4.9%-8.1%) and 6.1% ($P < .001$; 95% CI 4.1%-8.1%) higher probability of engaging with posts if the post content was related to weight and goals or plans, respectively. Regarding reply or comment characteristics, participants were 44.8% ($P < .001$; 95% CI 42.8%-46.9%) more likely to engage with a post when they received replies from other participants in the conversation or 46% ($P < .001$; 95% CI 44.1%-48.0%) more likely to engage if they received replies by interventionists. A 1 SD decrease in the sentiment in the previous replies or comments was associated with a 5.4% ($P < .001$; 95% CI 4.9%-5.9%) increase in the probability of participant engagement. Participants' engagement in previous posts was a strong predictor of future engagement—a 1% increase in participants' previous engagement was associated with a 0.76% ($P < .001$; 95% CI 0.74%-0.79%) increase in their probability to engage with a subsequent post. Robustness analyses showed that these results were largely consistent with the results from (1) multivariate linear regression results and

mixed-effects regression with participant-level fixed effects and (2) mixed-effects logistic regression with or without postlevel random effects and participant fixed effects. Details of the results from these additional regression analyses can be found in [Multimedia Appendix 1](#).

To confirm the importance of previously identified predictors and test how well the aforementioned variables can predict the probability of a participant engaging with a post, we performed a variety of machine learning-based classification algorithms with all the aforementioned predictors as the input and participant engagement as the outcome. Of the 32 models we tested, the ensemble approach of gradient boosting machine learning-based and deep learning-based classification algorithms performed the best, with an average area under the curve of 0.963 using 5-fold cross-validation (see more results in [Multimedia Appendix 1](#)). **Figure 2** shows the variable importance across 20 machine learning models (excluding ensemble models) we tested, with those indicated by yellow and red being more important variables. The results show that receiving a reply from other participants and interventionists, percentage of previous posts participants had engaged in, average sentiment in previous replies or comments, time of the post, and day of the week were the most important variables across models, which were consistent with the results from regression analyses. Finally, we performed out-of-sample predictions on a balanced sample with 1600 observations (800 observations with engagement and 800 observations without) and achieved 90.9% accuracy and 0.908 F_1 score at maximum.

Table 3. Mixed-effects regression results predicting participants' engagement (N=31,968)^a.

Mixed-effects regression	Values, mean (SD; range)	Coefficient (95% CI)	P value
Outcome: participants' engagement	0.140 (0.347; 0 to 1)	— ^b	—
Post characteristics			
Created by interventionists	0.583 (0.493; 0 to 1)	0.0627 (0.0507 to 0.0746)	<.001
Number of words	33.44 (23.80; 1 to 107)	0.0005 (0.0003 to 0.0008)	<.001
Content sentiment (standardized)	0 (1; -3.67 to 4.74)	-.0042 (-0.097 to 0.0012)	.13
Topics

Content sentiment (standardized)	0 (1; -7.84 to 5.91)	-0.0539 (-0.0589 to -0.0488)	<.001
Replied by other participants	0.026 (0.161; 0 to 1)	0.4484 (0.4279 to 0.4690)	<.001
Replied by interventionists	0.029 (0.167; 0 to 1)	0.4604 (0.4409 to 0.4798)	<.001
Participants characteristics			
Percentage previous posts commented or replied	13.16 (13.68; 0 to 100)	0.0076 (0.0074 to 0.0079)	<.001

^aThe model included postlevel random effects and also controlled for day of the week when the post was created and other baseline and sociodemographic characteristics of the participants, including treatment assignment, race, marital status, education, employment, number of people in the household, age, gender, baseline BMI, and weight.

^bNot available.

Figure 2. Variable importance of predicting participant engagement across 20 machine learning models. The x-axis shows different model names, and variables from top to bottom on the y-axis are baseline weight, number of people in the household, baseline BMI, age, post topic weight, post topic goal and plan, education, treatment assignment, post topic diet, post topic MyFitnessPal app, post topic exercise, employment status, marital status, post topic drink, post topic sleep, gender, race, post topic expressing emotion, post sentiment, whether the post is created by interventionists, day of the intervention when the post is created, word count of the post, replies or comments sentiment, day of the week when the post is created, percentage of previous posts engaged, and whether replied by other participants or by interventionists.

Discussion

Principal Findings

In this study, we conducted secondary analyses using data from a 2-arm pilot feasibility randomized controlled trial that delivered lifestyle interventions via Facebook. We analyzed commenting or replying behavior from 80 participants in response to each of the 761 posts generated by counselors and participants over the 16-week intervention period and linked them to predictors, including post characteristics (eg, time, post length, and post topic), conversation characteristics (eg, sentiment of the conversation and participants being replied to), and participant characteristics (eg, sociodemographics and previous commenting or replying behavior). Our findings suggest that although participants' comments or replies decreased over time, important characteristics of the post, the conversation attached to that post, and the participants' engagement patterns predicted whether a participant engaged with a specific post. For example, we found that participants who engaged more with prior posts were more likely to engage with future posts. Posts that were longer (with the maximum number of words not exceeding 107), were created by interventionists, or had content related to weight (eg, weigh-in posts) and goal setting are more likely to attract engagement. The latter is consistent with the design of the intervention—participants were asked to set diet and exercise goals for the week each Monday, report their progress on their goals on Sunday, and report their weight change for the week each Friday. This is also encouraging because goal setting [40] and frequent self-weighing [41] are key behavioral weight loss

Model ID

strategies. Furthermore, posts with replies or comments that directly mentioned the focal participant were much more likely to attract subsequent replies from that participant. Moreover, posts with replies or comments that contained negative sentiments were more likely to attract subsequent comments. This is likely because participants who share struggles, problems, and challenges are naturally more negative in sentiment (see [Multimedia Appendix 1](#) for examples of replies or comments with negative sentiments), and such content often attracts support and brainstorming from other participants who may feel called to help when others are struggling. These results were robust to multiple alternative specifications. Machine learning results also show that together, these characteristics can predict participant engagement with a high accuracy of 90.9%.

Implications

In this study, we demonstrate the potential of using NLP tools to analyze microlevel conversational data and identify factors influencing participants' commenting or replying behavior in a social media-delivered weight loss intervention. Our findings shed light on some important microlevel characteristics of the participants, posts, and conversations, which can shape participants' experiences during the intervention and predict their future engagement. These results have implications for the design and implementation of social media-delivered behavioral interventions in ways that maximize participant engagement. We previously reported a strong association between participant engagement and weight loss [31], which suggests that engagement-enhancing strategies could lead to more favorable outcomes. For example, enhancing engagement

early on may help with sustained engagement. Furthermore, we found that receiving replies appears to stimulate further engagement from the participant. This may also be a function of whether a participant shares something substantive about themselves in a comment. For example, if a participant's comment is "thanks!" the interventionist may just hit the "like" button; however, if a participant's comment is a question or sharing of a goal, the interventionist and other participants are more likely to reply to continue that conversation. Further research should explore the type of comments (eg, questions, sharing a problem, and setting a goal) that are most likely to elicit replies from others. Program content should be designed in ways that nudge participants to post more often and interact more with each other (eg, use open-ended questions and encourage peer-to-peer support). Although in this study we found that participants were more likely to respond to interventionists, greater peer-to-peer engagement could also facilitate stronger group cohesion, thereby further enhancing participant engagement. Posts in which participants share struggles, problems, and challenges they have encountered during the weight loss process may draw more participants into the conversation, which may generate richer brainstorming and social support, both of which could also enhance group cohesion. These implications could be applicable not only to social media-delivered weight loss interventions but also to other digital health interventions more generally.

Comparison With Prior Work

Although many studies have tested social media-delivered weight loss interventions or emphasized the importance of participant engagement in web-based communities [12-15,42], only a handful of studies have identified the factors that can influence participant engagement in digital health interventions [43,44], and most of them focused on macrolevel factors such as post type and participants' characteristics (eg, age and gender) [9,14]. Few studies have examined microlevel factors such as conversation dynamics. Several studies recognized this limitation and called for more research to identify all relevant factors that can predict participant engagement [28,43,45,46]. This study contributes to this line of research in two ways: (1) we demonstrate how content generated by interventionists and participants during the course of a digital intervention can be leveraged and combined with data science and NLP tools to identify microlevel predictors of participant engagement, and (2) we have identified many microlevel factors that influence participant engagement, which, to the best of our knowledge, have not been studied in previous social media-based behavioral interventions. This has practical implications for future intervention designs that can maximize participant engagement.

Similar to previous studies, we found that participant engagement is highly variable [17-19], and it generally declines over time [16,47]. Although many factors identified in this study have not been studied in the social media-based behavioral intervention context, our findings are consistent with psychological and sociological theories, as well as several empirical research on web-based communication. For example, our finding that posts created by interventionists are more popular is consistent with other studies on web-based communities, showing that important users or those with

designated roles are more likely to draw responses from other users [26], possibly because of preferential attachment [48]. Our finding that replies or comments with negative sentiments draw more engagement implies that participants are more likely to reply or comment when they see others sharing their struggles and challenges. This could be possibly explained by social support processes, which have substantial empirical support across various web-based settings [22-25,49]. Finally, the importance of being replied to by interventionists and other participants can be explained by the preference for reciprocity [50], which has been found to be an important driver for communication in many other web-based settings [20,21].

Limitations and Future Work

This study has several limitations that point to avenues for future research. First, our sample size was small (80 participants; 10,157 total posts, comments, and replies) and our participants were predominantly White (72/80, 90%) and female (68/80, 85%). This limits the generalizability of our results, following a long-standing pattern in weight loss studies of difficulty recruiting male participants [51]. Similarly, given that 96% (77/80) of our participants reported attaining a college degree or advanced degree, we cannot generalize our results to individuals with lower levels of education. Future studies should devise recruitment strategies that attract more male participants and participants with low levels of education to further explore the individual heterogeneity across people from different backgrounds. Second, this study did not fully tease out all possible confounding factors and thus cannot establish causality. For instance, participants who are more successful in losing weight might also be more likely to comment simply because they are paying more attention to the group and have more to say as they are applying the knowledge and strategies they are learning. Future studies should include larger trials, surveys with more longitudinal measures (eg, physical activity and diet tracking, mental health, and other behaviors), and qualitative studies to establish the possible bidirectional and causal relationships between engagement and these factors. Third, we focused on replies and comments and did not explore other types of engagement such as reactions and views of posts and comments. Although comments and replies have been considered more substantive than other engagements (eg, likes and "lurking"), other engagements potentially comprise a substantial proportion of social media use and thus warrant careful consideration in future studies [33]. Similarly, although we included participants' posts in our analysis, we did not include posts only with images or videos or investigate the factors influencing participants' decisions to create posts, which is another important form of engagement. In addition, although we included tags or mentions relationships in our study, most tags were automatically generated by Facebook during replies or comments. Future studies should consider whether deliberate tagging can nudge disengaged participants to re-engage with the program. Fourth, we assumed all participants had an opportunity to engage with every post in the group, and we considered all replies or comments when constructing the predictors for participants who did not engage with a certain post, which might not necessarily be the case if the participant did not see the post or the previous comments or replies. Future

studies could take additional information into account, such as what participants viewed and the time a participant spends on Facebook. This will allow researchers to construct more refined measures to reflect the condition under which participants make a decision of whether to engage. Finally, although we observed that longer posts are more likely to draw engagement from participants, it should be noted the posts in this intervention were generally short by design (mean 33.4, maximum 107 words). Social media marketing reports reveal that Facebook posts that have <50 characters receive the highest level of engagement relative to longer posts [52]. A/B testing of a wide range of post lengths and different types of posts (eg, goal setting vs problem sharing) is needed to determine the ideal length of posts to maximize engagement in behavioral interventions.

Conclusions

In this study, we performed secondary analyses using data from a pilot feasibility randomized weight loss trial that delivered a lifestyle intervention via Facebook and linked participants' engagement with several important predictors, including characteristics of the posts, replies or comments, and participants. Our results point to the potential of using data science and NLP tools to analyze microlevel behavioral or conversational data and identify factors influencing participants' engagement during the social media weight loss intervention, which have implications for the design and implementation of future interventions that could lead to more favorable weight loss outcomes. Future studies are warranted to validate our results and further explore these relationships in similar and larger trials.

Abstract

Background: Successful transition from pediatric to adult health care settings supports long-term health management and better overall outcomes in all domains. However, young people with spinal cord injuries (SCIs) continue to report challenges and unmet needs during the transition process. Including end users in health care research and intervention design is paramount as interventions designed in this way better meet their specific needs and are often more innovative. Although studies have reported involving young people with chronic conditions in the development of health care transition (HCT) interventions, few details have been provided as to how this was achieved.

Objective: This study outlined the co-design and development of an HCT intervention to support young people with SCIs. It contextualized the co-design process, methods, materials used, and steps implemented from defining the problem to conceiving and designing the solution. This was accomplished by understanding and listening to end users' needs and recommendations for HCT.

Methods: Using participatory methods, this qualitative study reports the co-design of an HCT intervention to support young people with SCIs and parents or caregivers. Two co-design workshops were conducted: one with young people with SCIs and one with parents and caregivers. Categories were defined through a hybrid deductive and inductive qualitative content analysis process that was informed by the Care Transitions Framework and guided the development of the HCT intervention. Following the creation of a prototype intervention, young people with SCIs, parents and caregivers, and key pediatric SCI stakeholders provided feedback on the intervention content and design in focus groups. Similar to the workshops, the focus groups were analyzed using a hybrid deductive and inductive qualitative content analysis process informed by the Care Transitions Framework. The Enhancing the Quality and Transparency of Health Research guidelines for qualitative research (Consolidated Criteria for Reporting Qualitative Research) were applied.

Results: Overall, 4 young people and 4 parents or caregivers participated in the co-design workshops. Key recommendations for the HCT intervention were that participants wanted a "one-stop shop" for all their transition information needs and an editable portable medical summary to take with them to appointments. On the basis of the analysis of participants' recommendations from the workshops, it was determined that a website would be an appropriate hosting platform for the interventions. The focus group feedback on the design and content of the prototype website was extremely positive, with minor recommendations for improvement.

Conclusions: This is the first study to co-design and develop an HCT intervention in partnership with young people with SCIs and parents and caregivers. Although the study sample was small, it has shown that it is possible to meaningfully engage and empower young people with SCIs and parents and caregivers in the co-design of an HCT intervention.

Introduction

Background

A key goal in the rehabilitation of children with a spinal cord injury (SCI) is to facilitate the attainment of a productive and satisfying life by addressing developmental milestones and the provision of education on managing the complex health issues that arise because of aging and living with an SCI [1]. Importantly, a seamless transition from the pediatric to the adult health care systems, termed health care transition (HCT), is a significant and critical factor in supporting the fulfillment of goals while fostering independence and improved health outcomes [2].

Supporting a seamless HCT has been on the international health care agenda for >3 decades [3-5], yet young people with chronic conditions continue to report facing a multitude of barriers to their move [6,7]. These barriers include fear of losing established relationships with pediatric providers and forming new ones with adult providers, inadequate preparation for and information on the adult health care system, lack of self-management skills and disease knowledge, and poor communication between the pediatric and adult health care providers [6,7]. Consequently, these barriers result in poor health outcomes such as nonadherence to treatment and medication, loss to follow-up, increased hospital admissions, and patient dissatisfaction [7]. As such, there is an opportunity to reduce the difficulties faced by young people with chronic conditions through the development of HCT interventions that prepare them for the move and improve the transfer process.

In recent years, there has been significant progress made toward improving HCT for young people with chronic conditions. Evidence suggests that a structured HCT process, including planning for transition, transfer assistance, and integration into adult services, can improve outcomes for young people with chronic conditions, such as patient satisfaction, population health, and the use of health care services [2]. However, to date, HCT research has been disease-specific, and studies are typically characterized at the lowest evidence level, making them difficult to apply in various contexts [2,8].

Similar to other young people with chronic conditions, young people with SCIs face many barriers and facilitators in their transition to adulthood with regard to both health care services and normative life milestones such as education, employment, social participation, and independent living [9]. A study conducted in the United States on 23 young people with SCIs and their caregivers identified processes within health care that acted as both a barrier to and facilitator of the transition to adulthood [9]. Facilitators included health care support comprising the transfer of medical records, clear communication of transition timelines and expectations, referrals to adult services, and collaboration between the pediatric and adult settings. Health care barriers to transition included complex

adult services, limited resources, and minimal previous exposure to the adult health care setting. In particular, the study indicated that, when it came to health care, there was a need for more condition-specific education for local, nonspecialized health care providers; better communication among health care providers; and an accessible, concise, and comprehensive medical history [9]. Evidence on the availability of HCT interventions for young people with SCIs that attempt to address these transition needs is scarce, with only 1 Australian article offering an explanation of their HCT efforts [10].

As the importance of end-user involvement in health care research and intervention design has been increasingly recognized, there has been a shift away from end users being passive participants in research, where research is conducted on them, to active participation, where research is conducted with them [11,12]. One such research approach, participatory action research (PAR), is particularly useful in co-design. PAR involves researchers collaborating with service users and key stakeholders in a collective and reflective inquiry to understand and improve practices and situations [13]. This process acknowledges that participants have knowledge and expertise to share, which is particularly important for the disability community whose voices have too often been silenced [14].

Collaboration within the PAR process takes place through iterative cycles of “planning, acting, and review” [15], and co-design can be used to facilitate the action stages. The co-design process actively involves all stakeholders in identifying solutions to local problems using their experience and expertise to explore the current needs of service users and develop and test concepts before improving the prototype in an iterative process [12]. Interventions designed in this way better meet the specific needs of end users and are often more innovative [11].

Although studies have reported involving young people with chronic conditions in the development of HCT interventions, few details have been provided as to how this was achieved [16]. As such, more transparency is needed regarding the process, methods and materials used to include young people with chronic conditions in intervention development.

The aim of this qualitative study was to fill this knowledge gap by providing a detailed explanation of the process involved in understanding the needs and recommendations for HCT as part of the co-design and development of an HCT intervention with young people with SCIs. This is the first study to co-design and develop an HCT intervention in partnership with young people with SCIs and parents or caregivers. Please note hereafter and unless otherwise specified, the term caregivers will be used to denote parents or caregivers. Addressing the needs of individuals and the current gap in services has the potential to improve transition outcomes and the quality of life of children and young people with an SCI.

Research Context and Conceptual Framework

The work presented in this paper forms part of a wider 3-year study informed by a PAR approach that aimed to co-design, develop, implement, and evaluate an HCT intervention to support young people with SCIs in New South Wales (NSW), Australia. Further details on the current SCI services in NSW can be found in an evidence series by the Agency for Clinical Innovation [17].

The study protocol has been published elsewhere [18]. In summary, the 3 study phases were informed by the Care Transitions Framework [19]. The Care Transitions Framework is an adaptation of the Consolidated Framework for Implementation Research, an established conceptual framework in implementation science [19]. The framework guides the research and evaluation of care transition interventions within a variety of settings and can be used in parts or as a whole. Organized into 8 domains, the Care Transitions Framework provides a comprehensive guide to potential questions that can be explored depending on the nature of the research and its goals [19]. Five of the domains for the overall study are presented in [Multimedia Appendix 1](#). The 3 remaining domains (external context, organizational characteristics, and characteristics and roles of providers) were addressed as part of the prestudy consultation process.

Methods

Study Design

The overarching 3-year PAR study consisted of 3 phases ([Multimedia Appendix 1](#)). Phase 1 used semistructured interviews to explore the experiences with HCT of young people with SCIs and caregivers and has been published elsewhere (Bray et al, under review). Briefly, these interviews revealed that young people with SCIs and caregivers faced barriers and had unmet needs in their transition to adult health care services (Bray et al, under review). During the phase 1 interviews, young people with SCIs and caregivers identified the need for a coordinated and streamlined handover from pediatric to adult health care providers and a “one-stop shop” for transition information, such as how it occurs, who to call for ongoing support and advice, and tips on how to transition successfully (Bray et al, under review).

This paper presents the findings from phase 2 of the PAR study, which consisted of 2 parts. Phase 2a built on the findings of the phase 1 interviews and engaged both young people with SCIs and caregivers as individuals with “lived experience” in co-design workshops to inform the development of a prototype HCT intervention. In continuation of the co-design process, phase 2b used focus groups to gather feedback on the prototype HCT intervention, leading to further refinement before phase 3 evaluation. As part of the PAR approach, the participatory methods used included collaboration, active engagement, and reflection that occurred through iterative cycles of “planning, acting, and review” [13,15]. This phase (phase 2) of the PAR study formed part of the acting phase of PAR and supported working collaboratively with the community of interest to identify actions necessary to achieve the desired outcomes.

This study has followed the Standards for Reporting Qualitative Research [20].

Ethics Approval

This study received ethics approval from the Western Sydney University Human Research and Ethics Committee (H14029) and was registered with the Australian New Zealand Clinical Trials Registry (ACTRN12621000500853). Participation in this study was voluntary. Written consent was obtained at the beginning of the study, and verbal consent was obtained at the beginning of each workshop or focus group. All young people aged <16 years also required written consent from a caregiver. Transcripts were deidentified, and participants were assigned a pseudonym to maintain confidentiality. Participants received an Aus \$30 (US \$20.30) e-gift card each as a *thank you* for their time.

Participants

Owing to the limited number of pediatric-onset SCI cases in Australia [21,22], participants were recruited from both metropolitan and rural areas of NSW. To be eligible for inclusion, participants needed to be young persons aged between 14 and 25 years and have sustained a pediatric-onset traumatic or nontraumatic SCI (at or before the age of 16 years) or be a parent or caregiver of the same. Individuals had to be preparing for or have made the transition from pediatric to adult health care services (including tertiary hospitals and community services). Sufficient English-language proficiency was another requirement to ensure that all participants could fully engage in the conversation. Exclusion criteria were individuals who were receiving rehabilitation treatment for an injury sustained in the previous 12 months. This exclusion criterion was implemented so as not to burden the individual or their family with the demands of participating in research or risk causing any additional emotional distress during this tremendous period of adjustment. Individuals with neural tube defects such as spina bifida were also excluded. Although the authors acknowledge that individuals with neural tube defects share many of the same clinical characteristics and complications as those with SCIs, these individuals also demonstrate distinct features [23]. Research on HCT also typically focuses purely on SCIs [9] or spina bifida [24,25], with children and young people with spina bifida reported as a separate group supported by their own services. As such, this study focused specifically on young people with pediatric-onset traumatic or nontraumatic SCIs.

Recruitment

Young people with SCIs and caregivers were recruited from the individuals who had participated in the previous phase of the overall study. We contacted all 9 participants first via email to determine availability. We then contacted the participants by phone to confirm their availability and book the workshop or focus group. Each participant was sent an SMS text message the day before the workshop or focus group to confirm attendance.

Rigor and Reflexivity

To maintain rigor within the study, credibility was ensured by reporting verbatim excerpts, tracking coding and category decisions, and confirming these through researcher triangulation

[26,27]. Although the study findings and the tailored intervention may not be generalizable to populations outside the study setting, providing a comprehensive description of the co-design process through detailed reports, thick descriptions, and analysis of contextual details, as described by Ponterotto [28], may allow for the transferability of the research method across contexts and medical conditions [29]. A comprehensive commentary reflecting on and cataloging the progress, obstacles, and successes of the research process increased dependability and confirmability by providing an audit trail for the study [29].

The primary researcher in this study (EAB) was an individual with an SCI, and a crucial step in their personal reflexivity [30] involved reflecting on how their position and perspective affected the study, in particular how being a member of the SCI community and having shared experiences but also common contacts allowed for the development of relationships with young people and caregivers. Developing these relationships at the beginning of the study and allowing time for non-research-focused conversations created a safe space in which young people could express their needs. Nevertheless, as the researcher sustained their SCI at the age of 22 years and did not use any pediatric services, the young people were the experts in this area.

Co-design Workshops (Phase 2a)

Methods

Overview

Two workshops were run on the web (owing to the COVID-19 pandemic) via videoconference (Zoom Video Communications): one for young people with SCIs and one for caregivers. Two researchers facilitated the workshops, one taking on the role of lead facilitator (EAB) and the second acting as cofacilitator and note-taker (LMR). Each workshop was run as a single group (all participants together all the time), with each participant invited to contribute their thoughts during each activity. Discussion prompters (eg, Ideafly [Biggerfly Ltd] and Microsoft PowerPoint) were used in the workshops to organize material from discussions, enhance feedback, and guide intervention development. The workshops were recorded and transcribed with the participants' permission.

Preworkshop Preparation

A reference group was consulted to provide expert advice on the appropriateness of the co-design workshop activities, identify any issues or barriers that could impede the success of the workshop, and provide advice on how to resolve these issues or barriers. This reference group consisted of a young person with an SCI and 3 health care professionals (n=1, 33% clinical nurse consultants and n=2, 67% occupational therapists) from 3 different pediatric SCI health care service providers.

Approximately 1 week before the workshops, the facilitators met to clarify roles and review the workshop schedule and timing of activities. Participants were also sent an information booklet (Multimedia Appendices 2 and 3) and a link to the videoconference meeting by email.

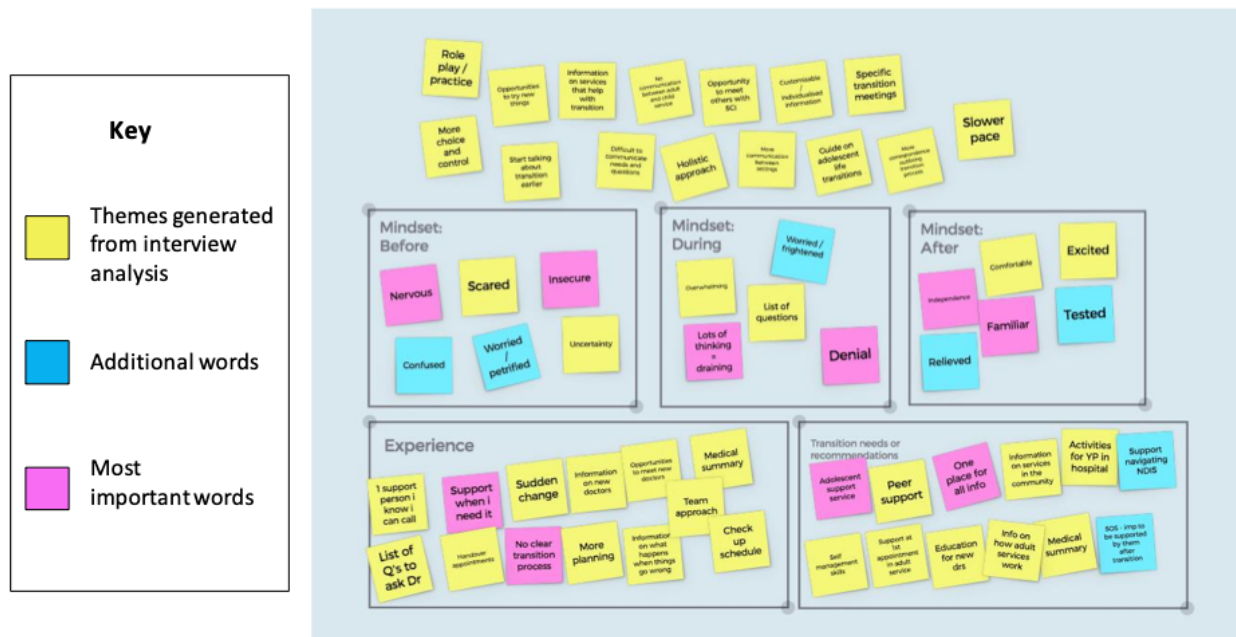

Workshop Warm-ups

Each workshop began with a reminder of the aims of the study followed by a fun icebreaker activity (Multimedia Appendix 4) to help build rapport and ease any anxiety. Given that we were discussing issues relating to their personal experience transitioning between health care services, we asked that participants maintain confidentiality, especially if any sensitive issues were discussed. At the same time, each participant was encouraged to share as much or as little as they were comfortable with. This created an atmosphere that promoted open and honest communication and sharing. In the young persons' workshop, this information was reiterated at the start of the second activity (without the icebreaker) as some young people joined the workshop after the completion of the first activity.

Young Persons' Co-design Workshop

The young persons' workshop was 120 minutes long and consisted of 2 activities. The first activity required participants to review the thematic analysis of the semistructured interviews conducted by EAB and LMR as part of phase 1 of the research study. Participants were encouraged to reflect on some of the common ideas and concepts (codes) generated by the facilitators, confirm their authenticity, and compare and discuss analytical decisions as they grouped codes into themes. A web tool (Ideafly) was used to create a whiteboard with Post-it notes to organize each idea or concept into predetermined boxes titled "Mindset: before," "Mindset: during," "Mindset: after," "Experience," and "Transition needs or recommendations" (Figure 1). These predetermined box labels aligned with the "Characteristics and Roles of Patients and Caregivers" domain of the Care Transitions Framework. Participants were also asked to add words or ideas that they believed had been omitted and highlight the most important word for them in each box. Participants' reflections on common ideas, concepts, and themes confirmed the thematic analysis conducted by EAB and LMR and have been published elsewhere (Bray et al, under review).

For the second activity, the researchers used the future workshop method [31,32] to facilitate discussion and generate ideas for the development of the HCT intervention. The future workshop method consists of 3 phases: a critique phase, a fantasy phase, and an implementation phase [31,32]. In the critique phase, the participants were asked to identify deficits or challenges related to the HCT experienced by young people with SCIs. The questions posed included the following: "What is the change you want to see? Or what did you need most to support your move but didn't have or receive?" In the fantasy phase, the participants were asked the following: "In a perfect world, how can this be achieved? Or what could we develop to support your move?" In the implementation phase, the participants transformed the "perfect world" ideas into a design for a practical and realizable HCT intervention ("How can we make this possible today?"). Participants had been provided with these 3 questions before the workshop in their information booklet. Using a Microsoft PowerPoint slide as a whiteboard, we discussed the participants' answers to the 3 posed questions and asked them to discuss their thought processes and ideas (Multimedia Appendix 5). The participants built on each other's ideas.

Figure 1. Screenshot of the first young peoples' co-design workshop activity.

Caregivers' Co-design Workshop

This 1-hour workshop mirrored activity 2 of the young persons' workshop (Multimedia Appendix 6). The questions posed to the caregivers included the following: (1) "What is the change you want to see? Or what did you need most to support your child's move but didn't have or receive?" (2) "In a perfect world how can this be achieved? Or what could we develop to support your child's move?" (3) "How can we make this possible today?"

Workshop Evaluation

At the end of the young persons' workshop, a short evaluation of the co-design workshop process took place. A web tool called Mentimeter (Mentimeter AB) was used to pose the following question: "Using 5 or more words, describe how you felt as a participant and what you thought of the workshop?"

Workshop Follow-up

Following the workshops, participants were provided with a link to a secure web-based Google document that included the questions posed in the workshops and a summary of the topics and ideas discussed. Participants were encouraged to cross-check information, add any information not covered during the workshops, and continue to develop the ideas generated.

Workshop Analysis

The audio recordings were transcribed and used in conjunction with the discussion prompters (Microsoft PowerPoint) to generate content themes for guiding the development of the HCT intervention. The researchers used a hybrid approach of deductive and inductive qualitative content analysis [26] of the transcripts, notes, and materials produced after each workshop. The reason this analysis method was chosen was that it allowed the researchers to organize and understand the data in a meaningful way and, through a manifest analysis, allowed the

researchers to describe "what the informants actually say" by remaining close to the verbatim text [33]. The analysis was conducted in 3 stages: preparation, organization, and reporting [26]. In the first stage, the researchers immersed themselves in the data to obtain a sense of them as a whole. In the next stage, the researchers organized and condensed the data into meaning units through a process of open coding, categorization, and abstraction for the inductive approach and used the Care Transitions Framework to develop a categorization matrix for coding for the deductive approach (Multimedia Appendix 7). Finally, the contents of the categories and subcategories are described in detail as part of reporting the results.

Results

Participants

Young people joined and left the workshop at different times because of other commitments. In total, 2 participants, both female with tetraplegia aged 20 and 21 years, were present for the first activity of the young persons' workshop. A total of 3 participants, 2 (67%) female (n=1, 50% with tetraplegia and n=1, 50% with paraplegia) and 1 (33%) male with tetraplegia aged between 17 and 20 years were present for the second activity; 1 (33%) had attended the previous activity, and 2 (67%) new people joined for the second activity. In total, 4 participants, all mothers, attended the caregivers' workshop. A total of 75% (3/4) of the mothers had children with tetraplegia, and 25% (1/4) had a child with paraplegia. Only 1 young person and 1 caregiver had not yet transitioned. In total, 89% (8/9) of the original participants from phase 1 of the overall PAR study contributed to the co-design workshops.

Recommendations for the HCT Intervention

Overview

Data from the workshops were categorized in alignment with the Care Transitions Framework as summarized in Table 1.

Table 1. Workshop analysis content categories.

Category 1: What Is the Intervention Designed to Achieve?

Although caregivers wanted an intervention that supported their children in achieving greater independence, young people wanted the intervention to offer a space for peer connection. However, both caregivers and young people requested that the intervention support a coordinated handover between the pediatric and adult health care services and their multidisciplinary team members, including medical, nursing, rehabilitation, and allied health professionals.

1.1: Coordinated Handover Between Services: “For There to Be More of a Relationship Built With the Doctor Before the Transition Occurs”

Both young people and caregivers advocated for a smoother and more streamlined HCT. They believed that greater communication between the 2 health care settings (pediatric and adult) was essential for this to happen:

The adult service neurologist knew her paediatric neurologist and that is [a] huge help because they can chat between themselves, especially [because] we have the same neurologist for 15 years and he knew everything about Drew. It's so easy [for them] to communicate, rather than going through me.
[Morgan, caregiver]

In addition, participants wanted their pediatric health care team to organize the initial introductions of the family unit to the new adult health care team before transition:

I think just having an introduction as a family transitions across would be good. [Jude, caregiver]

They felt this would reduce the need for young people and their caregivers to have to repeat their stories to different health care professionals:

Just a handover so people know where you are and you're not having to repeat yourself all the time.
[Kris, caregiver]

Furthermore, young people indicated a belief “that some doctors underestimate how big the transition actually is for young people” (Jamie, young person) and, as such, more support should be provided during the transition process. This would allow young people and their caregivers to build a relationship and rapport with their new health care team before moving and, in so doing, it would ease any anxiety around the transition:

For there to be more of a relationship built with the doctor before the transition occurs...so that the doctors are more aware of how the doctors in the children's hospital provide support and possibly adopt that, even though they're in the adult hospital. [Jamie, young person]

1.2: Greater Independence: “I Want to Start Moving That Stuff to Her, Getting Her to Do Things Independently”

Caregivers acknowledged that, around the age of 16 years, young people legally could take charge of their own health care but that a lack of self-management skills at this age can result in unanticipated errors that can both be financially costly and have a detrimental impact on one's health:

The issue of being 16 [is that] Taylor was in charge, really on paper—he's in charge of his own health care, while he wanted us, as parents, to guide some of that. He wanted to make his own decisions and [has] every right to...Taylor is the voice of his own body. He's not always right, but it's 16 when he's making some of those choices and those choices are very expensive choices if you're buying a chair or you're paying for things...there's so many things that we've got wrong that have been a trial and error.
[Rory, caregiver]

Further to their lack of skills and knowledge, some caregivers identified that their child did not want to take charge of their own health care. However, caregivers saw the relinquishing of responsibility for health care decisions to the young person as an important milestone in the move to adult health care services:

She doesn't even want to entertain the thought of ordering products for herself or ringing up to get a new commode pusher. She wants me to do all that for her, I'm happy to, but I would like to see that, in the transition coming up in the next couple of years, I want to start moving that stuff to her, getting her to do things independently herself. [Kris, caregiver]

Going forward in the young persons' move to adult health care services, caregivers saw that a requirement of the HCT intervention should be to build independence and the skills they need to manage their health care on their own:

So there's definitely something for me about...this kind of thing of letting young people become young people with that fierce independence, but to develop the skills that they actually see a chair as a piece of equipment that's necessary, that they see that they need that kind of life skills of being able to manage in situations. [Rory, caregiver]

1.3: Peer Connection: "Support Group of the People Going Through the Same Thing as You"

All young people identified having an intervention that supported the opportunity to connect with others going through a similar experience as an important priority:

A support system where everyone going through the same experiences is able to kind of bond and start friendships. [Jamie, young person]

Category 2: What Are the Features of the Intervention?

Young people and caregivers clearly outlined what they imagined an HCT intervention would need to include to achieve the desired outcomes outlined in the previous sections. These included information on the transition process and adult health care system, a medical summary including a contact list for health care professionals, accessible resources all located in one place, and a space to connect with others.

2.1: Information on the Transition Process and Adult Health Care System: "Written Information and Summary on the Transition Process"

Part of the struggle participants faced in their transition was a lack of knowledge of how and when the transition to adult health care would occur as well as how the adult health care system works:

It seems that some services change over or changed over when Jessie turned 16 and then others have stayed with paediatric services and so we've got this mix of some adult doctors ongoing with Jessie and some who are still in the paediatric system and it seems very messy for us. We're not sure whether we're in the adult system yet or in the children's system. [Jude, caregiver]

I didn't have the knowledge. For example, in intensive care in paediatrics, we always had the same person and he was constant. Now, when we ended up in ICU for six weeks, every four days is a new doctor and that is so disturbing. Having 15 years [with] the same

doctor and now, every four days, it was really hard to follow and it's not easy. [Morgan, caregiver]

To address this knowledge gap, participants recommended having more information and education on the transition process and the adult health care system:

Written information and summary on the transition process. [Drew, young person]

2.2: Medical Summary and Contact List: "Parallel Lists of What Was Before and What Was Now. Like, Paediatric Versus Adult."

Participants identified that a coordinated handover could be further supported with written documentation that is readily available to health care professionals, young people, and caregivers. A medical summary specifically created for the handover would mean that young people and their caregivers would not have to retell their stories:

A handover so people know where you are and you're not having to repeat yourself all the time. An updated information folio somewhere where you can access your information and where the doctors can access your information. [Kris, caregiver]

Participants envisioned that the medical summary would include the young person's medical history, a schedule for annual appointments and scans, experiences they valued in the pediatric health care setting, and accomplishments:

The medical history of each person, what experiences from the paediatrics that they really enjoyed and would love to be integrated in the adult hospitals just to make it not as daunting when the transition occurs. [Jamie, young person]

Getting a clear list of what are the ongoing check ins that Jessie needs for bladder, for bowel, for bones and how frequently we have to have those scans and tests done. I'm still trying to piece that together and it's incredibly messy and I keep thinking I'm going to miss him having an important scan or test done because I don't have a schedule that says "every two years, Jessie will need a bone scan. Every 12 months, he'll need a kidney test." [Jude, caregiver]

Only 1 young person in the group described having a summary of their health care created for the handover process. However, despite it being given to the new health care team, Taylor felt that he had to repeat this information and supplement it. He also reported that he thought he probably had a copy of that summary but was not sure where it was now:

I think it had that, but I had to also repeat what could have been written down more than added to the summary. [Taylor, young person]

In addition to the transition-specific medical summary, participants requested a contact list for their health care team that clearly displayed the pediatric health care professional and who would be taking over that role in the adult health care setting along with their contact details:

It would be nice to have the parallel lists of what was before and what was now. Like, paediatric versus

adult...First [the] name of every condition, then name of every doctor or CNC [Clinical Nurse Consultant] and then equivalent or similar match in adult services and their contacts. [Morgan, caregiver]

2.3: One-stop Shop of Resources: “There Should Be Pamphlets or a Website With All the Information”

What was evident from the discussions was that participants desired a “one-stop shop” or a repository where all HCT information was packaged in an easy-to-understand format and accessible:

There should be pamphlets or a website with all the information that people need to make it easily accessible in one place. [Jamie, young person]

It's a package of education, health and everything else that's in our lives that can't be segregated. [Rory, caregiver]

When asked about the information and resources they would like to be included in an HCT intervention, there were several requests (Table 2).

Young people also spoke about having the opportunity to share resources and collaborate, possibly using a web-based forum:

Just coming back to the opportunity to share the resources online, also possibly starting a forum within that in order to share—to help share those resources a bit more easily. [Jamie, young person]

Finally, participants wanted information and resources to come from reputable sources such as physicians:

A list of resources provided by doctors possibly on the forum. [Jamie, young person]

Table 2. Information and resources requested for inclusion in the health care transition intervention.

Information and resources requested	Participant quotes
Information on disability (general and SCI ^a -specific)	<ul style="list-style-type: none"> • “Things to do with disability and all stuff.” [Ashley, young person]
Information on the difference between the pediatric and adult health care settings	<ul style="list-style-type: none"> • “How the adult system works and possibly differentiates from the children’s system.” [Jamie, young person] • “Someone to explain what’s the difference between paediatric and adult.” [Drew, young person]
Information on social activities	<ul style="list-style-type: none"> • “Information on sport. Like wheelchair sports and disabled sports.” [Taylor, young person]
Alternate funding options	<ul style="list-style-type: none"> • “For people who don’t get funding, like charities. Stuff like that to get equipment, wheelchairs, and stuff.” [Taylor, young person]
Tips on building self-management skills	<ul style="list-style-type: none"> • “So managing all of these things is actually a skill which can be learnt either in some workshops or self-education...maybe you can request from a...Social Worker who might come and show some tips to your child and some mind mapping or Excel spreadsheets.” [Morgan, caregiver]
Education and employment support	<ul style="list-style-type: none"> • “It’s not just the transition of his care and things. It’s that transition to what you do beyond school and how do you do that when you have a spinal cord injury?” [Jude, caregiver]

^aSCI: spinal cord injury.

2.4: Support to Connect With Others: “To Be Doing Something Together to Help Form Relationships”

When asked to expand on how they would like to connect with others going through a similar experience, young people recommended having both one-on-one and group support options. They recommended that the one-on-one support be a formal program tailored to the young person’s individual needs, matching them with someone who is either of a similar age or injury or who may have experience of transition, depending on what the young person desires:

Maybe the same age, but also similar injuries. So if it's someone who is able to walk, then someone who—I guess [a] support worker who may be able to walk. [Taylor, young person]

The group support would be more informal and would involve monthly catch-ups of a more social nature (bowling, trivia, and games on the web):

Do an activity during that, instead of talking. To be doing something together to help form relationships. [Jamie young person]

Category 3: Who Is the Intended Target Group?

The ultimate beneficiaries of the intervention are young people with SCIs. However, participants noted that they saw the intervention “as a package that everybody takes a role [in]” (Rory, caregiver). As such, the HCT intervention needed to support young people, their caregivers, and health care professionals.

Workshop Evaluation

A total of 75% (3/4) of the young people completed the evaluation at the end of the co-design workshop answering the following question: “Using 5 or more words, describe how you feel as a participant today and what you thought of the workshop?” The feedback was positive, and young people reported that they felt valued and listened to and that the

workshops were fun and informative ([Multimedia Appendix 8](#)).

The Prototype HCT Intervention

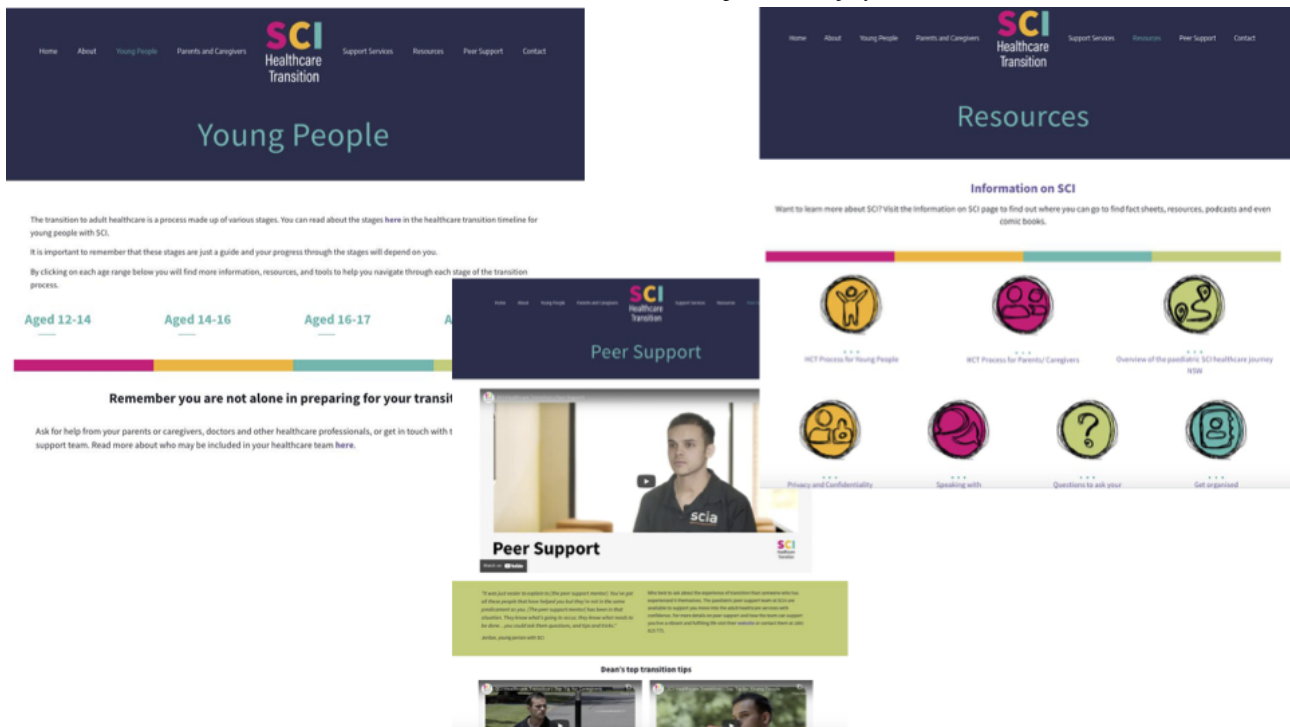

On the basis of the recommendations from participants in the workshops, it was determined that a website would be an appropriate platform on which to deliver the suite of information needs. Content categories from the workshop were used to guide the development of the prototype HCT intervention, the SCI Healthcare Transition website [34] ([Figure 2](#)). The development of the website occurred over a period of 4 months and was supported by a web designer, motion graphics designer and video editor.

The website was designed with the aim of supporting young people with SCIs to achieve greater health care independence, support the smooth and coordinated handover from children's to adult health care services, and offer young people with SCIs a way to access peer support. It aimed to achieve this by providing young people with SCIs and caregivers with a step-by-step guide to HCT categorized by age that included tools (eg, a goal-planning worksheet), tips (eg, a PDF on tips for talking to health care professionals), and resources (eg, information on SCIs) to help prepare for the move. It also provided a directory on where to access further support from health care professionals and peer mentors. The website used a combination of eye-catching colors and graphics along with videos, interactive quizzes, and PDFs that are both downloadable and can be filled in, with the intention of appealing to young people ([Figure 3](#)).

Figure 2. Screenshot of the SCI Healthcare Transition website home page. SCI: spinal cord injury.

Figure 3. A total of 3 screenshots of the SCI Healthcare Transition website. SCI: spinal cord injury.

Focus Group Evaluation of the Prototype HCT Intervention Development (Phase 2b)

Methods

Overview

Similar to the process outlined for phase 2a, 2 focus groups were run on the web (owing to the COVID-19 pandemic) via videoconference (Zoom): one with young people with SCIs and caregivers and the other with the study's reference group of SCI health care professionals. The proposed HCT intervention was presented to the 2 groups, each of whom provided constructive feedback on the overall content and the layout and structure, allowing for further refinement of the intervention. The focus group was facilitated by 2 of the study's researchers, one taking on the role of lead facilitator (EAB) and the second acting as cofacilitator and note-taker (LMR). The focus groups were run as a single group (all participants together all the time). Similar to the workshops, discussion prompters (Microsoft PowerPoint) were used to guide the discussion and feedback. The focus groups were recorded and transcribed with the permission of the participants.

Co-design Process Evaluation

At the end of the focus group with young persons with SCIs and caregivers, a short evaluation of the co-design process took place. The researcher reflected on the co-design process with participants and gathered evaluative feedback.

Focus Group Analysis

As in phase 2a, the focus group transcriptions were used in conjunction with the discussion prompters (Microsoft PowerPoint) to develop content themes for guiding the refinement of the prototype HCT intervention.

Results

Participants

Of the 9 participants contacted from phase 1 of the overall PAR study, 4 (44%) provided feedback to the focus groups. In total, 3 participants attended the young people with SCIs and caregiver focus group: 1 (33%) young person (female, aged 21 years with tetraplegia) and 2 (67%) caregivers (both mothers of children with tetraplegia). A caregiver (mother of a child with paraplegia) was unable to attend the focus group but submitted written responses to the questions.

A total of 3 participants were invited, and all attended the SCI health care professionals' focus group. The health care workers were from 3 different pediatric SCI service providers, and each had different professions (clinical nurse consultant, occupational therapist, and physiotherapist).

Recommendations

Overview

Data from the focus groups were categorized in alignment with the Care Transitions Framework as summarized in [Table 3](#).

Table 3. Focus group analysis content categories.

Process of implementation	
<ul style="list-style-type: none"> Website implementation 	—

^aNo subcategory.

Category 4: Does the Website Achieve What It Was Designed to Achieve?

The aim of the website, as identified in the workshop analysis, was to support young people with SCIs to achieve greater health care independence, support the smooth and coordinated handover from children’s to adult health care services, and offer young people with SCIs a way to access peer support. Participants were asked to keep these aims in mind when answering the first question: “Do the website’s features achieve these outcomes? If not, why not?” All participants responded positively, and no recommendations for changes with regard to the overall outcomes were made:

I think in terms of helping to guide and support the health care transition from kids to adults, it [the website] did a pretty comprehensive job. [Jude, caregiver]

Category 5: Website Features

Participants spoke about the features that they valued, however, had clear ideas on how the websites content could be further developed and refined.

5.1: Successful Features: “That Was...Really Awesome”

On the whole, participants spoke very highly of the website:

Your website is absolutely amazing. [Morgan, caregiver]

Young people and caregivers valued the wealth of information and noted that the fact sheets, resources, and links to podcasts and organizations were “handy to have in one place” (Morgan, caregiver) and “will encourage patients and their families to develop a necessary knowledge base” (Morgan, caregiver). Health care professionals affirmed this sentiment:

I suppose it’s kind of that link that I’ve always struggled with about trying to give more ownership to the young person of actually getting them to fill out bits themselves and then that kind of reveals any gaps in knowledge. [Avery, health care professional]

All participants liked the simplicity of the quizzes and checklists, and their interest was piqued by the motivational videos at the start and end of the intervention:

I love the About page how it’s got your video and the Peer Support one’s got Dean...that was...really

awesome...because straight away you’re like, “I want to click on that.” “I want to see what that’s about” and it’s just really kind of accessible and, teenagers, they kind of want to be fed information. [Robin, health care professional]

More specifically, participants reported that the medical summary template and health care goal-planning worksheet were comprehensive and useful for everyone, even for those who had already transitioned. Furthermore, the transition checklist was “a nice way of reminding young people about their responsibilities and their self-awareness” (Morgan, caregiver).

Not only did the participants approve of the content, but they also appreciated the website’s design scheme and simplicity. This was important for young people and caregivers as the transition between health care services is both stressful and overwhelming, and they often did not have the time or patience to navigate different websites to find information:

I just want to say how nice and colourful it is and that’s also important for people. Just to make it more inviting and happier because, as you know, it might be quite overwhelming when you are going through all of that. [Morgan, caregiver]

5.2: Recommendations for Improvement: “One Thing I Thought Would Have Been Really Useful Is...”

The participants had valuable recommendations for the further improvement of the website. They asked for more information on the National Disability Insurance Scheme (disability support funding), more information on the general life transitions of adolescence (study, employment, and living independently), and more education on SCIs (bladder and bowel management). In addition to the medical summary template already provided, young people and caregivers also wanted a schedule of health appointments template to record all necessary regular and ongoing health appointments; for example, bladder scans and bone density tests. Young people and caregivers could then get their health care team to check that they had not missed any important health checks:

One thing I thought would have been really useful is...once you’ve got your appointments calendar lined up, to just make sure that your rehab [rehabilitation] doctor looks over it to make sure you haven’t

forgotten to book in a bone scan or whatever else might be needed because it's really hard to remember all the bits and pieces that you need to check up on and I worry that there's something that we're missing because no-one's putting it together as a whole. [Jude, caregiver]

Participants also requested to hear or read more success stories and expand the website in the future to include a forum or mobile app for further peer connection opportunities:

Just add testimonials from participants with the same situation as Drew or with SCI. So it's a good thing because you can actually build a community here. You can gain support. It's hard. It's hard to find support these days. So I think it's a good thing. And also for caregivers like me. [Morgan, caregiver]

It would be awesome if, in a further extension of this, that they [young people] could somehow be connected, either on the website or in a social media group or an app [application] that they could opt into. [Reese, health care professional]

Category 6: Website Implementation

With regard to the website implementation, the researchers wanted to gain an understanding of the usability of the website as well as how best to inform young people and caregivers about it.

Although the participants acknowledged that the website needed to be functional and practical for young people of varying abilities and those that used different technologies (eg, eye gaze tracking software), they believed the website was easy to use and generally accessible to young people with multiple levels of physical abilities because of its simplicity:

All of the pages were very simple. They weren't too overcrowded with information. So it was really easy and quick to flick through. Jessie also had a look. He was able to navigate around it quite easily and simply using his usual equipment on the computer. [Jude, caregiver]

Participants appreciated the use of various formats of delivery, in particular the animation on the home page of the website, as they thought information delivered in this way was easier to digest than if a health care professional was speaking to them. In addition, participants reiterated that the simplicity of the website lent itself to being easy to use, and information was easy to comprehend for those that had limited time or a short attention span:

If anything is too complex, too busy, it just takes too much energy and it's too exhausting to try and navigate through it and sift through what you need to know. [Morgan, caregiver]

Participants believed that there was a place for all members of the SCI community to be involved in the implementation of the website, from health care professionals in the hospital setting to those in the community as well as community-based SCI support organizations. Participants believed it to be the role of all stakeholders to promote the use of the website by linking to

it from their own websites and advertising it in their newsletters and social media pages. Positively, the health care professionals who worked in these roles also envisaged themselves drawing on the website in their education sessions related to transition preparation:

I would actually...Show them the basics of it and go, "Go and have a look...This is all part of your preparation." [Avery, health care professional]

I would use this, absolutely, as a resource to actually talk our patients through the process of transition and it doesn't sound scary when it's coming from you guys and the way that you've presented that information. [Avery, health care professional]

Co-design Process Evaluation

Reflecting on the co-design process and their involvement, young people with SCIs and caregivers appreciated being given the opportunity to participate in the codevelopment of an intervention to support the HCT of young people with SCIs and caregivers. It made them feel respected, valued, and heard and provided participants with a sense of achievement:

It made us feel really respected that someone took the time to ask us what was useful for us to have in this. So often people preach at you and tell you what they think you should know and it was nice as part of this process for you to pause and ask, what would be useful for us? What did we want to see in here? [Jude, caregiver]

It feels engaging. Engaging and helpful. [Drew, young person]

I have a sense of achievement, it's nice to have something you did to help other people. [Morgan, caregiver]

Discussion

Principal Findings

Young people with SCIs and caregivers currently encounter obstacles in their HCT and report needing additional advice, information, and support to prepare for the move. This study has described the co-design and development of an HCT intervention to support the transition of young people with SCIs and caregivers from the pediatric to the adult health care setting. Information and advice to prepare for transition was purposefully presented in a manner that introduced young people to the transition process early and prompted them to learn more about their SCI and to start taking more responsibility for their own health care. Short videos informed young people about pediatric peer support services and offered "top transition tips" from a young adult who had experienced an HCT. The other tabs on the website provided links to support services, informational resources, and PDFs to support self-management skill development.

Although the purpose of this intervention was to provide support for young people with SCIs and their caregivers during their transition from pediatric to adult health care services, it must be acknowledged that this transition occurs during a broader

transition process—the transition to adulthood. The transition to adulthood and its implications have been previously discussed [9,35] and, as such, this was not the focus of this study. However, in the feedback focus groups, participants reported the need for more information on the general transitions, including study, employment, and independent living. Consequently, information on where to access support on topics such as sexuality, education, and employment was added to the website, although its focus remained on supporting the move from pediatric to adult health care services.

The participatory co-design approach used in this study supported the active engagement of young people with SCIs and caregivers in the design process and resulted in the development of an intervention that addressed the current gaps in the HCT process as identified by end users. These findings support the observations of others [36,37]. For example, a study from Ireland by Coyne et al [37] reported on the co-design of a website to support the transition of young people with long-term illnesses to adult health care services. Their study highlighted that a participatory co-design approach yielded a reliable, functional, and acceptable intervention to support young people in their transition to adult health care [37]. Beaudry et al [36] similarly described a participatory co-design approach in the development of a chatbot that aimed to promote the attainment of self-care skills during the transition to adult care. They also reported that the resulting intervention was feasible for supporting engagement during HCT. Furthermore, the involvement of health care professionals in the feedback focus groups in our study ensured that we gained a broader scope for the design of the intervention, ensuring that it not only fulfilled the needs of young people with SCIs but also complemented current services.

Including end users in disability research brings knowledge and experience that may not be held by the researchers themselves and that can add to the diversity of skills and knowledge required for more appropriately designed research [38]. Furthermore, PAR and co-design principles foster empowerment as people with disabilities gain control over their lives and make decisions on matters that affect them [14]. Neither Coyne et al [37] nor Beaudry et al [36] evaluated young peoples' experiences of being involved in the co-design process; however, our study did. Evaluation data from young people on their involvement in the co-design process highlighted that their inclusion empowered them, gave them a voice, and provided them with an opportunity to contribute to an intervention that would make a difference in their lives and the lives of others. This provides further evidence of the importance of giving young people with disabilities the opportunity to authentically and meaningfully participate in the research and codevelopment of interventions that affect their lives.

Acknowledgments

The authors thank all participants for their valuable feedback, creativity, and time. The SpineCare Foundation, Sydney, New South Wales, Australia, funded this project (grant number: not applicable). The funders had no involvement in the review or approval of the manuscript for publication.

Strengths and Limitations

Evaluation of the co-design process indicated that the participants valued the opportunity to be part of the development of a solution and appreciated being given a voice. However, the iterative and cyclical nature of the co-design process did present some challenges. Recruitment for the study and maintenance of engagement was a challenge across the different phases of the study. Of the 9 young people and caregivers who participated in the interviews during phase 1 of the study, 8 (89%) returned to participate in the co-design workshops, and 4 (44%) participated in the focus groups in phase 2. Reasons for the dropout included family stressors, relocation to another country, and nonresponse to phone or email. Owing to a paucity of participant numbers, we did not achieve a representative research sample, with no LGBTQ+ and no cultural and linguistically diverse representation (including Aboriginal and Torres Strait Islander input). A further limitation of our study relates to the inability to compare our findings with other similar studies because of a paucity of written literature on this topic [16].

Owing to the COVID-19 pandemic, activities initially intended to be held in person were moved to the web. This modification had its advantages as it eliminated geographical and mobility barriers to participation and fostered inclusive research practices. However, because of the additional pressures of COVID-19 and homeschooling on families, it was difficult to find times that were suitable to all, and it required a substantial amount of preparatory work on the part of the principal researcher (EAB) to organize workshops and focus groups.

The next phase of the PAR study is to assess the acceptability and feasibility of the HCT intervention. We plan to roll out the website with the same participants and conduct short evaluation telephone interviews based on the 8 focus areas in the framework by Bowen et al [39].

Conclusions

Engaging young people with SCIs and caregivers in the co-design of an HCT intervention has produced, in a relatively short time frame, a great depth of insight into the transition needs of young people with SCIs and their priorities for support. The result has been the collaborative development of an intervention that young people with SCIs, caregivers, and health care professionals believe will support the transition from child to adult health care services and equip young people with SCIs with practical and helpful tools to take charge of their health care. This is the first study to co-design and develop an HCT intervention in partnership with young people with SCIs and caregivers. Although the study sample was small, it has shown that it is possible to meaningfully engage young people with SCIs and caregivers in the co-design of an HCT intervention that leads to enhanced end-user acceptability.

Authors' Contributions

All authors were responsible for the study conception and design. EAB and LMR acquired the data, completed the data analysis and verification, and drafted the manuscript. All authors were responsible for reviewing and finalizing the manuscript, provided approval for the final version of the report, and agree to be accountable for all aspects of the work.

Abstract

Background: Physical activity (PA) has an impact on physical and mental health in neurotypical populations, and addressing these variables may improve the prevalent burden of anxiety in adults with autism spectrum disorder (ASD). Gamified mobile apps using behavior change techniques present a promising way of increasing PA and reducing sedentary time, thus reducing anxiety in adults with ASD.

Objective: This study aimed to compare the effectiveness of a gamified and behavior change technique–based mobile app, PuzzleWalk, versus a commercially available app, Google Fit, on increasing PA and reducing sedentary time as an adjunct anxiety treatment for this population.

Methods: A total of 24 adults with ASD were assigned to either the PuzzleWalk or Google Fit group for 5 weeks using a covariate-adaptive randomization design. PA and anxiety were assessed over 7 days at 3 different data collection periods (ie, baseline, intervention start, and intervention end) using triaxial accelerometers and the Beck Anxiety Inventory. Group differences in outcome variables were assessed using repeated-measures analysis of covariance, adjusting for age, sex, and BMI.

Results: The findings indicated that the PuzzleWalk group spent a significantly longer amount of time on app use compared with the Google Fit group ($F_{2,38}=5.07$; $P=.01$; partial $\eta^2=0.21$), whereas anxiety was unfavorably associated with increases in light PA and decreases in sedentary time after intervention (all $P<.05$).

Conclusions: Further research is needed to clarify the determinants of physical and mental health and their interrelationship in adults with ASD to identify the factors that facilitate the use and adoption of mobile health technologies in these individuals. Despite these mixed results, the small changes in PA or anxiety may be clinically significant for adults with ASD.

Introduction

Regular physical activity (PA) helps to reduce anxiety in the neurotypical population [1,2] and presents a potentially effective adjunct treatment for anxiety in people with autism spectrum disorder (ASD). Anxiety is one of the most common and debilitating mental health issues among adults with ASD [3,4]. A recent systematic review and meta-analysis study revealed that the lifetime prevalence of anxiety was >40% in a large sample of adults with ASD (n=26,070) included in the study [4]. The negative impact of chronic anxiety on those with ASD has been well documented, and evidence suggests that the presence of comorbid psychiatric disorders significantly interferes with active daily living and further increases the risk of clinical morbidity in these individuals [5,6].

Despite the prevalence and negative impact of anxiety on the everyday lives of those with ASD [7], there are few effective treatment options for this symptom. Most people with ASD rely on medications, which carry a high dependency risk [8,9], or cognitive behavioral therapy, which has demonstrated mixed results in alleviating this symptom [10,11]. In addition, antianxiety medication use is associated with several side effects, such as metabolic syndrome and weight gain [12,13], whereas cognitive behavioral therapy is both costly and labor intensive [14,15]. As a result, efforts have been made to identify adjunct treatments to help adults with ASD better manage anxiety [16,17]. The adult population with ASD is increasing [18,19], and there is a critical need for accessible and cost-effective adjunct anxiety treatments to alleviate this problem.

Although the level of benefits may vary from person to person, participation in regular PA is proven to help alleviate anxiety symptoms by improving self-efficacy [20], strengthening the sympathetic nervous system [21], and increasing neurogenesis in the human brain [22]. Research on PA interventions for adults with ASD is markedly lacking; however, there is support for the positive impact of PA or exercise on mental health in this population. Hillier et al [23] found that salivary cortisol and self-reported anxiety were reduced immediately after a low-intensity exercise session 1 day per week in a small sample of young adults with ASD. These effects were not maintained over the course of the 8-week intervention; however, the findings suggest that even low-intensity exercise can have a positive, albeit short-term, effect on anxiety in these individuals [23]. It is of interest to determine whether participation in regular PA can induce similar results in adults with ASD in the long term.

Although it is well understood that PA is a leading health indicator for both physical and mental health [24-26], there is little information on PA participation in adults with ASD. To date, only a few studies have addressed PA levels in adults with ASD, and the results have varied greatly. Eaves and Ho [27] reported that adults with ASD only engaged in moderate to vigorous PA (MVPA) once per week and spent approximately 13 hours per day sitting. In contrast, Frey et al [28] and Garcia-Pastor et al [29] found that adults with ASD met the guidelines of 150 minutes of weekly MVPA but were also highly sedentary. Lalonde et al [30] also observed that adults with ASD

had daily step counts similar to neurotypical adults. It is difficult to draw clear conclusions about these findings because of variability in the assessment methods and the functional ability of the samples. Most of the previous study findings were based on participants who attended segregated schools or centers and required extensive support, which was not representative of adults with ASD who were more intellectually able and autonomous.

To date, a limited number of studies have specifically attempted to increase PA in adults with ASD by using objective measures. Lalonde et al [30] used a goal-setting-based and reinforcement-based treatment to increase pedometer-measured walking steps in 5 young adults with ASD who attended a special education program. All participants were able to increase the number of walking steps to sufficient levels to achieve health benefits (ie, $\geq 10,000$ steps). Although these are encouraging findings, the highly structured and prompted nature of the intervention makes it inappropriate to generalize the findings to adults with ASD who are more intellectually able and autonomous. There has also been an effort to address physical fitness in individuals with ASD using a video modeling-incorporated mobile app. Although this novel intervention approach is promising, as the app was effective in increasing the heart rate and energy expenditure of participants with ASD, the findings were limited to children with ASD who required substantial assistance and supervision for proper execution [31]. It is important to identify PA and sedentary time interventions that are more suitable for independent adults with ASD who are self-determined for health behaviors.

Technology-based PA interventions have proven to be a promising method of increasing PA in the neurotypical population [32-34] and may be well suited for adults with ASD. Gamified mobile technology is a particularly promising tool that can increase PA and reduce sedentary time while also meeting the unique needs and interests of these individuals [35-37]. Lee et al [37] found that adults with ASD used technological devices for >6 hours per day, primarily for surfing the internet, using social media, and web-based gaming [37]. Emerging evidence suggests that adults with ASD are attracted to technology use because the human-technology interface creates consistency and predictability, as well as because of a lower social burden, compared with traditional face-to-face interaction [38,39]. Furthermore, individuals with ASD typically have distinctive strengths in visuospatial functioning, which is common to technology-based games, as well as a preference for learning and interaction through visual information [40-42]. Consequently, in the past few decades, health practitioners have actively used mobile technologies to offer a cost-effective and low-barrier platform for visual learning to identify and improve health outcomes in diverse clinical populations, including those with ASD [37,38,43].

Gamified behavioral interventions using smartphone apps have the advantage of providing personalization, feelings of amusement, and desire for continuation [44-46] and have rapidly expanded their technological potential to monitor and improve daily PA participation in adults with obesity and sedentary workers [35,47]. Nevertheless, the success of gamified mobile apps in promoting PA and reducing sedentary behavior is

questionable as most of the existing health or fitness apps in the commercial market are not sustainable stand-alone interventions and lack scientific evidence and health behavior theory in the app development process [48,49]. The overall low quality of evidence regarding the effectiveness of long-term behavior change makes it currently difficult to apply commercial PA-promoting apps to adults with ASD [50]. The purpose of this study was to (1) examine the effects of the competitive gamification and behavior change theory-based mobile app PuzzleWalk [37] on increasing PA and reducing sedentary time and anxiety in adults with ASD and (2) compare PuzzleWalk to a commercially available platform, Google Fit. It is hypothesized that (1) the use of PuzzleWalk will lead to higher levels of light PA and MVPA and lower levels of sedentary time and anxiety in adults with ASD than the use of Google Fit and (2) the increased PA or decreased sedentary time from both apps will be associated with reduced levels of anxiety in adults with ASD.

Methods

Participants

A total of 29 adults aged ≥ 18 years and diagnosed with ASD were recruited through state and regional agencies that serve people with ASD across the United States and online autism support groups on social media such as Facebook and Reddit. Evidence of ASD diagnosed by a qualified medical professional such as a pediatrician or clinical psychologist (ie, when and where) was required for study participation and obtained via self-report. In addition, eligible study participants met the following inclusion criteria: (1) self-reported medical diagnosis of anxiety or self-identification of experiencing anxiety symptoms for the past 3 or more months, (2) access to a supported device (smartphones with Android 4.4 and higher or iOS 9.0 and higher operating system), (3) cognitive ability to understand the purpose of the study, and (4) no prior experience using the PA mobile apps used in the study. Individuals with low cognitive function, co-occurring intellectual disabilities, or mobility impairments were excluded from this study. We hereby use the term *intellectually able* adults with ASD to refer to those who can make their own decisions regarding health behaviors without much assistance. A participant with a self-reported mild learning disorder that did not significantly interfere with active daily living and study participation was included in the study. A formal screening interview was conducted with each participant through a phone or face-to-face video call to verify participant eligibility and identify potential barriers to study participation. All participants provided written or digital consent before data collection.

Ethics Approval

The Institutional Review Board of Indiana University approved this study (protocol number 1807483245).

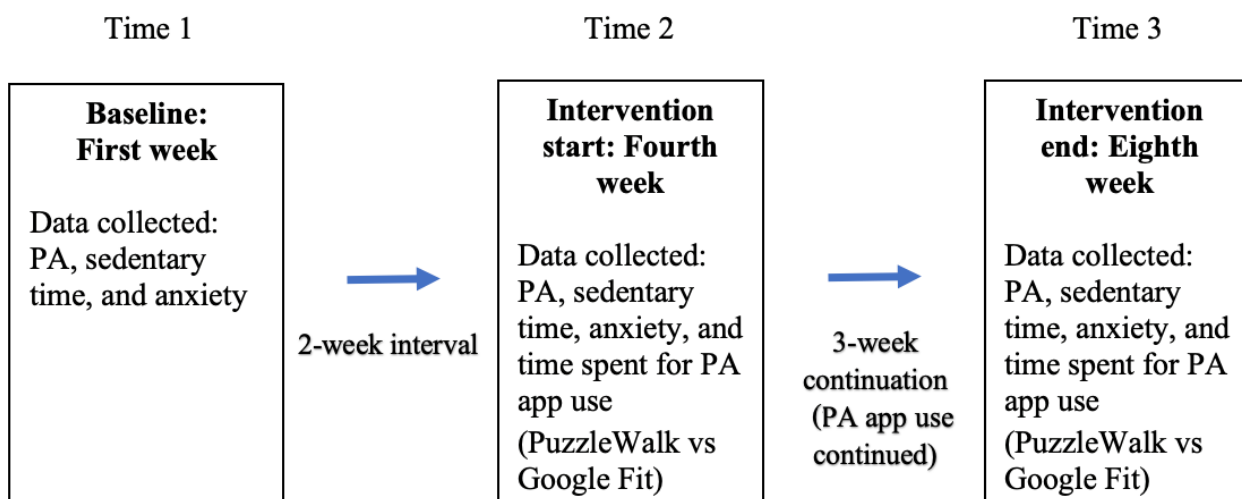

Procedure

On verification of the participant's eligibility through the screening interview, participants completed a web-based

demographic survey with an emphasis on BMI, waist circumference, medication use, and autism symptoms. Self-reported height and weight information were collected to calculate each participant's BMI (ie, kg/m^2 or $\text{lbs/in}^2 \times 703$) [51]. Participants were also asked to provide self-measured waist circumference, which can be an indicator of obesity-related disease risk [52]. The Autism Spectrum Quotient 10-item (AQ-10) questionnaire was included in the survey to examine the severity of autism symptoms (eg, social interaction deficits, sensory issues, and other autism-specific characteristics) [53]. The AQ-10 was designed for health care professionals to administer an informal ASD assessment of individuals with typical cognitive function [54]. The maximum possible score is 10, and individuals with a score of ≥ 6 are advised to consider referral for formal ASD assessment. The AQ-10 is one of the few autism screening tools available for adults [18]. After the completion of the demographic survey, study materials, including an accelerometer with an elastic belt, a USB cable charger, and study instruction sheets (ie, how to wear and charge the accelerometer and how to install and use the daily anxiety assessment [DAA] app for anxiety assessment) were either mailed or handed to remote and local participants, respectively.

A rubric was used to assess participant comfort and knowledge of study procedures before the start of the baseline and intervention periods, and case-by-case decisions were made by the research team when individuals were ready to start data collection. Before the start of the intervention period, participants were assigned to either the PuzzleWalk or Google Fit group according to age, sex, and BMI using a covariate-adaptive randomization process. Specifically, a minimization technique was applied to the randomization process by distributing the participants into 2 groups based on the aforementioned variables, which were identified before the start of data collection [55]. Covariate randomization aimed to minimize the imbalance in baseline characteristics across the 2 groups included in the study [56]. All participants received visualized step-by-step instructions (eg, search and download on Google Play or App Store, user registration, goal setting, and PA behavior tracking) on the assigned PA app (PuzzleWalk or Google Fit) and used it from the beginning of the intervention start (fourth week) until the end of the intervention (eighth week).

Participation required an approximate 2-month commitment: the first week for baseline and the fourth to eighth weeks for intervention. A 2-week interval was implemented between baseline and intervention onset to reduce the novelty effect in response to the accelerometer and PA app use [57] (see Figure 1 for the study timeline). Both the PuzzleWalk and Google Fit groups received reminders regarding the use of the PA app during the first week of the intervention period and autonomously continued to use the app until the intervention ended. Data collection occurred in the fall and early spring to avoid the impact of inclement weather on activity patterns. Participants who successfully completed the 2-month study received a US \$100 e-gift card as a token of appreciation.

Figure 1. Data collection time points. PA: physical activity.

Mobile Apps

Google Fit

Google Fit (Google LLC) is a PA-tracking platform developed by Google for Android and Apple iOS. The app was first launched to the public in 2014, and since its release, it has been one of the most popular health/fitness apps in the United States, with >2.6 million monthly active users (Statista 2022 [58]). The app uses a sensor built into a smartphone device to automatically track PA, including steps and active minutes. It also allows users to journal and record a variety of forms of PA (eg, cycling, weightlifting, and yoga) by manually setting the activity tracking mode. Google Fit uses a heart point-based reward system as a gamification strategy to provide users with individualized exercise tips incorporated with PA recommendations outlined by the American Heart Association. Google Fit users can earn one heart point for each minute of MVPA, with possible virtual rewards (ie, celebrative animation on the interface in addition to a green circle morphed into the user's profile image) when they reach a certain number of PA milestones (eg, 30 minutes of moderate PA a day or 150 minutes of MVPA per week). The number of heart points received based on active minutes is the app's primary gamification strategy. To the best of our knowledge, there are no peer-reviewed, data-based publications on the app's functional reliability and behavior change effectiveness. There are a few industrial reports and studies on Google Fit, although these studies focused on the basic functionality of the app and compatibility with wearable trackers [59,60]. We chose Google Fit as a comparison platform as it is free and easy to use, and, most importantly, it has been extensively used by neurotypical adults. As such, the comparison of Google Fit in this study will provide valuable insights into the usability/feasibility of a commercially available health app for promoting PA in adults with ASD.

PuzzleWalk

A gamified behavior change app, PuzzleWalk, available for both Android and Apple iOS, was developed to increase PA and reduce sedentary behavior in adults with ASD following a participatory, user-centered development process, including a needs analysis, literature review, and prototype design [37]. PuzzleWalk incorporates behavior change techniques (BCTs), a theory-based method of promoting healthy behavior change by leveraging psychological determinants, such as autonomy, perceived competence, and intrinsic and extrinsic motivation [61]. The example techniques included in PuzzleWalk are a comprehensive, visualized user guide, self-monitoring of target performance, contingent rewards, and goal setting [37].

It is a *spot the difference* puzzle game comprising 660 major city images around the world (see Figure 2). This format was chosen because it is easy to understand the purpose of the game, and it can quickly capture the user's interests without a complex comprehension process. Moreover, this visual image-based game facilitates visual interaction, which is a unique strength of individuals with ASD [40]. The most unique design element of PuzzleWalk is the conversion algorithm between steps and game-solving time. Specifically, the user's accumulated steps are directly converted to game-solving time to motivate PA participation. A review of the literature indicated that only a few available PA apps use this gamified token economy strategy for PA promotion. Pokémon Go uses a similar gamification strategy as the app links walking activities to the Pokémon character-hunting game supported by location tracking and augmented reality technologies; however, there is no direct conversion algorithm between PA (steps) and game time/opportunity. PuzzleWalk also uses a gamified leaderboard that ranks active users based on their steps and puzzle scores, with tangible rewards (ie, US \$10 e-gift cards) provided to the top 3 score leaders at the end of each month. This gamified leaderboard leveraged a BCT of prompt rewards contingent on efforts toward a target behavior [62,63].

Figure 2. PuzzleWalk user interfaces.

Mobile App Use Assessment

PA app use for the past 1 week was assessed through a self-report survey at 3 different data collection time points (ie, end of the fourth week, start of the eighth week, and end of the

eighth week) (see Table 1). Participants were asked to report the frequency (days of app use during the past 7 days) and duration (hours and minutes usually spent for app use). The time spent using the PA app was calculated using a minutes per day format.

Table 1. Durations of data collection.

Instrument used	Time 1: baseline (first week)	Time 2: intervention start (fourth week)	Time 3: intervention end (eighth week)	Total
Accelerometry (days)	7	7	7	21
Beck Anxiety Inventory for the past 7-day anxiety assessment	Days 1 and 7	Days 1 and 7	Days 1 and 7	6 times
Daily anxiety assessment (days)	7	7	7	21
Survey for physical activity app use	N/A ^a	Day 7	Days 1 and 7	3 times

^aN/A: not applicable.

Anxiety Assessment

The Beck Anxiety Inventory (BAI) was used to assess participants' prolonged state of anxiety. The BAI is a self-report scale comprising 21 items that measure the severity of anxiety symptoms during the past week, with high internal consistency (Cronbach α =.92) and test-retest reliability (r =0.75) [64]. Scores range from 0 to 63, with scores of ≥ 26 indicating potentially concerning levels of anxiety (ie, 0-7=minimal; 8-15=mild; 16-25=moderate, and ≥ 26 =concerningly severe). The

participants were asked to report the extent to which they had been bothered by each of the 21 symptoms in the past week. The participants completed the BAI at the start and end of each data collection period (a total of 6 times).

In addition to the BAI, time-specific and type of anxiety trigger questions were asked daily during each data collection period to better identify the contexts of potential anxiety triggers such as environmental, psychological, or sensory factors [65]. At the start of the study, participants downloaded the DAA mobile app

developed by the research team. The participants received a prompt at 8 PM each day during the data collection period to answer specific questions. This time was deemed appropriate for assessing perceived emotional changes over the course of the day based on pilot work and considering typical work/school schedules and bedtimes. The questions included “When did you feel anxious today?” and “What caused your anxiety today?” with the possible choices of (1) change or disruption to routine, (2) sensory oversensitivity or overstimulation, (3) confusion and worries about social and communication situations, (4) specific fears or phobias, (5) too many demands or expectations, (6) being prevented from preferred behaviors or interests, and (7) not applicable. As the traditional retrospective assessment approach can be less reliable [66], the DAA adopted the ecologic momentary assessment method to improve response reliability [67]. Low compliance can be an issue with this type of daily report; therefore, we implemented routine strategies to address this issue, including establishing an efficient data/compliance-tracking system and providing regular reminders to complete the task and monetary incentives [68]. Reminders were sent to the participants via email or SMS text messages based on their preferences recorded in the demographic survey. Only participants with valid survey compliance (ie, participation for 6 times in the BAI and participation in at least four DAAs in each data collection period) and monitor wear (ie, at least 3 valid days in each data collection period) received a monetary incentive.

PA and Sedentary Time Assessment

Daily walking steps, PA intensity, and sedentary time were measured using GT3X+ and ActiGraph triaxial accelerometers (ActiGraph). ActiGraph accelerometers have been extensively used to measure PA with moderate to high reliability in both laboratory and free-living conditions [69-71]. All participants were asked to wear an accelerometer on their right hip during waking hours for 7 consecutive days, including at least 2 weekdays and 1 weekend day over the 3 different data collection periods (baseline, start of the fourth-week intervention, and end of the eighth-week intervention). Accelerometers were programmed to calculate data in 60-second epochs [72]. Daily walking steps were measured using the ActiGraph pedometer function, and sedentary time and activity intensity were identified using the following activity counts per minute cutoffs: <100=sedentary, 100-2019=light, 2020-5999=moderate, >5999=vigorous, and ≥ 2020 =MVPA [73]. These cutoff points were proposed by Troiano et al [73] and have been validated in large data sets of free-living adults [74-76]. The minimum wear time for a valid day is ≥ 10 hours per day for wake time [77]. Although there is no scientific consensus on the minimum number of valid days, 4 days have been widely accepted in previous studies to reliably estimate habitual PA [78,79]. However, this study required at least 3 valid days of monitor wear in each data collection period in an effort to minimize sample loss [78].

In addition, an intraclass correlation (ICC) analysis was performed to validate the use of at least 3 valid days of monitor wear by examining the relationship between 3 valid days and ≥ 4 valid days on all PA and sedentary time outcomes at baseline. ICC values of ≥ 0.75 are generally regarded as good or

acceptable reliability [80]. The ICC results demonstrated that the reliability of 3 valid days for all PA and sedentary time variables was excellent (all ICC >0.90); therefore, participants with ≥ 3 valid days of monitor wear were included in the analyses. Overall, 2 participants' accelerometry data at the intervention start (fourth week) and 1 participant's accelerometry data at the intervention end (eighth week) did not satisfy the minimum number of 3 valid days; thus, their baseline accelerometry data were imputed according to the baseline observation carried forward method [81]. The criterion for nonwear time was 90 minutes of consecutive 0 counts [82], and the accelerometers were set to collect data at sampling rate of 30 Hz.

Data Analysis

Independent *t* tests and chi-square tests were performed for continuous and ordinal variables, respectively, to compare the baseline differences between the 2 groups. Data are presented as mean (SD) or frequency (percentage), according to the variable type. According to the scoring guidelines, the BAI scores for all 21 items (ie, not at all=0, mild=1, moderate=2, and severe=3) were summed to yield a total score of anxiety severity [64]. The BAI scores collected twice during each data collection period were averaged to represent each time point (ie, baseline, intervention start, and intervention end). Data on common anxiety triggers and time-specific occurrences were screened to include only participants with at least four responses to the DAA at each data collection time point. All participants met the compliance criteria, and 134 counts (baseline, $N=24$), 124 counts (intervention start, 23/24, 96%), and 107 counts (intervention end, 20/24, 83%) were included in the frequency (percentage) analyses.

Objectively measured PA data were first systematically cleaned and verified by examining the ranges and missing values according to the established validation criteria. The collected raw accelerometry data were then converted into activity counts using the ActiLife 6 Data Analysis Software (ActiGraph). With the aforementioned activity intensity cutoffs, the PA data were processed and extracted into an editable spreadsheet. Manual data screening was sequentially performed to verify the minimum required hours and valid days of monitor wear for data analysis; invalid data were eliminated.

An intention-to-treat analysis was conducted to maximize external validity, and the baseline observation carried forward method was used to impute missing data after randomization [81,83,84]. According to the guidelines on missing data in clinical trials by the European Medicines Agency (2010), the baseline observation carried forward method can be appropriate in randomized trial design studies in which researchers reasonably assume that the outcomes of a participant would return to their baseline levels in the long term after dropout [85]. In light of the general span of a mobile health intervention's effectiveness in promoting PA (eg, up to 3 months) [86], this method can also help maintain external validity and minimize sample loss.

The dependent variables were sedentary time (minutes per day), light PA (minutes per day), MVPA (minutes per day), steps per day, total activity counts (vector magnitude), average BAI

anxiety score, and PA app use (minutes per day). To assess PA and anxiety changes over the 3 data collection periods; all measures collected at baseline, intervention start, and intervention end were compared between time points and groups using a repeated-measures analysis of covariance (ANCOVA). Repeated-measures ANCOVA models were adjusted for baseline characteristics, including age, sex, and BMI. The Mauchly test of sphericity was used for each outcome variable to examine the equality of variances of within-group differences across the 3 different data collection time points. In general, if the P value was $<.05$, the assumption of sphericity was violated. Owing to the violation of the sphericity assumption, the Greenhouse-Geisser correction was applied to MVPA, steps, and total activity count variables to interpret the results of the within-group effects.

The effect size (partial η^2) was calculated and defined as >0.02 =small, >0.13 =medium, or >0.26 =large [87]. Owing to the violation of the normality assumption, Spearman rank correlation analyses were performed to determine the baseline correlations between the outcome variables and the impact of increased PA or decreased sedentary time on anxiety change. The degree of change in the outcome variables following PA app use was calculated by subtracting the baseline value from the average of intervention outcomes (eg, MVPA change = [MVPA at intervention start + intervention end]/2 – MVPA at baseline). Data analyses were performed using SPSS 26.0, and significance was declared at $P<.05$ (2-tailed).

Results

A total of 29 adults with ASD initially volunteered to participate in this study. Approximately 17% (5/29) of participants were eliminated before the start of data collection as they did not meet the eligibility criteria or lost study materials. The remaining 83% (24/29) of participants met the eligibility criteria and were enrolled in the study. Of the 24 participants, 3 (13%) from the PuzzleWalk group and 1 (4%) participant from the Google Fit group dropped out during either the intervention start or intervention end time point because of personal obligation ($n=1$, 4%), invalid monitor wear compliance ($n=1$, 4%), and restrictions on outdoor activities because of the COVID-19 pandemic ($n=2$, 8%). The retention rate was 83.3%. On the basis of the intention-to-treat standard, the baseline observation carried forward method was applied to these 4 cases; thus, no participants were lost after data collection was started. Overall, there were no statistically significant baseline differences between the 2 groups. The participant characteristics are presented in Table 2.

The average valid monitor wear for baseline, start of the intervention, and end of the intervention were for 5.8 (82.9%; SD 1.6) days, 5.7 (81.4%; SD 1.6) days, and 5.6 (80.0%; SD 1.4) days, respectively. Of the 24 participants, 13 (54%) at baseline, 10 (46%) at the start of the intervention, and 7 (35%) at the end of the intervention = wore the monitor for the full 7 days. On average, participants wore the monitor for 14.4 (SD 1.7) hours per day, 14.3 (SD 2.1) hours per day, and 14.0 (SD

2.0) hours per day during each data collection period. Regarding anxiety occurrence, adults with ASD experienced anxiety more frequently during the late afternoon—between 3 PM and 7 PM. Overall, participants felt relatively less anxiety during the week of intervention start; however, this positive change was slightly diminished during the last week of intervention (Figure 3).

Figures 4-7 show the descriptive statistics (mean and percentage change) for all outcome measures, including sedentary time, light PA, MVPA, steps, total activity counts, BAI score, and time spent on app use across the 3 data collection periods between the PuzzleWalk and Google Fit groups. The only baseline difference was in daily steps (PuzzleWalk mean 5157.3, SD 2987.2 steps per day, vs Google Fit mean 3094.0, SD 1506.1 steps per day; $P=.04$). There were no significant changes in any of the PA or sedentary time variables over time in either group. The app use time was significantly different between the 2 groups at intervention start ($P=.046$) and intervention end ($P=.045$). The PuzzleWalk group showed a significantly decreased time spent on app use at the start of the final intervention week ($P=.04$); however, the time increased at the end of the intervention ($P=.049$).

Repeated-measures ANCOVAs were performed with age, sex, and BMI as covariates to test if there was a time \times group interaction effect between the 2 groups (Tables 3 and 4). There was a significant within-group change over time in sedentary time ($P=.003$) and MVPA ($P=.04$). PA app use was the only variable that resulted in statistically significant pairwise and overall between-group and time \times group interaction differences. Specifically, PuzzleWalk participants showed a significant decrease in time spent on PA app use from the start of the intervention to the start of the eighth week (mean 203.5, SD 62.6 minutes per day, to mean 82.9, 38.2 minutes per day; $P=.008$); however, time significantly increased from the start of the eighth week to the end of the intervention (mean 82.9, SD 38.2 minutes per day, to 162.9, 48.3 minutes per day; $P=.01$). In addition, pairwise group differences were found to be statistically significant between PuzzleWalk and Google Fit groups at the start of the intervention (mean 203.5, SD 62.6 minutes per day, vs 12.9, 57.7 minutes per day; $P=.04$) and at the end of the intervention (mean 162.9, SD 48.3 minutes per day, vs 3.3, SD 44.5 minutes per day; $P=.03$) periods. When it comes to overall time \times group interactions, there were significant overall between-group ($P=.04$) and time \times group interaction ($P=.01$) effects on the time spent on PA app use, indicating that the overall increase in PA app use time was considerably higher in the PuzzleWalk group than in the Google Fit group.

Sedentary time was significantly negatively associated with MVPA ($P=.03$), steps ($P<.01$), and total activity counts ($P=.021$), whereas MVPA was positively associated with steps ($P<.01$) and total activity counts ($P<.01$) at baseline, and these relationships remained significant after the intervention. Anxiety level was not significantly associated with any PA variables or sedentary time at baseline but was changed to have a significant negative association with sedentary time ($P=.02$) and positive associations with light PA ($P=.045$), steps ($P=.03$), and total activity counts ($P=.045$) after the intervention (Table 5).

Discussion

Principal Findings

The findings from this feasibility study indicate that gamified PA-promoting mobile apps can be an effective tool for decreasing sedentary time and increasing MVPA in intellectually able adults with ASD. Notably, the PuzzleWalk mobile app, developed using BCTs and autism-specific design elements, was comparable with the commercially popular Google Fit in inducing changes in PA and sedentary time. However, the positive improvements in PA and sedentary time did not significantly reduce anxiety levels, although overall anxiety

severity for participants with ASD was positively changed from moderate to mild at the end of the intervention.

It appears that intellectually able adults with ASD can benefit similarly from both commercially available and best practice-guided PA mobile apps. Although there were no significant differences in PA and sedentary time between the 2 groups, there were varying trends in the data according to groups, which are worthy of mention. In the PuzzleWalk group, there was a downward trend in sedentary time and a short-term upward trend in MVPA, step count, and total activity count. Conversely, there was a slight intervention-induced increase in light PA and a clear upward trend in steps and total activity counts in the Google Fit group. These observations, in

conjunction with the significantly greater time spent on app use in the PuzzleWalk group compared with the Google Fit group, suggest that the specific research-based design elements of PuzzleWalk, including BCTs and competitive gamification, may pose an advantage over commercially popular apps that do not incorporate these elements. As shown in previous gamified PA interventions for neurotypical samples, adding competition elements to the intervention may be more effective in inducing PA or sedentary behavior changes than collaboration when there are no social connections among users [88,89]. It is of interest to see whether these trends are enhanced in a larger sample of adults with ASD.

Increasing evidence suggests that mobile app interventions can be effective in promoting PA mostly in the short term (eg, up to 3 months) [86]. In a recent study, the short- and long-term effects of a mobile phone-based PA app, together with brief in-person counseling, were evaluated for PA behavior change among inactive middle-aged women ($n=210$). The findings of this randomized clinical trial indicated that the intervention group's MVPA and total steps were significantly increased during the first 3-month intervention period, although the intervention effect was not maintained in the following 6 months [88]. Similar results of regression fallacy have been reported in earlier randomized controlled trials that examined the efficacy of smartphone sensor-based interventions on PA promotion in healthy adults, which found a substantial PA decline during long-term follow-up [83,89]. Given that adherence and engagement in mobile app interventions generally decline before 3 months [33,86], the attenuation of intervention effects observed in this study (ie, regression of PA outcomes at the intervention end) may correspond with the overall decline in time spent on PA app use during the intervention period. As such, it is critical for mobile app interventions to maximize participant engagement with the app and exposure to the intervention through additional health behavior management strategies such as motivational short message services and telephone coaching [86,90].

This study aimed to identify an anxiety treatment adjunct to, and not in replacement of, conventional therapies. The overall anxiety level decreased from moderate to mild, with decreases in sedentary time and increases in PA over time, in both groups. Although this change was not statistically significant, it may be of clinical or personal value to adults with ASD. A recent review and meta-analysis reported that PA may have a protective effect against anxiety symptoms and disorders; however, the authors cautioned against drawing firm conclusions because of the limited and heterogenic available research [1]. Kim et al [91] recently reported that the optimal range of PA for decreasing anxiety symptoms was 600 to 9000 metabolic equivalents (METs) minutes per week and 1200 to 3000 METs minutes per week for neurotypical men and women, respectively [91]. Individuals with ASD in this study had mean PA levels of 569.9 (SD 45.6) METs minutes per week at the intervention end, which did not meet this criterion [92]; therefore, the intervention-induced changes in PA may have been insufficient to further affect anxiety levels. In addition, many adults with ASD have difficulty articulating their emotions and feelings, and this could have affected the ability of participants in this

study to report the full extent of their anxiety symptoms [93]. Despite the lack of robust outcomes regarding intervention effectiveness, additional research on the long-term effects of PA interventions as a simple and economical way of alleviating the health burden of anxiety in adults with ASD is encouraged.

Interestingly, small intervention-induced changes in PA, sedentary time, and anxiety were unfavorably associated. Increases in light PA, steps, and total activity counts and decreases in sedentary time were associated with increased anxiety in adults with ASD. This is contrary to the preponderance of research and a general understanding of the relationships among PA, sedentary time, and anxiety [24,94]. Previous studies have shown that anxiety symptoms are associated with low PA levels and increased sedentary time [95]. Furthermore, Lee et al [96] found that adults with ASD reporting higher sedentary time had increased odds of developing physical and mental health conditions, including anxiety, associated with cardiovascular risk. The underlying mechanisms that explain the relationship between PA, sedentary time, and anxiety are understudied [1]; however, a potential explanation for the findings in this study is that PA-related social situations and environmental changes may have negatively contributed to anxiety symptoms in the sample [7,97]. Confusion and worries about social and communication situations were common anxiety triggers in adults with ASD in this study, as has been previously reported among those with ASD who are often self-aware of their incompetence and difficulty in social situations [7,65,97,98]. As the mobile apps used in this study prompted outdoor walking, which is difficult to perform in social isolation, it is reasonable to conclude that the prospect of entering the public to walk could have elevated anxiety in study participants. Specific types of anxiety were not assessed in this study; however, Hollocks et al [4] found that social phobia was a highly prevalent type of anxiety disorder in adults with ASD. Therefore, future efforts to study PA and sedentary time interventions for this population must consider the social expectations of the prescribed activity.

The major strengths of this study include (1) the use of a covariate-adaptive randomized controlled trial design to control the influence of covariates in the results [99], (2) objective assessment of PA and sedentary time, and (3) relatively good adherence to the study protocol and low attrition. Limitations include a small sample size; the use of self-report for the assessment of anxiety symptoms and app use time; and potential underestimation of PA, as accelerometry cannot accurately detect bicycling, swimming, and other upper-body movements [100]. Regardless, this feasibility, proof-of-concept study demonstrated that intellectually able adults with ASD could favor a gamified PA-promoting mobile app, and this use can induce small improvements in PA, sedentary time, and anxiety, which are worthy of further investigation.

Conclusions

This study demonstrates that a gamified BCT-based mobile app, PuzzleWalk, may be able to decrease the level of sedentary time and create a short-term impact on increasing MVPA, daily steps, and total activity counts among adults with ASD. However, the findings also suggest that anxiety in adults with ASD was

unfavorably related to increased light PA, steps, and total activity counts and decreased sedentary time after the intervention. Further longitudinal research is warranted to evaluate the long-term efficacy of PuzzleWalk in improving physical and mental health and to elucidate the underlying mechanisms that explain the roles of PA and sedentary time in changing anxiety symptoms in adults with ASD. Given the promising usability of a gamified app as a supplementary behavior change tactic, it is recommended that the design elements of mobile health interventions be user centered to meet

the unique needs and leverage the strengths of the target population (eg, visual support for users with autism). Furthermore, as supported by many previous findings, mobile health interventions should focus on increasing sustainability and long-term behavior change that can continuously promote regular PA participation. Finally, there is a need for more experimental studies conducted in real-world settings to verify the evidence for gamification and other BCTs in underserved populations [62].

None declared.

Editorial Notice

This randomized study was only retrospectively registered. The editor granted an exception from ICMJE rules mandating prospective registration of randomized trials because the risk of bias appears low and the study was considered formative, guiding the development of the application. However, readers are advised to carefully assess the validity of any potential explicit or implicit claims related to primary outcomes or effectiveness, as retrospective registration does not prevent authors from changing their outcome measures retrospectively.

Abstract

Background: The application of cell phones, similar portable devices (ie, tablets), apps, the internet, and GPS in evaluation have established new ways of collecting, storing, retrieving, transmitting, and processing data or information. However, evidence is incipient as to which technological resources remain at the center of assessment practice and the factors that promote their use by the assessment community.

Objective: This study aimed to analyze the relationship between the use of the National Program for Improving Primary Healthcare Access and Quality's (PMAQ-AB; Programa Nacional de Melhoria do Acesso e da Qualidade da Atenção Básica) mobile app and management system and the external evaluation quality of Brazil's PMAQ-AB.

Methods: We conducted a qualitative case study during the external evaluation of Brazil's PMAQ-AB. Data collection consisted of interviews, focus groups, and document analysis. A total of 7 members from the Department of Primary Care of the Ministry of Health and 47 researchers from various higher education and research institutions across the country participated in the study. Data were categorized using the ATLAS.ti software program, according to the quality standards of the Joint Committee on Standards for Educational Evaluation, following the content analysis approach by Bardin.

Results: The results related to feasibility, thematic scope, field activity management, standardized data collection, data consistency, and transparency. They demonstrated improvements and opportunities for advancements in evaluation mediated by the use of information technology (IT), favored the emergence of new practices and remodeling of existing ones, and took into account the multiple components required by the complex assessment of access and quality in primary health care. Difficulties in technology operation, inoperative systems, and lack of investment in equipment and human resources posed challenges to increasing the effectiveness of IT in evaluation.

Conclusions: The use of technology-based tools—the app and the management system—during the external evaluation offered evaluators a greater opportunity for stakeholder engagement. This also allowed the insertion of different organizational, operational,

and methodological components that are capable of triggering influences and confluences. In addition, this allowed connections in collaborative and synergistic networks to increase the quality and allow the development of a more consistent and efficient evaluation process with greater possibility of incorporating the results into public health policies.

KEYWORDS

information technology; information technology management; program evaluation; health evaluation; meta-evaluation; primary health care

Introduction

There has been a remarkable increase in investments in, and access to, information technology (IT) globally [1]. The application of cell phones, similar portable devices (ie, tablets), apps, information management systems, the internet, and GPS has expanded in evaluations [2], helping to overcome challenges related to time, resources, and limited data quality [2-4]. Technological tools currently available for evaluators are mainly used for data collection, management, storage, processing, and retrieval [5-7], as well as for improving coverage, accuracy, efficiency, and efficacy of evaluations, adding value to the information that is produced, which supports management decisions [3,4,7].

A growing demand from the national government in Brazil for improved data on primary health care (PHC) has boosted the development of new technology-based tools—an app and a management system [8]—which were then applied in the external evaluation of Brazil's National Program for Improving Primary Healthcare Access and Quality (PMAQ-AB; Programa

Nacional de Melhoria do Acesso e da Qualidade da Atenção Básica) in its three cycles: 2011-2012, 2013-2014, and 2015-2019. The evaluation consisted of interviews with PHC teams and observations of infrastructure and functioning. Thus, a total of 42,975 PHC teams from 5570 Brazilian municipalities were evaluated in the last evaluation cycle [9,10].

Therefore, the external evaluation of the PMAQ-AB used IT through an app (ie, a PMAQ-AB instrument) that was developed for this purpose and was accessible via tablets in order to overcome the challenges of improving the availability, quality, and understanding of data related to PHC access and quality in Brazil. It enabled online and offline use and data transference to a cloud management platform. Furthermore, the External Evaluation Management System (EEMS) [11] was implemented, and it enabled monitoring and management of field data collection, guaranteeing shorter decision-making time [8,12]. The use of components and technological resources brought knowledge updates to the evaluation team to achieve the objectives proposed by the evaluation. [Textbox 1](#) describes some features of the PMAQ-AB external evaluation app and the EEMS.

Textbox 1. Features of the PMAQ-AB app and the External Evaluation Management System.

National Program for Improving Primary Healthcare Access and Quality (PMAQ-AB) mobile app for external evaluation:

- Control of access to the app: access to the app after the interviewer has previously registered
- Control of feasibility of the evaluation app: filling in the identification details of the team of evaluators and the team to be evaluated
- Control of the evaluation app: it is mandatory to have answers to all questions
- Management of the conducted evaluations: this allows sending the finalized evaluations, viewing the obtained metadata, and viewing the location obtained by the GPS
- Finalization of evaluations: the questionnaire is finalized and locked for editing and is then ready to be sent
- Submission of evaluations: all evaluation data are transmitted to a cloud management system, requiring internet access at the time of submission
- Field diary: communication channel between supervisors and their interviewers

External Evaluation Management System:

- Monitoring panel: allows the external assessment to be viewed as it happens
- Registration of the fieldwork team, which would allow access to the external evaluation app
- Filling in the field diary if the user is a supervisor
- Verification of the consistency of the data collected by the evaluators
- The evaluations can be accompanied by the general coordinator while conducting the external evaluation
- Conflict regarding questionnaires: managing the resubmission of assessments; the supervisor must determine which is the correct submission among those sent

The use of software can support external evaluations, but its applicability brings new ethical and methodological challenges

that experts need to face so that the use of tools, platforms, and digital approaches reach their full potential [2,13]. The growing

incorporation of IT into work processes, driven by the accelerated evolution and variety of technological innovations, requires evaluators to use specific knowledge, means, techniques, and equipment. Since technology can influence the relationships, norms, practices, and aims of evaluation, it cannot be considered a neutral and random organizational phenomenon [14].

Advances in the understanding of which technological elements remain at the core of evaluation practice and the factors that promote their use by the evaluation community are needed [15]. Technologies are continuously changing; therefore, seeking evidence to elucidate the impacts and the reasons for their application may yield relevant contributions to the evaluation field [16]. Studies indicate the need for a systematic follow-up of technological trends and their influence on the roles and responsibilities of evaluators [2,15,17]. Moreover, only a few empirical studies have focused on the interaction between evaluators and technologies, mainly from the perspective of how this interaction facilitates or hampers quality standards needed for evaluations, which attribute value or merit to promote successful health care policies or programs. Therefore, evaluating the theoretical and methodological basis of the evaluation (ie, a meta-evaluation) is needed to understand the extent of success, which can be guided by quality standards [18-22].

It is also important to emphasize that the success or failure of IT implementation mainly depends on the relationships that are established during its use in practice [23]. Considering the importance of adopting technological innovations for evaluations with broad scopes and extensive territorial coverage—including remote areas, such as the external evaluation of the PMAQ-AB—this study aimed to analyze the relationship between the use of the PMAQ-AB mobile app and management system and the external evaluation quality of Brazil's PMAQ-AB.

Methods

Study Design

We conducted a summative meta-evaluation [21,22] after the assessment process was completed. To do so, we carried out a qualitative case study [24] from the perspective that its use would enable analyzing complex social phenomena in depth and in the context of the real world.

The theory that underlies this analysis is sociomateriality [25], which recognizes the importance of relationships and interactions between the social and the material; it emerges as a theoretical approach that can contribute to giving visibility to the understanding of IT in evaluative practices.

A meta-evaluation was performed in the context of the coordination of the PMAQ-AB external evaluation. Higher education and research institutions and the Department of Primary Care of the Ministry of Health (Departamento de Atenção Básica [DAB]–Ministério da Saúde [MS]) conducted the evaluations from the three cycles. Data collection occurred between July 2018 and December 2019 at the DAB-MS, Brasilia, and the main campuses of higher education and research institutions in Pelotas, Belo Horizonte, Rio de Janeiro, Salvador, Teresina, and Aracaju, Brazil.

The EEMS was intentionally chosen due to its innovative technological system and for being an important step in the large, complex, and innovative payment program (PMAQ-AB) that takes into account the performance of PHC teams [8-10].

Study Sample

We initially conducted a document study. We analyzed documents with public access that discussed external evaluation of the PMAQ-AB or those that were available at the DAB-MS for the purpose of training the fieldwork team. In this sense, the documents were used as communicative devices to elucidate the observed event. Thus, four documents regarding the third evaluative cycle that were published between 2017 and 2019 were included, and documents regarding the two previous cycles were excluded because their content was repetitive, as shown in Table 1.

Table 1. Documents used for data collection.

Document no.	Document title	Document type
D1	PMAQ-AB ^a Application: User Manual; Laboratory of Technological Innovation in Health, Federal University of Rio Grande do Norte	Manual on the use of the external evaluation data collection app made available and used for training the fieldwork team
D2	Field Management System: User Manual; Laboratory of Technological Innovation in Health, Federal University of Rio Grande do Norte	Manual on the External Evaluation Management System made available and used for training the fieldwork team
D3	Manual for PMAQ-AB Fieldwork: 3rd Cycle [12]	Aims to present the PMAQ-AB
D4	Methodological Note for the Certification of Primary Healthcare Teams [10]	Aims to present the applied methodology to certify teams that joined the third PMAQ-AB cycle

^aNational Program for Improving Primary Healthcare Access and Quality (Programa Nacional de Melhoria do Acesso e da Qualidade da Atenção Básica).

We used a purposive sample of 54 participants: 7 from the DAB-MS (1 coordinator and 6 technicians) and 47 from higher education and research institutions (6 coordinators and 41 researchers). Participants were part of the PMAQ-AB external evaluation team (third cycle).

Instrument Construction

The Item Matrix for Evaluating the External Evaluation of Primary Health Care [26] was used to elaborate our data collection instrument. Dimensions, subdimensions, items, and questions that were used to guide data collection were extracted (Table 2).

Table 2. Dimensions, subdimensions, items, and guiding questions used to collect data on the use of information technology in the evaluation of access and quality of primary health care, Brazil, 2020.

Dimensions and subdimensions	Items	Guiding questions
Stakeholder engagement		
<ul style="list-style-type: none"> Stakeholder identification (utility) Evaluator credibility (utility) 	<ul style="list-style-type: none"> Stakeholder identification Degree of stakeholder involvement and interaction, and participation mechanisms 	<ul style="list-style-type: none"> Comment on the degree of involvement and interaction and the participation mechanisms needed to identify the needs of interested parties and those affected by the claimant (Department of Primary Care) in the external assessment.
Evaluation design		
<ul style="list-style-type: none"> Practical procedures (feasibility) Evaluation impact (utility) 	<ul style="list-style-type: none"> Mechanisms for following the PMAQ-AB^a external evaluation Viability and feasibility of operational and methodological procedures 	<ul style="list-style-type: none"> In your opinion, did the use of the interview as a data collection technique provide credibility to the data collected in the external evaluation? In your opinion, were there any strategies for monitoring the evaluation by the interested parties during the external evaluation?
Evidence systematization and analysis		
<ul style="list-style-type: none"> Information scope and selection (utility) Valid information (accuracy) Systematic information (accuracy) 	<ul style="list-style-type: none"> Credibility of collected data through data collection technique Reaching useful, valid results through data collection procedures Use of tablets and software programs to increase credibility, trustworthiness, agility, and security in the process of administering questionnaires and in data storage and treatment 	<ul style="list-style-type: none"> Comment on the feasibility and viability of the operating procedures adopted during the external assessment to gather information. Did the information technology tools (tablets and software) used during the external evaluation enable credibility, reliability, agility, and security in the process of applying the external evaluation questionnaires? Were the data collection procedures adequate to achieve useful and valid results?

^aPMAQ-AB: National Program for Improving Primary Healthcare Access and Quality (Programa Nacional de Melhoria do Acesso e da Qualidade da Atenção Básica).

Data Collection Procedures

We conducted seven semistructured interviews: one with the coordinator of the General Commission for Monitoring and Evaluation of Primary Healthcare from the DAB-MS and six with the coordinators of higher education and research institutions. We conducted focus groups, following the method by Kitzinger [27], with one moderator and one rapporteur. Seven focus groups were conducted: one group included 7 members from the DAB-MS, and each of six groups included at least 6 researchers from the PMAQ-AB external evaluation.

Interviews and focus groups were audio recorded for approximately 1 hour. Notes were taken by the moderator in the focus group; however, few notes summarizing answers were taken. All material was transcribed, and transcripts were read and compared with the original recording immediately following the focus group. Each interview and focus group was identified using “I” or “FG,” respectively, followed by the sequential data collection number (eg, 1, 2, ..., n). I-DAB and FG-DAB identified

the evaluation members from the DAB-MS. The textual fragments extracted from each document (D) were identified by the reading sequence of the documents (ie, D1, D2, D3, and D4), as shown in Table 1.

Data Analysis

Content analysis, according to Bardin [28], was performed using the ATLAS.ti software program (version 8.4.24; Informer Technologies, Inc). First, interviews, focus groups, and documents were transcribed and imported into the software. A peer-review strategy was used, including a group of 6 researchers (OdGBJ, LMdFM, CSM, MBdS, NdSPDR, and TXdAP), to select citations (ie, context units) and link them to specific codes (ie, recording units). At this stage, comments were given to facilitate comprehension, and initial systematization of ideas was performed to interpret the collected information. Second, reports were developed and submitted to be assessed by 2 researchers (PdMR and SAdCU) in order to validate the linkage between citations and codes.

Following data codification, we selected and extracted citations, codes, and code groups representing dimensions, subdimensions, and items a priori for this study. The analyzed material was organized into two thematic categories: (1) technological and organizational infrastructure adding value to the utility of external evaluation and (2) use of IT and paths for feasibility and accuracy of external evaluation.

Ethics Approval

This study was approved by the research ethics committee of the Onofre Lopes University Hospital, Federal University of Rio Grande do Norte (Certificate of Presentation of Ethical Appreciation: 84537418.1.0000.5292) and followed the resolutions of the Brazilian National Commission for Ethics in Research. All participants signed the Free and Informed Consent Term.

Results

Credibility of the External Evaluator and Organization of the Fieldwork Team

The higher education and research institutions constitute the main institutional support for research and the training of researchers. They establish research and technology centers in the country with the capacity to meet the operational needs of external evaluation. The technological resources used in the fieldwork result from the cooperation established with the higher education and research institutions. This demonstrates that the DAB-MS was cautious about the evaluators' expertise in terms of evaluative research, production, and IT application (ie, assessment focus), as set out below:

The higher education and research institutions have an organizational structure to conduct data collection that defines a common profile of professional attributions to operate during the external evaluation phase. [D3]

The higher education and research institutions play a prominent role in the external evaluation of the PMAQ-AB, as they are prepared to develop research processes from conception to consolidation of data analysis and results, despite logistical challenges. [I2]

The operationalization of the external evaluation using IT required complex logistics that encouraged clear and objective communication between team members, delimiting the scope of work for each one. The documents analyzed in this study emphasize that the organizational structure and the definition of roles for the fieldwork team are fundamental for developing the evaluation and obtaining good results from the field activity.

The team that performs the evaluation is composed of a field coordinator, supervisors, and interviewers. Understanding the roles of team members, workflows and responsibilities point to progress in the work process and in the qualification of the obtained data. The application of the external assessment instruments in loco with the team of professionals and users was

carried out by the interviewers with the help of tablets. [D3]

The analyzed documents emphasize that the data obtained through interviews with professionals and users were generally used to certify the PHC teams and to improve public health policies; however, some participants considered the importance of external evaluation results to be an important database that could guide teaching and stimulate research on PHC in Brazil. This was particularly evident in the interview with the DAB-MS.

The results of the external evaluation served to certify the teams and guide the improvement of public health policies. [D4]

It is one of the main databases to understand, study, investigate, and analyze what is happening in primary health care in Brazil. [I-DAB]

Regarding data collection at the national level, the result of which will imply payment for performance, the documents analyzed in this study emphasized the importance of maintaining transparency and efficiency throughout the external evaluation process of the PMAQ-AB. Considering the issues inherent to the dynamics and complexity encountered in the field, a partnership with the higher education and research institutions was proposed due to their ability to promote the organization of actions developed by the work team.

PMAQ-AB Mobile App: Comprehensive Evaluation With a Wide Thematic Scope

An electronic modality was chosen, with data collected and sent through a specific app developed for use on a tablet. It is stated in one of the analyzed documents that the app can improve the performance of evaluators, facilitate data collection, and optimize transmission.

The External Evaluation of the PMAQ app aims to be a fundamental tool for data collection across the country. It was developed to simplify data collection, facilitate its use, and allow a better experience by the end user. [D1]

Interview and focus group participants highlighted that the external evaluation of the PMAQ-AB app, which was available for mobile devices (ie, tablets), made data collection across the country feasible, boosted field activity, reached a large number of respondents, and broadened coverage and evaluation scope. According to the documents analyzed, 42,975 PHC health teams from 5570 Brazilian municipalities were evaluated, in loco and simultaneously. The external evaluation instrument is composed of 903 questions.

The move from a paper tool to a tablet has supported advanced data collection as it is a comprehensive territory with broad coverage of teams to be assessed. [FG1]

Technology helped with data collection and processing to cover as many variables as possible. [I3]

PMAQ-AB Mobile App: Validation Structure and Obtaining Valid Results

The PMAQ-AB app allowed automatic verification of data consistency. Validation rules were established within the evaluation instrument to avoid entering incorrect information, with specific criteria for filling in the field, valid records, and expected input values to guarantee the integrity of the entered data, as illustrated in the following quote:

In the external evaluation tool, validation is related to fill-in of blanks (answers to patterns). Validation criteria are a) expected value typed in the tool; b) size of answer (number of characters); c) lack of information when the question is “non-applicable.” [D3]

Within this validation framework, an additional strategy was to create a duplicate questionnaire notification system, in which the app accused the interviewer of the existence of a conflicting evaluation in the database. Duplication of questionnaires leads to data inconsistency, as illustrated in the following quote:

Interviewers will be notified of duplicated questionnaires during submission. An alert informing the existence of an equivalent module filled for that team will appear in the external evaluation tool. [D3]

GPS was used to obtain the coordinates of the units that would participate in the external assessment to improve field activity. For some participants, this strategy could improve field activity by monitoring the location of interviewers during data collection, as noted below:

GPS was a technological advance used to improve field activity, identifying whether data are being collected at the defined location. [FG5]

The Development of the EEMS as a Resource for Managing the Evaluation Practice

The implementation of the EEMS appears in the analyzed documents as being strategic for online monitoring of data collection. The follow-up took place through reports, visualization of graphs, and the status of completed assessments. Access to the system is public, allowing monitoring by managers and local workers. The system has restricted access for higher education and research institutions, with reports prepared for the management of teams of interviewers.

An external evaluation panel was available at the EEMS. It is a public access system that enables follow-up of field activity, allowing for the external evaluation to be viewed as data that are collected in the field and uploaded to the national database. These reports can be downloaded in a spreadsheet format.

The system for public follow-up is divided into two sections: Informative Sections (with necessary information regarding conduction and follow-up of field activity) and Field Activity Follow-up Panel (allowing visualization of the external evaluation in parallel to its progress). [D2]

The EEMS allowed transparency and monitoring of data collection for coordinators and supervisors. In this proposal,

the documents emphasize that with restricted access, it was possible to obtain an overview of the field, generate statistics and fieldwork diaries, and download the evaluations carried out.

EEMS was developed to allow follow-up and management of field data collection and development of reports containing information collected in real time, facilitating management of higher education and research institutions. [D3]

The EEMS allowed supervisors and coordinators, even though they were not in the territory, to have daily control of the interviewers' activities during data collection. It was possible to identify and resolve inconsistencies, pending issues, and errors with the information recorded and sent after the application of the questionnaires, thereby increasing the accuracy of the data at each cycle. This was particularly evident in the focus groups.

The management system allowed daily control of collected data and follow-up of daily demand, reducing the number of inconsistencies after data collection; in many situations, we already had the answers to the problem. [FG4]

After sending data, they could be tracked using the platform. We could check time and inconsistencies, even though you were not in the field. The platform could resolve issues or observe what could be wrong out in the field. [FG2]

EEMS could establish alerts in case the questionnaires were filled by the interviewer at an incoherent time or time interval estimated for its completion. [D3]

Data consistency was verified by the evaluators according to the guidelines defined in the protocol for the analysis of the consistency and validation of collected data endorsed by the administration and teaching and research institutions. The parameters required by the app and the EEMS were defined a priori by the DAB-MS.

Use of IT: Skills Development, Inclusion of New Actors, and Possible Planning and Execution Problems

The use of IT has brought new training and learning opportunities for evaluators, often developing unusual skills. Considering the technological tools used to carry out the external evaluation of the PMAQ-AB, the documents highlight that training and simulation were fundamental for standardizing field activity throughout the country.

Presentation of registration tools and daily monitoring of field activity with EEMS demonstrations for all access profiles. Presentation of materials and tools for field activity. Simulation of use of electronic equipment and EEMS. [D3]

Despite the existence of training and education in essential content and basic precepts for understanding and acting in the field, in some focus groups, questions were raised about the lack of knowledge of some functionalities offered by the EEMS, which were known during the field activity. Monitoring the

development and implementation of technology is essential for participants to minimize problems related to its applicability in practice.

Technological problems could be fixed if we were following the evolution and implementation of technology. When we joined the database and the validator, we were unable to identify the location of the inconsistencies in the management system. Little by little, we got to know their functions. [FG6]

When the tablets were chosen to carry out the evaluation, the need became clear for investments in infrastructure (ie, hardware) for large-scale acquisition, due to the territorial extension of Brazil and the number of evaluations to be carried out simultaneously. Budgetary restrictions often do not allow for the acquisition of equipment with guaranteed use, making it difficult to carry out the evaluation, as one interviewee commented:

When we think about IT, tablets have a lifespan that cannot be ignored in the field and, as always, we work at the operational limit of tablets due to a lack of resources. We always have to consider the costs to ensure the hardware works and allows us to carry out the assessment. [I5]

The app used by the external evaluation was developed from the principle of facilitating and simplifying the process of collecting and sending data; however, some flaws were found in the app due to installation of its updates during the field activity. To address this and other issues, an IT team was included in the external assessment, as exemplified in the following quote:

The number of updates caused the app to malfunction. The IT support team at our institution resolved the issues. [FG6]

Discussion

Principal Findings

According to the results, evaluators interacted with people and with important technological components during the external evaluation of the PMAQ-AB, triggering influences, confluences, and collaborative and synergistic connections to increase evaluation quality. Technological resources made it possible to carry out the external evaluation of the PMAQ-AB across the country, supported operationalization of an evaluation with a broad thematic scope, provided resources for managing field activity, minimized errors, accelerated and standardized data collection, ensured information comprehensiveness with minimum inconsistencies, and allowed useful and valid results for team certification, health policies, and research.

Mobile technology with a specific app contributed to data collection following the objectives and expectations of all involved in the evaluation. Available resources were sufficient to provide rigorous application of a new external evaluation questionnaire, automatic verification of data consistency, and simplification of the work process in the field. Technology can also be used to guarantee quality and transparency during the evaluative process.

The EEMS collected the data from the finalized evaluation, enabled the coordination of the teams, and monitored the application of the instrument throughout the national territory. We highlight the ability to provide an overview of evaluations to the public, a daily registry of field activity, and management of resending the applied questionnaires among available resources. Difficulties could be identified, modified, and adjusted during data collection almost in real time. According to the results, the EEMS increased evaluation efficiency, reduced errors, and supported evaluators with a structure to manage the evaluative practice.

The collaboration between management and higher education and research institutions conferred credibility to incorporate IT into the evaluation. We highlighted the involvement of higher education and research institutions as important social actors for the external evaluation of the PMAQ-AB; their expertise added value to findings because they were evaluators who were external to the DAB-MS. Participation of higher education and research institutions during development and improvement of the EEMS was also emphasized, providing rules and resources for controlling field activity.

Presentation of materials and tools for data collection, attitudes and behaviors from human actors, and simulation of technology in the external evaluation of the PMAQ-AB are inherent to the learning process and were reflected in the application of the tool for data collection, standardized field activity, and improved communication.

Despite benefits, interaction with the mobile app and the EEMS during field activity presented challenges in the external evaluation of the PMAQ-AB. Factors such as technical aptitude, difficulties in technology operation, occasional system failure, and lack of investments in equipment and human resources were reported as potential barriers to increased efficiency of IT during evaluation.

Integration of Findings With the Current Literature

Enhanced efficiency and efficacy of data collection and accuracy are among the potential benefits of technology for evaluation practice [6,7,15,29,30], thus overcoming challenges related to timing, resources, and restrictions concerning data quality [2-4]. Technology also allows adjustments during evaluation, improves interventions and results, ensures feasible evaluations [6], ensures broad coverage during data collection (ie, inclusion of vulnerable groups and those who are difficult to reach) [2], and brings new voices and social participation (ie, diverse information) [6]. Technology can facilitate integration of different data sources to create a more comprehensive evaluation system [3], store large amounts of data [31], facilitate access and rapid exchange of information [1,4,32], and encourage evaluators to share public data [6].

Functionalities within the PMAQ-AB app allowed better integration of information, minimum inconsistencies, and secure data collection. Evaluators and app developers must guarantee adequate storage (ie, server security) [3], mainly due to the possibility of storing large amounts of data.

Consistencies are automatically verified with the advancement of digitalized evaluation, and data presenting discrepancies can

be identified during collection, contributing to their integrity [30]. Some authors consider app development relevant because the questionnaire can be applied in specific time intervals, and unanswered questions are signaled to the interviewer [3]. This scenario of greater control due to technology can create opportunities to improve the accountability of those involved with the evaluation [29].

Establishing a protocol for data management before initiating data collection increases efficiency, reduces errors, and supports evaluators with a structure adjusted to deal with challenges. This protocol must be shared with the entire team during evaluation planning [3]. Management and follow-up are conducted online by a leading researcher or leader of the evaluation team when interviewers conduct several evaluations. They are responsible for verifying data and identifying errors during data collection. Real-time feedback can also be provided in case of inconsistencies [5,6,30].

Regarding challenges for IT, the literature points out efficiency during the evaluation, the lack of technical ability [3], hardware malfunction [33], low institutional capacity due to insufficient budget to include technology into their operations, and difficulties regarding technological implementation [34]. Findings of what works and does not work should also be presented because this can help individuals and organizations to understand information, share learned lessons, make decisions, and continue progress [30].

Implications for Practice Emerging From This Work

The inclusion of new technologies into organizations influences new practices or reshapes existing practices [35,36]. The success of implementing information technology depends on interactions during the process and the final product. The use of different tools and processes aims to enhance and guarantee the quality of the evaluators' practice, and some of these efforts reflect existing structures [37].

The independence of the evaluator in the development and application of technological resources in conducting an evaluation also implies credibility for the collected data [38]. Implantation of systems for data collection management ensures credibility, use of the evaluation [39], and development of more participative and democratic evaluative approaches [40]. Technology can play a central role in evaluation management.

Although evaluators prefer the inclusion of technology due to the above-mentioned advantages, evaluative practices may require unusual demands (ie, knowledge and abilities). The development of evaluators' competencies is fundamental for facing potential challenges related to technology [41]. Therefore,

specific training regarding the system (ie, how to solve common problems or obtain additional technical support) must be included in the initial evaluative planning. Development of data security and interpersonal abilities is also relevant, both at individual evaluator and organizational levels [40].

Limitations of This Study

Collaboration between the DAB-MS and higher education and research institutions was successful during the meta-evaluation of the PMAQ-AB external evaluation. However, the inclusion of stakeholders (eg, municipal managers, health professionals, and users from PHC) would enhance the inclusiveness of the evaluation and broaden results. This inclusion was not feasible in this study, mainly because a meta-evaluation of the PMAQ-AB was not expected. An additional limitation of this study was the exclusion of software developers, hindering the understanding of technological points relevant to its applicability. This research fills a gap in empirical studies on the use of IT conceived from its sociomateriality and its effects on the quality of evaluative and meta-evaluative practices.

Conclusions

This study demonstrated that incorporating technology-based tools—the PMAQ-AB mobile app and the EEMS—during an external evaluation for data collection conferred utility, feasibility, and accuracy to the external evaluation of the PMAQ-AB. Implantation of technological resources was important to enhance the health evaluative system, with a reduction in operational and administrative costs; homogenization of data collection, guaranteeing data security and integrity; and optimized time and information flow. Cost-effective and clever use of technology offered evaluators a chance to include stakeholders and operational and methodological components that contributed to institutionalizing the evaluation process, allowed the development of a broader evaluative scope, and allowed for a more consistent evaluation with the potential for greater use of results in public health policies.

We recommend caution regarding the use of technology and adjustments of the software for evaluation needs, planning, training, digital inclusion, research integration, technology, and health services management. Further studies focusing on potential effects of using technology for new theoretical and methodological evaluation pathways are needed. The literature also lacks studies regarding the parameters used to determine the type of IT to be applied in evaluation processes, strategies for achieving interoperability of health information systems, and how technology could and should empower stakeholders to follow up evaluative processes.

Acknowledgments

The authors acknowledge the assistance provided by the Graduate Program in Collective Health of the Federal University of Rio Grande do Norte. We would like to express our sincere thanks to all stakeholders in this study for their willingness to share their experiences. This work was supported by the DAB-MS (Departamento de Atenção Básica—Ministério da Saúde), Brazil, and by the National Council for Science and Technology Development (grant 207493 / 2014-6). The funders had no role in the study design, data collection and analysis, decision to publish, or preparation of the manuscript. The authors thank Probatu Academic Services for providing scientific language translation, revision, and editing.

Authors' Contributions

OdGBJ, SAdCU, CRDVS, LMdFM, and CSM led the study, supervised all aspects of its conduction, and wrote the manuscript. OdGBJ, MBdS, NdSPDR, TXdAP, and MdSL collected the data, assisted with data analysis and interpretation of data, and wrote the manuscript. AAC, CRDVS, CSM, MdSL, MBdS, and TXdAP assisted with the study design and questionnaire item development. OdGBJ, SAdCU, CRDVS, LMdFM, CSM, and PdMR assisted with data analysis and interpretation of data. All authors helped to conceptualize ideas, analyzed and interpreted the data, drafted and revised the paper, and gave their final approval for the paper to be published.

Abstract

Background: The SARS-CoV-2 (COVID-19) pandemic may accelerate the adoption of digital, decentralized clinical trials. Conceptual recommendations for digitalized and remote clinical studies and technology are available to enable digitalization. Fully remote studies may break down some of the participation barriers in traditional trials. However, they add logistical complexity and offer fewer opportunities to intervene following a technical failure or adverse event.

Objective: Our group designed an end-to-end digitalized clinical study protocol, using the Food and Drug Administration (FDA)–cleared Current Health (CH) remote monitoring platform to collect symptoms and continuous physiological data of individuals recently infected with COVID-19 in the community. The purpose of this work is to provide a detailed example of an end-to-end digitalized protocol implementation based on conceptual recommendations by describing the study setup in detail, evaluating its performance, and identifying points of success and failure.

Methods: Primary recruitment was via social media and word of mouth. Informed consent was obtained during a virtual appointment, and the CH-monitoring kit was shipped directly to the participants. The wearable continuously recorded pulse rate (PR), respiratory rate (RR), oxygen saturation (SpO₂), skin temperature, and step count, while a tablet administered symptom surveys. Data were transmitted in real time to the CH cloud-based platform and displayed in the web-based dashboard, with alerts to the study team if the wearable was not charged or worn. The study duration was up to 30 days. The time to recruit, screen, consent, set up equipment, and collect data was quantified, and advertising engagement was tracked with a web analytics service.

Results: Of 13 different study advertisements, 5 (38.5%) were live on social media at any one time. In total, 38 eligibility forms were completed, and 19 (50%) respondents met the eligibility criteria. Of these, 9 (47.4%) were contactable and 8 (88.9%) provided informed consent. Deployment times ranged from 22 to 110 hours, and participants set up the equipment and started transmitting vital signs within 7.6 (IQR 6.3–10) hours of delivery. The mean wearable adherence was 70% (SD 19%), and the mean daily survey adherence was 88% (SD 21%) for the 8 participants. Vital signs were in normal ranges during study participation, and symptoms decreased over time.

Conclusions: Evaluation of clinical study implementation is important to capture what works and what might need to be modified. A well-calibrated approach to online advertising and enrollment can remove barriers to recruitment and lower costs but remains the most challenging part of research. Equipment was effectively and promptly shipped to participants and removed the risk of illness transmission associated with in-person encounters during a pandemic. Wearable technology incorporating continuous, clinical-grade monitoring offered an unprecedented level of detail and ecological validity. However, study planning, relationship building, and troubleshooting are more complex in the remote setting. The relevance of a study to potential participants remains key to its success.

Introduction

Clinical researchers have leveraged emerging technologies to increase study efficiency and accuracy for over 20 years [1]. Digitalized and decentralized clinical study design allows investigators to recruit more heterogeneous populations, reduce the burdens of participation, and capture the experience of participants in real-world settings [2-4]. The SARS-CoV-2 (COVID-19) pandemic may accelerate the shift toward digitalized and decentralized clinical studies [5], forcing researchers to implement remote solutions that limit in-person interaction, while preserving clinical study integrity [1,5]. These mitigations are essential to prevent clinical study disruption, which have detrimental immediate and long-term effects on outcomes, treatment, and cost [6].

Technology already exists to enable digitalization of most aspects of a successful clinical study from recruitment through outcome collection [7]. Online platforms, such as social media, have been shown to be time-efficient and cost-effective methods of recruitment [2,8]. Teleconsent coupled with e-consenting resources can ensure the 3 elements of consent (information, comprehension, and voluntariness) are met, and have moderate-to-high levels of user satisfaction and ease of use across different populations [3]. Remote data collection tools range from online platforms and custom apps for self-reporting outcomes to wearables that continuously collect physiological measurements [4]. Such observations can be collected at high frequencies, increasing the granularity of data to improve the capture of clinically relevant outcomes in ecologically valid settings, compared to traditional clinical studies that typically involve less frequent observations collected during in-person study visits [9,10]. Ultimately, continuously worn wearable data sources may enable digital biomarkers and predictive models that translate detailed data into trial endpoints, clinically actionable insights, and effective diagnoses [11-13].

A fully remote clinical study protocol requires consideration of external factors that have typically been more easily eliminated, or controlled for, in traditional protocols. Strategies for participant education and “nudges” must be adapted for digital delivery when the underlying research question relies on the data and is not focused on capturing voluntary engagement with the data collection instruments. There is less participant visibility and fewer opportunities to intervene and correct during remote data collection compared to in-person study visits. Remote observational studies, therefore, are less reliable because data collected in this manner are more vulnerable to inconsistency and reliant on participant compliance. The effect of human-computer interaction on data collection, for better or for worse, must be considered during analysis. To an extent, these effects can be monitored (or at least, contextualized) by collecting measures of adherence alongside the primary study outcomes. Logistical considerations, such as equipment shipment duration, become factors when eligibility and data

collection are time sensitive or following a technical failure or adverse event.

In this study, we designed an end-to-end digitalized clinical study protocol using the Current Health (CH) remote monitoring platform (Current Health Ltd.) to collect symptoms and continuous physiological data to build novel predictive algorithms of COVID-19 progression and severity in individuals who were recently infected in the community. Risk scores based on demographics and risk scores for hospitalized patients already exist [14]. However, by combining continuous remote patient monitoring with machine learning, the goal was to predict the risk of hospitalization, intensive care unit (ICU) treatment, or death for an individual infected with COVID-19 based on their vital signs while still in the community. The CH wearable and software platform were Food and Drug Administration (FDA) 510(k)-cleared for vital sign collection; therefore, confidence in the quality of vital sign observations captured by the CH wearable was higher than the unregulated general wellness wearables that are commercially available [9]. It was hoped that future CH platform integration of the risk algorithm developed from the vital sign data collected in this clinical study might improve resource allocation for patients after a COVID-19 diagnosis and enable more patient-centered management, increasing confidence for low- and high-risk patients and for those managing their care.

Given the need to recruit individuals positive for COVID-19 within 48 hours, key recruitment methods were social media and word of mouth. Recruitment through social media facilitated rapid reach, to an audience most likely to be eligible, in geographical locations associated with high numbers of COVID-19-positive cases and low vaccination rates [15-17].

Two recruitment methods, in person and pairing with test centers, were considered but not pursued. In-person recruitment was eliminated due to the increased risk of exposure and transmission of the infectious disease to the study team. Test center pairing was explored but was unsuccessful because test sites already had existing partnerships with academic institutions or were discouraged from advertising research studies that might deter COVID-19 testing.

Conceptual recommendations for digitalized and remote clinical studies have been outlined in the literature [7,18,19]. However, detailed examples, reviews, and learnings from actual implementation of these recommendations are limited. Our study implemented best-practice recommendations, although we were unable to progress beyond the pilot stage due to low recruitment. The goal of this paper is to describe the study setup in detail, evaluate its performance, and identify points of success and failure.

Methods

Trial Methodology

A scalable end-to-end digitalized protocol was designed for an observational clinical study in individuals who tested positive for COVID-19 in the community. Following the pilot phase, target recruitment was to be 2000 participants and enrollment was time sensitive following a positive COVID-19 test. The protocol eliminated in-person interaction and limited person-to-person interaction by utilizing commercially available technology. Each part of the research study, including recruitment, screening, consent, equipment setup, data collection, and follow-up, was automated, when possible.

Ethical Considerations

The study was advertised on social media platforms, including Facebook, Instagram, and LinkedIn, from March 2021 through May 2021. The language in the recruitment material ranged from general and inclusive, such as “positive COVID-19 test,” to emphasizing the time-sensitive inclusion criteria of “tested positive for COVID-19 in the past 48 hours” as a call to action ([Multimedia Appendix 1](#)). Emails were also distributed internally to employees of CH, and study information was shared with family and friends through word of mouth. The study was conducted according to the guidelines of the Declaration of Helsinki, and the study protocol and recruitment materials were approved by the Advarra Institutional Review Board (Protocol Pro00047371, December 15, 2020; Advarra, Columbia, MD, USA).

Advertisements and emails directed interested individuals to Community by Current Health, a central resource for all CH research studies [20]. The COVID-19 study page included the time-sensitive inclusion criteria (positive COVID-19 test in the past 48 hours), a study overview, frequently asked questions, and a button to “Volunteer Today,” which led to a web-based eligibility form (Jotform), and eligible subjects could schedule an appointment with the study team online. Individuals were also asked whether they were agreeable to be contacted for future studies. Eligibility questions were accompanied by a rule set based on inclusion/exclusion criteria ([Multimedia Appendix 2](#)) to automate most of the screening process. After the appointment was scheduled, the individual received a copy of the informed consent document. Study team members contacted eligible individuals using the contact number provided. If not eligible, a popup window indicated they were ineligible.

The virtual appointment with a study team member was typically the first point of interaction between the eligible individual and study team member. This appointment, while remote, was a chance to build rapport with the potential participant while taking them through the informed consent process. Teleconsent was similar to an in-person experience, where the details of the study, benefits, risks, and potential conflicts of interest were explained, and time was provided to address any questions [8]. If the eligible individual was still interested in participating, the informed consent form (ICF) was sent to them through software that enabled signature verification and was Health Insurance Portability and Accountability Act (HIPAA) compliant (DocuSign, Inc.). The consent process took approximately 10-15

minutes, and the study team received an updated ICF with the digital signature of the participant. The study team member who obtained the informed consent was designated as the point of contact with the participant throughout the study duration to maintain consistency and engagement. A central study team contact number was used to monitor communication and provide responses within 24 hours. The communication platform was flexible and included text, email, or phone contacts based on participant preference. A system was developed between the study team and the shipping team to track package movement. A logistics partner (Seko Worldwide LLC, Itasca, Illinois, USA) was engaged to distribute and return equipment. The tracking information was also sent to the participants to increase their engagement and to engender a sense of responsibility. Return labeling and packaging were provided. Once consent was obtained, study equipment was delivered to the participants within 1-2 business days.

Data Collection

During the pilot phase, the CH remote monitoring platform was used to collect vital signs and symptoms from 8 individuals who tested positive for COVID-19 (mean age 35.6 years (SD 10 years); 6 (75%) female; 7 (87.5%) White non-Hispanic; 1 (12.5%) Black or African American) for up to 30 days. Study endpoints included recovery (as defined by the Centers for Disease Control and Prevention Clinical Criteria), hospitalization, or death [21]. Therefore, study participation duration varied (mean 27.1 days, SD 5.4 days). The CH kit included a clinical-grade wearable that continuously recorded pulse rate (PR), respiratory rate (RR), oxygen saturation (SpO₂), skin temperature, and step count and a tablet configured to the local time zone of the participant that administered surveys and task reminders. Participants were spread across 3 US time zones (Eastern, Central, and Mountain). Vital signs collected by the wearable and survey responses recorded in the tablet were transmitted to the CH cloud-based platform as raw waveforms and displayed in the web-based dashboard where compliance to study procedures could be monitored. Vital signs were sent when the CH wearable was in range of the CH transmitter and stored for up to 10 hours on the wearable if out of range. The transmitter was enabled for both home Wi-Fi and cellular communication, broadening participation to those without home internet.

An email was sent parallel to study equipment delivery to prompt the participants to set up the equipment as soon as possible. The email contained recommendations regarding wearing and charging the wearable and answering the daily survey. There was a prompt to complete a welcome survey using a unique weblink (Jotform). The welcome survey included questions about the participant and took less than 5 minutes to complete ([Multimedia Appendix 3](#)). Although participants were encouraged to complete the welcome survey at the beginning of the study, survey responses were accepted at any point during the study duration.

The CH kit was set up independently by the participants in their home using the tablet-guided instructions. The study team was available to provide remote assistance if there were difficulties setting up the equipment. The participant wore the CH wearable

on the upper arm. The PR, SpO₂, motion, and skin temperature were recorded at up to 30 samples per minute, and RR was recorded at up to 15 samples per minute when the wearable was on-arm. Two notifications were received on the tablet each day at 9:00 a.m. and 10:00 a.m. (local time zone). The first was a reminder to charge the wearable, and the second was a reminder to complete a brief series of questions about symptoms and decisions each day (Multimedia Appendix 4). The participants were not able to see vital sign data or survey responses in real time. Participant adherence was remotely monitored by applying a threshold alarm to vital sign data. The study team were alerted when a participant did not transmit vital sign data to the CH platform for 4 or more hours. The study team escalated the alert by contacting the participant to see whether they were experiencing technical issues or were away from home or to remind the participant to wear the CH device. The vital signs were not monitored in real time, which was made explicitly clear during the consent process. Participants were encouraged to act as they normally would if they felt unwell. At the end of the study duration, the participants returned the CH kit via mail, receiving up to US \$100 (US \$25/week) if they successfully adhered to the study protocol, in recognition of their time.

Evaluation Methodology

Metrics were created to quantify each phase of the study that was delivered remotely: recruitment, screening, consent, equipment setup, and data collection (Multimedia Appendix 5). Facebook advertising engagement and CH website traffic were tracked with a web analytics service (Google LLC). Advertisement clicks and website views were counted. Metrics of data collected during the trial from the 8 participants, such as daily wearable adherence, vital signs per day (PR, RR, SpO₂), and symptoms, were calculated, in addition to quantitative metrics of trial evaluation. All metrics were assessed for distribution through visual inspection and the Shapiro-Wilk test. Where metrics were normally distributed, they are presented as the mean (SD), and where they were nonparametric (Shapiro-Wilk significant) they are summarized as the median (IQR).

Results

Enrollment Funnel

Of 13 different study advertisements, 5 (38.5%) were live on Facebook at any one time (Multimedia Appendix 1). There were 8852 clicks on the Facebook advertisements for a total spend of US \$6770.35. Community by Current Health and its COVID-19 study page were viewed 8932 and 618 times, respectively. There was a decrease in the mean unique advertisement clicks per day from 100.83 in March 2021 to 28.97 in May 2021. In total, 38 eligibility forms were completed,

and 19 (50%) respondents met the eligibility criteria. Of these, 9 (47.4%) were contactable (the remainder were uncontactable or deemed themselves “too sick” to take part). Informed consent was obtained from these 9 individuals, and 8 (88.9%) signed the ICF within 9 (SD 8) minutes of the study team sending the ICF via DocuSign (Table 1).

Deployment times ranged from 22 to 110 hours, with a median time of 41 (IQR 28-68) hours. Participants set up the study equipment and started transmitting vital signs within 7.6 (IQR 6.3-10) hours of delivery, and 5 (62.5%) of 8 participants completed the welcome survey in a median of 7.4 (IQR 7.2-53) hours of receiving the welcome email. In addition, 2 (25%) participants completed the welcome survey after the 30-day study period (time to task completion was 32 and 51 days, respectively), while 1 (12.5%) participant never completed the welcome survey. Welcome survey responses indicated that 7 (87.5%) participants did not have asthma, cancer, chronic obstructive pulmonary disease (COPD), diabetes, heart conditions, high blood pressure, sickle cell disease, or kidney disease; undergo an organ transplant; or take beta blockers. In addition, 3 (37.5%) of the participants were smokers, and 7 (87.5%) participants lived with other people but only 1 (12.5%) participant had another member in the household currently COVID-19 positive.

Study participation varied from 17 to 30 days, with 6 (75%) participants completing 30 days and 2 (25%) participants released at 17 and 20 days, respectively, having met the definition for recovery. The mortality rate was 0%, and none of the participants were hospitalized. The mean wearable adherence was 70% (SD 19%), and the mean daily survey adherence was 88% (SD 21%). The median daily wearable adherence ranged from 52% (IQR 29.2%-82.0%) to 92.7% (IQR 82.6%-96.1%). The median PR per day ranged from 65.4 (IQR 59.3-75.5) to 96.5 (IQR 89.9-100.1) beats per minute. The median RR per day ranged from 15.5 (14.1-18.2) breaths/min to 19.3 (15.9-23.0) breaths per minute. The median SpO₂ per day ranged from 95.8% (IQR 93.0%-97.2%) to 98.0% (IQR 96.7%-98.5%). Reported symptoms decreased over time (Multimedia Appendix 6). Participants triggered 87 technical alarms (12 [13.8%], for low battery and 75 [86.2%], for no data for >4 hours, although in many cases the data were buffered and transfer resumed once they had returned home). The median alarms per patient per day was 0.68 (IQR 0.57-1.0, range 0.25-1.6); these were predominantly in the morning. In addition, 4 (50%) participants met the criteria for wearable adherence (wearable worn for at least 20 hours a day and at least 6 days a week, up to 30 days). However, 4 (50%) missed 2 consecutive days of surveys and 1 (12.5%) failed to return the kit at the end. So, 2 (25%) of 8 participants met the strict criteria for full adherence to the study.

Table 1. Enrollment funnel.

Enrollment step	Participants, n (%)
Assessed for eligibility (N=38)	38 (100)
Eligible (N=38)	19 (50)
Informed consent call (N=19)	9 (47.4)
Enrolled (N=9)	8 (88.9)
Completed trial (N=8)	8 (100)

Discussion

Principal Findings

This work evaluated the performance of an end-to-end digitalized clinical study implemented using best-practice recommendations. In total, 8 participants were enrolled into the study; symptoms and continuous physiological data were collected using the CH platform for up to 30 days. Metrics associated with enrollment, deployment, and adherence to the study procedures were reported, and study data were summarized per day. During study participation, vital signs remained within their normal ranges and symptoms decreased over time ([Multimedia Appendix 6](#)). This study demonstrated both the advantages and the compromises inherent in decentralized, digitalized clinical trials, and we hope this experience will be valuable to other research groups considering a similar approach.

Throughout the trial, communication strategies were optimized to maintain engagement with participants without being invasive or time-consuming. A central number was created via Google Voice so that multiple study team members could be in communication with 1 participant from the same source. Email communication was timed around equipment delivery dates, and study milestones, to offer avenues for support at the times when most likely to be needed. Regular contact, by multiple channels, helped maintain engagement and reduced the likelihood of a participant being lost to follow-up. The study spanned several time zones, and rather than being a hindrance, this facilitated recruitment as study staff could offer longer “office hours” for participants. Investigators were nonetheless conscious to strike a balance between forming a relationship with a participant but allowing them sufficient space and anonymity for participant to re-engage if they forgot a study task.

The study logistics had to run parallel with participant communication. Engaging a logistics partner offered a level of flexibility in returning study equipment, and the participants were only paid their accrued study incentives once the equipment had been safely received. Collectively, these measures were reflected in most participants receiving equipment and beginning to transmit data within 48 hours of consent and all but 1 of the kits being returned at the close.

Decentralized, digitalized clinical trials also have unique challenges. Study planning, including multidisciplinary working and participant review, can either be facilitated or made more complex, depending on the circumstances of the work. All software must be HIPAA-compliant. Electronic documents must

be organized into a study master file that maintains collaboration but also the integrity of study and participant confidentiality. This is typically accomplished by keeping participant information separate from study identifiers. In the CH platform, a random token unique to each participant was generated and stored along with personally identifiable information (PII) in a secure PII enclave. All clinical data processing was then performed on de-identified data, including only that token.

Wearable devices must be validated in the study setting, including being used by the population in question without contemporaneous instruction, and there should be appropriate internet or cell coverage for data transmission (which may exclude certain populations). Wearable continuous monitoring provides vastly more data than single study visits, so consideration should be given to data storage, triage, and quality. A decision must be made a priori between storing raw data, which maintains maximum fidelity and flexibility for future investigation (but is costly), and committing to a level of aggregation. One argument for choosing wearables that record and store raw waveforms is that wearable sensors vary in quality (only some have achieved FDA 510k clearance for clinical-grade monitoring) and participants are out of sight of investigators. Storing the raw waveforms allows for retrospective audit of vital sign quality, which can be reassuring. At the very least, devices should be selected that supply an indication of data quality as metadata.

Given this potential to collect vast amounts of data, definitions of adherence must be set around the goals of the study and be realistic for the participants throughout their participation. More data are not always more informative, but more of the “right data” will be. Our definition of full adherence was strict, with a high bar set for wearable adherence and survey completion. Although this bar may have been appropriate and achievable in the more severe phases of the illness, once participants felt well again, they started to leave home and re-engage with work, and it proved too high for some. Equally, if technical alerts for no data are to be set, they should also be set at a threshold and cadence mindful of the study goals and likely participant behavior. Although a proportion of our no-data alarms reflected genuine technical difficulty or nonadherence, most were simply triggered by symptom-free participants leaving the house for more than 4 hours at a time.

A remote trial clearly facilitates some aspects of research in an infectious disease population and reduces the likelihood of disease transmission to participants and investigators. However, for those quarantining within their own homes, troubleshooting device issues can be made more complex. It can be hard for

them to retrieve deliveries of study components when the initial delivery has been missed. Patients who are acutely unwell may be less likely to see study advertisements. As discussed earlier, they may also be harder to connect with or may feel too sick or disinclined to participate. This may skew results toward less severe illness. Infections, by their nature, are time sensitive. Logistical delays or issues with equipment may leave some participants ineligible. Relationship building can be more difficult to foster when the participant and investigator never meet in person. It is harder to gauge understanding during the informed consent process, and some study data, particularly sensitive information or demographic details, may be harder to acquire. A balance must be struck between creating appropriate minor hurdles to ensure the participant is serious about completing the study, and ensuring overall ease of participation and appropriate incentives to recognize the minor inconvenience associated with data collection.

Comparison With Prior Work

Social media platforms hold much promise as avenues for recruitment. Their advertising models are designed and priced to target particular demographics in specific locations, and their advertisements are readily amenable to A-B testing. The platforms' broad reach and pricing models such as cost-per-click offer fine control over costs and potential savings to investigators. Ali et al [2] reported enrollment of 6602 participants with 9609 advertisement clicks and a total spending of US \$906 over the recruitment period. Although there were 8852 advertisement clicks (US \$6770.35) in our study, enrollment was much lower (9 participants). However, without a bricks-and-mortar institution, online recruitment can still struggle to achieve a signal amidst the noise. In the context of COVID-19 studies and the pandemic, ring fencing of some language on the platforms made this signaling more challenging. For example, Facebook prohibits advertisements containing content that asserts or implies personal attributes, including physical health.

Indeed, in our study, the initial phase of recruitment remained the most difficult. Advertisements and their amendments were often delayed, while their content was manually reviewed for language. Although 19 participants were eligible, only 9 agreed to a phone call, with many citing a worsening of their condition as a reason not to participate. In studies of rapidly evolving diseases, such as COVID-19, it would be prudent to tie the process of information and consent directly to testing in order to enroll potential participants once proven positive but before their symptoms become overwhelming.

However, once the challenges of initial recruitment were overcome and participants were in the funnel, all patients except 1 who received a phone call consented to the study. This success

at converting interest to consent and participation may have been because online recruitment removed perceived barriers to participation or because word of mouth was also used as a recruitment tool. A systematic review and meta-analysis of online patient recruitment in clinical trials found that traditional offline recruitment strategies (eg, word of mouth) result in higher conversion rates than online recruitment strategies [8]. Proximity to a study site was not required. There was no lead time to appointments, and scheduling and coordination of information sharing and consent were simplified. The economic burden on participants, in terms of travel, time, and opportunity cost, was reduced. In the context of COVID-19, there was no concern about viral transmission to participants or investigators from visiting an institution. Removing these barriers, real and perceived, may allow remote clinical trials to reach more marginalized communities, often the hardest for researchers to enroll and, in the case of COVID-19, disproportionately affected by the pandemic.

Limitations

Ultimately, the perceived relevance of a study to its participants, and the landscape in which it is deployed, will hold the key to its success. This pilot study was opened in February 2021 just as infection rates were falling and vaccination rates were rising. Despite incorporating recommendations for best practices in decentralized trials, and our success at enrolling participants once in the funnel and removing barriers to participation, we still missed our recruitment targets and evaluation of the implementation of a scalable end-to-end digitalized protocol was limited to a small sample size. Decentralized and virtual studies hold enormous promise, and may indeed revolutionize the way studies are conducted, but they will still likely remain 1 of many tools in the clinical trials toolkit.

Conclusion

Our pilot study demonstrated the advantages, challenges, and compromises inherent in digitalized, decentralized remote clinical trials. With a well-calibrated approach to online advertising and enrollment, barriers to recruitment can be removed and the cost reduced. Equipment can be effectively and promptly shipped to participants, without risk of illness transmission during a pandemic. Wearable technology incorporating continuous, clinical-grade monitoring can offer an unprecedented level of detail and ecological validity. However, study planning, relationship building, and troubleshooting are more challenging, and definitions of adherence must be crafted around anticipated participant behavior. The relevance of a study to potential participants, be it in person or remote, remains key to its success, particularly during a pandemic.

Abstract

Background: Digital health services can serve as scalable solutions to address the growing demand for mental health care. However, more research is needed to better understand the association between engagement with care and improvements in subclinical outcomes.

Objective: This study aims to fill this research gap by examining the relationship between members' engagement with the Ginger platform and changes in their psychological resilience.

Methods: We conducted a retrospective observational study of 3272 members who accessed Ginger, an on-demand mental health service, between January 2021 and November 2021. Each member completed the 10-item Connor-Davidson Resilience Scale questionnaire, a measure of psychological resilience, at baseline and again during a 6- to 16-week follow-up window. Depression and anxiety symptoms (9-item Patient Health Questionnaire and 7-item Generalized Anxiety Disorder) were also measured. Linear regression was used to identify the association between engagement with Ginger's multiple care modalities and changes in resilience. Moderator analysis was conducted to test whether clinical depression or anxiety at baseline moderated the relationship between engagement level and changes in resilience.

Results: Of the 3272 members, 2683 (82%) reported low resilience at baseline. The mean change in resilience was 0.77 (SD 5.50) points. Linear regression models showed that age and census region did not predict changes in resilience; however, male members showed larger improvements (coefficient=0.58; $P=.04$). Baseline mental health outcomes, including resilience and depression and anxiety symptoms, were strong predictors of changes in resilience. Every point decrease in baseline resilience is associated with a 0.28-point increase in change in resilience ($P<.001$), and members with no or mild depression and anxiety at baseline saw changes in resilience that were 1.44 points ($P<.001$) larger than their clinical counterparts. Engagement with the Ginger system predicted changes in resilience. Members who engaged with Ginger coaching, clinical services, or both improved their resilience by 1.82, 1.55, and 1.40 points, respectively ($P<.001$), more than those who only engaged with Ginger content. Screening negative for moderate to severe depression and anxiety at baseline was associated with larger improvements in resilience (coefficient=1.30; $P<.001$); however, subclinical status was not shown to be a moderator for the association between level of engagement and changes in resilience.

Conclusions: Engagement with Ginger services was associated with improvements in resilience. Members who engaged in coaching or clinical care had significantly larger improvements compared with those who only engaged in self-guided content, regardless of whether a member screened positive for clinical depression or anxiety at baseline.

KEYWORDS

behavioral coaching; psychological resilience; mental health; telehealth

Introduction

Background

Resilience is a multidimensional construct that may be viewed as one's ability to cope with stress or represent personal qualities that enable one to thrive in the face of adversity [1-3]. Resilience has been studied in a variety of disciplines, including psychology, psychiatry, sociology, genetics, and neuroscience among others [4,5]. The definition of resilience has evolved along with increased scientific knowledge in these disciplines. As such, researchers have argued that resilience is "the process of multiple biological, psychological, social, and ecological systems interacting in ways that help individuals to regain, sustain, or improve their mental wellbeing when challenged by one or more risk factors" [6]. Furthermore, research has shown that resilience can vary with factors such as time, context, gender, and cultural origin [7]. From a strength-based perspective, resilience can contribute to positive functioning and help prevent negative emotions, thoughts, and behaviors [8]. Studies have demonstrated that resilience is a mitigating factor for heightened stress and adverse mental health outcomes in life circumstances.[9]. Specifically, individuals with low or normal levels of resilience have been found to be more likely to experience mental distress than those with high resilience [10,11].

Although many researchers' conceptualization of resilience is somewhat related to the notions mentioned earlier, namely, individuals' ability to cope with stress and adverse circumstances, there is no consensus on the operational definition of resilience according to a recent meta-analysis [12]. Given this, studies such as this one must be explicit about the conceptualization of resilience used as well as the precise measurement strategy. For the purpose of this study, psychological resilience is defined as how well one is able to adapt to change and *bounce back* after stressful events, tragedy, or trauma. This framework is consistent with the 10-item Connor-Davidson Resilience Scale (CD-RISC-10), which is the survey instrument used to measure resilience in this study. The 10 topics included in the CD-RISC-10 were confidence, determination, flexibility, focus, grit, perseverance, personal growth, positivity, self-reliance, and weathering emotions. This measure is explained in more detail in the *Data* section.

In light of the current pandemic, there has been increased focus on employee mental health and recognition of the importance of resilience in daily stress management and overall well-being [13]. For many, the COVID-19 pandemic fundamentally changed how and where one works as well as the daily demands of their jobs, and many reported increased loneliness, anxiety, depression, and suicidal ideation [14-16]. Recent studies have found that individuals with lower resilience scores are more likely to experience mental distress and express greater difficulty coping with the emotional challenges of the COVID-19 pandemic [10,16]. Similarly, a population-based study in China at the peak of the pandemic found that psychological resilience was significantly negatively correlated with depression, anxiety, and somatization symptom scores [17]. In addition, a study among public workers found that resilience mediated the effect

of depression in public workers and their stress and anxiety levels during the pandemic [18].

Behavioral health coaching draws from several theoretical approaches that can effectively impact resilience or well-being. Coaching interventions address a variety of day-to-day challenges by identifying and working toward concrete and actionable goals. Resilience is seen as a proactive capability that supports the attainment of such goals and enhances overall mental health [19]. During the pandemic and postpandemic return to the office, many organizations have allocated increased resources toward the mental health and well-being of their employees, including resilience training and coaching-based interventions. However, a review of resilience intervention studies found that most in-person trainings were of short duration and had limited follow-up periods [13].

Previous studies have indicated a positive relationship between resilience and well-being, with higher resilience in the workplace setting associated with better mental health, reduced stress, and greater well-being [13]. Furthermore, the authors found that individuals who participated more often in the web-based resilience training program achieved the greatest improvements [13]. A recent multilevel meta-analysis found that resilience-promoting interventions yielded a small but significant overall effect on resilience [12]. One key finding was that ambiguity in conceptualizing and operationalizing resilience, in turn, leads to variability both between and within treatment effect sizes [12].

In addition to resilience-focused interventions, studies have found that general coaching interventions have also demonstrated that coaching can support resilience, even in the absence of it being the focus or aim of services. For example, a randomized controlled study of executives in a public health agency found that individual coaching sessions enhanced goal attainment, increased resilience and workplace well-being, and decreased depression and stress compared with controls [20]. Similarly, Lee et al [21] found that a health coaching program is an effective strategy for improving resiliency in youth.

Ginger offers various types of care designed to provide mental health support, including self-guided content, text-based behavioral health coaching, teletherapy, and telepsychiatry. Theoretically, each modality of care has a different effect on resilience. This hypothesis was tested in this study. Furthermore, given the clinical focus of therapy and psychiatry, these modalities may have different impacts on resilience depending on whether a member presents with clinical symptoms. It could be that these modalities are more effective at impacting resilience for these members if interventions designed to impact clinical symptoms are more impactful on resilience. Alternatively, if addressing clinical symptoms is the focus of care before addressing subclinical outcomes such as resilience, we could expect to see that therapy and psychiatry have a smaller impact on resilience (but perhaps have an equal or larger impact on a time horizon beyond the scope of this study). Given the unique Ginger context that offers multiple care modalities, testing whether clinical symptoms moderate the impact of engagement on resilience is possible. We are not aware of any existing studies that explicitly test this moderator hypothesis.

Overall, literature supports the relationship between resilience and other mental health and well-being outcomes and the fact that interventions, including coaching, can bolster resilience. Given that most of these studies have been conducted in controlled research settings, it is important to supplement this knowledge to better understand what is happening in real-world settings, particularly when a global pandemic introduces unique challenges to resilience.

Study Objectives

The purpose of this study was to examine changes in resilience among members seeking on-demand mental health treatment. We explicitly tested the following three hypotheses:

1. Change in resilience is associated with member characteristics at baseline, including demographic characteristics and baseline mental health outcomes (baseline resilience, depression symptoms, and anxiety symptoms).
2. Engagement with Ginger care is associated with larger improvements in resilience.
3. Baseline depression and anxiety symptoms moderate the association between engagement and changes in resilience.

Consistent with previous literature [10,11,13,17], we hypothesize that resilience will increase over the follow-up time points of treatment, and those with higher anxiety or depression symptom scores at intake will evidence smaller improvements or worsening in resilience over time.

Study Contributions

This study contributes to the literature on resilience in several ways. First, we present the results of one of the largest longitudinal studies of resilience. Our sample includes 3272 individuals. Second, to our knowledge, this is the first study to specifically examine resilience in the context of a digital mental health system that offers self-guided content, text-based behavioral health coaching, telepsychotherapy, and telepsychiatry. Third, by leveraging our rich data on Ginger members, we tested specific hypotheses that relate resilience to clinical depression and anxiety symptoms. In particular, we were able to test for the first time whether depression and anxiety symptoms moderate the impact of coaching and clinical interventions on resilience.

Methods

Overview

This was a retrospective observational study of Ginger members: individuals who joined Ginger, an on-demand mental health system. Data were collected between January 1, 2021, and November 13, 2021, from Ginger members residing in the United States. As part of its measurement-based care system, Ginger used the CD-RISC-10 as an indicator of resilience at intake as well as to track treatment progress beyond anxiety and depression symptom scores. By leveraging a retrospective design, this study contributes to the growing literature using real-world evidence. Although such studies often lack clear causal inference, they offer increased feasibility, larger samples, and robust external validity.

Participants

Study participants had access to the Ginger system as part of their employee or health plan benefits. Internal clinical protocols include the following exclusionary criteria, where self-directed telehealth is not likely appropriate and more specialized and urgent psychiatric services are required: (1) active suicidal ideation; (2) active high-risk self-harm behavior; (3) 2 or more hospitalizations within the past 6 months or 1 hospitalization in the past month for psychiatric reasons; (4) certain symptoms of psychosis that are poorly managed (eg, member is not medication compliant or symptoms are unresponsive to treatment) and are likely incompatible with telehealth; (5) a primary diagnosis of a substance use disorder or moderate to severe substance abuse issues, owing to the high complexity, severity, and risk frequently associated with such members, as well as the need for specialized care; (6) active eating disorders with symptoms considered high-risk; (7) ongoing grave disability, including certain patients who are bipolar with active mania or hypomania or mixed episodes who are unmedicated or have poor compliance with a medication regimen over time; and (8) two or more medical hospitalizations in the last month, owing to the high likelihood that the individual has a poorly controlled medical condition that requires close monitoring. For this study, we included Ginger users aged ≥ 18 years who downloaded the app during the data collection period.

Data

The Ginger System

Ginger provides virtual on-demand mental health services, primarily through employee or health plan benefits. Using a mobile app platform, Ginger members can access text-based behavioral health coaching, teletherapy, and telepsychiatry, as well as self-guided content and assessments. Individuals who are eligible for Ginger can download the mobile app, complete an onboarding process, and begin texting with a behavioral health coach within minutes. Members who are interested in or have been determined to be in need of a higher level of care can meet with a therapist or psychiatrist via video. All participants had access to self-care activities via mobile apps. Additional details regarding the Ginger system can be found in prior publications evaluating depression and anxiety outcomes as measured by the 9-item Patient Health Questionnaire (PHQ-9) and 7-item Generalized Anxiety Disorder (GAD-7) surveys [22,23].

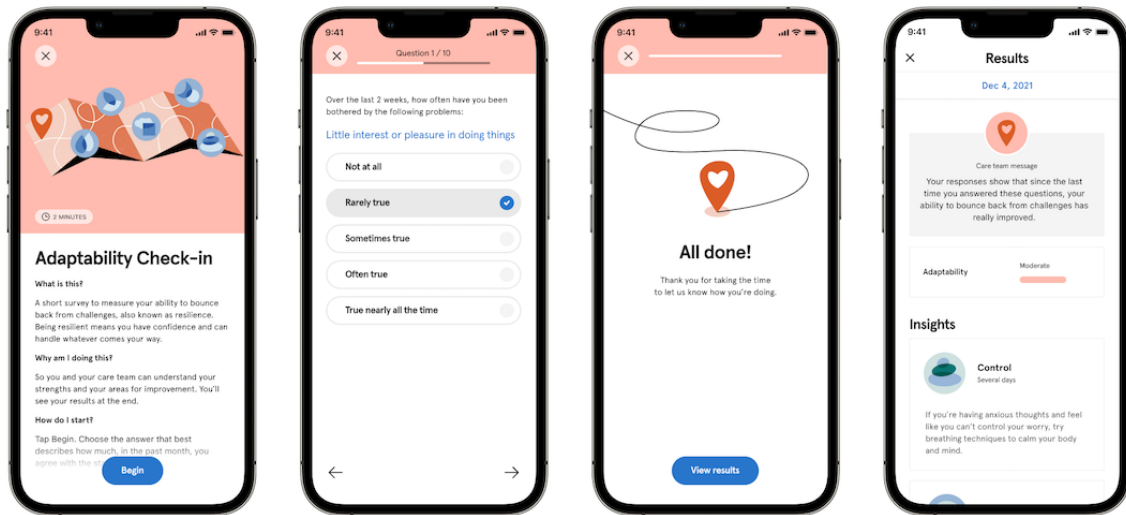

Data Collection

Ginger uses various assessments including the PHQ-9 and GAD-7 surveys as part of its measurement-based care system. Since December 2020, Ginger has used the CD-RISC-10 survey (referred to as an adaptability check-in within the app) to track progress beyond depression and anxiety symptom scores. This is particularly relevant to understand the needs of *subclinical* members (ie, members who do not exhibit clinically significant levels of depression or anxiety at intake). The CD-RISC-10 was selected because of its focus on behavioral health coaching to build resilience and its strength-based focus. A total of 7 CD-RISC-10 surveys were sent to members 1 week after enrollment, and follow-up surveys were sent to members every

30 days. Importantly, members who signed up but did not engage with the app past the 1-week mark did not complete the baseline survey. In this way, members with a low likelihood of meaningful engagement (a proxy for behavioral health needs)

were excluded from the sample. A visual depiction of how the CD-RISC-10 survey appears to the members is shown in Figure 1.

Figure 1. The 10-item Connor-Davidson Resilience Scale survey in the Ginger mobile app.

Measures

CD-RISC-10 Assessment Tool

A common assessment tool for resilience is the CD-RISC-10. As mentioned earlier, Ginger uses the CD-RISC-10 as a proxy measure of an individual's psychological resilience level. The original researchers initially developed a 25-item scale to measure resilience or how well one is able to adapt to change and *bounce back* after stressful events, tragedy, or trauma. A total of 2 brief versions, the 10-item (CD-RISC-10) [24] and the 2-item (CD-RISC-2) [25], were subsequently developed by other research teams. The CD-RISC-10 contains 10 of the original 25 items from the CD-RISC scale and has demonstrated robust validity, reliability, and practicality [24]. The 10 topics included in the CD-RISC-10 were confidence, determination, flexibility, focus, grit, perseverance, personal growth, positivity, self-reliance, and weathering emotions. For each of the 10 items, respondents were asked to rate items on a 5-point scale: not true at all (0), rarely true (1), sometimes true (2), often true (3), and true nearly all the time (4). A respondent's total score ranges from 0 to 40, with higher scores indicating greater resilience. Results from the US population indicate that the quartiles for this measure are as follows: Q1: 0 to 29, Q2: 30 to 32, Q3: 33 to 36 and Q4: 37 to 40 [22].

PHQ-9 Assessments

The PHQ-9 is a 9-item self-report questionnaire that assesses the frequency and severity of depression symptomatology within the previous 2 weeks. Each of the 9 items is based on the Diagnostic and Statistical Manual of Mental Disorders, 4th edition criteria for major depressive disorder and is scored on a 0 (not at all) to 3 (nearly every day) scale. Items include *Little*

interest or pleasure in doing things and *Feeling down, depressed, or hopeless*. Total scores range from 0 to 27, with higher scores indicating more depressive symptoms. A score of 10 is used as the clinical threshold [26].

GAD-7 Assessments

The GAD-7 is a valid, brief self-report tool used to assess the frequency and severity of anxious thoughts and behaviors over the past 2 weeks. Each of the 7 items is based on the Diagnostic and Statistical Manual of Mental Disorders, 4th edition diagnostic criteria for generalized anxiety disorder and is scored on a 0 (not at all) to 3 (nearly every day) scale, with total scores ranging from 0 to 21. Items include *Feeling nervous, anxious, or on edge* and *Not being able to stop or control worrying*. Consistent with existing literature [27], a score of 10 was used as the clinical threshold for this study.

Levels of Engagement

Coaching sessions were operationalized as the number of unique days on which members and coaches each exchanged at least five text messages, the minimum we believe is needed to capture a productive conversation between members and their coaches. Clinical sessions were operationalized as the number of video sessions completed with a clinician.

For this study, 5 different levels of engagement were considered based on members' engagement with self-guided content, text-based coaching, and teletherapy sessions. Specifically, members who engaged only with self-guided content and did not complete any coaching or clinical sessions were categorized as the *self-guided* group. *Low engagement* was defined as members who completed >4 coaching or >4 teletherapy sessions. Members who completed ≥4 text-based coaching sessions and

no clinical sessions were categorized as the *coaching only* group. Members who completed 4 or more clinical teletherapy sessions (with a therapist) and at most one coaching session were categorized as the *clinical only* group. We allow for *clinical only* members to have completed at most one coaching session, given that many members' point of entry to Ginger is a coaching session, after which they could be escalated to therapy and not

continue coaching. Finally, members who completed 4 or more coaching sessions coupled with at least one clinical session or members who completed 4 or more teletherapy sessions coupled with more than 1 coaching session were categorized as the *hybrid care* group. The descriptions and rationales for the creation of these groups are described in [Table 1](#).

Table 1. Engagement levels.

Engagement level	Definition	Rationale
Self-guided	Engagement only with self-guided content; 0 coaching and 0 clinical sessions	These are members who have engaged with the app's self-guided content but have not interacted with any coaching or clinical care. This group serves as the primary reference group in the linear regression models.
Low engagement	Between 0 and 3 total sessions comprising coaching or clinical care	Internal analyses suggest that 4 sessions are an inflection point for meaningful symptom reduction. These are members who have not reached this threshold.
Coaching only	≥4 coaching sessions and 0 clinical sessions	These are members who have completed at least the internally established threshold of 4 sessions but exclusively with coaching care.
Clinical only	≥4 clinical sessions and ≤1 coaching session	These are members who have completed at least the internally established threshold of 4 sessions but exclusively with clinical care.
Hybrid care	>1 coaching session and ≥4 clinical sessions or ≥1 clinical session and ≥4 coaching sessions	These are members who have completed more than the internally established threshold of 4 sessions using a combination of coaching and clinical care.

Baseline Characteristics

For each member, the following data were either collected at baseline or were fixed characteristics of members: age group, gender, geographic region, PHQ-9 score, and GAD-7 score. The demographic and location data were not self-reported. Instead, they were reported by a member's parent organization, which is either their employer or health insurance plan. Baseline PHQ-9 and GAD-7 data were collected using the Ginger system. The baseline PHQ-9 and GAD-7 scores were selected within 1 week before and after a member's baseline CD-RISC-10 score was collected, and the first PHQ-9 and GAD-7 scores were chosen. Members without baseline PHQ-9 and GAD-7 scores were excluded from analysis.

For many of our participants, the baseline characteristics were missing. The data were missing owing to 1 of 2 reasons. First, a member's parent organization may not share members' demographic information. Thus, missing demographic data are a signal of a member's parent organization and not necessarily a signal of information specific to a given member. For example, of the 197 parent organizations represented in this study, 118 (59.9%) reported all their members' gender information, 76 (38.6%) reported no gender information, and the remaining 3 (1.5%) organizations reported gender information for some but not all of their members.

Analyses

Sample

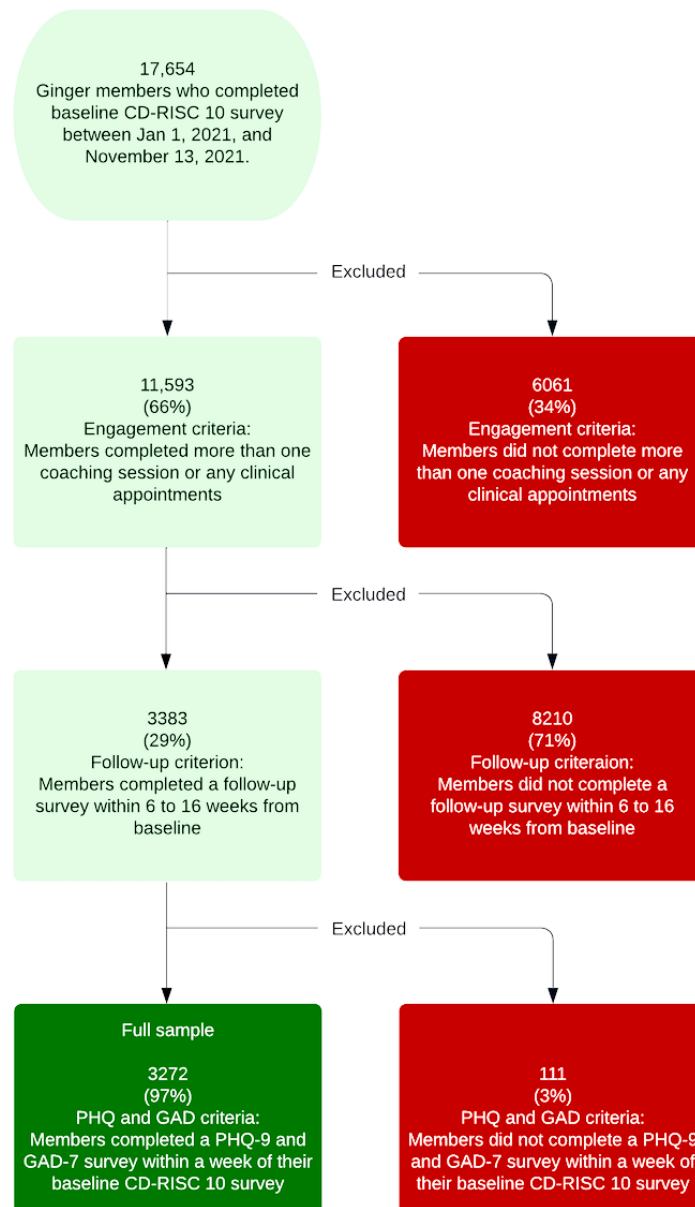

The sample for this study included Ginger members residing in the United States who completed a baseline survey between

January 1, 2021, and November 13, 2021. Members were excluded from the analysis if they satisfied any of the following criteria:

1. Engagement criterion: Members completed more than 1 coaching session or any number of clinical appointments before their baseline resilience scores. The members' baseline survey was sent after their first coaching session.
2. Follow-up criterion: A member did not have a follow-up resilience score between 6 and 16 weeks from baseline.
3. PHQ-9 and GAD-7 criteria: Members without valid PHQ-9 and GAD-7 scores within a week of their baseline resilience score.

There were 17,654 members in the baseline resilience survey, of whom 6061 (34.33%) were excluded for meeting the engagement exclusion criteria. Of the remaining 11,593 participants, 3383 (29.18%) completed a follow-up survey between 6 and 16 weeks from their baseline survey. Of these, 3.28% (111/3383) did not have a valid PHQ-9 or GAD-7 score and were thus excluded. The resulting 3272 members comprised the full sample for this study and were used for our descriptive analysis. Of these 3272 members, 2674 (81.72%) had a low baseline score (CD-RISC-10 score < 30) and comprised the low-resilience subsample for the study [24]. Given that the Ginger intervention is intended to improve resilience among members with low resilience at baseline, this subsample was used to analyze the association between engagement level and changes in resilience. [Figure 2](#) outlines the sample construction process.

Figure 2. Sample flowchart. CD-RISC-10: 10-item Connor-Davidson Resilience Scale; GAD-7: 7-item Generalized Anxiety Disorder; PHQ-9: 9-item Patient Health Questionnaire.

Summary Statistics and Subgroup Analysis

Our descriptive analysis summarized the changes in resilience scores by presenting the mean, median, and SD of these change scores. To analyze differences across subgroups of members, we used a 2-tailed Welch 2-tailed *t* test for differences in mean changes across groups with unequal variances when a category had 2 groups (eg, gender). For categories with more than 2 groups (eg, census regions), we used an *F* test as part of an ANOVA to test for significant differences in mean changes across the groups. Furthermore, to understand whether members with missing data had significantly different outcomes than those without missing data, we performed 2-tailed Welch *t* tests to compare mean changes across the missing and nonmissing groups.

The subgroups of focus in this study were based on baseline resilience, depression, and anxiety symptom scores. In particular, members are grouped by their presence at baseline with low resilience (CD-RISC-10 score < 30) and moderate to severe depression or anxiety (ie, PHQ-9 or GAD-7 score ≥ 10) [26-28].

Descriptive Multivariate Regressions

To understand the association between the demographic and baseline survey responses and changes in resilience, we estimated a multivariate linear ordinary least squares (OLS) regression. The dependent variable for this model was the change in resilience scores. The following categorical independent variables were included in the model: gender, age group, census region, and interacted indicators for whether a member's baseline PHQ-9 or GAD-7 score was ≥ 10. For depression and anxiety at baseline, interacted indicators were

included in the regression model to account for possible differences based on combinations of depression and anxiety clinical status. Given that missing demographic data are highly dependent on whether a member reports such data for any of their members, indicators for a member's parent organization were included as independent variables. In addition, given the relatively wide follow-up period (6-16 weeks), indicator variables for the number of weeks between a member's baseline and follow-up scores were included to account for secular time trends. The coefficients of the indicators for parent organization and weeks between scores have not been reported. For each of these independent variables, a category of members with missing data was included. Homoscedasticity was not assumed, and robust SEs were computed.

Moderator Analysis

To understand the association between engagement with Ginger coaching and changes in resilience scores, we leveraged a moderator model with baseline depression and anxiety clinical status as the moderator and the level of engagement category (eg, self-guided, coaching only, and clinical only) as the independent variable. For our moderator categorization, members with either moderate to severe depression or anxiety at baseline were included in the clinical group (ie, PHQ-9 or GAD-7 score ≥ 10), whereas all other members were included in the subclinical group. Clinical status at baseline was the hypothesized moderator of the association between the level of engagement and changes in resilience. We present the mean changes in resilience according to the clinical status for each engagement level. This analysis was restricted to members with low resilience at baseline (ie, CD-RISC-10 score < 30).

To formally test whether clinical status at baseline was a moderator for engagement, we used a multivariate OLS regression model that included an indicator for engagement level interacting with an indicator of clinical status at baseline.

Ethics Approval

This study represents a secondary analysis of pre-existing deidentified data. The study team did not have access to participants or information to identify participants and did not intend to recontact participants. This study protocol was reviewed by Advarra institutional review board and determined to be exempt from institutional review board oversight, as deidentified secondary data analysis is generally not regarded as human subject research.

Results

Summary Statistics and Subgroup Analysis

Figures 3 and 4 show the distribution of baseline resilience and changes in resilience, respectively, for the full sample of 3272 members. Baseline resilience was centered at 24 out of 40 points (mean 23.83, SD 6.47; median 24). The distribution is similar to a normal distribution; however, there is an excess mass toward the upper limit of the distribution and a relatively long left tail. We did not observe any evidence of scores being concentrated at any particular part of the distribution. Change in resilience was centered at 1 out of 40 points (mean 0.77, SD 5.50; median 1). The distribution was roughly normal, with a small number of outliers at either end of the distribution. All subsequent analyses were conducted including these outliers and excluding members below the fifth percentile for baseline resilience, below the fifth percentile for changes in resilience, and above the fifth percentile for changes in resilience. All the results were robust to excluding these outliers. For the sake of transparency, we presented the results inclusive of outliers.

Table 2 presents the number of members and statistics for members' baseline resilience scores and score changes at follow-up for the overall sample and subgroups based on demographic characteristics and mental health outcomes at baseline.

Figure 3. Distribution of baseline resilience (full sample). N=3272; mean=23.83; SD=6.47; median=24.

Figure 4. Distribution of changes in resilience at follow-up (full sample). N=3272; mean=.77; SD=5.5; median=1.

Table 2. Resilience score characteristics by overall sample and subgroups group.

Characteristics	Participants, n (%)	Resilience score		Resilience change	
		Mean (SD)	<i>P</i> value	Mean (SD)	<i>P</i> value

Demographics

Demographic data were missing for a large portion of the sample because of irregular reporting by members' employers or health plans. Of those without missing demographic data, most

participants were female (1377/1946, 70.76%) and aged ≥35 years (1045/2065, 50.61%). Members were most likely to live in the West (1052/2733, 38.49%) and South (994/2733,

36.37%); however, all 4 census regions were represented in the baseline sample.

The baseline statistics and changes at follow-up are presented in [Table 2](#). Columns 3 to 4 correspond to the baseline scores, and columns 5 to 6 correspond to the changes at follow-up. For each category (gender, age, etc), a *P* value is presented in the category's first row to test whether the difference in mean changes in scores across the category was statistically significant. In the row for groups with missing data, the *P* value corresponds to a 2-tailed *t* test of the difference in mean baseline scores between those with and without missing data.

For categories based on gender and census region, neither the mean baseline resilience score nor the mean changes at follow-up were statistically different across groups (all $P > .05$). The mean baseline resilience score across age groups was significantly different, with older members having higher baseline resilience scores. Differences in the mean change in resilience across age groups were not statistically significant. However, the mean baseline scores for members with missing gender and age data were significantly different from those without missing data. This pattern did not hold for mean changes at follow-up (ie, members with missing demographic data did not have significantly different mean changes at follow-up than those without missing data).

Mental Health Outcomes

The vast majority (2674/3272, 81.72%) of members reported low resilience at baseline (ie, CD-RISC-10 score < 30). On the basis of the PHQ-9 and GAD-7 scores at baseline, 45.14% (1477/3272) of the members screened positive for clinical depression at baseline (PHQ-9 score ≥ 10) and 40.55% (1327/3272) for clinical anxiety at baseline (GAD-7 score ≥ 10). Consistent with prior work [10,11], the differences in mean baseline scores between the clinical and nonclinical groups were statistically significant. Specifically, the mean baseline scores for members who screened positive for either clinical depression (mean 21.71, SD 6.38) or anxiety (mean 21.7, SD 6.44) were significantly lower than for those who screened negative for depression (mean 25.56, SD 6.01) or anxiety (mean 25.28, SD 6.07). Members with subclinical depression and anxiety at baseline demonstrated an average resilience score improvement of 0.86 and 0.82 points, respectively; however, changes in resilience between those with clinical and nonclinical symptom scores was nonsignificant.

By construction, members with low baseline resilience scored below those with high resilience (mean 21.74 vs 33.15). On an

average, members with low resilience at baseline demonstrated an increase of 1.28 points at follow-up. Conversely, members with high resilience at baseline evidenced decreasing scores (-1.54 points on average, SD 5.11) at follow-up. The difference in mean resilience score changes between these groups was significant ($P < .001$).

Engagement Level

The most common engagement level was low engagement, with 30.22% (989/3272) of members meeting the criteria. There were 15.25% (499/3272) of members in the *self-guided* group, 16.62% (544/3272) of members in the *coaching only* group, 20.47% (670/3272) of members in the *clinical only* group, and 17.42% (570/3272) of members in the *hybrid care* group. Both baseline resilience and changes in resilience differed significantly across the groups based on engagement levels (both $P < .001$). Specifically, members in the *coaching only* group had the highest mean baseline resilience scores (mean 24.61, SD 6.36) and the largest mean change in resilience (mean 1.26, SD 5.03). The *hybrid care* group had the lowest mean baseline resilience (mean 22.99, SD 6.18), and the *self-guided* group had the lowest mean change in resilience (mean -0.11, SD 5.64).

[Table 3](#) presents the results of the multivariate OLS regressions predicting changes in resilience at follow-up.

Gender predicted changes in resilience scores when controlling for all baseline characteristics; male participants (mean 1.07, SD 5.56) had significantly larger mean improvements in resilience scores than females (mean 0.67, SD 5.49; coefficient = 0.58; $P = .04$). Although [Table 2](#) shows that the mean change in scores for members with missing gender data was significantly different from those without missing data (not controlling for other variables, importantly, a member's parent organization), [Table 3](#) shows that these members are not associated with significantly different changes in scores. Similarly, age and census region did not predict changes in resilience scores when controlling for other variables.

Baseline resilience score was a strong predictor of changes in resilience scores at follow-up. Specifically, controlling for other variables, for each 1-point increase in baseline resilience score, the follow-up score decreased by 0.28 points, which was statistically significant at the 1% level. Baseline depression and anxiety were also strong predictors of changes at follow-up. Specifically, members without clinical depression or anxiety at baseline had mean resilience improvements of 1.44 points more than members with both clinical depression and anxiety ($P < .001$).

Engagement Level and Moderator Analysis

Figure 5 presents mean changes in resilience by the level of engagement received by a member between their baseline and follow-up scores. These results were restricted to members with low baseline resilience. Multimedia Appendix 1 presents similar results for the full sample. Members with self-guided engagement did not evidence significant improvements in mean resilience scores, based on a 5% significance level. Members with low engagement had significant improvements in resilience scores by approximately 1.0 points, whereas members with meaningful engagement (coaching only, clinical only, or hybrid care) had statistically significant improvements between 1.5 and 2.0 points between baseline and follow-up.

Table 4 reports the corresponding mean changes from a multivariate regression with the same set of independent

variables included in the previous section. Table 4 includes members with low baseline resilience. Multimedia Appendix 2 Table S1 presents regression results for the full sample. Members with self-guided services had the smallest changes among all members. Members with low engagement saw changes in resilience scores that are 0.91 points larger than those who completed self-guided services ($P=.01$), whereas members engaged with coaching only, clinical only, or hybrid care services saw changes that are 1.82, 1.55, and 1.40 points larger than the self-guided group, respectively (all $P<.001$). Given the 95% CIs for the estimated coefficients on the indicators for low engagement, coaching only, clinical only, and hybrid care engagement levels, we cannot reject the null hypothesis at the 5% level that changes in resilience are the same across these levels of engagement.

Figure 6 presents the same mean changes as Figure 5 but separately for subclinical members (ie, GAD-7 and PHQ-9 scores <10) and clinical members (ie, GAD-7 or PHQ-9 scores \geq 10). Figure 6 includes members with low baseline resilience. Multimedia Appendix 3 presents similar results for the full sample. Mean changes in resilience for clinical members were smaller than their subclinical counterparts across all engagement levels, except clinical only, where clinical and subclinical members saw similar improvements. On the basis of the 95% CIs around these means, the differences between clinical and subclinical members' resilience score changes were not statistically different within each engagement level.

Table 5 presents the results from an interacted moderator model to formally test whether subclinical status at baseline is a moderator for the association between engagement level and changes in resilience. Table 5 includes members with low baseline resilience. Multimedia Appendix 2 Table S2 presents regression results for the full sample. Interacted terms refer to the interaction between the multinomial engagement level

variable, which takes 1 of 5 values depending on a member's engagement and an indicator for members who screen negative for both depression and anxiety at baseline. The coefficients of the indicators for engagement level were similar to the model without interactions, indicating that engagement level predicted changes in resilience for clinical members. The coefficient of the indicator for subclinical status interacted with the indicator for self-guided engagement was positive and statistically significant (coefficient=1.39; $P=.02$), indicating that subclinical status is associated with larger improvements in resilience for that engagement level. The coefficients of the regressors interacting engagement level with subclinical status were not significant, indicating that subclinical members' improvements in resilience did not vary by engagement level. This indicates that subclinical members improved by roughly 1.4 points more than their clinical counterparts, regardless of their engagement level, thus rejecting the hypothesis that subclinical status is a moderator of the association between engagement level and changes in resilience.

Discussion

Principal Findings

The purpose of this study was to examine changes in resilience in members seeking on-demand mental health treatment as a function of both baseline symptoms of anxiety and depression, as well as engagement level. At baseline, most members (2674/3272, 81.72%) reported low resilience scores (ie, CD-RISC-10 <30; mean 23.83, SD 6.47), which was well below the benchmarks of the US general population [29]. Overall, members experienced an average improvement in resilience of 0.77 points with a large variance around the mean (SD 5.50). According to the results by engagement level, members in the coaching only group had the largest changes in mean resilience between baseline and follow-up (mean 1.26, SD 5.03), followed by those in the hybrid care group (mean 1.15, SD 5.03). Across all levels of engagement, members who did not present with moderate to severe depression or anxiety at baseline saw larger improvements than their clinical counterparts (a difference of 1.3 points; $P < .001$, when controlling for covariates). Given that the difference between clinical and subclinical members' improvements did not vary significantly across levels of engagement, we conclude that subclinical status is not a moderator for the association of levels of engagement with changes in resilience. That is, although subclinical members improved more than clinical members, the gap between these groups was stable across all levels of engagement.

In subgroup analyses, members with low resilience at baseline, on average, demonstrated a 1.28-point improvement in resilience scores at follow-up. Resilience has been conceptualized as a dynamic process, and engagement with coaching or teletherapy may contribute to improvements in resilience, even in the absence of it being the focus of services [4,20,30]. Conversely, members with high resilience scores at baseline demonstrated a decrease in the CD-RISC-10 at follow-up (mean -1.54, SD 5.11). These findings could be a function of several factors,

including regression to the mean or recalibration or self-discovery by members as part of treatment. Higher scores may leave less room for improvement. Prior research has shown that there is a ceiling effect in being able to detect improvement in individuals who self-report high resilience at baseline [31]. In addition, these findings could be the result of selection or attrition bias. Specifically, those with high resilience who continue to use treatment services may have a higher need for exogenous factors that impact resilience. On the basis of the results of the regression analyses, these findings could also be driven by members who reported high resilience (ie, CD-RISC-10 >30) but also presented with clinical depression or anxiety.

The construct of resilience can vary as a function of time, context, gender, and age [7]. However, our study did not find any statistically significant differences across demographic groups overall (ie, gender and location), with the exception of baseline resilience by age group. Specifically, those in the youngest age group demonstrated significantly lower baseline resilience (mean 22.84, SD 5.94) compared with other age groups. Resilience has been found to be greater in older adults, particularly those with emotional regulation ability and problem-solving ability [32]. When controlling for other baseline variables, our regression analysis found that male participants had a significantly larger mean change in resilience scores than female participants, suggesting that one must consider the socioecological context and treatment process when examining changes in resilience, including gender. Hirani et al [33] suggested that women typically score lower on measures of resilience because existing conceptualizations of resilience are not reflective of how gender roles, social expectations, perceptions, and environmental factors, among others, interact to differentially impact experiences for men and women and, in turn, their response to adversity.

We found that members with symptom scores within the clinical range (ie, PHQ-9 or GAD-7 score ≥ 10) demonstrated

significantly lower baseline resilience scores. When controlling for other baseline characteristics, members without clinical depression or anxiety at baseline had improvements in resilience of 1.4 points more than members with both clinical depression and anxiety. Given the negative association between resilience and clinical symptom severity [10,11], ongoing symptomatology may negatively affect changes in resilience. Moreover, members with clinical symptomatology may focus on symptom management before transitioning to a focus on positive psychological outcomes such as resilience. One may expect that improvements in mental health symptom scores would parallel changes in resilience over the course of treatment. In addition, resilience-focused interventions may serve as a preventive approach to reduce the exacerbation of mental health symptoms that would meet the clinical threshold.

Regarding the association between care engagement level and both baseline and changes in resilience, there were significant differences in the mean baseline resilience and changes in resilience between those with and without meaningful engagement (ie, coaching only, clinical only, or hybrid care vs self-guided or minimal engagement). Specifically, members with self-guided engagement did not show any improvement in resilience, followed by those with minimal engagement having a 0.5-point improvement on average. Those with meaningful engagement (ie, coaching only, clinical only, or hybrid care) demonstrated improvements in resilience between 1.06 and 1.26 points. Within the Ginger context, these findings support the hypothesis that engagement with a human care provider (which is true for members in the coaching only, clinical only, and hybrid care groups) can lead to larger improvements in resilience than engagement with self-guided content alone. This is perhaps not surprising, given the more intensive nature of care delivered by a human provider. Behavioral health coaches, therapists, and psychiatrists tailor their care to the specific needs of a member, whereas it is incumbent on a member to find and engage with content that is applicable to their needs. This does not rule out that resilience-focused content could have an impact on resilience; however, given the wide variety of content available on the Ginger platform, this study was not designed to test whether resilience-specific content was associated with greater or lesser improvements in resilience than the care provided by a trained human provider. These findings are not surprising, as previous research has demonstrated that individuals who had greater engagement in a web-based resilience training program achieved the greatest improvements [10].

Controlling for baseline characteristics, members with subclinical status at baseline had larger improvements in resilience across all engagement levels; however, our moderation analysis found that the association between care engagement and changes in resilience did not significantly differ by baseline subclinical status.

Limitations

From a research perspective, there is much ambiguity in approaching the concept of resilience and no current consensus

on the operational definition of resilience [12]. Moreover, the construct is sometimes assessed as a dynamic process and at other times as a personal trait or an outcome [4,13]. For example, some conceptualize resilience as the ability to *bounce back* from adversity, conflict, and failure [30]. Future research is needed to develop greater conceptual clarity around resilience, particularly as it relates to coaching interventions for depression and anxiety. This definition and conceptualization of resilience should fit the behavioral health coaching context [19]. There are many validated tools to assess resilience, in addition to the one used in this study (eg, the Resilience Scale for Adults, Psychological Capital Questionnaire, and Cognitive Hardiness Scale). Each of these tools reflects differing conceptualizations of resilience; thus, changes in resilience scores over time could capture different processes, with some being more static than others [19].

The construct of resilience can vary as a function of time, context, gender, age, and cultural origin [7]. A large percentage of the participants did not have age (1207/3272, 36.88%) or gender (1326/3272, 40.52%) reported and there was limited access to other demographic information of the study participants. Thus, we were unable to stratify analyses by key demographic factors or examine factors that could affect resiliency and treatment response (eg, marital status, family composition, significant life events, previous mental health treatment, sources of social support, and educational level). These analyses could provide additional insights into those who may best benefit from virtual care and those for whom additional support may be needed. In addition, because there was no comparison group in this retrospective observational study, we were unable to draw any causal inferences regarding the impact of the Ginger on-demand mental health platform.

Another limitation of this study is that baseline surveys for resilience, depression, and anxiety symptoms were conducted at different times. This could have led to measurement errors, as both types of outcomes could evolve before the other is measured. The lag between collecting CD-RISC-10 and PHQ-9 and GAD-7 (the latter 2 were collected at the same time) was intentional in an effort to avoid survey fatigue. Therefore, the results of this study should be interpreted with this lag in mind.

Conclusions

This study examined changes in resilience over time among members of an on-demand virtual mental health system. Overall, members with low baseline resilience and subclinical symptoms of anxiety and depression demonstrated the largest improvement in resilience over time. Even for interventions that did not focus on resilience, members could demonstrate improvements in resilience over the course of treatment with virtual-based treatment for anxiety and depression. Future studies should examine symptom scores of anxiety and depression over time in relation to resilience. In addition, the inclusion of measures such as perceived social support might provide additional insight into treatment, given its association with both mental health and resilience [4,34].

Abstract

Background: Novel interventions should be developed for people who have undergone psychological trauma. In a previous case study, we found that the number of intrusive memories of trauma could be reduced with a novel intervention. The intervention included a brief memory reminder, a visuospatial task and mental rotation, and targeted trauma memory hotspots one at a time in separate sessions.

Objective: This case series (N=3) extended the first case study with 3 new cases to determine whether a similar pattern of beneficial results is observed. We explored whether the brief intervention would result in reduced numbers of intrusive memories and whether it would impact symptoms of posttraumatic stress, depression and anxiety, and general functioning. Acceptability of the intervention was also explored.

Methods: A total of 3 women completed the study: 2 with posttraumatic stress disorder and other comorbidities and 1 with subthreshold posttraumatic stress disorder. The primary outcome was the change in the number of intrusive memories from the baseline phase to the intervention phase and at the 1-month follow-up, with an assessment of the intrusion frequency at 3 months. Participants monitored the number of intrusive memories in a daily diary for 1 week at baseline, for maximum of 6 weeks during the intervention phase and for 1 week at the 1-month and 3-month follow-ups. The intervention was delivered in person or digitally, with guidance from a clinical psychologist. A repeated AB design was used (A was a preintervention baseline phase and B intervention phase). Intrusions were targeted individually, creating repetitions of an AB design.

Results: The total number of intrusive memories was reduced from the baseline to the intervention phase for all participants. The total number for participant 3 (P3) reduced from 38.8 per week during the baseline phase to 18.0 per week in the intervention phase. It was 13 at the 3-month follow-up. The total number for P4 reduced from 10.8 per week at baseline to 4.7 per week in the intervention phase. It was 0 at the 3-month follow-up. The total number for P5 was reduced from 33.7 at baseline to 20.7 per week in the intervention phase. It was 8 at the 3-month follow-up. All participants reported reduction in posttraumatic stress

symptoms in the postintervention phase. Depression and anxiety symptoms reduced in 2 of the 3 participants in the postintervention phase. Acceptability was favorable.

Conclusions: We observed good compliance with the intervention and intrusive memory diary in all 3 cases. The number of intrusive memories was reduced for all participants during the intervention phase and at the 1-month follow-up, with some improvement in other symptoms and functioning. Further research should explore the remote delivery of the intervention and whether nonspecialists can deliver the intervention effectively.

Introduction

Background

Most people experience psychological trauma (eg, accidents or interpersonal violence) in their lives [1,2], and many (up to 37%) develop posttraumatic stress disorder (PTSD) after such experiences [3]. Intrusive memories are the core clinical symptoms of PTSD and are within the intrusion symptoms criterion of PTSD in the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5) [1,4]. Intrusive memories are persistent, unwanted upsetting memories of the traumatic event [1]. In their most extreme form, they can include reliving the traumatic event as if it were happening again (flashbacks). Other intrusion symptoms include dreams or nightmares about the traumatic event and emotional distress or physical reactivity after exposure to reminders of the traumatic event. Other symptom criteria include avoidance of memories or reminders of the trauma, along with negative alterations in cognition and mood [1]. Posttraumatic stress symptoms, even when subthreshold for a diagnosis of PTSD, can be associated with substantial distress, functional impairment, and comorbidity [5].

As noted previously [6], although evidence-based treatments for PTSD exist [7,8], the existing treatment options have some limitations. For example, current treatments require trauma survivors to talk in detail about the traumatic experience, which can be distressing, and many are reluctant to discuss their trauma in depth [9]. Dropout rates during PTSD treatment are high, up to 48% in clinical trials and approximately 18% overall and may be higher outside research trial settings in clinical practice [10-12]. Finally, existing options are time consuming, typically requiring numerous sessions, and there is often a lack of treatment providers specializing in empirically validated treatment of PTSD. Similar to numerous other countries, Iceland has mental health services that lack the capacity to offer treatments when needed by trauma survivors at the scale needed. These limitations to current treatments make the search for additional scalable treatment alternatives imperative.

A novel brief and simple intervention to reduce the number of intrusive memories after trauma has been developed based on cognitive science, as described elsewhere [13,14]. This intervention takes a single-symptom approach (not an entire disorder). The intervention includes a *brief memory reminder* cue for one *specific* intrusive memory of trauma, followed by

a 25-minute Tetris gameplay with mental rotation (ie, actively rotating the blocks in one's mind eye to best make lines; [15]). The intervention was initially examined based on recent memories of trauma [16-18]. It has been further explored for *older memories* of trauma using case studies and case series approaches [6,19-21]. These studies involved in-person delivery, that is, face-to-face sessions guided by a clinical psychologist or researcher.

We adapted the intervention for women in Iceland who experienced intrusive memories of trauma, as reported in a recent case study [6]. Some of the details of this case are now summarized for context and comparison with the 3 new cases presented here. As previously reported, the participant was a woman in her fifties with 4 distinct intrusive memories from a traumatic event that happened in childhood, that is, the intrusive memories were decades old. Each specific memory was targeted in a session (in person) with a clinical psychologist with expertise in trauma. The memory reminder used was to *briefly* bring the visual content of the memory to mind without becoming emotionally overwhelmed by a method agreed with the participant (here, for example, choosing 1 of her 4 specific memories to be targeted using the diary, then thinking about the memory for a few seconds only, and letting the psychologist know when the memory was in their mind). Next, the participant was taught to use mental rotation. She then played Tetris for 25 minutes using mental rotation. She monitored her specific intrusive memories in a daily diary so that the impact of the intervention on a distinct intrusive memory could be easily observed. The total number of intrusive memories decreased from 12.6 per week at baseline to 6.1 per week in the postintervention phase. Furthermore, the number of intrusive memories continued to reduce to only 1 memory per week at the 3-month follow-up. Symptoms of posttraumatic stress and depression and anxiety reduced in the postintervention phase, whereas functioning improved. The participants considered the intervention to be an acceptable way to reduce the number of intrusive memories. The next step in exploring the effects of the intervention involves examining if they extend to other cases of women after trauma and whether remote (rather than in person) delivery is a feasible delivery method given restrictions occurring during the COVID-19 pandemic (eg, isolation) [22].

Objectives

In this case series, we aimed to extend our previous case study to a short case series of trauma-exposed women in Iceland, drawn from an epidemiological study of trauma experienced

by women in Iceland. The intervention sessions took place either in person in a university setting or remotely using a web-based platform. We examined whether the novel intervention approach could reduce the number of intrusive memories of trauma (primary outcome) and whether reductions were maintained at follow-up (1 and 3 months). As before, the brief intervention was guided by a clinical psychologist, targeting one distinct intrusive memory at a time per session. The acceptability of the intervention was also explored along with adaptations in intervention delivery. Again, we explored whether having fewer intrusive traumatic memories would also be associated with improvements in general functioning, posttraumatic stress, and depression and anxiety symptoms (secondary outcomes). The design adopted here can be described as a within-subject *repeated* AB design in which each specific memory is targeted in separate sessions, so that we can consider the effects of an individual intervention session on each specific memory over time [6,20].

As in our previous study [6], we predicted that participants would report fewer intrusive memories (primary outcome) during the intervention phase than in the preceding baseline phase and that the reduction in the number of intrusions would be maintained at the 1-month follow-up in the diary. In addition, we explored a 3-month follow-up using a diary. We expected that the number of targeted intrusive memories would decrease relative to that of nontargeted memories. We also examined whether having fewer intrusive memories would be associated with reductions in symptoms of posttraumatic stress and depression and anxiety and associated with improvements in general functioning (secondary outcomes). Furthermore, we explored the feasibility and acceptability of the intervention, alongside adaptations in intervention delivery format, that is, remote (web-based) delivery.

Methods

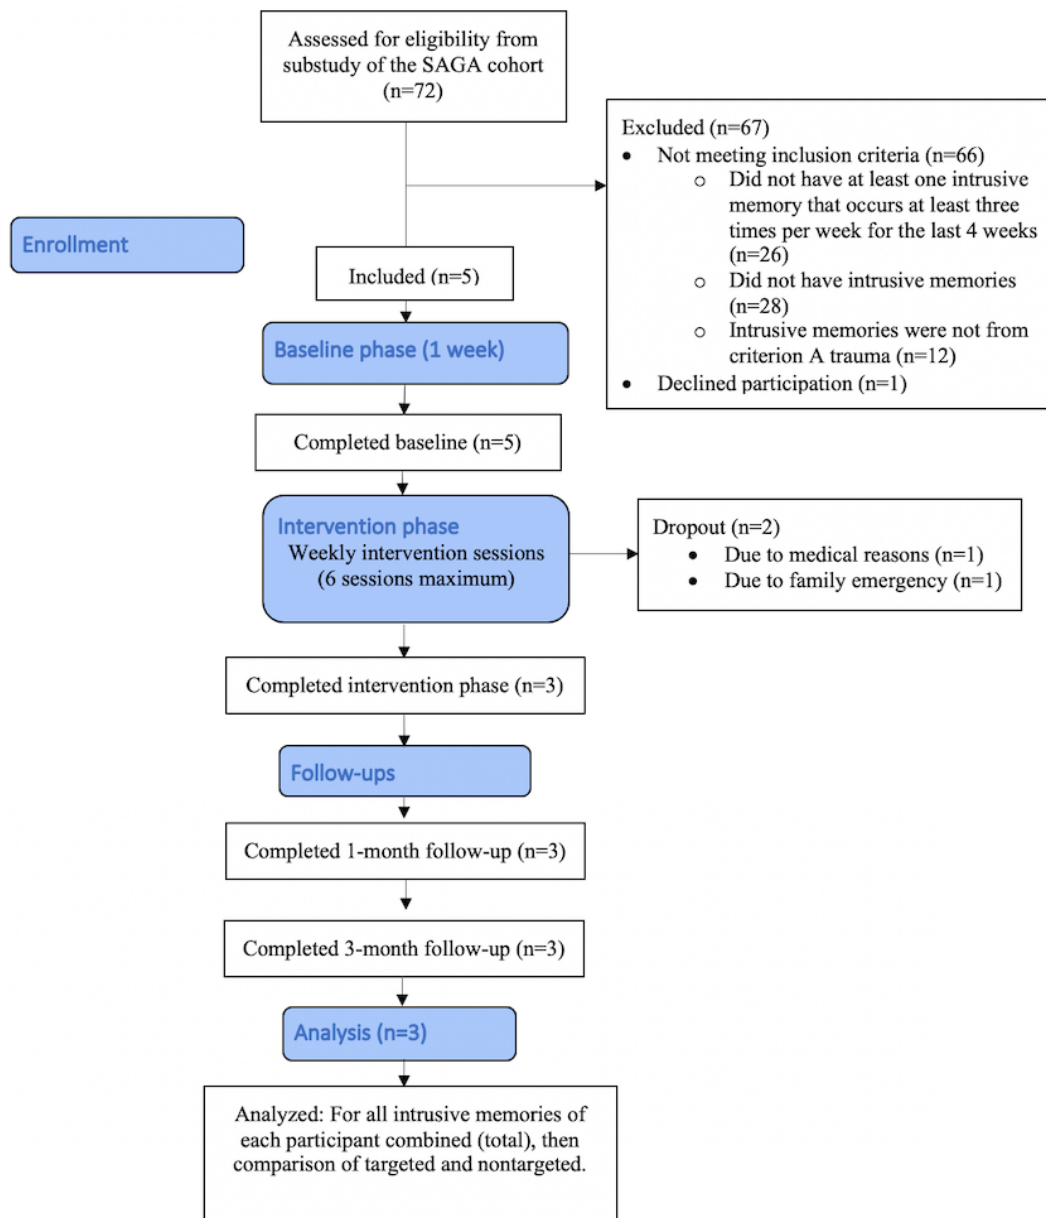

Participants

Participants were drawn from an epidemiological study of trauma experienced by women in Iceland (as in our previous

case study [6]). As described previously [6], women who participated in a substudy of the Stress-And-Gene-Analysis (SAGA) cohort study were screened for eligibility. The SAGA cohort study was a population-based longitudinal cohort study of women in Iceland who completed an extensive questionnaire on trauma history and mental health (baseline data collection was completed on July 1, 2019). The Social Trauma Project substudy compared 2 samples from the SAGA cohort study, with a probable diagnosis of PTSD (ie, Posttraumatic Stress Disorder Checklist-5 [PCL-5] score of ≥ 33 ; see *Measures* section) or not likely PTSD (ie, PCL-5 score in the lowest fifth), using clinical interviews. In all, 2 semistructured interviews were administered in the substudy (ie, the Mini International Neuropsychiatric Interview [MINI], which was also used to assess the exclusion criteria for this study, and the Clinician-Administered PTSD Scale for DSM-5 (CAPS-5; see *Measures* section).

Women who took part in the Social Trauma Project substudy (both likely PTSD group and not likely PTSD group) were screened for the presence of intrusive memories of trauma, as in our previous case study [6]. As before, screening included a short description of intrusive memories (memories that include sensory impressions such as sight, sound, and so on; often pictures or a film clip that pops into the mind's eye; are distressing and occur involuntarily). Next, they were asked questions regarding the presence of this symptom to assess their eligibility for participation in this study ("Do you have intrusive memories of trauma? If yes, how often in the past week have you experienced such memories?" and "How often have you experienced intrusive memories a week in the past four weeks?").

In this study, 72 women from the substudy, who provided their consent to be contacted for further research were assessed for inclusion in this study (Figure 1).

Figure 1. Adapted CONSORT (Consolidated Standards of Reporting Trials) flow diagram for the study. SAGA: Stress-And-Gene-Analysis.

Inclusion criteria were (1) having experienced criterion A trauma as defined by DSM-5 [1] (using criterion A on CAPS-5), (2) having at least one intrusive memory that occurs at least three times per week for the last 4 weeks (How many intrusive memories have you experienced in the last 4 weeks on average?), (3) being able and willing to attend 3 to 8 sessions with the researcher, (4) being able and willing to monitor intrusive memories in daily life, (5) having access to a smartphone, and (f) being able to speak and read study materials in Icelandic. The exclusion criteria were (1) current psychotic disorder (assessed with the MINI), (b) current manic episode (assessed with MINI), and (c) being acutely suicidal (assessed with the MINI).

In all, 5 women who met the inclusion criteria were included, ranging in age from 39 to 66 years (mean 49, SD 11 years). Participants are referred to as P1, P2, P3, P4, and P5. The initial 2 participants recruited did not complete the intervention sessions due to nonsuitability of the study timing in their lives (medical and family issues). Both P1 and P2 were excluded

from the data analyses, although data from the baseline were collected. After P1 and P2 wished to cease their participation, a question was added to the recruitment process asking if the participants foresaw any obstacles to their participation in the study. P1 did not meet any diagnostic criteria for psychological disorders according to the MINI. P2 met the diagnostic criteria for bipolar disorder and reported subthreshold PTSD symptoms.

A total of 3 patients completed the study, 2 (67%) with PTSD and other comorbidities and 1 (33%) with subthreshold PTSD. P3, woman aged ≥ 40 years, met the criteria for major depressive disorder and PTSD. P4, a woman aged ≥ 60 years, did not meet any diagnostic criteria but reported subthreshold PTSD according to the CAPS-5. P5, a woman aged ≥ 50 years, met the diagnostic criteria for major depressive disorder, social anxiety disorder, and PTSD. P3 reported having 10 different intrusive memories of physical violence that occurred in childhood. P4 reported having 3 different intrusive memories from childhood sexual abuse, and P5 reported 6 different intrusive memories from childhood sexual abuse.

Design

The case series used a single-symptom approach, in which each intrusive memory was targeted in different sessions, that is, one at a time [6,19]. Specifically, participants distinguished the content of their different intrusive memories and described them briefly; for example, for a participant who had four distinct intrusions, they may label them as (1) broken glass, (2) man's face, (3) blood on door, and (4) red car (the examples used are fictitious to preserve anonymity). Participants then monitored the occurrence of each distinct intrusion over time.

Thus, the design for each participant was a *repeated AB design* whereby the length of baseline (*A*, before intervention, monitoring only) and intervention (*B*) phases varied for each distinct intrusion, according to which intervention session the intrusive memory was targeted in. Thus, the baseline phases for each distinct intrusive memory were used as control periods in the comparison with the intervention, that is, the number before and number after being targeted.

A daily diary was used to monitor the number of each intrusive memory over time. That is, for 1 week before intervention, then over 6 weeks (maximum) of intervention; then for 1 week at the 1- and 3-month follow-ups. Intrusive memories were targeted individually in up to 6 intervention sessions. These sessions were guided by a clinical psychologist, who was a specialist in trauma-focused cognitive behavior therapy. After the first session, participants were able to self-administer the intervention if they wished for memories that they had already targeted in the session. P3 received 2 repetitions of an AB design, P4 only targeted 1 memory (and thus no repetitions of an AB design), and P5 received 4 repetitions of an AB design.

The primary outcome was the change in the number of intrusive memories per week from baseline to the intervention phase and to the long-term follow-ups (1 and 3 months). Participants further completed secondary outcomes—self-report measures for posttraumatic stress, depression and anxiety symptoms, and functional impairment—at baseline, the last intervention session, and 1- and 3-month follow-ups.

Procedure

Training

Researchers delivering the intervention (KT and JH; both licensed clinical psychologists trained in trauma-focused cognitive behavior therapy) underwent training and received clinical supervision, promoting adequate intervention delivery and protocol adherence. Training involved 2 *in vivo* workshops for 3 days and then again approximately 6 months later for 2 days, delivered by psychologists with expertise in developing the intervention and delivering it in other settings (MK and EAH). The theoretical background and practical aspects of the intervention (eg, how to explain and use the primary outcome measure) were covered in the workshops, as well as role-playing with trainers and feedback until sufficient performance was reached. While data collection was ongoing, the researchers received supervision. Such supervision included weekly supervision meetings, as well as more *in real time* support from a clinical supervisor via telephone directly after participant sessions regarding any case specific adaptations needed (EAH,

MK, and AB). Twice a month, the researchers joined remote (Zoom; Zoom Video Communications) peer-group training meetings with other international researchers about the intervention (convened by EAH and LS).

Baseline Session

A similar procedure was followed as in our previous case study [6]; in the baseline session, the researcher explained the nature of intrusive memories (ie, memories that include sensory impressions such as sight, sound, and so on; are predominantly similar to pictures or a film clip in the mind's eye; and are distressing and occur involuntarily). Participants identified their intrusive memories by giving a brief verbal account of the intrusion's visual content using only a few words. Researchers noted down the image's description on a *hotspots* sheet in a way that the participant could also see it. Participants then labeled each intrusive memory with a symbol (the first memory was labeled *A*, the second memory *B*, etc) and were instructed on how to monitor their frequency each day in a pen-and-paper diary (primary outcome measure). To indicate when a certain memory was experienced, the participants recorded the symbol corresponding to a given memory for each time frame of that day. Each diary was divided into 7 days and each day, into 4 periods (see *Measures* section). The participants also completed baseline questionnaires (secondary outcomes) in the baseline session.

Intervention Sessions

In each intervention session (maximum 6 sessions), the participant chose 1 intrusive memory to target (by looking through their diary entries) and completed the intervention procedure (guided by the researcher). The memory chosen could be the most distressing or frequent or one chosen to be targeted by the participant for other reasons. As in our previous case study [6], the intervention consisted of a brief memory reminder, that is, briefly thinking about the intrusive memory to bring the image to mind without it becoming emotionally overwhelming. Please note that the approach to bringing the memory to mind here differs procedurally from the memory reminder method in the studies by Kessler et al [19] or Kanstrup et al [20]. Participants were told, "To make the game as useful as possible, we first had to make sure the memory was in your mind before using the intervention. So, I want to ask you what do you think would be the best way for you to bring this memory to mind without it becoming emotionally overwhelming?" They then discussed with the researcher options for the best way for them to bring the memory into mind without it emotionally becoming overwhelming. To do this, they were given examples of writing it down briefly and not discussing it with the psychologist, thinking about it briefly again and not talking about it in detail, or finding another method. Here, all participants chose to bring to mind the memory they had chosen to target by briefly thinking about it for a few seconds with their eyes open and telling the psychologist when it had come fully to mind (without talking about it in detail). The psychologist confirmed that the participants were able to picture their memory (ie, see it in their mind's eye) before moving to the instructions about the gameplay.

After the memory reminder procedure, participants were trained on how to use the Tetris game and practiced using mental rotation. They then played Tetris using mental rotation for 25 minutes [15]. For in-person meetings, the Tetris gameplay was delivered with a Nintendo DS 10.1-inch screen, set to *Marathon* mode with the ghost piece off. When an intervention session took place remotely with a video call, Tetris gameplay was performed on the participants' own computer with a shared screen so that the researcher could monitor the gameplay, especially regarding mental rotation. Only one distinct intrusion was targeted for each session. To select which intrusion was targeted, the participant (not the researchers) selected which intrusive memory it was. At the end of the last intervention session, secondary outcome measures were completed again.

Participants were invited to self-administer the intervention for memories already targeted in a session using a mobile version of the Tetris created by Electronic Arts [23]. For example, when the intrusion came to mind involuntarily in daily life, they were told to use a similar procedure as they had learned with the researcher in session.

When the COVID-19 pandemic started (the University of Iceland closed on March 19, 2020), researchers switched to remote (rather than in person) delivery through Kara Connect, which is a General Data Protection Regulation-compliant web-based platform certified by the Icelandic Directorate of Health. The last intervention session for P3 was performed remotely, intervention sessions 2 and onward were performed remotely for P4, and all sessions were remotely delivered for P5. Tetris was played on the web on the participants' computers (ghost piece off and sound set to 0%) with a shared screen so that the researcher could monitor participants' gameplay via Kara Connect, which increased the likelihood of instruction adherence, especially regarding the use of mental rotation.

Follow-up

At both the 1- and 3-month follow-up time points, participants recorded the number of intrusions in their diary daily again for 1 week and completed the secondary outcome measures. Data were entered via laptop into a REDCap (Research Electronic Data Capture; Vanderbilt University) database (REDCap), an encrypted electronic software stored on a secure server [24].

Measures

Eligibility Assessments (Part of the SAGA Cohort Substudy)

Please note that the measures described here have already been described in our previous case study [6] and are repeated here for clarity.

The Clinician-Administered PTSD Scale (CAPS-5) is a 30-item semistructured interview used to assess symptoms of PTSD from an index of trauma and symptom severity (in the past month) according to DSM-5 [1]. Items are scored on a 5-point Likert scale (0=mild or subthreshold; 4=extreme or incapacitating). A symptom rating of 2 (ie, moderate) was the threshold for a possible diagnosis. For each symptom, frequency and intensity were assessed and rated separately. The CAPS-5

has excellent internal consistency (Cronbach $\alpha=.88$), test-retest reliability ($\alpha=.83$), and good convergent validity ($\alpha=.83$) [25]

The MINI for the Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition, assesses Axis I psychiatric disorders according to the Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition, using a structured diagnostic interview. For most diagnoses, the MINI has good sensitivity and specificity [25]. Interrater and test-retest reliability is good, with κ s in the high to very high range (κ s=0.79-1.00) [26].

Primary Outcome Measure

The intrusive memory diary, a pen-and-paper diary similar to that used in Thorarinsdottir et al [6], was adapted from previous experimental and clinical studies [16,20]. It involves daily recording, for 4 time points each day (morning, afternoon, evening, and night) for 1 week. The diary instructions defined the nature of intrusive memories as distressing and involuntary mental images (such as visual images or a film in the mind's eye). Participants were asked not to record voluntary (ie, deliberately recalled) thoughts or involuntary verbal thoughts without sensory content (intrusive verbal thoughts that had an imagery component could be included). Participants monitored the occurrence (or nonoccurrence) of their intrusive memories in the daily diary for 1 week before the intervention (baseline phase), for a maximum of 6 weeks during the intervention phase and then again for 1 week at both the 1- and 3-month follow-ups (note this was a daily diary, see retrospective amendment to clinical trial registration [CTR] NCT04209283). When indicating having an intrusion, participants used the symbol corresponding to that specific memory (eg, A or B as noted earlier), and therefore, it was possible to examine change in frequency (here calculated as the number per week) for each distinct memory individually.

The primary outcome was the change in the number of intrusive memories from the baseline to the intervention phase and at the 1-month follow-up. The original CTR additionally prespecified a measure of intrusive memories at the 3-month follow-up ("Change in the number of intrusive memories of trauma from baseline to 3 month follow-up") but incorrectly stated that the measure was "Questions about the frequency of intrusive memories for the past day or week (for each intrusive memory, to be tallied to arrive at a mean frequency for the memories for the previous day and for the week)," specifically "How often did this memory come up yesterday?" and "How often did this memory come up per day in the past week?" However, this was incorrect, as we had changed this measure at the study start to use the same diary as for the earlier time points (ie, daily diary), that is the "Number of intrusive memories of traumatic event recorded by participants in a diary daily (morning, afternoon, evening, night) per week over the baseline phase and during one week at three month follow-up." The measure has been updated retrospectively in the CTR for this 3-month period and should be interpreted with caution.

Secondary Outcome Measures

PTSD symptoms in the past month were evaluated using the PCL-5, a self-report scale with 20 items. Each symptom is rated on a 5-point Likert scale (0=not at all; 4=extremely), with higher

scores indicating greater severity. The PCL-5 evaluates the severity of PTSD symptoms according to DSM-5 criteria. It has strong internal and test-retest reliability and good convergent and discriminant validity [27]. Criteria for clinical significance are not available for the PCL-5; however, posttreatment scores of ≤ 24 can be interpreted as clinically significant change [28]. The Icelandic version of this measure in the SAGA cohort study had excellent internal consistency ($\alpha=.95$).

Depression symptoms in the past 2 weeks were evaluated using the Patient Health Questionnaire-9 (PHQ-9), a self-report measure with 9 items rated on a 4-point Likert scale (0=not at all; 3=nearly every day) [29]. The PHQ-9 evaluates depression symptoms and their severity and has good internal reliability and test-retest reliability [29]. The Icelandic version of the SAGA cohort study had good internal consistency ($\alpha=.89$). A 5-point change in the total PHQ-9 score was considered clinically significant [30].

Anxiety symptoms in the past 2 weeks were evaluated using the Generalized Anxiety Disorder-7 scale (GAD-7). In this self-report questionnaire, each item is rated on a 4-point Likert scale (0=not at all; 3=nearly every day). The GAD-7 assesses symptoms of general anxiety disorder and its severity and has great internal reliability and good test-retest reliability [31]. In general, the GAD-7 has presumably been useful for screening anxiety disorders [32]. The Icelandic version of the SAGA cohort study had good internal consistency ($\alpha=.90$). A 4-point change on the GAD-7 is considered clinically significant [33].

Functional impairment in the previous week was evaluated using the Sheehan Disability Scale (SDS). This self-report measure has three domains: (1) work or school, (2) social, and (3) family life, assessing functional impairment using a 11-point scale (0=not at all; 10=extremely) [34]. A 3-point change on the SDS scale has been considered indicative of response to treatment [35]. To assess the impairment associated with intrusive memories, scale adjustments were made. The SDS has been found to have good internal and test-retest reliability and good construct validity [34]. The Icelandic version of the SDS has been found to have good internal consistency in clinical groups ($\alpha=.84$) [36].

Self-guided adherence for daily life using the gameplay part of the intervention was rated “How often did you manage to play Tetris after you experienced an intrusive memory?” (11-point scale: 0=not at all; 10=every time).

Feasibility and acceptability ratings for the intervention were assessed with 2 ratings “Would you recommend playing Tetris to a friend?” and “Do you consider gameplay to be an acceptable way to reduce the daily frequency of intrusive memories?” The scores ranged from 0 to 10. Higher scores indicated greater acceptability. Open-ended questions included (1) “How did you feel about playing Tetris after you had an intrusive memory?” and (2) “Did you find the intervention helpful? If yes, how?”

The impact of intrusive memories on concentration, sleep, and stress in the past week was evaluated using 6 self-rated items: a total of 2 items assessed general concentration difficulties and difficulties in concentration due to intrusive memories (11-point scales; higher scores indicated greater difficulties), 1 item

assessed concentration disruption in minutes in the past week, and 2 items assessed the impact of intrusive memories on sleep (11-point scale; higher scores indicated greater sleep disturbance). An item assessed the impact of intrusive memories on stress levels (0=not at all; 10=affected very much).

General impact of intrusive memories was assessed using 2 ratings of intensity and vividness of the intrusions on a 11-point scale (0=not at all; 10=very distressing or vivid).

Intrusion diary adherence item was assessed using the rating “How accurately did you fill out the diary?” (0=not at all; 10=very accurate).

Impact of intrusive memories on daily functioning was evaluated via an open-ended question: “How have the intrusive memories affected your ability to function in your daily life in the past week?” and a self-rated question, “Have the intrusive memories affected your ability to function in your daily life?” (11-point scale, a higher score indicated greater impact).

Data Analysis

Number of Intrusive Memories

The number of intrusive memories of trauma was recorded by participants in the diary daily (morning, afternoon, evening, and night) during the baseline phase and each week during the intervention phase (weeks 1-6) and during 1 week at the 1-month follow-up. The primary outcome was the change in the number of intrusive memories of the trauma. The timeframe was baseline week to the intervention phase (weeks 1-6) and follow-up (1 month). In practice, owing to scheduling reasons, the baseline phase was longer than 1 week, and as anticipated, the number of intervention weeks varied. Therefore, because these periods had different time lengths, the mean number *per week* was calculated for comparability. Missing data were dealt with by excluding these time points from the calculations and using available data (see *Results* section). For example, a participant had a baseline period of 14 days, but data were present for only 6.5 days; thus, the total number of intrusions per week was calculated as $10 \text{ intrusions} / 6.5 \text{ days} \times 7 = 10.8$ intrusive memories per week during baseline.

When examining change over time, the percentage reduction in total intrusions per week was calculated from the baseline phase to the intervention phase to other periods as follows: $1 - (\text{mean number per week during intervention phase} / \text{mean number per week during baseline}) \times 100$. For example, for the same participant there were 4.7 intrusions per week in the intervention phase, which was calculated as $1 - (4.7 / 10.8) \times 100 = 57\%$ reduction in the intervention phase compared with the baseline.

Please note that at the 3 month-follow-up, we did not use the telephone questions on the CTR (NCT04209283) about the frequency of intrusive memories for the past day or week (eg, “How often did this memory come up per day in the past week?”) but instead replaced this with the same 1 week diary used at earlier time points. We noted the use of a diary at 3 months in our ethics submission, but we incorrectly specified it in our CTR and did not update the CTR on this point until the submission of this paper.

Change in the Number of Targeted Intrusive Memories Relative to Nontargeted Memories

We examined the number per week of targeted memories in comparison with nontargeted memories. This was done by calculating the number in the same way as described above for targeted memories (ie, each of targeted memories have different baseline and intervention periods). However, standard baseline and intervention periods were established for nontargeted memories (ie, same length of periods for all nontargeted memories), as they were not targeted by the intervention. The baseline for each nontargeted memory was 1 week (ie, before any memory was targeted), and the intervention phase was determined as the period from when any memory was targeted with the intervention.

Other Symptoms and Functioning

A descriptive approach was used to explore whether clinically meaningful changes were observed in the overall symptoms of posttraumatic stress, depression, anxiety, and functional impairment.

Ethics Approval

This study was approved by the National Bioethics Committee of Iceland (VSNb2017110046/03.01). The participants provided written informed consent before the start of the study. All the sessions followed a written protocol. No adverse events related to the intervention were reported. Participants were asked to briefly consider the visual content of the traumatic memories they selected, which might have resulted in some distress. Previous research has indicated that this intervention approach is well tolerated, including in inpatients with complex PTSD [19]. However, given the early stage of this research, an arrangement was made with an independent clinical psychologist who specializes in trauma for an interview free of charge to the participant and to be referred to a licensed clinical psychologist for treatment if needed. None of the participants had used these services.

Open Science Statement

The study was registered before the start of the study on ClinicalTrials.gov (NCT04209283) on December 24, 2019. The manuscript contains anonymized summary-level data. The study materials may be made available upon reasonable request with an appropriate material transfer agreement with the University of Iceland or Uppsala. We note that delivery of this intervention at present requires prerequisite training and supervision by psychologists with experience of developing it (see *Procedure, Training* section).

Results

Overview

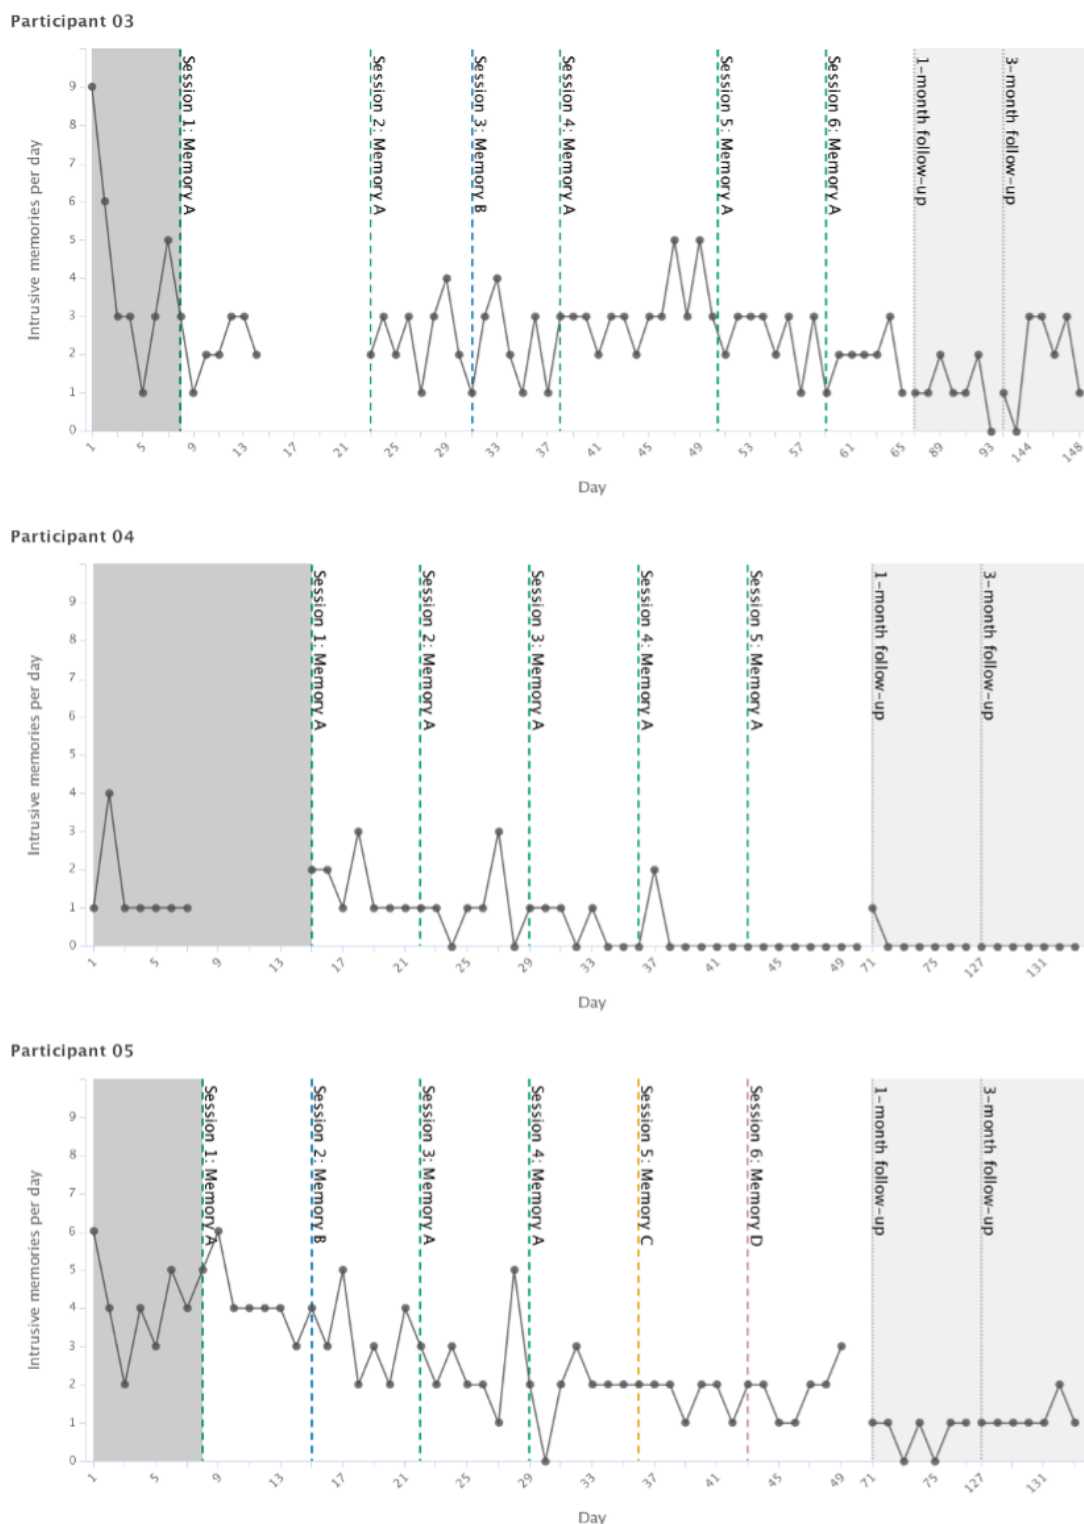

The number of intrusive memories and how many were targeted varied among participants. P3 reported having 10 different intrusive memories of physical violence during childhood. In all, 2 of the intrusions were targeted with the intervention; one of the memories (Memory A) was targeted 5 times and the other (Memory B) was targeted once. P3 monitored the memories quite accurately, but data were missing for days 15 to 22 during the intervention phase. P4 reported having 3 intrusive memories of childhood sexual abuse, of which only 1 (Memory A) was targeted with the intervention 5 times. P4 monitored the memories accurately, and data were missing for half of day 1 and for days 8 to 15 during the baseline phase. P5 reported having 6 intrusive memories of childhood sexual abuse, 4 of which were targeted. One of the memories (Memory A) was targeted 3 times, whereas the others (Memories B, C, and D) were targeted once. P5 accurately monitored their memories with no missing data. No attempts were made to retrieve the missing data. On average, 90% of the diary data were completed for all 3 participants. No data were missing for the secondary outcome measures.

Primary Outcome

Change in the Total Number of Intrusive Memories

The total number of intrusive memories per day throughout all phases for each participant (baseline, intervention, and 1 month) is shown in [Figure 2](#). In addition, as it is on the same measure, the diary used at 3 months is also shown in [Figure 2](#). Diary compliance was good for the outcome phases, with most missing data in the baseline phase. The number of intrusive memories per day fluctuated during the baseline phase for all the participants (N=3). P3 had 38.8 intrusive memories (summed across all 10 distinct intrusive memories) per week during the baseline phase. The number was reduced to 18.0 per week (54% reduction from baseline) during the intervention phase and further reduced to 8 at the 1-month follow-up week (80% reduction from baseline). P4 had 10.8 intrusions (summed across all 3 memories) per week during the baseline phase, and the number reduced to 4.7 per week (57% reduction from baseline) during the intervention phase and was further reduced to 1 (91% reduction from baseline) at the 1-month follow-up week ([Figure 2](#)). P5 had 33.7 intrusive memories (summed across all 6 distinct intrusive memories) per week during the baseline phase, which reduced to 20.7 per week (39% reduction from baseline) during the intervention phase. The number further reduced at the 1-month follow-up to 5 that week (85% reduction from baseline).

Figure 2. Graphs for visual inspection of primary outcome data for each participant (on the y-axis as total number of intrusive memories per day, ie, for all distinct memories combined). Days since study start are shown on the x-axis, which includes baseline (gray), intervention (white), and follow-up periods (light gray). Dashed vertical lines show when each intervention session was administered and which specific traumatic memory was targeted. Memories are labeled in order of when they were targeted (eg, Memory A was targeted in the first intervention session). Dotted vertical lines show the 1-month and 3-month follow-up periods. Gaps in the time series; for example, in the baseline, represent missing data.

We now consider each of the participant graphs shown in Figure 2. Visual inspection of P3 showed that relative to baseline after the first intervention session, the number of intrusions decreased. The number persisted with some fluctuation through the intervention period (days 8-65) and the 1-month and 3-month follow-ups. Visual inspection for P4 showed that relative to

baseline (which included missing data), the number of intrusions remained relatively steady until the fourth intervention session targeting the same memory (day 36), when there was a noticeable drop in occurrence to 0 that was maintained in the last intervention session and 1-month (and 3-month) follow-up. Visual inspection of P5 showed a slight drop in the frequency

of intrusions after the second intervention session with some fluctuations, until intervention session 5 (day 36), where the reduction in frequency became more stable (Figure 2). The frequency decreased even further at the 1-month follow-up (and at 3 months).

Data for the 3-Month Follow-up Diary

P3 had 13 intrusive memories in their diary at the 3-month follow-up (67% reduction from baseline). P4 had 0 intrusive memories (100% reduction from baseline) at the 3-month follow-up, whereas P5 had 8 in the week of the 3-month follow-up (76% reduction from baseline; Figure 2). Patterns in relation to diaries at earlier time points are noted in the *Change in the Total Number of Intrusive Memories* section; however, please see earlier notes about the change in measures at this time point in contrast to the original CTR.

Change in the Number of Targeted Intrusive Memories Relative to Nontargeted Memories

The number of targeted and nontargeted intrusions per week at baseline, in the postintervention phase, and at the 1- and 3-month follow-ups are displayed in Table 1. The mean number of individual targeted memories was 7.6 (SD 4.3) per week in the baseline phase and reduced to 5.8 (SD 2.7) per week in the intervention phase. For individual memories, refer to Table 1. However, for nontargeted intrusions, the baseline rate for individual memories was very low, such as 1 per week. Therefore, these percentages are not included in Table 1. The mean number of nontargeted memories was 2.5 (SD 3.3) per week in the baseline phase and reduced to 0.2 (SD 0.4) memories per week in the intervention phase. The number of targeted memories continued to decrease at the 1-month follow-up week to 2.0 (SD 2.5), and nontargeted memories were reduced to 0 memories. At the 3-month follow-up, the mean number of targeted memories was 3.0 (SD 3.4), and the frequency for nontargeted memories was again 0 that week.

Table 1. Number of intrusive memories per week in the baseline phase, postintervention phase, and at 1 and 3-month follow-ups from baseline phase for each participant (P)^a.

^aTotal intrusions do not equate to the sum of intrusions for each memory here because the length of the baseline and intervention phases differ across each memory and the total. See the *Data analysis* section for further details.

^bSpecific intrusive memories targeted by the intervention.

Secondary Outcomes

Ratings of Adherence to Completing the Diary, General Impact of Intrusive Memories (Vividness and Distress), and Use of the Intervention in Daily Life

Self-reported accuracy for filling out the daily intrusion diaries was high throughout the study period (Table 2). For the general

impact of intrusive memories, the ratings for vividness of the intrusions did not change considerably, although if anything, showed some decline (Table 2). Distress associated with intrusions more clearly diminished during the intervention and follow-up phases for all 3 participants (Table 2). For use of the gameplay intervention in daily life, ratings of the self-guided

adherence to Tetris gameplay after experiencing an intrusive memory between sessions are also shown in [Table 2](#).

Table 2. Ratings for adherence to intrusive memory diary, general impact of intrusive memories, and use of the gameplay intervention in daily life (N=3).

^aHow accurately did you complete the diary? 0=not at all; 10=very accurately.

^bP: participant.

^cMissing data.

^dDuring the last week, how vivid was your intrusive memory? 0=not at all; 10=very vivid.

^eDuring the last week, how distressing were your intrusive memories? 0=not at all; 10=very distressing.

^fHow often did you manage to play Tetris after you experienced an intrusive memory? 0=never; 10=every time.

Feasibility and Acceptability of Using a Computer Gameplay Intervention

Participants were asked if they would recommend the intervention to a friend. P₃ rated this item at 9, P₅ gave it a rating of 8 (highly likely to recommend to a friend), and P₄ rated the item at 3 (unlikely to recommend to a friend). They also rated if they considered gameplay to be an acceptable way to reduce intrusive memories. P₃ and P₅ rated the item at 8 (high acceptability), and P₄ rated it at 3 (low acceptability). When participants were asked to rate how they felt about playing Tetris after having an intrusion, P₃ noted that "It reduced the emotion, sometimes I was able to concentrate and think my way through it. Sometimes I experienced a kind of peace within." P₄ said, "I played so there was no room for other thoughts," and P₅ reported, "Sometimes it's difficult to play for 25 minutes, but I played as many times as I could, for 5 to 25 minutes." When the participants were asked if they found the intervention helpful, P₃ reported, "When I was able to plan ahead while playing the game, my brain could not interrupt me. The emotion that causes distress fades." P₄ said, "Yes, I could not think about

anything else whilst playing," and P₅ reported, "I felt a physical calmness, like the pit in my stomach was shrinking."

Self-report Measures for Posttraumatic Stress, Depression and Anxiety Symptoms, and General Functioning

There was a clear reduction in posttraumatic stress symptoms (PCL-5) from baseline to the postintervention phase, which tended to continue to drop further during follow-up for all 3 participants who completed the intervention, suggesting clinical improvement ([Table 3](#)). Depression symptoms (on the PHQ-9) and anxiety symptoms (on the GAD-7) seemed to follow a similar pattern for 2 (P₃ and P₅) out of the 3 participants, showing reductions in the postintervention phase and during follow-up. Functional impairment (as measured by the SDS) was reduced for the same 2 out of 3 participants (P₃ and P₅) from baseline to the postintervention phase and at the 1-month follow-up, but for P₃, it increased at 3 months. It should be noted that P₄'s ratings for all of these measures were low at baseline ([Table 3](#)).

^dGAD-7: Generalized Anxiety Disorder-7 scale; score range 0 to 21.

^eSDS: Sheehan Disability Scale; score range 0 (unimpaired) to 30 (highly impaired).

^fIn the past week, how much did your intrusive memories disrupt your concentration? 0=not at all disruptive; 10=extremely disruptive.

^gIn the past week, how much difficulty did you have concentrating generally? 0=no concentration difficulty at all; 10=extreme concentration difficulty.

^hWhen you had an intrusive memory, how long did it disrupt your concentration (in minutes) in the past week? 0 (<1 min) to 5 (>60 min).

ⁱDid your intrusive memories interfere with sleep during the night in the past week? 0=not at all; 10=interfered very much.

^jDid you experience any nightmares that interfered with your sleep during the night in the past week? 0=did not experience any nightmares; 10=experienced a lot of nightmares.

^kIn the past week, did your intrusive memories affect how stressed you felt? 0=not at all; 10=affected very much.

^lHave the intrusive memories affected your ability to function in your daily life? 0=not at all; 10=affected very much.

Impact of Intrusive Memories on Concentration, Sleep, Stress, and Daily Functioning

The ratings of the impact of intrusive memories on concentration, stress, and sleep are included in [Table 3](#). P5 reported improved concentration after her intrusions over the course of the intervention and follow-up period. At baseline,

when P5 experienced an intrusive memory, her concentration was disrupted for 10 to 30 minutes on average, and this time was reduced to 1 to 5 minutes at follow-up. P3 reported a slight improvement in concentration with respect to intrusive memories specifically but not in general. Ratings on concentration disruption from intrusive memories were low at baseline for P4 and did not change in the postintervention phase. The effect of

intrusive memories on sleep did not change for P3 or P4, whereas P5 showed some reduction. Nightmares were reduced for both P3 and P5, whereas nightmares were almost nonexistent for P4. The stress levels associated with intrusions were reduced during the intervention and follow-up periods for P3 and P5.

The reported impact of intrusive memories on the ability to function in daily life over the intervention and follow-up periods showed improvement (except for P4, who scored 0 at baseline). At baseline, the participants were asked to respond to an open question about how their intrusive memories impacted their ability to function in daily life. At baseline, P3 said, "When I have this overwhelming feeling, I find it difficult to be around other people, the worst thing is how it affects my ability to stay present for my daughters." P4 said, "I have anger inside me, I constantly think back to how no-one noticed what was done to me." P5 reported, "I get very stressed and anxious; it takes a lot of energy to get out of the emotion..." In the last intervention session, P3 reported, "The intrusions disrupt my concentration," and P5 said, "I experience distress and nightmares." At the 1-month follow-up, P3 disclosed, "When I am under a lot of stress, they disturb me more." P5 reported, "The images no longer have color, cause less disruption and are less frequent." At the 3-month follow-up, P3 said, "I am under a lot of stress and dealing with a certain communication problem which triggers my PTSD and the intrusions" and that "I can now comprehend that this is only a memory, and I don't feel as distressed." P5 reported, "They mostly impact my anxiety" and "I am not a person that easily believes in things, but this intervention works." For all phases following the baseline, P4 reported, "The memories have no impact anymore."

Discussion

Principal Findings

The aim of this case series was to extend our previous case study by evaluating a novel visuospatial intervention designed to reduce the number of intrusive memories of trauma [6,14,37]. The intervention was adapted to the Icelandic setting from previous clinical studies [6,19,20]. The total number of intrusive memories per week (primary outcome) was reduced between 38% and 56% from baseline to the intervention phase, in line with earlier results found by Kessler et al [19] and what we found in our earlier case study [6]. Importantly, we also found in this case series that the frequency of intrusive memories continued to decrease at the 1-month follow-up (the reduction from baseline was approximately 85%). In the diary used at the 3-month follow-up, the reduction from baseline was from 66% to 100%; although this measure replaced another one and was not prespecified, further investigation is required. These results are similar with what we found in the earlier case study [6] in which the frequency also continued to reduce from 52% in the postintervention phase to 76% at the 1-month follow-up and to 92% at the 3-month follow-up. These results indicate that the reduction in the frequency of intrusions might continue rather than rebound, which could be because of the simplicity of self-administered use of the intervention, giving participants the chance to use it independently, if needed. Reductions in distress related to intrusive memories were evident in all

participants. A limitation of the study is that the 3-month diary data must be treated as exploratory, as it was not preregistered in the CTR (though it was in our ethics approval), and further studies should include this.

Not only did the targeted intrusions reduce in this case series but nontargeted intrusions were also reduced in the intervention phase. Although this appears relatively more so than the targeted ones, results must be treated with caution because of the potential floor effects on the low baseline number of nontargeted intrusions rendering comparisons misleading. Kessler et al [19] found that overall, targeted memories were reduced by 64% and nontargeted memories by 11%. The sample of participants in the study by Kessler et al [19] was inpatients with a diagnosis of complex PTSD with a larger number of different memories and baseline symptom rates, whereas the participants in this case series were non-treatment seeking with less symptom severity. Furthermore, targeted memories were reported to be much more distressing than nontargeted ones and may, in some cases, need more time to reduce in frequency (hence, the long-term effect described earlier in this section). It would be clinically interesting in future studies to see if there were links between treating a memory (say from the same trauma) that could generalize to reductions in nontargeted memories of the same episode.

We examined whether a reduction in the number of intrusions would have an impact on the symptoms of posttraumatic stress, depression and anxiety symptoms, and general functioning (secondary outcomes). The general pattern was that posttraumatic stress symptoms were reduced for all participants in the postintervention phase (cutoffs for clinical significance were not available for this measure). Depression and anxiety symptoms were reduced at times suggestive of a clinically significant change for 2 (P3 and P5) of the 3 participants in the postintervention phase [30,33], whereby a 5-point change in the PHQ-9 total score and a 4-point change on the GAD-7 can be considered clinically significant. Symptoms tended to be reduced further at follow-up. It should be noted that P4 had very low levels of distress, depression and anxiety symptoms, and impaired function at baseline. The overall findings are similar to those of our previous case study [6] and the study by Kessler et al [19]. These results provide preliminary evidence that a reduction in the number of intrusions from using this intervention could possibly reduce other symptoms connected to intrusive memories after trauma and improve functioning, with important implications for the quality of life. For the 2 (out of 3) participants who had a reduction in posttraumatic stress symptoms, depression and anxiety, and impairments in concentration and other factors related to intrusive memories, the overall pattern for secondary measures was that some improvements tended to continue for a longer term.

P3 and P5 rated the intervention as acceptable; using Tetris gameplay was an acceptable method to reduce the frequency of their intrusive memories and noted that they would recommend the intervention to a friend. This is similar to what Holmes et al [38] found among refugees and what we found in our earlier case study [6]. However, P4 did not rate the intervention as acceptable and was unlikely to recommend it to a friend, although she noted that it was helpful. It is important

to further develop how the intervention can be made more feasible and acceptable to a range of users.

Two of the participants ceased participation in the study after the baseline phase; the reasons were unrelated to the intervention but were related to scheduling issues in their daily life. However, it is important to determine who is most likely to benefit from the intervention and how to educate individuals about it in a way that increases the chance of people making an informed choice of whether they are able to try it or have the time to take part in a course of treatment. It could also be explored whether the intervention could have an impact on the frequency of intrusive memories with fewer guided intervention sessions, which would reduce the participation load.

Owing to the COVID-19 pandemic, the delivery of the intervention was changed from face to face to remote (eg, web-based communication via Kara Connect). Originally, our plan was to gradually move toward remote delivery in future studies. When the pandemic struck, it forced the change to occur more quickly during the intervention phase of the study. This turned out to be a positive development, as the data did not suggest that the intervention became less effective by being delivered remotely. Recent research by Singh et al [39] indicated that this novel intervention delivered remotely could be an acceptable method to reduce the number of intrusive memories among health care staff. The number of intrusive memories was reduced to 0 at the 5-week follow-up in all 3 participants [39]. Continued remote delivery using a web-based platform instead of face-to-face delivery will be important in future studies [40], thereby removing geographical restraints and making it possible to reach people regardless of where they live or whether they are in quarantine (eg, owing to the COVID-19 pandemic) [22].

Conclusions

Targeting established intrusive memories of trauma that participants had been experiencing for some years (eg, from childhood sexual abuse) with a brief visuospatial intervention, involving a brief memory reminder and Tetris gameplay with mental rotation, seems to show promise for further exploration as a method to reduce their frequency. These early data suggest that the intervention might also result in symptom reduction related to posttraumatic stress, anxiety and depression, and improved functioning; however, further studies are needed. Because of its simplicity, this intervention might be capable of removing common barriers to existing treatment options after trauma, such as for PTSD, including some patients' reluctance to talk about and describe their trauma in detail to a therapist, high costs, and a limited number of qualified therapists [9]. The intervention might even be delivered by nonexperts in evidence-based trauma-focused therapy after brief training, with ongoing supervision—something that should be further examined.

The results of this study are encouraging, and the effects of the intervention on the number of intrusive memories need to be further explored. Continuing to develop this kind of scalable intervention is crucial to reach a large number of people in need of treatment after experiencing trauma. Future research should further examine the feasibility and acceptability of remote delivery by nonexperts in mental health (rather than only qualified clinical psychologists) and whether fewer intervention sessions can yield similar results. Randomized controlled trials are required to assess the intervention.

Abstract

Background: As more people are surviving stroke, there is a growing need for services and programs that support the long-term needs of people living with the effects of stroke. Exercise has many benefits; however, most people with stroke do not have access to specialized exercise programs that meet their needs in their communities. To catalyze the implementation of these programs, our team developed the Stroke Recovery in Motion Implementation Planner, an evidence-informed implementation guide for teams planning a community-based exercise program for people with stroke.

Objective: This study aimed to conduct a user evaluation to elicit user perceptions of the usefulness and acceptability of the Planner to inform revisions.

Methods: This mixed methods study used a concurrent triangulation design. We used purposive sampling to enroll a diverse sample of end users (program managers and coordinators, rehabilitation health partners, and fitness professionals) from three main groups: those who are currently planning a program, those who intend to plan a program in the future, and those who had previously planned a program. Participants reviewed the Planner and completed a questionnaire and interviews to identify positive features, areas of improvement, value, and feasibility. We used descriptive statistics for quantitative data and content analysis for qualitative data. We triangulated the data sources to identify Planner modifications.

Results: A total of 39 people participated in this study. Overall, the feedback was positive, highlighting the value of the Planner's comprehensiveness, tools and templates, and real-world examples. The identified areas for improvement included clarifying the

need for specific steps, refining navigation, and creating more action-oriented content. Most participants reported an increase in knowledge and confidence after reading the Planner and reported that using the resource would improve their planning approach.

Conclusions: We used a rigorous and user-centered process to develop and evaluate the Planner. End users indicated that it is a valuable resource and identified specific changes for improvement. The Planner was subsequently updated and is now publicly available for community planning teams to use in the planning and delivery of evidence-informed, sustainable, community-based exercise programs for people with stroke.

Introduction

Community-Based Exercise Programs for People With Stroke

There are >13 million new cases of stroke per year worldwide [1], and 1 in 4 adults aged >25 years will experience a stroke in their lifetime [2]. Advances in acute stroke treatment have significantly reduced mortality; however, this increased survival rate has led to more people living with chronic stroke-related disabilities. With stroke now being a leading cause of long-term disability [3,4], rehabilitation researchers have identified enhancing brain recovery and promoting long-term healthy behaviors as a priority; this research has generated a wealth of new evidence-based stroke recovery practices [5,6]. However, there is a need to move this evidence into practice and close the gap between best and current stroke rehabilitation practices [7].

Although many individuals see improvements during the acute rehabilitation phase after the stroke, many lose their initial gains when they return to the community, and their disability progresses over time [8]. Evidence suggests that exercise improves motor function [9,10], health-related quality of life [11,12], cognitive function [13,14], and cardiovascular risk factors [15,16] in those with stroke. The implementation of community-based exercise programs, which are defined as “structured, instructional programs of exercise for groups or individuals delivered outside the public health care setting and available in community settings,” are avenues for engaging in lifelong physical activity [17]. Community programs that are focused primarily on walking, such as outdoor walking or mall walking programs, are often difficult to follow for individuals with mobility impairment from stroke, and many traditional fitness facilities and health clubs have accessibility barriers [18] that present additional challenges for people with stroke. Thus, people living with stroke may require adaptations to meet their unique needs and abilities. Stroke exercise programs should incorporate functional tasks that mimic daily activities, be guided by trained personnel knowledgeable in stroke and stroke-related impairments, and be delivered with an appropriate instructor-to-participant ratio [17]. Moreover, pre-exercise medical clearance by a health care provider and further eligibility screening by exercise providers are recommended to ensure the safety and appropriateness of adapted programs [17]. Despite the established benefits of ongoing exercise and evidence-based recommendations in the design and delivery of community-based exercise programs for stroke [17], most people

with stroke do not have access to such community-based exercise programs that provide the specialized support to meet their long-term needs.

In 2016, the Heart and Stroke Foundation’s Canadian Partnership for Stroke Recovery (CPSR) [19] convened its Knowledge Translation Advisory Committee to identify priority areas for knowledge translation. The committee, comprising people with stroke, caregivers, stroke recovery experts, health care providers, policy makers, and knowledge translation and mobilization experts, identified poststroke exercise as a high priority and specifically identified the need to develop sustainable evidence-based and community-based exercise programs for people with stroke. Within Canada and internationally, researchers and clinicians have developed various community-based exercise programs for people with stroke [20-22]; there is now a need to catalyze the implementation of these evidence-based approaches to optimize the health and social benefits for people with stroke.

Development of the Stroke Recovery in Motion Implementation Planner

Building on this momentum, our team aimed to develop an evidence-informed resource [23] to guide community program planners (eg, program managers and coordinators, rehabilitation health partners, fitness professionals, people with stroke, and caregivers) through the process of planning for the successful implementation of community-based exercise programs for people with stroke. We used a multistep process over 3 years to develop the Stroke Recovery in Motion Implementation Planner (hereafter referred to as the “Planner”; [Figure 1](#)).

The well-established Knowledge-to-Action (KTA) cycle, which helps bring the results of health care research into effective changes in practice, provided the overarching framework for the planning process [24-26]. It also builds on the CAN-IMPLEMENT guideline adaptation process, which divides the KTA cycle into 3 substantive planning phases [27,28]. Furthermore, the planning model incorporates elements of the Implementation Roadmap, which is based on the KTA cycle, and further breaks the 3 planning phases into practical steps and activities to facilitate implementation planning and execution [29]. The planning process is underpinned by 6 guiding principles ([Textbox 1](#)).

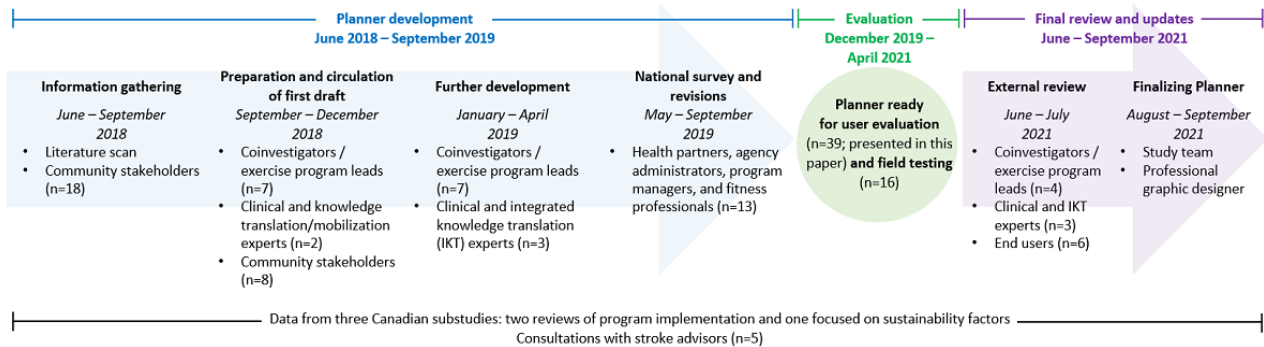

The “Planner development” phase ([Figure 1](#)) informed early decisions related to the content and organization of the Planner.

For example, we identified the type of information and tools that would be most helpful to end users, decided on the use of a generic approach that could be applied to any stroke-specific community-based exercise program, worked to include real-world examples, and reduced technical language. As part of this development process, we conducted a national survey of potential end users across Canada (health partners, agency administrators, program managers, and fitness professionals). Of the 21 invited people, 13 (62%) reviewed the initial Planner prototype and completed a web-based questionnaire on what they liked and what could be improved.

As the prototype was developed, the research team engaged stroke advisors, including members from an existing group of Stroke Community Advisors through the CPSR. These stroke advisors (3 people with stroke and 2 caregivers of an individual with stroke) reviewed the Planner and provided feedback on the content and format to ensure that people with stroke, their families, and caregivers were reflected appropriately.

On completing this rigorous initial Planner development process, the resource was deemed *ready for evaluation (user evaluation and field testing)*.

Figure 1. Summary of the Planner development process and stakeholders involved in the process.

Textbox 1. Implementation Planning Roadmap guiding principles underpinning the Stroke Recovery in Motion Implementation Planner.

Characteristics of the planning approach:

- Intended for exercise programs *situated within the community* and provided by organizations with a mandate for community service (vs provision of individual therapeutic care)
- *Participant centered* (putting people with stroke and caregivers at the center of decisions and seeing them as experts working with service providers to achieve the best outcomes) [30]
- *Participatory and inclusive* (people with stroke and other relevant stakeholders, including health care partners, involved in cocreating the implementation plan)
- *Evidence-informed* (uses effective approaches to planning and implementation and incorporates the use of local data in making decisions)
- Aimed at *strengthening participant health outcomes*
- Focused on *sustaining successful programs*

Study Objectives

The purpose of the study was to conduct a dual-component evaluation of the Planner comprising a user evaluation and field test. The objective of the user evaluation was to elicit user perceptions of the usefulness and acceptability of the Planner and revise the Planner based on the data. The objective of the field test was to describe how teams used the Planner in real-world conditions; describe the effects of using the Planner on participants' implementation planning knowledge, attitudes, and activities; and identify factors influencing Planner use [31].

The goal of this paper (part 1) is to describe the results of the user evaluation and the revisions we subsequently made to the Planner. The results of the field test are reported separately in part 2 [31].

To guide the reporting of this study, we used guidelines for mixed methods studies (GRAMMS [Good Reporting of a Mixed Methods Study]) [32], qualitative studies (COREQ

[Consolidated Criteria for Reporting Qualitative Studies]) [33], and survey studies (CROSS [Checklist for Reporting of Survey Studies]) [34]. These checklists are provided in [Multimedia Appendix 1](#) [32-34].

Methods

Design

The user evaluation was a mixed methods study that used a concurrent triangulation design [35]. We used a convergent model where cross-sectional questionnaire data (closed and open-ended questions) and interview and focus group data were collected and analyzed separately, with the quantitative and qualitative findings merged during the interpretive phase [35]. The quantitative and qualitative data were assigned equal weight. The quantitative data facilitated identifying the “what”; specifically, it helped us identify what aspects of the Planner were most frequently identified as needing modification or removal, which enabled prioritization of essential changes. The

qualitative data helped us understand the “why” of the participant feedback and provided insight into how we could best address participant concerns as we revised the Planner. The qualitative data also provided additional ideas to strengthen the Planner, which may not have been captured in the structured questionnaire. The settings for this study were Canada and Australia.

Sampling and Recruitment

We used purposeful sampling. All staff involved or interested in the planning and delivery of community-based exercise programs for people with stroke were eligible to participate in the user evaluation, including community and municipal program directors, managers and coordinators, regional health authority staff, fitness or exercise professionals, physiotherapists, and other consulting health partners. We identified potential participants through the professional networks of (1) study coinvestigators, many of whom have developed exercise programs; (2) individuals who previously participated in the Planner development process; and (3) participants enrolled in the study (ie, snowball sampling).

In Canada, we aimed to identify participants from different geographical regions with various population densities. Using definitions from Statistics Canada [36], we created a matrix based on geographical region and population size category. As recruitment progressed, we aimed to identify individuals from the remaining undersampled cells (region × urban or rural) in our recruitment matrix. As the Canadian study progressed, we identified an emergent opportunity to include participants from Australia. One of the coinvestigators returned to Tasmania, Australia, where there was a state goal to increase community-based exercise opportunities for people with stroke.

Unlike Canada, Tasmania had low rates of COVID-19 and fewer pandemic restrictions during the study period, and community-based program planning and implementation proceeded as usual. This gave us a unique opportunity to use the professional network of the coinvestigator, who was situated in an urban area of Tasmania, to identify participants who were currently actively engaged in the planning and delivery of community-based exercise programs for people with stroke. We consulted and received approval from our funding partner (CPSR) for the addition of participants from Australia, as there was perceived value in having an international perspective on the Planner.

We started recruiting individuals to prospectively field test the Planner in December 2019. In March 2020, the COVID-19 pandemic caused significant challenges for recruitment as the pandemic resulted in many teams stopping community-based program planning. In May 2020, we amended our protocol to add 2 additional groups (Table 1) to our study with different levels of experience in planning community-based exercise programs for people with stroke, allowing data collection on the Planner within pandemic restrictions. Study enrollment was completed in February 2021. The eligibility criteria for each participant group are presented in Table 1.

All 3 groups participated in the user evaluation component. The *current* program planners engaged in additional study activities as part of the field test component of the evaluation [31].

The study staff contacted potential participants via email with study information. If there was no response, we sent 2 follow-up reminders. Interested participants connected with the study staff to review the requirements, confirm eligibility, obtain informed written consent, and schedule a time for the study activities.

Table 1. Eligibility criteria and data collection methods for the 3 groups of participants in the study.

Participant group	Inclusion criteria	Data collection methods
<i>Current</i> program planners	<ul style="list-style-type: none"> Interested in implementing a community-based exercise program for people with stroke in the next 6 to 12 months Are willing to use the Planner to guide their planning process 	<ul style="list-style-type: none"> Questionnaire Baseline interview or focus group Monitoring interviews End-of-study interview or focus group
<i>Future</i> program planners ^a	<ul style="list-style-type: none"> Have a vested interest in community-based exercise programs for people with stroke and the development of a useful resource for program planning Have not previously launched a community-based exercise program for people with stroke and are not currently considering planning a program 	<ul style="list-style-type: none"> Questionnaire Follow-up interview or focus group
<i>Past</i> program planners ^a	<ul style="list-style-type: none"> Have previously implemented a community-based exercise program for people with stroke in the past 1 to 5 years 	<ul style="list-style-type: none"> Interview or focus group about past experience Questionnaire Follow-up interview or focus group

^aNew participant group added in May 2020.

Data Collection

The study participants completed a web-based questionnaire and a minimum of 1 interview. The order of the activities and the content of the questionnaire and interviews were tailored to each group (Table 1). Participants received an honorarium at a rate of CAD \$25 (US \$19.5) per hour to compensate for their time.

Questionnaire

Each participant completed a web-based questionnaire created in LimeSurvey (LimeSurvey GmbH) [37]. This was a “restricted” questionnaire, meaning that only participants enrolled in the study could complete the questionnaire through a single-use unique URL generated by the research team. There was no validated instrument that met our needs; therefore, the

core study team created a questionnaire that was specific to the Planner content during the development phase (Figure 1). It was tested internally with 2 other research team members for functionality and clarity and then administered to 13 end users who represented people who were currently running programs, had run programs in the past, or were interested stakeholders. We then modified the questionnaire to tailor the content to the 3 participant groups and optimize functionality (eg, adding branching logic). Participants were required to read the Planner before starting the questionnaire. Depending on the group, the questionnaire had between 79 and 89 closed-ended questions, most of which also included open textboxes to expand on their selected answers, and between 11 and 22 open-ended questions. Questions were spread across 7 sections and focused on participants' impressions of the Planner sections and tools (keep, modify, or remove), format and presentation, value of the Planner for community program planners, impact of the Planner on knowledge and confidence, and questions on respondents' demographics and experience. The estimated time to read the Planner and complete the questionnaire was 4 hours. [Multimedia Appendix 2](#) presents the questionnaires administered to the 3 study groups.

Interviews and Focus Groups

Each participant completed at least one interview or focus group. Some participants took part in the study as a team and therefore chose to complete a focus group together. The semistructured interview and focus group guides were developed by the research team and informed through discussions with end users in the Planner development phase. Question topics included overall impressions of the Planner, likes and dislikes regarding the Planner, in-depth discussion about the questionnaire responses, and perceived feasibility of the planning process. In addition, *past* program planners were asked to compare their current experience using the Planner with their previous experience. [Multimedia Appendix 3](#) presents the semistructured interview and focus group guides.

Current program planners completed brief "monitoring" interviews that were scheduled every 1 to 2 months with the research staff. Discussion points during these interviews included how they had been using the Planner, what they liked about using it, and what was missing.

Interviews and focus groups were conducted either in person, through video calls, or by phone, depending on participant preference. Sessions were facilitated by 1 of 4 female researchers (1 master's degree-prepared nurse researcher [J Reszel], 1 PhD-prepared rehabilitation researcher [TN], 1 master's degree-prepared nutrition researcher [KE], and 1 PhD-prepared physiotherapy researcher [MLB]) experienced in qualitative data collection. None of them had pre-existing relationships with the participants. The interviewers worked to create a nonjudgmental environment and welcomed both positive and negative feedback. On average, the interviews and focus groups lasted 44 (range 21-106) minutes, and the monitoring interviews lasted 24 (range 13-39) minutes. The interviews were audio recorded and transcribed verbatim. Altogether, there were 42.9 hours of audio recordings, yielding 912 pages of transcripts. Field notes were made after the interviews and focus groups to

document researcher reflections and observations, including participant interactions.

Data Analysis

Questionnaire

We analyzed the data using descriptive statistics in SPSS (version 27; IBM Corp) [38]. For nominal data (eg, gender and geographical location) and ordinal data (eg, confidence and knowledge), we calculated frequencies and percentages to illustrate the distribution of the responses across categories. For continuous data (eg, years of experience), we calculated measures of central tendency (eg, mean and median) and measures of variability (eg, SD and range). The text in the open-ended questions was analyzed by grouping content into categories to identify what participants liked and disliked about the Planner steps, tools, format, and planning approach. Given the small sample size, no comparisons were made based on role, organization, or geography.

Interviews and Focus Groups

We used conventional content analysis, an inductive approach through which the codes and categories emerged from the data [39]. Each transcript was verified against the audio recording, read as a whole, and then segments of the text were labeled with codes in Microsoft Word. As the analysis progressed, we continued to develop our coding scheme while adding emerging codes. To enhance the trustworthiness of our findings, 40% of the transcripts were coded independently by 2 researchers [40]. The 2 researchers met regularly to compare their coding, resolve discrepancies, and update the coding scheme. All the transcripts were revisited to apply the final version of the coding scheme. We reached inductive thematic saturation [41] as no new codes were added after the 31st transcript (out of 67 transcripts). Data analysis occurred concurrently with data collection, with interview probes evolving to explore emerging themes from the analysis. The team reviewed and discussed field notes, and no notable group dynamics were identified. Although transcripts were not returned to participants, in the final stages of the study, 4 interview participants reviewed and shared their impressions of the revised Planner. This participant check allowed the study team to assess the extent to which we successfully applied the study findings to the Planner.

Triangulation of Quantitative and Qualitative Data to Inform Planner Revisions

On completion of the descriptive analysis of the questionnaire data and coding of the qualitative data, we created a master data summary document that included both data sets to facilitate comparing and contrasting. The core research team met regularly during this triangulation phase (>40 hours of meetings) and discussed the similarities and differences between the qualitative and quantitative data.

The team focused on changes to be made in the Planner, grounded in the study data. First, to identify "essential" changes, we reviewed the questionnaire data by using a threshold of 75%, a commonly used figure to define consensus [42]. Where <75% of respondents (in any of the 3 participant groups) selected the most positive response option for a question (ie, keep as is;

strongly agree or agree), we carefully reviewed the open-ended questionnaire responses and qualitative interview data for that Planner section to determine the required changes. Next, even when consensus was reached (ie, $\geq 75\%$), we still reviewed every comment provided in the questionnaire and interviews to identify other opportunities to enhance the Planner. Decisions regarding whether to address the suggestions were based on (1) alignment with the guiding principles underpinning the Planner ([Textbox 1](#)), (2) alignment with evidence from implementation science (eg, best and promising practices for implementation) and pedagogical science (eg, value of repetition for learning), (3) the significance of the suggestions, and (4) the feasibility of the changes related to formatting and design constraints.

Ethics Approval

We obtained ethics approval from the Ottawa Health Science Network Research Ethics Board (protocol 20190594-01H) and the Tasmania Health and Medical Human Research Ethics

Committee (project ID 23559) for the initial and amended protocols. All participants signed an informed consent form before starting any study activities, and all study procedures were conducted in accordance with privacy and confidentiality requirements.

Results

Overview

We enrolled 39 participants between December 2019 and February 2021. We contacted 27 *current* program planners, of whom 16 (59%) enrolled; 14 *future* program planners, of whom 9 (64%) enrolled; and 43 *past* program planners, of whom 14 (33%) enrolled. The participant demographic data are presented in [Table 2](#), participant roles based on employment setting are presented in [Table 3](#), and the types of data collected during the study are presented in [Table 4](#).

Overall Impressions of the Planner

Overall, feedback on the Planner was positive. All questionnaire participants felt that the Planner addressed the key factors to consider when planning a community-based exercise program for people with stroke; almost all (34/36, 94%) felt it would help them make decisions informed by evidence, and most (29/36, 81%) indicated that it would improve their usual approach to planning:

The Planner is a very good teaching tool and I think you could easily work through that with a team. It would put your team all on the same page and certainly enhance some people's background...I think it would keep the group on the same page and have a good idea of what we're doing, why we're doing it, who we're doing it for, and the benefits. [Fitness or exercise professional, ID38]

Most participants (26/28, 93%) reported that reading the Planner increased their knowledge of how to use evidence to inform decision-making in program planning. Nearly as many participants (24/28, 86%) also reported that reading the Planner increased their confidence in their ability to plan an adapted or specialized fitness program.

Several *past* program planners who had successfully launched and sustained programs commented on the alignment between the Planner and their own experiences and the added benefit of the Planner:

Initially it [the Planner] was overwhelming and I went "oh my gosh I missed every single step"...But then I looked back and I saw that I did most of it, but just not necessarily with as much intention or thought. A lot of it [Planner content] is just kind of intuitive and I did it but it wasn't as thoughtful. [Rehabilitation health professional, ID37]

Nearly all *future* and *past* program planners (19/21, 91%) indicated that they would likely use the Planner for future program planning. Similarly, most questionnaire participants (33/36, 92%) said they would likely recommend it to colleagues to support program planning, described by one participant as follows:

If I knew somebody was thinking of [planning a program], I think a resource such as this would be the exact one they should be using. If I were in a position where I was implementing or supporting or advising on the implementation of a program, I would definitely recommend the use of this resource at the planning stage in order to make sure that everything has been thought about. [Rehabilitation health professional, ID21]

Most questionnaire participants (34/36, 94%) agreed that the Planner could be applied to planning programs that were not stroke specific, including exercise programs for people with other health conditions and nonexercise programs:

I'm working on a different program and some of the concepts in the Planner have helped develop that program. It's not an exercise program but the Planner has helped me think about other things when it comes to programming. [Program manager or coordinator, ID12]

Although the most commonly reported first impression of the Planner was that it was long and possibly overwhelming, over three-quarters (28/36, 78%) of the questionnaire participants agreed that the Planner presented the right amount of information. Most participants indicated that after reading and digesting the information, they saw great value in all the presented materials and could not identify materials that could be removed. Participants recognized the need to strike a balance between making the Planner a comprehensive information source for people with various roles and experience levels while also ensuring that the material was not overly long or onerous to read:

As far as usability, it's trying to walk that fine line between providing too much information and not enough information. Because you get a variety of people, from those who have never implemented a community-based program, to those who are very used to that. Trying to make it work for both those groups, how do you do that as best as possible? That's not an easy answer. [Program manager or coordinator, ID13]

All questionnaire participants (36/36, 100%) agreed that the Planner was well organized, and nearly all agreed that it was easy to read and understand (35/36, 97%) and clearly presented the planning process (33/36, 92%). Participants were split on the format of the Planner: 56% (20/36) of participants would have preferred a web-based version over a paper-based version, and 28% (10/36) did not have a preference. Participants frequently desired access to both a web-based version for easy navigation and tool completion and a paper-based version for hard copy use.

Feedback That Prompted Changes to the Planner

Planner Content

There were several recurring comments related to the Planner content, which cut across sections and tools that resulted in edits. For example, we observed a discordance in some participant settings between the Implementation Planning Roadmap and the “usual way things are done,” reflecting a difference in philosophy. To address this, we made the guiding principles and assumptions explicit at the beginning of the Planner to make the approach and values transparent and explain the rationale for the planning process (Textbox 1). Furthermore, some participants expressed concerns about the theoretical language used in the Planner. We carefully reviewed the Planner and simplified the technical terms wherever possible.

For questions assessing specific Planner sections and tools, 70% (30/43) of the items were deemed “necessary—keep as is” by at least 75% of the questionnaire participants (Multimedia Appendix 4). Key content changes were made to the Planner and tools based on the participant feedback (Table 5).

Table 5. Examples of key content changes made to the Planner and tools.

Identified area of improvement	Changes made to the Planner and tools
Include more information to clarify why specific steps and activities are important to complete during implementation planning (eg, forming planning partnership, decision-making methods, terms of reference, celebrating the launch, and preparing an evaluation plan)	<ul style="list-style-type: none"> • “Why is this important” statements were emphasized throughout the Planner to provide the rationale and potential benefits of completing the step or activity
Include more examples of the real-world solutions used by other teams to address planning challenges; include examples of completed tools from planning teams	<ul style="list-style-type: none"> • Addition of the “Tips and Potholes” section at the end of each planning phase to highlight the success factors and challenges encountered by teams involved in the development and evaluation of the Planner • Added samples of completed tools created by study sites (with permission)
Wherever possible, make content action oriented	<ul style="list-style-type: none"> • Implementation Planning Roadmap revised from 13 steps to 8 steps and Planner guidance edited to provide greater clarity and focus on specific activities and tasks to complete • All tools reviewed and edited to ensure templates provide concrete guidance • Creation of standardized cover sheets for each tool, which include “Why is this important?” and “How to use this tool” statements
Include information on how to consider the specific needs of people with stroke or caregivers as planning partners	<ul style="list-style-type: none"> • New section and tool with specific guidance on factors to consider and questions to ask when engaging people with stroke and caregiver partners in the team • Voices of people with stroke and caregivers were brought to the forefront by inserting verbatim quotes collected during our evaluation throughout the Planner
Include more exercise program–specific information to facilitate program comparisons	<ul style="list-style-type: none"> • Creation of a “program comparison template” with guiding questions for planning teams to assess the history, attributes, and requirements of programs under consideration
Emphasize the importance of considering and addressing program sustainability factors early and often	<ul style="list-style-type: none"> • Sustainability information was included in all 3 phases of the Planner • Creation of a new section on sustainability capacity • Key sustainability factors identified in the end-of-phase checklists and throughout tools
Make tools concise (eg, implementation work plan and assessment of barriers) and avoid duplication between tools (eg, community assessments)	<ul style="list-style-type: none"> • Tool content reorganized, simplified, and relabeled to align more clearly with road map steps • Repetitive content merged and the number of tools reduced • Longer tools split into easy-to-manage sections (eg, identifying barriers to program, program users, and program setting became 3 short work-sheets)

Planner Format and Organization

The participants offered constructive comments on how to optimize the format and organization of the Planner, which resulted in several key changes ([Table 6](#)).

Table 6. Examples of key format and organization changes made to the Planner and tools.

Identified area of improvement	Changes made to the Planner and tools
Simplify structure, balance the workload across the 3 phases, and reorder the sequence of activities and steps	<ul style="list-style-type: none"> • Implementation Planning Roadmap reduced and simplified from 13 steps to 8 steps • Implementation planning process reorganized to better balance planning activities within and across the 3 phases • Phase 2 and 3 steps reordered to make the planning sequence more logical (eg, developing an evaluation plan before launching the exercise program)
Improve navigation; clearly align Planner content with the phases and steps of the road map	<ul style="list-style-type: none"> • Road map figure moved to the start of the Planner as a key navigation element • Planner redesigned to better link content to road map phase and step and orient the reader to the location on the map • Professional graphic design concept developed to facilitate navigation
Facilitate different “starting points” in the Planner to help situate readers from different contexts and starting places in their planning journey	<ul style="list-style-type: none"> • Developed a new “Where do we start?” section in the Planner introduction to outline different planning scenarios and potential starting points and how to use the Planner accordingly • Directed readers to the progress checklists at the end of each phase to assess what work still needs to be completed
Keep the body of the Planner concise for easy reading	<ul style="list-style-type: none"> • Selected content (eg, additional resources and program samples) moved from the body of the Planner to the appendix as “Read more” sections for interested readers
Provide easy access to tools and appendices (additional resources); ensure tools are fillable and editable	<ul style="list-style-type: none"> • Tools summarized at end of each phase with links • PDF and original, editable files provided for easy download • Design concept to include both hard copy and web-based versions of the Planner

Feedback Considered but Existing Approach Maintained

The study participants made some suggestions for Planner modifications that after careful consideration, we decided not to make. Here, we provide 2 key examples with the rationale.

First, some participants requested that to facilitate use, the Planner should be separated into different sections to assign specific content to different roles on the planning team. However, the desire to distinguish between those “planning” and those “delivering” was not aligned with our guiding principle of using a participatory and inclusive approach. Planning teams are most effective when those delivering the program (eg, fitness or exercise professionals) and using the program (eg, people with stroke) are engaged early in the planning process. In addition, team members’ roles may be fluid over time and in different contexts. Therefore, we left the Planner as one document designed for all team members, with the goal of encouraging awareness of and participation in the full planning process. The importance of an integrated planning team was supported by a study participant who regularly delivered community programming:

I was really excited about having “boots on the ground” kind of people [on the planning team].

Because often times you don’t hear about these things until after others have made the decision and you’re like “oh if only you had talked to the people who actually implement these things. It would have been helpful.” Because the concept of policy can often vary greatly from the reality. [Fitness or exercise professional, ID22]

Second, several participants commented on the level of repetition throughout the Planner and recommended making the document shorter and more concise. Although we carefully reviewed the Planner and eliminated unnecessary redundancies, some repetition was left in for pedagogical reasons [43]. Repetition helps readers remember and understand the information. We also recognized that some readers would not read the Planner from start to finish and skip from section to section; therefore, we chose to judiciously repeat essential contextual information throughout the Planner.

Positive Feedback on the Planner Supporting the Existing Approach and Resulting in Enhancements

All the participants provided positive feedback on the Planner and identified features that they found useful. We used this positive feedback to identify content and features to keep in the final version. We also identified ways of expanding upon and further enhancing these features where possible (Table 7).

Table 7. Sections and features of the Planner rated positively with illustrative quotes.

Positive feedback on the Planner	Illustrative quote	Planner decisions made based on positive feedback
Although many participants felt they would not necessarily need to use all Planner tools to implement every exercise program, they generally appreciated the inclusion of various tools, should they be needed.	“Although I feel all [tools] are important to keep, I don’t feel I would use them all each time I would start a program. It would depend on the type of organization I was working with and how much detail would be needed, thus having all the tools available is important.” [Rehabilitation health professional, ID32]	<ul style="list-style-type: none"> Kept a variety of tools to meet the needs and contexts of different planning teams Created cover pages for each tool, further highlighting who, how, when, and why planning teams can use the various tools
Although many participants felt the Planner was long, most participants appreciated the comprehensiveness of the Planner and the breadth of information presented.	“There’s lots of information. You can go lots of places to look at program planning information, but having it all consolidated...is really helpful to me. Because I could get lost and I could go down a significant rabbit hole if I start Googling all this stuff on my own. To forego the Google rabbit hole is very helpful.” [Program manager or coordinator, ID35]	<ul style="list-style-type: none"> Kept the Planner as a comprehensive document to meet the needs of various planning team members New content added based on participant feedback to improve comprehensiveness; for example, more details on developing a planning partnership, how to engage people with stroke and caregiver partners, and web-based program information
Nearly all participants commented positively on the summary checklists at the end of each phase as a clear way of assessing progress and the remaining planning tasks.	“I did like the progress checklists. I really liked that at the end of each section. It was a nice way to kind of bring all of that together and in a practical tool that people can use.” [Rehabilitation health professional, ID33]	<ul style="list-style-type: none"> Kept checklists at the end of each phase Phase checklists were made into a separate tool for easy access and printing Content of checklists was integrated into the implementation work plan
Many participants valued the quotes and field notes from other planning teams to learn about real-world successes and challenges and highlight the importance of the various planning steps.	“I liked the field notes about programs—this is what happened and this is the result...It makes it relatable; when you’re reading all the info, it pulls you back into the practical side of it, which is good.” [Fitness or exercise professional, ID31]	<ul style="list-style-type: none"> New quotes from study participants added throughout the Planner “Tips and Potholes” added to the end of each phase to further highlight study participant experiences and learnings

Planner Revisions

Using the data reported in this study, we revised both the content and format of the Planner. Integrating this feedback involved extensive rewriting and editing by the core study team; contracting the graphic designer; and a final review by 16 coinvestigators, consultants, end users, and stroke advisors. The

largest revision of the Planner involved improving the overall structure and navigation ([Figure 2](#)).

The Stroke Recovery in Motion Implementation Planner is now hosted through March of Dimes Canada, a Canadian nonprofit organization offering services for people with disabilities, including the After Stroke program focused on stroke recovery in the community [44]. The Planner is free and publicly available here [23].

Figure 2. Implementation Planning Roadmap from the Planner summarizing the phases, steps, and activities.

Discussion

Principal Findings

This paper provides a comprehensive description of how the Planner was developed, informing consumers of the rigorous process used. Our mixed methods user evaluation demonstrated that, overall, end users viewed the Planner positively and indicated that it was a useful and valuable resource. They reported that it would improve the planning process and help them make planning decisions informed by evidence. The participants' constructive feedback on the content and organization was used to revise and strengthen the Planner.

Comparison With Prior Work

Our development process aligns with that used by others to develop implementation guides and toolkits in different settings, including selecting an underpinning theory or framework [45-48], searching the academic and gray literature [46-50], consulting experts and consumers [45-48,50], and refining the guide based on end user feedback [45,46,48-50].

Some participants provided feedback consistent with findings reported in the literature; for example, perceptions that the implementation process could be overwhelming or the guide too long [50,51], the need to reduce the number of steps and technical language [51], and the desire for new content and tools to address team needs [48,49,51]. Engaging a wide variety of stakeholders in the development process and using several user-centered design strategies ensured that the final product was grounded in the needs and experiences of those who will use it in real-world settings [52].

The use of an implementation framework can contribute to more systematic planning, delivery, and evaluation of programs, thereby contributing to improved success and sustainability [53]. However, many implementers lack knowledge and

experience in using these frameworks [53], and many third-sector organizations (eg, voluntary and community organizations and social enterprises [54]) face capacity and capability issues when implementing evidence-based interventions [55]. Leeman et al [56] identified "tools" as a strategy for building implementation capacity in community-based practitioners. The Planner is an evidence-informed tool for building the capacity of practitioners (in this context, community program planners, health professionals, fitness professionals, people with stroke, and caregivers) to plan for implementation in an applied and approachable way. Most study participants reported an increase in knowledge and confidence after reading the Planner, including many who reported being experienced program planners.

The Planner is based on the KTA, CAN-IMPLEMENT, and Implementation Roadmap frameworks [24,25,27-29] and is grounded in implementation science and practice. Studies on third-sector organizations in general [55] and on poststroke exercise specifically [57-60] have revealed factors that can influence program implementation, such as equipment, space, time, staffing, training, funding, marketing and recruitment, class capacity, sustainability, program adaptation challenges, organizational culture and priorities, and collaboration between organizations and professionals [55,57-60]. The Planner is specifically designed to help planning teams identify these and other factors unique to their settings, which may impede or support the implementation of community-based exercise programs for people with stroke. The Planner offers strategies, including some recommended by others [55,57], to overcome these barriers. Most importantly, the Planner provides a step-by-step action-oriented road map to plan for successful implementation and sustainability.

Limitations and Strengths

This study has some limitations that should be acknowledged. A key challenge was conducting the study during the COVID-19 pandemic. Although we successfully recruited 39 participants to review the Planner, the data collection period coincided with the pandemic, a time of high personal and professional stress. It is unknown how the stress of the pandemic may have influenced decisions to participate in the evaluation or how it influenced participants' perspectives of the Planner. However, nearly half of the individuals approached to participate did so despite the burden of having to read the comprehensive Planner, complete a lengthy questionnaire, and participate in an interview. This suggests that those who participated were strongly committed to providing input on the Planner and provided thoughtful and detailed feedback.

Although our sample was diverse, we would have liked to have enrolled more fitness professionals, given their role in delivering exercise programs. There may be several reasons for their limited enrollment. For the *current* program planning group, our primary contact was often the manager or coordinator or health partner. These planning leads had sometimes not yet identified the fitness professional team members and were unable to connect the research team with fitness professional study candidates. Furthermore, the pandemic led to the closure of community centers and fitness facilities, and therefore, many fitness professionals were not actively employed during this time. Despite these challenges, approximately 20% (8/39) of the study participants were fitness or exercise professionals who offered rich and thoughtful guidance on how to improve the Planner to meet their needs.

Finally, the user evaluation involved the hard copy version of the Planner, and therefore, the findings may not reflect perceptions of a web-based format. Plans are underway to develop a web-based toolkit based on the hard copy version.

A strength of the study was the mixed methods design, which facilitated assessing perceptions of the Planner through a comprehensive questionnaire with standard questions for all participants, followed by an interview for in-depth discussions on dimensions that were particularly important to each participant. We used multiple types of triangulation, including

methods (questionnaires and interviews), sources (participants from diverse settings), and analysts (coding and interpretation by multiple researchers), all of which enhanced the quality and credibility of our findings [61]. The targeted enrollment of stakeholders from 3 groups (*current*, *future*, and *past*) allowed us to collect data (and reach saturation) from a broad range of stakeholders in various geographical areas with differing experiences in community-based exercise programs for people with stroke. Our rigorous analysis process resulted in every comment being reviewed and carefully considered to inform the Planner revisions and facilitated improved relevance and feasibility of the Planner.

Future Directions

With the Planner finalized and freely and publicly available for use by community teams, we now have the opportunity to further evaluate its ongoing use and impact. Access and use will be monitored through website statistics and consumer inquiries. Working with key stakeholders, we also plan to augment the Planner to better address culturally tailored physical activity programs for racialized populations with stroke, as well as issues related to planning web-based programs for people with stroke. Finally, future work will involve developing products that distill the Planner information into alternate formats to meet diverse learning needs, including video vignettes, infographics, a condensed pocket guide, and a presentation slide deck.

Conclusions

Community-based exercise programs are urgently required to address community reintegration and transitions for people living with the effects of stroke. The Stroke Recovery in Motion Implementation Planner [23] was designed to address the limited use of evidence-informed planning practices for community-based exercise programs for people with stroke. Guided by knowledge from the field of implementation science on how to facilitate implementation, we used a rigorous process to develop and evaluate the Planner. The evaluation revealed that the Planner was perceived to be a valuable resource that may be used to guide interdisciplinary teams in the planning and delivery of evidence-informed, sustainable, community-based exercise programs for people with stroke.

Acknowledgments

The authors would like to thank all the study participants, who generously gave their time amidst the challenges of the COVID-19 pandemic to provide them with detailed and insightful input on the Stroke Recovery in Motion Implementation Planner. IDG is a recipient of a Canadian Institutes of Health Research Foundation grant (grant number 143237). NMS was supported by a Heart and Stroke Foundation Mid-Career Investigator award. AT was supported by a Clinician-Scientist Award (phase II) from the Ontario Heart and Stroke Foundation (P-19-TA-1192). The authors would like to acknowledge Dr Robert Teasell, Dr Sharon Straus, Dr Justin Presseau, Dr Elizabeth Inness, and Dr Elizabeth Lynch, who contributed to the design of the Stroke Recovery in Motion Implementation Planner. The authors would also like to acknowledge Patrick Faucher for the final graphic design of the Planner.

This project has been made possible by Brain Canada Foundation through the Canada Brain Research Fund, with the financial support of Health Canada and the Heart and Stroke Foundation Canadian Partnership for Stroke Recovery. The views expressed herein do not necessarily represent the views of the Minister of Health or the Government of Canada.

Authors' Contributions

IDG and MTB co-led all aspects of the study. IDG, MTB, JvdH, GA MLB, JJE, JLM, MLAN, MP, J Richardson, NMS, and AT contributed to the conceptualization and design of the study. J Reszel, TN, KE, and MLB collected the data; J Reszel, TN, JvdH, and IDG analyzed the questionnaire and interview data; and J Reszel drafted the initial manuscript. All authors participated in the writing of this manuscript and reviewed and approved the final manuscript.

Abstract

Background: The Stroke Recovery in Motion Implementation Planner guides teams through the process of planning for the implementation of community-based exercise programs for people with stroke, in alignment with implementation science frameworks.

Objective: The purpose of this study was to conduct a field test with end users to describe how teams used the Planner in real-world conditions; describe the effects of Planner use on participants' implementation-planning knowledge, attitudes, and activities; and identify factors influencing the use of the Planner.

Methods: This field test study used a longitudinal qualitative design. We recruited teams across Canada who intended to implement a community-based exercise program for people with stroke in the next 6 to 12 months and were willing to use the Planner to guide their work. We completed semistructured interviews at the time of enrollment, monitoring calls every 1 to 2 months, and at the end of the study to learn about implementation-planning work completed and Planner use. The interviews were analyzed using conventional content analysis. Completed Planner steps were plotted onto a timeline for comparison across teams.

Results: We enrolled 12 participants (program managers and coordinators, rehabilitation professionals, and fitness professionals) from 5 planning teams. The teams were enrolled in the study between 4 and 14 months, and we conducted 25 interviews. We observed that the teams worked through the planning process in diverse and nonlinear ways, adapted to their context. All teams

provided examples of how using the Planner changed their implementation-planning knowledge (eg, knowing the steps), attitudes (eg, valuing community engagement), and activities (eg, hosting stakeholder meetings). We identified team, organizational, and broader contextual factors that hindered and facilitated uptake of the Planner. Participants shared valuable *tips from the field* to help future teams optimize use of the Planner.

Conclusions: The Stroke Recovery in Motion Implementation Planner is an adaptable resource that may be used in diverse settings to plan community-based exercise programs for people with stroke. These findings may be informative to others who are developing resources to build the capacity of those working in community-based settings to implement new programs and practices. Future work is needed to monitor the use and understand the effect of using the Planner on exercise program implementation and sustainability.

KEYWORDS

knowledge translation; knowledge mobilization; implementation science; implementation planning; stroke; rehabilitation; capacity building; community-based exercise programs

Introduction

Background

With more people surviving stroke [1], community-based exercise programs [2-4] have emerged to provide safe and effective exercise opportunities for people living with the effects of stroke. Although participating in exercise after stroke conveys broad benefits [5], most people with stroke lack access to these specialized exercise programs in their own communities. As a result of this gap, the Canadian Partnership for Stroke Recovery identified increasing implementation and sustainability of these community-based exercise programs as a knowledge translation priority [6,7].

Planning and implementing new evidence-based practices and programs is a complex process requiring specific knowledge and skills. There is a growing body of literature and resources aimed at building the capacity for implementation science, but there is less support for building the capacity of those actually practicing implementation [8-10]. Practitioners may not have the knowledge or skills to apply implementation science theories or frameworks in their work [11,12], nor do they report feeling confident in their ability to complete key steps in implementation planning, such as conducting a barriers and facilitators assessment [12]. Community organizations in particular may face barriers to implementing evidence-based practices, including a lack of implementation expertise [13].

As a means to build implementation-planning capacity for community-based exercise programs for people with stroke, our team developed an implementation-planning guide, the Stroke Recovery in Motion Implementation Planner (hereafter referred to as the Planner) [14]. The Planner was based on established knowledge translation and implementation frameworks, including the Knowledge-to-Action framework [15], CAN-IMPLEMENT [16,17], and the Implementation Planning Roadmap [18]. The focus of the Planner is on implementation *planning*, which is a process that turns strategy into action through three phases: phase 1: establishing a diverse, interdisciplinary planning team and working together to understand the community population, their needs, potential program options, and the available resources; phase 2: conducting a barriers and drivers assessment and developing

tailored solutions (implementation strategies), as well as building an evaluation plan; and phase 3: launching, monitoring, and maintaining the exercise program.

Many strategies promoting uptake of evidence-based practices focus on modifying the individual or their environment. Throughout the Planner development and evaluation process [7], we prioritized the design of the product itself by applying a user-centered design approach [19]. User-centered design is an iterative process whereby the needs and context of the intended users are central to informing the content and design of the product [19,20]. An example of a user-centered design strategy is to field test the product. Through prolonged engagement with end users who provide feedback on their experience with the product, field testing facilitates an understanding of how the product is being applied in real-world settings [21]. Such an exploratory approach can help to challenge the prototype and subsequently lead to meaningful changes [22], thereby creating a product that is more functional, acceptable, and effective. Upon completing a prototype of the Planner [7], we conducted a field test study with end users to explore how the Planner was used and adapted in diverse settings.

Objectives

This study was part of a larger research program that developed and evaluated the Planner, which included a cross-sectional user evaluation of the Planner by diverse stakeholders (reported elsewhere [7]) and the field test reported here. The objectives of the field test were to (1) describe how teams used the Planner in real-world conditions; (2) describe the effects of using the Planner on participants' implementation-planning knowledge, attitudes, and activities; and (3) identify factors influencing use of the Planner.

Methods

Design

This field test study used a longitudinal qualitative design [23,24], which facilitated in-depth discussions about use and impressions of the Planner over time. We used the Consolidated Criteria for Reporting Qualitative Research (COREQ) checklist

[25] to inform the reporting of this study ([Multimedia Appendix 1](#)).

Participants and Setting

Using the professional networks of the study team, we identified primary contacts (ie, team leads tasked with program planning) at Canadian community organizations that were intending to implement a community-based exercise program for people with stroke in the next 6 to 12 months (*current* planners) and willing to use the Planner to guide their ongoing planning. We welcomed representatives from several occupations, including program managers and coordinators, health partners (eg, physiotherapists and occupational therapists), and fitness professionals. As the purpose of this study was to observe how teams used the Planner to guide planning processes, teams were required to be at an early stage in their planning. A research team member (J Reszel) contacted potential participants by email with study information, with up to two reminders. If the contact was interested in participating, a memorandum of understanding was signed between the participating organization and our research institution. We asked the contact person to nominate other planning team members (ie, snowball sampling) whom we could invite to take part in the study. All participants signed an individual consent form. Participants did not receive any incentives to test the Planner or fund their program initiatives; however, participants were provided an honorarium to compensate them for time spent on study activities.

Initially, we aimed to enroll 9 to 12 teams to field test the Planner; however, the onset of the COVID-19 pandemic resulted in significant disruptions to community-based program planning and the closure of many facilities. This recruitment challenge caused us to lower our enrollment to 5 teams prepared to use the Planner to guide program planning during this period.

Data Collection

The field test teams participated in 3 core data collection points. After reading the Planner and completing a questionnaire [7], all participants completed a *baseline* interview or focus group to discuss their initial impressions of the planning process. Next, research staff conducted *monitoring interviews* (ideally every 1-2 months) with a primary contact for each team to discuss planning work completed, Planner sections and tools used, and feedback on what was helpful and what was not. Each monitoring call started with the researcher summarizing the last call, allowing the participants to make corrections. Finally, primary contacts completed an *end-of-study* interview. At this time (February-March 2021), each team was at a different point in their planning process, but this end-of-study interview provided an opportunity for participants to reflect on their overall experience of using the Planner to date and share final feedback. The primary contact was the team member who was taking the lead in the planning process and had the most direct experience working through all Planner steps and activities. We anticipated that this person could therefore provide the richest updates on the team's work throughout the process.

In keeping with a user-centered design approach, the baseline, monitoring, and end-of-study interview guides ([Multimedia Appendix 2](#)) focused on the users' needs and their experiences

and contexts as they engaged with the Planner [19,20]. The discussions were all conducted by video call or phone. The interviews were audio recorded, and the baseline and end-of-study interviews were transcribed verbatim. Field notes were written after the discussions to document observations about the setting and participants' (including interactions between participants in focus groups) and interviewer's reflections. All data collection was conducted by 1 cisgender female research coordinator (J Reszel), a master's-prepared registered nurse experienced in qualitative research. At the start of the study, the researcher had no relationship with participants. Extensive notes were taken during each monitoring call and later verified and enhanced using the audio recording to complete the call log ([Multimedia Appendix 3](#)). In addition, we asked each team to share completed planning tools to understand how teams used and adapted the Planner material.

Data Analysis

Applying a cross-sectional approach [23], we used conventional content analysis [26] to inductively code all transcripts and monitoring-interview notes as they became available. This allowed us to identify what the teams were currently working on and their perceptions of the Planner at that time. This approach facilitated probing and follow-up in the subsequent interviews with the participant. All interviews were coded in Microsoft Word by 1 research staff member (J Reszel), with 20% coded independently by a second research team member (TN) as a form of analyst triangulation to enhance credibility [27,28]. Any differences in coding were discussed and resolved by the 2 coders. As analysis progressed, coding and findings were discussed at regularly scheduled meetings with the core research team. We also discussed the field notes for additional context on the setting and team dynamics, such as the extent to which different participants contributed to the discussion and which questions they answered versus those they did not answer. As codes emerged from the transcripts and notes, and the coding scheme was developed, we grouped similar codes into broader categories, including contextual information, Planner feedback, the planning process, and how the Planner is used. We also analyzed the data temporally [23] to identify changes in perceptions over time and to create timelines to map if and when teams completed the various Planner activities. The completed Planner tools were reviewed by the research team and documented as completed or not. When reviewing the tools, the researchers assessed whether the teams made any adaptations to the tools and whether they were used as intended. Exemplary completed tools were identified to be included in the Planner, with permission.

Ethics Approval

We received ethics approval for this study from the Ottawa Health Science Research Ethics Board (20190594-01H). Before starting any study procedure, each participant signed a consent form.

Results

Demographic and Contextual Information on Planning Teams

We enrolled 5 planning teams in Canada. The teams were

diverse in their geography and composition. There were teams representing the west coast to east coast of Canada in urban and rural settings. The teams ranged from a single person leading all aspects of planning to interdisciplinary teams sharing the planning work (Table 1).

Table 1. Attributes of teams taking part in the field test study.

	Team 1	Team 2	Team 3	Team 4	Team 5
Planning team information					
Geographic area of planning team	Western Canada	Western Canada	Atlantic Canada	Central Canada	Central Canada
Number of people on core planning team identified at the time of study	4	1	6	4	2
Occupations of planning team members	Physiotherapist; fitness coordinator; fitness professionals	Program coordinator	Physiotherapist; program coordinator; fitness professional; person with stroke	Physiotherapist; occupational therapist; rehabilitation manager	Program coordinators
Multiorganization collaboration?	Yes (municipality and private physiotherapy practice)	No (municipality only)	Yes (municipality and health authority)	Initially: no (primary care center only); during study: yes (municipality and primary care center)	No (community-based nonprofit only)
Types of partners participating ^a in planning process	Brain injury group; municipality; physiotherapy clients; stroke club	Local university; health authority; local stroke association	Health authority; inpatient rehabilitation services; outpatient rehabilitation services; municipality	Allied health partners in clinic; clinic clients; municipality	Internal staff; past program participants
Program information					
Planned geographic area for program implementation	City	City	City	City	National (web-based)
Population density of community where program would be offered	Rural or mostly rural	Urban or mostly urban	Urban or mostly urban	Rural or mostly rural	Combination of urban and rural
Size of community where program would be offered	10,000 to 24,999	>50,000	25,000 to 50,000	5000 to 9999	National
Type of organization planning to offer program	Municipality	Municipality	Municipality	Family health team	Web-based

^aRanging from consultation to collaboration, as per the International Association for Public Participation (IAP2) Spectrum of Public Participation [29].

Team Composition

To provide context for interpreting the findings, we provide a brief description of each planning team before describing the study participants.

Team 1 included a physiotherapist in private practice and a program coordinator from the municipality who had previously collaborated to plan and implement other adapted fitness programs in the community. On the basis of their previously successful partnership and the perceived need for stroke-specific community programs, they decided to plan a new program together.

Team 2 comprised a single program coordinator from the municipality who was working within its usual organizational model whereby an individual coordinator is largely responsible for all planning activities. The municipality had an existing suite

of adapted fitness programs and wished to explore adding a stroke-specific exercise class to its model.

Team 3 was led by a physiotherapist who had previously piloted a stroke-specific exercise program in a long-term care setting. The municipality had expressed interest in collaborating with the health authority on an adapted exercise program. The physiotherapist subsequently formed a new partnership with the municipality to begin planning a stroke-specific exercise program in the community.

Team 4 comprised rehabilitation health professionals and a manager from a primary care clinic affiliated with the local hospital. The team members had experience planning and implementing other group programs tailored to various health conditions within their primary care setting and were considering offering a stroke-specific program in their clinic.

Team 5 included 2 program coordinators from a nonprofit organization planning a web-based adapted exercise program. Before the COVID-19 pandemic, the program was offered in person. The onset of the pandemic provided an opportunity to explore whether the program could transition to a new web-based format reaching a broader geographical area.

Field Test Study Participants and Data Collected

From these 5 teams, we enrolled 12 participants. Between February 2020 and March 2021, we conducted 25 interviews and focus groups with the 12 participants: the 7 baseline sessions lasted an average of 57 (range 40-75) minutes, the 13 monitoring calls lasted an average of 27 (range 18-35) minutes, and the 5 end-of-study sessions lasted an average of 44 (range 31-53) minutes. On average, the planning teams were followed by the research team for 9.6 (range 4-14) months (Table 2).

Table 2. Data collection approaches and description of study participants (N=12).

^aWe lost contact with team 1 between month 2 and month 11, both inclusive, and no data were collected during this time.

^bFG: focus group.

^cA participant from team 1 did not complete the questionnaire that included these demographic questions.

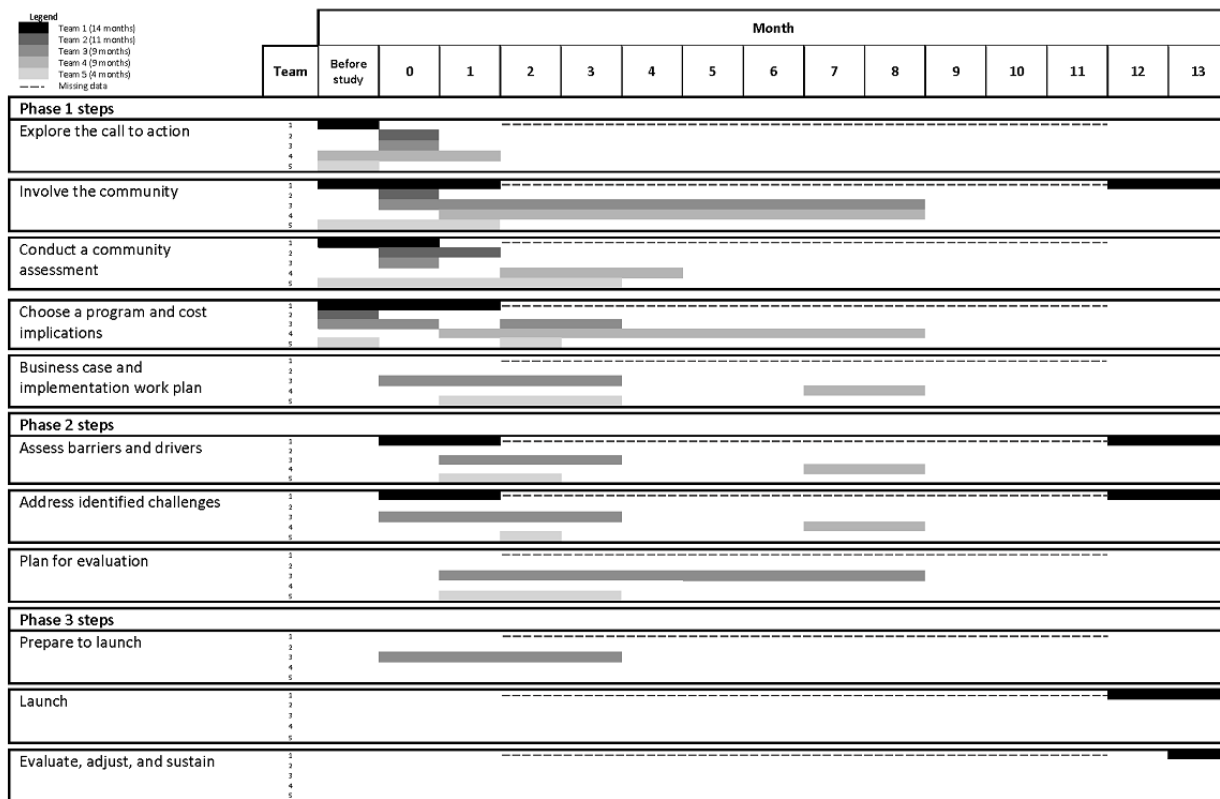

How Teams Used the Planner in Real-world Conditions

Overview

The 5 teams varied in how they used the Planner, ranging from methodically working through each step to using the Planner more as a reference guide when needed. Figure 1 provides a visual summary of the phases and steps the teams completed during the study period. Most of their planning progress focused on phase 1. Teams took from 1 to ≥8 months to focus on the

early planning activities. Because of the impact of the pandemic (eg, facility closures and suspended programs), the teams completed fewer activities beyond phase 1. Despite these challenges, of the 5 teams, 4 (80%) were able to complete at least one step in phase 2 or phase 3. Instead of moving through the steps sequentially, the teams tended to use a nonlinear approach to address many tasks concurrently and revisited some steps multiple times. The results are organized by implementation-planning phase and step.

Figure 1. Summary of Planner phases and steps completed by field test teams during the study period.

Explore the Call to Action

The call to action was one of the first steps completed by each team. Although most (4/5, 80%) of the teams had previously been considering the value of planning a stroke-specific exercise program in their community, these teams described how participating in the field test prompted them to formally start their planning process.

Involve the Community

We observed that involving the community was the step that required the greatest amount of time (Figure 1), reflecting the need to engage community partners throughout the entire planning process. All teams had an intensive focus on involving the community at the front end as they identified key partners to join the planning team and relevant stakeholders to consult. Participants from all teams reported that using the Planner prompted them to consider alternative ways of identifying and engaging people or groups. For example, team 2 reconsidered their usual way of working independently within their own organization and began reaching out to stroke-related organizations in the community. Team 3 decided to add representatives from key referral sources as well as a person living with stroke and their caregiver to the planning team and explored the need for developing a formal partnership agreement. Involving these different partners informed referral pathways and how to accommodate participant needs. This team used the Planner itself as a tool to structure team meetings and engage team members:

I think it (the Planner) was quite good actually because it just allowed me to know where to focus

and make some plans around how those meetings were going to look. It was really very helpful for meeting planning to focus from a team perspective. I think if it was just myself doing it I might have been able to manage without the Planner, but when you're trying to actually organize your thoughts and articulate them to other people I think the Planner was really helpful in doing that. [Physiotherapist, team 3, ID6, end of study]

Conduct a Community Assessment

The teams described several methods to conduct their community assessments, which were completed at various time points in the planning process. For example, based on an early assessment of services in the community and the number of people living with stroke, team 1 decided to move forward with planning and implementing a program. However, after launching the program and having lower than anticipated enrollment, this team appreciated the importance of taking the time to complete a detailed community needs assessment upfront:

Make sure there's a need for it in your community...do that research before you start so that you're not launching a program that you get only three registrants for, and you don't know if you can run it after all that work. [Physiotherapist, team 1, ID1, end of study]

At the start of the planning process, team 4 felt confident that they would offer a future program in their clinic setting. However, as they took inventory of the programs currently offered, they realized that their initial idea was similar to an

existing program at their organization. As a result, this team revisited their initial program idea and formed a new partnership with the municipal recreation center to address the service gap they identified. This marked the first time that their organization established a formal partnership with an external organization to plan (and potentially implement) a program in their community.

Team 5 had started their community assessment before enrolling in the study and described administering a survey to potential participants and staff. This allowed them to collect information on community needs, interests, and preferences. They also saw these community surveys as a form of *preadvertising* for their future program and used the survey results in drafting their business case.

Choose a Program and Cost Implications

Of the 5 teams, 4 (80%) had selected an exercise program before joining the study. These decisions were made based on team members' knowledge of, and experiences with, existing programs. Team 4 had not selected a program and undertook a comprehensive process to explore the various options, including reading the content in the Planner, exploring program websites and resources, and connecting with exercise program contacts and other teams who had previously used the programs.

Although many (3/5, 60%) of the teams reported that their organization had a set participant enrollment fee, they indicated that the budget planning tool in the Planner helped them to assess what items and resources they had available to them and what unique start-up and ongoing costs they needed to budget for a program designed specifically for people with stroke.

Business Case and Implementation Work Plan

In total, 40% (2/5) of the teams completed a business case. Team 3 used the business case template in the Planner and adapted it to suit the needs of their team. Team 5 was required to use their organization's template to prepare a business case; however, the team was able to use information from the Planner document and steps completed to produce a comprehensive business case in alignment with their usual organizational processes.

The Planner included an implementation work plan template, although only team 4 used it. The reasons given by other teams for not using the implementation work plan included having another preferred method for tracking planning work or not being able to prepare a detailed work plan at this time because of the uncertainty and limitations imposed by the COVID-19-related restrictions.

Assess Barriers and Drivers and Address Identified Challenges

Of the 5 teams, 4 (80%) assessed barriers and drivers to program implementation and started planning for how challenges could be addressed. Although this step is described in phase 2, exploring potential barriers tended to occur early and simultaneously with phase 1 activities. In total, 60% (3/5) of the teams engaged with their community planning partners to explore potential challenges, which often resulted in the formation of practical solutions. For example, team 1 held a stakeholder meeting with representatives from local stroke and

brain injury groups where they identified concerns related to the location, program time, transportation, and costs. Team 3 had a meeting with their stroke and caregiver planning partners and learned about potential barriers related to the accessibility of the building. This led to changes in their program screening form and development of an information sheet for future participants.

Team 1 proceeded to launch a program but revisited their barriers assessment when they encountered enrollment issues. To understand the factors discouraging people from participating, they continued working with their community partners to identify potential issues with referral pathways, reassess barriers to participation, and consider how these could be addressed in future program sessions.

Prepare to Launch and Launch the Program

Because of the pandemic, only 40% (2/5) of the teams worked on this step. Team 3 aimed to complete as much planning work as possible, including launch-readiness activities, with the intention of launching the program when pandemic conditions allowed. However, this site was never able to launch because of ongoing COVID-19-related restrictions. After approximately one year, team 1 was able to launch a session of their exercise program.

Develop Evaluation Plan, Monitor Delivery and Use, and Assess Program and Participant Outcomes

Although unable to launch, 40% (2/5) of the teams did spend time exploring how they could evaluate their program. Team 3 prepared a participant satisfaction survey, selected client-centered before-and-after measures, and collaborated with their internal evaluation team to identify available data that could be pulled to show broader system impact. Team 5 reviewed the program-fidelity templates included in the Planner and subsequently selected and adapted one of the tools for use in their setting.

Although at baseline team 1 indicated that the Planner made them think about the importance of developing a comprehensive monitoring plan that includes before-and-after participant outcome measures, at the end of the study the participants explained that they had overlooked this, and it was never implemented. However, they planned to administer a participant satisfaction survey.

Evaluate, Adjust, and Sustain

Because of pandemic-related restrictions and delays, none of the enrolled field test teams evaluated, made adjustments, or focused on sustainment during the study period.

Effects of Using the Planner

Participants' Changing Perceptions of the Planner Itself

As some participants used the Planner, their impressions of the proposed process changed. For example, upon first reviewing the Planner, at least one member from every team expressed concerns about the length and potential complexity of the planning process and tools. However, after gradually working through the planning process over several months during field testing, the participants' feedback became more positive as they

saw the benefits. The following quotes illustrate how a program coordinator changed their views over time as they used the Planner:

There is too much information. It's overwhelming to read, review, use, and implement. [Program coordinator, team 5, ID12, baseline]

Once you get over the size of it, I can't stress enough what a great resource it is...This [Planner] really gave me a great overview of the right way to plan something...When you see something laid out from start to finish it makes a real big difference. The Planner is going to be so helpful for all programming that I am involved in moving forward. I have learned so much. [Program coordinator, team 5, ID12, end of study]

Building Capacity for Implementation Planning

All teams gave examples of how the Planner led them to undertake steps and activities that contributed positively to their

implementation planning, which they would not have undertaken otherwise. All teams identified ways in which the Planner changed their overall approach to program planning. A participant identified themselves as a *ready-set-go* personality and indicated that the Planner helped them to pause and consider other activities to enhance the success of programs in their organization (eg, conducting a thorough community assessment and developing referral pathways from the community). Another participant identified several Planner steps that were not part of their organization's usual practices (eg, partner engagement, decision-making methods, and planning for evaluation at the outset) and acknowledged that although these steps would lengthen the planning process, it would be worthwhile. All teams indicated that they would use the Planner for program planning in the future, both to continue planning their current program (when the pandemic-related restrictions allow) and for other program planning. We have summarized the participants' usual planning process and provided examples of how the Planner changed their implementation-planning knowledge, attitudes, and activities ([Table 3](#)).

Table 3. Examples of the effects of the Planner on study participants' implementation-planning knowledge, attitudes, and activities.

Team	Summary of usual approach to planning	Examples of how the Planner influenced planning knowledge, attitudes, and activities	Illustrative quotes from interviews
1	<ul style="list-style-type: none"> Participants gave differing views: <ul style="list-style-type: none"> Comprehensive, formalized planning process generally in alignment with the SRiM^a Implementation Planner (fitness coordinator) No formal planning framework; experience launching adapted exercise programs (private practice physiotherapist) 	<ul style="list-style-type: none"> Increased knowledge regarding participant-centered considerations (eg, room location) Decision to host a stakeholder meeting to engage community members in the planning process 	<p>“We had a stakeholder meeting as a result of utilizing the toolkit. Had I been doing this on my own, I probably would have thought I didn't need to do that, but it was really good to have. I looked at the Planner before the meeting to think about who do we invite to this meeting? Who are the key stakeholders? What are the key questions we should be discussing at this planning stage? And when we had the stakeholder meeting, it just brought up some really valid points around who are we targeting? Who are we missing? What are the barriers?” [Physiotherapist, team 1, ID1, monitoring interview 1]</p>
2	<ul style="list-style-type: none"> Program coordinators have significant autonomy to propose and launch new programs. Typically driven by the program of interest and the recreation center, rather than by a formal assessment of needs in the community 	<ul style="list-style-type: none"> More positive attitudes about the benefits of completing early planning steps (eg, partnerships and community assessment) before launching Shifting from an individualized to a more inclusive community-centered planning model 	<p>“We've been talking about new programs and talking about building relationships with other community partners and the health system, and I'm like, that's that idea within the Planner—doing that full community survey and getting into the actual community.” [Program coordinator, team 2, ID5, end of study]</p>
3	<ul style="list-style-type: none"> Programs are typically initiated by staff members within the organization, either as an organizational or provincial directive, or by a frontline staff member seeking managerial approval for a specific program. 	<ul style="list-style-type: none"> Increased ability to use a community-centered approach and successfully engage a diverse team of community stakeholders on the planning team Increased understanding of program planning by working through the Planner 	<p>“Just having that [the Planner] as a reference guide for future planning...I think I have a better understanding of how to go about the planning.” [Physiotherapist, team 3, ID6, end of study]</p>
4	<ul style="list-style-type: none"> Programs to be offered typically built into the job descriptions of clinic staff and based on needs observed in clinic Programs typically planned and implemented in the clinic setting by clinic staff 	<ul style="list-style-type: none"> The Planner process prompted them to shift from a planning team at 1 organization to forming a new partnership with the municipality 	<p>“Especially I should say like never working with an outside partner...I'm used to teaching group exercise classes in the hospital, but now we're looking at doing them outside with groups and partners; it's uncharted territory for me...Because we are a hospital, a lot of that stuff that the Planner goes through we didn't have to do because it was already established for us. And now that we've decided we are going to be working with the municipality, we're looking to the Planner even more now for the implementation planning.” [Physiotherapist, team 4, ID10, end of study]</p>
5	<ul style="list-style-type: none"> Program planning typically driven by an observed community need or through a desire to expand or adapt an existing successful program to other regions 	<ul style="list-style-type: none"> More positive attitudes toward using a formal framework to structure their process Increased knowledge about new steps to integrate into their process (eg, planning for evaluation and fidelity assessment upfront) 	<p>“The process has been amazing and it has been really refreshing—we were just rushing to [adapt this program], to now having the process to go oh yeah, let's use this Planner to direct our focus...we definitely wouldn't have come to the same place without the Planner.” [Program coordinator, team 5, ID11, end of study]</p>

^aSRiM: Stroke Recovery in Motion.

Conditions That Hindered or Facilitated Uptake of the Planner Process by Community Groups

By following the 5 teams and comparing their engagement with the process defined in the Planner, we identified conditions that made the recommended planning elements easier or more difficult to apply in practice. These factors typically related to organizational context and support, team leadership style, the

value placed on community-partner engagement, and the COVID-19 pandemic.

Challenging Conditions

Teams who followed their organization's usual processes for planning programs sometimes prematurely judged recommended activities in the Planner as not applicable. Planner use was challenging for organizations and staff primarily focused on the number of programs developed and launched. The

comprehensive planning process was viewed as potentially too long to meet usual organizational timelines. The *one-person show* model, in which planning activities are undertaken by 1 organization or person without engagement of a diverse team, similarly discouraged consideration and use of the entire planning process. In addition, organizational contextual factors such as restructuring and changing priorities, as well as broader contextual factors such as the COVID-19 pandemic, created barriers and delays to following the planning process. The COVID-19 pandemic presented significant challenges because organizational priorities and planning timelines shifted quickly and often to address changing pandemic conditions, and difficulties were encountered in forming and maintaining external partnerships.

Supportive Conditions

Embracing the Planner process was facilitated by a firm belief in the role of community-based organizations in enhancing the health and well-being of people with stroke. Organizational leaders who valued an evidence-informed planning approach and provided their staff with the dedicated time and resources

to work through planning activities created positive conditions supportive of using the Planner. Another positive factor was having a team lead who was open-minded to the Planner process and willing to undertake new steps and activities. Several team leads acknowledged that they personally did not have all the answers or resources and worked early on to identify a diverse group of people to join their core planning team and act as advisers. This openness and engagement led to these teams working through later Planner activities successfully (eg, asking people with stroke and caregivers about their needs and preferences and collaborating with fitness professionals on participant-screening protocols). Finally, for some (2/5, 40%) of the teams, an unanticipated condition that supported Planner use related to the COVID-19 pandemic—with the closure of many services, team members described having *more* time to dedicate to planning.

Lessons Learned on How to Effectively Use the Planner

On the basis of their field test experience, participants offered insightful suggestions about how to apply the Planner ([Textbox 1](#)), which may be informative to future users.

Textbox 1. Lessons learned from field test participants on how to most effectively use the Stroke Recovery in Motion Implementation Planner.

Suggestions for how to use the Planner and illustrative quotes

- The Planner is a comprehensive document with a lot of information. Get the *big picture* overview, use strategies to break up the content, and flag priority areas for your team.
 - “I was trying to read it all at once when I wasn’t actively doing any planning. Now I am going through it one section at a time and just trying to tackle that section. I’m actively planning as I’m doing it and checking off the tasks, and it definitely feels more manageable.” [Physiotherapist, team 4, ID10, monitoring interview 1]
 - “Even though it’s long, read the whole thing first...If someone’s just starting and they’re going to use the Planner, read it first to keep in mind what you’ve done in the past and then highlight and make notes on the sections that you know are really going to be useful to you. So that way when you do go back you know exactly where to go.” [Program coordinator, team 5, ID12, end of study]
- Do not treat the process as completely linear—give yourself permission to jump around the Planner.
 - “Depending on their personalities, some people are very like ‘I must follow the steps. I must do the step-by-step-by-step’ and I am an example of that person. And so there are some times where it was like well I’ve gotten to here and I haven’t been able to do a proper community survey therefore stop, I cannot go any further because I haven’t done this step yet. Well no, you could still flip forward and see what else you can get started on.” [Program coordinator, team 2, ID5, end of study]
- Take time and get the early stages of the planning process right.
 - “Even if you think you have this all in the bag and you have a program that’s going to start in a couple of months, it’s still really important to go through all of the process because you really need to have those evaluation bits in place from the outset...It’s the depth of quality. Having the time to put into this process will save you time down the road and avoids situations that you can’t really get yourself out of...would that have looked different if we had a different process in place from the beginning?” [Program coordinator, team 5, ID11, end of study]
- Engage with the Planner steps and tools beyond just ticking items off. Take an active approach with the Planner and use it to actually engage with people and organizations.
 - [related to using a Planner tool to assess the facility] “Actually have them go in the building and go through [the checklist] instead of just doing it by memory and what they think it’s going to be. Have someone actually go and do a walk-through of the building.” [Physiotherapist, team 3, ID6, end of study]
- Following the planning process can be more manageable if the load is shared among the team members. Identify a team lead who has the full view of the Planner and can delegate tasks and activities to other team members.
 - “I would have looked at delegating a little bit more. I did a little bit of ‘okay you do this, you do that,’ but I think it could have been done more effectively where [other planning team members] could have taken on some of the bigger pieces...” [Physiotherapist, team 3, ID6, end of study]

Discussion

Principal Findings

We followed 5 diverse teams as they used a newly created implementation-planning guide, the Stroke Recovery in Motion Implementation Planner, to plan for the implementation of community-based exercise programs for people with stroke. Because of the COVID-19 pandemic, none of the teams were able to work through the full planning process, with most activities focused on the first of the 3 phases. The findings of this field test study showed that teams took different approaches to applying and adapting the Planner in their settings. All teams indicated that the Planner influenced their approach to program planning and that they intended to continue using the resource in the future. We identified various team, organizational, and broader contextual factors that hindered or facilitated uptake of the Planner by teams. Study participants shared valuable *tips from the field* to help future teams optimize their use of the Planner. Given the paucity of literature reporting implementation toolkit evaluations [30,31], the findings of this study contribute data from our evaluative work on a novel implementation toolkit.

Comparison With Prior Work

A key finding was that the teams did not complete the planning process in a linear manner. All teams conducted multiple steps simultaneously, with some steps being revisited multiple times during the planning process, a pattern reported elsewhere [16]. We also observed that many planning activities (including those across multiple phases) were worked on early in the planning journey. Although we attributed this finding partly to pandemic-related challenges, previous research found a similar pattern, with teams reporting using an implementation guide most frequently in the early stages [32]. Furthermore, despite all having access to the Planner, no 2 teams followed an identical planning path. Although we are unable to speak to the impact of these diverse planning journeys in terms of implementation outcomes, a previous study using an implementation guide found that it facilitated standardization, while allowing flexibility according to the individual context and resources, with all sites successfully implementing the planned program [33]. Among the barriers to implementation, one of the most common relates to challenges adapting evidence-based interventions [13]. The Planner was therefore designed to be a practical approach to planning based on evidence, which means that it is to be used in alignment with the local context [18]. It was not designed as a *recipe* that must be followed in a lock-step manner. The finding that diverse teams could, in fact, adapt and navigate the planning process in various ways suggests that the resource was applied as intended in real-world settings.

Even experienced planners described new things they learned from the Planner and how this improved their processes, suggesting that the Planner positively influenced end users' planning capabilities, similar to other work reporting improvements in practitioner implementation skills [34]. In our study, 60% (3/5) of the planning teams were led by, or included, rehabilitation professionals. A recent study [12] of 384 allied health professionals (nearly half of whom were rehabilitation

professionals) indicated that these practitioners reported lower levels of confidence in planning, implementation, and evaluation. Nearly all expressed an interest in learning about knowledge translation, with web-based training and resources (such as the Planner) being the preferred format [12].

Fitness professionals are another group essential to planning and implementing fitness programming; yet, it is largely unknown how fitness instructors engage in knowledge translation and implementation and what barriers and facilitators they encounter [35]. Although it is well acknowledged that fitness professionals have a critical role in delivering physical activity interventions and programs, there is limited information on this diverse group's capacity and training needs [36]. In alignment with the Planner guiding principle of *inclusiveness* [7], we assert that fitness professionals are essential in cocreating the implementation plan. This field test included 12 participants, but only 2 (17%) were fitness professionals, which we attribute to the pandemic-related closure of fitness facilities and layoffs of fitness professionals. The inclusion of only 2 fitness professionals in our study was insufficient to reflect the overall heterogeneity of this group related to education, qualifications, and practice settings. Understanding this diversity and its effect on Planner use by this group may be important because there is evidence that fitness trainers with higher levels of education are more likely to access scientific journals than those with lower education, who prefer mass media and the internet [35]. Future work is needed to understand the implementation capacity and training needs of fitness professionals to enhance full participation in implementation planning.

In this study we used a passive form of implementation; that is, the teams had access to the Planner guide and tools, but no active implementation facilitation or support or any financial incentives were provided. However, there is evidence to suggest that active facilitation can enhance implementation efforts [37,38]. Given the potential value of implementation facilitation, our research team formed a new partnership with March of Dimes Canada, with the goal of having the Planner endorsed and supported by a well-connected and reputable organization in community-based stroke care. March of Dimes Canada has a national After Stroke program [39] that includes regional coordinators, providing the infrastructure to develop its organizational role in implementation facilitation by supporting sites using the Planner. There is an opportunity for future exploratory work that can contribute to the implementation literature on the role of a national organization and its regional coordinators in disseminating and supporting the use of the Planner. Furthermore, although the purpose of this study was not to assess the impact of the Planner on program outcomes, previous literature has reported that implementation toolkits may contribute to improved clinical outcomes [30]; future work is needed to evaluate the influence of the Planner on program outcomes and sustainability.

We identified several cross-cutting barriers and facilitators to following the implementation-planning process proposed in the guide, including organizational context and support, team leadership style, and the value placed on community-partner engagement. These factors were also identified in a review as core capacity-building domains (leadership, organizational

climate and culture, partnerships, workforce development, and financial processes) that can be modified to build capacity for the implementation of evidence-based practices [40]. Knowing that simply creating an implementation guide does not guarantee use, we have carefully considered the barriers and facilitators identified in the evaluation of the Planner and have used this information to make changes to the Planner itself. For instance, related to community-partnership engagement, we added new content to the Planner on partnership agreements and a sample invitation letter for stroke and caregiver partners [7]. Furthermore, to address the potential barrier of perceiving that some Planner activities were not applicable, we added “Why is this important” statements throughout to clearly show the potential benefits of completing the various steps, activities, and tools [7].

Finally, it is noteworthy that 80% (4/5) of the teams had already selected the specific exercise program they wanted to implement before enrolling in the study. The finding that most teams had already selected a program speaks to the reality that for many teams, identifying a program is, in fact, the starting point that launches their implementation-planning journey. Observing that not every team starts with a *blank slate* at step 1, we revised the Planner to illustrate various starting points, with directions on how to use the Planner accordingly [7].

Limitations and Strengths

The greatest limitation of this study was conducting a prospective field test during a pandemic. The pandemic created significant recruitment challenges, and we were unable to recruit our originally planned sample size. Furthermore, for the teams we did enroll in the field test study, the closure of community facilities and the public health restrictions led to significant planning delays. The enrolled teams were therefore unable to progress through the entire planning process, with only 20% (1/5) of the teams able to launch a program during the study period. The purpose of this study was not to ascertain the effectiveness of the Planner related to program implementation and outcomes; rather, we sought to understand if, how, and why the Planner was used in practice. Despite the pandemic-related planning challenges, many teams were still able to work through many steps and provided valuable insight on how they used the Planner, allowing us to meet the field test study objectives. However, it is important to acknowledge that because the teams engaged much more heavily in the early phases and activities of the Planner, we do not have the same depth of understanding of how teams would use the Planner in the later stages (ie, program launch, evaluation, and sustainability).

Furthermore, most (4/5, 80%) of the teams indicated that it was the study itself that prompted them to officially launch their planning activities. The study data collection procedures may have caused participants to engage more with the Planner (eg, completing Planner activities in anticipation of an upcoming monitoring interview with the study team). However, to model more typical program-planning scenarios, the research team did not provide any program funding and provided only minimal assistance with connecting study participants with resources (eg, people and websites). The interviewer (J Reszel) did not contribute to making decisions in the program-planning process. Finally, it is important to note that the monitoring calls and end-of-study interview were completed with 1 primary contact at each site, and their perceptions and experience of working through the Planner may not represent the experiences of their team members.

A strength of the study was the diversity of the sample, which included planning teams with differing compositions based in both urban and rural settings across the country. This allowed us to observe the use of the Planner in a variety of settings, which enhances the transferability of the findings. In addition, despite the challenging pandemic conditions, we were able to maintain contact with 80% (4/5) of the teams throughout the study period, allowing us to collect comprehensive data on Planner use and experiences over time.

Conclusions

Catalyzing the expansion of safe, effective, and sustainable community-based exercise programs is important to the long-term health of people with stroke. The Stroke Recovery in Motion Implementation Planner [14] is an adaptable resource that may be used in diverse settings to plan and implement community-based exercise programs for people with stroke. The results of this study contribute to the implementation science literature by describing how end users made use of an implementation guide and the influence of the guide on implementation-planning knowledge, attitudes, and activities. These findings may be informative to others who are developing resources to build the capacity of those working in community-based settings to implement new programs and practices. Future work is needed to understand how teams use the Planner to launch, evaluate, and sustain programs; to monitor ongoing use; and to understand the effect and outcomes of using the Planner. The Planner is now hosted by March of Dimes Canada and can be accessed on the organization’s website [14].

Acknowledgments

The authors thank all the study participants who generously gave their time amid the challenges of the COVID-19 pandemic to provide them with detailed and insightful input on the Planner. IDG is a recipient of a Canadian Institutes of Health Research Foundation grant (FDN 143237). NMS was supported by a Heart and Stroke Foundation Mid-Career Investigator award. AT is supported by a Clinician-Scientist Award (Phase II) from the Ontario Heart and Stroke Foundation (P-19-TA-1192). The authors acknowledge Patrick Faucher for the final graphic design of the Planner. This project has been made possible by Brain Canada Foundation through the Canada Brain Research Fun, with the financial support of Health Canada and the Heart and Stroke Foundation Canadian Partnership for Stroke Recovery. The views expressed herein do not necessarily represent the views of the Minister of Health or the Government of Canada.

Authors' Contributions

IDG and MTB coled all aspects of the study. IDG, MTB, JvdH, GA, MLB, KE, JJE, JLM, MLAN, MP, J Richardson, NMS, and AT contributed to the conceptualization and the design of the study. J Reszel collected the data. J Reszel, TN, JvdH, and IDG analyzed the data. J Reszel drafted the initial manuscript. All authors participated in the writing of this manuscript and reviewed and approved the final manuscript.

Abstract

Background: During the COVID-19 pandemic, individuals with a positive viral test were enrolled in a study, within 48 hours, to remotely monitor their vital signs to characterize disease progression and recovery. A virtual trial design was adopted to reduce risks to participants and the research community in a study titled Risk Stratification and Early Alerting Regarding COVID-19 Hospitalization (RiskSEARCH). The Food and Drug Administration–cleared Current Health platform with a wearable device is a continuous remote patient monitoring technology that supports hospital-at-home care and is used as a data collection tool. Enrolled participants wore the Current Health wearable device continuously for up to 30 days and took a daily symptom survey via a tablet that was provided. A qualitative substudy was conducted in parallel to better understand virtual trial implementation, including barriers and facilitators for participants.

Objective: This study aimed to understand the barriers and facilitators of the user experience of interacting with a virtual care platform and research team, while participating in a fully virtual study using qualitative and quantitative data.

Methods: Semistructured interviews were conducted to understand participants' experience of participating in a virtual study during a global pandemic. The schedule included their experience of enrollment and their interactions with equipment and study staff. A total of 3 RiskSEARCH participants were interviewed over telephone, and transcriptions were inductively coded and analyzed using thematic analysis. Themes were mapped onto the Theoretical Domains Framework (TDF) to identify and describe the factors that influenced study adherence. Quantitative metrics, including adherence to wearable and scheduled tasks collected as part of the RiskSEARCH main study, were paired with the interviews to present an overall picture of participation.

Results: All participants exceeded our definition of a fully adherent participant and reported that participation was feasible and had a low burden. The symptoms progressively resolved during the trial. Inductive thematic analysis identified 13 main themes from the interview data, which were deductively mapped onto 11 of the 14 TDF domains, highlighting barriers and facilitators for each.

Conclusions: Participants in the RiskSEARCH substudy showed high levels of adherence and engagement throughout participation. Although participants experienced some challenges in setting up and maintaining the Current Health kit (eg, charging devices), they reported feeling that the requirements of participation were both reasonable and realistic. We demonstrated that the TDF can be used for inductive thematic analysis. We anticipate expanding this work in future virtual studies and trials to identify barriers and enabling factors for implementation.

Introduction

Background

With the onset of the COVID-19 pandemic in 2020, we have seen rapid shifts in the way people work, engage with education and health care, and conduct their activities of daily life [1]. Many traditional clinical trials have slowed to a halt because of health care shortages and fear of increasing viral transmission [2]. Studies involving human participants have adapted to better use digitalized, decentralized, or virtual trial designs by the end of 2020 (though perhaps not as drastically as expected) [3]. Similar to remote working, virtual trial designs were a possibility that existed before the pandemic but have become a necessity for many researchers wanting to reduce the risk of transmission in human participants and the research community alike, while still conducting research [4,5].

Virtual clinical trials (VCTs) are site-less and rely on technologies such as apps, web-based platforms, wearable devices, and remote monitoring [6]. Digitized clinical trials also use technology to recruit and retain participants and for data collection and analysis [7]. Digitized clinical trials or VCTs leverage digital health technologies to improve participant access and engagement [7-9]. These trial designs have the potential to lower the cost of these studies and expand participation by making trials more accessible to participants [9,10].

With the shift to virtual, digitalized clinical trial designs, it may be helpful for study participants to understand specific implementation issues, including barriers and facilitators. Recruitment and retention in clinical trials are persistent challenges, whether traditional or virtual [7,11,12]. In VCTs, the study participant will likely have to interact with technology they may not have previous experience with, such as a remote continuous monitor, new apps for e-consenting and tracking, or daily surveys delivered by tablets [13,14]. There will almost certainly be a learning curve, with any instruction or assistance available also delivered remotely. Besides technical barriers, there may also be concerns about participant privacy when it comes to sharing sensitive health information [9].

Current Health and Risk Stratification and Early Alerting Regarding COVID-19 Hospitalization

Current Health (Current Health Ltd, Edinburgh, United Kingdom) is a medical technology company that creates a platform that enables continuous remote patient monitoring to support hospital at home programs and care [15]. The Food and Drug Administration–cleared Current Health kit includes a wearable device, which is a small, round disk that is attached to a band and worn on the upper arm. It monitors respiration rate, heart rate, oxygen saturation, skin temperature, and activity [15]. It can be integrated with peripheral devices, including those measuring blood pressure, axillary temperature, spirometry, weight, and continuous glucose. It also incorporates a tablet that can deliver surveys, reminders to take measurements

(eg, blood pressure, weight), or a video connection to a health care provider or investigator. It requires approximately 5 minutes for a participant to set up the Current Health kit, including measuring and selecting the correct arm band size, and begin transmitting vital sign data via the secure wireless home hub. The home hub allows the Current Health platform to operate without an in-home Wi-Fi connection, thereby making the technology more inclusive.

The Current Health platform was used in the study, Risk Stratification and Early Alerting Regarding COVID-19 Hospitalization (RiskSEARCH; NCT04709068) [16], funded by the US Department of Health and Human Services branch, the Biomedical Advanced Research and Development Authority. Its purpose was to remotely monitor individuals who tested positive for COVID-19 infection, within the previous 48 hours, to learn more about disease progression and recovery. The enrolled participants wore the Current Health wearable device continuously for up to 30 days. Health data were collected to develop predictive models for the risks of hospitalization and death.

As part of the main study, the research team designed a qualitative substudy run in parallel to gain an in-depth understanding of the participant's experience of taking part in a virtual study. Participants first had to show that they were eligible for the study by answering a web-based eligibility questionnaire, chose a time to connect with a study coordinator to be consented and enrolled, and finally had to set up and use the Current Health kit, which was shipped to their home address, all without meeting the study personnel in person. Once enrolled, participants were asked to answer a daily symptom survey delivered via a tablet and wear the Current Health wearable device 24 hours a day, except when charging the device or showering, bathing, or swimming. For the substudy, participants also agreed to conduct an interview of up to 40 minutes about the experience of participating in the RiskSEARCH study and using the Current Health kit.

The RiskSEARCH study did not progress beyond the pilot phase because of the changing landscape of the COVID-19 pandemic, including vaccine development and receding waves of infection, which negatively affected recruitment [17]. However, the substudy collected in-depth data on 3 participants, presented here as a case series, and qualitative analysis applying the Theoretical Domains Framework (TDF) to better understand the participant experience.

Theoretical Domains Framework

Virtual studies such as RiskSEARCH have many components that demand behavioral adaptation to adhere to the study intervention (eg, engaging in specific ways with the Current Health platform). The TDF synthesizes 128 theoretical constructs from 33 theories into a combined theoretical framework comprising 14 domains [18]. The TDF has been used to evaluate implementation problems, understand the mechanisms of change, and design interventions. The TDF helps

researchers identify and describe the factors that influence a set of behaviors (eg, study adherence). More specifically, it can help investigate implementation issues, including barriers and facilitators, to participating in studies such as the RiskSEARCH study and adopting the behavior changes necessary for adherence.

This is an exploratory piece of research based on a virtually delivered study run during the global COVID-19 pandemic from March 2021 to May 2021. The study team conducted this research to explore the participant experience for improving (1) recruitment and retention in future studies, (2) user experience with the Current Health platform, and (3) the ease with which the platform can be harnessed in other clinical studies, and in particular, virtual studies. We hope that these findings will aid other investigators to successfully conduct virtual studies and VCTs.

Methods

The RiskSEARCH Main Study

The RiskSEARCH study was a virtual, time-sensitive trial for individuals, aged >21 years, who tested positive for COVID-19 infection. The primary purpose of this study was to develop a machine learning–based algorithm to predict the likelihood of requiring a hospital stay of at least 24 hours using data collected from a remote patient monitoring wearable device and symptom surveys. This study used the Current Health platform for hospital-grade remote patient monitoring of vital signs and daily symptom surveys. Participants were recruited through advertisements on social media (Facebook, LinkedIn, etc) and word of mouth from March 2021 to May 2021. If an individual met the inclusion and exclusion criteria ([Multimedia Appendix 1](#)) and were interested in participating, they had 48 hours to enroll in the study. They were then consented and shipped a Current Health kit. The details of the main study will be published in a separate paper.

Textbox 1. Research objectives.

Research objectives

- To explore recruitment and retention for the Risk Stratification and Early Alerting Regarding COVID-19 Hospitalization (COVID-19) study
- To explore the feasibility, acceptability, and usability of the intervention, that is, the Current Health wearable device and tablet
- To explore barriers and facilitators of study compliance

Topic Guide and Interviewing

On the basis of the literature, our research objectives, and previous experience in developing interviews to understand engagement with digital technology, the study team designed an interview schedule ([Multimedia Appendix 2](#)) to explore barriers and facilitators around different aspects of the study and intervention (web-based enrollment, answering the daily survey, charging the wearable device, etc). One-to-one interviews were conducted by JP via telephone at a prearranged, mutually convenient time. JP was a senior clinical research scientist at Current Health at the time of this study, has >10 years of experience conducting interviews for qualitative and

Each day, the participants were sent a 21-question survey to complete on the Current Health tablet. The survey asked if participants experienced 8 specific symptoms (chills, fever, nausea, diarrhea, sore throat, dry cough, muscle ache, and loss of smell or taste) and whether they were better, worse, or the same as the previous day. In addition, there was a free-text response in which participants could add any other symptoms they were experiencing. Questions were also included about whether participants were likely to contact a health care provider or attend a hospital based on how they felt that day. This symptom survey was developed and piloted internally before it was shared with the RiskSEARCH study participants. Its purpose was to capture the symptoms and symptom severity associated with COVID-19 infections, to help drive the prediction model of the main study. In parallel, participants were asked to wear the Current Health wearable device for up to 30 days, taking it off only to charge (up to 30 minutes every 24 hours), shower, bathe, or swim.

Qualitative Substudy

We used semistructured interviews and reported the results following the consolidated criteria for reporting qualitative research checklist [19]. Specifically, we wanted to understand what it was like to use the Current Health kit and participate in a fully remote virtual study during a global pandemic. We collected in-depth data on the acceptability of the RiskSEARCH study and Current Health kit. Focused qualitative and quantitative research provided insights into the user experience of interacting with the Current Health kit, the Current Health research team, enrollment process, and participation in a fully virtual study.

Research Objectives

The research objectives of this study are presented in [Textbox 1](#).

mixed methods research, holds a Doctor of Public Health and Master of Public Health in epidemiology, and is a woman.

Recruitment and Procedure

Although we planned to use a purposive sampling strategy, we changed to convenience sampling when the main study recruitment remained low. A total of 7 participants were offered the opportunity to participate in a one-to-one interview with a research team member (JP). Participants were approached by the study coordinator (JLT) through text messaging or telephone conversations after building rapport through the study enrollment process. A total of 4 participants agreed to participate in the study, and 3 interviews were conducted. A participant could not be contacted to set up the interview. No relationship was

established between the interviewer and the interviewee before the commencement of the study. The participants knew that JP was a research scientist at Current Health and was interested in understanding their experience of participating in RiskSEARCH and using the Current Health kit.

Participants who agreed to participate in the interview were sent a PDF version of the informed consent form (ICF). Participants were sent the ICF via DocuSign (DocuSign, Inc) 24 hours before the interview. Participants could sign ahead of the call with the researcher or wait until the call to complete the ICF and ask any questions before signing. The researcher (JP) ensured that the

participant questions were answered and that the participants understood the risks of study participation. Participants could opt out of recording the interviews, but none chose this option.

Intervention

Once enrolled in the main study, participants were required to wear the Current Health device at all times, except when charging the device (20-30 minutes every 24 hours) or when showering, bathing, or swimming. They were also required to keep the tablet charged and answer the daily symptom surveys delivered by the wearable device. [Textbox 2](#) shows the components of the intervention.

Textbox 2. Components of the intervention.

Components

- Be home to receive the Current Health kit delivered by FedEx
- Open Current Health box
- Set up home hub which includes plugging hub into the wall
- Select correct armband size using included sizing guide (out of 3 sizes)
- Charge wearable device on included dock until fully charged, indicated by green lights, and charge daily thereafter
- Insert wearable device into armband and wear next to skin under clothing
- Remove wearable device for showering, bathing, or swimming
- Charge tablet daily
- Answer daily symptom surveys delivered on the tablet
- At the completion of the main study (up to 30 days), repackage the Current Health kit back into the box and use the return label provided to arrange return
- For substudy, arrange a mutually convenient time to be interviewed
- Participate in an over-the-phone interview lasting up to 40 minutes about using the Current Health kit and participating in the Risk Stratification and Early Alerting Regarding COVID-19 Hospitalization study

Data Collection

Participant interviews were conducted over telephone and audio recorded using a laptop application (Windows Voice Recorder, Microsoft Corporation) and a handheld digital recorder as a backup. Interviews were anonymized and transcribed using Trint software (Trint Ltd) and checked, corrected, and edited for accuracy by the researcher who conducted the interviews (JP). Familiarization with the data began at this early stage. Participants were also asked to take a modified Telehealth Usability Questionnaire (TUQ) sent to them via an email link. The TUQ is a validated survey tool that quantifies the usability of telehealth implementations and services [20]. No repeat

interviews were carried out, no field notes were made, transcripts were not returned to participants for correction, and participants did not provide feedback on the findings.

Metrics

As part of the main study, interview participants also contributed quantitative data, such as daily symptom surveys submitted via tablets. The data collected relevant to the substudy included the following variables as shown in [Textbox 3](#).

The participants' symptoms and vital sign alarms were presented alongside the qualitative results, as their clinical course may have influenced their experiences.

Textbox 3. Data collected.

Variables

1. Wearable adherence: the time the wearable device was worn compared with the study duration.
2. Daily survey adherence: the number of daily surveys completed compared with the number of daily surveys assigned.
3. Fully adherent, determined using 3 criteria: wearables worn for at least 20 hours a day and at least 6 days a week up to 30 days, daily survey responses at least 6 days a week up to 30 days, and a returned Current Health kit at the end of study participation.
4. Vital signs alarms: alarm thresholds were set for vital sign data going out of range, which could only be seen by the study team.

Analysis

A researcher (JP) conducted the interviews, transcribed the audio recordings using Trint transcription software, and coded the data using NVivo Qualitative Data Analysis Software (version 12; QSR International) [21]. We used reflexive thematic analysis [22]. Data were analyzed inductively following the steps of Braun and Clarke [22,23], specifically (1) familiarization of data, (2) generating initial codes, (3) searching for themes, (4) reviewing themes, (5) defining and naming themes, and (6) producing the report. Initial codes were inductively generated from the interview transcripts, iteratively condensed, and expanded into themes. The themes were then deductively mapped onto the domains of the TDF.

Ethics Approval

Ethics approval was obtained from the Institutional Review Board, Advarra (Columbia, Maryland, ethics approval number

Pro00047371). The collected data were stored in compliance with the European Union General Data Protection Regulation, Current Health Research Data Management Policy, US Health Insurance Portability and Accountability Act, and Current Health Research Data Management Policy. Data were anonymized, and all personal identifiers were removed.

Results

Participant Characteristics and Quantitative Results

Overview

Participant details are provided in [Table 1](#) and discussed in further sections.

Table 1. Participant characteristics.

Participant ID	Gender	Age (years), range	Wearable adherence (%)	Daily survey adherence (%)	Telehealth Usability Questionnaire score
RS001	Female	30 to 35	83	76	7
RS006	Female	40 to 45	63	90	— ^a
RS008	Female	35 to 40	92	100	—

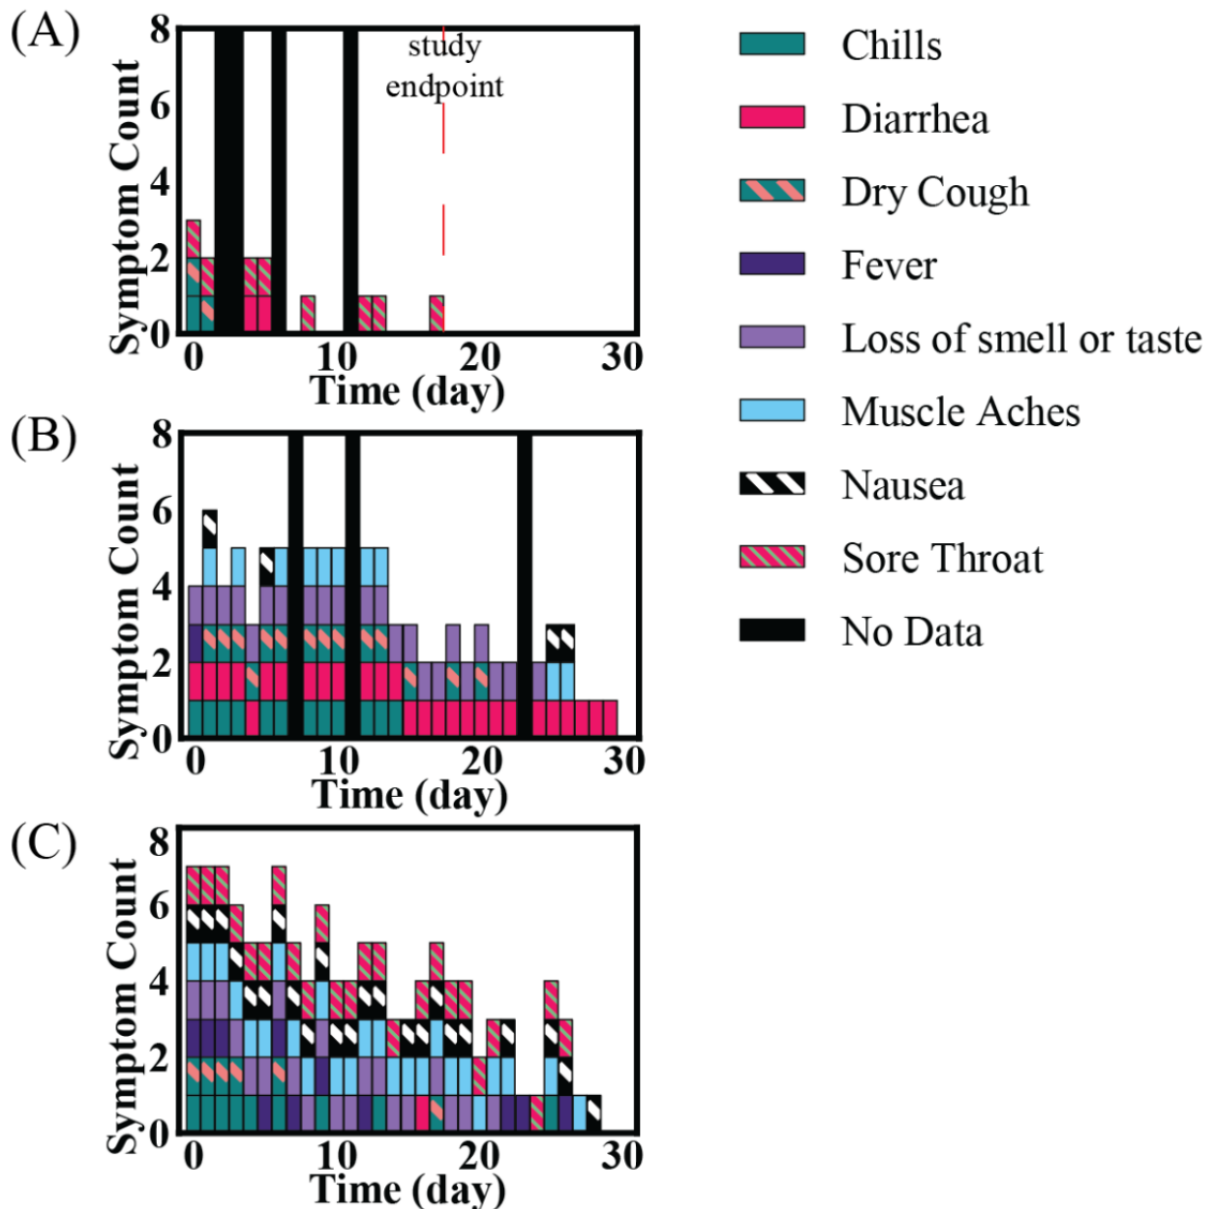

^aParticipants did not complete the Telehealth Usability Questionnaire.

Case 1

RS001 initially reported experiencing chills, dry cough, and a sore throat. She did not report experiencing any other symptoms for the duration of her study. By day 6, RS001's chills and dry

cough resolved and did not reoccur. However, she reported a sore throat periodically throughout her 17 days in the study. ([Figure 1A](#)) Over the course of the study, the only vital sign that triggered an alarm on the Current Health dashboard was a high respiration rate, which occurred on days 0, 3, and 9.

Figure 1. Symptom survey data for participants, daily symptoms reported by participants: (A) RS001, (B) RS006, and (C) RS008. Reported symptoms varied by participants. White gaps between days indicate the participant reported feeling no symptoms. Black bars indicate the days that the participant did not complete the daily symptom survey. Red hatched line indicates the study duration ended before 30 days.

Case 2

RS006 experienced all 8 symptoms, specifically asked about in the daily symptom survey over the course of the study. Her fever resolved on day 1 and did not reoccur. Conversely, her diarrhea did not resolve until day 30. Her symptoms decreased over the 30 days of study participation (Figure 1B). This trend in self-reported symptoms aligned with her vital signs data. RS006 triggered 34 alarms, but no alarms were triggered from day 23 onward. Nearly half of the alarms triggered were for a high pulse rate with a low amount of motion detected (ie, the participant’s pulse rate was high while not exerting themselves physically). Other alarms triggered were for low oxygen saturation and a high respiration rate with a low amount of motion detected.

Case 3

RS008 experienced all 8 symptoms included in the daily symptom survey, although diarrhea was reported only once on day 16. Nausea was the most persistent symptom, continuing until day 28. No symptoms were reported on days 29 or 30. As with the other participants, RS008’s symptoms improved over the course of the study (Figure 1C), which was also reflected in her vital signs data. RS008 triggered 10 alarms during the 30-day study period. No alarms were triggered after day 19.

Although all participants were asked to follow a link provided via email to complete the TUQ survey, only one participant completed the survey. This participant scored *strongly agree* (7 on the 7-point Likert scale) to all 21 questions of the TUQ, indicating high levels of usefulness, ease of use, effectiveness, reliability, and satisfaction with the Current Health kit.

Qualitative Results

Overview

In all, 3 interviews were conducted toward the end of study participation when participants were feeling better. Interviews ranged from 18 to 35 minutes. Inductive thematic analysis helped identify 13 main themes and subthemes associated with the participant experience of using the Current Health kit and being part of the RiskSEARCH study and included (1) Participant Situations, (2) Getting Started, (3) Study Support, (4) Study Communication, (5) Protecting and Contributing, (6) Determination, (7) Study Pros & Cons, (8) Optimism, (9)

Uncertainty, (10) Payment, (11) Accessing Data, (12) Memory & Reminders, and (13) Making Habits.

These themes were deductively mapped to the TDF domains. These domains are described below and presented in [Table 2](#). There were 3 domains of the TDF in which we did not match any data to: *Intentions*, *Goals*, and *Emotion*.

The main domains of the TDF, which we were able to map our themes onto, were *Environmental Context and Resources*; *Knowledge combined with Skill*; *Social/Professional Role and Identity*; *Beliefs about Capabilities*; *Optimism*; *Beliefs about Consequences*; *Reinforcement*; *Memory, Attention, and Decision Processes*; *Social Influences*; and *Behavioral Regulation*.

Table 2. Theoretical Domains Framework (TDF) constructs, Risk Stratification and Early Alerting Regarding COVID-19 Hospitalization (RiskSEARCH) themes, and description.

TDF constructs	RiskSEARCH themes	Description
Environmental context and resources	Participant Situations: being sick with COVID-19 infection; caretaking responsibilities	<ul style="list-style-type: none"> Study participants were recruited and went through the study after testing positive for COVID-19 infection Study required steps that may have been more challenging for participants who had many caretaking responsibilities
Environmental context and resources	Getting Started: enrollment; kit components; for example, wearables; unknowns; suggestions	<ul style="list-style-type: none"> Participants had to self-navigate through a web-based enrollment system and website Current Health kit required setup by the participant themselves (though they did have access to technology and study team support) Communication between tablet or wearable and participant Wearable needed charging 30 minutes every 24 hours. Participant did not know the battery level of the wearable, but green lights on charger indicated that it was fully charged Suggestions for improving any aspect of the Current Health kit
Knowledge combined with skill	Study Support ^a : personnel; materials	<ul style="list-style-type: none"> Technology support was available 24/7 to help with any aspect of setting up or using the wearable The study team was available on demand to answer any questions relating to the study or Current Health kit The Quick Start Guide was available in a hard-copy booklet in the Current Health kit or digitally accessible via the tablet “Study Support’ double coded with Social Influences”
Knowledge combined with skill	Study Communication ^a : passive; active	<ul style="list-style-type: none"> Website as a source for information on the study and COVID-19 pandemic “Study Communication’ double coded with Social Influences”
Social or professional role and identity	Protecting and Contributing	<ul style="list-style-type: none"> Help or protect others; feeling a sense of community responsibility; wanting to help in a difficult time; being someone who helps Motivation to help others A sense of contributing toward the management of the COVID-19 pandemic
Beliefs about capabilities	Determination	<ul style="list-style-type: none"> The level of commitment while engaging with the Current Health kit—survey or tablet or wearable
Optimism	Study Pros and Cons	<ul style="list-style-type: none"> Positive and negative aspects of the study
Optimism	Optimism	<ul style="list-style-type: none"> Seeing the positive in the bad situation of being tested positive for COVID-19 infection
Beliefs about consequences	Uncertainty	<ul style="list-style-type: none"> Feedback regarding user’s “performance” or whether kit was working properly
Reinforcement	Payment	<ul style="list-style-type: none"> Study participants expressing their views on the US \$100 offered for their time and effort
Reinforcement	Accessing Data	<ul style="list-style-type: none"> Having access to own data The wearable device does not transmit data to the participant
Memory, attention, and decision processes	Memory and Reminders	<ul style="list-style-type: none"> Remembering to charge and wear the wearable Reminders to take the survey every day Reminders to charge the tablet and take the survey
Social influences	Study Support ^a : personnel	<ul style="list-style-type: none"> Possibility to contact technology support or study team “Double coded with Knowledge combined with Skill”
Social influences	Study Communication ^a : active	<ul style="list-style-type: none"> Via email, text, or telephone call “Study Communication’ double coded with Knowledge combined with Skill”

TDF constructs	RiskSEARCH themes	Description
Behavioral regulation	Making Habits	<ul style="list-style-type: none"> Habit formation around charging the wearable and tablet and taking the survey Ability to support routine or habit formation

^aMapped to 2 different domains from the TDF.

Environmental Context and Resources

Many contextual factors impacted the participants' ability to successfully participate in the RiskSEARCH virtual study, including the Current Health kit functionality and design, being sick with COVID-19 infection, caretaking responsibilities, and comfort of the wearable device.

First, they had to navigate through a web-based enrollment process that included clicking on an advertisement that took the participant to a brief eligibility screening questionnaire and onto an appointment booker to connect with a member of the study team for consent. Although 2 participants said that the enrollment process was smooth and easy, another participant reported some minor problems that required contact with the study team:

I think it was pretty easy. [RS008]

So when I went to enroll, it didn't give me a time slot, like it said that there was no one available. I guess you have to like, talk to someone at first and I remember it led me - it led me all the way to the end. But then I said, like, there was no - no one available for my initial call... So I emailed and then they were available. But it was like, still on the same day. I feel like it was a glitch or something. [RS001]

Second, participants were required to set up the Current Health kit that was delivered to their home, select the correct-sized armband, charge the device and tablet, insert the device into the armband, and begin wearing it. In all, 2 participants described the setup as an easy process with a participant providing negative feedback on the tablet stand, which they described as nonessential and fussy:

Because like, one of the first things in the instructions is...take out the stand, put the...um...put the tablet on the stand. Like I just said, you could take all of that out because at first I thought I had to do it for it to get started and I didn't, and it wasn't like standing up and it just seemed like a waste. [RS001]

It was super easy in the box set up that, you know, getting the tablet and everything and then getting the little charging dock. And I mean, it was easy and then I got it connected to my wifi and started wearing it that day. [RS006]

The third participant experienced problems during setup. The Current Health kit shipping was delayed, and when she began setting it up, there was a problem with connectivity, which she reported took her a few hours to work out:

And then once I got the stuff here, yeah I started setting it up and then either the mobile or the wifi

wouldn't work...it just didn't want to connect the wifi or wearable device. [RS008]

Through the process of enrollment and setting up the wearables, participants were sick with COVID-19 infection, which meant that the usual barriers to joining a study may have been more difficult than usual. As a study team, we attempted to make the process as easy as possible for the participants:

It [enrollment] was super easy to me. I mean, even while, you know, sick as a dog with COVID I was still able to navigate and do it. So if I was able to, then you know, anybody could as long as you read and understand what you read, you can do it. [RS006]

Furthermore, study adherence may have been more difficult for participants who had caretaking responsibilities:

It's hard when you're a caretaker and you've got, you know, your mom with breast cancer. So you have to keep her schedule up plus her meds. Plus your schedule and your meds and then hubby and his schedule and his schedule. It can get overwhelming, I guess, but it was just because I probably was out of my routine. [RS006]

Adherence could also be influenced by the comfort of the wearable device, which we asked participants to wear as close to 24/7 as possible, only removing the wearable device to shower, bathe, swim, or charge. They could switch arms but needed to wear it next to their skin, under their clothes. In all, 2 participants said that it was comfortable and did not give them any problems, even during sleep. A third participant provided suggestions for improvement:

Maybe if the band was...it could get...more air towards it, so you won't get so much sweat under it...It's you know, really gross with activity sometimes...so maybe just more airing. [RS008]

Knowledge Combined with Skill

The domains of Knowledge and Skills were combined. Participants had to acquire an understanding of how to use the wearable device and tablet for adherence. Participants were provided with a printed and digital version of the QuickStart Guide (QSG) in the Current Health box and on the tablet. All participants reported using the hard copy QSG, which was positioned to be very visible upon opening the box, and none of the participants were aware that the QSG was also available on the tablet:

I remember getting everything [Current Health kit] and then I just - as soon as you open the box, I mean, like literally step by step, as long as you follow that booklet inside. That's what I did. I read it first. And then I started looking at stuff and I went back and I

was like, OK, step 1 is this, step 2 is this. I mean, it hooked up in like literally ten minutes. [RS006]

When a participant encountered problems with setup or connection, they had access to the study team and Current Health's 24/7 technical support to get things working:

I mean, I couldn't connect, of course. Then finally I was like, OK...then I realized I could reach out to the email person or the person that was like head of tech things like and say, OK, it's not working. [RS008]

An important aspect of technical support is the speed at which they respond, so that the participants do not become frustrated and no data are lost:

...they contacted me pretty fast, so...I didn't think I was going to have a response like that. [RS008]

Participants had to develop skills to interact with the tablet to take daily symptom surveys and to ensure that the tablet and wearable device were charged and working. They also had to experiment with the device fit to ensure comfort:

It's [survey] very, very easy to understand straight to the point, like you ask exactly what you need to know. And I love how it gets to all the symptoms, you can hit yes or no. And then it even asks you okay is it better than the day before this time or worse. I have loved that because some of my symptoms are a lot better and some of them are staying worse or getting worse and it varies daily. And so, yeah, I love that. That's really cool. [RS006]

Now, if you've got the band too tight on your arm, your arm will hurt. That's a learning process whenever you're starting. I did that...Then I got it loosened up and it's like perfect now. [RS006]

Social or Professional Role and Identity

The participants talked about their reasons for joining the study and contributing their time and effort. They were motivated to help in what few ways they felt they could, especially when it was difficult to help beyond isolation at home. Having a sense of contribution to efforts around the COVID-19 pandemic is important:

Look, I'm trying to be a good...I'm trying to be a good human. We're trying to quarantine and stay away from people. [RS006]

...well, I'll apply and see and help out the community and help out the hospital or where all this data was going to go to help you guys. See if it would do anything good for covid. [RS008]

Beliefs About Capabilities

The participant who had problems with the setup of the Current Health kit showed particular determination in working through the issues and troubleshooting until she could get it working. Although she had access to technical support, she was determined to troubleshoot initial connection problems independently:

And then once I got the stuff here [Current Health kit], I started setting it up and then either the mobile

or the wi-fi wouldn't work... I tried doing stuff on my own... it just didn't want to connect to the wi-fi or wearable device...I was like OK, I'm not going to play with this anymore. And then stayed up, like all night cause I was like OK, I am not letting this thing beat me. I was just determined to like...I'm going to figure this out somehow and then yeah... I don't even know what time it was, I don't know, it was like twelve or one-o'clock in the morning when I finally got it to work. [RS008]

Optimism

A participant showed tremendous optimism in the face of the COVID-19 pandemic and her own personal trouble in being sick with the disease. This participant focused on what it was teaching her and helping her focus on gratitude for aspects of life that were going well:

It's [COVID] definitely teaching us and it's making me learn and making me more aware and I'm thankful for it if you wanna know the truth. [RS006]

Yeah, that's...that's a positive way to look at things, huh? [Interviewer]

Yes, ma'am. I mean, well, you got to be positive. I was already down to the bottom. You know, I was already at the bottom of the COVID barrel. [RS006]

Although we did not hear that our participants expressed pessimism in relation to the COVID-19 pandemic or their involvement in the study, we asked them if there were any negative aspects to participating in the study. The participants mentioned that charging and remembering to charge the device and tablet were inconvenient tasks. A participant said that you could become tired of wearing the device, but she did not mind wearing it. Wearing the device could also pique the curiosity of strangers:

The only negative thing is people ask, what is that on your arm? [RS006]

Oh, interesting. [Interviewer]

Yes, that would be I would say the only thing, just getting questions about what is it? What are you wearing? And so I just tell them, I'm in a medical study since I had COVID and I'm just giving all my data and vitals and having stuff recorded. That's what I tell them. [RS006]

Beliefs About Consequences

The Current Health platform at the time of this study did not relay any information to the participants. It took some time for participants to adjust to wearing and charging the device and trusting that the data were being transmitted appropriately. Participants did not always know if data would be lost if they left their homes. The biggest issue that came up for participants around charging the device was not knowing how much battery it had left, making it difficult to plan charging the device. The tablet was less of an issue because they could leave it on the charger and only use it once per day to take and submit their daily symptom survey. Several suggestions have been made to

make the battery life more apparent to the user, which are now being integrated into the product:

I don't know if it's possible, but like if it told you if you needed to charge your device. Like I know it tells you, please recharge it but if there's like a way it told you that it had a low battery the actual like...I have no idea if it's possible but like, if it somehow would like, oh, your little arm band has low battery, charge it. [RS001]

So I guess, you know, I wasn't sure if like, it would work if I wasn't in my house. [RS001]

After a power outage, a participant expressed concern over the lost data and whether the device was still transmitting the data:

I was having an issue about the connection and I emailed [the Study Coordinator] and I was like, are you getting this [vital signs data] and she said, Yes, you're fine, you're good, it's okay. Cause we had like a power outage so our Internet went out and everything. And I was like, Are you still getting this? Yes, it holds data for eight to ten hours. I said, Okay, just making sure because I thought I'd done messed it up [laughs]. [RS006]

We found this domain to be linked with a concern that participants had about their own study adherence (ie, transmitting vital signs data) and desire to participate in the study to the best of their ability.

Reinforcement

A participant felt that the study would be more engaging if she could see some of her own data, and plans are underway to allow participants and patients to receive feedback on their data from wearing the device.

Participants were asked what they thought about the US \$100 they were offered for the time and effort they took to participate in the study. Participants received this payment after the study ended and the equipment was returned to Current Health. All participants thought it was a nice gesture but said it was not the thing that motivated them to participate:

I think it's fine, like it didn't...it didn't sway me to participate or not participate...It's just a nice added bonus. [RS001]

I think it's more than fair...I mean, all you're doing is just wearing this device. It's not like you're having to drive anywhere. You're not having to go out of your way. All you have to do is hook up some equipment, wear the device and save the box. And then when you're done, pack it all up and send it in. Woo hoo, I mean. It is not that hard. So I mean, I think it's very fair. [RS006]

I think it's like a nice thing...I didn't do it for the money, I mean, I'm still waiting on that. [RS008]

Memory, Attention, and Decision Processes

The participants in the RiskSEARCH study had high levels of adherence to wearing the device and taking the daily survey (see the aforementioned results). For the few times they did not

answer the symptom survey or wear the device, we asked them to think about the reasons. A major contributor to not wearing the device was forgetting to put it back on after removing it for charging, bathing, or showering. For the tablet, it was forgetting to take the survey:

Yes, I think I forgot to put it on...And then other than that, I don't think I...I did stop it early because I went on vacation and I didn't bring it with me [participant asked to stop participating before going on vacation as symptoms had resolved]. [RS001]

I think I pretty much wore it all the time. Sometimes...like whatever going to the shower or whatever, then maybe I...might've like left it on the charger a little bit longer. [RS008]

Behavioral Regulation

Participants spoke about the importance of routine and habits for remaining adherent by wearing a charged device and having a charged tablet to take daily symptom surveys. On days when a participant was out of routine or when normal habits could not be completed, there was an increased risk of forgetting to do these things:

I was literally running all day long from home like 9:00 that morning until about 5:30 yesterday afternoon is when I finally stopped and got home. And when I came in and made something to eat, I didn't even...I got, I was out of my routine that day. And I didn't even think about it. I didn't even think about it until three o'clock this morning. [RS006]

Social Influences

Participants had access to the Current Health technical support 24/7 and the study team close to 24/7. It was critical that we not lose participants or otherwise good adherence because of problems or questions that could not be responded to quickly. The participants could access technical support over telephone and the study team over telephone, email, or text. Participants spoke highly about the study's clinical research associate who was primarily responsible for enrolling participants and helping them get set up.

The lady that I was coordinating with was...she was super sweet, she was super informative. Anytime I had a question all I had to do with text or message, and she literally got back to me that same day. [RS006]

We also looked for feedback about study aspects, such as communication, frequency of messaging, and the Current Health kit itself. We asked in-depth questions about their experience using the study website, study-related emails, texts, and telephone calls. Participants found the methods of communication acceptable and unobtrusive and said that they liked having several avenues available to them for communication with the study team.

Discussion

Principal Findings

To gain a more thorough understanding of participant experience in a fully remote virtual trial during a global pandemic, semistructured interviews were conducted with 3 of the 7 participants in the RiskSEARCH study. All participants met our criteria for being fully adherent to the study and reported through interviews or the TUQ that participation requirements in both the main study (up to 30 days of wearing a wearable device on the upper arm, responding to daily surveys, and communicating with the study team when necessary) and the substudy were feasible and low burden.

Having quick and easy access to support from the study team and Current Health technical support was a critical enabling factor for staying engaged [24]. Future virtual studies should ensure that this resource, a dedicated and responsive study team or technical support, is accessible to participants (Textbox 4). This may necessitate staffing across time zones or during out-of-office hours. Participants reported some barriers around

setting up the Current Health kit, keeping devices charged, and remembering to take surveys but described these as minor challenges and showed high adherence while wearing the device and submitting responses to daily symptom surveys. Combining subjective (qualitative and self-report) and objective (quantitative like the number of surveys submitted and hours of vital signs data transmitted) data, the researchers assumed that high adherence was at least partly tied to ease of participation. A participant reported high levels of adherence (ie, reported not wearing the device on only 2 to 3 occasions that were a few hours long), while objectively showing 63% wearable device adherence. In reviewing the data, we believe that some data may have been lost when the participant was away from the home hub for >8 hours. Several factors may contribute to the differences in objective and subjective measures when collecting remote data such as perception, unknown technical issues, or improper use of digital technology. We found that the overall motivation for enrolling was a wish to contribute positively to the COVID-19 effort. In this small sample, we found adherence to be the easy part, whereas the key challenge for the research team was recruitment to the main study amidst the rapidly shifting landscape of the pandemic.

Textbox 4. Recommendations.

Recommendations

- Provide participants quick and easy access to support from the study team or technical support for any digital health technologies used in the study.
- Collect in-depth information around factors that impact on study enrollment and adherence; for example, processes, communications with study team, advertisements, and trouble setting up or using technology.
- Identify discrepancies in subjective and objective measures of study adherence and try to understand why those might exist; for example, participant perception, unknown technical issues, or improper use of digital technology.
- Identify agreement in subjective and objective measures of study adherence to understand what is working well.
- Consider using the Theoretical Domains Framework (or similar framework) for assessing potential implementation problems in virtual trials.

The interview schedule (Multimedia Appendix 2) was developed with the purpose of understanding the participant's experience of interacting with the Current Health kit and the ability and motivation to adhere to the study intervention. This interview schedule can be used in other qualitative studies looking to identify components of the study, such as digital technology and study materials, that facilitate or prevent adherence. We explored the barriers and facilitators to the web-based study enrollment process, communication with the study team, study advertisements and recruitment messaging, troubleshooting, burden of participating in the study, ease of use of the Current Health kit, and benefits and disadvantages of participating in the RiskSEARCH study. The data were then inductively coded into themes related to the TDF domains. The TDF is frequently used to develop interview schedules, with interviews coded into 14 domains of the TDF. The authors could not find research conducted as it was for this study, with an interview schedule developed independently of the TDF with themes from analyzed interview data and then mapped onto the TDF.

The TDF worked well for our qualitative data and the process of mapping inductive themes onto domains from the TDF was relatively straightforward. We chose the TDF because it was developed to make behavior change theories more accessible

to implementation researchers [18]. It was revised and validated in 2005 [25] to help researchers identify and describe the barriers and facilitators that could influence behavior and thereby impact implementation. Evidence suggests that theoretically based health interventions are more successful than interventions with no such base [26]. We needed a method for theoretically assessing any potential implementation problems encountered while running the RiskSEARCH study; the TDF provided this method. We are unaware of the use of TDF in other virtual studies or VCTs.

The interview schedule, created independently of the TDF, produced themes that mapped most heavily onto the domains *Environmental Context and Resources* and *Knowledge* combined with *Skills*. We believe this is an indication of the critical aspects of the product itself, the built environment of the participants, and the knowledge and skill acquisition that are essential for setting up and using the Current Health kit.

There were 3 domains that we did not map any themes to: *Intentions*, *Emotions*, and *Goals*. Though we did not map any themes to the TDF domain of *Intentions* it was clear throughout each interview that participants made a conscious effort to be fully adherent by wearing the device as long and as often as

possible, answering the daily symptom survey, and returning the Current Health kit once the study was over. As for *Emotions*, we found that participants were content to wear the device and be adherent. For the one participant who had trouble setting up her Current Health kit, she did not describe feeling frustrated or annoyed but simply determined to get her Current Health kit working without assistance, although knowing that technical support was available. This was not a study designed to get participants to create and follow goals, which is why we likely did not have any themes that could be mapped to the domain *Goals*. In future interview schedules, we could consider targeting these domains to obtain the most complete picture of implementation using the TDF.

Limitations

The biggest limiting factor in this study was the sample size. Although “data saturation” is a term with some conceptual and methodological issues and is not a necessity in every type of qualitative research [27,28], this study would have benefited from more interviews and in particular from interviewees who were different ages, male, and not adherent or those who experienced technical challenges, troubleshooting, and had opportunities to develop strategies around device charging and remembering to complete the daily symptom survey. There is also a possibility that more interviews would have led to more themes that could have been mapped onto the 3 domains of the TDF, for which we did not have data. However, reaching saturation does not necessarily invalidate our findings [29]. Despite the low number of interviews, we believe these exploratory findings add value to identifying barriers and facilitators to adherence in virtual studies and specifically, studies that require using wearables and submitting daily digitally delivered surveys.

Future Work

We hope to expand these preliminary findings to future virtual studies and VCTs that will surely outlive the current COVID-19

pandemic [30]. As a study team, we are highly motivated to reduce the burden placed on study participants to make study adherence as easy and enjoyable as possible and to encourage a more diverse study population by removing logistical barriers to participation [31]. The findings from this exploratory research will contribute to the best-practices literature for VCTs and help improve the Current Health kit and study delivery for future research participants. We believe that there is also more to learn about motivating factors for participants willing to enroll and participate in infectious disease research. We are also developing a means of providing the participant’s own data to them to help with engagement and memory around charging and wearing the device and believe that this will affect adherence metrics and overall levels of study engagement.

As the COVID-19 pandemic stretches on and the need for VCTs continues to grow, there is also a need for continuing research that helps us understand the participants’ experience of engaging in these studies, including the barriers and enabling factors that influence adherence. The RiskSEARCH study did not progress beyond the pilot study because of limited recruitment, highlighting an ongoing need to improve recruitment for clinical studies, whether virtual or in person. Despite the problems with recruiting, we believe we have learned some critical lessons about the conduct of virtual study or trial presented in this paper and have produced tools to continue collecting this type of data.

Conclusions

Participants in the RiskSEARCH substudy showed high levels of adherence and engagement throughout their participation. Although participants experienced some challenges in setting up and maintaining the Current Health kit (eg, charging devices), they reported feeling that the requirements of participation were both reasonable and realistic. We have shown that the TDF can be used for inductive thematic analysis. We anticipate expanding this work in future virtual studies and trials to identify barriers and enabling factors for implementation.

Acknowledgments

This work was supported by Current Health, Ltd. Additional time on the Risk Stratification and Early Alerting Regarding COVID-19 Hospitalization main study was supported in part by federal funds from the Department of Health and Human Services, Office of the Assistant Secretary for Preparedness and Response; Biomedical Advanced Research and Development Authority, Division of Research Innovation and Ventures under contract 75A50120C00190.

Authors' Contributions

JP was involved in finalizing the study protocol, implementing the study processes, conducting interviews with participants, analyzing the qualitative data, and drafting the manuscript. JLT was the RiskSEARCH study coordinator responsible for implementing the study processes and drafting the quantitative metrics sections. NZ was involved in implementing the study processes, developing the graphic display for symptoms in the quantitative section, and reviewing the manuscript. AW and MW were involved in finalizing the study protocol and reviewing the manuscript.

Conflicts of Interest

JP, JLT, MW, AW, and NZ are employees of Current Health, a Best Buy company, and receive compensation that supports the conduct of this research.

Abstract

Background: A large body of research has identified modifiable cognitions and behaviors (actions) associated with psychological health. However, little is known regarding the actions that are most strongly associated with psychological health or the frequency with which they should be performed.

Objective: This paper described 2 studies that used survey methodology to create the Things You Do Questionnaire (TYDQ), which aims to identify and rank actions (items) and domains of actions (factors) most strongly associated with psychological health.

Methods: We used digital marketing strategies to recruit Australian adult participants, who were asked to complete 2 web-based surveys comprising versions of the TYDQ; validated measures of depression, anxiety, and satisfaction with life; and demographic questions. In study 1, a total of 3040 participants rated how often they performed each of the 96 items comprising the TYDQ. This design was replicated in study 2, in which a 59-item version of the TYDQ was completed by 3160 participants. In both studies, the factor structure and validity were examined, as were the associations between individual TYDQ items and 3 mental health outcomes: depression, anxiety, and satisfaction with life.

Results: In study 1, factor analyses revealed that a 5-factor model comprising 27 items achieved an optimum balance between brevity and variance and accounted for 38.1%, 31.4%, and 33.2% of the variance in scores on measures of depression, anxiety, and satisfaction with life, respectively. The factors were interpreted as realistic thinking, meaningful activities, goals and plans, healthy habits, and social connections. These 5 factors were more strongly associated with psychological health than those such as practicing kindness, exercising gratitude, and practicing spirituality. This pattern of results was replicated across gender, age groups, and depression severity. The 5-factor solution found in study 1 was replicated in study 2. Analyses revealed that a 21-item version accounted for 46.8%, 38.2%, and 38.1% of the variance in scores on measures of depression, anxiety, and satisfaction with life, respectively.

Conclusions: These findings indicate that some actions are more strongly associated with psychological health than others and that these activities fall within 5 broad domains, which represent skills often taught in psychological treatments. Subsequent studies are planned to explore the reliability of these items and results in other samples and to examine patterns of change in scores during treatment for anxiety and depression. If replicated, these efforts will assist in the development of new psychological interventions and provide an evidence base for public mental health campaigns designed to promote good mental health and prevent the emergence of common mental disorders.

Introduction

Depressive and anxiety disorders are highly prevalent conditions associated with significant distress, disability, and reduced quality of life [1,2]. These conditions exist along a continuum of severity, and it is now recognized that subclinical or subsyndromal variants can also cause functional disability [3] and considerable economic costs [4]. These disorders are characterized by maladaptive patterns of cognition, behavior, habits, and interpersonal and social engagement, which form the basis for accepted diagnostic criteria [5,6]. Maladaptive patterns of thinking and behavior trigger symptoms and impede recovery. Although the specific mechanisms of change during psychotherapy are not well understood [7-9], the premise that these maladaptive patterns can be modified or changed underlies the teaching of psychological skills within several treatment approaches, including cognitive therapy [10], behavior therapy [11,12], mindfulness [13], and interpersonal therapy [14].

Therefore, identifying adaptive and maladaptive patterns is a priority during treatment, and several approaches have been used to deconstruct these patterns into measurable and modifiable cognitions and behaviors (*actions*). One approach involves creating questionnaires to measure the quality and frequency of use of cognitive and behavioral skills (cognitive behavioral therapy) taught in psychological treatments [15-21]. Examples of items in these questionnaires include *I made an effort to evaluate my negative thoughts by considering just the facts* [19] and *I worked on a project that was meaningful to me* [21]. Consistent with psychological models, these and other studies have found small to moderate relationships between the frequency and quality of cognitive behavioral therapy-related actions and symptom severity over treatment. Although useful in clinical settings, disadvantages with many of these questionnaires include their tendency to focus solely on skills taught in therapy, their frequent use of highly technical language to describe cognitions and behaviors, and the exclusion of a large range of other activities that might be linked to mental health outcomes and that might represent important targets for intervention.

Other researchers surveyed consumers and mental health professionals to generate lists of actions believed to affect the symptoms of anxiety and depression [22-26]. Examples of actions identified in these studies include *focusing on the positive* [25] and *doing more things you enjoy* [22]. Many of the actions identified in this research are consistent with the skills taught and promoted in psychological treatments. Unsurprisingly, studies have also shown that prompting these types of actions is associated with symptom reduction [27]. However, a weakness of many of these measures is that they fail to inquire about the frequency of performing such actions. Such information can be important for developing interventions to improve mental health or prevent mental ill health.

An additional and parallel body of work has sought to examine the relationship between mental health and quality of life. This

has led to the development of numerous measures, such as the Quality of Life Inventory [28] and the World Health Organization Quality of Life Scale [29], which have been demonstrated to reliably and validly measure satisfaction across multiple life domains (eg, physical health, psychological health, and relationships) while being reliable across both general and clinical populations. More recent quality of life measures, such as the Brunnsvikken Brief Quality of Life Scale [30], have aimed to create freely accessible and brief versions that maintain strong validity and reliability profiles. Although helpful in determining satisfaction levels across different life domains, quality of life measures have not been designed to inquire about the frequency with which people engage in modifiable activities, which limits the utility of these tools.

Several research domains have identified actions that are associated with psychological health; however, several important questions remain unanswered. First, we do not know how often actions need to be performed each day or week for a person to experience an improvement in psychological health. Second, we do not know which actions or domains of actions are most strongly associated with improved mental health. Third, research has not yet explored whether particular actions are more helpful for different people according to their clinical presentation, personality, or demographic characteristics.

The studies presented in this paper are part of a research program, the Things You Do Project, designed to examine these questions with the overall aim of identifying and confirming the everyday actions that are most strongly associated with good mental health. The potential value of this information is not only in the treatment of mental disorder but also in the evidence-based prevention of mental disorder and promotion of mental health at the population level. Consistent with the World Health Organization's definition of health as not only the absence of symptoms but also the presence of a positive state of well-being [31], we used the term *psychological health* in this paper to describe not only the absence or reduction in symptoms of anxiety or depression but also an improvement in well-being, measured based on self-reported satisfaction with life.

In this paper, we have described 2 studies that used survey methodology to create the Things You Do Questionnaire (TYDQ), which aims to identify and rank actions and domains of actions most strongly associated with psychological health. Recognizing the complexity of this objective and the range of potential methods, we opted for a broad and systematic approach to scale development [32].

In the first study, participants rated the frequency with which they completed a range of actions previously identified to be associated with psychological health. Responses were analyzed to assess the factor structure, reliability, validity, and strength of association of TYDQ items with psychological health. In the second study, participants rated a shorter version of the TYDQ. In both studies, participants also completed validated measures of depression, anxiety, and satisfaction with life. Formal

hypotheses were not proposed, but we expected that the process of ranking actions and domains of actions would generate a parsimonious list of psychological health items.

Study 1

The aims of study 1 were to (1) generate a large list of actions previously associated with psychological health and explore the relationship between the weekly frequency of performing these actions and symptoms of anxiety, depression, and life satisfaction; (2) explore the underlying factor structures of the TYDQ and rank the association between the actions and factors and psychological health; (3) explore the importance of different actions across different subgroups; and (4) develop a parsimonious list of items.

Methods

Ethics Approval

A web-based survey design was used for data collection. The study was reviewed and approved by the Macquarie University Human Research Ethics Committee (MQ HREC: 5201700988), and informed consent was obtained from all participants. All methods were performed in accordance with the relevant guidelines and regulations.

The data sets used and analyzed during this study are available from the corresponding author (NT) upon reasonable request.

Questionnaire and Item Generation

An initial list of items was derived from a review of the literature on actions associated with psychological skills identified through multiple sources. These included reviews of (1) skills typically taught in psychological therapies (eg, cognitive skills, behavioral activation, exposure, goal setting, problem solving, social skills training, applied relaxation, mindfulness, acceptance, gratitude, and kindness); (2) actions associated with psychological health, such as healthy daily routines (eg, sleep hygiene, nutrition, and moderated use of electronic devices), physical health (eg, exercise, yoga, stretching, and walking), social activity (eg, talking to friends and spending time with people), meaningful and satisfying activities (eg, doing fun activities), and spiritual and religious activities; (3) symptoms of high prevalence mental disorders as described in psychiatric diagnostic systems [5,6]; (4) previous questionnaires developed by the authors [20], other questionnaires, or similar lists [17-19,22,23]; and (5) consultations with colleagues.

Our research team, consisting of psychiatrists, clinical psychologists, and data analysts with experience in questionnaire development, created a preliminary list comprising >500 actions. Each action was phrased as a verb, and references to psychological techniques or orientations, such as practicing mindfulness, were avoided. During the planning phase, we met regularly to identify, review, edit, and categorize the list, which was reduced to 272 items after duplicates and overlapping items were removed. The items were categorized according to the mechanisms or processes associated with each item; that is, a priori attempts were made to identify theoretical clusters. For example, some items were categorized as primarily concerned with cognitive actions (primary cluster), and within this cluster,

they were subdivided into actions associated with challenging unhelpful thoughts, focusing on the future (secondary clusters). In instances where items belonged to multiple clusters, categorization was based on consensus. To capture a broad range of items, the list was shared with colleagues outside the research group, who made further recommendations. The final list of 96 items was based on the following criteria: (1) actions that can be performed daily; (2) measurable, that is, a person can be expected to reliably estimate the frequency of actions over a week; (3) can be completed by most adults; (4) described as a positive action, that is, an action that can be considered a strength; (5) modifiable, that is, can be changed by the person; and (6) did not duplicate another item.

A 5-point Likert rating scale was used to ask participants how often they performed these behaviors over the past week by using the following scoring system: 0=Not at all (0 days per week); 1=1 or 2 days per week; 2=3 to 4 days per week; 3=5 to 6 days per week; and 4=every day (7 days per week). None of the items were reverse scored. After completing the TYDQ, participants were also invited to nominate other actions that were not included in the 96 items they used to improve their mental health.

Participants and Procedure

The survey was promoted to adults across Australia via websites and web-based newsletters from Australian mental health services and Facebook posts and advertisements. Advertisements invited people to participate in a study that aimed to *identify activities and habits that affect mental health*. Consenting participants provided demographic details and completed web-based questionnaires. Participants were required to be aged ≥ 18 years. No other exclusion criteria were applied. Details of the sample are included in the *Results* section.

Measures

Three standardized outcome measures were used to evaluate and rank the association of the items with psychological well-being.

Patient Health Questionnaire 9-Item Scale

The Patient Health Questionnaire 9-item (PHQ-9) scale measures the occurrence of Diagnostic and Statistical Manual IV–congruent depressive symptoms over the past 2 weeks by using a 4-point Likert scale ranging from 0 (*not at all*) to 3 (*nearly every day*). Higher scores indicate greater symptom severity [33]. The PHQ-9 has good internal consistency and is sensitive to change [34], with a total score of ≥ 10 usually but not always associated with a diagnosis of major depressive disorder [35,36]. The Cronbach α in this study was .90.

Generalized Anxiety Disorder 7-Item Scale

The Generalized Anxiety Disorder 7-item (GAD-7) scale measures the occurrence of general anxiety symptoms over the past 2 weeks by using a 4-point Likert scale ranging from 0 (*not at all*) to 3 (*nearly every day*). The GAD-7 is sensitive to Diagnostic and Statistical Manual IV–congruent GAD, social phobia, and panic disorder, with increasing scores indicating greater severity of symptoms [34,37]. The GAD-7 has been shown to demonstrate sound psychometric properties, with a

total score ≥ 10 usually indicating a likely diagnosis of an anxiety disorder [38]. The Cronbach α in this study was .92.

Satisfaction With Life Scale

The Satisfaction With Life Scale (SWLS) is a 5-item scale that measures attitudes toward life satisfaction by using a 7-point Likert scale ranging from 1 (*strongly disagree*) to 7 (*strongly agree*), with higher scores indicating greater life satisfaction. The SWLS has demonstrated good psychometric properties [39,40] and has been used extensively as a measure of life satisfaction in mental health research [41]. The Cronbach α of the SWLS in this study was .90.

Statistical Analyses

The examination of the relationship between the TYDQ items and the standardized scales was operationalized in three detailed and comprehensive steps: (1) item-level analysis, (2) factor analysis, and (3) generalizability of factor solutions.

Item-Level Analysis

First, a series of univariate regression models (ANOVA) was used to quantify and statistically test the association between each of the TYDQ item scores and the PHQ-9, GAD-7, and SWLS outcome scores. The strength of the association between items and outcomes was summarized with an R^2 metric, noting the proportion of the variance explained by each TYDQ item and each outcome. The R^2 values were used to weigh and rank the 96 items.

To further visualize the relative importance of different TYDQ items, each possible TYDQ item score, ranging from 0 (*not at all*) to 4 (*daily*), was tabulated with its corresponding PHQ-9, GAD-7, and SWLS outcomes to form a heat map [42]. Comparing the corresponding outcome scores with the range of TYDQ values enabled the identification of the minimal weekly behavioral frequency score needed to achieve optimal PHQ-9, GAD-7, and SWLS outcome scores for each TYDQ item. The optimal TYDQ score was defined as the minimum weekly behavioral frequency beyond which no additional statistically significant improvement can be observed.

Factor Formation and Analysis

Second, a series of exploratory factor analyses (EFAs) was used to examine how different TYDQ items formed composite latent factors of behavior. An initial EFA was used to identify the factors based on a full list of 96 items. An additional 3 EFAs were conducted to identify latent factors among the subsets of TYDQ items that were associated more closely with the PHQ-9, GAD-7, and SWLS. These EFAs analyzed the subsets of items based on a minimum of 5%, 10%, and 15% R^2 relationship to any one mental health outcome with the aim of identifying more parsimonious lists of factors closely related to psychological health. A factor was considered viable when the item set comprised a composite eigenvalue greater than 1. Additional diagnostic analyses were used to assess each of the identified factors, including item reliability analysis, mean item intercorrelation, and the ability of the identified factors to replicate each item (ie, commonalities).

All identified factors were tested and ranked for their strength of association with the 3 outcomes by using the same analytics and visualization approach used to evaluate TYDQ items. To further evaluate the importance of different behavioral TYDQ factors for mental health, a series of binary logistic regressions was conducted to test the association between the factor scores and the probability of an individual presenting with PHQ-9 or GAD-7 scores that would be considered within the clinical range.

Each factor was assigned a proposed label, which aimed to represent the overall theme of those items. Consensus regarding the factor label was achieved through discussion and debate, considering other labels could have been used.

Generalizability of Factors Solutions Across Different Subgroups

A series of confirmatory factor analyses (CFAs) were conducted to examine the reliability of the EFAs within a sample cross-validation analysis (5 randomized subsamples) and the validity of the factor structure along with key subgroups that differed based on age (<30, 30-44, 45-60, >60 years), gender (male, female, and other), the severity of depressive or anxiety symptoms (minimal-mild, moderate, and severe), an indication of employment, and tertiary education. These CFA tests followed the methodology and reporting conventions outlined by Putnick and Bornstein [43] for the examination of measurement invariance, including the examination of configural invariance, metric invariance, scalar invariance, and strict invariance. From the viewpoint of scale development, this step sought to evaluate the reliability and generalizability of the identified factor solutions along relevant subgroups in clinical research (dimensionality).

All analyses were performed using R statistical software version 4.1.1 [44] and the Lavaan package [45]. A conservative P value of .01 was considered the threshold for statistical significance, reflecting the large sample and the multiple number of tests conducted. In all analyses, participants with missing data were not included in the analyses owing to difficulty imputing unbiased missing outcomes in a high-dimensional analysis and cross-sectional settings. All EFAs and CFAs were based on weighted least-squares estimators to account for the ordinal categorical TYDQ item score range. For all EFAs, with the aim of identifying unique subsets of items, a varimax factor rotation was adopted to maximize the number of factors identified and minimize item-factor cross-loadings [46].

Items with factor loadings < 0.50 , a threshold that aimed to achieve a conservative balance between recommendations in the literature [32,47], were suppressed as were items with suboptimal association with their corresponding factor (accounting for $< 25\%$ of the factor variance) [48].

Results

Item and Sample Description

Participants in study 1 were recruited from March to June 2018, during which time 3755 people consented to participate and 3040 (80.96%) completed the questionnaire. Sample characteristics are presented in Table 1. Participants had a broad

range of both demographics (age, gender, location, education, and employment) and mental health symptoms. Approximately half of the sample scored above the clinical cutoffs on the PHQ-9 (n=1710, 48.1%), GAD-7 (n=2020, 57.9%), and SWLS (n=2188, 64%), allowing the testing of the association of everyday behaviors for those above and below recognized clinical cutoffs on the PHQ-9 and GAD-7.

[Multimedia Appendix 1](#) includes each of the 96 items ordered based on the a priori primary and secondary theoretical clusters created during item development and based on the observed average weekly score. [Multimedia Appendix 1](#) also uses a heatmap to indicate the frequency with which participants reported performing each item each week. For example, the first item in [Multimedia Appendix 1](#) was the 13th item presented in the survey and read I read, listened, or watched something I

enjoyed. A priori, this item was categorized as an Activity/Meaning (primary and secondary clusters), and the average weekly score was 2.72 (mean TYDQ weekly score), indicating that the mean frequency reported was between 4 and 6 days each week. The final column indicates that 37.4% (n=1404) of the sample reported doing this action daily, whereas 3.7% (n=139) reported not doing this action in the previous 7 days.

As shown in [Multimedia Appendix 1](#), the frequency of actions (TYDQ mean scores) ranged across and within clusters. For example, 2 of the highest frequency scores were observed within the *Healthy Routine* cluster, with daily showers or baths reported by 69.3% (n=2602) of the sample, and avoidance of illicit drugs or misuse of medication reported by 83.3% (n=3128).

^aPHQ-9: Patient Health Questionnaire 9-item.

^bGAD-7: Generalized Anxiety Disorder 7 item.

^cSWLS: Satisfaction With Life Scale.

Item-Level Analysis

The 96 items were then subjected to tests of the strength of association with each of the PHQ-9, GAD-7, and SWLS outcomes. The results from this first series of analyses are presented in [Multimedia Appendix 2](#) for each item, with items grouped around the a priori clusters. The columns of the table report the mean PHQ-9, GAD-7, and SWLS scores observed with differing rates of weekly behavioral frequency. The PHQ-9, GAD-7, and SWLS scores were further incorporated into a heat map visualization to highlight the TYDQ items associated with the highest symptom scores among the 96 TYDQ items, where red hues indicate deterioration of psychological health (ie, symptom scores and satisfaction with life) and blue hues indicate improved psychological health.

The proportion of symptom variance explained (R^2) was reported as a summary measure of the association between each item and outcome. In [Multimedia Appendix 2](#), the presentation order of the 96 items illustrates the relative ability of TYDQ items to account for the cumulative variance of the 3 outcomes, with the strongest items reported at the top of each a priori cluster. Together, the 96 items were significantly associated with each of the 3 outcomes (TYD outcome regression β test resulting in $P<.001$), except item TYDQ 57 (*I fulfilled my responsibilities even though I didn't want to*) and its association with GAD-7 outcomes. Most items showed a linear relationship between higher frequency and lower symptom scores, with a minority

of items showing a flattened, convexed, or positive relationship with PHQ-9 and GAD-7 outcomes. However, the strength of the association between each of the items and each outcome varied substantially, both within and across clusters. For example, TYDQ 16, *I treated myself with respect*, illustrated the strongest association with depressive symptoms (accounting for 22.5% of all PHQ-9 scores); TYDQ 70, *I kept a realistic perspective on things*, was the strongest correlate of anxiety symptoms (accounting for 21.1% of all GAD-7 scores); and TYDQ 54, *I had something to look forward to*, was the strongest correlate of satisfaction with life (accounting for 25.9% of all SWLS scores). Across the items, the threshold of activity associated with optimal well-being varied from half a week to daily, with the majority of items requiring frequent (*almost every day*) but not necessarily daily activity.

Factor Formation and Analysis

EFA was conducted to identify underlying groupings among the items and to explore a brief, latent factor structure of behaviors associated with psychological health. The results from the EFA of the complete 96-item list are presented in [Multimedia Appendix 3](#). In total, 16 factors were identified, with 56 of the items demonstrating factor loadings above 0.5 for any 1 factor. Factors with loadings of ≤ 0.5 were suppressed. Across the TYDQ list, the factors appeared to form along their a priori clusters, with most items grouped within their clusters. No item-factor cross-loadings were identified above the loading of 0.5.

The results of the tests of association between the resulting factor scores and each of the PHQ-9, GAD-7, and SWLS outcomes are further reported in [Multimedia Appendix 3](#), which describes the outcomes of a series of 4 EFAs, each testing a different number of items (see [Multimedia Appendix 3](#) for items). This shows that the complete list of 16 factors, based on 56 items, accounted for 41%, 37%, and 32% of the outcome R^2 , respectively. The resulting 16 factors can also be seen as varying in their strength of association with the 3 outcomes, with estimates of R^2 ranging from <0.1% to 24%.

The EFA was repeated with another subset of items (68 items), selected based on the individual item's ability to account for at least 5% of any of the 3 symptom outcomes ($R^2 > 5\%$), which provided an opportunity to examine patterns among TYDQ items more closely related to psychological health. The analysis identified 11 factors, with only 45 items demonstrating factor loadings > 0.5 for any one factor. The items were clustered within their respective a priori clusters, and no item-factor cross-loadings were identified. A test of the association between the resulting factor scores and each of the PHQ-9, GAD-7, and SWLS outcomes illustrated that a complete list of 11 factors based on 45 items accounted for 33%, 29%, and 32% of the outcome R^2 , respectively, with each of the individual factors varying in their strength of association from 5% to 21% ([Multimedia Appendix 4](#)).

In a third EFA, an even briefer subset of items (35 items) was selected based on the item's ability to account for a minimum of 10% of any of the 3 symptom outcomes. This resulted in 5 factors and 27 items with a factor loading above 0.5 for any 1 factor. No item-factor cross-loadings were identified. A test of association between the resulting factor scores and each of the PHQ-9, GAD-7, and SWLS outcomes revealed a list of 5 factors based on 27 items, which accounted for 38%, 31%, and 33% of the outcomes R^2 , respectively ([Multimedia Appendix 4](#)). The formation of factors largely followed the a priori clusters, and the resulting factors varied 3-fold in their strength of association with each of the outcomes (9%-28%).

A fourth EFA, which included items, identified a stringent $R^2 > 15\%$ criterion. This resulted in a brief set of items (8 items) found to represent a single composite factor combining key items from several domains. Although this result is interesting, the PHQ-9, GAD-7, and SWLS variance explained by a single factor ([Multimedia Appendix 4](#)) was suboptimal ($R^2 = 36.6\%$, $R^2 = 26.7\%$, and $R^2 = 32.9\%$, respectively), and the representation of multiple domains, including activity planning, self-representation, and values through a single nonspecific factor, would inevitably limit the ability to assess and interpret the type of behavior.

Together, these EFAs illustrate that the 96-item list could be reduced to a more parsimonious and selective item list, with an optimal 5-factor, 27-item solution that retained $> 90\%$ of the strength of association with each of the symptom outcomes, with only a quarter of the items (27/96, 28%). Each factor solution was further assessed for item reliability, mean item intercorrelation within each factor, and the ability of the

identified factors to replicate each item (commonalities), as collated in [Multimedia Appendix 5](#).

Generalizability of Factor Solutions Across Different Subgroups

A series of CFAs were conducted to examine the measurement invariance of the 5-factor solution as a brief but sensitive measure of psychological well-being across 5 categories, namely age groups, gender, depression and anxiety symptoms, education, and employment. The results from the CFAs are collated in [Multimedia Appendix 6](#). The identification of TYDQ differences in the intercept and residual scores indicated that gender, age, and baseline symptoms were associated with different frequencies of weekly activity, although the TYDQ scores formed the same latent patterns across these groups. To check for the potential of alternate models, we reran the EFA within each of the age, sex, and PHQ-9 subgroups. The results identified the 5-factor solution reliably replicated as the most prominent latent solution when no parameter restraints were made or when the rotation methodology was changed ([Multimedia Appendix 7](#)). Together, the results from these CFAs illustrate that the latent 5-factor structure identified was statistically reliable, generalized across subgroups of clinical interest, and replicated across differing aspects of the statistical methodology (rotation and parameter constraint).

Discussion

Study 1 involved a comprehensive series of methodological and statistical steps designed to create a large list of actions associated with psychological health, test their strength of association with defined mental health outcomes, and develop a parsimonious list of items. To begin with, 96 items previously associated with psychological health were identified and administered to a large and diverse adult sample, along with measures of depression, anxiety, and satisfaction with life.

Several factor solutions were explored, and through a systematic process of dimension reduction, EFA solutions based on 56 items, 45 items, 27 items, and 8 items were examined. The 27-item solution, which comprised 5 factors, was found to be optimal, as it represented 38%, 31%, and 33% of the variance in scores of measures of depression, anxiety, and satisfaction with life, respectively. A series of CFAs indicated that the factor structure was robust across different subgroups, with these 5 factors interpreted as (1) realistic thinking, (2) meaningful activities, (3) goals and plans, (4) healthy habits, and (5) social connections.

Surprisingly, some items and factors that were expected to show strong relationships with psychological health, such as actions associated with kindness, gratitude, and spirituality, were not represented in the 5-factor solution. In contrast, items associated with skills commonly taught in psychological treatments, such as challenging unhelpful thoughts and engaging in pleasant activities, were very strongly associated with psychological health. Importantly, the results of study 1 not only identified items and factors that are strongly associated with psychological health but also found that the frequency of performing those actions was associated with improved well-being.

In summary, the results of study 1 provided preliminary psychometric evidence for the TYDQ as a measure of modifiable actions associated with psychological health. The reliability of the strong relationship between the 5-factor 27-item list found in study 1 needs to be replicated in further studies, which is one of the aims of study 2. Given the surprising finding that some items and factors were not strongly associated with psychological health, such items should also be retested.

Study 2

Overview

The objective of study 2 was to explore the reliability of the results of study 1 by replicating the design used in study 1 using a briefer version of the TYDQ. The aims were to (1) generate a shortened list of items based on the results of study 1 and explore the relationship between the weekly frequency of performing these items and outcomes of psychological health; (2) explore the underlying factor structures and rank the association between the items, factors, and psychological health; (3) explore the importance of different actions across different subgroups; and (4) develop a parsimonious list of items.

It should be noted that study 2 was conducted when major cities across Australia were locked down in response to the COVID-19 pandemic, which, on the one hand, represents a significantly changed context to that of study 1 but, on the other hand, provides an opportunity to test the items and the questionnaire in a psychologically challenging context.

Methods

Ethics Approval

The design of study 2 replicated that used in study 1. Ethics approval for data collection was obtained from the Macquarie University Human Research Ethics Committee (MQ HREC: 5201700988), and informed consent was obtained from all participants.

Questionnaire

Study 2 evaluated a version of the TYDQ comprising 59 of the 96 original items ([Multimedia Appendix 8](#)), with each item using the same 5-point rating scale used in study 1. This brief list was constructed in several steps. First, items that accounted for at least 5% of the PHQ-9, GAD-7, and SWLS were identified, resulting in an initial list of 67 items. Second, this list was edited to remove items with similar wording or duplicated items, resulting in the removal of 23 items. Third, 15 additional items from the original 96 item list were added to test the association between items, such as kindness to others and gratitude, which were considered clinically important and expected in study 1 to be associated with the outcomes but were not. We reviewed each of these steps.

Participants and Procedure

The procedure used in study 1 was repeated in study 2. As shown in [Table 1](#), a total of 3756 participants consented to participate in the study and started filling the questionnaires, which were available between June and August 2020. These

dates coincided with social and travel restrictions across Australia owing to the impact of the COVID-19 pandemic.

Other Measures

The outcome measures used in study 1 were also used in study 2.

Statistical Analyses

The three analytical steps in study 1 were repeated: (1) item-level analyses, (2) factor formation and analyses, and (3) analyses that explored the generalizability of factor solutions across different subgroups. Additional analyses were conducted to compare study 1 and study 2 samples on TYDQ scores, the strength of association between the items and symptom outcomes, and factors. For example, the comparison of TYDQ scores from the 2 studies was operationalized by treating the studies as a group variable and regressing this variable on the TYDQ item scores. Similarly, the association between TYDQ items and symptom outcomes was tested by regressing the TYDQ item score, group, and item-by-group interaction on outcome measures.

Results

Item-Level Analysis

A total of 3756 people consented to participate in study 2, and 3160 (84.13%) completed all the questionnaires. Participant characteristics and comparison with the study 1 sample are presented in [Multimedia Appendix 8](#). These results indicate significant differences between the samples across most demographic variables, symptom severity, satisfaction with life, use of medications for anxiety or depression, and mental health service use.

The TYDQ score for each item, the association of each TYDQ item with the 3 symptom outcomes, and testing of differences between the 2 study samples are included in [Multimedia Appendix 8](#). The results indicated a significant increase in the average score of most TYDQ items from study 1 to study 2. The results also indicate that the strength of association between most TYDQ items and each of the 3 outcomes was greater in study 2 than in study 1. However, the relative strength of association across and between the items and the outcomes was similar in magnitude across the samples, as seen in the heat map.

Factor Formation, Item Reduction, and Analysis

In the second step, the 59 items were subjected to a dimension-reduction analysis. The complete list of 59 items identified a 10-factor solution when no parameter constraints were imposed on the data, with 9 of these factors overlapping with the study 1 EFA solution ([Multimedia Appendix 9](#)). Using the inclusion criterion of $R^2 > 10\%$, a 26-item solution was identified using the data from study 2, replicating the pattern of the 5 factors identified in study 1. Using the inclusion criteria of $R^2 > 10\%$ and reanalyzing the results of study 1 resulted in an even more parsimonious 21-item solution ([Multimedia Appendix 9](#)) that reliably retained the factor structure. The 5 factors and the 21-item solution identified in the reanalysis of study 1 results ([Multimedia Appendix 9](#); inclusion criteria of $R^2 > 10\%$) were

then compared with the same 21 items from the study 2 results, and associations between the 5 factors and the 3 outcome variables were compared across samples ([Multimedia Appendix 10](#)). This demonstrated close similarities in strength, directionality, significance, and optimal frequency cutoffs between the 2 samples.

A set of 3 EFAs were then conducted for item subsets with no selection criteria, inclusion criteria of $R^2 > 10\%$, and inclusion criteria of $R^2 > 15\%$. The 5-factor 21-item solution associated with the $R^2 > 10\%$ criteria in study 2 accounted for the highest amount of PHQ-9, GAD-7, and SWLS outcome variance ($R^2 = 46.8\%$, $R^2 = 38.2\%$, and $R^2 = 38.1\%$, respectively). Consistent with this, a reanalysis of the data from study 1 using the same $R^2 > 10\%$ criteria demonstrated that this 5-factor 21-item solution accounted for the highest amount of PHQ-9, GAD-7, and SWLS outcome variance ($R^2 = 37.1\%$, $R^2 = 30.0\%$, and $R^2 = 30.5\%$, respectively).

Generalizability of Factor Solutions Across Different Subgroups

CFAs seeking to verify a 5-factor 21-item solution across the study 1 and study 2 samples resulted in metric invariance (similarities in factors and item loading) but not scalar or strict invariance ([Multimedia Appendix 11](#)). This result is consistent with the interpretation that participants from the 2 studies differed in their means but not item or factor importance.

In brief, the overall results of study 2 replicated the results and 5-factor model obtained in study 1, albeit with a 21- rather than a 27-item solution. These results confirm the strength of the relationship between key items in the TYDQ and psychological health outcomes and the underlying factor structure.

Discussion

Study 2 examined the performance of a shortened version of the TYDQ. The survey was completed by 3160 people, and although the sample was significantly different from that of study 1, the overall patterns of results obtained in study 1 were replicated. The 5-factor structure observed in study 1 was supported and accounted for 46.8%, 38.2%, and 38.1% of the variance in the symptoms of depression, anxiety, and satisfaction with life, respectively. These solutions were achieved using a parsimonious 21-item list. Importantly, and again consistent with the results of study 1, the observations that some items and factors expected to show strong relationships with psychological health, such as showing kindness to others and expressing gratitude, were not found to be associated with well-being. The implications and limitations of these results are discussed in the subsequent section.

General Discussion

This paper describes 2 studies reporting on the initial development and evaluation of the TYDQ, which aims to measure modifiable actions that are strongly associated with psychological health. The detailed and systematic approach followed accepted scale development methods [32] and attempted to address the limitations of previous work by

including a broad range of modifiable actions, exploring their frequency over a 1-week timeframe, identifying the actions most strongly related to the target outcomes, and testing the generalizability of results across age, gender, and baseline symptom severity.

Principal Findings

Study 1 examined the performance of a 96-item version of TYDQ. A 27-item 5-factor solution achieved an optimal balance between accounting for sufficient variance in outcome measures of depression, anxiety, and satisfaction with life and parsimony. These five factors were interpreted as actions concerned with (1) realistic thinking, (2) meaningful activities, (3) goals and plans, (4) healthy habits, and (5) social connections. There was a strong relationship between the frequency of performing the actions associated with these factors each week and improved psychological health, with results indicating that they should be performed at least half a week or more to optimize their psychological health. Importantly, the factor structure was consistent across demographic variables, including gender and age groups.

Overall, these findings were replicated in study 2, which evaluated a shortened 59-item version by using the same systematic analytic strategy. Study 2 was conducted during a period when participants were mostly in lockdown owing to the impact of the COVID-19 pandemic in Australia. However, the strength of the relationship between the frequency of target actions and outcomes increased relative to study 1. The same 5-factor solution found in study 1 was also found in study 2, although slight differences in the item loadings were observed across the 2 samples. An item-reduction exercise revealed that a 5-factor 21-item version solution achieved an optimal balance between item parsimony and accounting for sufficient variance across the 3 outcome measures. These results appear to confirm the robustness of the 5 factors but also suggest that the 21-item list ([Multimedia Appendix 9](#)) should not be considered final, and additional survey design efforts could further improve the brevity and validity of the items identified. In any case, the 96-item and 59-item lists are provided in [Multimedia Appendix 11](#).

Comparison With Prior Work

The overall results are consistent with previous research regarding key items associated with psychological health, including cognitions and actions such as, *I did something enjoyable, I kept a realistic perspective on things, I had something to look forward to, and I treated myself with respect*. These 5 factors confirm the importance of many of the skills taught in psychological interventions, including cognitive therapy [10], behavior therapy [12,49], and others. Various combinations of these skills and actions have been recognized as contributing to psychological health [50-52] and are frequently included in public mental health campaigns. Thus, the contribution of our preliminary study is not to identify the actions and factors associated with psychological health. Instead, these studies extend the literature by comparing the relative benefits of different types of actions on psychological health and the frequency with which these factors are associated with psychological health. The findings indicate that performing

these actions for at least half the days of the week is important for psychological health across age, gender and demographic groups, as well as in different severity levels of mood symptoms. This proposed frequency needs to be carefully evaluated using a longitudinal study; however, if supported, it would indicate a key target for psychological interventions as well as for public health interventions designed to promote psychological health and prevent common mood disorders in the community.

An additional and important finding was that some actions were less strongly associated with psychological health than expected. For example, acts of kindness, practicing gratitude, and spirituality are widely considered important for psychological health; however, in this study, these actions were not found to be as important as those relevant to the 5 factors. This lack of findings is broadly consistent with the results of empirical studies [53-59].

For example, in a systematic review and meta-analysis of 27 experimental studies examining the relationships between acts of kindness and different measures of subjective well-being, including measures of psychological health, Curry et al [53] found the overall effect of kindness to be small to medium ($\delta=0.28$); however, they noted that most of the reviewed studies were underpowered to detect small differences. In a series of meta-analyses examining the findings of 38 studies, Dickens [54] showed that when compared with waitlist, inactive, or no-treatment control groups, gratitude interventions were associated with decreased depressive symptoms and improved positive affect, well-being, happiness, and life satisfaction, albeit with small effect sizes (Cohen $d=0.13-0.30$). In a more recent review of the effect of gratitude traits and interventions, Jans-Beken et al [60] concluded that gratitude interventions were not found to reliably improve symptoms, such as depression and anxiety, but they were associated with improved happiness and life satisfaction. In a meta-analysis of 48 longitudinal studies, Garssen et al [56] reported an overall positive effect of religion or spirituality on mental health; however, similar to studies examining the relationships between mental health and acts of kindness and practicing gratitude, the effects were small, with a random weighted average effect size of $r=0.08$.

Given the large number and broad cross-section of people completing the 2 surveys, these findings appear to be robust. However, given the preliminary nature of the 2 studies reported here, we propose that the findings should not be interpreted as such actions are not helpful; rather, it is likely that different actions are important at different stages of psychological health and for particular individuals and age groups. For example, it is commonly recognized in clinical practice that people who are severely depressed are more likely to benefit from actions involving increasing reinforcement and pleasure than from practicing gratitude, but once their mood has lifted, actions such as practicing gratitude and showing kindness to others may help maintain psychological health. In addition, it should be noted that the results obtained here are relevant to the outcomes of interest, namely, symptoms of depression, anxiety, and satisfaction with life, and that choosing other outcome measures may result in other factors and items ascending in importance. This raises the possibility of future research exploring the

relationship between everyday actions and a much broader range of mental health outcomes, including the general p factor, which extends beyond internalizing disorders to include externalizing and thought or psychotic disorders [61].

Limitations

The preliminary and cross-sectional nature of the 2 studies reported here are associated with several limitations. First, despite the large sample sizes and consistent results across subsamples, the work should be considered preliminary and tested in other samples, including people with different cultural and demographic backgrounds. In addition, the items and factors identified here need to be tested using longitudinal or interventional research designs to gauge their sensitivity to change and reliability over time. The robustness of the 5 factors should also be tested across differing statistical methods for identifying dimensionality, for example, using different statistical criteria for selecting items or using latent profiling.

We also acknowledge that the initial selection of items used to develop the TYDQ, despite the breadth of our inquiries, involved some subjective choices. We have shared lists to assist independent replication and further development (Multimedia Appendix 12). Related to these limitations, we also acknowledge that the terms we generated to describe the factors were based on our clinical and psychometric decisions, and that other research groups may have generated other labels for each of the factors. We also acknowledge that although most of the actions were relatively simple to understand by participants, some actions were more difficult for participants to measure; for example, the item *I treated myself with respect*. This raises important questions about how people interpreted some of the items, which may in turn affect both the reliability and validity of the results. This is further complicated by the observation that a person's interpretation of the questions may change over time and with their experience of the action. Finally, we acknowledge that the focus of this study is primarily on the relationship between actions and symptoms and may not be generalizable to other concepts of psychological well-being, happiness, or thriving [62].

Strengths

The strengths of this study include the development of a questionnaire containing items that were not obviously associated with any specific psychological model or approach, evaluated through a systematic and detailed analytic procedure that included multiple tests of generalizability by using 2 large sample sizes. This procedure contributes to the literature by comparing the relative strengths of several groups of modifiable actions and the minimum frequency required for such actions to affect psychological health. An additional strength is that the results were mostly replicated although the second sample was obtained during a challenging period for the community characterized by social restrictions related to the impacts of the COVID-19 pandemic.

Conclusions

In conclusion, these studies provide preliminary evidence for actions and factors strongly associated with psychological health and the frequency with which they should be performed. Future

studies are planned to further explore the patterns of change in brief versions of the TYDQ, including samples of people seeking treatment for mental health conditions. We hope that these efforts will assist in the development of new psychological

interventions and provide an evidence base for public mental health campaigns designed to promote good mental health and prevent the emergence of common mental disorders.

Acknowledgments

The studies reported in this paper were partly funded by donations from the Mental Wheels Foundation, which had no role in study design or analysis.

Abstract

Background: Referral linkages are crucial for efficient functioning of primary health care (PHC) systems. Fast Healthcare Interoperability Resource (FHIR) is an open global standard that facilitates structuring of health information for coordinated exchange among stakeholders.

Objective: The objective of this study is to design FHIR profiles and present methodology and the profiled FHIR resource for Maternal and Child Health referral use cases in Ebonyi state, Nigeria—a typical low- and middle-income country (LMIC) setting.

Methods: Practicing doctors, midwives, and nurses were purposefully sampled and surveyed. Different referral forms were reviewed. The union of data sets from surveys and forms was aggregated and mapped to base patient FHIR resource elements, and extensions were created for data sets not in the core FHIR specification. This study also introduced FHIR and its relation to the World Health Organization's (WHO's) International Classification of Diseases.

Results: We found many different data elements from the referral forms and survey responses even in urban settings. The resulting FHIR standard profile is published on GitHub for adaptation or adoption as necessary to aid alignment with WHO recommendations. Understanding data sets used in health care and clinical practice for information sharing is crucial in properly standardizing information sharing, particularly during the management of COVID-19 and other infectious diseases. Development organizations and governments can use this methodology and profile to fast-track FHIR standards adoption for paper and electronic information sharing at PHC systems in LMICs.

Conclusions: We presented our methodology for profiling the referral resource crucial for the standardized exchange of new and expectant moms' information. Using data from frontline providers and mapping to the FHIR profile helped contextualize the standardized profile.

Introduction

Background

Health care is a complex sector that involves medical professionals, allied health workers, the information and communication technology (ICT) workforce, and various other stakeholders. The World Health Organization (WHO) highlights the importance of 6 building blocks of any health system: service delivery, health workforce, health information systems, access to essential medicines, financing, and leadership or governance [1]. Therefore, the health information systems block is very critical and plays an important role in data capture, processing, and usage. Substantial investments have been made in the development and strengthening of routine health information systems (RHIS) in many low- and middle-income countries (LMICs) over the past 2 decades [2,3]. Although early RHISs were produced using paper-based health facility reports, many LMICs have implemented newer web-based systems over the past decade [4,5]. Given that substantial investments have been made in strengthening RHISs in LMICs in recent years, researchers have a growing demand for more real-time data [6]. Besides, data for policy and operational decision-making in LMICs, including Nigeria, have been largely limited to report generation, process monitoring, and early surveillance responses. Reliable, quality, timely, and transparent health service data are essential for an efficient health system [7]. Globally, health care interoperability has been identified as vital to seamless care coordination among the different stakeholders.

Global Health Care Interoperability

According to the World Health Organization (WHO) Europe's 2016 e-Health in practice report, Estonia is the first country to implement electronic health records (EHRs) [8]. The famous X-Road facilitates Estonia's exchange network, an interoperability layer launched in 2001, with several different services added over the years. Estonia achieved success with over 99% of electronic medical subscriptions in 2018. Estonia's X-Road interoperability layer connects over 2700 services across 700 institutions and enterprises across several sectors, including health care. The United Kingdom's national service specification was based on the Health Level 7 (HL7) version 3 standard and is now transitioning to the HL7 Fast Healthcare Interoperability Resource (FHIR). However, local implementation was left to providers to determine, most of whom already run different versions of HL7 version 2 [9]. This National Health Service project started with 2 main use cases: the Summary Care Records and the Detailed Care Records [9]. Canada launched a national Infoway project to standardize and foster collaboration among pan-Canadian health care solutions [10]. After leveraging the CEN TC251 standards for referrals, discharge letters, laboratory, prescriptions, reimbursements, radiology requests, and reports, a national program was deemed successful in Denmark. These use cases were pilot-tested via 15 independently managed projects [10]. In 2008, a report highlighted that in the United States, "only 15 to 20 percent of medical doctors have access to computerized patient records and only a small fraction of the billions of medical transactions happen electronically" [10]. Such a low usage led to the creation of Health Information Technology for Economic and Clinical Health, which was

launched in 2009 to incentivize digitization, and things have since changed.

Interoperability in LMICs

Some LMIC health systems services are still paper-dependent for recording and transmitting health information. Paper records are limited because only one person can access them at a time. Systematic digitization of health systems has driven the development and implementation of national digital health strategies in Nigeria and other LMICs [11,12]. From our literature search [13] and to our knowledge, LMICs still struggle with patient-level interoperability project implementations, which has limited recording successes. Nigeria is a typical LMIC because it has one of the highest global burdens of maternal mortality [14]. Furthermore, there are more primary health care (PHC) facilities (approximately 10 times) than hospitals in Nigeria; hence, here we focus on PHCs. PHCs have the highest potential for impact in the Nigerian health system because most health services are delivered at the PHC level. In a typical PHC network, the possible use cases for health information interchange may include the following:

- Interdepartmental care communication
- Inter-PHC or PHC to secondary hospital referral
- Reporting of decentralized laboratory results
- Triangulation of immunization and surveillance information
- Payment settlement
- Diagnostic information exchange

Nigeria used the DHIS2 for routine reporting of the delivery of health information system services. Routine health information systems (RHISs) continue to collect data on a wide range of diseases and conditions [6]. These RHIS data are analyzed to assess community-level initiatives such as policies to boost community engagement and strengthen referrals from traditional birth attendants to increase demand for maternal and child care [15-17]. The COVID-19 pandemic has further exposed the weakness in health systems worldwide and the value of linkages.

Health Care Interoperability Standards

The international organizations for certifying and ratifying widely used digital health standards are the ISO/TC (International Organization for Standards' Health Informatics Technical Committee) 215 and CEN/TC (European Committee for Standards' Health ICT Technical committee) 251. For instance, ISO 21090:2011 is a ratified HL7 version 3 data type for information interchange. Similarly, ISO 13606-1:2019 is a ratified description of archetype reference models. HL7 is a leading health care standard development organization that has facilitated many standards, including the HL7 version 2 messaging standard, HL7 version 3 Clinical Document Architecture document exchange standard, and the HL7 FHIR. FHIR was popularized because it supports REpresentational State Transfer (REST)-based web-based (real-time) transactions and its extension for services. FHIR is now emerging as the de facto global standard for health care data interchange. The FHIR community includes Microsoft, Google, Apple, and many electronic medical record and EHR vendors [18-20]. In addition, the WHO has recently published a digital adaptation kit to support countries deploying standards for antenatal care [21].

Terminologies

In addition to data interchange standards, terminology categorization helps guarantee consistent and uniform understanding (and meaning) of terms in health care systems (within and across geographies). The leading terminologies for disease, procedure, and other concept classification are Systematized Nomenclature of Medicine–Clinical Terms (SNOMED-CT) and the International Classification of Diseases (ICD). Other technology providers are Logical Observation Identifiers Names and Codes (LOINC) for laboratory result reporting and Digital Imaging and Communication in Medicine (DICOM) for imaging data reporting. This study used ICD because it uses a free license compared to the better developed SNOMED-CT for disease classification. Code systems such as the WHO ICD-10 use statistical classification of medical concepts and entities into coded groups, assigning identifiers [22]. Codes allow for the unique identification of these concepts in an information processing system. These codes classify diseases, procedures, billing, history or symptoms, and case summaries (jurisdictional and international aggregate reporting). Simultaneously, service providers, including clinicians, use clinical terms in information processing tools.

Study Objectives

The project's main objective is to use a referral use case to profile, validate, and present data elements relevant to exchanging health information at the PHC level of care. Profiling is the strategy for defining FHIR models by domesticating the international core standard through specific use cases by structured authoring and publishing. Global best practices facilitate digital health information exchange for better care by using standardized data. Digital tools can only communicate using data in certain formats (eg, XML or JSON), organized in an agreed structure [23].

Methods

Overview

We reviewed paper referral forms and surveyed frontline health workers, drawing inspiration from similar work conducted by Odisho et al [24]. We checked how consistent the referral data sets were. Aggregated referral data sets were then mapped to

and FHIR extensions profiled. We also modeled data types and cardinalities, including references to other profiles, resources, and terminology binding to ICD-10.

Stakeholder Interviews and Data Set Identification

We established the research focus by addressing the data flow in the maternal and child health information flow value chain in Ebonyi State, Nigeria. Nigeria has between 28,000 and 36,000 health facilities overall. Ebonyi state is one of the 36 subregional governments in Nigeria with 171 “functional” PHC centers and 13 general hospitals [25]. Although from the National Health workforce Registry, there are up to 830 health facilities in the state [26]. Based on our use case, a strategic point of data exchange among multiple PHC centers or PHC centers and hospitals is the referral chain for pregnant women. We used the purposeful snowball sampling technique to identify health care providers in Ebonyi State and share the survey questionnaire.

We sent out questionnaires and a request for a copy of “referral forms” was used for 24 health workers in their respective health facilities in Ebonyi State. Between June 10 and 17, 2019, all 24 health workers completed and returned the questionnaires, and only 3 provided referral paper forms. Respondents were a mix of medical doctors, midwives, and nurses, as shown in Table 1.

We acknowledge the possibility of selection bias, and, for instance, these providers were mostly from health facilities in Abakaliki, the state capital and the main metropolitan city. We consider this bias insignificant as we measured consistency or variation in referral data sets among providers, which was significant. Each provider was from a different health facility (except the tertiary hospital doctors).

The structured questionnaire used asked the following questions:

1. What information is shared when referring-out a pregnant woman?
2. What information is expected when referring-in a pregnant woman?
3. What forms are used, and what are the contents of these forms?
4. What information is the client or caregiver expected to know or have at the recipient end?

Table 1. Distribution of respondents and their roles.

Workstation	Roles, n		
	Nurse	Midwife	Doctor
Primary health care clinics	3	3	4
Secondary health care (general hospitals)	4	2	3
Tertiary health care (teaching hospital)	0	1	3
State Ministry of Health	0	1	0

Profiling, Validation, and Publishing

We started by creating a default patient profile with no extension by using the Forge tool and uploading it on the simplifier.net web interface under the BlockMom project for validation [27]. This first step was to confirm that the example of the base

patient resource instance is FHIR-conformant. From the stakeholder interviews, we aggregated information data sets. We then mapped them to the standard patient resource to create a referral resource with extensions that capture all the identified data points. We further created the bare XML schema for easy file-based resource instance validation. The codes in XML and

JSON formats are freely available on the GitHub directory [28]. Our steps and tools used are shown in Figure 1.

We modeled the FHIR referral use case profile of information flow regarding pregnant women from one PHC center—for example, PHC center 1 to PHC center 2—or general hospital.

Afterward, these resource mapping outputs were then synthesized into JSON and XML machine-readable data formats on the basis of FHIR resources for antenatal referral. We have further indicated the resources category affected by our referral bundle in green in Figure 2.

Figure 1. Steps to profiling and publishing the Fast Healthcare Interoperability Resource.

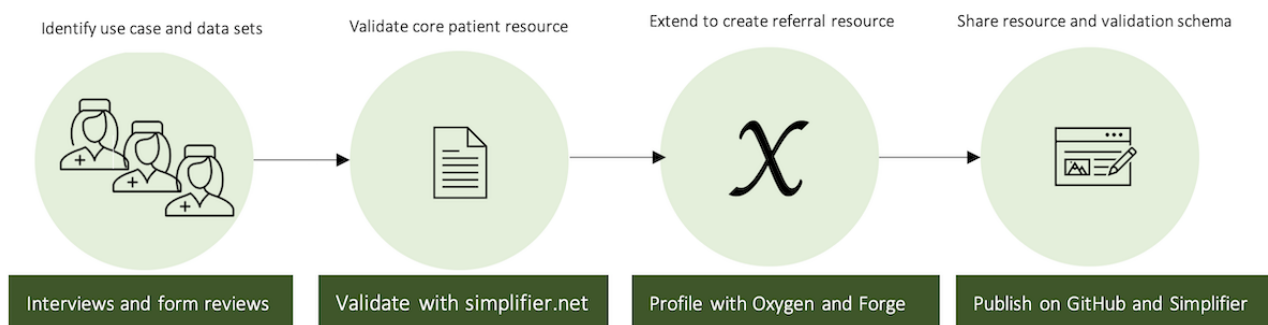

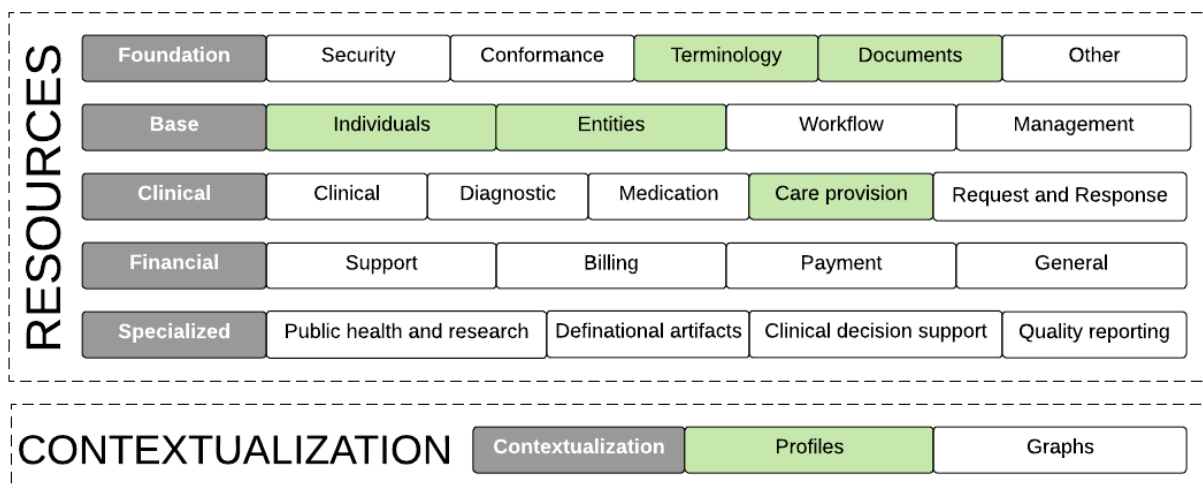

Figure 2. Resources considered for the Referral bundle.

Binding With ICD-10 Terminology

An example referral use case is described in Sierra Leone’s digital health strategy 2018-2023, “Table 2- Scenario: The vision in Practice” [12]. Asuma, a pregnant woman described in the use case, was referred to the clinic from the community by a roaming community health extension worker. See page 25 of Sierra Leone’s national digital health strategy for more information on this use case. In ICD-10, the “Personal History of malaria” code is Z8613. The code allows for unique identification in any information system using the same coding system, thus distinguishing this from, say, B500, which

represents “Plasmodium falciparum malaria with cerebral complication,” which is a case of complicated malaria with intermittent coma. We analyzed the 21 chapters of ICD-10. Table 2 highlights those that are most relevant for in-depth study when designing a Maternal and Child Health (MNCH) information management system [10].

Code O98.6 represents “Protozoal disease complicating pregnancy, childbirth, and the puerperium.” This is synonymous with “Malaria in pregnancy” or “Maternal malaria during pregnancy,” both not explicitly coded in ICD-10 [29]. “Malaria in pregnancy” is the scenario described in the Sierra Leone MNCH digital health use case from the preceding paragraph.

Table 2. Key Maternal and Child Health chapters of the International Classification of Diseases, Tenth Revision coding system.

Chapter	Description	Code range
XV	Pregnancy, childbirth, and the puerperium	O00xx to O99xx
XVI	Certain conditions originating in the perinatal period	P00xx to P96xx
XVIII	Symptoms, signs, and abnormal clinical and laboratory findings not elsewhere classified	R00xx to R99xx
XX	External causes of morbidity and mortality	V01xx to Y98xx
XXI	Factors influencing health status and contact with health services	Z00xx to Z99xx

Ethics Consideration

This study was exempted from ethics approval by the University of Malta ethics review board.

Results

Survey Outputs

In addition to responses from these surveys, 3 different referral forms for referral tracking among pregnant women used in the state were made available by respondents. The forms were then mapped to survey questions to generate a unified form with a union of content from the 3 forms in [Table 3](#).

Survey responses from care providers varied widely and included extraneous information than in the referral forms. Based on the 24 health care providers' responses for the first 2

questions—"What Information is shared when referring a pregnant woman?" and "what information is expected when receiving a pregnant woman?"—none of the responses matched for all respondents. In response to question 3—"what forms are used?"—3 respondents said "referral letter" and 7 said "referral form." Three respondents noted that referral forms varied by health institutions, while one indicated that they do not use any forms for referral. Other forms listed by respondents are the consent form, investigation form, chemistry form, hematology form, results form, ultrasound form, laboratory form, radiology form, and virology form. In response to the question, "What information is the client, or their caregiver expected to have or know?" At the same time, 2 respondents said "null," the rest of them listed information that completely varied. When we mapped the aggregated responses with the form details from [Table 3](#), the list of data sets will be similar to that shown in [Textbox 1](#).

REST and FHIR

Our artifact assumes the use of the REST paradigm for information exchange. In this section, we explain the technicalities of REST. REST is the foundation for the scale of the internet as we know it today [30]. While FHIR supports many different communication paradigms, REST is responsible for its popularity. The REST paradigm leverages the HTTP protocol with the simple client-server architecture with variants of catch-less/catching, stateless/stateful, or n-tired architectures and hierarchies. For further technical details of these ICT concepts, please refer to Thomas Fielding's thesis introducing REST in 2000 [30].

Similar to traditional REST, FHIR's REST paradigm considers entities and concepts as resources. Each of the resource instances is unique and is represented using a uniform resource identifier (URI). The URI may also be used for locating the resource if it points to the location on a given server (in which case, it can also be referred to as URL). There are a finite number of ways a client can manipulate entities and concepts (resources) located in an FHIR server using REST requests of get, put, post, delete, options, head, trace, and connect.

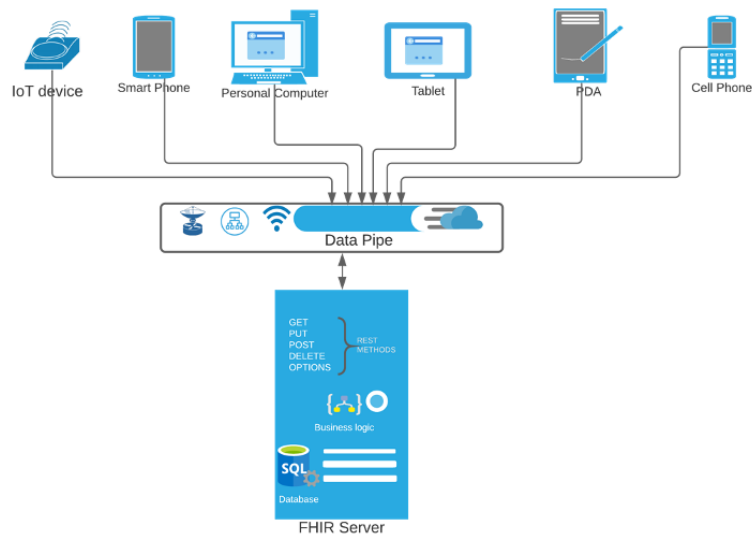

The server responds to the client's HTTP requests after performing internal business logics unique to each server

implementation. The clients will receive the same response for similar HTTP requests irrespective of whether they are for a mobile app, web browser, computer application, or embedded device, as shown in Figure 4.

Both the client and server use the header and body components of the HTTP request or response for their information exchange, depending on the HTTP method used. The server always returns a status code indicating success or failure or a variant of either with further detail for each request. FHIR servers can use the OperationOutcome resource to provide structured details of request failure to the clients in the event of failure. There are over 100 different FHIR resources [31]. When the request succeeds, the client is sent the resource by the server.

Methods may or may not be allowed (or even implemented) by the server for a particular resource and may be specified by the client's server response. The header has many attributes that can be set, for instance, to indicate the data type it accepts, authorization credentials, connection, content encoding, caching, and more. The content-type attribute can indicate the resource as either XML or JSON format—both native to FHIR. FHIR, similar to REST, is an open standard and thus aligns with key principles of digital development [32].

Figure 4. A typical client-server REpresentational State Transfer interface. FHIR: Fast Healthcare Interoperability Resource; IoT: Internet of Things; PDA: personal digital assistant.

Discussion

Principal Findings

We could not use the core FHIR resource because it did not contain all the data sets as aggregated in Figure 4. To add and extend the outstanding data sets, FHIR designers provide for and allow extensibility using profile extensions. FHIR contributors and balloting-process use the 80-20 rule to determine what makes it into the core FHIR resource [33]. It is understandable if there are no contributions from Nigeria or many other LMICs because they are often not represented at HL7 FHIR balloting. Our referral form reviews and data set mapping also lay credence to our hypothesis that the core patient resource needs an extension for our use case.

Our study shows that traditional paper referral forms currently in use vary widely in Nigeria's PHC system as illustrated in the word art in Multimedia Appendix 1. The implication is that interinstitution care coordination will remain suboptimal as much of the essential information will be missing. This work will help policy makers and PHC centers in Nigeria understand the need to standardize or enforce agreed referral standards. In addition, the steps we have outlined in this work will help guide institutions as they standardize or adopt FHIR.

While the surveys were conducted before the COVID-19 pandemic, their findings are relevant for continued functioning of the PHC centers even amid and after the COVID-19 pandemic. The pandemic has exposed the weakness of health systems and shown the importance of interconnected and interoperable health systems. Emerging technologies are being proposed in response to the pandemic [34] and new models are emerging for health information interoperability [35] in LMICs. Even when PHC centers are digitized, referrals among health facilities in many LMICs with different software vendors do

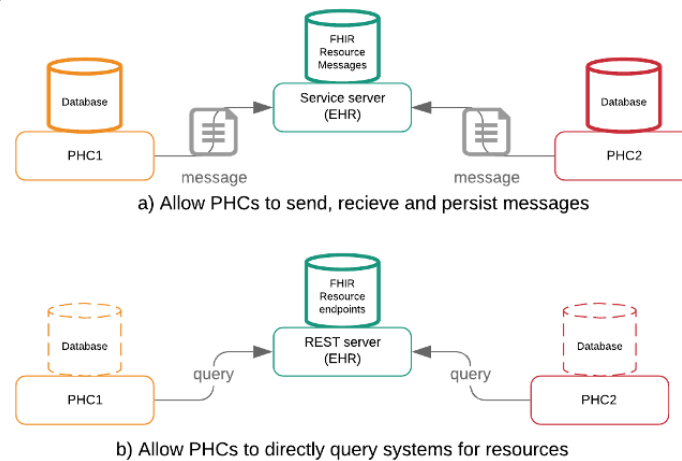

not happen seamlessly. Our research shows that referral practices for pregnant women varied significantly even in urban settings.

The key output of this study is the FHIR referral resource artifact, which will help vendors design consistent referral data sets and ensure out-of-the-box interoperability. This resource remains broad and from the core patient resource. FHIR allows for organizational or national extensions and adaptations [33]. Health authorities in many LMIC countries will benefit from standardizing and exposing its required referral data model for Women and Child Health, which encompasses MNCH [24]. Publishing a public FHIR specification that can be leveraged by MNCH solution implementers will help simplify interface implementations.

We here illustrate that our approach differs from traditional health information exchange approaches. Figure 5A shows the traditional document- and message-based information (which is still supported by FHIR) where both databases are required to retain the messages being exchanged. Figure 5B shows that the end point query approach using REST method calls is used to access or share FHIR resources being exchanged.

Women continue to die owing to preventable causes at the point of giving birth. Many of these deaths happen before, during, and after delivery. In addition, maternal health has been highlighted in some LMIC national digital health strategies (ie, Nigeria and Sierra Leone) as a priority health area [11]. Furthermore, our BlockMom model used the ICD terminology over the SNOMED-CT model owing to its favorable pricing license. For instance, SNOMED licenses are based on the number of health facilities using the terminology service, though there are requirements to apply for a waiver for certain implementations in LMICs. Moreover, the model's deliberate focus on FHIR over other HL7 or ISO standards was because it is free and open for adaptation, adoption, and testing in LMICs.

Figure 5. Fast Healthcare Interoperability Resource (FHIR) paradigms in a 2–public health care (PHC) system referral exchange scenario. EHR: electronic health record. REST: REpresentational State Transfer.

Limitations

We used on-file schema and the ICD-10 version 2021 text file to validate profiled resources. Even though the bare schema was provided in the GitHub directory, standard practice would be to set up an FHIR server for this purpose. This is the focus of our future study. Although many mobile-based solutions are available in PHC centers in LMICs, these profiles can only be used with a mobile-based solution that uses patient-specific information rather than aggregated information, as is the case with many community health worker information systems. Furthermore, ICD-11 2022 release has just been launched by the WHO, which emphasizes following the profiling process and not necessarily the output [36].

We also noted that unique identification metrics and characteristics, as explained by McFarlane et al [37] and Chukwu [38], were not part of the data sets proposed and made available during referral. This aspect was profiled as part of the FHIR resource. Besides, this may be the case as the patient-required abridged historical information is assumed to be comprehensive enough. Nevertheless, in a digital platform where a unique identifier is important, this assumption will not hold true. We assumed cryptographically generated unique identification mechanisms in this prototype.

A key limitation of our survey approach was that we did not prevalidate the questionnaire before use. In addition, our

sampling methodology used a snowball strategy that targeted health workers from the most urban part of Ebonyi State, Nigeria. We are aware and acknowledge that this may seem inherently biased. However, our aim for the survey was to determine consistency or otherwise of the referral data sets, which we determine to vary widely across all respondents. In addition, since Abakaliki is the state capital and the main metropolitan city in the state, it is expected to have a standardized referral form; however, it does not.

Conclusions

Questionnaire responses were collected from health care providers, and referral forms from health institutions in Nigeria were reviewed. Survey responses and fields of referral forms show variability in referral data sets across respondents and forms. Here we have made a case for FHIR, an emerging health care data interchange standard, and have profiled a referral resource for PHC information exchange targeted at LMICs. This paper describes the profiling steps, including key questionnaire responses and mapping of referral forms. We have proposed the use of ICD-10 terminology and used file-based schema validation. The methodology and artifacts will be invaluable for the research and implementation community targeting LMICs. Our future work will set up the server and configure the appropriate binding for this and other resources.

Abstract

Background: The COVID-19 pandemic increased the availability and use of population and individual health data to optimize tracking and analysis of the spread of the virus. Many health care services have had to rapidly digitalize in order to maintain the continuity of care provision. Data collection and dissemination have provided critical support for defending against the spread of the virus since the beginning of the pandemic; however, little is known about public perceptions of and attitudes toward the use, privacy, and security of data.

Objective: The goal of this study is to better understand people's willingness to share data in the context of the COVID-19 pandemic.

Methods: A web-based survey was conducted on individuals' use of and attitudes toward health data for individuals aged 18 years and older, and in particular, with a reported diagnosis of a chronic health condition placing them at the highest risk of severe COVID-19.

Results: In total, 4764 individuals responded to this web-based survey, of whom 4674 (98.1%) reported a medical diagnosis of at least 1 health condition (3 per person on average), with type 2 diabetes (n=2974, 62.7%), hypertension (n=2147, 45.2%), and type 1 diabetes (n=1299, 27.4%) being most prominent in our sample. In general, more people are comfortable with sharing anonymized data than personally identifiable data. People reported feeling comfortable sharing data that were able to benefit others; 66% (3121 respondents) would share personal identifiable data if its primary purpose was deemed beneficial for the health of others. Almost two-thirds (n=3026; 63.9%) would consent to sharing personal, sensitive health data with government or health authority organizations. Conversely, over a quarter of respondents (n=1297, 27.8%) stated that they did not trust any organization to protect their data, and 54% (n=2528) of them reported concerns about the implications of sharing personal information. Almost two-thirds (n=3054, 65%) of respondents were concerned about the provisions of appropriate legislation that seeks to prevent data misuse and hold organizations accountable in the case of data misuse.

Conclusions: Although our survey focused mainly on the views of those living with chronic health conditions, the results indicate that data sensitivity is highly contextual. More people are more comfortable with sharing anonymized data rather than personally identifiable data. Willingness to share data also depended on the receiving body, highlighting trust as a key theme, in particular who may have access to shared personal health data and how they may be used in the future. The nascency of legal guidance in this area suggests a need for humanitarian guidelines for data responsibility during disaster relief operations such as pandemics and for involving the public in their development.

KEYWORDS

COVID-19; data; data ethics; privacy; sharing; ethics; attitude; perception; data sharing; survey; understanding; security; health data; willingness

Introduction

The World Health Organization declared the COVID-19 outbreak a public health emergency on January 30, 2020; after 6 weeks, it was categorized as a pandemic [1]. Certain groups of people are particularly likely to have serious or severe symptoms of COVID-19 [2]. Preliminary data suggest that people with obesity are at an increased risk of severe COVID-19 [3]. Type 2 diabetes mellitus and hypertension are the most common comorbidities in patients with COVID-19 [4]. According to several reports, including those from the Centers for Disease Control and Prevention, patients with type 2 diabetes are at a greater risk of death than those without type 2 diabetes [5].

Digital health technologies are being used in the fight against COVID-19 [6]. Global health care systems have seen an influx in the incidence of the same novel condition, and the contagious nature of the condition has driven the shift to remote medicine. Many health care pathways have been rapidly digitalized with face-to-face services seeing a drop in usage [7]. This has increased the collection, sharing, and use of data in digital form. Technology is used for remote monitoring, general practitioner consultations, providing structured education, and tracking the spread of disease. As well as the technologies themselves, the data they generate are also useful [8].

Timely, secure, and reliable data access and sharing are critical to understanding COVID-19, controlling its spread, improving the effectiveness and acceptance of government policies, and fostering global cooperation in the race to develop and distribute effective therapies and vaccines. During the COVID-19 pandemic, data are being rapidly shared to understand the location of infections, confirmed cases, recoveries, and deaths. The main data points of interest for this are geolocation and biometric data, both of which are available from users' mobile devices. However, there are serious concerns regarding the objectivity and accuracy of these data, and their utility has been compromised by inconsistent collection and definitions. This, in turn, feeds back into individuals' trust in the collecting organizations and in the extent to which their shared data will actually be used to help others, and this needs to be matched by the trustworthiness of those organizations.

During an unprecedented time, some digital responses to the crisis have precipitated novel data governance and privacy challenges [9]. Governments are taking extraordinary measures to track, trace, and contain the spread of COVID-19 by transitioning to digital technologies and advanced analytics to collect, process, and share data for effective frontline responses. Government-mandated apps are bringing the fight against COVID-19 onto users' devices and have generally adopted pragmatic and contextualized approaches, but they have prompted concerns about security and privacy and the control

and use of data beyond the pandemic [10]. There is a trade-off between effectiveness and privacy, centralized and decentralized implementations, and the links to trace and isolate policies.

While the exceptional measures implemented in some countries may prove effective in limiting the spread of the virus, some have provoked controversy in terms of privacy and other fundamental rights, particularly when they lack transparency and public consultation [11]. In South Korea, the specificity of publicly available anonymized data raised privacy concerns when some researchers found that data trails were so detailed that individuals could be identified [12]. In Italy, the Department of Prevention released specific guidelines on the application of the European Union's and national data privacy rules in the context of the COVID-19 pandemic [13]. Similarly, the United Kingdom's Information Commissioner's Office, an independent authority set up to uphold information rights in public interest, confirmed that there would be no regulatory action taken against organizations that fail to meet the data protection standards if noncompliance results from the COVID-19 pandemic [14,15]. In China, new arrivals to the country are tested for COVID-19, instructed to download a government-mandated app, and wear a wristband that is linked to the app to monitor movement with a technology similar to that used in Singapore [16,17]. The United Kingdom's Track and Trace app was the center of a debate on centralization of data [18]. On May 5, 2020, the Government revealed its first attempt at a contact-tracing app, but 6 weeks later admitted that the app was flawed and it would switch to a more privacy-preserving model devised by Apple and Google [19,20]. Transparency is a key theme. One of the most common misconceptions about the United Kingdom's Track and Trace app was that it could allow users to specifically identify and map COVID-19 cases among their contacts and in their vicinity [21].

This study seeks to understand the opinions of British people with long-term health conditions on the themes of data privacy and security, data ethics, and data misuse and to assess the possible trade-offs in data utilization to manage a crisis such as the COVID-19 pandemic [22]. It is important to understand the concerns of people with long-term health conditions such as type 2 diabetes and hypertension as these conditions have been shown to be key risk factors in the progression and prognosis of COVID - 19 [23,24].

Methods

Study Design and Setting

A web-based survey study was conducted with a mixed methods design conforming to the checklist for reporting results of internet electronic surveys [25]. An email invitation to participate, which included a weblink to the survey, was sent to 11,213 people who had consented to be contacted for research opportunities.

Quantitative information (closed and multiple-choice questions) was collected on four topics: (1) demographic characteristics, (2) COVID-19 symptoms and clinical diagnoses, (3) sharing and privacy of pre- and post-COVID-19 health data, and (4) COVID-19 lockdown behaviors. Responses from the final topic are not included in this analysis.

The survey contained 31 questions: 26 closed questions, 1 open question, and 4 demographic questions. Questions on sharing and privacy of pre- and post-COVID-19 health data were answered on a 5-point Likert scale with responses ranging from *strongly disagree* to *strongly agree* or from *not concerned at all* to *very concerned*.

Participants

People aged ≥ 18 years who had joined the Diabetes.co.uk community were surveyed. The survey commenced with 1 screening question: "Do you consent to take part in the study?" Respondents who consented went on to complete the survey.

Procedure

Data collection occurred between July 6 and August 31, 2020. The survey was administered through the Jisc Online Surveys software and comprised closed, open, and multiple-choice questions. The survey was designed to elicit individual responses to questions about retrospective data use and privacy prior to the COVID-19 pandemic and prospective use during the COVID-19 pandemic.

It is intended to have multiple windows of data collection for several reasons: people's recollections of pre-COVID-19 attitudes may be unreliable, and changes in the course, apparent seriousness, and confidence in scientific understanding of the pandemic will have evolved.

The type and wording of each question was composed by the research team. The order of questions was not randomized. The survey followed a predetermined logic where contingent questions were included or automatically skipped on the basis

of responses. Qualitative data were collected with 1 open question exploring what respondents would like to see happening: "What would you like to see happen to improve the COVID-19 situation?" (question 30).

Analysis

We exported all data from Jisc and conducted data analysis using SPSS (version 22; IBM Corp). We conducted descriptive data analyses of sample distributions and characteristics. Pearson *r* correlation coefficients were used to determine the relation between prior data-sharing behavior and attitudes toward data-sharing activity in the context of the COVID-19 pandemic. The data from the open question were read through and then categorized into themes.

Ethical Considerations

Ethics approval was obtained from the Human Research Ethics Committee of the University of Warwick (BSREC 144/19-20). Web-based informed consent was required before the survey could be accessed.

Results

Survey Respondents

Of 11,213 people emailed, 10,705 clicked through to the survey; in total, 4764 gave their consent and began the survey. As indicated in [Table 1](#), all of them completed the survey and were included in the analysis. All respondents were located in the United Kingdom. In total, 2287 (48.0%) respondents were male and 3083 (64.8%) were aged between 55 and 74 years. A total of 115 (2.8%) respondents reported having been clinically diagnosed with COVID-19. The majority of patients ($n=4674$, 98.1%) reported a prior clinical diagnosis of at least one health condition (on average 3 per person). There was a high prevalence of individuals living with type 2 diabetes ($n=2974$, 62.7%), hypertension ($n=2147$, 45.2%), type 1 diabetes ($n=1299$, 27.4), obesity ($n=892$, 18.8%), and depression ($n=871$, 18.3%). Respondent demographics are shown in [Table 1](#).

Table 1. Respondent demographics (N=4764).

Characteristics	Respondents, n (%)
Gender

Other	44 (0.9)
Chinese, Japanese, or East Asian	7 (0.1)
Prefer not to say	132 (2.8)

^aFrequently occurring health conditions selected.

^bRespondents selected multiple statuses; for example, full-time employed and furloughed.

COVID-19 Symptoms and Clinical Diagnosis

Of the 4764 respondents who completed the survey, 494 stated they had had symptoms of COVID-19. The most common symptoms were the following: a continuous cough (n=467, 94%), fever (n=325, 65.7%), difficulty breathing (n=384, 77.7%), and loss of taste (n=324, 65.5%). In total, 384 (77.7%) respondents reported another symptom, predominantly fatigue (16.4%).

Of those reporting symptoms, 111 (22.5%) reported a clinical diagnosis of COVID-19. Of these respondents, 73 (63.5%) reported that their symptoms were severe or very severe. In total, 26 (22.6%) respondents reported that their symptoms were not severe at all. All respondents who reported a clinical diagnosis of COVID-19 reported at least one symptom, including loss of smell or taste (63.1%), fever (62.2%), difficulty breathing (61.3%), or continuous cough (53.2%).

A total of 131 (2.8%) respondents reported that a household member had been tested and was clinically diagnosed with COVID-19.

Sharing and Privacy of Pre-COVID-19 Health Data

Prior to the COVID-19 pandemic, almost half of the respondents (n=2313, 49.2%) agreed or strongly agreed that they often

consented to anonymized sharing of their private health data, while only 608 (13%) respondents often consented to sharing of private health data without anonymization. Two-thirds of respondents (n=3113, 66.7%) disagreed or strongly disagreed with sharing their private health data without anonymization. Similarly, 3121 (66.3%) respondents would share their data if it keeps other people healthy; 3026 (63.9%) respondents agreed or strongly agreed to sharing private health data with the government or health authority; 1911 (40.7%) respondents agreed or strongly agreed to share their private health data with services that provide health services to the National Health Service (NHS) such as the Low Carb Program and PushDoctor. Only 232 (5%) participants agreed or strongly agreed to share private health data with social media platforms. Over a quarter of respondents (n=1297, 27.8%) agreed or strongly agreed that they did not trust *any* organization to protect their private health data. Just under a quarter of respondents (n=1094, 23.5%) agreed or strongly agreed that they were not concerned by the implications of sharing private health data. General health data-sharing responses are shown in [Table 2](#). Respondents who reported that they felt “neutral” in response to the statements were excluded.

Table 2. General health data sharing responses.

Question	Disagree or strongly disagree, n (%)	Agree or strongly agree, n (%)
I often consent to share my private health data with any organisation as long as it is anonymised	1273 (27.1)	2313 (49.2)
I often consent to share my private health data to any organisation without anonymisation	3113 (66.7)	599 (13)
I am not concerned about the implications of sharing my private health data	2528 (54.2)	1094 (23.5)
I don't trust any organisation to protect my private health data	1541 (33.8)	1297 (27.8)
I'm happy to share my private health data if it helps keep other people healthy	526 (11.2)	3121 (66.3)

Sharing and Privacy of Post-COVID-19 Health Data

Over half (n=3026, 63.9%) agreed or strongly agreed to share their private data with the government or health authority if asked; 1911 (40.7%) respondents would happily consent to share their private data with services that provide health services to the NHS such as the Low Carb Program and PushDoctor, if asked. Only 232 (5%) participants agreed or strongly agreed that they would consent to sharing private data with social media if asked.

Almost half of respondents (n=2228, 47.1%) were concerned or very concerned about who would have access to their personal health data in the context of the COVID-19 pandemic and 2310

(49.1%) respondents were concerned or very concerned about how their personal health data may be used in the future. Almost two-thirds of respondents (n=3054, 65%) were concerned or very concerned around the legislation of data misuse.

Just over a third of respondents (n=1563, 33.4%) would consent to share their private data with any organization if it was providing essential COVID-19 support services such as the supermarkets, pharmacies, and banks. Responses toward the use of post-COVID-19 patient data is shown in [Table 3](#), along with the sentiment toward the use of patient data in the context of the COVID-19 pandemic, and [Table 4](#) shows the sentiment toward future use or misuse of data collected and used under the provisions of the COVID-19 pandemic.

Table 3. Responses toward the use of post–COVID-19 patient data.

Question	Disagree or strongly disagree	Agree or strongly agree
I would happily consent to share my private health data with the government or health authority	728 (15.4)	3026 (63.9)
I would happily consent to share my private health data with social media e.g Twitter, Facebook, Google	4023 (85.9)	232 (5)
I would happily consent to share my private health data with services that provide health services to the NHS ^a such as Low Carb Program, PushDoctor, Babylon Health	1351 (18.8)	1911 (40.7)

^aNHS: National Health Service.

Table 4. Sentiment toward future use or misuse of data collected and used under the provisions of the COVID-19 pandemic.

Question	Not concerned at all	Concerned or very concerned
In light of COVID-19, how concerned are you about who would have access to your personal health data?	1138 (14)	2228 (47.1)
How concerned are you about how your personal health data may be used in the future?	1162 (24.7)	2310 (49.1)
How concerned are you around the legislation of data misuse?	644 (13.6)	3054 (65)

Prior Willingness to Share Data

Correlations between retrospective data-sharing that happened in the context of generalized concerns and attitude changes associated with the course of the pandemic were determined. Changes were not linked to any specific studies, policies, or measures. There were strong correlations in the attitudes of people exhibiting high levels of concern about future uses of shared data and concerns about access ($r_{4685}=0.816$; $P<.001$). There was a strong correlation between people exhibiting attitudes of concern that firmer legislation for data misuse is needed and concerns about future repurposing and reuse of personal health data collected during the COVID-19 pandemic ($r_{4663}=0.636$; $P<.001$). The Pearson r correlation coefficient as a normalized measure of the strength of a possible linear correlation, lying between -1 and $+1$. The Pearson r correlation coefficient measures nonlinear correlations (eg, when extreme views are highly correlated but more moderate ones are more independent).

Respondents agreed to share their personal data with roughly the same parties prior to the COVID-19 pandemic and within the context of the COVID-19 pandemic; governments and health authorities ($r_{4710}=0.762$; $P<.001$), health service providers such as the Low Carb Program and PushDoctor ($r_{4662}=0.783$; $P<.001$), and social media platforms such as Twitter, Facebook, and Google ($r_{4662}=0.736$; $P<.001$).

COVID-19 News and Information

Of the 4764 respondents, 2666 (56.1%) were concerned that they may be receiving misinformation about COVID-19 from trusted sources, 1079 (22.7%) were not concerned (genuinely unconcerned and those who feel that they are in control of the consumption of news and information), and 1006 (21.2%) had never considered it.

In total, 4237 responded to the open-ended question of what they would like to see happening to improve the COVID-19 situation. The majority of respondents shared a single response:

1348 (31.8%) stated they would like to see a reliable vaccine and treatment, 884 (20.8%) stated they would like to see balanced information from the government, and 485 (11.4%) wanted to see stricter measures to prevent the transmission of COVID-19.

Discussion

Principal Findings

Our study provides insights into public perception and attitudes toward the use of identifiable health data in the context of the COVID-19 pandemic; in particular, the perspectives of those living with chronic, long-term health conditions, with an average of 4 health conditions reported per respondent.

Our study suggests that data sensitivity is highly contextual. A significant proportion of people felt that their own attitudes have shifted as a result of the COVID-19 pandemic. More people reported being comfortable with sharing private health data with any organization during rather than before the COVID-19 pandemic. In order, people appear to trust their data with the government, health organizations, and social media. There is significant distrust of private health data use by social media organizations (eg, Twitter, Facebook, and Google) even though social media is used as a channel for communication by people caught up in crises such as emergency relief operations after earthquakes, tsunamis, and typhoons; where it provides a trusted and highly salient source of information about what is happening and what to do [26,27]. This is surprising as although users worldwide report that privacy and use of personal data are important issues, most rarely make an effort actively to protect these data and often even give them away voluntarily on social media where even innocuous data can reveal sensitive health information when suitably processed [28,29]. People treat data revelation and sharing differently depending on the perceived sensitivity of the data, and the sensitivity attached to different types of data is neither stable nor uniform.

When examining the correlations between retrospective views of data-sharing behavior and comfort regarding data-sharing in

the context of the COVID-19 pandemic, individuals were comfortable (or not) in sharing personal data with the same organizations prior to and during the COVID-19 pandemic, suggesting that COVID-19 has not drastically shifted people's willingness to share or withhold their personal data. This may be because attitudes have shifted both retrospectively and prospectively and also depends on whether people accurately remember and report their past views and actions. One of the strongest correlations observed in the analysis was between high levels of concern about the requirement for stronger legislation protecting individuals from data misuse and future repurposing and reuse. This highlights the need for improved communication, transparency, and potentially stronger regulation on how such data may be repurposed in the future, who will be accountable for inappropriate use of data, and a commitment to cease or reverse exceptional uses of data when the crisis is over. Individuals' data rights are protected by law in regulation such as General Data Protection Regulation 2018 in Europe and Health Insurance Portability and Accountability Act in the United States, which make clear the scope, purpose, and time limitations of data usage [30,31]. Concerns may therefore reflect ignorance of existing rules, doubts over enforcement, or a belief that current legislation does not go far enough (for instance, in the requirement of erasure after 3 years rather than a shorter time duration).

A key theme emerging from the literature that was confirmed in this study is the importance of trust [32-34]. Over a quarter of respondents stated they did not trust any organization to protect their data, over half reported concern about the implications of sharing personal information, and almost two-thirds were concerned about data misuse regulation not being strict enough. When asked during the pandemic (the United Kingdom's first wave), almost half of respondents were concerned about who would have access to their personal health data and a similar number were concerned about how their personal health data might be used in the future. This is consistent with prior research suggesting that public involvement in data policy is crucial to bolstering trust and provides support for legislation that is more enforceable [35]. Attitudes may have been perturbed by news stories relating to cybersecurity and privacy and by policy announcements (eg, around Huawei, the Online Harms Bill, etc) [36,37].

Although there are no directly comparable studies, the results from this study complement prior research on public perceptions about COVID-19 and data-sharing. Data privacy and protection are important concepts [38]. Data policy tends to address human concerns about privacy by making rules about data protection; however, this can lead to category errors since data protection can undermine privacy.

Willingness to share anonymized personal health information varies depending on the degree to which the receiving body is trusted and the uses to which the data will be put [39,40]. The more commercial the objectives of the receiving institution appear, the less respondents are willing to share their personal health information. This in turn suggests that anonymization's disadvantages (in terms of confirming data and correlating shared with other data) might be offset by better (wider, deeper, and more accurate) sampling leading to greater validity of

results. Further evidence comes from the interaction (or correlation) between these attitudinal responses and other characteristics, meaning that nonanonymized collection might lead to biased results.

Virus tracking apps are used at scale by governments; however, concerns about transparency, privacy, and morality remain [41,42]. There has been substantial research into the challenges involved in the digital response to the COVID-19 pandemic and proposed methodologies for the ethical design and use of digital public health tools [43,44]. Clear and effective data ethics is both a moral and a practical obligation. The nascency of legal guidance in this area combining ethics, law, and humanitarian impulses suggests the requirement for humanitarian guidelines for data responsibility during global crises such as pandemics. Therefore, rather than recalibrating the expectations of people with regard to their own privacy, the requirements for the use of data should be broader and more comprehensive as ethically collected big data could prove to be extremely useful in the prediction, monitoring, and mitigation of pandemics such as COVID-19 [45].

Strengths and Limitations

Despite the importance of the findings reported here, it is important to note that this study had several limitations. Conducting this study via a web-based survey carries a risk of response bias, simply because the respondents are likely to be more technology-savvy than the general population. However, the population studied (those with chronic health conditions) is of interest as these participants have a degree of awareness and the ability to self-manage their condition that is not (yet) typical of the population at large, and this sheds light on how policies that raise awareness may lead to greater effectiveness in terms of uptake of technical solutions and effectiveness of public health advice and other policies.

Participants were asked to rate retrospectively their perceptions of data sharing prior to the COVID-19 pandemic; these ratings may be inaccurate owing to faulty memories and response bias. There is some ambiguity between what people (now) thought they would have done had they been asked and how they responded to actual requests for consent to data-sharing. In particular, one could disagree with a statement like "I often consent to share my private health data to any organisation without anonymisation" simply because one rarely recalls being asked to share (even without a principled objection to such sharing should the occasion arise). In addition, the phraseology of the questionnaire refers to data that have either been anonymized or are identifiable. This dichotomous representation leaves out pseudonymized data. The participants were not educated about the concepts of anonymization prior to answering the questions potentially allowing ambiguity of the terminology to cause a strong bias in the response behavior.

In addition, the sample is concentrated on people with diabetes and those with other diagnosed health conditions, rather than the general population. This is a strength as well as a weakness as it focuses on a population with particular circumstances and perspectives and one that may be more representative of a post-COVID-19 population that has been sensitized to a continuing health concern than the current population. This in

turn means that a comparison of these findings with a similar survey of the general population can shed light on the potential impact of awareness-raising policies.

Another strength of the study is the high number of respondents who completed the questionnaire. In total, 4764 people participated in the study. This provides a unique insight into the views of a population deemed as being at the highest risk of severe disease and mortality related to COVID-19 [46]. There was a skew in the representation of the demographic distribution of individuals in the nationwide population of people living with chronic health conditions, since White people were overrepresented in our sample (n=4434, 93.4%) but not overrepresented among those with diabetes more generally. While our survey focused on those with diabetes, the results provide novel insight into concepts crucial for societal trust in data use and sharing initiatives.

While the study design did not allow us to ascertain whether technology use itself was correlated with higher acceptance of data-sharing, such an analysis is possible and will be an important topic for future research.

The study's findings suggest potential targets for further study and possible considerations for policy makers. There are two main implications: storing and processing data in

pseudonymized form and emphasizing the use of synthetic data (generated from models estimated from real data but not involving any actual or identifiable human beings).

Understanding attitudes toward data sensitivities and trust can contribute to developing policies, improving transparency, and increasing the trust, speed, focus, and effectiveness of epidemic responses. Future practice should emphasize transparent data-sharing and privacy initiatives, while research should evaluate whether this does indeed lead to greater levels of trust and engagement. Encouraging ethical and relevant data-sharing can provide significant epidemic intelligence and support public health emergency relief operations [47].

Conclusions

Data sensitivity is highly contextual. More people are comfortable with sharing anonymized data than personally identifiable data. Willingness to share data also varied depending on the receiving body, highlighting trust as a key theme, who may have access to shared personal health data and how it may be used in the future. The nascency of legal guidance in this area suggests the requirement for humanitarian guidelines for data responsibility during disaster relief operations such as pandemics, and the requirement to involve the public in their development.

Abstract

Background: Working with eHealth requires health care organizations to make structural changes in the way they work. Organizational structure and process must be adjusted to provide high-quality care. This study is a follow-up study of a systematic literature review on optimally organizing hybrid health care (eHealth and face to face) using the Donabedian Structure-Process-Outcome (SPO) framework to translate the findings into a modus operandi for health care organizations.

Objective: This study aimed to develop an SPO-based quality assessment model for organizing hybrid health care using an accompanying self-assessment questionnaire. Health care organizations can use this model and a questionnaire to manage and improve their hybrid health care.

Methods: Concept mapping was used to enrich and validate evidence-based knowledge from a literature review using practice-based knowledge from experts. First, brainstorming was conducted. The participants listed all the factors that contributed to the effective organization of hybrid health care and the associated outcomes. Data from the brainstorming phase were combined with data from the literature study, and duplicates were removed. Next, the participants rated the factors on importance and measurability and grouped them into clusters. Finally, using multivariate statistical analysis (multidimensional scaling and hierarchical cluster analysis) and group interpretation, an SPO-based quality management model and an accompanying questionnaire were constructed.

Results: All participants (n=39) were familiar with eHealth and were health care professionals, managers, researchers, patients, or eHealth suppliers. The brainstorming and literature review resulted in a list of 314 factors. After removing the duplicates, 78 factors remained. Using multivariate statistical analyses and group interpretations, a quality management model and questionnaire incorporating 8 clusters and 33 factors were developed. The 8 clusters included the following: Vision, strategy, and organization; Quality information technology infrastructure and systems; Quality eHealth application; Providing support to health care professionals; Skills, knowledge, and attitude of health care professionals; Attentiveness to the patient; Patient outcomes; and Learning system. The SPO categories were positioned as overarching themes to emphasize the interrelations between the clusters. Finally, a proposal was made to use the self-assessment questionnaire in practice, allowing measurement of the quality of each factor.

Conclusions: The quality of hybrid care is determined by organizational, technological, process, and personal factors. The 33 most important factors were clustered in a quality management model and self-assessment questionnaire called the Hybrid Health Care Quality Assessment. The model visualizes the interrelations between the factors. Using a questionnaire, each factor can be

assessed to determine how effectively it is organized and developed over time. Health care organizations can use the Hybrid Health Care Quality Assessment to identify improvement opportunities for solid and sustainable hybrid health care.

Introduction

Background

In recent years, the use of eHealth has expanded, encouraged by the increasing pressure on health care [1,2] and growing interest in patient empowerment [3,4]. On the one hand, an aging population and an increase in chronic diseases are causing a higher and more complex demand for health care. In addition, the COVID-19 pandemic has accelerated pressure on health care [5-8]. Therefore, innovations such as eHealth are required to maintain accessibility and high quality of health care [9-12]. On the other hand, digital health technologies have significantly accelerated patients' involvement [13-16]. In line with these developments, health care organizations have intensively integrated eHealth into traditional face-to-face consultations [17]. The combination of eHealth and face-to-face consultations can be defined as hybrid health care [18,19]. A few examples of hybrid health care are telemonitoring systems for patients with chronic diseases [20,21], web-based video coaching [22,23], and direct web-based access to medical records of patients [24,25], all of which are integrated into traditional health care.

Although health care organizations are increasingly providing hybrid health care, integrating eHealth into the daily care process is challenging. Working with hybrid health care requires organizations to change the way they work. The roles of health

care providers and patients are changing, and the available resources are used differently [4,22,26,27]. Organizational structure and work processes must be adapted to ensure high-quality hybrid care [28-31]. Several studies have examined ways to promote eHealth adoption, such as increasing the adaptability of the technology or stakeholders' value [32,33]. However, it remains challenging to organize hybrid health care effectively and sustainably [17]. There is a need for further research on how hybrid health care can be improved to add value to patients and health care providers when they work with eHealth. Therefore, we recently performed a systematic literature review to optimally organize hybrid health care [17].

In the systematic literature review, the Donabedian Structure-Process-Outcome (SPO) framework was used to identify indicators related to the integration of eHealth into health care organizations [17,34-36] (Figure 1). According to Donabedian, health care quality is based on the aspects of these 3 categories and their relationships. The SPO framework and its categories are described in detail in a literature review [17].

In the literature review, we identified 111 potential indicators under the SPO categories that impact eHealth integration. The study demonstrated that 3 principles are important for successful integration. First, the patient's role must be centrally placed in the organization of hybrid care. Second, technology must be well attuned to the organizational structure and daily care process. Third, the deployment of human resources must be aligned with desired results [17].

Figure 1. Donabedian Structure-Process-Outcome framework.

Objectives

To translate the findings from the literature study into a modus operandi for health care organizations, we aimed to develop a model that can help health care organizations organize hybrid health care and identify improvement opportunities for a solid and sustainable integration of eHealth. To achieve this aim, the objectives of the concept mapping study included the following: (1) enrich and validate evidence-based knowledge from the literature review with practice-based knowledge from experts

and (2) develop an SPO-based model for organizing hybrid health care with an accompanying self-assessment questionnaire.

Methods

Concept Mapping

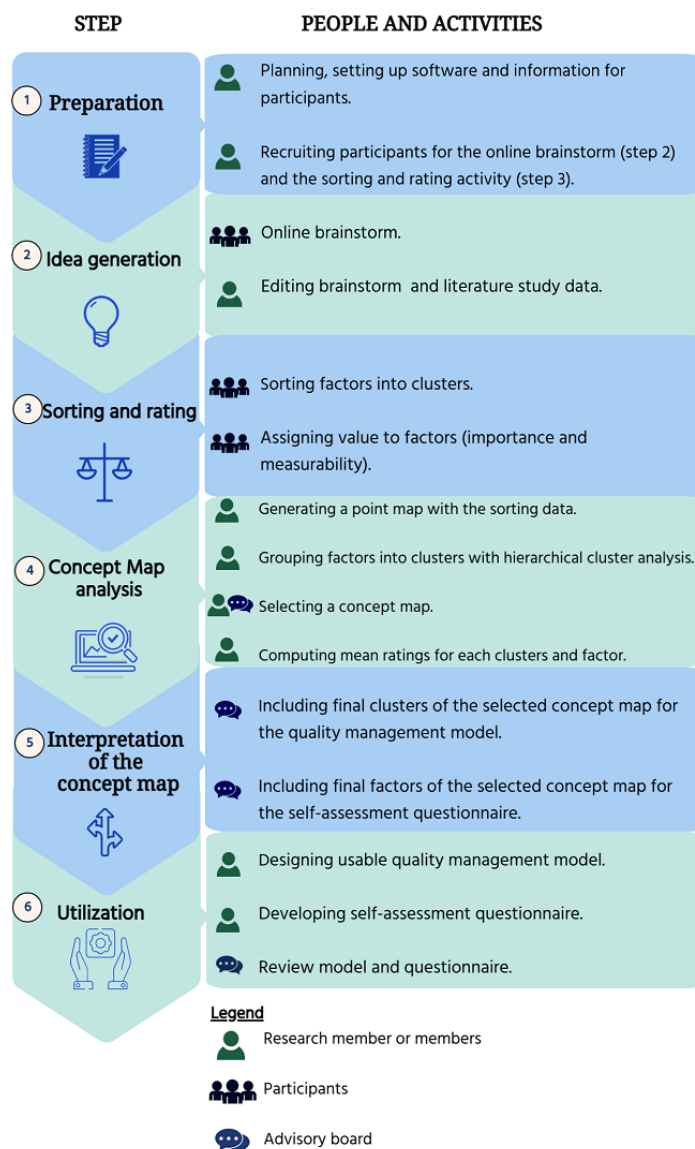

Concept mapping is a highly structured methodology for organizing ideas from different stakeholders and other data sources to produce a common framework for complex topics that can be used for evaluation or planning [37-40]. The method

integrates qualitative data collection with quantitative analysis to construct an interpretable pictorial view of different ideas and concepts and how these are interrelated [41,42]. Concept mapping has been used worldwide, for a diverse range of health care projects and studies to develop conceptual frameworks, as well as health and eHealth evaluations [43-49].

In this study, the 6-step concept mapping approach of Trochim and McLinden [42] was followed [49] to develop a usable,

tailored, SPO-based quality management model for hybrid health care and an accompanying questionnaire. The six steps of concept mapping are as follows: (1) preparation, (2) idea generation, (3) sorting and rating, (4) concept mapping analysis, (5) map interpretation, and (6) utilization. Each step involves different activities leading to an output, which serves as an input for the next step. The steps and activities are explained in Figure 2 and in the paragraphs below. All the steps were supported by the GroupWisdom webtool [41,42].

Figure 2. Concept mapping steps and study activities.

Step 1: Preparation

Concept mapping is most effective when multiple stakeholders participate in all the steps of the concept mapping process [50]. There is no strict limitation to the number of participants, ranging from small groups of 8 to 15 people to groups of hundreds of participants [50]. For this study, participants with eHealth experience, those employed by health care organizations, and patients with eHealth experience were recruited. The amount or kind of eHealth experience, health care setting, or disease was not relevant for inclusion. The goal was to create a diverse group in which different experiences,

perceptions, and viewpoints complemented each other. We aimed to include a mix of health care professionals, patient experts (patients and caregivers), managers, directors, project leaders, researchers, and eHealth suppliers.

Potential participants were approached to attend both brainstorming in step 2 and sorting and rating in step 3. Participants were invited via the research team’s network, social media, and snowballing. Before agreeing to participate, participants received an information letter about the concept mapping method, the study’s purpose, and the SPO framework. None of the potential participants were familiar with our

previous literature study results. A selected group was asked to participate in step 4 (concept mapping), step 5 (interpretation), and step 6 (utilization), which will be explained in the subsequent sections.

Step 2: Idea Generation

Web-Based Brainstorming

In step 2, data from the participants were collected and combined with data from the literature study. Idea generation with participants was organized by brainstorming. Brainstorming is the most common method used in concept mapping, and can be either group brainstorming or individual brainstorming [42]. In this study, web-based brainstorming was conducted by the participants. Participants received a link via email with instructions, giving them access to the web-based brainstorm program of the GroupWisdom webtool. Before starting the brainstorming session, informed consent was provided, and participant characteristics (age, eHealth experience, professional background, and work setting) were collected to generate general background information about the participants. When the brainstorming started session, the following instruction was presented: "Name all factors, which you believe contribute to effective organization of patient care with eHealth, and what the outcomes of this care should be. Keep the 'Structure-Process-Outcome' framework in mind."

For 23 days, the participants could list as many factors they considered essential contributors to effective hybrid health care. Participants could see each other's inputs and save their brainstorming results in the meantime. They received reminders after 10 and 15 days.

Editing Brainstorming and Literature Study Data

After closing the web-based brainstorming session, the brainstorming and literature study data were combined for sorting and rating. A manageable amount of data for sorting and rating is ideally ≤ 100 to prevent redundancy and a loss of participants' motivation [51,52]. To generate a final set of up to 100 factors, duplicates and factors that did not match the brainstorming instructions were removed. For this purpose, each factor was assessed independently by the authors, RT-S and ET-K. The assessments were compared, and disagreements were resolved by discussion between RT-S and ET-K. Next, RT-S edited the remaining factors for grammar and spelling.

Authors, MK and AR reviewed the editing process to check whether they would conclude the same selection and wording and made recommendations where appropriate. Finally, the set was entered into the GroupWisdom webtool, serving as an input for the sorting and rating activities.

Step 3: Sorting and Rating

At the beginning of step 3, the participants received instructions for the sorting and rating tasks. For the sorting task, the participants were asked to cluster the factors into self-created clusters and assign names to the clusters. The participants were instructed to keep the Donabedian SPO categories in mind while sorting each factor into self-created clusters. For the rating task, each participant was asked to rate each factor by relevancy on a 5-point Likert scale, ranging from 1 (*not important at all* or

not feasible to measure) to 5 (*very important* or *very feasible to measure*) by answering the questions, "How important is this factor for effective patient care with eHealth?" and "How feasible to measure is this factor?"

The participants had the opportunity to sort and rate over 3 weeks. They could save their activities and return later and received reminders after 10 and 15 days. The sorting data were approved for concept mapping analysis for participants who completed 75% of the sorting activity and created at least three clusters [41]. The rating data were included when the participant rated at least one factor.

Step 4: Concept Mapping Analysis

Concept mapping analysis consisted of four main activities: (1) generating a point map with the sorting data, (2) grouping factors into clusters using hierarchical cluster analysis, (3) selecting a concept map from the hierarchical cluster analysis, and (4) computing average ratings for each factor and cluster of the selected concept map [50]. All computations were based on the concept mapping approach of Kane et al [53,54] and conducted using the GroupWisdom webtool.

Generating a Point Map With the Sorting Data

Data from the rating step were analyzed to create a point map [45,53,55,56]. A point map is a 2-dimensional point map, in which each point represents a factor [53]. The point map visually displayed the locations of all factors. Factors closer to each other on the point map were sorted together more frequently by the participants, whereas more distant factors on the map were sorted together less frequently [42,50,53]. The point map was constructed using a similarity matrix and multidimensional scaling algorithm. First, the similarity matrix indicated the number of times various factors were grouped together. Next, a multidimensional scaling algorithm plotted factors as points on a point map [42,54,55]. Subsequently, a stress value (0-1) was calculated, indicating the degree to which the distances on the point map fit the original similarity matrix [38,54]. The better the fit, the lower is the stress value.

Grouping Factors Into Clusters With Hierarchical Cluster Analysis

The point map provided the input for the hierarchical cluster analysis. The hierarchical cluster analysis grouped factors into clusters [44] using Ward algorithm [57]. The algorithm proposed several concept map solutions, where 2 clusters were merged at each following the proposed solution.

Selecting a Concept Map

From the proposed concept map solutions, a concept map that made sense for conceptualization was selected. There is no single correct number of clusters or mathematical decision criterion for selecting a concept map solution [38,56]. This study selected the number of clusters for the concept map by determining the range of the highest and lowest number of clusters. The range was the average number of clusters made by the participant and its SD.

Subsequently, the cluster solutions in this range were reviewed to select the cluster level by following the cluster tree in the Methods section of the studies by Trochim [53] and Kane et al

[54]. Finally, in a meeting, 2 authors (RT-S and ET-K) and 2 participants reviewed the merging of clusters, beginning with the highest number of clusters and moving to the lowest. The 2 study participants were asked to join this meeting because of their extensive experience with eHealth, daily care processes, research, operational management, and concept mapping.

After establishing the number of clusters in the concept map, each factor was reviewed for compatibility with the cluster and to determine whether it was appropriate to move the factor to a different cluster. A cluster and its content were appropriate for inclusion when they were considered essential and usable for the quality management model [53].

In addition, each cluster received a name and description based on the cluster names that emerged from the sorting activity.

Computing Mean Ratings for Each Cluster and Factor of the Selected Concept Map

After the cluster map was selected, the relationships between ratings were computed using pattern-match and Go-zones [42].

Pattern-match and its Pearson product-moment (r value) were calculated to compare how the clusters of the selected concept map were rated on importance and measurability. The pattern-match visualized the mean ratings of each cluster in a ladder graph, connecting lines between the mean ratings on importance and measurable of each cluster [50,57]. The r value represented the correlation strength between the 2 mean ratings of all clusters [50,57].

Finally, multiple Go-zones were computed: a Go-zone of the total point map and Go-zones per cluster of the selected concept map. Go-zone is a 4-quadrant graph with an x-y graph [50], visualizing the mean ranking results of each factor on the questions “How important is this factor” and “How feasible to measure is this factor.” The minimum and maximum values for each axis were the minimum and maximum average Likert scores, respectively. The upper-right quadrant is called the *Go-zone* because it shows factors rated above the mean for both importance and measurability [42,58]. The pattern-match and Go-zone showed how important and measurable each cluster and its factors were rated for quality assessment by the individual participants during the step, sorting and rating.

The selected concept map, with its calculation of importance and measurability for each cluster and factor, formed the basis of interpretation in the next step [53].

Step 5: Interpretation of the Concept Map

The selected concept map, with its pattern-match and Go-zones, was discussed with an advisory board. On the basis of the pattern-match and Go-zones, the advisory board decided which clusters and factors should be included in the quality management model and the accompanying questionnaire. The advisory board consisted of 4 study participants from the brainstorming and sorting step, of whom, 2 also participated in step 4, concept mapping analysis. The advisors were chosen because they could be future model users. In addition, all had extensive experience with eHealth, health care business, and as health care professionals (general practitioners, nurses,

anesthetists, and clinical psychologists) in different health care settings.

The advisors voted individually on which clusters and factors of the selected concept map should be included in the quality management model and questionnaire to ensure usability. Using a web-based survey, the following questions were asked: “Which cluster should be included in the quality management model based on the mean cluster rating scores of the pattern matches? Please, specify your choice.” and “On which factors should the questionnaire give focus? Guide your choice by the Go-zones of each cluster and the Go-zone of the total point map. Please specify your choice.” The advisors could not see each other’s votes. By 75% (3/4) agreement or more, the concerned clusters and factors were operationalized in the quality assessment model and questionnaire. Where there was less agreement, the advisors viewed all responses, including the comments, and were asked to vote again. This process was repeated until a 75% consensus was reached. The web-based survey results were used as inputs to develop the quality management model and its questionnaire.

Step 6: Utilization

Quality Management Model

The remaining clusters and their positions in the selected concept map provided the blueprint for the quality management model. First, the excluded clusters and factors were removed from the concept map. Second, the concept map with the remaining clusters was used to produce a logic model. A logic model is a framework that visualizes the interrelations between the clusters in graphic form and is therefore valuable for quality evaluation [59]. The SPO framework [34,35] was used to identify logical interrelationships between the clusters. Accordingly, noticeable SPO connections between the clusters were drawn on the map by RT-S. A simplified version of the logic model was designed for clarity and readability. Authors SW, ET-K, and RT-S discussed the design of the quality management model to ensure the usability and clarity of the model.

Self-assessment Questionnaire

The questionnaire was drafted by RT-S with the remaining factors, taking the advisors’ comments into account. The questionnaire should give care organizations insight into the quality of hybrid care and how quality develops over time. On the one hand, the questionnaire must be easy to use and uniformly independent of the type of health care organization, type of eHealth, and disease. On the other hand, the questionnaire results must provide specific guidance to improve the quality of specific clusters and factors.

The concept model and questionnaire were submitted to the advisors for peer review of usability and clarity. Their comments were processed by RT-S, resulting in an improved draft. Finally, ET-K and SW peer reviewed the last draft to ensure that the representatives’ comments were implemented entirely in the quality management model and the related questionnaire.

Ethics Approval

Approval by an ethics committee was not needed because no intervention or trial has occurred in the sense that the research

participants were subjected to actions or had modes of behavior imposed on them [60].

Results

Participant Characteristics (Step 1)

A total of 39 people participated in this study. The participants had a mean age of 45.2 (SD 11.1) years and were mainly working at the family medicine clinic (12/39, 31%) or hospital (10/39, 26%) within a management function (16/39, 41%) or as a health care professional (14/39, 36%). A total of 59%

(23/39) of the participants estimated their eHealth experience to be extensive. The 3 most commonly used eHealth tools were apps (37/147, 25.2% participants), web portals (35/147, 23.8% participants), and video communication (34/147, 23.1% participants). An overview of the participants' characteristics is shown in Table 1.

Of the 39 participants, 38 (97%) completed the brainstorming sessions. In all, 18% (7/38) of the participants dropped out after the brainstorming session, and a new participant joined the sorting and rating phase. In total, 79% (31/39) of the participants completed the sorting and rating phase (Figure 3).

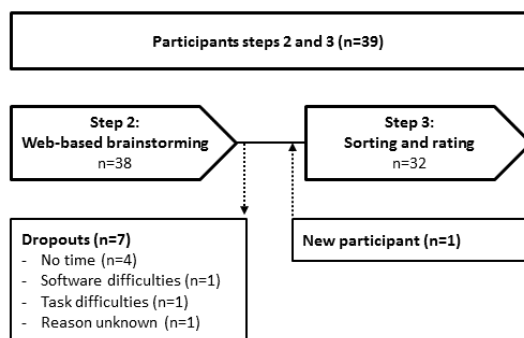

Table 1. Participant characteristics (N=39).

^aMany participants had dual roles, from which they were asked to choose one role.

^bParticipants could select multiple answers.

Figure 3. Number of participants at steps 2 and 3.

Idea Generation (Step 2)

Brainstorming during idea generation resulted in a list of 203 factors. A total of 111 potential indicators were extracted from the literature study [17]. Both lists were aggregated, resulting in a list of 314 factors. Editing of the data led to a final list of 78 factors. These 78 factors served as inputs for the sorting and rating activity. The list of 78 factors is provided in Multimedia Appendix 1.

Sorting and Rating (Step 3)

The rating data of the 32 participants were included in this study. All factors received mean rating scores of >3.1, for both importance and measurability. The mean ratings on the questions, “How important is this factor for successful integration of eHealth?” and “How feasible to measure is this factor” are described in Multimedia Appendix 1.

The sorting data of 8 people were excluded, with the reason “less than 75% sorted” (n=4, 50%) or “sorted in two clusters” (n=4, 50%). The mean number of clusters of the approved data was 7 (SD 3.5) with a range of 3 to 15 clusters.

Concept Mapping Analysis (Step 4)

Visual Representation

The point map in Figure 4 shows how the 78 factors are related according to the sorting data. The point map had a stress value of 0.26, indicating that it had a good fit with the original similarity matrix [38,54].

The point map displays the locations of all factors that were frequently sorted closer together by the participants, whereas unrelated factors were plotted farther from each other. The number of points corresponds to the number of factors presented in Multimedia Appendix 1.

Figure 4. Point map.

Selecting the Concept Map

Concept map solutions ranging from 11-cluster to 3-cluster options were reviewed (mean 7, SD 3.5). The 9-cluster concept map was selected to make the most sense of conceptualization. A few factors (n=14) were unanimously replaced, leading to the concept map shown in Figure 5. Replaced factors and their

reasons are presented in Multimedia Appendix 2. The 9 clusters were labeled and received a short description, as described in Table 2. The number of points corresponds to the number of factors presented in Multimedia Appendix 1. The clusters represent how the participants sorted the factors into self-created clusters using the proposed cluster labels.

Figure 5. Nine-cluster concept map. IT: information technology.

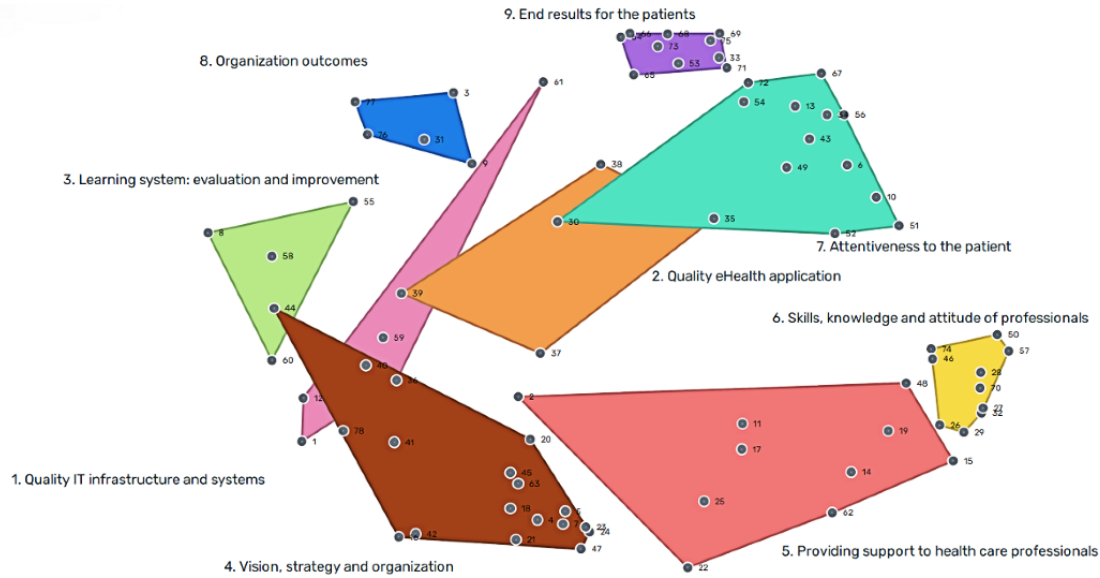

Table 2. Clusters labels and descriptions.

Cluster number ^a	Cluster label	Description	Included factors, n
1	Quality information technology infrastructure and systems	Conditions concerning technology, information technology systems, and data.	6
2	Quality eHealth application	Conditions concerning the eHealth application.	4
3	Learning system: evaluation and improvement	Evaluation and realignment with stakeholders and the patient care objectives for a continuous development.	4
4	Vision, strategy, and organization	Responsibilities of the health care organization concerning vision, strategy, policy, leadership, funding, and work process designs.	16
5	Providing support to health care professionals	Conditions arranged by the health care organization to encourage the use of eHealth among its health care professionals.	10
6	Skills, knowledge, and attitude of health care professionals	Health care professionals' ability to provide hybrid care.	10
7	Attentiveness to the patient	Organize the daily care process in line with the patient's needs, demand for care, and its capacity.	13
8	Organization outcomes	Outcomes for the health care organization; for example, quality health care provision and health care logistics.	5
9	End results for the patient	Outcomes for the patients; for example, health, added value, satisfaction, ownership, and convenience.	10

^aNumber corresponds with the number of the concerning cluster in Figure 5.

Mean Ratings for Each Cluster and Factor of the Selected Concept Map

The pattern-match showed that all clusters had a mean score between 3.75 and 4.27 on the importance and a mean score between 3.79 and 4.10 on measurability (Figure 6). The cluster with the highest mean score on importance was *Attentiveness to the patient* (mean 4.27, SD 0.27), and the cluster with the highest mean score on measurability was *End results for the*

patients (mean 4.10, SD 0.17). On the contrary, the cluster with the lowest mean score on importance was *Organization outcomes* (mean 3.75, SD 0.36), whereas the cluster *Quality eHealth application* (mean 3.79, SD 0.45) had the lowest mean score on measurability. The *r* value was 0.63, indicating a predictable alignment between the rating of importance and the rating of measurability. The mean ratings of the factors and Go-zones per cluster are included in Multimedia Appendix 3.

Figure 6. Pattern-match between the cluster-mean scoring on importance and measurability, with Pearson product-moment. IT: information technology.

Interpretation of the Concept Map (Step 5)

The pattern-match and Go-zones were input to determine which clusters and factors of the selected concept map should be included in the quality management model and questionnaire. Decisions were made in 2 voting rounds. Of the 9 clusters, the cluster *Organization outcomes* was not included in the quality management model, based on the voting (3/4, 75% of the advisors had doubts about including the cluster in the model)

and after discussion with the research team. The factors included in the questionnaire concerned those placed in the Go-zone of the total point map or the Go-zone of the clusters. As a result, 8 clusters remained in the model and 33 factors in the questionnaire remained as a manageable utility for quality assessment (Textbox 1). Multimedia Appendix 3 presents the responses and comments of the advisory board during the voting rounds.

Textbox 1. The included clusters and factors.

Quality Information technology infrastructure and systems (1)

- Information technology architecture available within the health care organization (1).
- Back-up scenario during technical problems (12).

Quality eHealth application (2)

- The eHealth application is user-friendly (35).

Learning system: evaluation and improvement (3)

- Cocreation: eHealth is developed, implemented and redeveloped with different stakeholders (8).
- Monitoring and evaluation of service and treatment results (58).

Vision, strategy, and organization (4)

- Support the implementation and development of eHealth in the organization with good project management (4).
- Mobilizing funding for working with eHealth (16).
- Clear internal policies regarding the use of eHealth (18).
- Vision supported by the line, “Why are we doing this?” (21).
- Care delivery with eHealth complies with laws and regulations (41).
- Financial reimbursements for eHealth deployment (42).
- Redesign the current work process and review what contributes to the desired care outcomes (47).

Providing support toward health care professionals (5)

- Health care professionals have easy access to information technology resources; for example, device, internet, screen, or headset (2).
- Embedding eHealth in the daily practice of health care professionals (11).
- Training and supervision for health care professionals (15).
- Help desk for health care professionals (17).
- Information on the treatment with eHealth is clear and accessible to the health care professional (19).

Skills, knowledge, and attitude of health care professionals (6)

- Good balance between face to face and eHealth for the health care professional (46).
- The health care professional has confidence in the eHealth application (70).
- The health care professional is satisfied with working with eHealth (74).

Attentiveness to the patient (7)

- Clear communication to the patient about how care is offered (10).
- Personalized care, considering patient needs with regard to (deployment of) eHealth (13).
- The patient has easy access to the necessary information technology resources; for example, device, Internet, and so on (30).
- Patients receive practical support in using the eHealth application; for example, a help desk (49).
- The patient has confidence in the eHealth application (67).
- The patient has the flexibility to use eHealth wherever and whenever it is convenient (72).

End results for the patient (9)

- The patient can integrate the use of eHealth in their daily life (33).
- Treatment with eHealth has a positive influence on the patient’s health (64).
- Treatment with eHealth contributes to the patient’s self-reliance (65).
- The patient is satisfied (68).
- The patient has easy access to care (71).
- eHealth provides logistical convenience for the patient (73).

- eHealth has added value for the patient (75).

Utilization (Step 6)

Utilization Model

The clusters and factors excluded from the voting rounds were removed from the selected concept map. The remaining clusters (n=8) and their factors (n=33) led to nonoverlapping clusters on the concept map. Above the clusters, the SPO categories were positioned as overarching themes to emphasize the interrelations

between the clusters. In addition, a complex cluster map can be simplified into a logic model. Figures 7A-C show the simplification of the model.

The overarching categories, *structure*, *process* and *outcomes* and the clusters' interconnections refer to the Donabedian SPO framework [34,35]. The cluster *Learning system* is visualized in the arrows with the dashed line. The numbers inside the clusters represent the number of factors included.

Figure 7. Simplification of the model. (A) Removing the excluded cluster and factors from the selected concept map and adding the overarching categories' structure, process, and outcome. (B) Drawing a logic interrelationship with structure, process, and outcome categories. (C) Simplification into a quality management model. IT: information technology.

Utilization Questionnaire

The remaining 33 factors were included in the questionnaire, where each factor can be measured on how effectively it is organized and developed over time. The advisory board noted that measuring the quality progress of hybrid health care is very

important, in addition to learning and continuous improvement with stakeholders. Subsequently, the idea was to enrich the questionnaire with a quality progress tracker based on the plan-do-check-act (PDCA) cycles of Deming [61]. Incorporating the PDCA cycle makes it possible to assess the quality easily

and uniformly with tailored feedback for health care organizations. PDCA is a well-known cycle method for continuous improvement and quality measurement [61]. The PDCA cycles assess each factor's quality by measuring the extent to which *The objective is tangible?* (plan), *The plan is implemented?* (do), *To what extent is the plan realized?* (check), and *Providing feedback on the quality of the execution to make improvements* (act) [61]. Each factor can be monitored on the quality level of the PDCA cycles using a Likert score (0-10). A score of 0 means there is *no plan to improve the concerning factor*, and a score of 10 means *continue improvement with stakeholders*. The Likert scoring is based on the PDCA cycles and the 2 factors of the cluster Learning system, which include the following: (1) *Cocreation: eHealth is being developed and implemented with various stakeholders* and (2) *Monitoring and evaluation of service- and treatment outcomes*. Using the PDCA cycles in combination with a Likert score provides a health care organization insight into improvement possibilities for each factor or cluster.

Finally, the model and questionnaire obtained a more convenient workname Hybrid Health Care Quality Assessment (HHQA). The HHQA model and questionnaire with suggestions on how to use it are explained in [Multimedia Appendix 4](#).

Discussion

Principal Findings

In this concept mapping study, we aimed to develop an SPO-based model and an accompanying self-assessment questionnaire for hybrid health care. By combining practice-based knowledge from eHealth users with an evidence-based literature review, we found that organizational, technological, and process and personal factors affect the quality of hybrid health care. Health care organizations must understand that these factors play a role in organizing hybrid health care and should be familiar with ways to improve them. The authors developed the HHQA, which can be used to systematically assess and improve the quality of hybrid health care.

The HHQA model includes 8 clusters. Cluster 1 (*Vision, strategy, and organization*) includes the responsibilities of the management to set the vision, strategy, policy, leadership, finance, and project management. Cluster 2 (*Quality information technology infrastructure and systems*) focuses on information technology infrastructure and back-up scenarios by information technology issues. Cluster 3 (*Quality eHealth application*) concerns the user-friendliness of the digital health application itself. Cluster 4 (*Providing support toward care professional*) and cluster 5 (*Skills, knowledge, and attitude of health care professionals*) include factors concerning health care providers. Cluster 4 focuses on factors that should be arranged for the individual health care professional by the care organization, and cluster 5 includes the responsibilities of the professional. The patient is central in cluster 6 (*Attentiveness to the patient*). This cluster contains the measurement of factors that allow patients to increase their self-management and consider the individual patient's needs. Patient centeredness is also reflected in cluster 7 (*Patient outcomes*), including factors such as patient's health outcomes, added value, satisfaction, ownership, and

convenience. Finally, cluster 8 (*Learning system*), forms the relationship between the continued development of hybrid health care with stakeholders and health care provision objectives. The factors in cluster 8 provide insight into where alignment can be improved with other organizational criteria and actions, such as cost-benefit or capacity management.

The interdependencies of the clusters are logically expressed in the HHQA model because of the overarching categories of the Donabedian SPO framework. Moreover, according to eHealth users, clusters consist of the most important factors for the quality of hybrid health care. Using the questionnaire, each factor (33 in total) was measured to determine how effectively it was organized and developed over time. Subsequently, the main results of the questionnaire were shown at the cluster level. It was possible to zoom in on the relevant factors for each cluster.

Comparison With Literature

In our previous literature review [17], we concluded that the capabilities of patients, health care professionals, and technology play a crucial role in the quality of hybrid health care. We also concluded that offering hybrid health care requires adjusting the daily care process and appropriate process monitoring. The conclusions from the literature review are reflected in the HHQA clusters, namely, the patient's role is visible in the clusters *Attentiveness to the patient* and *Patient outcomes*; the health care professional's role is central in the clusters *Providing support toward health care professionals* and *Skills, knowledge, and attitude of professionals*; and technology is covered in the clusters *Quality information technology infrastructure and systems* and *Quality eHealth application*. The adjustment of the daily care processes is elaborated in the cluster *Vision, strategy, and organization*. Finally, monitoring is embedded in the cluster *Learning system* and the PDCA-progress tracker.

The 8 clusters of the HHQA model fit the 3 overarching categories of the Donabedian SPO framework. According to Donabedian [34], health care quality is based on aspects of these 3 categories and their relationships. The interaction between the categories can be bidirectional and is an "unbroken chain of antecedents, followed by intermediate ends, which are themselves the means to still further ends" [35]. Our research translated the complex interaction between the categories, structure, process, and outcome into user language.

The HHQA connects essential contributions to the quality of hybrid health care using a progress tracker. The relationship between quality contributors and continuous improvement also appears in the European Foundation for Quality Management Model (EFQM) [62,63]; nonadoption, abandonment, scale-up, spread, sustainability (NASSS) [32]; and the Consolidated Framework for Implementation Research (CFIR) [64,65]. All models approach the organizational structure, process, and outcomes with continuous improvement in a structured manner, but with different focus areas. For example, the EFQM is not specified for health care, in contrast to the NASSS and CFIR. The NASSS focuses on the adoption of technology and reduces implementation complexity, whereas the CFIR emphasizes on implementation in general. However, none of them have been

specified for quality assessment and improvement of hybrid health care.

Nevertheless, it is interesting to conduct a detailed examination of the assessment questionnaires of the EFQM and NASSS. The EFQM deployed the Results-Approach-Deployed-Assessment-Refinement (RADAR) method [66,67], a questionnaire to assess the quality improvement at each EFQM criteria, which incorporates the continued improvement circle. The assessment using the RADAR method is similar to the PDCA cycle in our questionnaire, as both monitor continuous quality improvement by completing the cycle plan-executing-monitoring and refining. However, the RADAR, similar to the EFQM model, is not specified for hybrid health care. In addition, the NASSS comes with a questionnaire to monitor the complexity of technology implementation in health care [68], but the focus is on project management instead of the hybrid health care process itself. Furthermore, there are other questionnaires measuring the quality of eHealth [69-72] or the quality of health care [73,74]. However, these questionnaires are concerned with the quality assessment of eHealth nationwide [68,70], the quality of a specific digital health application [70,72], or measuring the quality of a specific disease pathway [73,74]. To the best of our knowledge, HHQA is the first questionnaire measuring the quality of hybrid health care at an organizational level, taking the role of the patient, health care professionals, and technology into account, accompanied by an improvement progress tracker. Therefore, the authors recommend using the HHQA to measure and improve the quality of hybrid health care.

Strengths and Limitations

This study has several strengths. First, the HHQA was developed in cocreation with stakeholders who are direct users of eHealth. Therefore, the HHQA content was drawn from inside the health care system itself and not conceived or imposed outside the health care organizations. Second, stakeholders choose the included clusters and factors. The researcher only played a facilitating role. Consequently, the clusters and factors accurately reflect stakeholders' views and values, expressed in their own words and visual representations. Third, the stakeholder group was diverse and consisted of representatives of health care professionals, patients, managers, researchers, and eHealth designers. Nevertheless, the stress value of the point map shows that the stakeholders' outcomes are highly compatible. Therefore, the study results are likely to be generalizable to everyday practices. Fourth, the model and questionnaire were developed by combining scientific and practice-based knowledge. Together, these strengths result in

important factors for effective hybrid health care covering different users' needs and organization requirements.

Our study had some limitations. First, the questionnaire had not yet been tested in health care organizations. This will be conducted in a follow-up study. Although eHealth users from different health care organizations have reviewed the model and questionnaire, the model and questionnaire may still be too abstract for daily practice, as is often the case in scientific research [75-77]. A follow-up study could provide concrete recommendations on how to use the HHQA. Second, it is conceivable that other factors and clusters could be included in other participants and health care environments. We attempted to overcome this problem by creating diverse groups of participants with different backgrounds, various eHealth experiences, and different kinds of health care settings. In addition, combining idea generation through brainstorming with results from a systematic literature review reduces the risk of bias. Third, based on the analysis of the concept mapping phase, 14 factors were moved to other clusters. However, some of these factors were moved far across the map, which was not entirely in line with the spirit of group concept mapping. Nevertheless, we deemed it necessary to move these factors for substantive reasons. Fourth, the advisory group consisted of 4 participants. We wanted to avoid overquestioning the participants and, therefore, deliberately selected a group of delegates who reflected on the diversity among the participants and who also had experience with quality management and concept mapping. Combined with in-depth preparation and discussion among the research groups, this appeared to be the most feasible solution.

Finally, it is worth pointing out that the HHQA gives a first general impression of improvement, as there is much to be gained in taking the role of the patient, health care professionals, and used technology into account [17]. Furthermore, the authors will continue with follow-up research and warmly welcome repetition of the study to improve the HHQA, taking into account the different users and health care environments.

Conclusions

This study developed a quality management model and an accompanying self-assessment questionnaire tailored for hybrid health care, the HHQA. A quality model for hybrid care is indispensable for effectively integrating eHealth into regular care and delivering high-quality health care. The HHQA covers all relevant aspects for the assessment and sustainable improvement of hybrid health care and the interrelations of eHealth with organizational, technical, and human factors. The next step is to validate and apply the HHQA model and questionnaire in practice.

Acknowledgments

Abstract

Background: Early prevention of gestational diabetes mellitus (GDM) can reduce the incidence of not only GDM, but also adverse perinatal pregnancy outcomes. Moreover, it is of great significance to prevent or reduce the occurrence of type 2 diabetes. Mobile health (mHealth) apps can help pregnant women effectively prevent GDM by providing risk prediction, lifestyle support, peer support, professional support, and other functions. Before designing mHealth apps, developers must understand the views and needs of pregnant women, and closely combine users' needs to develop app functions, in order to better improve user experience and increase the usage rate of these apps in the future.

Objective: The objective of this study was to understand the views of the high-risk population of gestational diabetes mellitus on the development of mobile health apps and the demand for app functions, so as to provide a basis for the development of gestational diabetes mellitus prevention apps.

Methods: Fifteen pregnant women with at least one risk factor for gestational diabetes were recruited from July to September 2021, and were interviewed via a semistructured interview using the purpose sampling method. The transcribed data were analyzed by the traditional content analysis method, and themes were extracted.

Results: Respondents wanted to develop user-friendly and fully functional mobile apps for the prevention of gestational diabetes mellitus. Pregnant women's requirements for app function development include: personalized customization, accurate information support, interactive design, practical tool support, visual presentation, convenient professional support, peer support, reasonable reminder function, appropriate maternal and infant auxiliary function, and differentiated incentive function. These function settings can encourage pregnant women to improve or maintain healthy living habits during their use of the app

Conclusions: This study discusses the functional requirements of target users for gestational diabetes mellitus prevention apps, which can provide reference for the development of future applications.

Introduction

Gestational diabetes mellitus (GDM) refers to the first occurrence of abnormal glucose tolerance of varying degrees

during pregnancy, which is one of the most common complications of pregnancy [1]. Due to differences in diagnostic criteria and race, the global incidence of GDM is between 1% and 25% [2]. A previous study has shown that the incidence of GDM in China is 14.8%, and with the adjustment of the fertility

policy and the increase in elderly people and obese pregnant women, the incidence of GDM shows a trend of increasing every year [3,4]. GDM brings serious threats and challenges to both maternal and infant health. GDM can increase the risks of pregnancy hypertension, abortion, polyhydramnios, premature delivery, dystocia, and cesarean section [4-6]. Women who have a history of GDM have a 50%-73% risk of recurrence of GDM when they get pregnant again and a 10-fold higher risk of developing type 2 diabetes in 5 to 10 years after delivery, and the risk of cardiovascular disease is also higher in these women than in normal women [7]. Compared with the offspring of healthy women, the offspring of GDM patients have higher risks of fetal malformation, macrosomia, large for gestational age, hyperinsulinemia, neonatal hypoglycemia, pathological jaundice, and respiratory distress syndrome [8,9]. In addition, these children have increased risks of obesity, abnormal glucose tolerance, and type 2 diabetes when they become adults, bringing heavy economic burden to countries around the world [10]. Therefore, early preventive measures for pregnant women at high risk of GDM are of great significance in reducing the incidence of GDM, reducing adverse perinatal pregnancy outcomes, and preventing or reducing the occurrence of type 2 diabetes.

Mobile health (mHealth) refers to medical treatment and health management through mobile devices, such as mobile phones, patient health data monitoring devices, palm computers, and other wireless devices [11]. Mobile information technology can bridge the communication between medical service providers and users, helping doctors understand the health status of users and providing clinical decision support, so as to achieve remote diagnosis and treatment. At the same time, users' needs for self-management support can be met to improve their compliance and self-management behaviors [12-14]. In addition, mobile information technology can greatly save users' time and transportation costs, relieve the burden of medical treatment faced by hospitals and community health service institutions, and make the limited medical service resources the most effective. Therefore, mHealth has significant potential in the medical and health fields [15,16].

As one of the main forms of mHealth management, mHealth apps refer to health service platforms that use smartphones, tablets, and other mobile devices as terminals and rely on mobile internet technology to provide services for patients and medical staff [17]. With the popularity of mobile devices, more than 500 million smartphone users worldwide use mHealth apps for health management [18]. Due to their unique biofeedback function, mHealth apps can carry out real-time health assessment and provide feedback on patients' health status, which can be considered beneficial for medical staff to implement personalized and precise health management for patients, and can have good application prospects [19]. At present, mHealth apps have been widely used in the prevention and health management of diabetes patients and have achieved satisfactory results [20]. However, currently, apps are mostly developed for commercial needs and purposes, the needs of patients are seldom taken into account during development, and few patients are invited to participate in the design process of apps [21-23]. Studies have shown that lack of interest in apps, fees, and fear

of personal information disclosure are the main reasons that hinder users from downloading and sticking with apps [24]. Therefore, when developing mHealth apps, it is necessary to take users as the center, pay attention to users' preferences and needs for using apps, and design apps that can meet users' needs, so as to improve users' experiences, increase users' stickiness in using apps, and improve patients' compliance with self-management.

User-centered design (UCD), which is part of human-computer interaction, takes user needs into account at every stage of product development. It is an important step and a relatively mature design method for building application programs [25]. Its core is to understand users and build their psychological model into system functions, so as to provide customized high-quality nursing services for each user more effectively [26]. In the process of app development, UCD gives priority to the needs of users, which can improve the stickiness and autonomy of users, and bring positive emotional experience to users, so as to meet the needs, preferences, and goals of users, and improve the quality of apps. The World Health Organization recommends that it be integrated into the whole process of an mHealth intervention to ensure the effectiveness of the intervention [27-30]. In recent years, UCD technology has been applied in the development of mHealth apps and has achieved certain effects in the areas of lifestyle intervention for patients with chronic diseases [25]. Studies have shown that most health management apps are not designed with user-centered methods, leading to poor usability and less use of these apps [31].

At present, some apps for GDM health management have been developed by scholars, but few studies have applied mHealth apps to GDM prevention management [32]. As mentioned above, understanding the usage preferences of mHealth apps among people at risk of gestational diabetes is crucial for the development of GDM prevention apps. However, there is no evidence that people at risk of gestational diabetes have a preference for mHealth apps. Qualitative research methods can dig deep into the inner needs of pregnant women. Therefore, the purpose of this study was to use a user-centered qualitative research method to interview pregnant women at high risk of GDM in early pregnancy, in order to explore the needs and preferences of these pregnant women for the functions and design of mHealth apps. The results can provide a reference for the design and development of mHealth apps for the prevention of gestational diabetes, and can help to adjust intervention measures, improve the acceptance and effectiveness of app use by pregnant women, and improve user engagement.

Methods

Study Design

In this study, the descriptive qualitative research method was adopted and the semistructured in-depth interview method was used to collect data. According to the purpose of the study, the interview outline was designed based on previous experience and reference to relevant literature. Before the formal interview, 2 pregnant women were preinterviewed, and the interview outline was modified appropriately according to the results of

the preinterview analysis. The formal interview outline has been presented in [Textbox 1](#).

Textbox 1. Semistructured interview guide used in this study.

Guide

1. Which mobile health management apps have you used before? What features do you find particularly useful in these apps? Or which features are not very useful and could be improved further?
2. If an app for gestational diabetes prevention is developed to assist your daily health management, what functions do you expect it to have?
3. What are your requirements for the interface design of an app?
4. What other requirements that you would like us to consider for developing an app for gestational diabetes prevention?

Participants and Recruitment

The maximum difference sampling strategy was adopted to select pregnant women with different age, occupation, parity, and gestational diabetes risk factors as far as possible for the purpose of sampling, so as to ensure diversity among the respondents. From July to September 2021, in the obstetrics clinic of a third-class hospital in Beijing, a researcher publicized the project to pregnant women, who made an appointment to establish routine health records, and invited pregnant women to share their experiences and opinions in depth in the form of face-to-face interviews. The inclusion criteria were as follows: (1) at least one risk factor for gestational diabetes (eg, advanced maternal age, overweight or obesity, family history of diabetes, history of GDM, history of macrosomia, and impaired fasting glucose); (2) gestational age <12 weeks; (3) experience of using sports apps, maternal and child health apps, or other health management apps; (4) good communication skills; and (5) informed consent and voluntary participation in this study. The exclusion criteria were as follows: (1) age <18 years and (2) presence of mental disorders. The interviews in this study were stopped when no new topics appeared, that is, the data were saturated. A total of 16 pregnant women were interviewed, and 1 of the women dropped out because she had something else to do halfway. Finally, 15 women participated in semistructured interviews (participant #1 to participant #15). The mean age of the respondents was 32 (SD 3.44) years, and the mean gestational age was 6.8 (SD 0.74) weeks. There were 12 first-time pregnancies and 3 second-time pregnancies. One of the pregnant women was a stay-at-home mother, and the other 14 were from different occupations. Six had 2 or more risk factors, and the remaining 9 had only 1 risk factor. Among the 15 pregnant women, 1 was of Hui nationality and the other 14 were of Han nationality. With regard to the education level, 3 had junior college or below education, 10 had undergraduate education, and 2 had graduate or above education. In terms of cost, 1 of the 15 pregnant women was self-paid, while the rest were covered by medical insurance.

Data Collection

Face-to-face interviews were conducted. Each interview was conducted in a quiet outpatient lounge with no third person to disturb. The interview duration was 20-40 minutes. Before the interview, interviewers introduced to interviewees the definition, harm, and intervention status of gestational diabetes. The purpose and significance of the interviews were also informed. Interviewees were told that their privacy would be protected by the researchers. The interview was recorded with the consent

of the interviewees. The interview was conducted according to the interview outline. During the interview, the interviewers carefully listened to the statements; appropriately responded to them with questioning, repetition, clarification, response, and summary; encouraged participants to fully express their ideas; avoided inductive questioning; and timely recorded the key information of the interview. At the same time, they paid attention to observe and record the interviewees' nonverbal information, such as a pause, a smile, body language, and mood change. After each interview, a reflective diary was written to reflect on the problems in the interview and correct them in the next interview. After the interview, the interviewees were thanked for their participation and were informed of the possibility of contacting them again for further information.

Data Analysis

Data collection and analysis were conducted simultaneously. After each interview, interviewers listened to the original materials repeatedly. The materials were transcribed within 24 hours. Uncertainties were clarified in time in combination with on-site notes. The traditional content analysis method was used for data analysis. The final transcribed text was merged into a single text by topic. Interviewers read the text several times to get a sense of the whole text. Selection criteria were determined according to research objectives and research questions. Based on this standard, the text content was classified, and meaningful statements were extracted and coded. Interviewers read and analyzed the semantic units carefully, and distinguished and summarized the theme. Researchers also looked for the relationship between subjects, and formed a theme group. This cycle continued until saturation (no new themes or subthemes were present) [33].

Quality Control

Before the interviews, the researchers received training in qualitative research, read a large number of relevant literature and books, and learned the analytical methods of qualitative research. The interviewers were involved in the obstetrics clinic as student nurses. As a research tool, researchers always remained neutral. Interviewers truthfully recorded the information provided by interviewees and analyzed their body language and facial expressions. Two researchers with training independently analyzed and discussed the data until the coding information reached a consensus. In the process of data analysis, researchers paid attention to the use of suspension to avoid interference caused by researchers. This study has been reported according to the requirements of the Consolidated Criteria for

Reporting Qualitative Research (COREQ) checklist for qualitative studies [34].

Ethical Considerations

Before each interview, the interviewee was given an explained on the research objectives, methods, expected benefits, and potential risks. Interviewers informed interviewees that relevant information would be strictly confidential. Interviewees could choose to accept or refuse participation in the study, and they could withdraw from the study at any time during the interview. During the interview, interviewees were told that they could refuse to answer any questions that they did not want to answer. Interviewees voluntarily participated in the interviews. In addition, interviewees were told that the content would be used only for scientific research. The interview information was coded, and the researchers did not compromise the privacy of the interviewees.

Ethics Approval

This study was approved by the Ethics Committee of Capital Medical University (batch number: Z2019SY037) and the Ethics Committee of the hospital conducting the interviews (batch number: 2019-P2-204-02).

Results

Design

Theme 1: User-Friendly Interface Design

Pregnant women expected clear logic between modules on the app interface and human-computer interaction.

Apps should have logic. What are the second-level interface and third-level interface after opening app? This hierarchy and interface framework should be clear. Make sure the entry and return routes are clear, and then the modules are clear. [Participant #1]

Categorize weight management, diet and exercise so that they can be easily seen on the home page. As clear as the app module of hospital appointment. Don't make me look for it, because it's too hard to look for it. A lot of apps these days are really annoying. [Participant #4]

Hopefully the app doesn't lag, is smooth to use and doesn't have too many ads. [Participant #6]

App can be divided into modules, like what's this, what's that. And when it updates content, don't always change the location. [Participant #7]

The app guidelines should be clear. For example, interface modules can be divided into early pregnancy, middle pregnancy and delivery, which are mainly practical and simple. [Participant #10]

Theme 2: Rich Functionality

Pregnant women hoped that the health management apps they use would cover the common functions of blood glucose management during pregnancy, so as to minimize the use of multiple apps.

Now everyone has several apps in their mobile phones. I hope that in the future there will be an app that contains all pregnancy programs, as convenient as possible. [Participant #4]

If the software can provide a one-stop service and integrate these commonly used functions together, I will use only one app. I think it will be much better. [Participant #11]

Functional Requirements

Theme 1: Personalized Customization

Pregnant women hoped to obtain personalized recipes customized by medical staff according to their own dietary preferences in mHealth apps, and hoped that these apps have a complete food bank and that they can search for the glycemic index of foods in the apps, so that they could flexibly carry out dietary replacement to reduce their dietary decision confusion.

I've always fantasized about an app that recommends foods I love. I don't have to think about matching my diet myself. It's all done for me, so I just follow the app. But only if I can choose what I like to eat, or if the app removes several ingredients I don't like to eat from the recipe. It would be nice if the app had a search function. For example, if I want to eat strawberries, I can see what the glycemic index of strawberries is and whether it's recommended for me to eat them. [Participant #1]

I find it convenient to have recommended recipes in the app so I don't have to think about whether the food is edible or not. It's not realistic for me to follow the recipes exactly, but I'm free to mix and match, as long as the total calories are right, and I think it's better. [Participant #4]

In addition, some pregnant women also expressed a need for exercise customization.

I hope the app can let me choose the exercise I want to do every day. For example, today I want to do yoga, and the app can calculate how long I need to do yoga according to my current weight and calorie intake to reach the goal of burning all calories. [Participant #4]

Theme 2: Accurate Information Support

As the pace of work and life is accelerating, some pregnant women stated that popular science articles recommended by mHealth apps should have attractive titles, be relevant to them, and be more accurate.

At my age, when I have to juggle work and family, I really don't have much free time. For popular science articles, the content is already boring, and if the volume is any longer, users will have no interest or time to read it. [Participant #1]

I hope that the app can set up a function of a prenatal assistant to tell me what I should do at different gestational weeks and whether I should have an empty

stomach, etc. This is my favorite feature. [Participant #1]

The app should recommend relevant contents for pregnant women based on their individual weight and test values. I think this will be better, because I think people are extremely busy nowadays, especially when they have children. [Participant #4]

We hope that the app can push suitable exercise types for pregnant women according to their gestational weeks. [Participant #7]

If it's a video, it can be put in the appropriate module and I'll pay attention to it when I get to that stage of pregnancy. For example, if it's about breastfeeding, it'll be put in the third trimester and I'll click on it when I'm in labor. [Participant #10]

Only when the title of an article is clear and relevant to me will I read it. For example, if I'm eight weeks pregnant, what do I need to be aware of at this stage? I might click on it. But if it's about what to eat and control, I'm probably not going to read it. [Participant #11]

Theme 3: Interactive Design

Pregnant women hoped that mHealth apps have the function of setting daily calorie and exercise goals. After the pregnant women input their own diet, exercise, and blood sugar monitoring data, the system should provide immediate feedback and professional feedback according to their health management standards, so that the pregnant women can make self-adjustments to achieve their daily management goals.

I hope the app can record the number of steps on the day, and tell me whether the amount of exercise today meets the standard, so as to give me an evaluation. [Participant #1]

If I have a problem with my blood sugar, I may check my blood sugar every once in a while and record the result of each time on the app. Then the application platform will give feedback based on my data and tell me what I need to pay attention to in the next step. I think it would be nice to have that kind of feedback. [Participant #4]

The app can score me according to my exercise level every week, and then give me an adjustment plan, which forms a closed loop from input, scoring and feedback. [Participant #10]

Theme 4: Practical Tool Support

Pregnant women hoped that mHealth apps can be used as tools to assist them in self-management and that these apps can record their steps to help them know whether their exercise meets the standard, or can remind and motivate them to exercise.

Although I am in a first-tier city like Beijing, there are few pregnant women around me who do yoga or swim. Especially when you're expecting your first child, families are very cautious. The elders in the family are so ingrained in their beliefs that they may not be comfortable with their children doing yoga

during pregnancy, and most would probably prefer to stick to walking during pregnancy. Therefore, it is sufficient for the app to record the number of steps of motion. [Participant #5]

For example, I can punch in the app to record my steps today. [Participant #7]

In addition, pregnant women hoped that mHealth apps have the function of weight recording to show the trend of their own weight change and that these apps can automatically compare the actual weight increase of pregnant women with the recommended weight increase range to determine whether the weight gain is reasonable, so as to help pregnant women manage their weight during pregnancy.

The app needs to have the function of weight graph, through which we can see the recent trend of pregnant women's weight. I remember when I was pregnant with my first child, there was an app that told me how much weight I needed to gain in my current gestational week. [Participant #4]

I am using an app for weight monitoring. I need to input my weight into the app every day to observe the change of my weight. [Participant #9]

In addition, some pregnant women hoped that mHealth apps can be used as practical tools to assist doctors in pregnancy management.

The app itself is also a tool to help doctors manage pregnancy health for pregnant women. Since everyone is different, doctors will definitely need to manage pregnancy according to their different physical conditions. It would be better if the app could be linked to hospital records and checklists. [Participant #6]

Theme 5: Visual Presentation

Some pregnant women stated that they do not have time to watch live broadcasts because of the fast pace of life. They hoped that the information on mHealth apps can be presented in the form of cartoon pictures, risk assessment forms, recorded videos, and short videos, so as to obtain relevant information more quickly.

The recommended article can be in the form of text with cartoon pictures, or it can be one of those risk self-assessment scales for pregnant women to rate their recent status. If the risk score is higher than a certain point, the woman has gestational diabetes. [Participant #10]

The live broadcast lasts a long time, and I may not be able to listen to it, because the pace of life is fast now, and life is so busy every day. Let alone live broadcast, I may skip to watch the recorded broadcast. [Participant #5]

I think recording is better than live broadcasting. Medical staff can put the video of the lecture in the corresponding module. If I had time, I would listen. [Participant #10]

I may not have time to watch the health education live broadcast, if there is a replay, I will watch it. It's better to put subtitles on the video because it's slow and I tend to skip to the subtitles or just read the document. [Participant #6]

If experts' lectures are made into some short videos, I may watch them at any time. [Participant #4]

Theme 6: Convenient Professional Support

Some pregnant women hoped that mHealth apps can provide the online consultation function of experts, so that it is more convenient to contact experts and solve some minor problems that are not too urgent, in order to avoid the cost of time and energy from the round trip to the hospital.

It's more difficult for pregnant women to get to the hospital. If I have any minor questions, I would like to consult one of the experts while they are giving an online lecture. I hope the app can provide free online consultation. [Participant #1]

Pregnant women may have some simple problems, but it is not convenient to come to the hospital for registration. It would be better if the app could provide online consultations with doctors. Doctors can choose to reply to pregnant women's information when they have time, there is no rush to reply immediately. [Participant #4]

It would be better if pregnant women had some problems that did not need to go to the hospital and could be answered online at a lower cost than going to the hospital. [Participant #9]

Theme 7: Peer Support

Some pregnant women hoped to set up a function like WeChat Moments or a forum, in order to facilitate access to other pregnant women who have encountered problems and facilitate the exchange of experiences between pregnant women, so as to better deal with the problems of pregnancy.

When I was first pregnant, I went to the forum to see what other people were like when they were pregnant. Many people would share their early pregnancy experiences on the forum, such as problems with their checklists. [Participant #1]

If I have some problems, I will look at other users' posts to see how they solve the problems. For example, I have a tummy ache at the early stage of pregnancy, so I will search for users who have the same experience on the Internet. If most users say this is normal, it means that tummy ache is ok. [Participant #8]

Theme 8: Reasonable Reminder Function

Pregnant women hoped to set reminders according to their own needs. Excessive reminders can disturb pregnant women.

We may not always want to record our diet every day. I hope the app can remind me when I forget to fill in. [Participant #7]

I hope the app has a reminder function, such as when I should do activities, when I should drink water, timely reminding me will be better. [Participant #10]

I think it is still necessary to set reminders, because the pace of work and life is fast now, pregnant women cannot remember everything every day. [Participant #14]

However, some pregnant women believed that an app's reminder function would cause some trouble, so they had little demand for the reminder function.

Because there are too many reminders in the app, I don't set any reminders in all my apps. I turn them off. If I want to keep track of something important, I'll set up a reminder myself. [Participant #9]

Theme 9: Appropriate Maternal and Infant Auxiliary Function

Some pregnant women wanted to add mother-baby support tools to mHealth apps to make it through the pregnancy better.

I hope the app can tell me the growth of my baby, so that I can know the development of the baby. In addition, I hope the app can tell me what changes a pregnant woman will have during pregnancy and what changes are normal. [Participant #1]

I think the app can add a function to record the gestational weeks. [Participant #2]

I have heard that some apps can record contractions and fetal movements. Is it possible to add these functions? [Participant #3]

I think there should be a keyword search function, I can query relevant articles, just like Baidu, I want to know can be found in it. [Participant #9]

Theme 10: Differentiated Incentive Function

Different pregnant women had different views on the redemption function of points. Some thought that it would be better if the points can be exchanged for items they need, while some thought that it has no incentive effect on them.

It is possible to get points by checking in, posting, reading articles, ranking points, and exchanging points for small things, etc. Some people may prefer this function. [Participant #5]

I think it would be nice if I could exchange my accumulated points for something to use during pregnancy or in the future. [Participant #6]

I don't like those things very much. They are not very useful. I sometimes check to see how many points I have, but I don't think the points are of any use to me. [Participant #7]

Discussion

Principal Findings

From the perspective of users, this study discussed the views and function requirements of pregnant women at high risk of GDM with regard to the development of mHealth apps for

preventing GDM, which can provide a reference for app developers to develop apps in line with users' usage habits in the future. In this study, pregnant women hoped that when using apps for management, they could receive personalized health management strategies according to their different stages of pregnancy and could receive immediate feedback on their daily management, helping them make adjustments. When pregnant women encountered difficulties in self-management, they hoped to obtain expert and peer resources in the apps to provide them with social support. In addition, pregnant women hoped that developers and professionals would consider the need for quick and accurate information acquisition when designing mHealth apps and would develop user-friendly apps. They stated that the content should be visual and attractive, and should provide both valuable and accurate information to meet the needs of information support.

Comparison With Prior Work

This study found that it is of great significance to formulate corresponding personalized management strategies for pregnant women based on the results of their health assessment, which is similar to the results of previous studies [35-37]. A research report pointed out that women were dissatisfied with the limited response of apps, and hoped that the apps could specifically analyze the characteristics of users and provide different solutions [38]. The biggest difference between personalized apps and other apps is that personalized apps can provide personalized services for pregnant women in different stages of pregnancy [39]. Studies have shown that personalized features in apps could improve users' compliance with lifestyle interventions, which is one of the most common intervention strategies in mHealth apps [40].

Interactive function is considered to be the most popular function in mobile medical apps [41]. The biggest advantage of interactive apps is that they can formulate targeted behavior change plans for users, continuously monitor the behavior characteristics of users, and then give targeted feedback according to the implementation of users' behaviors, which can motivate users to complete behavior changes [42]. Interactive design strengthens the connection between the user and the mobile app, providing psychological support for pregnant women [43]. In this study, pregnant women hope that the apps could compare the health information of pregnant women with the recommended behavioral goals, and provide feedback instantly for pregnant women to help them make timely behavioral adjustments, which is consistent with previous research results [44-46]. Some studies have used telephone or WeChat groups to intervene in pregnant women at high risk of GDM [47,48]. However, it is difficult to achieve instant feedback between doctors and patients, and the information of telephone and WeChat groups is also easily forgotten and covered. Therefore, it is important to design an app to prevent gestational diabetes. There is also a study using an app that counts low glycemic index function to provide dietary guidance to obese pregnant women, but this app has a single function and is designed for dietary guidance only, which cannot achieve the goal of interaction, resulting in an insignificant intervention effect [49].

Due to time constraints, most working pregnant women hoped apps would accurately push information related to themselves. Previous studies have found that providing users with personally relevant information was an important factor in promoting the use of mHealth programs [50]. In addition, Naughton et al [51] found that pushing personalized and relevant information could increase the value of contents and prevent users from falling out of mHealth management. In a qualitative study of Saudi women, it was found that due to social and cultural restrictions, some obese women could not do enough physical exercise outdoors [52]. Interviewees hoped that apps could recommend exercise methods that meet actual conditions for users and provide advice according to users' preferences.

Most pregnant women hoped that information could be in visual forms, such as illustrations and videos, to increase attractiveness. Presenting content in a visual way can help women obtain more information in a short period of time to meet women's needs for pregnancy knowledge. Previous studies have pointed out that multimedia could adapt to the learning styles of different individuals, enable pregnant women to take the initiative in learning, and encourage pregnant women to actively study [53,54]. Some studies have pointed out that the memory acquired by watching videos was stronger than that acquired by browsing text or pictures [55]. This study found that in terms of the video presentation form, pregnant women were more inclined to short videos or recorded videos. Therefore, when designing apps, developers should use a visual method as much as possible to present a variety of health information and educational resources for pregnant women to meet their needs for information support.

During the daily management of pregnancy, pregnant women will obtain decision-making information from different channels. Studies have shown [56] that pregnant women tend to trust professional decision support. Professional support provided by medical staff can meet the needs of pregnant women in pregnancy health care, which relieves anxiety and uncertainty of women during pregnancy [57,58] and helps pregnant women establish a healthy lifestyle [59]. When professionals cannot provide timely and effective feedback, pregnant women usually seek help from relatives and friends or through the internet. However, due to the poor quality of advice from various parties, pregnant women often get confused and make wrong decisions, which is not conducive to health management [60]. This study found that pregnant women hoped to obtain professional feedback from apps when they encountered problems or in the process of daily health management. This is similar to previous studies by Edwards et al [61] and Lau et al [43]. Previous studies have shown that when patients were unable to communicate effectively with experts, they felt bored and useless to use an app, resulting in a low utilization rate [36]. Therefore, when developing apps in the future, professional support functions should be added. In addition, when apps are actually used to manage the health of pregnant women, managers should coordinate the workload distribution of medical staff and include answering questions from pregnant women into their work scope, providing users with timely and effective professional support.

In addition to professional support, peer support also plays an important role in the formation and maintenance of patients'

self-management abilities. Peers can communicate with each other on their own experience, attitudes, and concepts, giving relevant suggestions to each other. Pregnant women in this study hoped that they could share confusion, emotion, and experience with peers who had similar needs and common goals through an app; thus, these women can obtain information and emotional support. This is similar to the findings of McDonald et al [62]. Studies have shown that peer support could overcome loneliness, powerlessness, and stress in pregnant women and increase maternal self-efficacy. Emotional support and exchange of experiences with peers are more acceptable to pregnant women. In addition, pregnant women can gain motivation from peer support to use an app [63]. Previous studies have found that providing a communication platform for users in a GDM prevention app could allow users to exchange their experiences and deal with problems during pregnancy, motivate users to achieve their expected goals, and increase the frequency of usage [64]. Therefore, apps should provide a module for pregnant women to communicate with their peers, allowing them to learn problem-solving skills through mutual assistance and to enhance psychological support.

Although some pregnant women in this interview study believed that the point reward function was of little significance, research has proven that the introduction of game mechanics could increase the user's sense of achievement and could cause the user to put more effort into accomplishing goals. Cafazzo et al [65] incorporated a gamification mechanism when designing a diabetes blood sugar management program. When young patients regularly checked their blood glucose, they could obtain corresponding points. These points could be redeemed for iTunes codes to purchase music and applications. The frequency of blood glucose monitoring increased by nearly 50% in patients using the apps. Ekezie et al [64] provided a virtual map for gestational diabetes mellitus patients in his app to improve the interest of patients' exercise, and set a step ranking list to encourage users to achieve exercise goals through competition, so as to increase user efficiency. It is suggested that when developing gestational diabetes prevention apps in the future, the gamification and reward mechanisms should be improved according to users' needs. Furthermore, more attractive methods should be set up to better assist patients in performing self-management, as well as raise their enthusiasm for using these apps.

Strengths and Limitations

Previous research has mostly focused on the user's experience and evaluation of developed apps after using them, and few

users have participated in the design of apps, leading to poor user stickiness. In this study, we conducted deep interviews on the preferences and functional needs of mHealth apps among people at risk for gestational diabetes, and the findings are important to guide the development of future interventions and other pregnancy health apps. In addition, the strength of this study is that the data analysis was performed by two researchers and information was continuously validated during the data analysis process. One of the researchers was the interviewer and the other was not involved in the interview. Therefore, in the process of data analysis, the two researchers had a different understanding of the existing data. Then they discussed and finally reached a more objective and unified opinion, and provided the analysis results to the participants to make their opinions expressed fully and correctly.

This study has several limitations. First, this study only interviewed 15 pregnant women in the same hospital in Beijing, China. Regardless of the fact that the sample size of this study reached saturation, the method of maximum difference sampling was adopted to select the research objects as much as possible. However, no interviewees from rural groups were included; thus, the interview results may not reflect the diverse needs of all pregnant women, making it difficult to generalize the findings to women in rural areas or different cultural situations. Before the formal interview, interviewers trained and practiced to improve their interviewing skills. However, as interviewers were conducting interviews for the first time, their interviewing experience and skills were limited, which may have affected the comprehensiveness of data collection. In addition, interviewers conducted interviews as medical interns, which made some interviewees reluctant to express their true feelings and needs, leading to a potential impact on data collection.

Conclusion

mHealth apps can provide new tools for the health management of people at risk for gestational diabetes. Before the development of a gestational diabetes prevention app, this study deeply collected the views and functional requirements of mHealth app development from gestational diabetes risk groups. The results can provide valuable information for the future development of mHealth apps related to the prevention of gestational diabetes that meet users' needs, and can provide a reference for the design of intervention content in the future. In addition, the findings can provide a reference for the development of other types of apps during pregnancy.

Acknowledgments

The authors sincerely thank all the interviewees for their active participation in this study. This study was supported by the National Natural Science Foundation of China (project number 71904133).

Authors' Contributions

BD performed data collection, performed data analysis and interpretation, and drafted the manuscript. ZL assisted in qualitative data analysis and interpretation, and co-drafted the manuscript. BG participated in manuscript review. WL conceived and designed the study and was responsible for revising the manuscript. All authors read and approved the final manuscript.

Abstract

Background: The transition from active treatment to long-term cancer survivorship leaves the needs of many cancer survivors unaddressed as they struggle with physical, cognitive, psychological, and social consequences of cancer and its treatment. The lack of guidance after treatment has forced cancer survivors to manage long-term effects on their own, which has an impact on their overall health, quality of life, and social participation. Mobile health (mHealth) interventions can be used to promote self-management and evidence-informed education.

Objective: This study aims to design an mHealth app for cancer survivors with disabilities that will offer interventions to improve their quality of life and increase their self-efficacy to manage cancer as a chronic condition.

Methods: We organized 3 co-design workshops with cancer survivors (n=5). These workshops included persona development based on data from 25 interviews with cancer survivors with disabilities; prototype ideation, where we sketched ideas for the prototype; and prototype development, where participants critiqued, and suggested improvements for, the wireframes.

Results: These workshops helped us to define the challenges that cancer survivors with disabilities face as well as important considerations when designing an mHealth app for cancer survivors with disabilities, such as the need for including flexibility, engagement, socialization, and a minimalistic design. We also outline guidelines for other researchers to follow when planning their own co-design workshops, which include allowing more time for discussion among participants, having small participant groups, keeping workshops engaging and inclusive, and letting participants dream big.

Conclusions: Using a co-design process aided us in developing a prototype of an mHealth app for cancer survivors with disabilities as well as a list of guidelines that other researchers can use to develop their own co-design workshops and design their app. Furthermore, working together with cancer survivors ensured that the design team had a deeper sense of empathy toward the target users and kept the focus on our ultimate goal: creating something that cancer survivors would want to use and benefit from. Future work will include usability testing of a high-fidelity prototype based on the results of these workshops.

Introduction

Background

There are an estimated 16.9 million cancer survivors in the United States, and the number is projected to increase to 22.2

million by 2030 [1]. There is tremendous variability in cancer incidence and survivorship globally because of variation in the prevalence of risk factors as well as access to high-quality preventive, screening, and treatment options [2]. Approximately 40% of cancer survivors experience long-term physical,

cognitive, and psychological effects of cancer and its treatment [3,4]. Common long-term effects include pain, fatigue, cognitive effects (eg, cognitive dysfunction or forgetfulness), and psychosocial distress symptoms such as anxiety and depression that can in turn lead to activity limitations and participation restrictions. Long-term effects can negatively affect social participation and health-related quality of life [5]; yet, cancer survivors report that these issues are inadequately addressed within the cancer care system, leaving patients to figure out the impact and long-term management of cancer-related impairments on their own [6]. It is within the purview of the interdisciplinary field of cancer rehabilitation to address the “physical, psychological and cognitive impairments in an effort to maintain or restore function, reduce symptom burden, maximize independence and improve quality of life” [7] of patients with cancer, including those in long-term survivorship. An evidence-informed approach to cancer rehabilitation and survivorship support is the use of self-management interventions that help people learn to deal with the medical, social, and emotional impacts of cancer and its treatment. An emerging body of literature demonstrates that self-management interventions have a positive impact on cancer survivors’ physical and psychological well-being and quality of life [8-10].

It should be noted that interdisciplinary cancer rehabilitation and survivorship services are significantly underused by cancer survivors [11]. Estimates suggest that <10% of the people with cancer-related impairments receive services [12,13]. The reason for this underuse is multifactorial, and in-person access to cancer rehabilitation and survivorship services has been identified as a contributing factor; for example, in the United States, there has been a decentralization of cancer care to favor high-quality cancer care in the community rather than in specialty hospitals. Diffusion of rehabilitation services in these community settings has been limited [14]. Indeed, cancer survivorship and rehabilitation programs are clustered in specialty care centers where fewer than half of the people with cancer receive treatment [15]. Access to rehabilitation services may be further exacerbated for cancer survivors with known disabilities because physical, cognitive, and emotional impairments can make care coordination, scheduling, and travel to and from appointments particularly onerous [7]. Furthermore, evidence suggests that oncologists receive limited education about cancer rehabilitation as well as its benefits and indications [16]. This can make service providers unlikely to initiate referrals for rehabilitation services. In addition, most National Cancer Institute–designated cancer centers do not provide information about cancer rehabilitation services on their websites, further restricting access and awareness of these potentially beneficial interventions [17]. This leads to a gap between the people who need support and those who receive it.

Mobile health (mHealth) interventions have been identified as a way to close the gap between the people who need rehabilitation services and those who are able to access them. mHealth interventions have a potentially democratizing impact on access to care because people are able to take in their own hands the tools to monitor and manage their health. mHealth interventions can provide people with tools to promote self-management, symptom monitoring, and evidence-informed

education [18], as well as opportunities for peer support and information sharing [19]. Although a variety of mHealth symptom management apps have been developed for cancer survivors, the apps tend to focus on monitoring and managing individual symptoms such as pain and fatigue [10]. As a result, existing mHealth self-management interventions often fail to address the knowledge and skills that cancer survivors with known disabilities need to achieve their goals of creating a meaningful life in spite of the aftereffects of cancer and its treatment [5]; for example, our qualitative research with cancer survivors indicated that many people were uncertain of how and when to communicate about the impact that the aftereffects of cancer had on their abilities to fulfill their social roles and responsibilities [20]. These findings point to an unmet need for strategies to help survivors articulate the impact of cancer on their daily lives and to self-advocate for support and accommodations.

Objectives

To address the unmet needs of cancer survivors who can benefit from ongoing support, we are developing a self-management intervention for cancer survivors with known disabilities called WeCanManage. WeCanManage is conceptualized as a psychoeducational intervention theoretically grounded in Individual and Family Self-Management Theory [21]. The active ingredients of the intervention include instruction and structured practice in (1) the problem-solving–based self-management process of goal setting and action planning supplemented with evidence-informed strategies such as energy conservation and environmental modifications, (2) mindfulness practices [22], and (3) self-advocacy skills. These complementary approaches empower users to build their self-efficacy, the presumed mechanism of change [23], in medical management, role management, and emotional management of cancer as a chronic condition [24]. Consistent with emerging best practices for remote learning, content will be delivered through mobile microlearning modules [25] for a maximum of 10 minutes per day over a 4-week period. Engagement activities will be embedded across the intervention to promote deeper learning and integration into daily life and routines [26,27]. We plan to deliver WeCanManage as an mHealth app, because internet-based self-management interventions provide users with a practical, flexible, and cost-effective alternative to face-to-face interventions [28-32].

For mHealth and rehabilitation tools to be acceptable, accessible, and responsive to the needs of the intended users, Jones et al [33] highlight the importance of proactive engagement of stakeholders, including members of the disability community. However, patient input is rarely included in the development of self-management interventions [8]. To ensure that the WeCanManage platform and design meets the needs and preferences of our target end users, we engaged a cohort of cancer survivors in the design process.

Whereas user-centered design is the process of focusing on users and their needs throughout the stages of the design process [34], co-design, or participatory design, takes this process one step further where designers and users collaborate during the design process [35]. Co-design can be valuable when developing

health-related apps [36,37] and can incorporate engaging techniques such as scenarios or storytelling approaches [38], developing or discussing personas [39-41], reporting on likes or dislikes regarding apps [42], voting on features and solutions [43], sketching out prototypes [38,44,45], redesigning or critiquing prototypes [36,40,46], and answering questionnaires [41,45]. Supplies can be minimal, such as paper, Post-it notes, and posters [45,47,48].

In our work, we primarily use 2 common co-design techniques: persona development and prototyping. Personas are fictional representations of users that help designers to understand and empathize with users [49,50] by challenging them to think “beyond their personal experiences” [39]. Each persona can have a set of characteristics, such as their gender, age, profession, goals, personal history, health issues, technological skills, and hobbies; often, a photograph is included [50]. Personas can include disabilities, which can raise awareness of accessibility and ensure that a design can be used by all [51]. Cocreating personas with people with disabilities can provide even more insight into their experiences [52]. Despite the fact that personas are not real people, they are often developed based on analysis of common themes discovered during user interviews [51,53,54]. Co-design workshops can be effective alongside user interviews [55], particularly because they can be helpful for persona creation. Another common activity during co-design workshops is prototyping. These are often wireframes (low-fidelity sketches) of a potential design that can help lead to higher-fidelity prototypes that are functional and closer to the finished product [56].

To build our intervention and app design, we recruited cancer survivors with disabilities to work with us toward creating a persona (workshop 1) and a prototype of an mHealth app that would empower the community of survivors to self-manage the lifelong effects of their cancer treatment (workshops 2 and 3).

Our research questions (RQs) are as follows:

- RQ1: What are the important design features for an mHealth platform for cancer survivors with disabilities?
- RQ2: What is needed to create an effective co-design environment for this target group?

Methods

Recruitment

To design an mHealth app for cancer survivors with disabilities, we recruited a diverse group of cancer survivors with known disabilities (n=5), whom we call *survivor scientists*, using a citizen scientist approach, to collaborate with our interdisciplinary research and development team [57]. Our inclusion criteria included participants self-identifying as a cancer survivor living with long-term physical, cognitive, or social effects of cancer and its treatment and that they had an established relationship with a faculty member or an institutional or organizational partner. The survivor scientists had experienced breast cancer, head and neck cancer, sarcoma, brain cancer, and leukemia, as well as a range of long-term effects of cancer (including cognitive changes, visual impairments, communication challenges, and decreased functional mobility

and fine motor control). All (5/5, 100%) of the survivor scientists were cancer-free and at least 5 years after diagnosis and completion of primary treatment. Several (3/5, 60%) of the survivor scientists are also active in cancer and disability advocacy organizations. The survivor scientists have a variety of professional backgrounds, including social work, graphic design, research support, and rehabilitation medicine with certification in cancer rehabilitation.

Together with the 5 survivor scientists (n=2, 40% men and n=3, 60% women), our team led 3 co-design workshops from July 2021 to October 2021. The first 2 workshops were conducted 2 weeks apart in July, and the third was conducted approximately 3 months later in October to provide enough time for our team to implement wireframes based on feedback from the previous 2 workshops. It should be noted that after the second workshop, we also provided the survivor scientists with the opportunity to continue to work with the research team in smaller groups and assigned them tasks related to their own interests, such as helping with content relating to cancer and disabilities. This work continued after the third workshop as well.

The participants received monetary compensation for their involvement in the co-design process. These workshops included (1) persona development, (2) prototype ideation, and (3) prototype development (wireframes). We developed a semistructured guide for each workshop based on the guide provided in Bradway et al [58]. Refer to [Multimedia Appendices 1-3](#) for our guides for all 3 workshops. The workshops consisted of the design team (8 researchers, faculty, and students from the Departments of Computer Science and Occupational Therapy and Disability Studies from 2 universities) working in combination with our 5 survivor scientists. It should be noted that our last workshop had fewer participants because, of the 5 survivor scientists, 1 (20%) could not attend; in addition, of the 8 members of the design team, 1 (13%) researcher and 2 (25%) undergraduate students who had completed their research experience did not attend; therefore, the total number of participants went from 13 (n=8, 62%, design team members and n=5, 38%, survivor scientists) to 9 (n=5, 56%, design team members and n=4, 44%, survivor scientists). Because of COVID-19-related restrictions, all 3 workshops were held over Zoom, a videoconferencing platform. The workshops were video recorded. The first workshop lasted for 2 hours, and the remaining 2 workshops lasted for 2.5 hours each. This duration is consistent with previous research [40], and we chose an amount of time that would be long enough to accomplish our goals and still keep participants engaged but not too long, particularly because the workshops were conducted on the web, after work, and with participants who had long-term disabilities as a result of cancer.

Within a week after each workshop, the design team met and summarized the main findings from the workshop. These notes were used to inform the development of the workshops that followed; for example, based on the challenges discovered in workshop 1 and the prototype features that the participants mentioned wanting in workshop 2, we developed the low-fidelity prototype that was then shared with the participants in workshop 3 for their feedback.

Although our goal was to create an mHealth app for cancer survivors with disabilities that (1) normalized their experiences as a survivor, (2) taught problem-solving self-management skills, (3) introduced mindfulness-based practices, and (4) addressed self-advocacy skills and disability and survivor rights, the goal of the co-design workshops was to ensure that we would be designing these modules in a way that was usable and engaging to cancer survivors with disabilities.

Ethics Approval

We obtained institutional review board approval from the participating universities in the larger project (University of Illinois Chicago #2020-1067, Northeastern Illinois University #79, and Northwestern University #NUUIC21CC03). The survivor scientists functioned as members of the design team, and no personally identifying data were gathered about them. Ground rules for participation to ensure respect and confidentiality throughout the process were established and agreed to by all participants. All cancer survivors who participated in formative qualitative interviews provided written informed consent before data collection in compliance with approved institutional review board protocols at the collaborating institutions. More details on the interview process and findings from this phase of the study have been reported elsewhere [20].

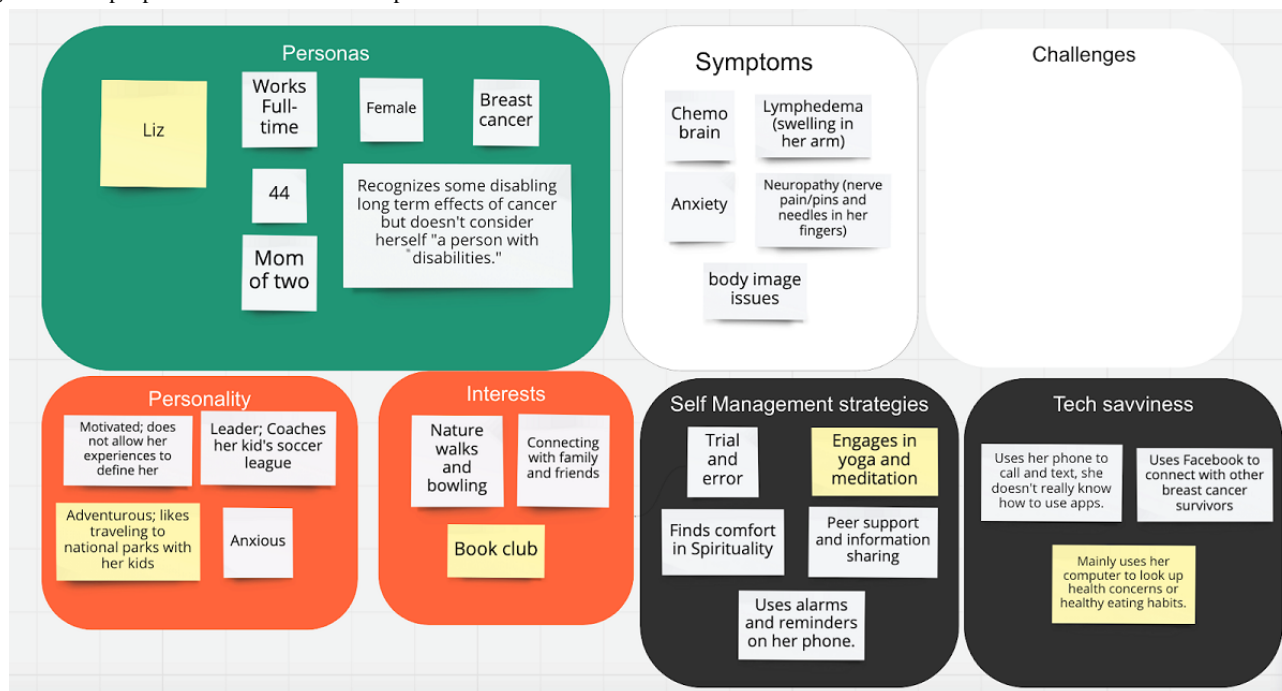

Results

Workshop 1: Persona Development Methodology

The aim of our first workshop was to complete the design of personas to help the design team understand the needs and challenges of cancer survivors with disabilities and build empathy through persona development. The survivor scientists (n=5) attended our first persona development workshop and worked alongside our team of researchers. In advance of this workshop, the research team created 2 personas of cancer

survivors with disabilities, using Miro, a visual collaboration platform. These personas were developed based on preliminary analysis of 25 qualitative interviews of breast cancer, sarcoma, and head and neck cancer survivors to foster empathy for the struggles of survivors living with long-term disabilities. Specifically, demographic and clinical data were extracted from the data corpus (demographic surveys, interview transcripts, and field notes) to ground the preliminary personas in the lived experience of survivors of breast cancer, head and neck cancer, and sarcoma. Conceptually, we structured our personas in accordance with the World Health Organization's International Classification of Functioning, Disability, and Health (ICF) framework [59]. The ICF is an internationally recognized biopsychosocial framework that recognizes the dynamic interaction between impairments in body structures and function, activity limitations and participation restrictions, and environmental factors in people's lived experiences of disability. Extracted data included age, gender, race and ethnicity, cancer type, primary symptoms, and impact on social roles and participation. Although our work was informed by the literature [50,51] and the ICF, the categories chosen were based on common themes from our analysis that would make the personas more relatable. We input the data into a persona template provided by Miro to create 2 distinct personas. We decided not to include an image to avoid participants accepting what we provided as a given, but we wanted them to improve upon and complete the profiles. Figure 1 shows a sample of one of the personas developed for the workshop. The challenges section was intentionally left blank for the survivor scientists to fill in that category themselves.

We used 2 breakout rooms to discuss, modify, and complete each persona. Using a Zoom poll, the survivor scientists ranked the most relevant challenges that a cancer survivor was likely to face. Finally, we discussed the ranking results with the survivor scientists.

Figure 1. Sample persona before the workshop.

Workshop 1: Persona Development Results

During these breakout sessions, the survivor scientists critiqued the personas and described the needs and challenges; for example, in breakout room 1, the survivor scientists modified the persona for Liz, a breast cancer survivor, by providing more details making her even more relatable (Figure 2). Liz is now an African American woman, with a partner, and children aged 5 and 14 years. She works in retail, which requires prolonged standing and heavy lifting and has limited insurance tied to her job. The survivors discussed challenges, some of which include financial pressures, long-term symptoms interfering in her life, isolation because of lack of peer support, concern regarding the emotional toll on her children and relationship with her partner, and body image concerns. The survivor scientists felt that these details helped to encapsulate the complexity of living with the long-term effects of breast cancer while juggling multiple roles and responsibilities.

In breakout room 2, the survivor scientists discussed Solomon, a man aged 56 years, who is divorced and is on the fence regarding looking for a romantic partner because of body image issues as a result of head and neck cancer. His interests originally included karaoke and barbecues with his family most weekends. However, the survivor scientists discussed how he may have once enjoyed karaoke and eating with his friends before cancer, but now singing would be difficult, and eating

with friends would cause anxiety because of his slower eating speed. The results of both breakout sessions showed that the survivor scientists deemed it important to acknowledge the high levels of anxiety caused by role loss, fear of recurrence, financial toxicity, and the strain that cancer continues to impose on relationships with family and friends. In addition, the survivor scientists wanted to highlight the challenges that cancer survivors encounter when re-establishing leisure roles and maintaining their employment because of physical and cognitive limitations, as well as the impact that role loss has on a person's identity and sense of self. Use of compensatory strategies and adaptation were also discussed.

After the breakout sessions, participants reconvened in the larger group and shared their enhanced personas. Using the challenges identified in both breakout sessions, we had participants select the 3 challenges that they felt were most important using Zoom's polling feature. The results, presented in Figure 3, reveal that isolation, financial pressures, and anxiety or depression were the biggest challenges. These were closely followed by participation in work and leisure, as well as social roles. It should be noted that 6 participants completed the Zoom poll because, of the 8 members of the design team, 1 (13%), a researcher, is also a breast cancer survivor and provided feedback alongside the survivor scientists based on her own experiences as a survivor.

Figure 2. Sample persona after the workshop.

Figure 3. Ranking the results of the persona workshop.

Workshop 2: Prototype Ideation Methodology

The aim for the second workshop was to determine what features cancer survivors with long-term disabilities like in current apps. We first asked the survivor scientists to list (in the Zoom chat) the apps they like in general as well as the apps they dislike to encourage them to think about design. We then directed them to a shared Google Sheets document where they each had a column with their names to list the features they liked in apps and the features they did not like. We generated a word cloud using a free word cloud generator [60] with the results. Next, we divided participants into 2 breakout rooms (intentionally placing them with different people than at the previous workshop as well as keeping in mind diversity in terms of disability and gender). We showed each group different potential content and asked them how they would deliver this content so that it would be inclusive and engaging to cancer survivors. Using the Miro board, we also asked them to provide us with sketch ideas for

how they envisioned the app. Although there were design limitations in terms of technical capabilities and budget on the development side, we told the survivor scientists to think in terms of an open universe where anything is possible because we did not want to limit their thinking. Once merged back into the larger group, each group presented their work to the other group. Using features that both groups felt were important in the design of the app, we had the participants rank the features that were most important to them using Slido, a live polling platform (Cisco Systems, Inc).

Workshop 2: Prototype Ideation Results

After the participants had listed their likes and dislikes in apps, we generated a word cloud (Figure 4). The features that the survivors liked included networking, ease of use, and simplicity, whereas the features that the survivors disliked included lack of user-friendliness, too many notifications and advertisements, and poor navigation.

Figure 4. (A) Participants' likes in apps. (B) Participants' dislikes in apps.

After we divided the survivors into 2 groups and asked them to think about ideas for sketches (using Miro) that they envisioned for the app, one of the groups asked the workshop leader to sketch a learning pathway to be able to provide ease of navigation and engagement (Figure 5A). The participants also mentioned that the app should include photos of people from different backgrounds in terms of race, disability, and age. In addition, they discussed including the use of animation, which can help those with attention disorders, icons instead of only text for those with cognitive disabilities, and customizable color choices and simpler layouts for those with visual impairments. In the second breakout room, of the 5 survivor scientists, 1 (20%) created a paper mockup that she felt would look engaging, and based on her drawing which she held up to the camera, along with feedback from the rest of the breakout room

participants, workshop leaders sketched it using the Miro board (Figure 5B). The survivor scientists felt that the content should be engaging, with videos as well as content that was easy to access. Furthermore, they discussed that apps for people with disabilities tend to be poorly designed and “ugly” and that good design would alienate no one. They were very happy to be part of the process of designing the app.

After gathering all the information that the survivors added to the sticky notes in Miro, the word cloud, and the sketches, we asked the survivors to rank the features from most important to least important (Figure 6). The top 3 features that were most important to the survivor scientists were customizability and personalization, ease of navigation and searchable content, and accessibility. This was followed by minimal design.

Figure 5. Workshop sketches. (A) Breakout room 1. (B) Breakout room 2.

Figure 6. Features ranked from most important to least important.

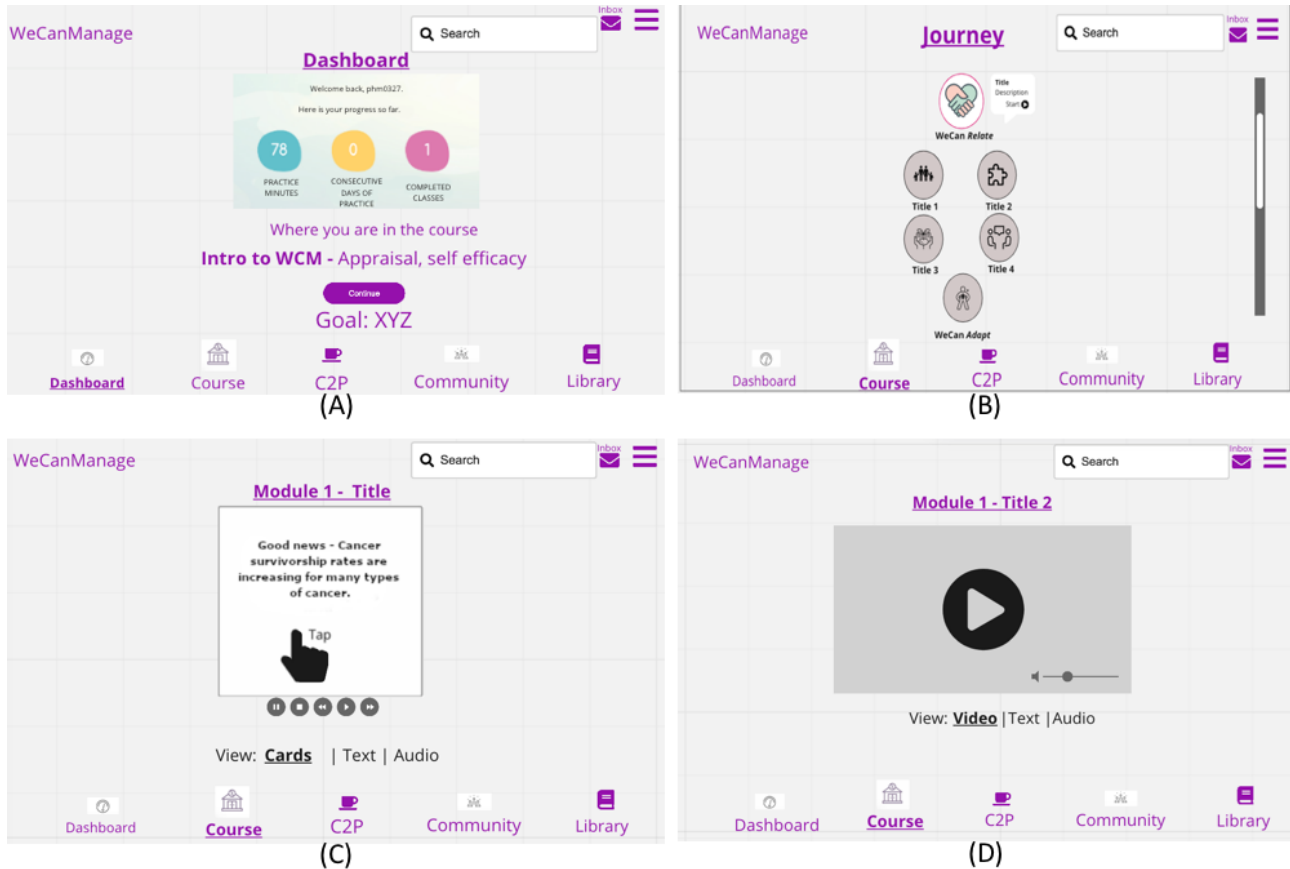

Workshop 3: Prototype Development Methodology

In our third workshop, we wanted to find out what the participants thought of the low-fidelity prototype that was created to address the challenges raised in workshop 1 (eg, isolation) and the features they mentioned wanting in workshop 2 (eg, customization). We also wanted to learn what improvements could be made. We divided the researchers and survivor scientists into 2 breakout rooms to critique the wireframes. After coming together in the larger Zoom room, both groups presented their thoughts on the design. We also led a conversation on whether to include a community forum or a feed-like aspect in the app. As shown in Figure 7A, the first screen presented to the survivor scientists was the Dashboard. To meet the survivor scientists' needs for personalization, we incorporated a section for a personalized goal that the user would type in and be working toward achieving. This would be visible on the landing page after logging in. We also matched the

pathway that the survivors requested from the previous sketch (Figure 5A) in the Course tab (Figure 7B). Connect to Peers (C2P; the C2P tab) was provided as a space for users to build their network and connect with other cancer survivors through direct messaging, with the Community section being a place where users can share their experience and support one another through forums. The Library section would contain helpful resources. When logging into a course, the users will be offered a series of microlessons subdivided into 4 content modules: *WeCanRelate* seeks to normalize and validate their experiences as survivors, *WeCanAdapt* focuses on problem-solving-based self-management skill building to promote self-efficacy, *WeCanBreathe* introduces mindfulness-based practices, and *WeCanSpeakUp* addresses self-advocacy skills as well as disability and survivor rights. Users will also be given the opportunity to select the mode of presentation they prefer, which includes formatting the participative cards (or video) into text or audio (Figures 7C and Figures 7D). This will allow users to

comfortably access the content in the mode that best supports their learning style and access needs. We also provide knowledge checks throughout each course module.

Figure 7. Wireframes. (A) Dashboard page. (B) Course navigation. (C) Cards module. (D) Video module. C2P: Connect to Peers; WCM: WeCanManage.

Workshop 3: Prototype Development Results

On the basis of the results of the workshop, the survivor scientists liked the wireframes but had concerns with the main Dashboard screen having too much information and the Journey

screen having too much white space, and they did not like the terminology used, such as the words dashboard, course, and quiz. Figures 8A and Figures 8B show sketches of the home screen and Journey page, respectively, revised after discussions with the survivor scientists.

Figure 8. (A) Updated home screen. (B) Updated Journey page. C2P: Connect to Peers.

Although we had a larger group discussion on whether to include community forums or a feed-like design (as available on many social networking sites), the participants did not have a strong preference for one format over the other. The survivor scientists liked that there was a way to contact peers on the site either directly or through the forum or feed option.

Discussion

Principal Findings

We formulated our RQs to discover what design features are important for an mHealth platform for cancer survivors with disabilities (RQ1) and what would be needed to create an effective co-design environment for this target group (RQ2).

The 3 workshops provided us with a strong foundation to move forward with well-defined goals for designing an mHealth app for cancer survivors with disabilities. Our results indicate that participants wanted an mHealth app that encompasses (1) flexibility, (2) engagement, (3) socialization, and (4) a minimalistic design.

Our first finding is that participants wanted *flexibility* in the app. The top-ranked feature that the survivor scientists wanted in workshop 2 was customization and personalization. Participants wanted an app that can be easily customized to their preferences and their access needs. They also wanted accessibility features and an app that was easily searchable. Therefore, in our design for workshop 3, to suit the content to the learning needs of the individual we provided the option to view content (whether video or cards) in an audio-only or text-only format, providing flexibility to the user.

Furthermore, the survivor scientists, in workshop 2, reported liking features that were participative. Users are more receptive to mHealth apps when they are *engaging* [61]. The survivor scientists recommended the use of color, video, and interaction. They also liked the idea of a learning pathway for the course content. We incorporated this feedback in the prototype shown to the participants in workshop 3. As noted in the study by Jessen et al [40], participants liked receiving recognition from an mHealth app for finishing tasks and setting up their own goals and subgoals. Similarly, we found that participants liked being able to input their goals and view them on the main screen. In addition, we discovered that participants enjoyed ways to determine their progress through quiz-like activities and a journey section that kept track of their course pathway.

The participants reported in workshop 1 that one of the biggest challenges was isolation. Although engaging features can be beneficial in an mHealth app, communicating with others going through similar experiences has been found to be a key feature in supporting mHealth apps [40]. Therefore, we found that survivor scientists wanted *socialization* as well. In our design, we showed participants in workshop 3 the different ways in which users could interact with each other. Participants liked having a way to connect directly with peers going through similar experiences (the C2P section) and benefit from being able to ask questions or post comments to the community of cancer survivors (the Community section). This enhanced their socialization experience.

Although including goals, progress, and opportunities for socialization are effective techniques, similar to other studies we found that the app should be designed using a *minimalistic design* approach [62]. In workshop 2, our participants reported preferring minimal design. This concept was supported again in workshop 3, when participants reported not liking when there was too much content on the screen. They wanted a clean and simple interface that would engage them and allow them to easily comprehend where to go. This was most noted on the home screen, which they felt was initially too cluttered.

Comparison With Prior Work

The study was able to extend previous research by addressing RQ1 and providing tips on creating mHealth apps through what

we learned in our co-design workshops (flexibility, engagement, socialization, and a minimalistic design). Furthermore, our work extends previous work on planning successful co-design workshops for health-related apps [36,37], particularly for internet-based co-design workshops. Näkki and Antikainen [63] found that using web-based tools can make it easier and cheaper to include users as co-designers. People with disabilities benefit from being able to work in remote settings, which therefore promotes a more inclusive environment [64]. The Zoom-based co-design workshops, despite their limitations, provided flexibility for the survivor scientists in terms of geographical limitations and participants with disabilities being comfortable and able to work out of their own homes. In our work, to address RQ2, we found that successful co-design workshops should be engaging, inclusive, provide more time for participants to speak up, use smaller participant groups, and let participants think big (provide a universe where anything is possible).

Researchers should keep the co-design process as *engaging* as possible while keeping in mind their target users, the technology, and any limitations [40,58]. Although keeping it engaging is true in face-to-face workshops as well, this can be even more pronounced in a web-based environment where “Zoom fatigue” [65] can be prevalent. Engaging techniques can be included in numerous ways. In our case, we incorporated many web-based tools such as Zoom’s breakout rooms, poll and chat features, Slido, word clouds, and Miro.

In addition, to help keep it engaging, a significant portion of time should be allotted *for participants to speak up*. Arsand and Demiris [38] discuss allocating sufficient time for several meetings with users to allow time for their creative ideas. In our first workshop we had many more activities planned that we did not get to complete because we did not allocate enough time for participation of the survivor scientists. We made adjustments by adding the needed time and not finishing everything as planned; for example, we had allocated 20 minutes for the breakout session in workshop 1, which we modified to 30 minutes while in the breakout rooms. We also provided 10 minutes for the survivor scientists to discuss their challenges, but this was not enough; therefore, we continued to let them talk and decided not to complete all the topics that came later in the list included in the workshop guide. Staying flexible allowed us to provide additional time to the participants. Additional time for conversation may be particularly important in a web-based format, which limits some of the informal communication and connections inherent in in-person workshops. Learning from this, we set the time allocated for the next 2 workshops to 2.5 hours (instead of 2 hours) and provided extra time for the breakout rooms and survivor scientist discussion (refer to [Multimedia Appendices 2 and 3](#)). Finally, we reduced the amount of time that we presented to make it more engaging and participatory. Providing survivors with additional time and opportunities for feedback and sharing of ideas in the workshops was crucial because many of their ideas helped to shape the design of the app.

For participants to be comfortable speaking up and participating, previous work has shown that breaking out into *smaller working groups* can be helpful [66,67]. Using Zoom breakout rooms in web-based workshops can foster engagement and reduce “Zoom

fatigue” [67]. We only included 5 survivor scientists, but, with the addition of the researchers, workshops 1 and 2 had 13 participants each. Although the breakout rooms were very helpful in facilitating the division of the team into smaller groups, after the second workshop we also recruited survivor scientists to work individually with a researcher on content development or design; for example, of the 5 survivor scientists, 1 (20%) came up with the idea of modifying WeCanManage course content into modules whose titles will all begin with WeCan; for example, WeCanRelate. Another survivor scientist offered to work on content development for specific cancer symptom management resources, whereas another will focus on more of the disability aspects. Having survivor scientists self-select into areas based on their own skills and interests enabled them to be even more efficient and feel useful in the co-design process.

Another approach to encourage participants to speak up is through creating an *inclusive environment*. Creating a comfortable and inclusive environment in co-design workshops is one of the lessons found in the study by Bradway et al [58]. Similarly, we wanted the environment to be welcoming to all. Therefore, we began the first workshop with time for rapport building and informal conversation before establishing ground rules aimed at creating an environment of trust and respect. The ground rules included emphasizing that everything discussed in the workshops was confidential, and all opinions were valid. We reminded participants of this at the beginning of the next 2 workshops. Although there may be differing opinions, it is important to show respect for all the different views, particularly because participants can be very passionate about an app that would be of direct benefit to them. Although there are a limited number of inclusive apps [68], ensuring respect for co-designers with their own particular backgrounds and disabilities can lead to the creation of apps that are more inclusive because the co-designers keep in mind their own personal experiences and disabilities in the design process.

In addition to making co-design participants feel comfortable sharing their ideas, it is important to allow them “the latitude to dream big and imagine a best-case scenario with no constraints” [69]. The concept of *dreaming big* and providing a universe where anything is possible can promote creativity

and facilitate learning about what users find important in a design [69-72]. To encourage participants to speak up, we did not limit their ideas by mentioning technical or budgetary considerations but encouraged them to dream big. Particularly in a web-based co-design workshop, dreaming big could be even more difficult for participants with limited technical skills. However, we saw how important and useful this was throughout the design process; for example, although the learning pathway sketch (Figure 5A) was how the participants were picturing the design to be, after speaking with our development team we toned it down to a parallel tile-based design (Figure 7B). Later, this was modified after further conversations with the survivor scientists, using a compromise approach that worked for the development team as well as the design team (Figure 8B). Having co-designers who are not limited to the practical aspects of design can help to encourage creative thinking and lead to a more meaningful design.

Limitations

We encountered limitations in the co-design process because of technical difficulties and pandemic-related hurdles. Because of COVID-19–related restrictions, we conducted all workshops with survivor scientists over Zoom. Although this provided flexibility in terms of location and scheduling, we were limited in that we could not use Post-it notes, posters, and paper during the workshops. We conducted most of our designing of personas and prototypes through Miro. As the technology can be challenging for first-time users, we chose to have 1 person from our design team lead the Miro board activities in each breakout session.

Conclusions

The results from the co-design workshops provided our research team with a deeper level of empathy for our target users and a better understanding of long-term survivorship challenges and needs for an mHealth app. The collaborative development aided in creating a shared vision of target users among researchers and survivor scientists, while being an engaging co-design experience. Future work will continue to include survivor scientists in the design process as we create a high-fidelity prototype and conduct usability testing, which will be followed by the implementation of the app.

Abstract

Background: Mass media campaigns are effective for influencing a broad range of health behaviors. Prior to launching a campaign, developers often conduct ad testing to help identify the strengths and weaknesses of the message executions among the campaign's target audience. This process allows for changes to be made to ads, making them more relevant to or better received by the target audience before they are finalized. To assess the effectiveness of an ad's message and execution, campaign ads are often rated using a single item or multiple items on a scale, and scores are calculated. Endorsement of a 6-item perceived message effectiveness (PME) scale, defined as the practice of using a target audience's evaluative ratings to inform message selection, is one approach commonly used to select messages for antitobacco campaigns; however, the 6-item PME scale often does not produce enough specificity to make important decisions on ad optimization. In addition, the PME scale is typically used with adult populations for smoking cessation messages.

Objective: This study includes the development of the Message Assessment Scale, a new tobacco prevention message testing scale for youth and young adults.

Methods: Data were derived from numerous cross-sectional surveys designed to test the relevance and potential efficacy of antitobacco truth campaign ads. Participants aged 15-24 years (N=6108) responded to a set of 12 core attitudinal items, including relevance (both personal and cultural) as well as comprehension of the ad's main message.

Results: Analyses were completed in two phases. In phase I, mean scores were calculated for each of the 12 attitudinal items by ad type, with higher scores indicating more endorsement of the item. Next, all items were submitted to exploratory factor analysis. A four-factor model fit was revealed and verified with confirmatory factor analysis, resulting in the following constructs: personally relevant, culturally relevant, the strength of messaging, and negative attributes. In phase II, ads were categorized by performance (high/medium/low), and constructs identified in phase I were correlated with key campaign outcomes (ie, main fact agreement and likelihood to vape). Phase II confirmed that the four constructs identified in phase I were all significantly correlated with main fact agreement and vape intentions.

Conclusions: Findings from this study advance the field by establishing an expanded set of validated items to comprehensively assess the potential effectiveness of advertising executions. This set of items expands the portfolio of ad testing measures for ads focused on tobacco use prevention. Findings can inform how best to optimize ad executions and message delivery for health behavior campaigns, particularly those focused on tobacco use prevention among youth and young adult populations.

Introduction

Mass media public education campaigns are an effective population-level intervention for influencing a broad range of health behaviors. Prior to launching a campaign, developers often conduct message testing to assess creative executions that will be effective among the specific audience targeted by the campaign. For a campaign to be effective, messages must resonate with the target audience to influence changes in knowledge, attitudes, and intentions, and in turn, the specific health behavior of interest. According to the Centers for Disease Control and Prevention, when campaign messages are delivered to attain sufficient reach, frequency, and duration, one can expect changes in campaign-targeted attitudes after the campaign has aired for 12 to 18 months and can expect behavioral changes after the campaign has aired for 18 to 24 months [1]. To assess message effectiveness, campaign messages are often rated using a single item or multiple items on a scale, and scores are calculated [2].

Perceived message effectiveness (PME), defined as the practice of using a target audience's evaluative ratings to inform message selection, is one approach to assess message effectiveness. Measuring PME using six items (ie, the ad is powerful, the ad is meaningful, the ad captures my attention, the ad is informative, the ad is convincing, and the ad is worth remembering) on a 5-point agreement scale has been shown to be a valid predictor of ad effectiveness [3]. The assumption is that messages scoring higher on the PME scale would be more likely to affect actual message effectiveness, for example, changing knowledge, attitudes, intentions, and ultimately the behavior of interest [4].

Several studies demonstrate the predictive validity of PME for changes in attitudes, intentions, and behaviors related to substance use among young people, particularly related to antitobacco campaigns [3,5-8]. For example, a recent systematic review of longitudinal studies in the antitobacco campaign literature examined the use of PME as a validated indicator of message effectiveness; researchers found that across 6 studies, PME provided predictive validity in measuring the effectiveness of antitobacco-related messages. In particular, the review confirmed that PME was associated with a variety of beliefs (eg, beliefs about smoking and quitting smoking) and behaviors (eg, message recall, conversations about ads, quit intentions, and cessation behavior) [8]. Although PME has been widely used for message selection, the scale often does not produce enough specificity to effectively modify or optimize an ad execution to improve its efficacy. Ad optimization refers to the process of using data to guide modifications/changes to ads that make them more relevant to or better received by the target audience. In addition to PME not providing enough specificity, PME has also primarily been used to assess smoking cessation media messages designed for adult populations.

The purpose of this study was to develop and validate additional measures to assess message effectiveness while providing additional evidence for ad optimization for tobacco prevention campaigns designed for youth and young adults. Data related to ad optimization, prior to campaign launch, can increase the likelihood of maximizing campaign resources. Findings from this study can broaden the capacity of evaluators to conduct message testing for antitobacco campaigns, particularly with respect to younger populations.

Methods

Overview

This study was conducted in two phases. Phase I used data from 11 cross-sectional surveys, conducted using the Dynata online panel from December 2016 to September 2018. Surveys were identical (with the exception of minor customizations, specific to the ads) and were conducted to assess receptivity to truth campaign ads that messaged on tobacco use but varied in their strategic goals. Participants were randomized to view only one ad, to avoid positional bias, before completing the survey. Each survey included 12 items related to message receptivity, including perceptions of effectiveness and relevance. The final sample included 2577 participants, aged 15-24 years, across 5 antitobacco ads (n=1275) and 6 antivape ads (n=1302). During this phase, mean scores were calculated for each of the 12 items by ad type, and factor analyses were run. Factor analyses were run at this phase to identify how the 12 items fit together and mapped onto different constructs.

The phase II analysis was conducted to validate constructs identified at phase I. Together, these constructs would go on to be referred to as the Message Assessment Scale. Phase II included the constructs identified at phase I in 13 cross-sectional forced exposure surveys, conducted using the Dynata online panel from July 2014 to June 2019 to test truth campaign ads. The final sample included 3531 participants, aged 15-24 years, across 10 antitobacco ads (n=2633) and 3 antivape ads (n=898). Mean scores for the constructs were examined across ads to assess campaign-aligned performance, and correlations were run to examine the relationship between construct scores for antivape ads, main fact agreement, and vape intentions. The goal of the correlation analysis at this phase was to determine if the constructs identified at phase I impacted campaign outcomes in a campaign-aligned direction.

Ethical Considerations

All study protocols were reviewed and approved for human participation in research by the institutional review board of Advarra Inc (Pro00034056; formally Chesapeake IRB). Informed consent was included in the online survey and participants could check "Yes, I would like to continue" or "No, I do not wish to take part in this study." Parental permission was collected from minor participants younger than 18 years.

Measures

Attitudinal Items

Ad *likability* was assessed using the item “In general, what is your impression of this ad?” Response options were on a 5-point Likert scale including “dislike it a lot,” “dislike it somewhat,” “neither like nor dislike it,” “like it somewhat,” and “like it a lot.” Average likability was reported, ranging from 1 to 5, with higher scores indicating a more likable ad.

All other attitudinal items were assessed on a 5-point Likert scale including “strongly disagree,” “disagree,” “neither agree nor disagree,” “agree,” and “strongly agree.” The following base was used: “How strongly do you agree or disagree with each of the following statements about the ad?” Items included “It told me something I didn’t already know,” “It gave me good reasons not to [smoke; use e-cigarettes/vape],” “It really speaks to me,” “I identify with what this message says,” “It is for people like me,” “It is relevant for my generation,” “It feels modern/current,” “It is an acceptable way to talk about the issue of [smoking; using e-cigarettes/vaping],” “It is motivating,” “It is believable,” “It makes me want to tell someone about it,” “It is confusing,” “It is too fast,” and “It is offensive.”

Main Fact Agreement

Each of the 13 cross-sectional surveys used in phase II included main facts for the ad being tested. Participants were asked “How strongly do you agree or disagree that the video communicates each of the following messages?” Examples of facts included were “Just because vaping is safer than cigarettes, doesn’t make it safe” and “People who vape are being tested on.” Response options were on a 5-point Likert scale ranging from “strongly disagree that the ad conveys this message” to “strongly agree that the ad conveys this message.” Higher scores indicated greater fact agreement.

Vape Intentions

Self-reported change in likelihood to use or try vapes or e-cigarettes after seeing each ad was assessed by the item “Since having seen this ad are you...?” Answer options included “much more likely to use or try vapes or e-cigarettes including JUUL,” “somewhat more likely to use or try vapes or e-cigarettes including JUUL,” “no change in my likelihood to use or try vapes or e-cigarettes including JUUL,” “somewhat less likely to use or try vapes or e-cigarettes including JUUL,” and “much less likely to use or try vapes or e-cigarettes including JUUL.” Items were categorized for analysis into “more likely,” “no change,” and “less likely” to use or try vapes or e-cigarettes including JUUL.

Demographics

Demographic items included age (grouped as 15-17 years, 18-21 years, and 22-24 years), gender (male and female), race/ethnicity (non-Hispanic White; Hispanic, Latino, or Spanish origin; non-Hispanic Black or African American; and non-Hispanic other/declined), and subjective financial situation (do not meet

basic expenses, just meet basic expenses with nothing left over, meet needs with a little left over, and live comfortably).

Analysis Plan

Descriptive statistics were calculated to identify the phase I and phase II samples. In the phase I analysis, mean scores were calculated for each of the 12 attitudinal items by ad type, with higher scores indicating more endorsement of that item. The 12 attitudinal items were then entered into an exploratory factor analysis to determine possible factor structures. Factor loadings and subsequent interpretation of the relative component scores indicated that a four-factor solution best fit the data. Using the supported four-factor structure, a confirmatory factor analysis (CFA), using varimax rotation, was conducted to determine the validity of the scale, check model fit, and examine internal consistency for each identified factor using Cronbach alpha. Final factors and corresponding psychometric properties are presented to represent phase I results.

In phase II, an external marketing consultant, with a decade’s long experience analyzing truth pre- and postmarket data, placed the 13 ads into high (n=6 ads), medium (n=4 ads), or low (n=3 ads) performance groups based on the original goals of each advertisement such as agreement with key targeted beliefs like “ending youth smoking is an achievable goal” and relative performance of each against strategic objectives. Mean scores were examined across all ads in each ad performance group to determine how these four constructs varied by performance. Mean scores were also used to determine if items performed in a campaign-aligned direction such that more agreement on items indicated the ads were more relevant and message comprehension was higher. Finally, correlations were examined between construct scores for the antivape ads and main fact agreement as well as between construct scores for the antivape ads and self-reported change in likelihood (ie, a decrease in intentions) to vape since having seen the ad. Data were analyzed using SPSS (IBM Corp) and MPlus (Muthén and Muthén) statistical modeling programs.

Results

Sample Description

Participant characteristics are summarized in [Table 1](#). At phase I, the mean age was 19.4 (SD 2.9) years, while at phase II, the mean age was 18.8 (SD 2.5) years. Of the 2577 participants in phase I, 1315 (51%) were male and 1262 (49.9%) were female. The majority (n=1378, 53.5%) were non-Hispanic White. Of the 3531 participants in phase II, 1793 (50.8%) were male and 1738 (49.2%) were female. Non-Hispanic White respondents also represented the largest racial category (n=1829, 51.8%). Finally, at phase I, most (n=1649, 64%) respondents reported meeting their financial needs either “comfortably” or with “a little left over,” and at phase II, most (n=2317, 65.6%) respondents also reported meeting their financial needs either “comfortably” or with “a little left over.”

Table 1. Sample characteristics for the phase I and phase II samples.

Characteristic	Phase I (n=2577), n (%)	Phase II (n=3531), n (%)
Age (years)		
15-17	834 (32.4)	1193 (33.8)
18-21	1030 (40.0)	1833 (51.9)
22-24	713 (27.7)	505 (14.3)
Gender		
Male	1315 (51.0)	1793 (50.8)
Female	1262 (49.0)	1738 (49.2)
Race/ethnicity		
Non-Hispanic White	1378 (53.5)	1829 (51.8)
Hispanic, Latino, or Spanish origin	518 (15.3)	504 (14.3)
Non-Hispanic Black or African American	393 (20.1)	746 (21.1)
Non-Hispanic, Other/Declined	288 (11.2)	452 (12.8)
Subjective financial situation		
Do not meet basic expenses	191 (7.4)	248 (7.0)
Just meet basic expenses with nothing left over	737 (28.6)	966 (27.4)
Meet needs with a little left over	1071 (41.6)	1418 (40.2)
Live comfortably	578 (22.4)	899 (25.5)

Phase I

CFA results are summarized in [Table 2](#). The factor analysis revealed four new constructs (personally relevant, culturally relevant, strength of message, and negative attributes) with a total of 12 items. Fit statistics indicated that the four-factor model fit the data well (comparative fit index 0.97, root mean square error of approximation 0.05, standardized root mean squared residual 0.03; $\chi^2_{66}=9182.5$; $P<.001$) [9].

Mean scores for each of the 12 items tested in phase I are listed in [Table 3](#) by ad type (antitobacco and antivape). Mean score analyses indicated that the items performed similarly across antitobacco and antivape ads. The personal relevance, cultural relevance, and strength of message items had higher overall mean scores (scores closer to 5 indicated more agreement that the ads were personally relevant, were culturally relevant, and had strong messaging). The negative attribute items, however, had lower overall mean scores, indicating less confusion, offensiveness, or pacing concerns.

Table 2. Confirmatory factor analysis results for the phase I sample.

	Estimate	SE	Est/SE
Personally relevant			
It really speaks to me	0.83	0.01	83.50
I identify with what this message says	0.73	0.01	55.50
It is for people like me	0.72	0.02	49.24
Culturally relevant			
It is relevant for my generation	0.75	0.02	48.31
It feels modern/current	0.72	0.02	45.76
It is an acceptable way to talk about the issue	0.75	0.02	50.76
Strength of message			
It is motivating	0.81	0.01	74.20
It is believable	0.73	0.01	51.19
It makes me want to tell someone about it	0.74	0.01	56.79
Negative attributes			
It is confusing	0.81	0.02	39.06
It is offensive	0.57	0.03	22.97
The pace was too fast	0.56	0.02	25.23

Table 3. Mean scores for the items tested in phase I, by ad type.

	Antitobacco ads (n=1275), mean (SD)	Antivape ads (n=1302), mean (SD)
Personally relevant (range 1-5)		
It really speaks to me	3.36 (1.12)	2.99 (1.17)
I identify with what this message says	3.41 (1.12)	3.28 (1.09)
It is for people like me	3.64 (1.08)	3.17 (1.16)
Culturally relevant (range 1-5)		
It is relevant for my generation	3.97 (0.91)	3.78 (1.08)
It feels modern/current	3.92 (0.90)	3.55 (1.07)
It is an acceptable way to talk about the issue	3.93 (0.94)	3.65 (1.06)
Strength of message (range 1-5)		
It is motivating	3.69 (0.99)	3.25 (1.11)
It is believable	4.02 (0.88)	3.69 (1.01)
It makes me want to tell someone about it	3.49 (1.12)	3.21 (1.13)
Negative attributes (range 1-5)		
It is confusing	2.02 (1.05)	2.23 (1.07)
It is offensive	2.04 (1.09)	2.01 (0.99)
It is too fast	2.34 (1.02)	2.54 (1.06)

Phase II

Internal consistency for the constructs identified at phase I was assessed using Cronbach alpha. The four new constructs had alpha scores above .69, indicating an acceptable level of internal consistency (Table 4). Mean scores for the personal relevance, cultural relevance, and strength of message constructs were the highest for the high-performance ads. Accordingly, the mean

scores for the negative attributes constructs were the lowest for the high-performance ads (Table 4).

Correlations with main fact agreement and vape intentions for the antivape ads are summarized in Tables 5 and 6. Overall, results revealed that the personal relevance, cultural relevance, and strength of message constructs were significantly positively correlated with main fact agreement and vape intentions for most of the antivape ads. In other words, as personal relevance,

cultural relevance, and strength of message scores increased, participants were more likely to agree with the ads' main fact and report a decrease in intentions to vape. Results also revealed

that higher scores on the negative attributes construct showed an overall significant inverse relationship with main fact agreement and vape intentions.

Table 4. Mean scores for the four constructs tested in phase II, by ad performance level.

	Alpha	High performance (n=6 ads), mean (SD)	Medium performance (n=4 ads), mean (SD)	Low performance (n=3 ads), mean (SD)
Personally relevant ^a	.77	3.57 (0.21) ^b	3.45 (0.07)	3.08 (0.19)
Culturally relevant ^a	.79	3.80 (0.15) ^c	3.89 (N/A) ^{d,e}	3.56 (0.25)
Strength of message ^a	.69	3.69 (0.23)	3.49 (0.08)	3.34 (0.21)
Negative attributes ^a	.75	2.18 (0.10)	2.24 (0.13)	2.55 (0.19)

^aRange of possible scores for constructs was 1-5.

^bn=5 ads in the "high performance" group for this item.

^cn=2 ads in the "high performance" group for this item.

^dN/A: not applicable.

^en=1 ad in the "medium performance" group for this item.

Table 5. Correlations with main fact agreement for the phase II antivape ads.

Ad tested	Antivape ad 1 (n=298), <i>r</i> (<i>P</i> value)	Antivape ad 2 (n=299), <i>r</i> (<i>P</i> value)	Antivape ad 3 (n=301), <i>r</i> (<i>P</i> value)
Personally relevant	0.20 (.001)	0.32 (<.001)	0.24 (<.001)
Culturally relevant	0.23 (<.001)	0.43 (<.001)	0.35 (<.001)
Strength of message	0.21 (<.001)	0.45 (<.001)	0.28 (<.001)
Negative attributes	-0.19 (.001)	-0.22 (<.001)	-0.23 (<.001)

Table 6. Correlations with vape intentions for the phase II antivape ads.

Ad tested	Antivape ad 1 (n=298), <i>r</i> (<i>P</i> value)	Antivape ad 2 (n=299), <i>r</i> (<i>P</i> value)	Antivape ad 3 (n=301), <i>r</i> (<i>P</i> value)
Personally relevant	0.21 (.004)	0.20 (.008)	0.13 (.11)
Culturally relevant	0.28 (<.001)	0.30 (<.001)	0.19 (.02)
Strength of message	0.23 (.002)	0.32 (<.001)	0.12 (.14)
Negative attributes	-0.02 (.78)	-0.32 (<.001)	-0.13 (.10)

Discussion

Principal Findings

Study findings demonstrate the utility of an expanded set of ad testing items to aid in message selection and optimization (four constructs). The set of validated constructs, when used together, are referred to as the Message Assessment Scale. The constructs can be used to assess each individual item or by calculating construct scores. These constructs provide useful specific data to inform how best to increase an ad's relevance and effectiveness, specific to a youth and young adult audience. For example, an ad may perform low on cultural relevance, in which case qualitative responses to the overall advertisement "likes" and "dislikes" would be coded. The initial low score on this scale would tip researchers off to the need to dive deeper and look for comments in the qualitative questions, which could inform the low score and provide insight on how to improve it. The ads in this study that best met their goals were more personally and culturally relevant, and had stronger messaging than the lower performing ads. This is especially important

because the validated constructs were significantly correlated with intentions not to vape for antivape ads. The better an ad performs on these constructs, the more potential it has to decrease vape intentions among a youth and young adult audience. Ad optimization, based on construct results, demonstrates the utility of maximizing message effectiveness for health behavior campaigns.

In **Table 3**, we see higher mean scores on the constructs for antitobacco (combustible products) versus antivape ads. These findings were not surprising given how long antitobacco (cigarette) ads have been on air, rates of smoking at that time, and the consensus around their impact on health. Constructs were developed from antivape ads airing early in the vaping epidemic, a period of time in which we were trying to stop a behavior that youth were really enjoying. An antivape message at that time felt less relevant to our audience because there was no data to indicate health or other negative implications from vaping yet.

The Message Assessment Scale can help establish benchmarks for modifying aspects of the execution, the placement of the

execution, and the frequency of airing the execution. Ad testing, thus, informs placement and frequency decisions. For example, ads scoring higher on the measures may receive more or less frequent rotation on television or digital platforms, an ad on television or digital platforms may be coupled with another ad that increases scores, or a digital ad may be selected to be elevated to a television spot. Additionally, qualitative items related to ad receptivity and disapproval can be coupled with data from quantitative items to comprehensively assess likeability, level of novel information, and whether the execution provides motivation. For example, asking “what did you like most about the ad” and “what did you dislike about the ad” with open-ended responses can provide meaningful data that may not have been received from quantitative items with predetermined answer options. Moreover, the measures also provide insight into the possible reasons for low testing scores, including issues related to pacing and ad characteristics. If an ad is seen as offensive or confusing, this may interfere with the ad’s ability to effectively deliver a message to the target audience.

Limitations

Although this study has many strengths, there are some limitations. First, the study used panel data, which does not

reflect a probabilistic sample. As such, responses may not be generalizable to a broader population. However, sample quotas were set to yield approximately equal proportions by gender and age group. Additionally, this work did not examine correlations to in-market performance, which would ultimately test the ability of the constructs to predict how an ad may perform in the real-world.

Conclusions

Findings advance the field by establishing an expanded set of validated items to comprehensively assess the potential effectiveness of advertising executions. The constructs can provide critical information for message optimization and message selection, particularly among a youth and young adult audience. Ensuring ads meet testing benchmarks before airing them across media platforms helps ensure cost efficiency while providing critical empirical evidence that messages will effectively shift knowledge, attitudes, and beliefs among the target audience. Future studies should explore whether the constructs perform similarly across demographic subgroups and correlate to actual campaign performance.

Abstract

Background: Patients with end-stage kidney disease (ESKD) wait roughly 4 years for a kidney transplant. A potential way to reduce wait times is using hepatitis C virus (HCV)-viremic kidneys.

Objective: As preparation for developing a shared decision-making tool to assist patients with ESKD with the decision to accept an HCV-viremic kidney transplant, our initial goal was to assess the feasibility of using The Gambler II, a health utility assessment tool, in an ambulatory dialysis clinic setting. Our secondary goals were to collect health utilities for patients with ESKD and to explore whether the use of race-matched versus race-mismatched exemplars impacted the knowledge gained during the assessment process.

Methods: We used The Gambler II to elicit utilities for the following ESKD-related health states: hemodialysis, kidney transplant with HCV-unexposed kidney, and transplantation with HCV-viremic kidney. We created race exemplar video clips describing these health states and randomly assigned patients into the race-matched or race-mismatched video arms. We obtained utilities for these 3 health states from each patient, and we evaluated knowledge about ESKD and HCV-associated health conditions with pre- and postintervention knowledge assessments.

Results: A total of 63 patients with hemodialysis from 4 outpatient Dialysis Center Inc sites completed the study. Mean adjusted standard gamble utilities for hemodialysis, transplant with HCV-unexposed kidney, and transplantation with HCV-viremic kidney were 82.5, 89, and 75.5, respectively. General group knowledge assessment scores improved by 10 points ($P < .05$) following utility assessment process. The use of race-matched exemplars had little effect on the results of the knowledge assessment of patients.

Conclusions: Using The Gambler II to collect utilities for patients with ESKD in an ambulatory dialysis clinic setting proved feasible. In addition, educational information about health states provided as part of the utility assessment process tool improved patients' knowledge and understanding about ESKD-related health states and implications of organ transplantation with HCV-viremic kidneys. A wide variation in patient health state utilities reinforces the importance of incorporating patients' preferences into decisions regarding use of HCV-viremic kidneys for transplantation.

KEYWORDS

health utility assessment; patient reported outcomes; end-stage kidney disease; hemodialysis; hepatitis C

Introduction

Chronic kidney disease disproportionately impacts African Americans, making it a prototypical disease in which to investigate disparities in health utility assessments (HUAs) [1]. Due to the limited availability of organs and the large number of patients with end-stage kidney disease (ESKD) on waiting lists for transplantation, the average patient waits roughly 4 years before receiving a kidney transplant [2]. Patients with African American racial background who have ESKD wait even longer at an average of 4.5 years [2-4]. One path toward increasing the availability of organs and reducing waiting times is to use hepatitis C virus (HCV)-viremic kidneys for transplantation. The decision to accept transplantation with an HCV-viremic kidney hinges on the balance between the decreased waiting time afforded by accepting such an organ and each patient's values and preferences about receiving such an organ. These trade-offs make this decision an ideal setting for shared decision-making (SDM) [5]. SDM clarifies patients' values and preferences, can improve self-efficacy, and engages patients in conversations with their clinicians about treatment choices [5,6].

As of 2017, a total of 746,557 patients in the United States have ESKD [3]. A total of 101,337 patients with ESKD were wait-listed for kidney transplantation in 2019, while the number of patients receiving kidney transplants in 2019 was 24,273 [7]. Studies show that receiving a kidney transplant, even with an HCV-viremic organ, can improve the survival and quality of life and reduce lifetime costs for patients with ESKD who are currently on dialysis [8]. Importantly, using HCV-viremic organs can increase the availability of otherwise high-quality organs and potentially reduce the waiting time for some patients to receive kidney transplants [9]. However, some patients, even after undergoing successful transplantation with an HCV-viremic kidney, have worries and concerns that continue to impact their quality of life. Thus, including individual patient's values and preferences regarding the relevant health states is a critical component of SDM. In anticipation of the future development of an SDM tool, the primary goal of this study was to assess the feasibility of using The Gambler II, a health utility assessment tool, in an ambulatory dialysis clinic setting. Our secondary goals were to collect utilities for patients with ESKD and to explore whether the use of race-matched versus race-mismatched exemplars impacted the knowledge gained during the assessment process.

The Gambler II is a health utility assessment software platform that can use a variety of assessment techniques to gather patients' utilities [10,11]. These include the visual analog scale (VAS), standard gamble (SG), and time trade-off (TTO) [12] (Multimedia Appendix 1 A). The utility assessment process itself provides an opportunity to educate patients about the health states for which values and preferences are being sought [13,14]. The Gambler II uses video clips of patient actors to describe health states. In addition, The Gambler II can match the demographics of patient actors in the video clips to those of the patient whose utilities are being assessed. This latter feature provided us with an opportunity to explore a hypothesis, based on exemplification theory, that information communicated

by people who mostly resemble the participant is more likely to engage and inform the participant [15,16].

Our longer-term goal is to develop an SDM tool that can be used by clinicians to facilitate discussions about acceptance of HCV-viremic kidneys, particularly for patients who may have longer predicted waiting times on transplant lists. The tool would assess patients' utilities for hemodialysis and transplantation with either an HCV-unexposed or an HCV-viremic kidney and would use that information along with patient-specific demographic information and predictions of organ availability based on factors including age, sex, blood type, dialysis vintage, calculated panel reactive antibodies, comorbidities, and the region in which the transplant is being carried out to make a recommendation for the best transplantation strategy for that patient. As many patients on dialysis, particularly African Americans living in less affluent urban areas, are impacted by the digital divide and have less access to home computers and the internet [6], we envision using this tool in ambulatory dialysis clinic settings with readily available computing platforms such as laptop and tablet computers.

Methods

Ethics Approval

This study was reviewed and approved by the University of Cincinnati Institutional Review Board (UC IRB ID – 2019-0792) as well as by the Dialysis Clinic Inc Administrative Review Office. Both boards approved the study before patient recruitment began. No compensation was provided to the patients for this research.

Study Design

Patient Recruitment

We worked with physicians in the Division of Nephrology and Hypertension to help recruit patients with chronic hemodialysis receiving treatment at any of the 4 outpatient dialysis centers in the greater Cincinnati metropolitan area managed by Dialysis Center Inc (DCI) [17]. Inclusion criteria were a diagnosis of ESKD, receiving intermittent facility hemodialysis at the designated outpatient center (DCI), and the ability to understand the English language. We included adults between the ages of 21 and 80 years. Patients with significant cognitive or reading deficits were excluded from the study. Patients who did not opt out of being contacted were given further explanation on the purpose of the study to assess their interest and willingness to participate.

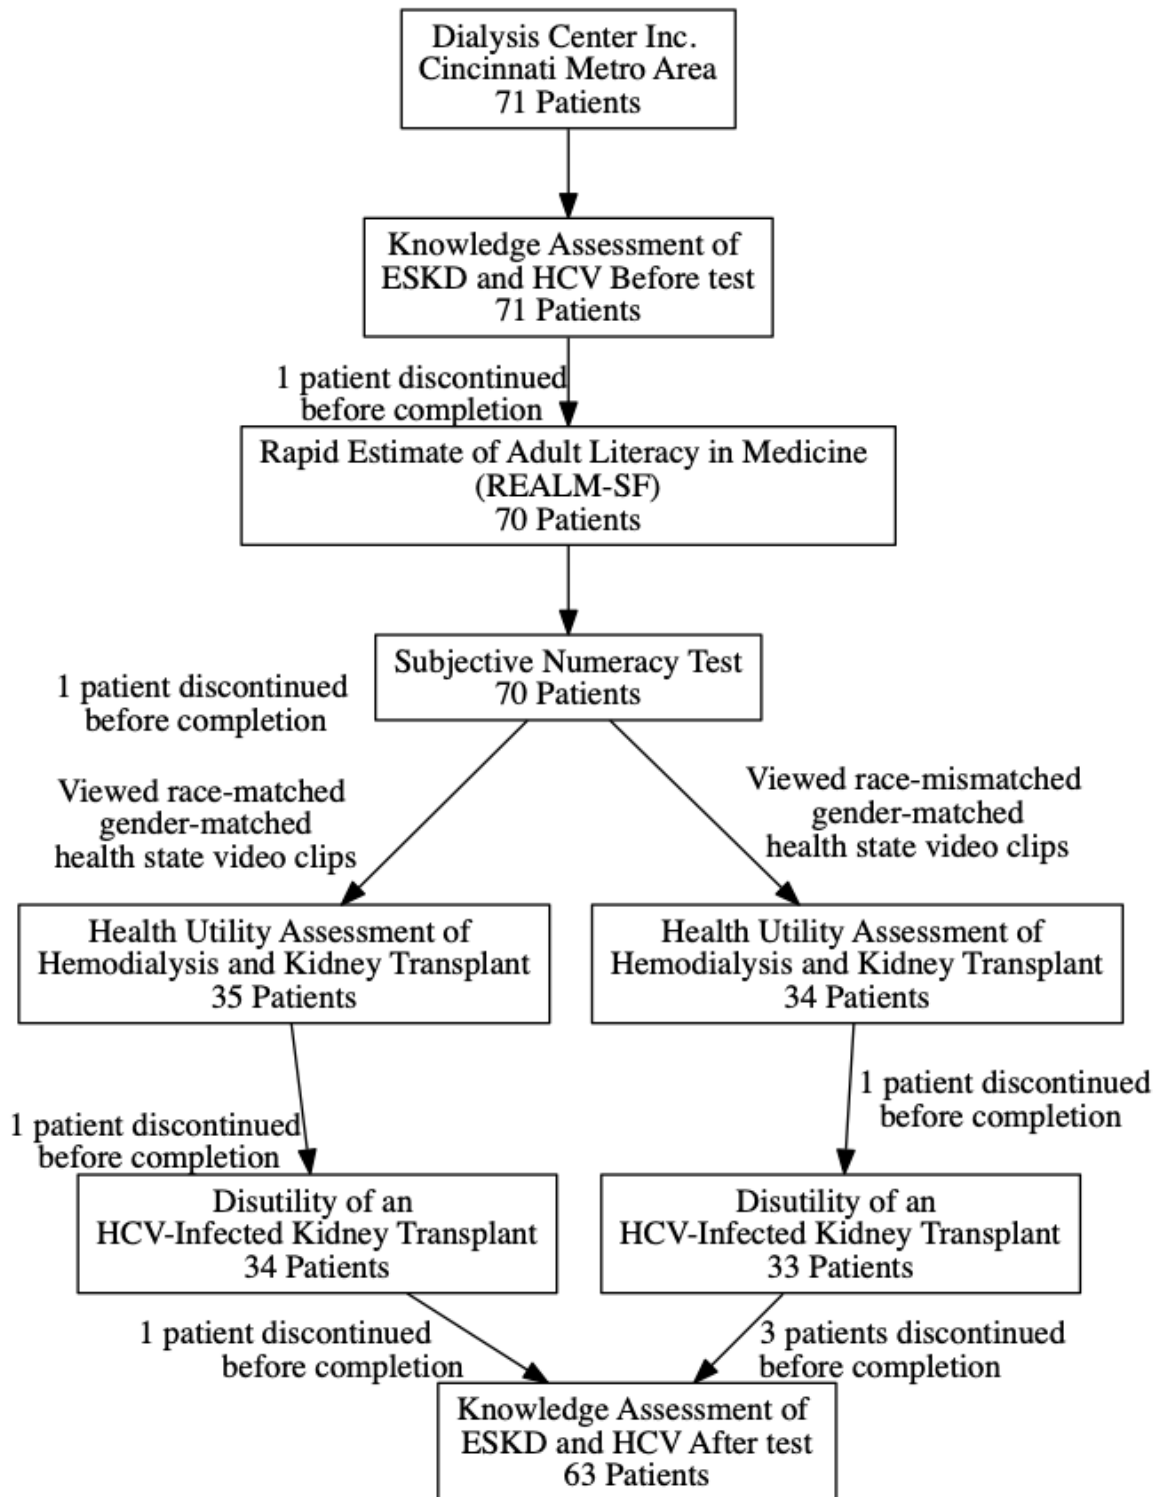

Study Flow

Patients were recruited from 4 DCI sites in the Cincinnati metropolitan region. Prior to participating in the utility assessment process, they underwent a knowledge assessment survey. We collected demographic information and assessed health literacy using the Rapid Estimate of Adult Literacy in Medicine and subjective numeracy. We randomized patients to 1 of 2 study arms in which they viewed either race-matched or race-mismatched video clips describing each of the 3 health states. The patients' utilities for these health states were obtained, and then a postinterview knowledge assessment was

repeated (Figure 1). Those patients who indicated interest were met by the study principal investigator (AAA) in their local dialysis center, underwent a formal consent process, and answered on a laptop computer a minimal amount of demographic and clinical information, completing a short survey on educational status, time on dialysis, history of prior kidney transplant, and interest in a future kidney transplant. The patients then completed a Research Electronic Data Capture (REDCap)

survey evaluating subjective numeracy and health literacy along with a short previsit knowledge assessment [18-20]. At any time, patients could withdraw from the study and did not have to provide a reason for withdrawal. To understand preintervention state of knowledge about hemodialysis, HCV infection, and kidney transplantation, we developed a 10-item multiple-choice questionnaire (Multimedia Appendix 1 B).

Figure 1. Study flow. ESKD: end-stage kidney disease; HCV: hepatitis C virus.

One of our secondary goals was to evaluate the impact of patients viewing race-matched versus race-mismatched video clips describing the health states being assessed. As mentioned, exemplification theory suggests that people are more engaged and receptive when they are presented with visual information by people who look most like themselves [16]. We hypothesized that learning about relevant health states would be greater among patients who receive video clip information from patient actors who are similar to them as opposed to receiving information from those who are different (eg, race, gender, and age category). We evaluated this by measuring the change score on the knowledge survey given before and after the HUA sessions. We did not provide any training materials prior to the HUA sessions and did not assume patients had knowledge about hepatitis C or any other knowledge besides their current understanding of dialysis and kidney transplant. We determined that 30 patients would be required in each study arm to detect a difference as small as 12 points (on a scale of 0 to 100) in the change score between pre- and postknowledge survey (power of 0.80 with an alpha of .05), using a 2-sided *t* test. We randomized patients into 1 of 2 study arms (Multimedia Appendix 1 C). The first arm presented patients with video clips of race- and gender-matched health state descriptions, while the second arm presented patients with video clips purposely mismatched for race (Figure 2 and Figure 3). The entire interview process lasted roughly 1 hour and took place while patients were receiving their 3- to 4-hour long dialysis treatment.

Another secondary goal of our study was to collect utilities for the 3 ESKD-related health states described above. While studies have assessed patient utilities for hemodialysis and kidney transplantation, to our knowledge, none have explored health utilities for transplantation with HCV-viremic kidneys [21,22]. We collected these data using the 3 HUA methods of visual analog scale (“feeling thermometer”), standard gamble, and time trade-off. We broke the assessment process into 2 parts. First, we assessed health states of intermittent hemodialysis and transplantation with an HCV-unexposed kidney, using anchor states of “Well” (without ESKD) and “Dead.” We next assessed the health state of transplantation with an HCV-viremic kidney using transplantation with an HCV-unexposed kidney as the best outcome and Dead as anchor states. Patients entered one of these two HUA groups to explicitly assess how much of a risk they were willing to take (in the standard gamble) to avoid receiving an HCV-viremic kidney given the opportunity of a noninfected kidney transplant (Multimedia Appendix 1 D).

To control for possible confounding, we also collected demographic information (age, sex, and race), highest educational level attained, dialysis vintage, history of prior kidney transplant, interest in receiving a transplanted kidney, health literacy using the Rapid Estimate of Adult Literacy in Medicine Short Form, and subjective numeracy [20-22].

Figure 2. Screenshots of different health utility assessments. Top: patient evaluating the hemodialysis health state through the standard gamble utility assessment. Bottom: patients evaluating kidney transplant using the time trade-off; The Gambler uses life tables to determine the duration of life expectancy for the time trade-off. The video clip in the figure demonstrates how a user can watch a demographically matched patient actor describe the health state being assessed. We did not incorporate the image of the patient actor to protect their privacy. ESKD: end-stage kidney disease.

Tools

We conducted surveys and performed HUAs using a laptop computer (2014 Apple MacBook Pro running Mac OS 10.14) while we met with most patients in their community dialysis center during their usual intermittent hemodialysis sessions. Patients used either headphones, earbuds, or audio output from the laptop to hear the video clips that were part of The Gambler II. We used Google Chrome version 80 as the web browser to access The Gambler II and REDCap (9.1.10). Patient actors used a standard script for each health state, which was developed and vetted by team members (MHE, HJD, SS, CVT, and GRM). We recorded 12 different video clips describing the 3 health states for all combinations of gender and race (ie, men, women, African American, and White) using Apple's QuickTime X 10.5 with video mastering done on Adobe Premiere and Adobe Audition 2019. Due to restrictions of social distancing during the COVID-19 pandemic, the institutional review board granted an amendment to the protocol that allowed us to interview some patients remotely [23]. For these patients, we used several teleconferencing applications including Microsoft Teams, Microsoft Skype, and Cisco's WebEx to administer surveys and conduct HUAs.

We used The Gambler II to perform health utility assessments [11]. For survey data collection, we used REDCap, a web-based survey platform designed to capture users' data with web forms

[18]. All data were collected and stored on a secure server at the University of Cincinnati. Access to data was restricted to institutional review board-authorized users with login credentials. We analyzed data using Python (Python Software Foundation) and R (The R foundation) [24-26].

Results

Demographic Data

We recruited 71 patients from 4 DCI sites in the Cincinnati Metropolitan area. A total of 63 patients consented and completed the study. Of those who consented, 62 (98%) enrolled in the study during dialysis clinic visits, while 1 (2%) enrolled through teleconferencing software at their residence. The cohort's age range was from 24 to 80 years, with a median age of 59 years and mean age of 58 years (Multimedia Appendix 1). Moreover, 44 (70%) patients had African American racial backgrounds, and 19 (30%) were European American. A high school diploma was the most frequent highest level of educational attainment (Table 1). The median Rapid Estimate of Adult Literacy in Medicine Short Form and subjective numeracy scores were 7.0 and 4.0, respectively. In addition, of the 63 patients, 54 (86%) had not received a previous kidney transplant, and 47 (75%) had an interest in receiving a kidney transplant. The participants spent an average of 5.9 years on dialysis (African Americans: 7.3 years, European Americans: 2.79 years; $P=.07$; Multimedia Appendix 1).

Table 1. Summary statistics of the population broken into race-matched versus race-mismatched study arms.

Characteristics	Values			P value
	Overall (n=63)	Race-matched videos (n=33)	Race-mismatched videos (n=33)	
Age (years), mean (SD)	57.8 (12.3)	56.1 (13.5)	59.8 (10.8)	.26

Knowledge Assessments

We conducted a knowledge assessment using a 10-item questionnaire administered before the utility assessment as a pretest and after as a posttest (Multimedia Appendix 1). The Cronbach alpha for the pretest was .990, and it was .994 for the posttest. As shown in Tables 2 and 3, for the cohort, the improvement in test scores (mean and median 10.0 points)

following the utility assessment process and viewing of health state videos were clinically and statistically significant ($P < .001$, paired Wilcoxon t test). However, there was not a statistically significant difference in pretest versus posttest change scores between the 2 study arms, or between African Americans compared with European Americans, with P values of .95 and .96 (Mann-Whitney test), respectively.

Table 2. Evaluation of patients' health literacy, numeracy, and their knowledge of end-stage kidney disease and hepatitis C stratified by study arm.

Tests	Overall, mean (SD)	Race-matched videos, mean (SD)	Race-mismatched videos, mean (SD)	P value ^a
Before test	79.0 (17.3)	80.2 (17.2)	77.7 (17.7)	.59
After test	89.0 (15.9)	89.6 (15.8)	88.2 (16.1)	.77

End-Stage Kidney Disease Health Utilities

We assessed utilities from patients on chronic intermittent hemodialysis for 3 health states relevant to decision-making about kidney transplantation. The results are reported in Tables 4 and 5 and are depicted pictorially in Figure 4. With all 3 assessment methods, means utilities were highest for

transplantation with an HCV-unexposed kidney. Hemodialysis had the lowest average utility assessed with the VAS, while transplantation with an HCV-viremic kidney had the lowest utility using the TTO and SG. Looking at ranking of utilities within each patient, 47 (75%) and 39 (62%) of the patients rated transplantation with an HCV-viremic kidney lower than hemodialysis with SG utilities and TTO utilities, respectively.

Table 4. Health utilities evaluation of race-matched vs race-mismatched video patient cohort.

Health utilities	Overall, mean (SD)	Race-matched videos, mean (SD)	Race-mismatched videos, mean (SD)	<i>P</i> value ^a
Visual analog scale				
Hemodialysis	57.9 (25.9)	63.2 (26.7)	52.0 (25.3)	.11

^aP value denotes comparison between race-matched and race-mismatch population health utilities. This assumes that if $P \leq .05$, there was a significant difference in health utilities between race-matched (same race) and race-mismatched (different race) health utilities.

^bHealth utility normalization equation: Raw hepatitis C virus utility * Kidney transplant utility = hepatitis C virus utility.

Figure 4. Radar plot of the health state utilities. (A) Visual analog scale; (B) standard gamble; and (C) time trade-off. The 3 figure panels show the utilities assessed for each of the 63 patients in the study. Each panel summarizes results for the 3 different utility assessment methods. Different colors are used to represent each of the 3 health states: hemodialysis, transplantation with a hepatitis C (HCV)–unexposed kidney, and transplantation with an HCV-viremic kidney. Each number on the outside circle represents a single patient’s utility scores.

Utility assessments for transplantation with an HCV-infected kidney were carried out with anchor states of transplant with HCV-unexposed kidney as the best outcome and death as the worst outcome. We normalized these utilities to the same 0-100 scale used for the other health states by multiplying the raw utility for transplant with HCV-exposed kidney times the utility of transplant with an HCV-unexposed kidney. Normalized utility means using VAS, SG, and TTO assessments were 66.3, 75.5, and 73.8, respectively. Looking at the raw SG utility weights for transplantation with an HCV-viremic kidney, given a choice between transplantation with an HCV-unexposed kidney and an HCV-viremic kidney, patients were willing to take a 24.5% chance of dying to avoid receiving an HCV-viremic kidney. We did not find statistically significant differences in utilities between race-matched and race-mismatched study arms. However, we did find that African Americans on average had higher utility weights than European Americans for hemodialysis evaluated with the TTO (83.2 versus 73.6, respectively; $P=.04$ [Mann-Whitney]).

Discussion

Principal Results

Regarding our primary study goal, we found that using our health utility assessment tool in an ambulatory community dialysis clinic setting was feasible. The entire process took approximately 1 hour per patient, with health utility assessments taking approximately 30 minutes on average. Barriers regarding home internet access may have increased the acceptability of utility assessment in the community dialysis clinic setting [27]. Many patients expressed pleasure at the opportunity to engage in a value-added activity while they were “captive” during their 3- to 4-hour dialysis session. This bodes well for plans to conduct shared decision-making visits using The Gambler II platform in these same community dialysis clinics.

Secondary Results

Our second goal was to collect health utilities from patients with dialysis for several ESKD health states relevant to the decision about kidney transplantation. We found a wide variation in health utilities from patient to patient. Consistent with prior studies, utilities assessed using the SG technique were higher than those determined with the VAS or TTO techniques. SG holistically incorporates risk attitude into its assessment, and since most people are risk averse, SG utilities tend to be higher [28]. Of note, there was a wide variation in utilities for transplantation with an HCV-viremic kidney, and in a few instances, patients had lower utilities for this health state than for continued hemodialysis. While mean SG utilities for transplant with an HCV-viremic kidney were lower than hemodialysis (75.5 vs 82.5), standard deviations were large (28 and 23, respectively), which further demonstrated significant differences in utility values across the patients. To this point, 30 (48%) patients had higher SG utilities for transplant with an HCV-viremic kidney compared with hemodialysis. We also explored whether there were racial differences in health state utilities between patients with African American and European American backgrounds. We found African Americans had higher TTO utilities for hemodialysis compared to their

European American counterparts. One possible explanation is the phenomenon of accommodation. While quality of life may diminish markedly when patients move from a better state of health to a health state marred by chronic disease or disability, studies have shown that, over time, many patients accommodate to the new health state with an accompanying improvement in assessments of quality of life [29,30]. Indeed, in subanalyses stratified by race, African Americans had a significantly longer dialysis vintage (7.3 years) compared with European Americans (2.8 years; $P=.04$).

During the testing of The Gambler II in a clinical setting, the COVID-19 pandemic interrupted patient recruitment. We performed a subanalysis on patients who enrolled after the COVID-19 interruption. We found that gender and study arm did not have a statistically significant impact on knowledge scores or utilities. Stratifying by race, we found that African Americans had higher SG utilities for all but hemodialysis (Multimedia Appendix 1). Furthermore, African Americans had higher TTO utilities for all 3 health states (Multimedia Appendix 1). African Americans had a mean utility of 87.6 for transplantation with an HCV-viremic kidney compared to a mean utility of 69.3 for European Americans ($P=.004$) during the pandemic. We did not see similar differences among patients in the prepandemic cohort given the small sample size of European Americans ($n\leq 5$).

To our knowledge, this is the first paper directly eliciting health utilities from patients with dialysis for transplant with an HCV-viremic kidney. Our major finding is that patients' utilities for this outcome vary dramatically, and that for some patients, the worry and concern associated with even a successful transplant of an HCV-viremic kidney may result in a utility weight lower than their current health state of chronic intermittent hemodialysis. We found a slight negative correlation between the difference between the SG utility for transplant with an HCV-viremic kidney and hemodialysis and dialysis vintage. For patients who have a longer dialysis vintage, SG utility for transplant with an HCV-viremic kidney and hemodialysis had a negative correlation (-0.16). This means that there is a trend toward a more negative view of transplant with an HCV-viremic kidney compared with hemodialysis among patients who have been on dialysis for a longer time. We also examined how patients' history of a failed kidney transplant may affect health utilities. We compared this patient population hemodialysis and transplant with an HCV-viremic kidney SG utilities. There was a compelling but not statistically significant trend toward a larger decrement in this value among patients with prior failed kidney transplant (-15.6 versus -5.5 ; $P=.29$). However, our cohort only had 9 (14%) patients with a prior transplant.

Regarding our third goal, our study showed that health state videos narrated by patient actors, viewed as part of the process of assessing patients' values and preferences for health outcomes of ESKD, can improve knowledge about these health states. On average, knowledge scores improved by 10 points between the pretest and posttest, demonstrating that these videos can educate patients about the relevant health states as a beneficial side effect of the utility assessment process. While we expected to find a positive impact of using race-matched exemplars compared

with race-mismatched exemplars, there were no significant differences between study arms on knowledge gain. Whether our study simply lacked the power to detect a difference and whether matching patient demographics truly matters is a question for further investigation. Of note, patients watching videos narrated by African American patient actors had greater knowledge gains (median 10.0) than those viewing videos narrated by European American patient actors (median 5.0), although this was not statistically significant ($P=.25$).

Regardless, patients found the videos informative and impactful. Following the utility assessment process, several patients voiced their appreciation for the video descriptions of health states. Some patients even reported being moved to tears.

Comparison With Prior Work

Prior studies noted the potential benefits of using HCV-viremic kidneys to expand the pool of organs available to hemodialysis patients, thus reducing waiting times for transplantation and providing opportunities for transplantation in patients who might not have received a kidney otherwise. Cost-effectiveness analyses have shown the strategy to be cost-effective at a policy level for the general population of patients with ESKD [13,22]. However, none of these analyses used utility assessments from actual patients for the outcome transplant with an HCV-viremic kidney [31,32]. Given the marked patient-to-patient variability in utilities for the 3 health states we studied, patient preferences for health states must be considered in the shared decision-making process about transplantation with an HCV-viremic versus an HCV-uninfected kidney.

The Gambler II provides a consistent and efficient platform to elicit patient utilities and could be integrated into a tool to facilitate shared decision-making. One could envision such a tool that performs personalized decision analyses, using a combination of individual patient's utilities along with clinical and demographic information needed to estimate organ waiting

list times, to provide estimates of quality-adjusted survival or life expectancy with each strategy for that individual patient.

Limitations

Our study had some limitations. Given the demographics of the Cincinnati metropolitan area dialysis clinics in our study, it was difficult to recruit patients with European American racial backgrounds in equal numbers to those with African American backgrounds. In addition, the COVID-19 pandemic negatively impacted our total recruitment due to a pause in study activities between March and October of 2020 [23]. A possible contributing factor to utility weights for transplant with an HCV-viremic kidney being lower than hemodialysis for some patients was the way we assessed utilities for this health state separately from hemodialysis and transplant with an HCV-unexposed kidney. We wanted an explicit measure of the utility differences between transplant with an HCV-unexposed and an HCV-viremic kidney. This measure would include in the SG assessment an estimate of the willingness of patients to risk death to avoid such a transplant. However, the normalized utility values for this health state were not directly assessed compared with transplant with an HCV-unexposed kidney.

Conclusions

In conclusion, we found that it is feasible to use a computer platform to assess patients' utilities for health states related to ESKD in ambulatory community dialysis clinics. Furthermore, we demonstrated that utility weights vary dramatically from person to person. These findings have implications for the future development of shared decision-making tools to aid clinicians and their patients with the challenging question of whether to accept transplantation with HCV-viremic kidneys in patients to reduce waiting times and decrease time spent on hemodialysis. This decision will depend upon both expected organ-waiting list times for HCV-unexposed and HCV-exposed kidneys and individual patient's values and preferences for these relevant health states.

Acknowledgments

We wish to thank the patients who entered as participants in the study as well as Dialysis Center Inc for allowing us access to patients in their facilities. We thank our colleagues in the University of Cincinnati's Department of Biomedical Informatics, Division of Nephrology and Hypertension, Center for Health Informatics, and Cincinnati Children's Hospital Medical Center for their assistance with patient recruitment and technical support.

MHE and AAA have investigator-initiated grant support from Bristol Meyers-Squibb (CV-185-764). MHE also has grant support from the National Institute of Child Health and Human Development (R01HD094213) and the National Center for Advancing Translational Sciences (UL1TR001425). The funders had no role in study design, data collection and analysis, decision to publish, or preparation of the manuscript.

Data Availability

Data related to this study and The Gambler software are available to use upon request.

Authors' Contributions

Multimedia Appendix 1

Manuscript appendix containing select demographic information about the patients, the questions asked of patients before and after the assessment, and information given to patients throughout the assessment. It also contains the explanation for the health utility assessments, screenshots of the assessments, and utility information generated from the patient assessment.

Abstract

Background: Young Black women between the ages of 18 and 24 years are disproportionately impacted by HIV, yet they have a low self-perception of HIV risk and limited exposure to prevention strategies. Pre-exposure prophylaxis (PrEP) is a safe and effective biomedical HIV prevention strategy for those at risk for HIV infection, but uptake has been slow among cisgender women. Family planning clinics are a primary source of health care access for young women, providing an ideal opportunity to integrate PrEP information and care into existing clinic practices.

Objective: The aim of this study was to use a multistage, community-engaged process to develop a mobile health app and to evaluate the feasibility and acceptability of the app.

Methods: Using user-centered design, the *In the Loop* app was developed in collaboration with a community advisory board of young Black women. This study employed a multistage design, which included community-engaged app development, user testing, and evaluation of the app's feasibility and acceptability. A pre- and postdesign was used to assess the impact of the app on PrEP knowledge immediately after app use. Descriptive statistics (eg, mean, SD, and percentage values) were used to describe the sample, and Wilcoxon matched-pairs signed-ranks test was used to detect changes in PrEP knowledge before and immediately after using the app.

Results: A total of 50 sexually active, young Black women, aged 18-24 (mean 21, SD 1.9) years, were enrolled in this study. Analysis comparing scores before and immediately after use of the app revealed a significant increase in PrEP content knowledge scores on a 7-item true or false scale ($\tau=-6.04$, $P<.001$). Overall, participants considered the *In the Loop* app feasible and acceptable to use while waiting for a family planning visit. The majority of participants ($n=46$, 92%) agreed that they would recommend *In the Loop* to friends to learn more about PrEP. Participants rated the overall quality of the app 4.3 on a 1-5 scale (1=very poor and 5=very good). Of 50 participants, 40 (80%) agreed that the app was easy to use, and 48 (96%) agreed that they found the information in the app easy to understand. Finally, 40 (80%) agreed that they had enjoyed using the app while waiting for their family planning visit.

Conclusions: Our findings suggest that young Black women waiting for family planning visits found the *In the Loop* app to be feasible and acceptable. This study demonstrates the value of engaging young Black women in the app design process. As family planning clinics are a primary source of health care access for young women, they provide an ideal setting to integrate PrEP information and care into existing clinic practices. Next steps in the development of the *In the Loop* app include implementing

user-suggested improvements and conducting efficacy testing in a randomized controlled trial to determine the app's impact on PrEP uptake.

KEYWORDS

mHealth; adolescent health; young Black women; pre-exposure prophylaxis; HIV; mobile health; PrEP; mobile app

Introduction

Approximately 23% of all people living with HIV in the United States are cisgender women, and women accounted for 19% of new infections in 2018 [1]. The majority (87%) of HIV infections among women are due to heterosexual sex [1]. Black women are disproportionately impacted by HIV, with an 18-fold higher risk of acquiring HIV compared to White women [2]. In Chicago, 85.9% of new HIV infections among women occur among non-Hispanic Black women [3]. In particular, young Black women aged 18-24 years often have multiple co-occurring risk factors (eg, high HIV density in sexual networks, concurrent sexual partners, experiences of violence, substance use, and sex partners with incarceration history), yet they have a low self-perception of HIV risk, complicating HIV prevention efforts [3-7].

Pre-exposure prophylaxis (PrEP) is a safe and effective biomedical HIV prevention strategy for those at risk for HIV infection, including young Black women [8,9]. PrEP has the advantage over other prevention interventions of allowing women to have autonomy and control over their sexual health because it does not require a sexual partner's permission or cooperation for use [10]. However, women make up a disproportionately low percentage of PrEP users in the United States [11]. The Centers for Disease Control and Prevention estimates that 468,000 women in the United States are eligible for PrEP, but only 19,000 women have ever been prescribed PrEP [11-13]. From 2014 to 2016, only 2% of women who have indication for PrEP received a prescription, and women accounted for less than 5% of all PrEP users in 2016 [10]. Chicago is a leading city in PrEP implementation, but uptake of PrEP among women is extremely low. For example, of the patients who have initiated PrEP in sexually transmitted infections (STI) clinics of the Chicago Department of Public Health, only 1.5% are women [2,14]. Known individual-level barriers to PrEP uptake among women include low rates of PrEP knowledge, low perceived risk of HIV acquisition, and lack of awareness of how and where to access PrEP [2,14]. Increasing knowledge, risk perception, awareness, and uptake of PrEP among young Black women who may be at an increased risk for HIV are key public health interventions that have the potential to reduce new HIV infections [15].

Family planning clinics are primary sources of health care access for young women, providing an ideal opportunity to integrate PrEP information and care into existing clinic practices [16,17]. A total of 60% of women, including young Black women, consider family planning clinics their primary source of medical care, with 40% indicating it is their only source of health care [17]. In 2018, Title X family planning clinics served over 3.9 million patients, most of whom were young (63%), female

(87%), and had low income (65%) [18]. Over 1 million HIV tests were performed in Title X clinics in 2018, establishing a precedent for receiving HIV prevention services at family planning clinics [18]. Optimizing PrEP awareness via integration with family planning services has the potential to increase PrEP uptake and impact incidence on a population level, but it has not yet been fully explored or implemented.

The ubiquitous nature of new digital media, characterized by its adaptability and interactivity, offers opportunities to disseminate confidential information to adolescents in a relevant, youth-friendly format. Mobile health (mHealth) approaches have been proven to be most impactful when integrated into existing health system functions, rather than as stand-alone solutions [19,20]. Given the limited provider time per patient, brief theory-driven mHealth intervention models delivered in family planning clinics waiting rooms have the potential to aid patients in increasing knowledge, informing decision-making, and framing questions to providers [21-23].

Researchers have identified the lack of tailored apps for minority communities as an ongoing challenge in digital media intervention [24,25]. To date, no studies have been conducted to design, target, and promote an mHealth intervention to enhance HIV risk assessment, increase PrEP knowledge, and influence PrEP uptake among young Black women within a family planning setting. Patients prefer health information to be interactive [26]; a waiting room-based mHealth intervention uses a current missed opportunity to enhance HIV risk assessment and provide patient education about PrEP, and it has the potential for high impact [22,23]. This pilot study is the first step in designing and implementing an mHealth HIV prevention and PrEP promotion intervention tailored for young Black women.

Methods

This pilot study employed a multistage design that included community-engaged app development, user testing, and evaluation of the app's feasibility and acceptability.

Ethics Approval

All procedures were approved by the Institutional Review Board at Lurie Children's Hospital and the University of Chicago (2018-2189).

Setting

The 2017 rate (27.9 per 100,000 population) of HIV infection diagnoses in Chicago is approximately 2.5 times higher than the national rate, and the prevalence rate for Chicago (827.9 per 100,000 population) is nearly 3 times the national rate [27]. Community areas on the West and South sides of Chicago represent a concentrated HIV epidemic, with HIV prevalence

consistently over 5% [3,27]. The study recruitment site was a Planned Parenthood Illinois clinic that is located centrally within the city and serves predominantly patients of color.

In the Loop App Prototype Development

A community advisory board (CAB) of 9 young Black women was formed to guide and tailor content of the app prototype. CAB participants were recruited through partner agencies, email listservs, and flyers posted throughout the community. Recruitment flyers included information about the project, participation expectations, and learning opportunities (ie, the app design process). Our goal was to have a group of 8-10 young women who met the inclusion criteria for the larger pilot study to participate in the CAB. CAB members were provided with a US \$50 incentive for each 2-hour meeting they attended.

Guided by user-centered design and the information systems research frameworks, the study team conducted relevance, rigor, and design cycles to refine and adapt an existing prototype app called *miPrEP* [28]. The *miPrEP* app was developed to increase PrEP knowledge and engagement among young Black men who have sex with men [29]. The CAB conducted 4 design sprints over a 3-month period; sessions were guided by generating app content and approving mock-ups (ie, iterative design process). In the rigor cycle, the CAB members met and reviewed the available components of the *miPrEP* app. The *miPrEP* app contained basic PrEP information, as well as a video about how PrEP works in the body. The study team identified and presented additional health-based apps to the CAB for review. Existing content and desired features of an adapted sexual health app were discussed and ranked. Finally, features and content were identified for inclusion and tailoring for the *In the Loop* prototype. In the design cycle, a low fidelity prototype was developed. Paper and pencil mock-ups were used to design the visual assets, video content, and text materials. The prototype of *In the Loop* was created using paper models to represent each intervention component and a Google slide deck to demonstrate app navigation and flow. All elements were iteratively revised with the CAB until there was consensus on the content, quantities, and the form of the app.

User Testing and Pilot Evaluation

Potential participants were recruited from a Planned Parenthood clinic waiting room and, if interested and eligible, they completed informed consent and the study procedures. Participants were eligible if they (1) reported being cisgender women; (2) identified as African American or Black; (3) were English speakers; (4) were aged 18-24 years (inclusive); (5) reported vaginal or anal sex with a male partner within the past 6 months; (6) were seeking testing or treatment for a sexually transmitted infection, or seeking contraception or abortion services; (7) self-reported being HIV-negative; (8) were not currently pregnant; and (9) were neither currently taking PrEP

as HIV prevention nor intending to initiate PrEP at the current clinic appointment.

A pre- and postdesign assessment was used in this pilot study to evaluate the impact of the app on PrEP knowledge immediately after using the app. PrEP knowledge was measured via 7 true or false items that were selected based on use in previous studies with cisgender women [14,30]. Other study aims were to assess usability, including basic feasibility and acceptability of the app prototype among young Black women. Usability was assessed through open-ended questions that asked participants their opinion about the app (eg, “what did you like about using *In the Loop* while waiting for your appointment?” and “what information would you add to *In the Loop* app?”) and ways to improve the app (eg, text or graphic display, navigation, and content). Acceptability of *In the Loop* was evaluated using a series of 9 items derived from an abbreviated acceptability rating scale used in prior research [31]. Participants used a 5-point Likert scale (1=strongly disagree and 5=strongly agree) to rate the extent to which they agreed with each acceptability statement (eg, “I found the information in the app easy to understand and comprehend”). The measure was administered at the immediate postintervention assessment. Overall interest in using mHealth for sexual health was measured via a 7-item scale based on previous research with adolescents (eg, “how likely are you to download a sexual health mobile phone app?”) [32-34]. Finally, participants were asked about preferences toward emerging modalities of PrEP, specifically their interest in a vaginal ring, implant, or injection, or PrEP combined with birth control [35].

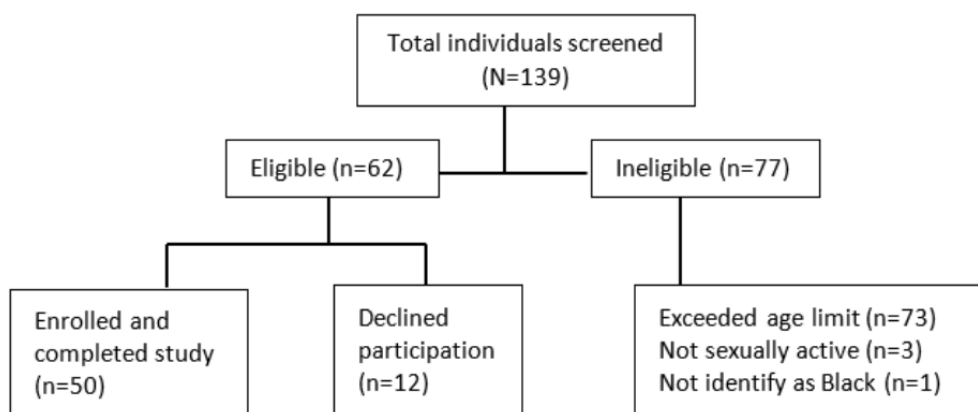

Analysis

Descriptive statistics (eg, mean, SD, and percentage values) were used to describe the sample, and Wilcoxon matched-pairs signed-ranks test was used to detect changes in PrEP knowledge before and immediately after using the app [36]. Open-ended responses were recorded verbatim and were thematically coded by the first author (AKJ), following a standardized procedure [37]. Each open-ended response was read twice, themes were then created based on response content, and each response was coded into one of 4 main themes. If the response contained more than one theme, it was coded as having both themes.

Results

Participant Characteristics

The *In the Loop* prototype was evaluated from July 2019 through August 2019. A total of 50 sexually active, young Black women aged 18-24 (mean 21, SD 1.9) years were enrolled in the study. Initially, a total of 139 individuals were screened, with 62 being eligible; of those eligible, 50 (81%) enrolled and completed the study visit (Figure 1).

Figure 1. CONSORT (Consolidated Standards of Reporting Trials) flow diagram.

Of the 50 participants, 23 (46%) reported being current students, with 21 (42%) participants reporting their highest level of education as some college education, 19 (38%) as high school graduate, and 9 (18%) of them reported having completed college (Table 1). The majority of participants (n=37, 74%) were employed either full- or part-time. To characterize potential social determinants of health that impact HIV transmission, participants reported whether they had ever received government assistance (n=19, 38%) and whether they had ever been homeless (n=11, 22%).

A total of 44 (88%) participants reported identifying as straight or heterosexual, and 6 (12%) reported their sexual orientation as bisexual. In terms of sexual behavior, the majority (n=42, 84%) reported having 1 sex partner in the past 3 months. Inconsistent condom use was common, with 43 (86%) participants reporting sometimes or never using condoms during vaginal sex; 9 (18%) participants reported having sex with a person whose HIV status they did not know; 6 (12%) of them had a recent STI diagnosis, and 24 (48%) had experienced an unplanned pregnancy.

Table 1. Participant characteristics (N=50).

Characteristics	Values
Age, mean (SD)	21 (1.9)
Sexual orientation, n (%)	
Straight	44 (88)
Bisexual	6 (12)
Hispanic or Latina ethnicity, n (%)	
No	47 (94)
Yes	3 (6)
Education level, n (%)	
Some high school	1 (2)
High school or General Education Diploma	19 (38)
Some college or Associate of Arts degree	21 (42)
Completed college or Bachelor of Arts degree	9 (18)
Current student, n (%)	
Yes	23 (46)
No	27 (54)
Received government aid, n (%)	
Yes	19 (38)
No	29 (58)
Unsure	2 (4)
Employment, n (%)	
No	13 (26)
Part-time	23 (46)
Full-time	14 (28)
Ever been homeless, n (%)	
Yes	11 (22)
No	39 (78)
Sexual behavior in the past 3 months, n (%)	
1 sex partner	42 (84)
2 or more sex partners with no overlap	6 (12)
2 or more sex partners with overlap	2 (4)
Condom use in vaginal sex, n (%)	
Always	6 (12)
Sometimes	25 (50)
Never	18 (36)
Condom use in anal sex, n (%)	
Always	1 (2)
Sometimes	4 (8)
Never	5 (10)
Did not have anal sex	40 (80)
Had sex with a person whose HIV status you did not know, n (%)	
Yes	9 (18)
No	41 (82)

Characteristics	Values
Had a sexually transmitted infection, n (%)	
Yes	6 (12)
No	44 (88)
Unplanned pregnancies, n (%)	
Yes	24 (48)
No	26 (52)
How likely are you to become infected with HIV based on current behavior, n (%)	
Very unlikely	22 (44)
Unlikely	22 (44)
Somewhat likely	6 (12)

PrEP Knowledge

Prior to using the app, 30 (60%) participants reported having “never heard of PrEP” and 44 (88%) considered themselves as “very unlikely or unlikely” at risk for HIV based on their current sexual behaviors. Analysis comparing scores before and immediately after using the app revealed a significant increase in PrEP content knowledge scores on a 7-item true or false scale. Total mean scores improved from 2.8 (SD 1.2) prior to using the app to 4.9 (SD 1.4) immediately after using the app ($z=-6.04$, $P<.001$). In item-by-item analysis, 4 of 7 items showed statistically significant improvements from before to

immediately after app use (Table 2). After using the app, 13 (26%) participants reported they were “very likely” to start PrEP in the next 3 months, and 46 (92%) participants agreed with the statement “PrEP is a good option for HIV prevention for young women like me.”

In the immediate postsurvey, participants were asked whether they were interested in other PrEP modalities (Figure 2), including vaginal ring, implant, or injection, or PrEP combined with birth control. The most frequently endorsed mode was a dual method option with PrEP and birth control combined; 39 (78%) participants endorsed this option.

Table 2. Pre-exposure prophylaxis (PrEP) knowledge before and immediately after use of the app (N=50).

True or false items	Negative ranks, n (%)	Ties, n (%)	Z scores
PrEP can be bought over the counter without a prescription	6 (12)	39 (78)	-0.63
PrEP needs to be taken daily in order to be effective	13 (26)	36 (72)	-3.60 ^a
PrEP is only recommended for gay and bisexual men	42 (84)	7 (14)	-6.48 ^a
PrEP can be used to prevent infection after being exposed to HIV	29 (58)	20 (40)	-5.39 ^a
PrEP can be taken by both men and women to prevent HIV infection	4 (8)	44 (88)	-1.34
You need to be at least 18 years of age to get PrEP	11 (22)	37 (74)	-2.89 ^a
Only HIV doctors can prescribe PrEP	9 (18)	37 (74)	-1.73

^a $P<.001$.

Figure 2. Interest in alternate PrEP modalities (N=50). PrEP: pre-exposure prophylaxis.

Technology Use for Sexual Health

When participants were asked about interest levels in using technology as part of sexual health care, 22 (44%) indicated they were very interested, and 21 (42%) reported being somewhat interested. A total of 31 (63%) indicated they were very interested in using a mobile app for sexual health education, 10 (21%) indicated they were somewhat interested, and 8 (16%) indicated no interest. Just over half (n=26, 52%) of the sample reported being very interested in receiving sexual health reminders via email (n=29, 57%) or text message (n=25, 51%). Finally, only 17 (35%) participants reported being very interested in learning about sexual health topics via internet games.

In the Loop App Acceptability and Usability

Overall, participants considered the *In the Loop* app feasible and acceptable to use while waiting for a family planning visit. More specifically, 46 (92%) participants agreed that they would recommend *In the Loop* to friends to learn more about PrEP. Participants also reported that they liked using the app—rated 4.6 on a scale from 1 (strongly disagree) to 5 (strongly agree). Participants rated the overall quality of the app 4.3 on a scale from 1 (very poor) to 5 (very good); 40 (80%) participants

agreed that the app was easy to use, and 48 (96%) agreed that they found the information in the app easy to understand. Finally, 40 (80%) agreed that they had enjoyed using the app while waiting for their family planning visit.

Participants were also asked to provide open-ended feedback on improvements that could be made to the app, which were summarized into four different themes to inform future refinement: increasing interactive components, refining app navigation, refining app aesthetics, and increasing sexual health and HIV prevention information (Table 3). Finally, participants responded to an open-ended question providing insight to their favorite parts of the app, including liking the fact that the main character is a young Black woman (“I liked that it was relatable. I liked that there was a character that looked like me” [participant ID, ie, PID 66]), that it did not require a lot of time to use (“It was quick. Wasn’t long. Wasn’t boring” [PID 15]), and that it was private or confidential (“Private on the iPad” [PID 50]).

Two functional bugs were identified in testing the app with users. The first bug caused a video to stall if the navigate back button was pushed; the second bug caused an incorrect follow-up prompt to be displayed. Both bugs, once identified, were remedied.

Table 3. Suggested app improvements.

Theme	Illustrative quote
Increase interactive components	<ul style="list-style-type: none"> “It was kind of wordy. They should highlight words, so it won’t look like a whole paragraph. The paragraph is intimidating. Should be more interactive.” [PID 71]
Refine app navigation	<ul style="list-style-type: none"> “Pointing out things, like for each section, so they know what they can press and where to move on, or how to leave the video.” [PID 60]
Refine app esthetics	<ul style="list-style-type: none"> “The blue is okay, but add more bright colors...like when you are navigating change the colors up.” [PID 82]
Increase sexual health and HIV prevention information	<ul style="list-style-type: none"> “Add place that people can go to get STI^a testing or on PrEP^b. Like if you want to go somewhere else you put in your zipcode and go.” [PID 28] “More about mechanisms or each birth control option; how some of these birth controls are inserted; how does it work?” [PID 16]

^aSTI: sexually transmitted infection.

^bPrEP: pre-exposure prophylaxis.

Discussion

Principal Findings

This study demonstrates that using an app in a family planning clinic waiting room is feasible and acceptable to young Black women. As family planning clinics are primary sources of health care for young Black women, integrating PrEP services into their practices is a critical component of comprehensive reproductive health care. Further, providing high-quality, confidential information via an mHealth app while waiting for clinic visits makes the most of a current missed opportunity. The *In the Loop* app is an innovative strategy to engage young Black women in HIV prevention.

In the Loop followed key tenets of developing effective mHealth interventions, including incorporating ease of modification and tailoring to the target population. Our team, in collaboration with young Black women, modified the content of an existing PrEP knowledge app and tailored it to be specific to the needs of the target population. Through user testing, we identified and addressed 2 bugs in the app. Finally, we gathered feedback on further refinements such as increasing the interactive components and refining the app navigation. The majority of participants were interested in using technology as part of sexual health care, with an app being the most popular mode of technology selected.

Comparison With Prior Work

Cordova et al [38] designed and evaluated an mHealth intervention—*Storytelling 4 Empowerment*—to provide HIV, STI, and drug abuse prevention information to adolescents in primary care waiting rooms. In the acceptability pilot, participants reported approval of using down time while waiting for clinic visits; however, they also highlighted the need for privacy in shared spaces. Participants recommended privacy covers over tablets. In our pilot study, participants noted that the app felt private and did not raise concerns over privacy of participating in an mHealth app in a family planning clinic waiting room; nevertheless, it should be considered best practice to use privacy screens on tablets as recommended by Cordova et al [38].

In a systematic review, Chávez et al [39] highlighted the fact that apps tailored to adolescents’ specific race, ethnicity, and gender identity demonstrated stronger effects on health behavior compared to apps that were not tailored. Results from our community-engaged app development demonstrated high levels of app acceptability among the target population. Not only is the tailoring of mHealth important to success, but also the inclusion of the target population in mHealth development is critical for ensuring salience and acceptability.

In a 2020 systematic review of mHealth strategies to promote PrEP uptake, only 1 app was identified that was tailored specifically for young women; it was designed for those aged 11-14 years in Western Kenya [40,41]. No apps were identified that were tailored for young Black women in the United States. The results of the review highlight the need for mHealth strategies designed specifically to meet the needs of young Black women. We believe that our app will help to fill this gap.

Limitations

Results of this pilot study must be interpreted in light of several limitations. First, the app was tailored exclusively for young Black women in a single urban setting, and thus our results cannot be generalized to other populations of young Black women. Further, the intervention was tailored for young Black women who have sex with men; further research is needed to tailor the intervention for young Black women who have sex with women or transgender and gender-diverse individuals. Second, the high positive rating of the app may be biased due to social desirability. We attempted to mitigate the effect of this bias by using computer-assisted questionnaires. Finally, although *In the Loop* was found to be acceptable and feasible, and to have an immediate impact on PrEP knowledge, future studies are needed to determine the sustained effect of the app on PrEP knowledge and to determine whether the app can improve PrEP uptake. Our results are limited, as they reflect prescores and immediate postscores without randomization; future studies should use randomization and assess durable effects of the intervention. Despite these limitations, this formative research may help guide future design and implementation of mHealth

interventions in family planning settings, optimizing their chances for success.

Conclusions

Overall, our findings suggest that young Black women waiting for family planning visits found *In the Loop* to be feasible and acceptable. Further, this study demonstrates the value of engaging young Black women in the design process. As family

planning clinics are primary sources of health care access for young women, they provide an ideal setting to integrate PrEP information and care into existing clinic practices. mHealth approaches can be scaled rapidly with fidelity. Future studies should evaluate the efficacy and durability of the *In the Loop* app in improving PrEP knowledge and uptake among PrEP-eligible young Black women.

Acknowledgments

The authors would like to thank staff at University of Chicago's Ci3 Lab who created the digital esthetics and the app prototype. The authors would also like to thank the community advisory board and study participants for their time and expertise. Finally, the authors would like to acknowledge the partnership of Planned Parenthood, Illinois, where this pilot study was conducted.

Abstract

Background: Smoking cessation smartphone apps have emerged as highly accessible tools to support smoking cessation efforts. It is unknown how specific app features contribute to user engagement over time and relate to smoking outcomes.

Objective: To provide a feature-level analysis of the Smiling Instead of Smoking app (version 2) and to link feature use to subsequent smoking cessation.

Methods: Nondaily smokers (N=100) used the app for a period of 49 days (1 week before quitting and 6 weeks after quitting). Participants self-reported 30-day point-prevalence abstinence at the end of this period and at a 6-month follow up (the survey response rate was 94% and 89% at these points, respectively). Self-reported 30-day point prevalence abstinence rates were 40% at the end of treatment and 56% at the 6-month follow up. The app engaged users in both positive psychology content and traditional behavioral smoking cessation content. The app sent push notifications to prompt participants to complete prescribed content (ie, a “happiness exercise” every day and a “behavioral challenge” to use the app’s smoking cessation tools on 15 out of 49 days). Actions that participants took within the app were timestamped and recorded.

Results: Participants used the app on 24.7 (SD 13.8) days out of the 49 prescribed days, interacting with the happiness content on more days than the smoking content (23.8, SD 13.8 days vs 17.8, SD 10.3 days; $t_{99}=9.28$ [2-tailed]; $P<.001$). The prescribed content was frequently completed (45% of happiness exercises; 57% of behavioral challenges) and ad libitum tools were used on ≤ 7 days. Most participants used each ad libitum smoking cessation tool at least once, with higher use of personalized content ($\geq 92\%$ used “strategies,” “cigarette log,” “smoke alarms,” and “personal reasons”) than purely didactic content (79% viewed “benefits of quitting smoking”). The number of days participants used the app significantly predicted 30-day point-prevalence abstinence at the end of treatment (odds ratio [OR] 1.05, 95% CI 1.02-1.09; $P=.002$) and at the 6-month follow up (OR 1.04, 95% CI 1.008-1.07; $P=.01$). The number of days participants engaged with the happiness content significantly predicted smoking abstinence at the end of treatment (OR 1.05, 95% CI 1.02-1.08; $P=.002$) and at the 6-month follow up (OR 1.04, 95% CI 1.007-1.07;

$P=.02$). This effect was not significant for the number of days participants engaged with the smoking cessation content of the app, either at the end of treatment (OR 1.04, 95% CI 0.996-1.08, $P=.08$) or at the 6-month follow up (OR 1.02, 95% CI 0.98-1.06; $P=.29$).

Conclusions: Greater app usage predicted greater odds of self-reported 30-day point-prevalence abstinence at both the end of treatment and over the long term, suggesting that the app had a therapeutic benefit. Positive psychology content and prescriptive clarity may promote sustained app engagement over time.

Introduction

Mobile technologies have recently emerged as highly accessible support tools for health behavior change and mental health promotion. This has been particularly true for smoking cessation, with notable increases in the use of [1,2] and referral to [3] mobile technologies designed to support quitting. User engagement with smartphone apps, however, represents a critical challenge. It has been estimated that less than 5% of apps continue to be used 15 to 30 days after the initial app download [4]. Note that to our knowledge, a standardized operational definition of app engagement has not yet been established [5]; throughout this paper, we use the term “app engagement” to denote user behavior, that is, an app user interacting with the app’s user interface.

App engagement is important for several reasons. First, it is through interaction with an app that app users engage in therapeutic activities. Such engagement can take different forms. An app may present information, provide a tool or behavior change strategy, assign homework, or prompt the app user to take specific actions (eg, call a clinician) [1]. It can be assumed that the more app users interact with the app, the more they will engage in thoughts, feelings, and actions that are believed to be beneficial to their smoking cessation goal. This logic is consistent with findings across the eHealth literature demonstrating that greater engagement with eHealth tools (eg, websites) is associated with more favorable outcomes related to smoking cessation [6-8].

A critically useful feature of smartphone apps is their potential utility in providing sustained support over time. Several studies suggest that extending behavioral support helps smokers remain abstinent in the long term, with longer treatments lasting 8 to 12 weeks [9-11]. If longer treatment is better, the next question is what app users should be doing within a smoking cessation app. The vast majority of publicly available smoking cessation apps focus on simple tools: calculators to track money saved and health benefits accrued or calendars to track the days until or since the chosen quit day [1]. The apps provided on Smokefree.gov, a recommended mHealth referral site for treating smokers in health care settings [3], are more sophisticated. They offer a variety of tools and trackers (eg, time-based and GPS-based reminders to abstain from smoking at high-risk times or in high-risk locations and daily tips and

milestone achievement badges) while also providing tailored feedback for overcoming urges to smoke due to cravings and mood states. These apps are able to capture the initial engagement of a very large number of smokers (there are over 25,000 and 13,000 users to date for QuitGuide and quitSTART, respectively) [12]. It is unclear, however, to what extent and how these apps sustain engagement over time.

A new generation of smoking cessation apps is emerging. In such apps, there are additional ways that smoking cessation is supported. The nature of these approaches varies widely from app to app, including contingency management [13,14], motion-sensor detection of smoking [15], carbon monoxide level monitoring [16], using gaming to engage smokers in skills practice [17] or other activities promoting smoking cessation [18], promoting nicotine replacement therapy adherence [19], prescribing bouts of physical activity [20], mindfulness training [21], and acceptance and commitment therapy (ACT) [22,23]. Most of these apps are in the early stages of development, and study protocols have been published, but the studies are ongoing. A handful of pilot feasibility studies exist, only a few of which offer insight into app usage over time. App usage ranged from 7 days for a smartphone app using a gamification approach to smoking cessation [18], to 34 and 32 days, respectively, in a pilot randomized control trial that compared an ACT-based app to the National Cancer Institute (NCI)’s app QuitGuide [22]. The largest randomized trial to date reported 24 days of app use for the app iCanQuit, an ACT-based smoking cessation app, compared to 7 days of use for an earlier version of NCI’s QuitGuide, a version that was largely text-based and did not include trackers or tools [23].

In this paper, we present a feature-level analysis of app usage over time of the Smiling Instead of Smoking (SiS) app. To our knowledge, this is only the second research project that links feature-level app use to subsequent smoking cessation. The first such project provided a feature-level analysis of the app SmartQuit [24], an early version of iCanQuit [23]. The feature-level analysis of SmartQuit [24] indicated that the use of 3 features was prospectively linked to smoking cessation at follow up; 2 of these features were ACT focused (ie, tracking ACT skills practice and tracking the practice of letting urges pass); the remaining feature was a traditional US Clinical Practice Guidelines (USCPG) feature (ie, viewing the quit plan) [24]. In that analysis, the team noted little overlap between the

popularity of the app's features and their subsequent link to smoking cessation success.

The app we are examining in this paper, the SiS app, was developed specifically for nondaily smokers [25-27]. Nondaily smoking is a widespread, increasingly prevalent pattern of smoking. Currently, 24.3% of all adult smokers smoke on a nondaily basis [28], which constitutes a 27% increase over the past decade [29]. Despite such prevalence, particularly in ethnic minority groups [30-34] and vulnerable populations, such as persons with mental health and substance use challenges [35], behavioral and pharmacological recommendations for nondaily smoking remain unaddressed in clinical practice guidelines [36]. Nicotine replacement therapies have been tried but so far have failed to show efficacy in achieving smoking abstinence in nondaily smokers [37,38], in line with a lack of interest among nondaily smokers in pharmacotherapy for smoking cessation [39,40]. Nondaily smokers are, however, highly motivated to quit smoking. Compared to daily smokers, they have greater current intentions to quit smoking [31,41,42] and more recent and planned cessation efforts [42-45]. These factors point to the utility of behavioral support, which can be delivered effectively via smartphone technology.

The therapeutic goal of the SiS app is to maintain positive affect while smokers undergo a quit attempt. Positive affect often decreases during a quit attempt [46], as smokers struggle with cravings and adjusting to a smoke-free life. Indeed, recently, a decrease in positive affect has been suggested as a new symptom of tobacco withdrawal, based on data from 24 trials involving 2054 participants showing a medium effect size (Cohen $d=-0.40$) for an overall decrease in positive affect [47]. Maintaining positive affect during this time, however, may be especially beneficial, because greater positive affect is associated with increased self-efficacy to quit smoking [48], decreased desire to smoke [49,50], and greater readiness to process self-relevant health information [51], all of which are constructs highlighted in dominant health behavior theories as causal agents in successful behavioral change [52-56].

Smoking cessation apps can deliver a wide array of content, but users must engage with the information to benefit. The SiS app engages users in short, daily exercises to boost their positive affect. This boost in positive affect is intended to increase their readiness to engage in the smoking cessation materials provided in the app [51]. Moreover, completing happiness-boosting exercises is intrinsically rewarding, in and of itself. Having rewarding experiences while using the app may, in turn, entice app users to return to the app on subsequent days. This dynamic is evident across a diversity of settings, and positive psychology interventions have been found to be highly appealing to patients [57], resulting in better treatment adherence [58,59] and engagement [60].

In the initial study of version 1 of the SiS app ($N=30$), the "happiness exercises" appeared to be a driving factor in app engagement [26]. In this paper, we are examining app usage of participants in a larger trial, using version 2 of this app. The overall app usage was quite high, with smokers using the SiS app for an average of 24 days within the prescribed period of 49 days [27]. Using these data, our goals were to (1) describe

how nondaily smokers used the app and (2) test if app usage patterns (ie, any app use, use of happiness content, and use of smoking content) during the prescribed treatment period predicted smoking abstinence (ie, self-reported 30-day point-prevalence abstinence [PPA]) at the end of treatment and at a 6-month postquit follow up.

Methods

Participants

In this secondary data analysis, we examined app usage data from 100 adult nondaily smokers participating in a single-arm study. The eligibility criteria for the study were as follows: age at least 18 years, nondaily smoking habit (ie, smoking at least weekly but no more than 25 out of the past 30 days), smartphone ownership (Android or iPhone only), willingness to make a quit attempt as part of the study, willingness to name friends and family members who could help study staff with updating contact information for follow-up assessments, and fluency in the English language. Note that our operational definition of nondaily smokers was designed to include the majority of nondaily smokers while targeting nondaily smokers who would routinely engage in nondaily smoking and thus might benefit from an app providing continuous support, and nondaily smokers who were not too close to being daily smokers. We have kept this operational definition consistent across our studies on nondaily smokers [26,40]. Nationally representative data at the time suggested that it would include 72% of nondaily smokers [31]. Participants who completed a baseline survey and who were successfully onboarded to the app via phone were included in this secondary data analysis. The average age of participants was 35.9 (SD 11.4) years. More than half (61/100, 61%) were female, and the majority were white (75/100, 75%) and employed (63/100, 63%), either full-time (44/100, 44%) or part-time (19/100, 19%). Thirty-eight participants (38/100, 38%) had a college degree or higher. Most had previously smoked daily (70/100, 70%). Typically, approximately half of nondaily smokers are former daily smokers [61-63]. Most participants had previously tried to quit smoking (77/100, 77%), a rate that was slightly higher than that reported by nondaily smokers in the 2000 National Health Interview Survey, in which 65% reported having tried to quit [42]. Participants smoked on average on 14.7 (SD 4.6) days out of the past 30 days and smoked 4.6 (SD 3.3) cigarettes per smoking day. Half had tried e-cigarettes (57/100, 57%).

Procedures

Recruitment occurred between June and November 2019. Participants were recruited nationwide using online resources. After screening, participants completed an onboarding phone call with study staff, during which they were guided through downloading, installing, and using the app. This onboarding phone call marked the beginning of the treatment period: participants were instructed to use the app for the subsequent 49 days. The onboarding call was scheduled to occur 1 week prior to the participants' chosen quit day, so that the prescribed app use period covered 1 week before and 6 weeks after the initial quit day (participants could reschedule their quit day within the app). App usage for all participants was recorded by

the app. Participants also completed online surveys 2, 6, 12, and 24 weeks after the initial quit day, with response rates of 96/100 (96%), 96/100 (96%), 94/100 (94%), and 89/100 (89%), respectively.

Ethics Approval

The study procedures were approved by the Mass General Brigham Institutional Review Board (2018P002699) and are detailed elsewhere [27]. The trial has been registered on ClinicalTrials.gov (NCT03951766).

Outcomes

App Utilization

Actions that participants took within the app were timestamped by the app and recorded on a secure server. From these data, we coded the number of days participants used certain features of the app and the percentage of participants who used that feature at least once after onboarding.

Smoking Cessation

In online surveys, participants were asked to indicate their smoking status using the following options: “I smoke daily,” “I smoke nondaily (and have smoked in the past 7 days),” “I smoke nondaily (but have NOT smoked in the past 7 days),” and “I do not smoke at all.” Participants who reported not smoking at all were then asked if they had been completely abstinent since their originally chosen quit day, during the past 7 days, and during the past 30 days. From this, we coded 30-day PPA at the end of treatment and at the 6-month follow up.

Description of the SiS App

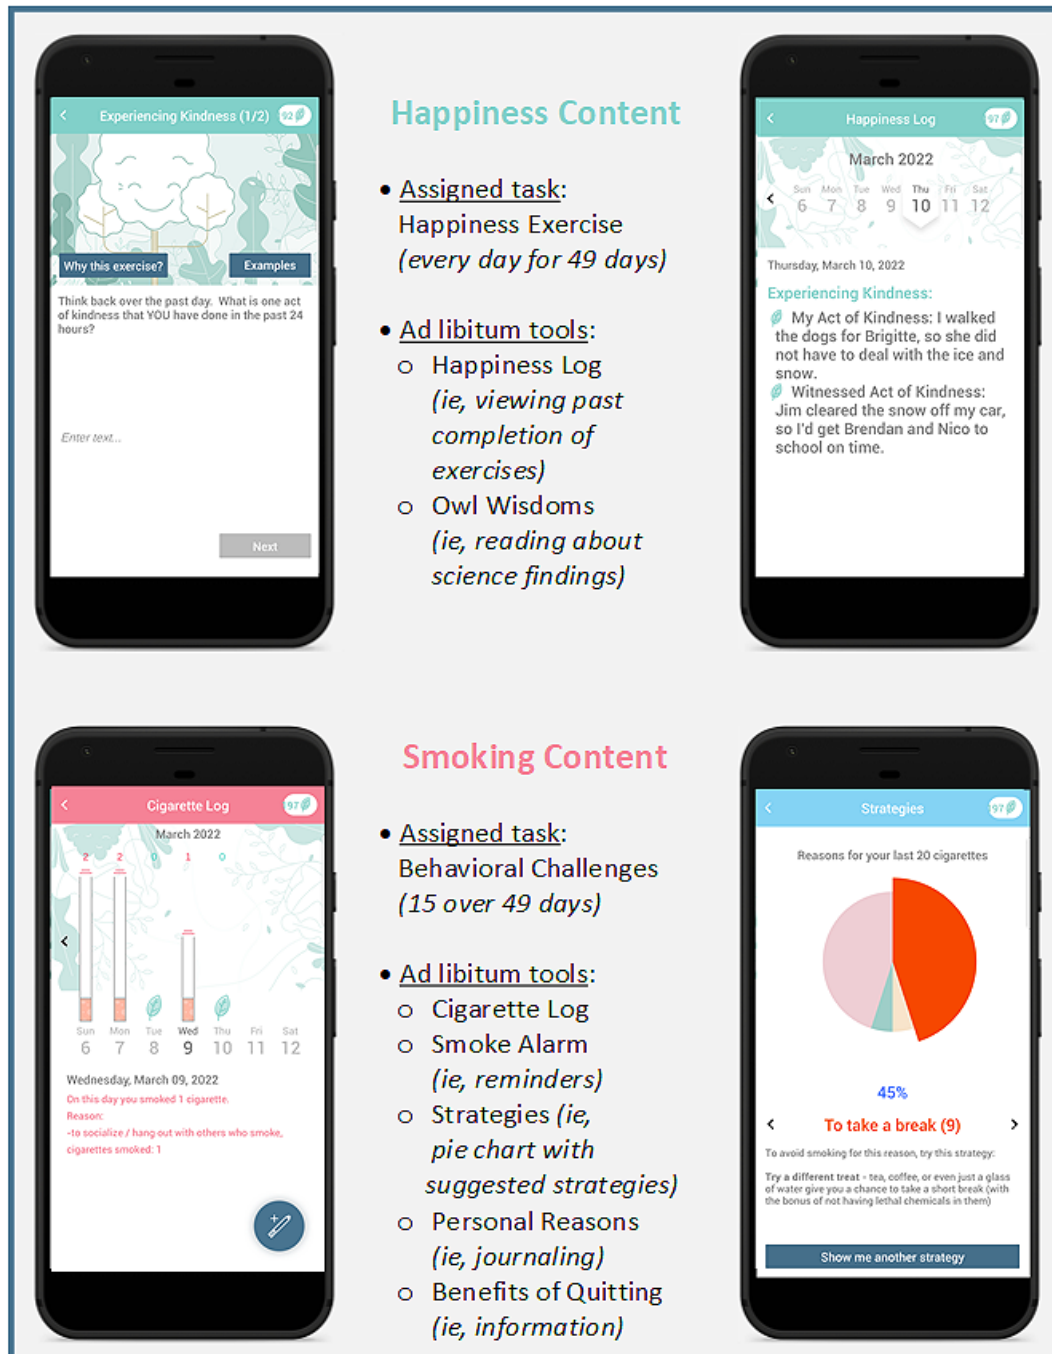

Version 2 of the SiS app (Figure 1) engaged app users in both positive psychology content designed to maintain their positive affect and traditional behavioral smoking cessation content to guide their quit attempt. During onboarding, study staff walked participants through the app and how to use it. They started with the happiness content, including showing the participants the specific buttons that explained the positive psychology framework used by the app (ie, the buttons labeled “why happiness” and “why this exercise”). These buttons were prominently displayed when engaging in the positive psychology content of the app and provided text explaining why app users were asked to complete happiness exercises in order to support their smoking cessation efforts. Study staff then moved on to “behavioral challenges,” and used these as an organizing structure to guide participants through the smoking tools.

To elicit positive affect, participants were asked to complete a happiness exercise each day. Each day, the app chose 1 of 5 happiness exercises (Multimedia Appendix 1) to be completed that day. To complete the exercise, participants had to enter text into the app (eg, to describe good things that had happened to them or to describe something they had savored). These 5 exercises had been tested previously in an online survey that randomized survey takers into completing 1 of these exercises or 1 of 2 control exercises, which showed that these happiness exercises increased in-the-moment happiness [64]. Optionally, app users could review their past entries in the “happiness log,” and could use the feature called “owl wisdoms” to read about scientific findings that showcase the utility of engaging in happiness-enhancing activities.

For smoking content, participants were asked to complete temporally appropriate “behavioral challenges” every 3 to 4 days (on 15 of 49 days). These behavioral challenges were anchored on the participant’s quit day, which they specified in the app upon app installation. Participants could reset the quit day at any point, causing the app to adjust the schedule of the behavioral challenges accordingly. These behavioral challenges prompted users to use the smoking cessation tools provided within the app, in the order recommended by the NCI’s “Clearing the Air” brochure [65]. The tools included a cigarette log to log smoked cigarettes, a strategy guide, which provided a pie chart of users’ smoking triggers and suggested strategies for them, an alarm feature that let users set reminders to stay smoke free at upcoming times and events, a journal function to enter personal reasons for quitting smoking, and an informational section where the benefits of quitting smoking were presented. After the first month, behavioral challenges also directed participants to use the app’s ad libitum happiness tools (ie, the happiness log and “owl wisdoms”).

In total, app use entailed both prescribed (ie, happiness exercises and behavioral challenges) and ad libitum app activities that pertained to either happiness or smoking cessation (Figure 1). During the onboarding call, study staff set clear expectations that the participants should complete the happiness exercise every day for 49 days (ie, during the treatment period) and optionally thereafter and that they should complete every behavioral challenge. The app sent push notifications to prompt participants to complete the prescribed content. For the happiness exercise, the push notification was either sent at 10 AM to announce the exercise, at a random time between 12 PM and 2 PM to remind them to complete the exercise, or at 7 PM (if the exercise was still incomplete). For behavioral challenges, the push notification was always sent at 10 AM.

Figure 1. Features of the Smiling instead of Smoking 2 app.

Analyses

To describe app use during the prescribed 49-day app use period, we calculated the average number of days on which participants used the app overall and specific functions within the app. We also calculated the percentage of participants who used specific functions of the app at least once after onboarding and the percentage of times the prescribed activities (ie, happiness exercises and behavioral challenges) were completed. To test if participants seemed to prefer one happiness exercise over another, we calculated the number of times the participants completed each of the 5 exercises and then used a hierarchical linear model to test if the categorical variable denoting each exercise significantly predicted this number. Observations were modeled as nested within persons.

To test if app usage during the prescribed treatment period predicted smoking abstinence, we used a series of univariate logistic regressions, where self-reported 30-day PPA was the dependent variable (with 1 indicating “abstinent” and 0 indicating “not abstinent”) and app usage was the univariate predictor. We examined 3 different summaries of app usage: the overall number of days the app was used, the number of days the happiness content was used, and the number of days the smoking cessation content was used. Based on the app usage pattern observed in the first SiS study [26], we expected the correlation of the number of days the app was used and the number of days the happiness content was engaged with to be very high. We calculated them separately, however, to create conceptual clarity in our prediction of smoking cessation. We

fit the same models for smoking abstinence at the end of treatment (ie, 6 weeks after the initially chosen quit day) and at the end of follow up (ie, 6 months after the initially chosen quit day). Participants were assumed to be smoking if they did not complete the surveys (there were 4% and 11% nonresponse rates at weeks 6 and 24, respectively). The logistic regression results are presented with odds ratios (ORs) and the Wald 95% CI, as well as the *C* statistic (an indicator of correct classification). All analyses were completed in SAS 9.4 for Windows (SAS Institute).

Results

App Usage

Participants used the SiS app an average of 24.1 (SD 14.1) days out of the 49 prescribed days (Figure 2). Overall, they interacted with the happiness content on more days than the

smoking-related content (23.2 days, SD 14.1, vs 16.7 days, SD 10.3; $t_{99}=9.47$ [2-tailed]; $P<.001$). Participants completed the behavioral challenges more consistently than the happiness exercises, with participants completing 56.6% (SD 28.1%) of the behavioral challenges, on average, compared to 44.8% (SD 28.8%) of the happiness exercises ($t_{99}=7.44$; $P<.001$). The completion rate of the happiness exercises differed by exercise type ($F_{4,396}=2.82$; $P=.03$). Tukey adjusted posthoc pairwise comparisons showed that participants completed the “rose, thorn, and bud” exercise more often than the “savoring” exercise (4.6 days, SD 3.1, vs 4.1 days, SD 2.8; $P=.02$). The completion rates of the other 3 exercise types (“3 good things”: 4.5 days, SD 3.0, “experiencing kindness”: 4.4 days, SD 3.1, and “reliving happy moments”: 4.4 days, SD 3.0) were intermediate to the “rose, thorn, and bud” and “savoring” exercises and did not differ from any other exercise type.

Figure 2. App usage over time. SiS2: Smiling Instead of Smoking, version 2.

Ad libitum tools were used relatively sparingly. The behavioral challenges appeared to have been successful in initially engaging participants with specific tools, as indicated by the high percentage of participants using each tool at least once after the onboarding day (Table 1). For example, 93 participants (93%) used the “personal reasons” tool, and 93 participants (93%) used “smoke alarms” at least once after onboarding. The number of days on which participants used these smoking cessation tools,

however, was relatively low. Of these tools, the “cigarette log” was used the most (average 7.2 days), and the “benefits of quitting” the least (average 2.5 days). The happiness-focused ad libitum tools were similarly infrequently used. The exception was the happiness log, which was viewed on 22.1 of 49 days; however, it should be noted that upon completion of the assigned happiness exercises, participants automatically landed on the happiness log.

Table 1. Description of app use during the prescribed app use period (ie, 49 days).

App use	Days used of possible 49, mean (SD)	Participants (N=100) with at least one day of use after onboarding, n (%)
Overall		
Any use of the app	24.1 (14.1)	99 (99)
Any happiness content	23.2 (14.1)	98 (98)
Any smoking content	16.7 (10.3)	98 (98)
Assigned tasks		
“Happiness exercises” completed	22.0 (14.1)	96 (96)
“Behavioral challenges” completed	8.5 (4.2)	100 (100)
Ad libitum tasks		
“Happiness log” viewed	22.1 (14.1)	96 (96)
“Owl wisdoms” viewed	3.6 (3.3)	78 (78)
“Happiness information” viewed	2.0 (3.2)	60 (60)
“Cigarette log” viewed/edited	7.2 (6.5)	96 (96)
“Smoke alarms” viewed/edited	4.6 (3.0)	93 (93)
“Strategies” viewed/edited	4.1 (3.3)	94 (94)
“Personal reasons” viewed/edited	3.5 (3.2)	92 (92)
“Benefits of quitting” viewed	2.5 (2.3)	79 (79)

Relationship of App Usage to Smoking Abstinence

As illustrated in Figure 3, overall, the number of days with any use of the app significantly predicted smoking abstinence at 6 weeks (1 more day of use: OR 1.052, 95% CI 1.019-1.086; $P=.002$; $C=.69$) and 6 months postquitting (1 more day of use: OR 1.038, 95% CI 1.008-1.070; $P=.014$; $C=.65$). The number of days participants engaged with the SiS 2 app’s happiness content significantly predicted smoking abstinence at the end of treatment (1 more day of use: OR 1.050, 95% CI 1.017-1.084; $P=.002$; $C=.69$) and at 6-month follow up (1 more day of use:

OR 1.037, 95% CI 1.007-1.069; $P=.016$; $C=.65$). This effect was not significant for the number of days participants engaged with the smoking cessation content of the SiS 2 app, at either the end of treatment (1 more day of use: OR 1.036, 95% CI 0.996-1.079; $P=.08$; $C=.64$) or at the 6-month follow up (1 more day of use: OR 1.021, 95% CI 0.982-1.062; $P=.29$; $C=.59$). The correlation between these 3 app usage indices was high, especially between any content and happiness content ($r=0.995$), but only somewhat lower for smoking content with any content ($r=0.89$) and happiness content ($r=0.88$).

Figure 3. Odds ratio of app usage predicting self-reported 30-day point prevalence abstinence. The odds ratio is based on a single-day increase in app usage of the indicated content (ie, "any content," "happiness content," "or smoking cessation content").

Discussion

Key Findings

This secondary data analysis of participants enrolled in a smartphone app-based smoking cessation study provided insight into how feature-level app usage behaviors relate to smoking cessation outcomes. The app under study, the SiS 2 app, is part of an emerging generation of smartphone apps that offer a treatment framework beyond standard USCPG content. In our feature-level analysis of the SiS 2 app, we found that overall greater app usage predicted higher chances of subsequent smoking cessation. This finding is in line with the feature-level analysis of the app SmartQuit [24], which showed that greater app use was positively related to subsequent smoking cessation. It suggests that there was a potential therapeutic effect of engaging with the SiS 2 app, though a causal relationship could not be established in this observational study.

Divergent from SmartQuit findings, for SiS 2 the popularity of the app's features aligned with smoking cessation success, where greater usage of the happiness components of the app predicted greater chances of 30-day PPA at both the end of treatment and at the 6-month follow up. This finding suggests that the positive psychology components of SiS 2 are an important factor in supporting smoking abstinence. This is in line with findings from in-person treatment studies that indicate the value of positive psychology in smoking cessation [66,67]. Our findings here suggest this value may extend to the smartphone app environment. Particularly noteworthy is the high level of engagement with the SiS 2 app (ie, sustained use over 49 days, with multiple uses per week), largely driven by the positive psychology content. In mHealth research, touch point frequency is an emerging area of investigation, with some apps focusing solely on reminding app users not to smoke at key timepoints [15], as simple reminders can be powerful tools in smoking cessation [68]. The high touch point frequency observed for the SiS 2 app speaks to its ability to remain present in smokers' minds as they navigate smoking cessation.

Prescriptive Clarity

Our results highlighted a rather stark difference in the completion rates of assigned versus ad libitum tasks. Happiness exercises were completed on 45% of days, and 57% of assigned behavioral challenges were completed. These completion rates are in line with the completion rates reported for a mindfulness smoking cessation app for adolescents; participants completed 13 of 22 (61%) of the assigned mindfulness modules [69]. The ad libitum tools, on the other hand, were sparsely used: they were used on only 7 days for the most popular ad libitum tool. This finding suggests that prescriptive clarity may be of critical importance in driving app usage, and therefore in achieving an app's therapeutic effect. In the SiS 2 app, there was prescriptive clarity: clear expectations were set about treatment length (ie, 49 days), and which specific actions to complete (ie, daily happiness exercises and 15 behavioral challenges). These expectations were reinforced with proactive push notifications. The iCanQuit app [70] also had prescriptive clarity: a set number of modules were required to be completed. Both apps had high app engagement over time. By contrast, the NCI app QuitGuide

lacks prescriptive clarity. Many potentially useful tools are offered by QuitGuide, but it is not clear which tools to use, when, and for how long. Future research that experimentally tests whether prescribed content is more engaging would be useful to inform the development of health behavior apps.

To date, text messaging has shown greater smoking cessation benefits than smartphone apps [71], potentially in part due to prescriptive clarity. Text-messaging interventions have prescriptive clarity (ie, there is a set number of days in the program; information is provided on specific days, in proactive, succinct fashion; and actions to be taken are clearly spelled out), while many apps do not [1]. Our data show that participants are willing to complete assigned tasks much more than use ad libitum tools. Data from a randomized trial conducted in the United Kingdom show that assigning daily tasks within a smoking cessation app versus offering the same content without the specific daily tasks led to improved smoking cessation rates [72]. Combined, these findings lead us to believe that prescriptive clarity is a critically important feature in the development of smartphone apps targeting smoking cessation.

Long-term Engagement

Smartphone app technology has the potential to provide ongoing support for smoking cessation over long periods of time. To date, this potential has been largely unexplored, including in our own work. To our knowledge, few studies have examined app engagement; these studies have focused on factors contributing to initial app use [73] or have tested the value of push notifications in enhancing engagement [74]. These studies have not provided insight into the content features and app parameters that promote long-term engagement. In-person smoking cessation interventions typically provide 8 to 12 weeks of support. The SiS 2 app provided assigned tasks for 49 days and continued use of the app's ad libitum tools as needed, a treatment length in line with the support offered via the NCI's Smokefree text-messaging interventions, and similar to the UK Smoke Free app, which provides assigned daily tasks for 31 days [72]. This treatment length roughly covers the time from preparation to action according to the transtheoretical model of change and does not address maintenance [55]. In fact, originally, the SiS app spanned only 21 days [26], a length that was specifically chosen to provide support during the acute "cessation" phase [75] of the process of smoking cessation. Based on user feedback, we increased treatment length to 49 days in version 2. Our app usage data demonstrate that this increased treatment length was well tolerated, opening the door to potentially further increasing treatment length to provide support during the maintenance phase of smoking cessation. To date, however, very little research exists to guide the intervention content of smartphone apps to support sustained user engagement and long-term abstinence from smoking.

Limitations

This secondary data analysis was based on a single-arm trial, and therefore causal inferences about the observed effects cannot be drawn. Our analyses were exploratory. They hint at the value of positive psychology to engage app users in smoking cessation over time and the value of prescriptive clarity, but we did not design this study, nor the SiS 2 app, to address these questions.

In considering these effects, it should be kept in mind that the participants were asked to complete happiness content on a more frequent basis than smoking cessation content (ie, daily vs every 3 to 4 days) and that the smoking cessation tools had a shelf-life (eg, “smoke alarms” became less useful as cravings diminished; participants could log cigarettes, but not smoke-free days). In terms of generalizability, it should be noted that the SiS 2 study used an interactive onboarding procedure via phone. While this is in line with warm handoff models for smoking

cessation [76,77], app usage patterns within the context of a clinical trial are typically higher than real-life app use [78].

Conclusions

In the SiS 2 app, greater app usage predicted greater chances of self-reporting 30-day PPA at both the end of treatment and at a 6-month follow up. This finding strengthens the rationale for testing this app in a randomized trial. Feature-level analysis of app usage patterns suggests that positive psychology content and prescriptive clarity may promote app engagement.

Abstract

Background: Disparities in COVID-19 incidence, hospitalization, and mortality rates among African Americans suggest the need for targeted interventions. Use of targeted, theory-driven messages in behavioral and communication interventions could empower African Americans to engage in behaviors that prevent COVID-19.

Objective: To address this need, we performed a formative study that aimed to develop and design a culturally appropriate, theory-based library of messages targeting concerns around COVID-19 vaccines that could be used in behavioral and communication interventions for African Americans.

Methods: Message development occurred between January 2021 and February 2022. Initial messages were designed by a multidisciplinary team of researchers, community leaders, and community members. Kreuter's 5 strategies (ie, linguistic, peripheral, evidential, sociocultural, and constituent-involving strategies) were used to achieve cultural appropriateness. After forming a community-academic partnership, message development occurred in 4 phases: (1) adaptation of a message library using the literature, (2) review by 6 clinical and research experts for content validation, (3) input and review by a 6-member community advisory panel (CAP), and (4) message pretesting with African Americans via semistructured interviews in a qualitative study.

Results: Themes from the semistructured interviews among 30 African Americans were as follows: (1) community reactions to the messages, (2) community questions and information needs, (3) suggestions for additional content, and (4) suggestions to improve comprehension, relevance, and trustworthiness. Feedback from the CAP, community members, and scientific experts was used by members of the community-academic partnership to iteratively update message content to maximize cultural appropriateness. The final message library had 18 message subsets for adults and 17 message subsets for parents and caregivers of children. These subsets were placed into 3 categories: (1) vaccine development, (2) vaccine safety, and (3) vaccine effectiveness.

Conclusions: We used a 4-phase, systematic process using multiple community engagement approaches to create messages for African Americans to support interventions to improve COVID-19 vaccination rates among adults and children. The newly developed messages were deemed to be culturally appropriate according to experts and members of the African American community. Future research should evaluate the impact of these messages on COVID-19 vaccination rates among African Americans.

KEYWORDS

African American; Black American; Black; minority; ethnic; culturally sensitive; cultural sensitivity; inclusive; vulnerable; COVID-19; vaccination; vaccine; health promotion; campaign; messaging; culturally appropriate; theory; adults; children; disparity; health belief model; community engagement; public engagement; public awareness; community-based; health information; health communication; health intervention; vulnerable population; community health; patient education

Introduction

Background

Since December 2020, 3 vaccines have been approved in the United States to prevent severe disease and death caused by COVID-19. The 2-dose vaccinations developed by *Pfizer* and *Moderna* are approved for use in individuals aged 18 years and older and under emergency use authorization (EAU) for children aged 6 months to 17 years [1]. The 1-dose *Johnson & Johnson* vaccination is under EAU for adults aged 18 years and older [1]. Although highly effective [2], vaccination rates remain suboptimal, especially among populations who could benefit most. For example, African Americans comprise 12.4% of the US population but only 10.1% of those who have initiated the series and 10.3% of those who have completed the series as of March 10, 2022 [3]. Despite African Americans being almost 2 times more likely than White Americans to die from COVID-19 [4], vaccine hesitancy remains a major hindrance to reduced vaccine uptake among African Americans [5-9].

Emerging studies demonstrate that vaccine hesitancy is deeply rooted in several overlapping areas: (1) mistrust in health care, government, and research [10-13]; (2) structural racism [14]; and (3) lack of understanding of science related to vaccine-specific issues (eg, efficacy, safety, speed of development) [13,15]. Lack of information, misinformation, and disinformation further drive vaccine hesitancy [10], with social or mass media as the primary source [15]. Because effective communication is necessary to help African Americans make informed decisions about COVID-19 vaccines [16], studies have begun to explore the communication strategies necessary to increase COVID-19 vaccination [17-19]. Trusted messengers are key to COVID-19 information being well received and used [20].

The specific messages related to COVID-19 vaccination are as important as the messenger. Information sources have been developed and disseminated widely to educate communities on messages to use to educate communities on COVID-19 vaccination to increase uptake [21,22]. A few emerging studies have tested messages, including persuasive messaging [18], video-based messages [23], and behavioral nudges [24], on vaccination intention or uptake. African Americans suggest the need for messages that are accurate, targeted, culturally appropriate, and community based [25,26]. However, perceptions of the messages remain unknown, and none (to the best of our knowledge) have actively engaged the African American community to develop or refine the messages on COVID-19 vaccination to ensure cultural appropriateness. Such engagement is key because African Americans' values and decision-making about the COVID-19 vaccine are strongly shaped by culture [10,12,13,27], and targeting will maximize

“fit” of information to an individual's unique characteristics [28,29].

Conceptual Framework

Message development was guided by 2 psychosocial decision-making models: (1) theory of reasoned action (TRA) [30] and (2) the Health Belief Model (HBM) [31]. These health behavior theoretical models are commonly used to understand vaccination decision-making. The TRA predicts that behavioral intentions to vaccinate against COVID-19 are based on attitudes and subjective norms. The HBM predicts that the likelihood of vaccinating against COVID-19 is based on perceived susceptibility of the individual to SARS-CoV-2, perceived severity of COVID-19, and whether perceived benefits of vaccination outweigh perceived barriers.

Kreuter et al [32] proposed 5 strategies to achieve cultural appropriateness that were used to guide message development. *Peripheral strategies* increase communication appeal through the title, fonts, colors, and images. *Evidential strategies* provide data on impact of a health issue in a certain group. *Sociocultural strategies* address health issues from the social and cultural values of a group. *Linguistic strategies* fit the program to the native language of a certain group. Lastly, *constituent-involving strategies* ensure community members' inclusion in program planning. Developing culturally appropriate, theory-based messages that can be used in communication and behavioral interventions may address concerns about COVID-19 vaccination among African Americans. Because social marketing campaigns have been effective in changing knowledge, attitudes, intentions, and behavior at the community level [33-35], they can disseminate theory-based, culturally appropriate messages and potentially increase COVID-19 vaccination acceptability and uptake. Social marketing is “the application of proven concepts and techniques drawn from the commercial sector to promote changes in diverse socially important behaviors such as drug use, sexual behavior... This marketing approach has an immense potential to affect major social problems if we can only learn how to harness its power” [34].

Study Objectives

We describe the development of a theory-based, culturally appropriate library of motivational messages for a social marketing campaign to promote COVID-19 vaccination among African Americans who are vaccine hesitant. Message development occurred in 4 phases: (1) adaptation of a message library based on the literature, (2) review by clinical and research experts for content validation, (3) input and review by a community advisory panel (CAP), and (4) message pretesting via a qualitative study with African American community members to evaluate the accuracy, relevance, and persuasiveness

of the messages. The long-term goal is for these messages to be used within interventions aimed at increasing COVID-19 vaccination among African Americans.

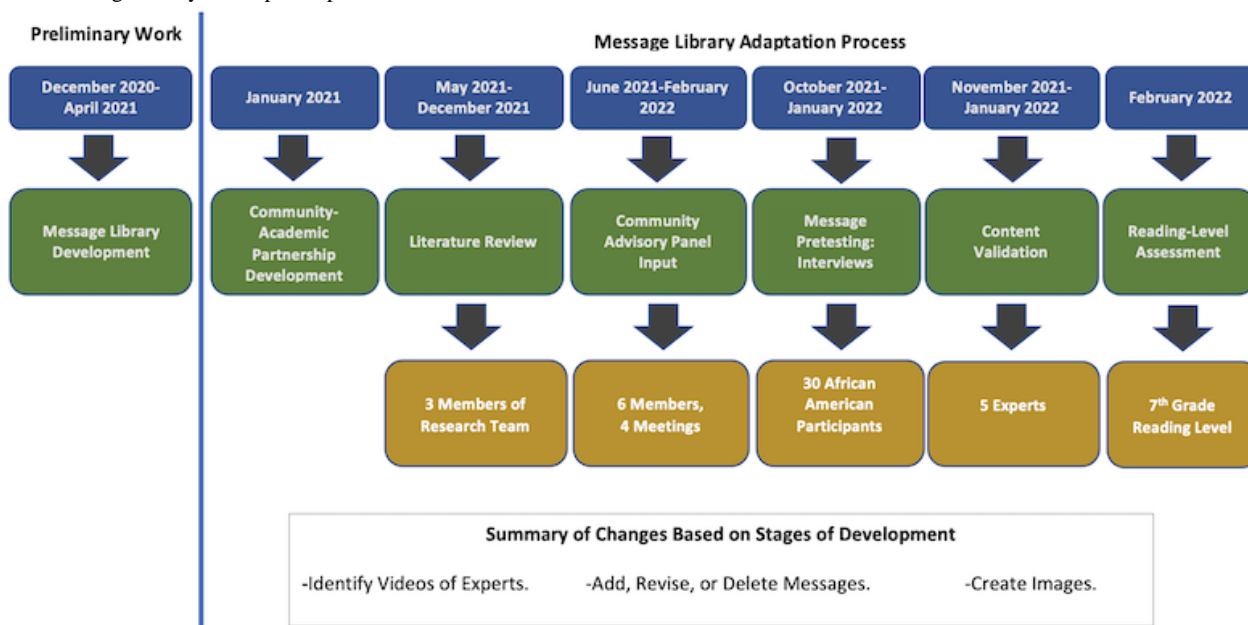

Methods

Study Design

We conducted a formative study to design and develop a theory-based, culturally appropriate message library that could be used in behavioral and communication interventions to increase COVID-19 vaccine uptake among African Americans. In the existing COVID-19 library, 1 message subset for adults

and 1 for parents and caregivers of adolescents was developed and iteratively adapted by coauthors JCE (a behavioral scientist with a background in biology and vaccine hesitancy) and JD (a basic scientist with a background in infectious disease) on the basis of emerging literature and feedback from over 30 educational sessions provided to communities on COVID-19 and the vaccine. A community-academic partnership was formed to iteratively adapt the message library over a 1-year period to ensure that it was theory based, culturally appropriate, and up to date. Our adaptation process occurred through 6 phases, with community input at each phase. See Figure 1 for a depiction of the 1-year process to yield the final message library of adult and parent message sets.

Figure 1. Message library development process.

Development of a Community-Academic Partnership, January 2021

A community-academic partnership was developed between 2 academic partners, Meharry Medical College and St Jude Children’s Research Hospital, and 1 community partner, the Congregational Health and Education Network (CHEN) in 2021. This partnership yielded an interdisciplinary team of experts in basic science, epidemiology, behavioral science, communication, and community engagement. The purpose of this partnership was (1) to develop messages and products for a social marketing campaign using community engagement principles and (2) to implement and evaluate the social marketing campaign. CHEN, a 501c(3), is a collaboration between Nashville General Hospital at Meharry Medical College and other academic institutions, along with faith-based organizations serving African American and Latino congregants [36]. A focus for CHEN during the COVID-19 pandemic was to improve vaccine health literacy and uptake to reduce health inequities in vaccination and related outcomes. The community partner (CHEN) ensured that the messaging represented the top vaccination concerns and was culturally appropriate. The academic partners offered guidance, when needed, to ensure that the partnership was equitable, and

bidirectional engagement occurred in all research phases. They also ensured scientific accuracy of messages.

Adaptation of the Existing Message Library, May-January 2022

Members of the research team conducted a literature search to identify reasons for COVID-19 vaccine hesitancy and acceptance, along with potential strategies to improve coverage among African Americans. See Multimedia Appendix 1 for the methods and results of the search. This search was conducted from May 2021 until January 2022 to ensure that the library had the latest updates before the launch of the social marketing campaign. Using the literature, the TRA [30] and the HBM [31], and the experiences and skills of the research team, we adapted the existing message library to ensure accuracy and relevance.

Input from the Community Advisory Panel, June 2021-February 2022

An 8-member CAP was formed to provide feedback on concerns about the vaccine and potential strategies to increase vaccination. This panel meets quarterly and comprises African Americans in the Nashville, Tennessee, metropolitan statistical area. Organizations represented included the Matthew Walker

Comprehensive Health Center, Health Leads, the National Association for the Advancement of Colored People, the Community Partners' Network, and the Nashville Health Disparities Coalition. Additional members included a young adult, a physician, and a parent. A subgroup of the CAP (n=4, 50%) reviewed the content and provided feedback on the messages. The feedback from the meetings and content review from the subgroup were used to iteratively develop the messages and images for the library.

Message Pretesting With African Americans, October 2021-January 2022

Study Design

We conducted a phenomenological, qualitative study [37] to create messages that could be used to assist in decision-making on COVID-19 vaccination among African Americans. Specifically, we conducted semistructured interviews (1) to identify reasons participants decided to receive or decline the vaccine for their self or child and (2) to gain feedback on messaging relevance, acceptability, and comprehensibility. This protocol was guided by the HBM [31], the TRA [30], and the community partner (CHEN) and CAP input. Social marketing campaign content (ie, draft messages, images/graphics) was iteratively revised using the data.

Sampling and Recruitment

We recruited a purposive sample of African Americans in the southeastern United States who met the following eligibility criteria: (1) adults aged 18 years or older and vaccinated or unvaccinated and (2) parents or caregivers of children aged 5-18 years and vaccinated or unvaccinated. Our community partner (CHEN) and the CAP members recruited participants via email, telephone, or word-of-mouth by using their social network and existing databases. ResearchMatch (RM), an online research recruitment tool, was also used for recruitment [38].

Data Collection

Interested participants completed a screener. If they qualified, then they completed informed consent procedures and a brief 12-item survey on barriers to COVID-19 vaccination, with response options on a 5-point Likert-type agreement scale. The screener, consent, and demographic survey were completed via Research Electronic Data Capture (REDCap; Vanderbilt University) [39], a secure web-based data collection application. Then, participants were emailed a copy of the adult and parent message sets a minimum of 3 days before the interview.

Participant interviews were conducted by a trained interviewer and lasted 45-60 minutes. Open-ended scripted questions were asked using an interview guide. Questions included (1) attitudes and beliefs about COVID-19 and vaccination, (2) facilitators and barriers to COVID-19 vaccination, (3) message library content and images, and (4) dissemination strategies. For the message development section of interviews, specific questions included the following:

- What is your overall view and purpose of the message?
- Which parts of this message did you not understand or were not clear?
- What should be added to the message?

- What message should be removed or changed?

Follow-up questions were asked for clarification and to facilitate in-depth discussion. Participants were paid a US \$50 gift card. Interviews were recorded, transcribed verbatim, and de-identified for data analysis.

Data Analyses

Qualitative data coding and analysis was managed by the Vanderbilt University Qualitative Research Core, led by a PhD-level psychologist. Data coding and analysis were conducted following Consolidated Criteria for Reporting Qualitative Studies (COREQ) guidelines, an evidence-based qualitative methodology [40]. A hierarchical coding system was developed and refined using the interview guide and a preliminary review of the transcripts. Experienced qualitative coders first established reliability in using the coding system on 2 transcripts, reconciling any discrepancies, and then independently coded the remaining transcripts. We used an iterative inductive/deductive approach to qualitative data analysis [41,42]. Inductively, we sorted the quotations by coding category to identify higher-order themes and relationships between themes. Deductively, we were guided by the HBM and the TRA. The transcripts, quotations, and codes were managed using Microsoft Excel 2016 and IBM SPSS Statistics version 28.0. Survey data were also analyzed using SPSS Statistics version 28.0. Descriptive analysis (eg, means, frequencies) and bivariate analysis (eg, chi-square tests, Fisher exact tests) were performed to describe patterns in the data.

Message Library Revision Process

Using the original message library, the research team iteratively modified the message sets and added visuals and videos to "match" the messages to increase comprehensibility and appropriateness. A subgroup of the research team met regularly to discuss interview findings and the message library, and subsequent changes were made. Then, all members of the partnership met to discuss the changes and identify additional needed modifications. Each new iteration of the messages and visuals was developed using peripheral, evidential, linguistic, and sociocultural strategies [32]. A final meeting was held to ensure that all feedback was incorporated into the message library and was culturally appropriate.

Content Validation of Messages by Experts, November 2021-January 2022

Five experts were identified to review the content for accuracy and relevance. These reviews were conducted strategically due to the ever-changing nature of COVID-19 pandemic updates. Specifically, 2 experts reviewed the content prior to, 1 during, and 3 after community review. Selection criteria for these content reviewers were experience in SARS-CoV-2/COVID-19 research, including vaccination, expertise in the use of psychosocial theory, and willingness and ability to review the items.

Adapted from Lawshe [43], we used qualitative and quantitative methods in a 2-phase content review process. Specifically, each message subset was quantitatively evaluated for relevance by using a 3-point Likert scale: "essential," "useful but not

essential,” and “not necessary.” Then, experts reviewed the messages for perceived accuracy and clarity by providing written comments and edits for improvement. Using these methods, we iteratively refined the messages.

Ethical Considerations

This research was approved by Meharry Medical College’s Institutional Review Board (Protocol 21-03-1076). All participants provided oral informed consent.

Results

Community Advisory Panel Feedback

The CAP members’ feedback evolved throughout the message library development process. At the beginning of each meeting, the researchers gained insight into the community’s thinking about the COVID-19 vaccine to determine trends in hesitancy. Top concerns included vaccine safety, the speed of vaccine development, mistrust in research and health care, politicization of the vaccine, and conspiracy theories (eg, tracking chip in the vaccine). We then asked about the presentation of messaging. Members suggested that messages should be concise yet comprehensible across reading levels. Members further indicated

the need to discuss immediate and long-term benefits and the risks of vaccination so that the community can make an informed decision. A few members further suggested the need to use numbers and images to explain these concerns more clearly.

Select members of the CAP were asked to conduct a detailed review of the messages and images to identify ways to make the content more relatable and comprehensible. Some even provided preferred sources of content (eg, NPR (National Public Radio), which is media organization that seeks to create a more informed public via air, online, or in-person) to help develop the material. Collectively, we used the feedback from the quarterly advisory panel meetings and subgroup review of messages to update the library.

Semistructured Interviews

Sociodemographics

Most participants were female and had a college degree or higher. More than half had a household income less than US \$80,000. The mean age was 38.6 years (SD 9.49 years). See [Table 1](#) for sociodemographics by subgroup: vaccinated adult, unvaccinated adult, adult with unvaccinated child, and adult with vaccinated child.

Table 1. Sociodemographics of African American interview participants (N=30).

Characteristic	Parent ^a with vaccinated child (N=7)	Parent with unvaccinated child (N=7)	Adult, vaccinated (N=9)	Adult, unvaccinated (N=7)
Age (years), mean (SD)	42.4 (6.1)	37.4 (6.2)	36.1 (12.5)	39.1 (11.1)
Gender, n (%)				
Male	2 (29)	1 (14)	2 (22)	1 (14)
Female	5 (71)	6 (86)	7 (78)	6 (86)
Education, n (%)				
Some college or lower	2 (29)	2 (29)	2 (22)	1 (14)
College degree or higher	5 (71)	5 (71)	7 (78)	6 (86)
Household income (US \$), n (%)				
≤40,000	2 (29)	2 (29)	2 (22)	3 (42)
40,001-80,000	2 (29)	0	2 (22)	2 (29)
>80,000	3 (42)	4 (57)	3 (34)	0
Not available	0	1 (14)	2 (22)	2 (29)

^aParents had children aged 5-18 years.

Summary of Findings

Using the inductive-deductive approach, we identified 4 primary themes specific to the development of messages related to COVID-19 and the vaccines in the qualitative study. Messages were referenced in the text by the theme and message number (eg, 1.01 is the first quotation related to theme 1). See [Multimedia Appendix 2](#) for quotations related to each theme.

Theme 1: Community Reactions to the Messages

Overall, the community members found that the messages were “very helpful” and had a “community feel.” Specifically, the messages were inclusive and comprehensive and had a good

balance between science and simple language. The messages were viewed as “good,” “persuasive” (quotation 1.02), and “educational” (quotations 1.01-1.02). Most participants stated that the reading level was good, and suggested a few edits to specific messages (eg, whether the messenger RNA [mRNA] vaccine changes your DNA). Although there were mixed reviews, most perceived the length and number of messages in each set to be appropriate.

For message presentation, many perceived that there were good analogies and comparisons to increase comprehension (quotation 1.03). If applicable to the message set, participants liked the balance of benefits and risks of vaccines. Lastly, a few

participants cited the messages as relatable, trustworthy, and credible. Collectively, participants perceived that the information helped guide decision-making and did not simply “tell you” to take the vaccine.

Theme 2: Questions and Information Needs

Some participants had questions after reviewing the messages. A participant wanted to know where specific evidence for the general numbers on some websites (eg, the Centers for Disease Control and Prevention [44]) could be found. Other questions were related to long-term effects of the vaccine, “why we even need the vaccine,” mixing vaccines and boosters, or the number of boosters after the first dose (quotation 2.01). Others asked about the relationship of COVID-19 vaccines and fertility. Lastly, participants asked how existing conditions (eg, diabetes, asthma) were related to the severity of COVID-19.

Theme 3: Suggestions for Additional Content

Most participants had suggestions for additional content or context for specific message sets. A suggestion for overall messages was to add a statement that science evolves as more data are collected to communicate new findings, which are constantly being added to increase our knowledge of COVID-19. For vaccine safety, additional information was requested on mRNA, along with the 30-year history of studies of mRNA and its use in vaccines (quotation 3.01). Participants asked for more information on the clinical trial process and better justification for boosters and their side effects. As it relates to vaccines and infertility, a suggestion was made to provide recommendations from gynecology professionals and experts and information about long-term effects of COVID-19 vaccines on infertility. Lastly, a few participants wanted to know whether the vaccines can lead to sexual dysfunction (quotation 3.02).

Distrusting in the government and pharmaceutical companies, participants wanted more details about the COVID vaccines (ie, development, testing, and ingredients; quotation 3.03). For vaccine effectiveness, participants asked about healthy people getting the virus and how outcomes of the vaccinated compare to those of the unvaccinated (quotation 3.04). They also asked why natural immunity is not better than vaccine-induced immunity. Participants wanted more information on variants (eg, Omicron), their severity, and how variants affect vaccine effectiveness.

For children specifically, participants asked for data on successes and challenges during development (quotation 3.05), along with updates on vaccine safety. Participants also suggested reinforcing other preventive behaviors, such as sanitizing, healthy eating, and physical distancing (quotation 3.06). Some further wanted to know alternative ways to boost their immune system without taking a vaccine or booster (quotations 3.07 and 3.08). A few suggested the need to encourage conversations with doctors, especially for those with underlying medical conditions, prior to getting the vaccine.

Theme 4: Suggestions to Increase Comprehension, Relevance, and Trustworthiness

A few suggestions were made to enhance comprehension. One suggestion was to provide definitions for specific terms (eg,

high risk; quotation 4.01). Providing an easier-to-understand presentation of statistics was commonly mentioned. For example, participants further suggested the “need for statistics or more data” to help understand the vaccine development process. Participants emphasized the importance of clarifying the magnitude of potential side effects. Visuals were suggested to improve understandability of messages. Participants also suggested the use of specific terms such as “vaccination” and not “shot.” Lastly, 1 (3%) participant suggested having information available in other languages (eg, Arabic).

A few participants indicated the need for messages to be tied to things people already understand, such as flu or smallpox vaccines, to increase relevance. Other suggestions were to use videos and images to reflect content. Some participants also wanted videos of personal testimonies of individuals who were undecided about the vaccine and their decision-making process to get vaccinated (quotation 4.02). Notably, testimonials were also perceived by others to be too contrived (quotation 4.03). To increase trustworthiness, participants suggested providing proof that doctors or health professionals (quotation 4.04) supported this work, along with the addition of informational sources, especially links to studies that provide supportive evidence. Lastly, participants encouraged honesty and transparency in information related to the COVID-19 vaccines.

Content Validation

In total, 6 reviewers validated the content. Of these 6, 2 (33%) were White Americans, and 4 (67%) were African Americans; 4 (67%) were female, and 2 (33%) were male. In addition, 1 (17%) reviewer provided feedback for only adult concerns. Reviewers’ areas of expertise included vaccine development, immunology, vaccine-preventable disease and immunizations, and nurse safety. Messages were iteratively updated based on feedback of experts. Most message subsets were classified as essential or useful but not essential. Content edits and additions to the message library reflected the updates on the coronavirus and the vaccine and strategies to ensure comprehensibility and accuracy. Reordering, rephrasing, and adding (eg, analogies) of content were conducted to increase clarity. Because updates are ongoing for COVID-19, content was deemed evidential once primary concepts (eg, process of vaccine development or purpose of boosters) were validated, with the intent to continue to update the library with expert review.

Reading Grade Level Assessment

To finalize the library messages, a readability assessment was conducted. We used 3 primary reading grade level assessment tools and an online consensus tool to assess the reading grade level of the adult and parent message sets. First, the Flesch Reading Ease Score [45] was calculated in Microsoft Word. Higher scores indicate easier readability by the user. Second, the Flesch-Kincaid Grade Level [46] was calculated in Microsoft Word to determine a US school grade level. The Flesch Reading Ease and Flesch-Kincaid Grade Levels are calculated by considering the average sentence length (total number of words divided by total number of sentences) and the average syllables per word (total number of syllables divided by the total number of words) using different underlying formulas. Third, the Simple Measure of Gobbledygook (SMOG) index was hand-scored, in

addition to being automatically calculated to determine a US [47] school grade level. The SMOG index is calculated using the number of words with multiple syllables in three 10-sentence samples at the beginning, middle, and end of the text. These 3 readability assessment tools all use word difficulty and sentence length as the main factors in determining how easy or how hard the material is to read. Finally, an online readability calculator [48] was used to determine readability consensus. The online calculator applied 7 commonly used readability formulas to provide a consensus rating. See [Table 2](#) for readability assessment results.

The readability assessment revealed acceptable reading grade level scores for all readability formulas applied. The usual recommended reading grade level is fifth-sixth grade to optimize comprehension, according to the American Medical Association and the United States Department of Health and Human Services. However, in combination with the iterative development process and ongoing review by the community partner (CHEN), the CAP, and experts, the messages reflected use of plain language when polysyllabic or complex words were unavoidable.

Table 2. Reading grade level results.

Readability assessment tool	Adult library	Parent library
Flesch Reading Ease Score	62.0 (standard/average)	62.5 (standard/average)
Flesch-Kincaid Grade Level	8.4 (8th grade)	8.3 (8th grade)
SMOG ^a index	7.7 (8th grade)	7.6 (8th grade)
Readability consensus ^b	<ul style="list-style-type: none"> Grade level: 8 Reading level: standard/average Age of reader: 12-14 years (7th-8th grade) 	<ul style="list-style-type: none"> Grade level: 8 Reading level: standard/average Age of reader: 12-14 years (7th-8th grade)

^aSMOG: Simple Measure of Gobbledygook.

^bReadability consensus was based on the application of 7 readability formulas using an online calculator available [44].

Message Set Finalization

After completion of the readability assessment, members of the research team conducted a final review to ensure

comprehensibility and accuracy. Minor edits were made. See [Table 3](#) for an example of a concern, along with an example of a message for the concern after the adaptation process.

Table 3. Example of a message for tailoring a variable postiterative development process.

Vaccine concern	Example message
Category 1: vaccine development	
“Human protections in research” [adult and parent]	Many people wonder about taking part in research and if they will be protected. We know there have been past research studies that were not done right [provides examples of historical research abuses]. To begin to address this issue, we give a few examples to show every person is protected when they take part in research and how the community could benefit after the research study is done [provides examples of human protections in research].
“Who is at the table?” [Adult and parent]	Many people wonder if people of all racial backgrounds were involved when the vaccines were developed. Individuals from all races were at the table to help guide the process [provides examples of scientists of all racial/ethnic backgrounds and their role in the development process].
Category 2: vaccine safety	
“mRNA ^a and DNA” [adult]	We all have mRNA in every cell in our bodies. mRNA is known as messenger RNA. It is the “recipe” that tells the cells in our body to make certain proteins. The mRNA protein in the Pfizer and Moderna COVID-19 vaccines shows up, teaches the immune system how to develop antibodies against SARS-CoV-2 (the virus that causes COVID-19), and then quickly dissolves. mRNA never enters the nucleus of the cell where your DNA is kept. Your body learns how to protect itself against future SARS-CoV-2 infection without ever having to risk getting the virus or the serious outcomes of getting sick with COVID-19.
“Infertility” [adult]	The antibody to the spike protein does not make a woman infertile or unable to get pregnant. There was a false claim that there were similarities between the SARS-CoV-2 spike protein and the surface of a protein on placental cells. Placental cells are needed for a successful pregnancy. SARS-CoV-2 spike protein and the placental cells are not the same. This means the vaccine will not cause the immune system to make antibodies against the placental protein.
“Your child’s heart” [parent]	Many parents ask about the COVID-19 vaccine and how it can affect the hearts of children. In the United States, there has been an increase in myocarditis and pericarditis cases after getting the mRNA COVID-19 vaccine. Myocarditis is mild inflammation of the heart. Pericarditis is mild inflammation of the sack around the heart. For children under 16 years of age, myocarditis risk is 37 times higher for children with COVID-19 than the children without COVID-19. So, myocarditis does not happen often. The American Academy of Pediatrics says children and teens should get the COVID-19 vaccines.
“My child has underlying medical conditions.” [Parent]	The Pfizer vaccine can be given to children 5 [years] and older with underlying medical conditions like diabetes or autoimmune diseases. It cannot cause COVID-19, even in those with weak immune systems. Children with underlying medical conditions took part in the clinical trials and serious reactions to the vaccine [were] rare. However, children with underlying medical conditions are more apt to have problems from COVID-19.
Category 3: vaccine effectiveness	
“Boosters. Why?” [Adult]	All routine [vaccines] require booster doses to have full protection [adds examples]. So the COVID-19 vaccine is not any different. Booster shots are given to jumpstart the body’s immune system to produce more antibodies against the original SARS-CoV-2 (the virus that causes COVID-19) and help protect against new variants. Because antibody levels decrease over time, boosters are needed to keep us protected.
“Variants and the vaccine” [adult]	As SARS-CoV-2 (the virus that causes COVID-19) continues to infect people, it is more likely to mutate. This means that the virus makes a new version of itself also known as a mutation. It is common for this to happen. Mutations affect how viruses work, like to help the virus better attach to our cells or lower the virus’s ability to attach to our cells. So it is important for people to complete COVID-19 vaccination. More mutations and new variants may lower or stop the protection provided by the vaccines.
“Natural immunity or vaccine immunity”	Natural immunity happens when your child’s body gets infected with the SARS-CoV-2 virus, the virus that causes COVID-19. While your child’s body will make antibodies against the virus, the danger is in your child getting very sick and maybe even dying. Immunity from getting a vaccine is very similar to immunity developed through natural infection but does not carry the increased risk of your child getting very sick or even death. Natural immunity provides less protection over time than the immunity gained by COVID-19. While people can gain immunity after getting the virus, studies show that more than one third of COVID-19 infections results in low levels of protective antibodies.
“Too many vaccines” [parent]	We all got different vaccines when we were babies, adolescents, and event adults [gives an example of multiple vaccines being given]. These vaccines are routinely given at the same time without serious side effects. So, getting more than one vaccine is something we have been doing since birth.

^amRNA: messenger RNA.

Final Message Library

The final message library had 2 message sets, 1 for adults and 1 for parents. There were 18 message subsets for adults and 17 message subsets for parents. These subsets were placed into 3 categories: vaccine development, vaccine safety, and vaccine effectiveness. Each message subset begins with expressing empathy toward the individuals' concern. Then the facts are provided around each concern, positive or negative. Lastly, the

message subset ends with a positive statement related to COVID-19 vaccination that addresses concerns. All message subsets were reviewed by community leaders and members (constituent-involving strategy). We briefly describe each subset for each group next. Each message subset was presented using 3 modes: content, image, and video. See [Table 4](#) to identify each concern, along with key message attributes and the associated strategy to achieve cultural appropriateness.

Table 4. Vaccine concern, key message attributes, types of visuals, and type of cultural targeting strategy.

Vaccine concern ^a	Key message attributes	Types of visuals	Cultural targeting strategy
Vaccine development			
Human protections in research	<ul style="list-style-type: none"> Acknowledge historical research abuses (eg, U.S. Public Health Service Syphilis Study, Henrietta Lacks). Provide examples of protections provided in research. Discuss how the community can be involved in the research process (eg, co-primary investigator, community advisory board, consultant). 	<ul style="list-style-type: none"> Not applicable 	Sociocultural, evidential
Who is at the table?	<ul style="list-style-type: none"> Discuss researchers (ie, current job, expertise) across all backgrounds and their role in the development process. List their current jobs. 	<ul style="list-style-type: none"> Researchers of diverse backgrounds (visual) Researcher describing role in vaccine development (video) 	Sociocultural, evidential, peripheral
Too new and too quick	<ul style="list-style-type: none"> Define mRNA^b and its role in the body. Discuss the mRNA vaccine history and how it works in the body. Define what mRNA does not do (change DNA). Compare mRNA vaccine development to existing vaccine development processes. Define the EUA^c. Discuss the number of vaccines given to date, adverse events, and how to identify those events. Confirm that being unvaccinated places one at higher risk of death compared to those who received the vaccine. 	<ul style="list-style-type: none"> Timeline of COVID-19 vaccine development (visual and video) 	Evidential, peripheral
How research works	<ul style="list-style-type: none"> Define research. Define clinical trials and their phases. Define types of researchers. Define sites of research and who can participate. Discuss what happens after research. 	<ul style="list-style-type: none"> Demonstration of phases in the clinical process and steps within each phase (visual) 	Evidential, peripheral
Vaccine safety			
mRNA and DNA	<ul style="list-style-type: none"> State years of mRNA existence and mRNA's role in the body. Explain the process of mRNA technology. Identify vaccines that use mRNA technology. Emphasize benefits of vaccination over natural immunity. 	<ul style="list-style-type: none"> Demonstration of the mRNA technology process (visual and video) 	Evidential, peripheral, linguistic
Infertility	<ul style="list-style-type: none"> Demonstrate how the proteins needed for pregnancy and needed to make the spike protein are not the same. Emphasize that women are able to conceive, have a healthy pregnancy and baby, and breastfeed after vaccination. State that babies receive antibodies from vaccinated mothers. Highlight that COVID-19 may impact fertility in men. Highlight cons of nonvaccination in pregnant women (eg, increased risk of stillbirth, newborn deaths, hospitalization). 	<ul style="list-style-type: none"> Explanation of pregnant women getting the vaccine or women conceiving getting vaccinated (video) 	Evidential, linguistic

Vaccine concern ^a	Key message attributes	Types of visuals	Cultural targeting strategy
Underlying medical conditions	<ul style="list-style-type: none"> State the reason to vaccinate with an underlying condition. State that the vaccine will not give an individual COVID-19. Discuss the vaccine schedule for those immunocompromised. Discuss the severity in COVID-19 if not vaccinated. State to consult with a doctor in getting the vaccine. 	<ul style="list-style-type: none"> Explanation of why those with underlying medical conditions need the vaccine (video) 	Evidential, linguistic
Your heart	<ul style="list-style-type: none"> Define myocarditis and pericarditis. Compare the rate of heart problems in those who get vaccinated compared to those who get COVID-19. Demonstrate the symptoms and treatment of heart disorders. Emphasize the recommendation by infectious disease experts and the American Academy of Pediatrics for children. 	<ul style="list-style-type: none"> Explanation of myocarditis and vaccination (video) 	Evidential, linguistic
GBS ^d (adult only)	<ul style="list-style-type: none"> Define GBS. Discuss the signs of GBS. Discuss the number of cases to date after vaccination. Emphasize that it is rare. 	<ul style="list-style-type: none"> Not applicable 	Evidential, linguistic
Blood clots (adult only)	<ul style="list-style-type: none"> Identify the number of cases with the Johnson & Johnson vaccine. Discuss why the Food and Drug Administration (FDA) halted the clinical trial to determine whether risks of blood clots outweigh the benefits of the vaccine. State recommendation of Moderna and Pfizer vaccines over the Johnson & Johnson vaccine. Discuss the symptoms of blood clots. State the blood clot risk for those vaccinated and unvaccinated. 	<ul style="list-style-type: none"> Symptoms of blood clots vs symptoms of COVID-19 (visual) 	Peripheral, evidential, linguistic
Side effects	<ul style="list-style-type: none"> Emphasize the number of years for COVID-19 research. Discuss the number of lives and hospitalizations prevented with vaccines. Identify the risk of allergic reactions and short-term side effects. Discuss that side effects are short-lived and everyone reacts differently. State that routine vaccinations show no long-term side effects. 	<ul style="list-style-type: none"> Side effects of vaccination compared to natural infection through SARS-CoV-2 (visual and video) 	Peripheral, evidential, linguistic
Too young (parent only)	<ul style="list-style-type: none"> Emphasize the impact of COVID-19 on children. Provide recommendations for COVID-19 vaccination by age. Emphasize that vaccination protects them and others. State that the long-term effects of COVID-19 in children are unknown, but long COVID is seen in many. 	<ul style="list-style-type: none"> Statistics of current COVID-19 cases in children and increases in COVID-19 cases, hospitalizations, and deaths in children overtime (visual) 	Evidential, peripheral, linguistic

Vaccine effectiveness

Vaccine concern ^a	Key message attributes	Types of visuals	Cultural targeting strategy
Unsure if it works	<ul style="list-style-type: none"> Define effectiveness and how to obtain it (ie, fully vaccinated). Demonstrate risks if not vaccinated. 	<ul style="list-style-type: none"> Comparison of risk of hospitalization and death of those vaccinated vs not vaccinated (visual) 	Peripheral, evidential, linguistic
Variants	<ul style="list-style-type: none"> Define “breakthrough case.” Discuss mutations and how new variants are created. Discuss the impact of emerging variants on vaccines and health. Emphasize the impact of virus on short- and long-term health. 	<ul style="list-style-type: none"> Not applicable 	Evidential, linguistic
Natural immunity	<ul style="list-style-type: none"> Define natural immunity versus vaccine-induced immunity. Emphasize vaccine-induced immunity being much safer than natural immunity. Discuss the “gamble” in natural immunity over vaccine-induced immunity. Discuss the benefits of vaccination despite having COVID-19. 	<ul style="list-style-type: none"> Comparison of the health risks of those with natural immunity and those vaccinated (visual and video) 	Peripheral, evidential, linguistic
Too many vaccines	<ul style="list-style-type: none"> Discuss the lack of danger of multiple vaccines at a time. Remind people of receiving many vaccines at once as a baby and preteen. Compare the number of proteins in the vaccine to the number of proteins if exposed to SARS-CoV-2. 	<ul style="list-style-type: none"> Not applicable 	Evidential, linguistic
Boosters. Why?	<ul style="list-style-type: none"> Define boosters and why they are needed. Discuss booster recommendations. Emphasize discussing getting a booster with a provider. 	<ul style="list-style-type: none"> Stating the vaccine dose and booster schedule of each vaccine (image) Defining a booster and why we need it (video) 	Evidential, peripheral, linguistic
Is it even needed?	<ul style="list-style-type: none"> Discuss transmission routes and rates by variant. Compare COVID-19 hospitalization, long COVID, and death rates among those vaccinated and unvaccinated. Discuss the susceptibility and severity of COVID-19 and the importance of vaccination. 	<ul style="list-style-type: none"> Tracker of COVID-19 rates and deaths (United States and Tennessee) 	Evidential, peripheral, linguistic

^aAll vaccine concerns were vetted by community leaders and members (ie, constituent-involving strategy) and edited to be comprehensible (ie, linguistics).

^bmRNA: messenger RNA.

^cEAU: emergency use authorization.

^dGBS: Guillain-Barré syndrome.

Vaccine Development

These message subsets target individuals who have concerns about the COVID-19 vaccines and the development process. The goal is to positively influence attitudes toward researchers and the process. There are 4 message sets in this category:

- Human protections in research/child protections in research
- Who is at the table?
- Too new and too quick
- How research works

Vaccine Safety

These message subsets target individuals who have concerns about the safety of the COVID-19 vaccines. The goal is to

demonstrate that the benefits of COVID-19 vaccination outweigh the harms of COVID-19 vaccination. There are 8 message sets in this category:

- mRNA and DNA
- Infertility/youth infertility
- Underlying medical conditions
- Your heart/your child’s heart
- Guillain-Barré syndrome (GBS; adults only)
- Blood clots (adults only)
- Side effects
- Child is too young (parents only)

Vaccine Effectiveness

These message subsets seek to demonstrate that the risk of SARS-CoV-2 and the severity of COVID-19 (ie, long-haul COVID-19, hospitalization, and death) are far greater when not vaccinated against COVID-19. These sets further demonstrate that the vaccine is effective and how variants may affect effectiveness. We also discussed the dosing schedule and role of boosters. There are 7 message sets in this category:

- Unsure if it works
- Variants and the vaccine
- Natural immunity or vaccine immunity
- Too many vaccines
- Boosters. Why?
- Is it even needed?

Discussion

Principal Findings

Our study aimed to develop and validate a message library for a social marketing campaign to increase COVID-19 vaccination among African Americans. The goal was to provide African American adults and parents with theory-based, culturally appropriate messaging on COVID-19 vaccines to motivate vaccine uptake. We described a multiphase process using community engagement approaches for the message library development with the HBM [31], the TRA [30], and Kreuter's [32] cultural targeting strategies serving as the conceptual frameworks. Our existing library allowed us to expeditiously adapt the messaging to meet the needs of African Americans. This process can be used by researchers and health care professionals to inform the development of culturally appropriate messages.

Use of formative research to build theory-based, culturally appropriate messaging while applying community engagement principles is critical for communities to play an active role in disease prevention and control measures, such as COVID-19 vaccination [26,49]. This method holds great promise in addressing health disparities, yet is in its infancy [50,51]. Applying Boyer et al's [52] multilevel approach to stakeholder engagement, we had community member involvement at all phases and varying levels to develop a message library to promote COVID-19 vaccination among African Americans. Engagement approaches included formation of a community-academic partnership, a CAP, and inclusion of community interviewees. Having the community-academic partnership and CAP allowed the community voice to be at the root of the messaging. Using each engagement approach, there was a balance of power to ensure that there was bidirectional communication and a deliberative process to foster respect, and even trust in some instances [53]. Furthermore, this process increased the likelihood of achieving cultural appropriateness of the messages.

Content validation has been recognized as a necessary component of message development and is highly valued [54]. The feedback provided by experts in the content review process was used to evolve the library with accurate and relevant messages. Furthermore, the suggestions for modification

enriched the messages. Messages were further tested with a purposeful sample of African Americans for cultural appropriateness (ie, evidential, linguistics, peripheral, and sociocultural strategies). Our results indicated that African American adults and parents viewed the messages positively and indicated that the messages were *persuasive*, *useful*, and *trustworthy*. Feedback yielded distinct strategies to increase relevance, comprehension, and appeal. It is important to understand the target audiences' response early to determine the likelihood of message effectiveness for the intervention [55].

Using this feedback from a multiphase process, our final message library yielded 18 message subsets for adults, and there were 17 message subsets for parents that were grounded in theory and cultural-targeting strategies. There were 3 preferred modes (ie, messages, images, and videos) for African American adults and parents. Studies demonstrate that multiple modes of communication are effective in increasing health literacy among populations, and plain-language messages, pictures, and videos are commonly cited, particularly in the context of community-level interventions [56]. We believe that this approach will be effective in reaching different characteristics of individuals.

Strengths

A major strength of this study is the use of theory and culturally appropriate strategies inclusive of community engagement to develop the COVID-19 message library for African American adults and parents. We used different levels of community engagement (ie, community-academic partnership, CAP, and interviewees) to ensure that the messages met the needs of our target population. In addition, we equipped the community with information about COVID-19 vaccines to ease concerns postvaccination or to make an informed decision about getting the vaccine. Furthermore, these individuals can now serve as education resources to their communities.

The next step in our partnership will be to test these messages in a 5-month social marketing campaign in a pilot study. Specifically, these messages are used on a website to provide information on COVID-19 vaccines. Shortened versions of these messages are used to market the website. We will evaluate the impact on attitudes, willingness, and self-reported vaccination status to be reported in a future manuscript. If the intervention demonstrates effectiveness, it could prove that theory-based, culturally appropriate messages in a social marketing campaign can be used as a motivational tool among African Americans.

Limitations

This study has limitations. Messages may not be generalizable to African Americans outside the southeastern United States. We had a small, purposeful sample, yet findings explained diverse perspectives to ensure messages encompassed multiple viewpoints toward the vaccine. There is potential for selection bias among content experts as they are medical professionals and clinicians from different disciplines and with clinical or research expertise. Furthermore, lack of access (ie, geographical barriers) to the vaccine could prevent uptake regardless of other concerns being addressed.

Conclusion

Vaccine hesitancy continues to negatively impact COVID-19 vaccination among African Americans. Effective interventions are needed to increase vaccine uptake. We believe we have

developed validated and pretested theory-based, culturally appropriate messages that can be motivational in different interventions aimed at increasing the COVID-19 vaccination rate among African Americans.

Acknowledgments

The authors thank members of the African American community for shedding light on the reasons for COVID-19 vaccination hesitancy. We also thank the COVID-19 experts for their invaluable insights into the intervention, particularly its content, images, and channels of delivery. This work was supported by the National Institute on Minority Health and Health Disparities (Award 3U54MD007586-34S7), the National Cancer Institute of the National Institutes of Health (Award P30CA021765 and 1K01CA237748-01A1), and the American Lebanese and Syrian Associated Charities (ALSAC) of St Jude Children's Research Hospital. This work is also supported by a subaward from the Association of American Medical Colleges through its cooperative agreement with the Centers for Disease Control and Prevention (CDC): "Improving Clinical and Public Health Outcomes through National Partnerships to Prevent and Control Emerging and Re-Emerging Infectious Disease Threats" (Award 6 NU50CK000586-02-02). The CDC is an agency within the Department of Health and Human Services (HHS). The content is solely the responsibility of the authors and does not necessarily represent the official views of the National Institutes of Health, the CDC, or the HHS and should not be considered an endorsement by the federal government.

Authors' Contributions

JCE was responsible for conceptualization, methodology, validation, formal analysis, resources, data curation, writing—original draft, writing—review and editing, visualization, supervision, planning administration, and funding acquisition; HMB and JD for conceptualization, writing—review and editing, visualization, supervision, planning administration, and funding acquisition; MS for conceptualization, writing—review and editing, visualization, and funding acquisition; KC and OL for conceptualization and writing—review and editing; and DS and KB for formal analysis and writing—review and editing.

Abstract

Background: Despite the well-known adverse health conditions and negative economic outcomes associated with mental health problems, accessing treatment is difficult due to reasons such as availability and cost. As a solution, digital mental health services have flooded the industry, and new studies are quickly emerging that support their potential as an accessible and cost-effective way to improve mental health outcomes. However, many mental health platforms typically use clinical tools such as the Patient Health Questionnaire-9 (PHQ-9) or General Anxiety Disorder-7 (GAD-7). Yet, many individuals that seek out care do not have clinical symptomatology and thus, traditional clinical measures may not adequately capture symptom improvement in general well-being. As an alternative, this study used the health-related quality of life (HRQoL) tool from the Centers for Disease Control and Prevention “Healthy Days” measure. This subjective measure of well-being is an effective way to capture HRQoL and might be better suited as an outcome measure for treatments that include both clinical and subclinical individuals.

Objective: The purpose of this study was to describe changes in HRQoL in clinical and subclinical members assessing virtual care and to examine the association between text-based behavioral coaching and virtual clinical sessions with changes in HRQoL.

Methods: A total of 288 members completed the 4-item HRQoL measure at baseline and at 1 month following use of the Ginger on demand behavioral health platform. Baseline anxiety and depression levels were collected using the GAD-7 and PHQ-9, respectively.

Results: Members completed on average 1.92 (SD 2.16) coaching sessions and 0.91 (SD 1.37) clinical sessions during the assessment month. Paired samples *t* tests revealed significant reductions in the average number of unhealthy mental health days between baseline (mean 16, SD 8.77 days) and follow-up (mean 13.2, SD 9.02 days; $t_{287}=5.73$; $P<.001$), and in the average number of days adversely impacted (mean_{baseline} 10.9, mean_{follow-up} 8.19; $t_{287}=6.26$; $P<.001$). Both subclinical members ($t_{103}=3.04$; $P=.003$) and clinical members ($t_{183}=5.5$; $P<.001$) demonstrated significant improvements through reductions in adversely impacted days over a month. Clinical members also demonstrated significant improvements through reductions in unhealthy mental health days ($t_{183}=5.82$; $P<.001$). Finally, member engagement with virtual clinical sessions significantly predicted changes in unhealthy mental health days ($B=-0.96$; $P=.04$).

Conclusions: To our knowledge, this study is one of the first to use the HRQoL measure as an outcome in an evaluation of a digital behavioral health platform. Using real-world longitudinal data, our preliminary yet promising results show that short-term engagement with virtual care can be an effective means to improve HRQoL for members with subclinical and clinical symptoms. Further follow-up of reported HRQoL over several months is needed.

Introduction

Nearly 1 in 5 adults in the United States (51.5 million people) experience mental health issues [1]. The World Health Organization estimates that anxiety and depression alone cost the global economy US \$1 trillion dollars each year in lost productivity, absenteeism, and medical costs [2]. Mental health issues have been exacerbated with the recent COVID-19 pandemic and underscore a critical moment of global need [3,4]. A recent meta-analysis found the global prevalence of diagnosable anxiety and depression during the pandemic was 27% and 28%, respectively [5]. Even among those with subclinical symptoms, nearly half of adults in the United States have reported symptoms of anxiety or depression during this time [6]. Timely intervention for those with subclinical symptoms is just as important to prevent development of more serious symptoms requiring more costly treatment.

Despite the well-known adverse health conditions and negative economic outcomes, accessing treatment for common mental health problems is difficult [7]. The demand for mental health services has outpaced the availability of qualified mental health professionals. A recent survey found that 1 in 4 individuals with depression or anxiety lack access to care or have unmet mental health needs [8]. In addition, long wait lists, high out-of-pocket expenses, and transportation burdens all continue to serve as barriers to receipt of effective services [9,10]. There is a growing need for scalable mental health solutions that increase both the availability of professionals and access to care for common mental health conditions. This is particularly important with the recent increase of mental health issues during the pandemic. Digital mental health services have flooded the industry, and new studies are emerging that support their potential to serve as cost-effective ways to manage anxiety and depression [11,12]. This type of support can even be beneficial for individuals who may be at risk for but do not yet experience clinically significant symptoms [13].

Many mental health platforms typically use clinical tools such as the Patient Health Questionnaire-9 (PHQ-9) or General Anxiety Disorder-7 (GAD-7) for assessing initial and treatment outcomes of depressive and anxiety symptoms, respectively. As behavioral coaching focuses on goal-oriented behavior and typically targets those with subclinical symptomatology, traditional clinical measures may not adequately capture symptom improvement in general mental health and well-being. State and federal health agencies have supported the population surveillance of health-related quality of life (HRQoL), which is a multidimensional concept that examines overall health related to perceived physical and mental health as well as daily functioning [14,15]. One common HRQoL tool is the Centers for Disease Control and Prevention (CDC) "Healthy Days" measure that asks about self-rated general health, physical health, mental health, and activity limitations over the past 30 days. This subjective measure of well-being is an effective way to capture HRQoL and might be better suited as an outcome measure for treatments that include both clinical individuals and individuals with symptoms not meeting clinical thresholds [16]. Yet, few studies have used this measure when evaluating digital behavioral health platforms. Financially, Humana found

that the cost of each reported unhealthy day is equivalent to 10 hospital admissions per thousand patients, with a potential increase of US \$15.64 per member per month in medical costs for each unhealthy day [17]. This highlights the potential long-term savings that could result from interventions targeting individual HRQoL. A previous health coaching study has already demonstrated significant reductions in reported unhealthy days among participants [18].

The purpose of this study was to examine self-reported HRQoL among members using an on demand digital health platform and the association of short-term text-based behavioral health coaching and virtual clinical sessions with healthy days over time. To that end, the study will describe baseline characteristics of members in terms of reported unhealthy days and changes over 1 month, describe changes in unhealthy days as a function of baseline anxiety and depressive symptoms, and examine the association between member engagement and changes in unhealthy days.

Methods

Participants

Participants were members who had access to the Ginger on demand behavioral health platform as part of their employer or health plan benefits. Internal clinical protocols include exclusionary criteria where self-directed telehealth is likely not appropriate and where more specialized and urgent psychiatric services are required (eg, active suicide ideation or active high-risk self-harm behavior; see Kunkle et al [19] for exhaustive list). This study included Ginger members 18 years or older who completed the baseline Healthy Days measure between November 2020 to November 2021 and who first accessed care within 1 month of completing their Healthy Days baseline.

Procedures

The Ginger platform provides members with access to virtual behavioral health coaching, teletherapy, telepsychiatry, and self-guided content and assessments, primarily via a mobile app platform. After downloading the mobile app, members can start texting with a behavioral health coach within minutes of requesting to connect. Ginger coaches are full-time employees who have an advanced degree in a field related to mental health or have accredited coach certification. While many members are solely engaged with text-based coaching services, some will request or require escalation to clinical services (teletherapy or telepsychiatry) depending on preference or clinical severity. When members are escalated to therapy or psychiatry, they may continue working with a coach provided they also seek additional specialized care concurrently. Additional detail regarding Ginger can be found in prior publications [19,20].

The Healthy Days measure was administered to members 4 times across the span of 4 months (once per month). Data were collected externally using the Survey Monkey platform. Only responses from survey items pertaining to the number of unhealthy mental health days and impacted days were of focus for this study. The PHQ-9 and GAD-7 were typically completed

at intake within 1 month of the Healthy Days baseline assessment.

Measures

The CDC Healthy Days measure contains four items: (1) “Would you say that in general your health is excellent, very good, good, fair, or poor?” (2) “Now thinking about your physical health, which includes physical illness and injury, for how many days during the past 30 days was your physical health not good?” (3) “Now thinking about your mental health, which includes stress, depression, and problems with emotions, for how many days during the past 30 days was your mental health not good?” and (4) “During the past 30 days, for about how many days did poor physical or mental health keep you from doing your usual activities, such as self-care, work, or recreation?” (referred to here as impacted days). For this study a change variable was calculated by subtracting reported unhealthy scores from time 1 from scores from time 2, where positive values indicate an increase in unhealthy days, whereas negative values indicate a reduction in unhealthy days.

The PHQ-9 is a 9-item self-report questionnaire that assesses the frequency and severity of depression symptomatology within the previous 2 weeks. Each of the 9 items is based on the *Diagnostic and Statistical Manual of Mental Disorders* (Fourth Edition; *DSM-IV*) criteria for major depressive disorder and are scored on a 0 (not at all) to 3 (nearly every day) scale. Items include “Little interest or pleasure in doing things” and “Feeling down, depressed, or hopeless.” Total scores can range from 0 to 27 with higher scores indicating more depressive symptoms. A score of 10 was used as the clinical threshold [21].

The GAD-7 is a valid brief self-report tool to assess the frequency and severity of anxious thoughts and behaviors over the past 2 weeks. Each of the 7 items are based on the *DSM-IV* diagnostic criteria for generalized anxiety disorder and are scored on a 0 (not at all) to 3 (nearly every day) scale, with total scores ranging from 0 to 21. Items include “Feeling nervous, anxious, or on edge” and “Not being able to stop or control worrying.” Consistent with existing literature, a score of 10 was used as the clinical threshold [22].

Member engagement with Ginger services was quantified as the number of coaching and clinical sessions. Coaching sessions were operationalized as the number of unique days where both members and coaches each sent at least 5 text messages. Ginger coaching is an on demand text-based service, and the operationalization of a “text-based coach session” has not been predetermined in the literature. As such, our threshold was decided based upon internal work that highlighted approximately 5 texts each way as the number of text messages needed to capture a productive conversation between members and their coaches. Clinical sessions were operationalized as the number of completed video sessions with a clinician.

Statistical Analysis

Analyses were conducted using RStudio (version 1.4.1717; RStudio, PBC). Data were first screened for outliers and normality. Descriptive statistics were used to describe baseline member characteristics. For changes in reported unhealthy days, paired sample *t* tests were used. Next, members were divided

into groups as a function of clinical thresholds using the PHQ-9 and GAD-7 scores at intake (ie, clinical vs subclinical). Additional paired sample *t* tests were performed to evaluate member differences in responses between time 1 and time 2 for clinical and subclinical groups separately. A Benjamini-Hochberg correction was used to adjust for multiple comparisons [23]. Finally, scatterplots suggested a linear trend between member engagement and changes in unhealthy days. As such, multiple linear regressions were performed to examine the association of member engagement (ie, coaching and clinical sessions) with changes in the number of unhealthy days. Baseline Healthy Days scores and the number of prior engagement levels were entered as covariates. All continuous variables were standardized for interpretability.

Ethics Approval

This is a secondary analysis of pre-existing deidentified data. The authors do not have access to participant identifying information and do not intend to recontact participants. Ginger’s research protocols and supporting policies have been reviewed and approved by Advarra’s institutional review board (Pro00046797) in accordance with the US Department of Health and Human Services regulations at 45 CFR 46.

Results

Descriptive Statistics

A total of 1496 members completed the Healthy Days measure at time 1 (intake), 351 (23.5%) members at time 2 (~30 days following intake; mean 31.9, SD 1.48 days), 114 members at time 3 (~60 days following intake), and 37 members at time 4 (~90 days following intake). The current analyses examined only members who had completed surveys at both time 1 (intake) and at time 2 (N=288). Data were missing at random for all primary outcome variables ($t > -0.70$ and $t < 1.54$; $P > .12$). Potential reasons for earlier drop-offs that should be taken into consideration when interpreting our results include members having achieved their coaching goals, members no longer interested in care, and members engaged at a monthly cadence and returned after the study evaluation month was finished. Demographic information about members was provided by employers but contained missing data. Of members in the analytical sample, 82 (28.5%) members were between the ages of 18-34 years, 96 (33.3%) members were 35 years of age or older, and 110 (38.2%) members did not have age reported. Regarding gender identity, 125 (43.4%) members identified as female, 33 (11.5%) as male, 14 (4.9%) as other, and 116 (40.3%) did not have gender reported.

Descriptive statistics for the primary variables are presented in Table 1. Members, on average, completed 1.92 (SD 2.16, range 0-12) coaching sessions and 0.91 (SD 1.37, range 0-5) video sessions with a clinician within a single month. A total of 179 (62.2%) members engaged exclusively with text-based coaching (no clinical sessions). Subclinical depression and anxiety levels were reported in 104 (36.1%) members, whereas 184 (63.9%) members reported clinical levels of depression or anxiety. Of members in the analytical sample, 71% (n=205) at time 1 and 77% (n=223) of members at time 2 reported feeling “good” or better in response to the question “Would you say that in general

your health is excellent, very good, good, fair, or poor?” (includes members who reported feeling “very good” and “excellent”). Bivariate correlations among the primary variables are presented in Figure 1. Of note, the number of unhealthy

mental health days was positively correlated with the number of impacted health days at each respective time point ($r=0.62$ at time 1, $r=0.65$ at time 2; $P<.001$).

Table 1. Descriptive statistics among primary variables.

	Values, mean (SD)	Min	Max
Physical health (time 1)	5.1 (7.8)	0	30
Mental health (time 1)	16.0 (8.8)	0	30
Impacted health (time 1)	10.9 (9.6)	0	30
Physical health (time 2)	5.6 (8.3)	0	30
Mental health (time 2)	13.2 (9.0)	0	30
Impacted health (time 2)	8.2 (8.5)	0	30
Coaching sessions	1.9 (2.2)	0	12

Figure 1. Correlations among primary variables. Note: Insignificant correlations where $P>.05$ are marked. Corr: correlation.

Pre-Post Changes in Reported Unhealthy Days

Members reported on average nearly 3 fewer unhealthy mental health days (mean -2.71 , SD 8.03) between baseline and 1

month later. Of the analytical sample, 61% ($n=175$) of members reported an improvement in unhealthy mental health days, whereas 39% ($n=113$) reported no improvement or an increase in unhealthy mental health days. Paired sample t tests were

performed to evaluate differences in member Healthy Days responses at time 1 compared to time 2 (Figure 2) across all continuous items. Results showed no significant improvements in unhealthy physical health days between time 1 (mean 5.08, SD 7.78 days) and time 2 (mean 5.60, SD 8.25 days; $t_{287}=-1.25$; $P=.21$). However, results showed significant improvements in unhealthy mental health days between time 1 (mean 16, SD 8.77 days) and time 2 (mean 13.2, SD 9.02 days; $t_{287}=5.73$;

$P<.001$), as well as significant improvements in adversely impacted days between time 1 (mean 10.9, SD 9.60 days) and time 2 (mean 8.19, SD 8.51 days; $t_{287}=6.26$; $P<.001$). Given Ginger is a mental health platform and significant changes were only observed for unhealthy mental health days and adversely impacted days, these two outcomes were explored in subsequent analyses.

Figure 2. Display of means across the items from the Healthy Days measure at time 1 and time 2 (N=288).

Comparison of Change in Healthy Days Between Clinical and Subclinical Members

Subclinical members showed trending reductions in reported unhealthy mental health days between time 1 (mean 9.92, SD 6.78 days) and time 2 (mean 8.44, SD 7.83 days; $t_{103}=1.87$; $P=.06$, adjusted $P=.06$). Clinical members also showed reductions in reported unhealthy mental health days between time 1 (mean 19.4, SD 7.91 days) and time 2 (mean 16.0, SD 8.52 days; $t_{183}=5.82$; $P<.001$; adjusted $P<.001$).

Similarly, subclinical members showed significant reductions in reported impacted days at time 1 (mean 5.15, SD 6.64 days) compared to time 2 (mean 3.47, SD 5.3 days; $t_{103}=3.04$; $P=.003$, adjusted $P=.003$). Clinical members also showed significant reductions in reported impacted days at time 1 (mean 14.2, SD 9.48 days) compared to time 2 (mean 10.9, SD 8.83 days; $t_{183}=5.50$; $P<.001$, adjusted $P=.001$).

Member Engagement on Changes in Reported Unhealthy Mental Health Days

The linear regression model predicting changes in reported unhealthy mental health days was significant ($F_{5,282}=14.6$; $P<.001$) and accounted for 21% of the variance. No significant main effects of coaching sessions ($B=0.61$; $P=.19$) were observed. However, there was a significant main effect of clinical sessions ($B=-0.96$; $P=.04$), where more clinical sessions was associated with a decrease in unhealthy mental health days. The model predicting changes in adversely impacted days was also significant ($F_{5,282}=22.2$; $P<.001$) and accounted for 28% of the variance. No significant main effects of coaching sessions ($B=0.43$; $P=.30$) or clinical sessions ($B=-0.40$; $P=.33$) were observed. Coefficients for both models are presented in Table 2.

Table 2. Summary of regression coefficients (N=288).

	Beta (SE)	P value
Model 1: Changes in the number of unhealthy mental health days		
(Intercept)	-2.71 (0.43)	<.001
Unhealthy mental health days (baseline)	-3.32 (0.43)	<.001
Prior coaching sessions	0.39 (0.47)	.42
Prior clinical sessions	0.59 (0.47)	.21
Clinical sessions	-0.96 (0.47)	.04
Coaching sessions	0.61 (0.47)	.19
Model 2: Changes in the number of adversely impacted days		
(Intercept)	-2.75 (0.38)	<.001
Unhealthy impacted days (baseline)	-3.87 (0.38)	<.001
Prior coaching sessions	-0.30 (0.42)	.48
Prior clinical sessions	0.10 (0.41)	.80
Clinical sessions	-0.40 (0.41)	.33
Coaching sessions	0.43 (0.41)	.30

Discussion

Principal Findings

This study evaluated the real-world association between digital care utilization in members with both subclinical and clinical symptoms of anxiety or depression. HRQoL at baseline suggested that members were, on average, demonstrating “frequent distress” and reporting more *unhealthy* mental health days than *healthy* mental health days (mean 16, SD 8.77 days; 53% of the month). The CDC defines having ≥ 14 unhealthy mental health days as “frequent distress [24].” Of note, our results also observed a relatively high number of unhealthy mental health days (mean 9.92, SD 6.78 days; 33% of the month) for subclinical members at baseline, highlighting the need for care for those that might not traditionally be recommended for clinical services (eg, individuals who might not have exceeded clinical thresholds using traditional PHQ-9 and GAD-7 assessment surveys). Bivariate correlations revealed a positive association between unhealthy mental health days and adversely impacted days, underscoring the relationship between mental health and daily functioning [25,26]. Overall, members evidenced significant improvements in reported unhealthy mental health days and adversely impacted days over the month. Furthermore, improvements in reported adversely impacted days were significant for both subclinical members and clinical members, and improvements in reported unhealthy mental health days were significant for clinical members. Our results also found that clinical sessions, but not coaching sessions, predicted changes in reported unhealthy mental health days over the month. Taken together, this study offers preliminary descriptives on a valuable but less commonly used outcome measure, specifically in a traditionally understudied but increasing population of individuals seeking out virtual care. The study further supports how virtual care is a promising strategy to meet the growing demand of mental health services.

Not all individuals seeking out care exceeded industry clinical thresholds. Thus, additional outcome measures, such as the Healthy Days measure, are needed to evaluate the effects of digital mental health care beyond clinically focused measures (eg, PHQ-9 and GAD-7). To our knowledge, we are one of the first to use the Healthy Days measure within this population (ie, individuals seeking out virtual mental health care). Overall, members reported a reduction of 2.71 unhealthy mental health days. Extrapolating from the Humana data [16], this would be equivalent to a decrease of 27.1 hospital admissions per thousand patients and a potential cost savings of US \$42.38 per member per month. Thus, virtual mental health care can be seen as a low-intensity approach to achieve better health outcomes at lower cost [12,13].

Our results found a significant association between the reduction in the number of reported unhealthy mental health days and member engagement with clinical sessions, but not with coaching sessions. Coaching, and even more so text-based coaching, differs fundamentally in their objectives and practices compared to clinical care [27,28]. Little is understood regarding the effects of text-based coaching on mental health outcomes. Our findings suggest that the amount of care needed to drive member improvement might vary between text-based coaching and clinical practices [29]. It is possible that additional time/sessions might be needed for coaching goals to be formed, implemented, and subsequently have an impact on behavioral change via a text-based medium [28-30]. Future studies should extend the follow-up window when evaluating coaching sessions and assess alternate trajectories of improvement in mental health (eg, nonlinear).

Limitations

There are several limitations to consider. One limitation is the potential for bias in our estimates and the increased likelihood that our results may not generalize to all individuals who engage with teletherapy. Furthermore, our cohort design did not have

a comparison group or random assignment to the treatment intervention. Thus, our ability to draw causal inferences is limited and improvements in reported unhealthy days could simply be due to a passage of time; however, we were able to demonstrate significant changes in members with both subclinical and clinical symptoms using real-world longitudinal data. Even though data were missing at random and may not bias results, future studies should implement procedures (eg, incentives) to encourage and capture more complete follow-up data. Future studies can also examine obstacles and facilitators for engagement in teletherapy. The study was also limited to available self-reported outcome data, and there was a large amount of attrition in members reporting unhealthy days over time. This could be due to most members not experiencing clinically meaningful baseline symptomatology and potentially quick improvements in functioning. It is also possible that because the survey was administered outside of the Ginger

platform (ie, Survey Monkey), the additional step of completing the measure might have been an added time burden. However, this approach allowed us to pilot and demonstrate the real-world attrition rate when using external data collection platforms.

Conclusions

To our knowledge, this study is one of the first to use the HRQoL measure as a primary outcome in an evaluation of a digital behavioral health platform. Using real-world longitudinal data, our preliminary yet promising results show that short-term engagement with virtual care can be an effective means to improve HRQoL for members with subclinical and clinical symptoms. Virtual care represents a scalable and well-suited approach to meet the growing need for mental health services that has outpaced the in-person availability of clinical mental health professionals. Future studies should examine the long-term impact of text-based coaching and clinical support on HRQoL.

Acknowledgments

We are grateful for the participation of the members who completed the survey, as well as the hard work and dedication of Ginger coaches and clinicians.

Conflicts of Interest

All authors are paid employees of Ginger.

Abstract

Background: Cold agglutinin disease (CAD) is a rare disorder, affecting 15% of patients with autoimmune hemolytic anemia. Few studies have assessed CAD symptoms and their impact on daily life, but these studies did not address the patients' perspectives.

Objective: The aims of this study were to increase the knowledge about CAD through a patient-centric survey and to gain a better understanding of the burden of this disease.

Methods: We conducted an internet-based survey in September 2020 among American patients registered on the CAD Unraveled website and members of the Cold Agglutinin Disease Foundation.

Results: A total of 50 respondents were included in this study. Totally, 90% (45/50) of the patients reported having experienced fatigue. Fatigue was mainly reported on a daily basis, and approximately one-third of these patients (13/45, 29%) said that their fatigue was constant throughout the day. It has also been shown that CAD has a great impact on patients' physical well-being, emotional well-being, social life, and household finances. The disease varies over time, with or without symptoms. A total of 88% (44/50) of the patients reported previous episodes of the increased intensity or sensitivity of their CAD symptoms, with a mean of 4.5 (SD 5.4) episodes reported during the past year. More than half of the patients (27/50, 54%) considered their disease to be moderate or severe, and 42% (21/50) of the study group reported that their symptoms had worsened since the time of diagnosis.

Conclusions: Our study has provided new data on CAD symptoms, particularly data on the importance and type of fatigue and the fluctuation of CAD symptoms.

Introduction

Background

Autoimmune hemolytic anemias (AIHAs) are rare and heterogeneous disorders characterized by the destruction of red blood cells by warm or cold antibodies, thereby causing anemia and other related health issues [1-4]. AIHA is classified into three categories: warm, cold, and mixed [1,5,6]. Warm AIHA is characterized by the binding of polyclonal immunoglobulin (often immunoglobulin G) to red blood cell antigens (Rh proteins or glycophorins A-D). This binding is referred to as *warm* in that it occurs at most temperatures but is maximal at 37 °C [4,5]. Cold agglutinin disease (CAD) is the most common form of cold AIHA, accounting for 15 to 25% of AIHA cases [5-7]. CAD is recognized by the presence of immunoglobulin M autoantibodies, also known as cold agglutinins, which are active and cause hemolysis at cold temperatures, usually 3 °C to 4 °C [5,7]. This cold AIHA is composed of CAD, formerly known as primary CAD, and cold agglutinin syndrome, formerly known as secondary CAD [7]. There is no known cause for CAD. Cold agglutinin syndrome is associated with underlying conditions such as infection, malignancy, or immune disease [4,7].

CAD is a rare disease. Berentsen et al [8] suggested variations between cold and warm climates, reporting an incidence of 9 cases per million people per year in North Italy and 2 cases per million people per year in Norway, with a prevalence of 50 per million people in Italy and 200 per million people in Norway. An incidence of 1.8 cases per million person-years was reported based on the Danish national patient register [4]. CAD primarily affects middle-aged to older individuals; however, the disease has been observed in people aged as young as 30 years [7,9-11]. Some studies have indicated that women are slightly more affected by the disease than men [9].

Diagnosis of CAD is established with hemolytic anemia, reticulocytosis, hyperbilirubinemia, elevated lactate dehydrogenase, and positive Coombs test for anti-C3d and classically negative anti-immunoglobulin G [9]. After the test findings suggest CAD, the antibody titer and thermal activity should be determined to prevent overdiagnosis, because most agglutinins are clinically insignificant [9].

Most people with CAD have symptoms of hemolytic anemia such as paleness, shortness of breath, rapid heart rate, fatigue, weakness, dark urine, or pain [6,9,12]. Many people with CAD also experience pain and bluish coloring of the hands and feet (acrocyanosis) or Raynaud disease owing to slow or poor blood circulation [6,9,12]. CAD symptoms can vary throughout the course of a patient's illness, involving fluctuation in CAD severity [7]. Anemia in CAD is often mild (hemoglobin level >10 g/dL) to moderate (hemoglobin level between 8 and 10 g/dL) and, in some cases, fully compensated, but it may be severe (hemoglobin level <8 g/dL) [13].

Importantly, febrile illness, trauma, and surgery can exacerbate hemolytic anemia [7,14], which can increase the risk of thromboembolic events and death [15]. Patients with mild anemia and minimal circulatory symptoms typically do not

require specific pharmacological treatment [4,6,13]. These patients are advised to avoid exposure to cold [6,13], to limit the intensity of acrocyanosis and risk of developing trophic disorders. Moreover, any bacterial or viral infection should be treated [6].

Seasonal variation of these symptoms has been reported [16]. Symptoms were reported to be more severe when the patient is exposed to cold temperatures. This can lead to delay in diagnosis during warm periods.

At the time of this study, there was no approved treatment for CAD. However, patients with moderate anemia and hemoglobin levels below approximately 10 g/dL or disabling cold-induced circulatory symptoms may require blood transfusions. Rituximab monotherapy or rituximab along with bendamustine are recommended as first-line therapy for patients with severe symptoms, depending on individual patient characteristics [6,17]. Corticosteroid treatment is not recommended for patients with CAD, especially for long-term treatment [6]. Novel pharmacological treatment options are also currently under development to improve clinical management [13,17] and consequently, the quality of life of patients [4].

In addition to these treatments, patients are recommended to avoid cold. Mild CAD symptoms may be managed by avoiding exposure to cold temperatures, avoiding cold food and water, using room heaters, and wearing warm clothing (warm shoes, scarves, gloves, earmuffs, warm inners, and stockings) [17].

Objectives

To enhance diagnosis and clinical management, it is necessary to better understand the symptom severity and impact of CAD from the patient's perspective. Qualitative studies on CAD are scarce and lacking. Su et al [12] found from qualitative interviews of 16 patients with CAD that the most frequently reported symptoms were fatigue, tiredness, or lack of energy and reaction to cold environments [2,12]. The rarity of CAD limits the ability to perform large-scale studies. The aims of this study were to increase the knowledge about CAD through a patient-centric survey and gain a better understanding of the burden of this disease from patients living with CAD in the United States.

Methods

Study Design and Participant Recruitment

This study included qualitative and quantitative research using a web-based questionnaire. The recruitment period started on September 1, 2020, and lasted for less than a month. Invitations to complete a self-administered questionnaire and follow-up emails were sent to members of the CAD Unraveled website, a website created by Sanofi and dedicated to providing support, information, and tools to patients with CAD to help them manage their condition. The Cold Agglutinin Disease Foundation (CADF), a nonprofit foundation dedicated to educating and supporting patients living with CAD, also shared the survey with its members. The study was based on voluntary and free participation of patients who agreed to participate in the survey. The study's inclusion criteria were as follows: patients self-reporting a diagnosis of CAD, aged ≥18 years,

residing in the United States, and being a registered member of the CAD Unraveled website or CADF.

Data Collection

The questionnaire (39 closed-ended questions and 5 open-ended questions) was designed by Carenity, in collaboration with Sanofi and CADF. The questionnaire was written in English, and the average estimated time needed to answer was 30 minutes.

The questionnaire started with a set of questions about the respondent's profile (eg, age, gender, place of residence, and profession), CAD characteristics, and disease status (eg, disease duration, age at diagnosis, type of CAD, symptoms experienced, and episodes experienced). CAD episodes were defined as a few hours during which a patient is affected by severe CAD symptoms.

The second part of the questionnaire was related to patient's perception of CAD severity and progression.

The third part assessed the patient's expectations of CAD-related fatigue management. Distinction between fatigue or tiredness, weakness, and lack of stamina was provided. Fatigue was defined as the feeling of tiredness or exhaustion or the need to rest because of lack of energy or strength and the need for extra sleep. Weakness was considered as a lack of physical or muscle strength and the feeling that extra effort is required to move arms, legs, or other muscles. Finally, lack of stamina was defined as an inability to maintain or sustain prolonged physical effort or activity.

The fourth part of the questionnaire evaluated the management methods used at the time of the survey, previous management methods, and patient satisfaction regarding management methods used at the time of the survey.

Finally, the last part explored the patient's perception of the CAD burden and the impact that CAD symptoms had on the patient's daily life, professional activities, and household finances (eg, impact owing to health care costs and work absenteeism). CAD burden was assessed at three time points (eg, when usual or regular symptoms were experienced, when symptom intensity or sensitivity increased or new symptoms occurred, and when no symptoms were experienced).

Statistical Analysis

Categorical variables are expressed as absolute frequencies and percentages. Continuous variable data are presented as mean (SD) for normal distribution and as median for nonnormal distribution. Narratives from open-ended questions were manually analyzed by identifying themes and subcategories.

Data processing and analysis were performed using RStudio (version 3.5.0; RStudio, Inc). Excel (Microsoft Corporation) 2013 was used to analyze the open-ended questions. The participants' personal information is not publicly available owing to privacy laws.

Ethics Approval

Written informed consent was obtained from all participants through information notice. The study protocol and patient materials were reviewed by the Western and Copernicus Group Institutional Review Board (formerly, New England Institutional Review Board; approval number 20202393).

Results

Description of the Study Population

A total of 116 participants started to fill in the questionnaire (registered as living in the United States or who had not indicated their country of residence), with 50 (43.1%) participants fulfilling the inclusion criteria and completing the questionnaire by September 24, 2020 (Figure 1). Patients were excluded from the study mainly because they indicated not living in the United States or not having CAD diagnosed by a health care professional.

Participants were located throughout the United States, with few participants from the Midwest. The mean age at enrollment was 66.7 (SD 8.5) years, and the men-to-women sex ratio was 0.22. Regarding employment status, 76% (38/50) of the patients declared that they were not working at the time of the survey and 20% (10/50) of the patients were working (Table 1).

At diagnosis, patients were on average aged 59.2 (SD 8.5) years. The main signs that led to diagnosis were blood tests (44/50, 88%) and presence of symptoms (26/50, 52%). Most patients (44/50, 88%) experienced symptoms before the diagnosis of CAD. The most frequently reported symptoms included fatigue (fatigue, tiredness, lack of stamina, or weakness; 37/50, 74%), shortness of breath (19/50, 38%), and acrocyanosis (18/50, 36%).

Among the 88% (44/50) of the patients who had experienced symptoms before being diagnosed, 34% (15/44) patients were diagnosed ≥ 2 years after their initial symptoms (Table 2). The delay between the development of initial symptoms and diagnosis was primarily owing to unawareness that the symptoms were associated with a disease (14/44, 32%) or because the patient had consulted multiple physicians before being properly diagnosed (13/44, 30%). The sociodemographic and clinical characteristics of the study participants are summarized in Tables 1 and 2.

Figure 1. Disposition of survey respondents. CAD: cold agglutinin disease; CADF: Cold Agglutinin Disease Foundation. *Indicates people who had agreed to receive invitations to participate in the study.

^bMultiple-choice question; complete list is given in Figure S1 in [Multimedia Appendix 1](#).

^cCold and blue limbs.

^dSample size: n=44.

CAD Symptoms Experienced and Perception of Disease Severity and Progression

More than half of the patients (27/50, 54%) considered their disease to be moderate or severe ([Table 3](#)). Patients with a severe form were principally affected by severe symptoms and were not satisfied with the efficiency of their management methods. Of the 50 patients, 31 (62%) patients reported that their CAD has progressed since their diagnosis: 21 (42%) patients thought that it has worsened and 10 (20%) thought that it has improved. Respondents who had experienced worsening of their CAD

symptoms indicated that it occurred when the intensity or sensitivity of their symptoms increased (8/21, 38%), when new CAD symptoms appeared (4/21, 19%), and when both CAD symptom intensity or sensitivity increased and new CAD symptoms appeared (2/21, 10%). CAD varied over time: 88% (44/50) of the patients experienced episodes with increased intensity and sensitivity of CAD symptoms, 72% (36/50) experienced episodes with new CAD symptoms, and 54% (7/50) experienced episodes without symptoms. A total of 40% (20/50) of the patients had experienced all 3 types of episodes. Among the 94% (47/50) patients who reported CAD episodes with

increased intensity or sensitivity or new CAD symptoms, the most cited symptoms experienced during a CAD episode were fatigue (fatigue, tiredness, lack of stamina, or weakness; 42/47, 89%) and shortness of breath (31/47, 66%; [Table 3](#)). In total, 94% (44/47) of the patients identified at least one factor that caused an increase in symptom intensity and sensitivity. Among the 13 factors cited, the three major triggers were cold temperature (39/47, 83%), winter (32/47, 68%), and air conditioning (26/47, 55%; [Table 3](#)).

Totally, 90% (45/50) of the patients reported having experienced fatigue (fatigue, tiredness, lack of stamina, or weakness). Among

these 45 patients, a total of 40 (89%) patients reported the symptoms at the time of the survey. In total, 47% (21/45) of the participants reported that it was moderate, 29% (13/45) reported that it was mild, and 13% (6/45) reported that it was severe. Fatigue was reported on a daily basis by 44% (20/45) of the patients, several times a week by 27% (12/45), and only after physical exertion by 16% (7/45) of the patients. When fatigue was experienced, 31% (14/45) of the patients mentioned that it usually fluctuated during the course of the day, 29% (13/45) reported that fatigue was constant throughout the day, and 22% (10/45) reported that fatigue symptoms were more intense in the afternoon.

^aCAD: cold agglutinin disease.

^bMultiple-choice question.

^cSample size: n=47.

^dHandling cold items (1/47, 2%), stress and physical activity (1/47, 2%), constant hemolysis creating chest pain in my sternum (1/47, 2%), overexertion (1/47, 2%), and unspecified (1/47, 2%).

Impact of CAD on Patients' Daily Life

When patients were asked in an open-ended question ("Which aspects of your daily life (emotionally, physically, socially, etc) are the most impacted by CAD?"), they named physical well-being (40 quotations), emotional well-being (31 quotations), and social life (28 quotations). Patients who reported an impact on their physical well-being primarily indicated the need to take naps (7 quotations), the inability to perform physical activities (7 quotations), and the need to limit their daily tasks (6 quotations). Emotional well-being was primarily affected owing to depression (7 quotations), frustration (6 quotations), or anxiety (4 quotations).

Among the 20% (10/50) of the patients who were employed at the time of the study, 90% (9/10) declared that CAD affected their professional life (Table 4). A total of 60% (30/50) of the patients reported that their household finances were affected by the disease. Totally, 83% (10/12) of the patients aged <60 years said that CAD affected their household finances, compared with 42% (8/19) of those aged >70 years. In total, 74% (37/50) of

the patients had to cover out-of-pocket cost associated with the disease. Alternative medicines (21/50, 42%), transportation costs to medical appointments (16/50, 32%), and office visits or hospital care (16/50, 32%) were the most cited out-of-pocket costs to be covered, with an average of 2 out-of-pocket costs per patient (Table 4).

When patients were asked, with suggested items, which CAD-related symptoms had the greatest impact on their daily life, 90% (45/50) of the patients reported fatigue, 58% (29/50) of the patients reported shortness of breath, and 44% (22/50) of the patients reported joint pain, headaches, or acrocyanosis.

Patients were most affected during episodes with increased symptom intensity, increased sensitivity, or new CAD symptoms (median ≥ 8 out of 10, with 10=very strong impact), followed by episodes with usual symptoms (median ≥ 6 out of 10, with 10=very strong impact). Patients were less affected when no symptoms were experienced (median ≤ 3 out of 10), but they still indicated a negative impact on their quality of life (Figure 2).

Table 4. Impact of CAD^a on patients with CAD in the United States recruited for the web-based survey (N=50).

Impact of CAD	Values, n (%)
Professional life^{b,c}	
Had to take time off work	6 (60)
Could not work as much as they would like to	5 (50)
Not as efficient at work	2 (20)
Concerned that they would not be able to do the job when applying for a new position	2 (20)
Not able to work outside from late fall to early spring	1 (10)
Had to make modifications to avoid handling cold items	1 (10)
Unspecified	1 (10)
Not affected	1 (10)
Household finances	
No impact	20 (40)
Mild impact	15 (30)
Moderate impact	11 (22)
Severe impact	3 (6)
Not sure	1 (2)
Out-of-pocket costs related to CAD	
Alternative medicines (eg, vitamins and herbal medicines)	21 (42)
Transportation for medical appointments	16 (32)
Office visits or hospital care	16 (32)
Treatment for CAD and any related side effects	14 (28)
Transportation to relocate to a warmer region	10 (20)
Household services (eg, house cleaning and yard work)	9 (18)

^aCAD: cold agglutinin disease.

^bMultiple-choice question.

^cSample size: n=10.

^dRental in warm area for 4 months each year (1/50, 2%); purchase more expensive health insurance (1/50, 2%); install a generator, which can be used if power is lost (1/50, 2%); move to a place for people aged >55 years, where everything is already available (1/50, 2%); and unspecified (1/50, 2%).

Figure 2. Impact of cold agglutinin disease on daily life reported by patients with that disease in the United States who were recruited for the web-based survey (N=50).

Impact of CAD-Related Fatigue

When patients who experienced fatigue, tiredness, lack of stamina, or weakness were asked in an open-ended question to describe how fatigue affected their daily life, they indicated that fatigue affected daily activities (38 quotations), associated fatigue with symptoms (37 quotations), and reported the need to implement solutions to cope with fatigue (31 quotations). Patients who reported fatigue-related symptoms primarily indicated weakness (22 quotations), difficulty in concentrating (6 quotations), and headaches (3 quotations). Those who indicated that fatigue affected their daily activities primarily

cited an impact in terms of difficulty in completing daily tasks or starting new projects (12 quotations), difficulty in doing household chores (8 quotations), and the need to avoid physical activities (7 quotations). When asked on a scale from 0 to 10 (0=fatigue has no impact; 10=fatigue has a strong impact), it was found that fatigue had a significant impact on all aspects of daily life that were cited: personal life, physical well-being, professional life, social life and leisure, and emotional well-being (median ≥ 7 out of 10; Figure 3). Patients who experienced fatigue on a daily basis reported a more severe impact on each aspect of their daily life.

Figure 3. Impact of fatigue on daily life, reported by patients with cold agglutinin disease in the United States who were recruited for the web-based survey (N=50). p25: 25th percentile; p75: 75th percentile. *n=44 respondents affected; **n=37 respondents affected.

Symptom Management Methods

In total, 92% (46/50) of the patients reported using a management method at the time of the survey. The management method most often reported was cold avoidance (41/50, 82%), followed by rituximab treatment (10/50, 20%) and blood transfusion (4/50, 8%). On average, patients reported using 1.4 (SD 0.79) management methods at the time of the survey.

The main management methods used by patients with CAD in the past were cold avoidance (41/50, 82%), rituximab treatment (23/50, 46%), and corticosteroid treatment (15/50, 30%). Before

the survey, patients reported using an average of 2.1 (SD 1.2) management methods.

A total of 32% (16/50) of the patients had to relocate away from where they used to live because of their CAD. Of these 16 patients, 9 (56%) patients relocated for part of the year and 7 (44%) patients relocated permanently. Totally, 59% (20/34) of the patients who had not relocated owing to CAD said that they want to do so. Incidentally, patients who relocated owing to CAD were more satisfied with their current management methods than those who did not relocate (7/15, 47% and 9/31, 29%, respectively).

Only 24% (12/50) of the patients declared having received blood transfusions owing to CAD in the previous 12 months. Among these 12 patients, 6 (50%) patients received at least three blood transfusions in the previous 12 months. When asked about their level of satisfaction regarding blood transfusion, half of the patients were satisfied, whereas the other half were unsatisfied (median 5 out of 10, with 10=agree with the item “I am satisfied with the way blood transfusions are performed”). Patients also reported that they often required assistance with transportation for blood transfusion appointments (median 6.5 out of 10, with 10=agree with the item “Someone often has to take me to or from my blood transfusions”) or that the time spent in having infusions had an impact on their activities (median 5.5 out of 10 with 10=agree with the item, “Time spent for a blood transfusion has an impact on other activities”).

Overall, among the 92% (46/50) of the patients who reported using a management method at the time of the survey, only 34% (16/46) were satisfied with the method used, primarily because of the improvement in CAD symptoms (4 quotations). A total of 31% (14/46) of the patients were dissatisfied with their current management method, including 11% (5/46) who were very dissatisfied. The most common reason for dissatisfaction was the lack of efficacy of the management method applied (5 quotations).

As CAD-related fatigue has a significant impact on the patients' quality of life, approximately all patients who experienced fatigue (44/45, 98%) had devised a coping mechanism to manage the symptoms. However, only 11% (5/45) of the patients sought professional help for fatigue. On average, patients implemented 5 coping mechanisms to deal with this symptom. However, only 28% (12/44) of the patients were satisfied with the coping mechanism that was implemented, among whom only 5% (2/44) were very satisfied. In contrast, 32% (14/44) of the patients were dissatisfied, including 9% (4/44) patients who were very dissatisfied.

Discussion

Principal Findings

This study brings new evidence of the burden of CAD from patients' perspectives.

In particular, our survey provided new data on fatigue experience (importance and type of fatigue). A total of 90% (45/50) of the patients reported having experienced fatigue (fatigue, tiredness, lack of stamina, or weakness). Fatigue was reported daily by 44% (20/45) of the patients, several times a week by 27% (12/45), and only after physical exertion by 16% (7/45) of the patients. When fatigue was experienced, patients mainly mentioned that it usually fluctuated during the course of the day. For example, in the survey, a patient stated the following:

Anything I need to routinely do, such as laundry, cooking, and light to moderate housework, leaves me completely drained.

Fatigue, which is common to many disorders, could also explain the long delay between the first symptoms and the initial diagnosis.

Our findings also reveal that CAD had a great impact on patients' daily activities, physical well-being, emotional well-being, social life, and household finances. For example, a patient stated the following in the results:

I have always been a very active person. Not being able to do the same activities is very hard emotionally. We look normal to most people, but we are not and that explanation is very hard for most people to understand and I get frustrated trying to explain CAD to people.

In total, 38% (19/50) of the patients experienced at least one CAD episode in the 12 months before the study. On average, they experienced 4 to 5 episodes during this time. Patients reported that CAD episodes were most often triggered by cold temperatures, winter, and air conditioning.

Finally, new data on disease severity and progression have been obtained. Most patients (27/50, 54%) considered their disease to be moderate or severe. Fatigue was reported to be the most prominent and most impactful symptom. People who were employed indicated that their work was affected by CAD. In total, 42% (21/50) of the study group reported that their symptoms had worsened since the time of diagnosis. To reduce the impact of CAD symptoms, most patients (46/50, 92%) reported using a management method.

These results confirm and supplement the findings from other studies.

Su et al [12] interviewed patients with CAD using a semistructured interview guide and demonstrated that fatigue, tiredness, or lack of energy; reaction to cold environments; shortness of breath; and trouble thinking or concentrating were the main symptoms experienced by patients and described the impact of CAD on daily activities. Nonetheless, that study included a very limited number of patients (n=16). This study, involving a large group of patients and using a questionnaire built with a patient advocacy group, allowed us to confirm the main findings published by Su et al [12] and provided additional evidence of the burden of CAD.

In comparison with other studies, our results also confirm the great impact of CAD on daily activities [12]. Moreover, the triggers quoted by patients (cold temperatures, winter, and air conditioning) were consistent with the information found in other studies [17]. Finally, the management method most often reported was cold avoidance, which is consistent with previous studies [6,17,18]. However, CAD symptoms have been shown to vary for the first time in a patient survey, implying variation in the impact of CAD. In addition, lack of satisfaction with the management methods used, which was not assessed in the previous studies, was shown.

Limitations

A few limitations of this study should be mentioned.

The self-administered web-based nature of the survey is likely to be biased toward patients who have access to the internet and are comfortable with using computers (ie, bias toward young patients). Approximately 10% of Americans do not use the internet [19], and many others may have access, but decline to

participate in web-based surveys. This bias may partly explain the difference between the study group profile, who were younger in terms of average age at the time of diagnosis (59.2 years) and average age at the time of study (66.7 years), compared with those in the previous studies. A multinational observational study of 232 patients with CAD by Berentsen et al [8] indicated a mean age of 67 years at disease onset, mean age of 68 years at the time of diagnosis, and mean age of 72 years at the time of study. In addition, the men-to-women sex ratio in our study group (0.22) varied from that (0.56) in the study by Berentsen et al [8]. Therefore, the results are likely to be biased toward women's perspective. It has been shown that this reflects the main characteristics of web-based users willing to share their experience with a disease [20].

Another potential limitation of a web-based survey is that it may exclude patients who are non-English-speaking or socioeconomically disadvantaged without internet access, who may have a different subset of symptoms, management methods, and diagnostic characteristics. In addition, if the information was not documented and the patient had to rely solely on memory to complete the questionnaire, certain clinical information may have been underestimated (eg, age at diagnosis, symptoms before diagnosis, number of CAD episodes over the past 12 months, symptoms during the episodes, and perception of disease severity). In addition, the study was only performed in the United States, and treatment, mental health, and so on can be different in other countries.

Patients were recruited from the CAD Unraveled website and CADF, which introduces a selection bias that may not be representative of the entire US population with the disease. This selection bias can be identified in the fact that the frequency of circulatory symptoms is lower in this study than in large studies among people with CAD [8,11]. However, our study population was different, as it was based in the United States (different states and temperature), with secondary CAD accepted. Collection of data was also different, as they were obtained from patients and not from physicians. The acrocyanosis reported in our study is only a part of the cold-induced circulatory symptoms. Other cold-induced circulatory symptoms are observed in CAD. For instance, in our study, 50% (25/50) of the patients reported Raynaud syndrome or acrocyanosis. Another selection bias can be the length of the survey. A total of 30 minutes were needed to complete the whole questionnaire, which could have affected the answer rate. Finally, among the 1155 patients reached, 50 (4.33%) patients completed the questionnaire and no hard criteria for diagnosis of CAD were used, which can bias the sample. The sample may not be representative of the entire US population with CAD. This participation rate can be explained by different factors (no

compensation, methodology used, presence of caregivers or people not diagnosed with CAD or with invalid emails in the CAD Unraveled database, overlap between both databases, reduction of the open survey window, etc).

The absence of a question on race and ethnicity is a limitation of our study, as it has historically affected access to care in the United States. In addition, recall bias could have affected the results, especially for the CAD burden, as it was asked at 3 different time points. As many patients (36/50, 72%) were retired or did not work owing to reasons other than CAD, our assessment of the potential impact of CAD on professional life was limited. Circulatory symptoms were not fully addressed in the context of impact on daily life. However, such impact can be substantial.

Finally, even with the purpose of the study being scientifically driven with no patient compensation, voluntary participation, and review by an ethics committee, a bias in information cannot be ruled out, as most of the questions were closed (39/45, 87%), limited in spontaneous reporting, and completed knowing the study was conducted by a pharmaceutical company. In addition, the study may be biased as it was conducted by a pharmaceutical company and Carenity, a company closely linked to the pharmaceutical company conducting the study. However, a patient advocacy group dedicated to CAD was involved to reduce this bias as much as possible.

Conclusions

In conclusion, our study provides new insights into the symptoms associated with CAD and the impact of the disease from the patient's perspective. It particularly highlights the importance and type of fatigue, seriousness of the disease as perceived by patients, impact of CAD even when no symptoms are experienced, and importance of CAD symptom variation, implying that the impact of CAD varies over time. In addition, difficulties in CAD diagnosis have been raised. Patients with CAD experienced difficulty in receiving proper diagnosis and treatment owing to their rare disease; hence, they should be diagnosed earlier and, then, closely monitored and advised by a health care provider with knowledge of how to treat the disease.

Additional studies are necessary to better understand the burden of CAD-related symptoms, especially fatigue, and the patient's needs regarding symptom management. It is also important to raise awareness among health care professionals regarding CAD-related symptoms to appropriately diagnose and support these patients. Specifically, health care professionals should proactively discuss ways to manage fatigue, which is not often discussed during consultations.

Acknowledgments

The authors wish to thank all people living with cold agglutinin disease who participated in this survey and Corinne Forster from the Cold Agglutinin Disease Foundation for her contributions to the design of the web-based survey. Editorial support was provided by Florentina Rafael (freelancer) as well as Tracy Royle and Helen Marshall of Ashfield Medcomms (an Ashfield Health company). Sanofi sponsored the study and the development of this manuscript.

Conflicts of Interest

FJ and LAS are employees and stockholders of Sanofi. EP is an employee and DT is a former employee of Carenity, a company that received funds from Sanofi to conduct the study. PAMW has served as a speaker for Sanofi.

Abstract

Background: Compared to other types of dementia, family caregivers of people with Lewy body dementia (LBD) report higher stress levels and more severe depressive symptoms. Although several digital support interventions for caregivers of persons with dementia exist, few target LBD specifically or leverage a fully remote and asynchronous approach suitable for pandemic circumstances.

Objective: We performed a pilot evaluation of a digital intervention designed to help caregivers of people with LBD address challenges they have experienced, with the end goal of reducing psychological distress in this population.

Methods: We recruited 15 family caregivers of people with LBD to participate in the quasi-experimental, single-arm, mixed methods study titled Virtual Online Communities for Aging Life Experience–Lewy Body Dementia (VOCALE-LBD). The study offers an 8-week web-based intervention that uses a digital discussion platform and involves moderation, peer-to-peer support, didactic training, and problem-solving skill enactment.

Results: Participants' baseline characteristics were the following: mean age 66 (SD 8) years; 14 of 15 (93%) of them were female; all (15/15, 100%) were White; and 8 (53%) of them had at least a postgraduate degree. Throughout the intervention, participants engaged in weekly web-based discussions, generating a total of 434 posts (average 4 posts per week). Attrition was 20% (3/15). Upon study exit, participants showed the following average improvements: 3.0 (SD 6.0) in depression, 8.3 (SD 16.7) in burden, 2.9 (SD 6.8) in stress, and 0.3 (SD 0.8) in loneliness. When looking at the proportion of participants with clinically significant improvement versus those with a worsening of ≥ 0.5 SD for each outcome, we observed net improvements of 50% (6/12), 33% (4/12), 25% (3/12), and 25% (3/12) in depression, loneliness, burden, and stress, respectively. In terms of the benefits of participation, participants reported that participation helped them “a great deal” to (1) improve their understanding of LBD (9/12, 75%), (2) gain confidence in dealing with difficult behaviors of the care recipient (6/12, 50%), and (3) improve in one's abilities to provide care to the care recipient (4/12, 33%).

Conclusions: The study generated promising feasibility and preliminary efficacy data for a low-cost, web-based intervention designed for caregivers of persons with LBD. Though the study was not powered for significance, we observed nominal average and net improvements in important psychological outcomes. Moreover, many caregivers reported that study participation helped them better understand the disease, feel more confident in dealing with difficult behaviors of the care recipient, and improve their ability to care for the care recipient. If validated in future studies, the intervention could be an accessible, on-demand resource for caregivers, enabling them to engage in moderated remote discussions with peers at their own convenience in terms of location, time of the day, and frequency.

Introduction

Lewy body dementias (LBDs), referring to both dementia with Lewy bodies and Parkinson disease dementia (PDD), are the second most common type of degenerative dementia in older adults [1]. These are complex disorders in which patients often exhibit disruptive behaviors that make caregiving challenging [1,2]. Compared to other types of dementia, caregivers of people with LBD report higher stress [3] and more severe depressive symptoms [4]. Many were unsatisfied with the support they received, even in pre-COVID-19 contexts [5]. The ongoing COVID-19 pandemic has multiplied the challenges for family caregivers of persons with LBD [6]. First, changes in daily life, such as limited in-person social contact, can exacerbate neurobehavioral symptoms, causing significant distress to caregivers [7]. Second, as older persons with dementia are especially susceptible to COVID-19 complications [8], caregivers of persons with LBD may engage in more restrictive, prolonged protective practices that affect their own opportunities for peer-to-peer connection, socialization, and physical and cognitive stimulation. Finally, many caregivers rely on support services that could be severely disrupted or even permanently discontinued amid the ongoing pandemic. As such, support interventions that conform to “the new normal” realities in the COVID-19 era for caregivers of persons with LBD are warranted.

A proliferation of interventions for informal caregivers of persons living with dementia has occurred in recent years, including digital interventions focusing on caregiver empowerment and the psychological health [9-13]. However, many of the digital interventions do not account for the unique characteristics of their target users, affecting their effectiveness and implementation potential [14], and still include in-person elements that might be suboptimal in pandemic circumstances. Many lack a fully remote, asynchronous approach that allows on-demand engagement in terms of location, time, and frequency and do not focus on LBD specifically. A fully remote, asynchronous intervention specifically designed for family caregivers of persons living with LBD, leveraging peer-to-peer support, may fill the gap and improve psychological health in this population.

This study examined the feasibility of such an intervention, called Virtual Online Communities for Aging Life Experience-Lewy Body Dementia (VOCALE-LBD), in terms of recruitment, retention, and preliminary efficacy concerning the following psychological outcomes: caregiver burden, depressive symptoms, stress, and loneliness using a quasi-experimental, single-arm, mixed methods design. Owing to the preliminary nature of the study, the quantitative analyses were not powered for significance but were used to examine whether the intervention was associated with trends in the expected directions of the outcome measures. The qualitative data, on the other hand, provided opportunities to better understand participants' experiences with the intervention and areas for improvement.

Methods

Study Design

This was a prospective, one-group, pre-post study to assess the feasibility and preliminary efficacy of a new web-based intervention involving moderation, peer-to-peer support, didactic training, and problem-solving skill enactment. Participants were granted access to the VOCALE-LBD intervention hosted on a private website.

Ethical Considerations

The University of Washington's (UW's) institutional review board (IRB) approved the study protocol (approval 13431). At enrollment, participants provided informed consent to be included in the study.

Participants

Participants were recruited from the Memory and Brain Wellness Center (MBWC) at Harborview Medical Center in Seattle, Washington. The MBWC encompasses both the MBWC clinic and the Alzheimer's Disease Research Center (ADRC) and has been designated as a Lewy Body Dementia Association Research Center of Excellence [15]. The MBWC evaluates over 1000 new patients on an annual basis, and it is the only major academic medical center serving the 5-state region of Washington, Wyoming, Alaska, Montana, and Idaho. The ADRC maintains a continually updated, comprehensive contact list of persons who have signed an IRB-approved consent form to be contacted about participation in research studies conducted by UW-affiliated researchers. Many of the Research Registry members have been evaluated at the MBWC clinic and hence have a recent, reliable clinical diagnosis of specific types of dementia such as Alzheimer disease, Parkinson disease dementia (PDD), Dementia with Lewy bodies (DLB), etc. Family members of clinic patients are also eligible to join the registry. All have expressed willingness to be contacted for potential study participation. Eligibility criteria for this study were as follows: being family or informal caregiver of a person with a diagnosis of LBD; being able to read, write, and speak English; having a device that can access the internet and be used for videoconferencing or telephone calls; and being ≥ 18 years old. Of note, when possible, MBWC clinicians aim to distinguish between DLB and other subtypes of dementia, such as PDD, and to educate patients and their caregivers on the exact diagnosis. As such, most, if not all, study participants cared for people who were highly likely to have a diagnosis of DLB. Participants were compensated up to US \$250 depending on their participation.

Intervention

We adapted a prior social networking intervention that was developed for older adults with prefrailty and frailty, VOCALE [16-18], to the needs of caregivers of individuals with LBD. Similar to our previous studies, the refined intervention included training and moderated web-based discussion components. Training sessions were performed remotely; participants were

introduced to the platform (Figure 1) and described activities to learn how to interact with the discussion board. Weekly thematic discussion prompts (Figure 2 shows an example of a prompt concerning hallucinations) allowed participants to respond to a specific topic of interest at their leisure and provided the participants an opportunity to interact with each other. The first 3 weeks were focused on the most salient LBD caregiving experiences featured in previous literature [5,19,20] and our previous formative work. Briefly, in this formative work, we conducted 8 individual interviews and 2 focus groups with caregivers of persons with LBD to identify relevant topics for the intervention. We used open-ended prompts to elicit ideas that caregivers would be interested in discussing during the study. Sleep problems, hallucinations and delusions, and self-care emerged as the topics of greatest interest and thus became our topics for the first 3 weeks.

The next 5 weeks involved psychoeducational materials based on problem-solving therapy (PST), a cognitive behavioral intervention focused on the adoption and application of adaptive problem-solving attitudes and skills [21]. PST has been used with individuals with different types of problems, including caregivers [22,23] and older adults with other health issues [24]. The intervention also incorporated personas or prototypical

examples of caregivers of persons with LBD (Figure 3 shows an example of a persona). Personas, or representations or archetypes grounded in real data, are often used in user-centered design to help inform product design [25]. In this context, we used personas to enable participants to practice solving realistic problems that they might face. Working with the personas also provided some other potential benefits, such as being able to practice problem-solving without sharing anything too personal, as well as having an outlet to focus on someone besides themselves.

Two research staff members served as the study’s moderators. Both were advanced practice nurses who received moderator training from the study team. Moderators logged in at least 3 times each weekday and at least once per weekend day to review any new comments and add comments to address questions, provide emotional support and validation, encourage dialogue, and redirect discussions as needed to stay on topic. The moderators did not provide any medical advice. Moderators also monitored for comments with inaccurate information and addressed them as needed through private email or discussion board comments. Lastly, moderators sent personalized reminder emails once a week to participants who had not yet posted. They replied to most participants’ comments.

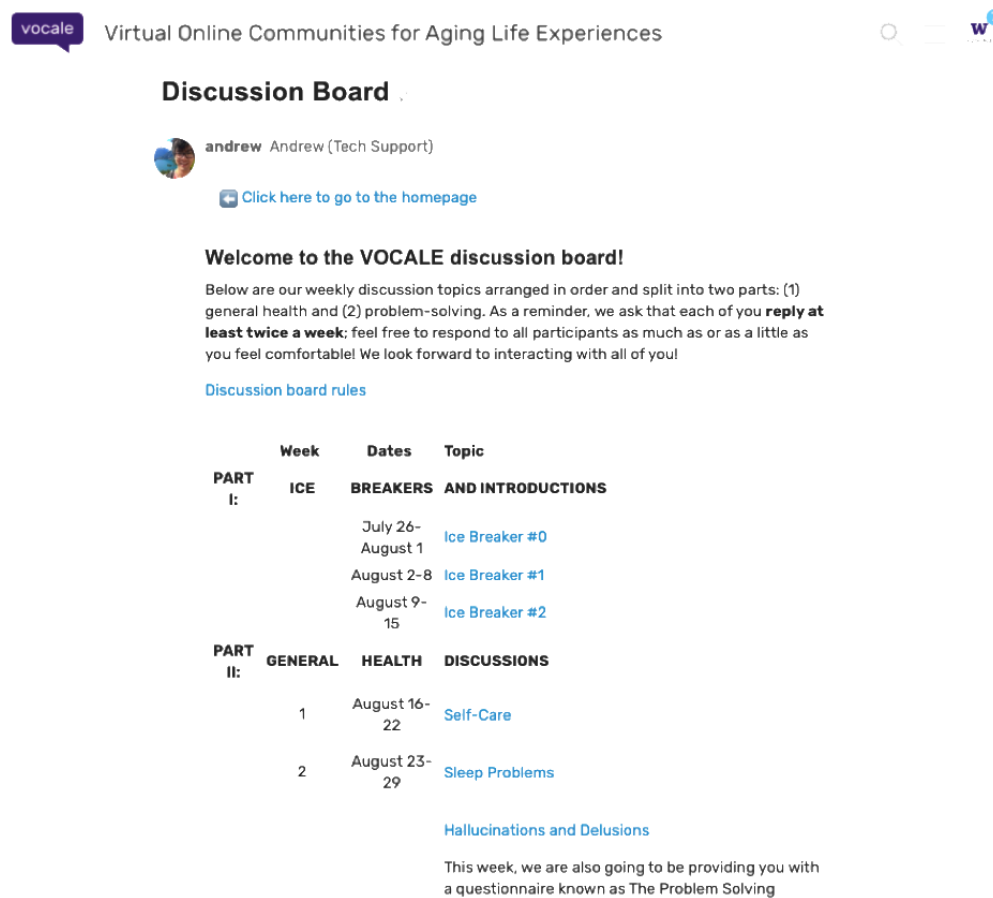

Figure 2. Virtual Online Communities for Aging Life Experience–Lewy Body Dementia sample weekly discussion prompt. LBD: Lewy body dementia.

[Click here to go back to the discussion board](#)

Good morning! Please read the prompt below and respond by clicking the 'Reply' button. As a reminder, we ask that all participants comment **at least twice a week** for full participation. Thank you so much and we look forward to a fruitful discussion!

This week, we are going to talk about hallucinations and delusions, which are common among people with LBD.

Many people with LBD experience visual hallucinations, meaning that they see things that aren't there. For example, someone may think they are seeing an intruder trying to come into the house. Non-visual hallucinations (perhaps involving hearing or smell) are less common but can also occur.

Delusions, which are misguided thoughts or opinions not grounded in reality, are also common with LBD. An example of a delusion is that a relative or caregiver has been replaced by an impostor - this is known as Capgras syndrome.

Both hallucinations and delusions can start off as misperceptions, such as seeing shapes or figures in complex patterns on a rug, or in a pile of leaves. Does your loved one experience either or both of these? Let's discuss. Here are some questions to consider:

- Can you describe some of the hallucinations and/or delusions? How often do they happen?
- What do you do when your loved one experiences hallucinations and/or delusions?
- How have they affected your loved one and yourself?
- Do you have any questions about hallucinations and delusions and what to do about them?
- Is there anything that you wish you knew about how to manage them better?

Click 'Reply' and please comment on your experiences below and respond to other participants.

▼ (1) Pam and Jim (click to expand)

In this scenario, we are going to try and help Pam, a person who is a caregiver for Jim. Jim has Lewy Body Dementia (LBD). We will help Pam with problem-solving. First, let's focus on helping Pam define her problems and her goals. Then, we'll help her solve them.

Pam and Jim

Pam is 69 years old and is a caregiver for her husband Jim, who is 70 years old. Jim needs help all the time. Their adult son, Steve, lives a few minutes away and helps with caregiving too. Pam tries her best to provide good care to Jim, who has a diagnosis of Lewy Body Dementia (LBD) and is experiencing symptoms including memory loss, trouble communicating, visual hallucinations, tremors, and sleep changes. Jim also has high blood pressure and diabetes.

Because of Jim's symptoms, Pam has to be by his side almost all the time during the day. Pam also often has to help Jim overnight. Recently, Pam started to experience pain in her back and joints. This affects her ability to take care of Jim. Pam is a bit frustrated about this. Even though life has become more difficult for Pam, she tries not to tell their children about her concerns because she does not want to be a burden.

Details about Pam:

- **Support community:** Husband, adult son
- **Personality:** Not very social
- **Location of residence:** House in a town in WA state
- **Health symptoms:** Joint and back pain, trouble sleeping
- **Technology access:** Uses a computer every day to play solitaire
- **Sources of health information:** TV, healthcare providers
- **Goals:** Improve ability to take care of Jim and manage her own health

Data Collection Procedures

All data collection sessions in this pilot were virtual and took place on Zoom. The study team collected data using Research Electronic Data Capture (REDCap) [26], a web-based survey platform, at 2 time points: baseline and post intervention. At

baseline, the research coordinator provided training on the discussion board website and administered a set of demographic and clinical questionnaires (described in *Measures*). The second postintervention assessment occurred between weeks 9 and 10 and included another set of questionnaires and exit interviews. Exit interviews lasted approximately an hour each and were

conducted with a semistructured interview guide that asked for caregiver feedback on topics including various program components, whether people felt a sense of community or support, what was learned or gained from the discussion, and motivations to participate. Caregivers were also given the opportunity to provide any additional feedback or suggestions.

Measures

Depressive Symptoms

We used the 20-item version of the Center for Epidemiologic Studies Depression (CES-D) Scale to assess depression [27]. For each statement, respondents indicated how often they felt depressed during the past week using a scale from 0=rarely or never to 3=most or all of the time. Scores could range from 0 through 60, with higher scores indicating an increased presence of depression symptoms.

Caregiver Burden

We used the full 22-item version of the Zarit Caregiver Burden Interview [28]. Caregivers rated each item on a 5-point scale from 0=never to 4=nearly always, yielding a possible range of 0 to 88. Higher values indicated greater levels of caregiver burden.

Perceived Stress

We used the full 10-item version of the Perceived Stress Scale [29]. Caregivers rated each item on a 5-point scale from 0=never to 4=very often, yielding a possible range of 0 to 40. Higher values indicated greater perceived stress.

Loneliness

We used a short 3-item version of the Revised UCLA Loneliness Scale [30]. Its possible range was from 0 to 6 with higher scores indicating greater loneliness.

Social Support

We used a 9-item questionnaire from the Medical Outcomes Study [31]. The questionnaire was designed to assess the amount of social support the participant had available. Responses were scored on a 5-point scale ranging from “none of the time” to “all of the time.” We computed total social support scores by summing the scores for all items after recoding responses. Scores could range from 0 through 45, with higher scores indicating increased social support.

Self-efficacy

We used a 5-item Health Self-Efficacy Measure [32]. For each statement, respondents indicated their level of agreement concerning their health management using a scale from 0=strongly disagree to 4=strongly agree. Scores could range from 0 through 20, with higher scores indicating stronger health self-efficacy.

Benefits of Participation

On conclusion of the study, we asked all caregivers 4 questions adapted from the REACH II study [33] about ways in which they benefited from participating in the study. Specifically, we asked whether their participation helped improve their understanding of LBD, improve their confidence and ability to deal with difficult behaviors of the care recipient, and make their caregiving life easier. The response options for each question were “not at all,” “some,” and “a great deal.”

Data Analysis

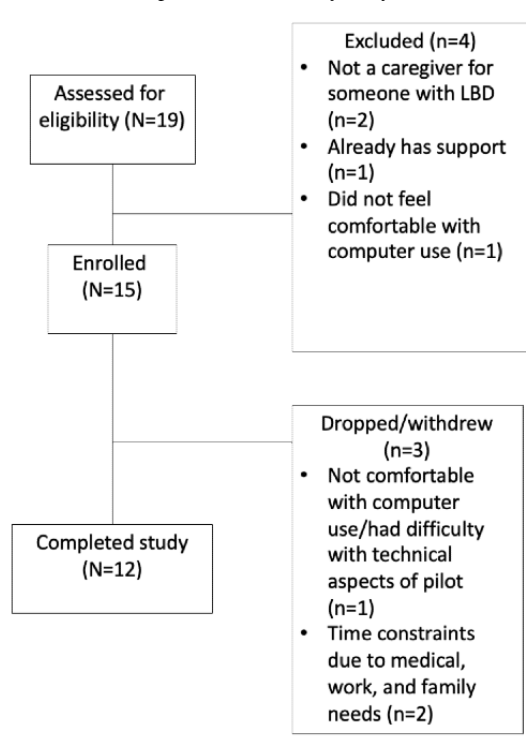

Descriptive statistics summarized demographics at baseline and outcome distributions by measurement occasions. We also calculated mean (SD) pre- and postintervention change scores for each of the measurements. Next, for each outcome, we calculated the number and percentage of individuals who improved by at least 0.5 SD from baseline to post intervention, and the number and percentage of those who worsened by at least 0.5 SD, and then we subtracted the former from the latter to calculate a net improvement score. We also calculated the number and percentage of individuals selecting response options from the benefit of the participation questionnaire.

Exit interviews were recorded and transcribed verbatim. We analyzed the data using an inductive method adapted from previous research concerning digital interventions for behavioral change [34]. The research team reviewed transcripts line by line and then created a table to organize interview data at the participant level into categories. Categories were based on the interview guide, such as motivations to participate in the study, what was learned from the experience, and participants' thoughts on different program components. Suggestions, critiques, and other comments from participants were categorized as actionable, not actionable, or needing further discussion and consideration in the future. After each participant's interview, data were added to the table, and common responses were tabulated. Data abstraction was performed by JK, and all the coauthors participated in the review of the table.

Results

Participants

Of the 19 potential candidates screened, 15 were eligible, consented to the study, and provided baseline data (Figure 4). A total of 3 participants left the study at weeks 2, 3, and 5, which yielded a total of 12 participants who completed the full protocol, resulting in an 80% retention rate. Table 1 summarizes the baseline data. The mean participant age was 66 (SD 8) years, all participants (n=15, 100%) were White, and 93% (14/15) were female. In total, 8 (53%) participants had at least a postgraduate degree, and 80% (12/15) of the participants provided more than 40 hours of care per week.

Figure 4. Flowchart for study screening, enrollment, and completion. LBD: Lewy body dementia.**Table 1.** Participant demographics (baseline; N=15).

Variables	Values
Sex, n (%)	
Female	14 (93)
Male	1 (7)
Age (years), mean (SD)	65.8 (8.3)
Caregiver relationship: spouse or partner, n (%)	15 (100)
White, not of Hispanic/Latino ethnicity, n (%)	15 (100)
Education level, n (%)	
High school diploma or General Educational Development	3 (20)
Vocational or associate's degree	3 (20)
Baccalaureate degree	1 (7)
Master's degree	5 (33)
Doctoral degree	3 (20)
Time spent as a caregiver (years), mean (SD)	3.8 (2.5)
Average care time per week, n (%)	
Up to 8 hours	1 (7)
20-39 hours	2 (17)
≥40 hours	12 (80)
Computer comfort level, n (%)	
Very uncomfortable	2 (17)
Neutral	1 (7)
Somewhat comfortable	6 (40)
Very comfortable	6 (40)

Data, Measures, and Analysis

Table 2 summarizes engagement metrics over time. Throughout the intervention, participants engaged in weekly web-based discussions, generating a total of 434 posts (average of 4 posts per week). On study exit (**Table 3**), participants showed the following mean improvements: 3.0 (SD 6.0) in depression, 8.3 (SD 16.7) in burden, 2.9 (SD 6.8) in stress, and 0.3 (SD 0.8) in loneliness. When we calculated differences in the proportion of participants with clinically significant improvement versus those with a worsening of ≥ 0.5 SD for each outcome (**Table 4**), we observed net improvements of 50% (6/12), 35% (4/12), 25% (3/12), and 25% (3/12) in depression, loneliness, burden, and stress, respectively. When we assessed the benefits of participation (**Table 5**), 75% (9/12) of the participants reported that participation helped them “a great deal” to improve their understanding of LBD compared to 25% (3/12) of them selecting the “some” response option. Similarly, in response to the question about confidence in dealing with difficult behaviors of the care recipient, 50% (6/12) of the participants selected “a great deal,” 42% (5/12) of them selected “some,” and 8% (1/12) of them selected “not at all.” Finally, in response to a question about improvement in one’s abilities to provide care to the care recipient, 33% (4/12) of the participants selected “a great deal,” 58% (7/12) of them selected “some,” and 8% (1/12) of them selected “not at all.”

Qualitative data from the exit interviews showed that of the 12 participants who completed the pilot, 92% (11/12) of them

reported they had a positive experience. All participants noted that they felt supported by other participants. Motivations for participating in the study included the following: wanting to support others (4/12, 33%), wanting to interact with others in similar situations and obtain feedback (6/12, 50%), and contributing to research (4/12, 33%).

When asked what they learned or gained from the pilot, 50% (6/12) of the participants mentioned the opportunity to hear from others who were caregivers of people with LBD, and 83% (10/12) of them discussed learning from others, such as solutions and strategies that others have used. Two-thirds (8/12, 67%) of participants felt that the problem-solving elements of the pilot were helpful. One-fourth (3/12, 25%) of participants felt that their baseline problem-solving skills were already robust; therefore, the intervention did not contribute to improvement. One-third (4/12, 33%) of participants did not feel that the intervention’s problem-solving framework was helpful, with 2 participants (17%) mentioning that they felt the framework was difficult to apply in real life. All participants offered constructive feedback regarding the personas. For example, one-third (4/12, 33%) of participants felt that they could not relate to one or both personas, and one-third (4/12, 33%) of them felt that the personas needed to be fleshed out with more details to be useful. Over half (7/12, 58%) of the participants would have preferred to discuss participants’ actual problems rather than those of the personas.

Table 2. Participant engagement (posts per week).

Participant ID	Posts, n								Total posts, n

Table 3. Baseline, postintervention, and change scores (N=15).

Parameters	Baseline, mean (SD)	Postintervention (n=12), mean (SD)	Change (n=12), mean (SD)
Depressive symptoms	13.3 (9.0)	10.9 (9.9)	-3.0 (6.0)
Health self-efficacy	21.5 (3.3)	21.8 (3.6)	-0.6 (4.3)
Perceived stress	16.2 (7.2)	13.0 (9.0)	-2.9 (6.8)
Loneliness	5.4 (1.7)	5.0 (1.7)	-0.33 (0.8)
Social support	32.3 (7.9)	33.08 (7.1)	-0.33 (4.2)
Caregiving burden	39.1 (10.8)	36.3 (17.0)	-8.3 (16.6)

Table 4. Clinically significant changes^a (N=12).

Variable	Improved, n (%)	Worsened, n (%)	Net improvement ^b , n (%)
Depressive symptoms	8 (70)	2 (17)	6 (50)
Health self-efficacy	3 (25)	4 (33)	-1 (-8)
Perceived stress	5 (42)	2 (17)	3 (25)
Loneliness	4 (33)	0 (0)	4 (33)
Social support	3 (25)	2 (12)	1 (8)
Caregiving burden	5 (42)	2 (17)	3 (25)

^aClinically significant improvement and worsening was defined as an unadjusted standardized change of ≥ 0.5 SD from baseline to follow-up.

^bNet improvement = participants who improved – participants who worsened.

Table 5. Benefits of participating in the study (N=12).

Question or response categories	Participants, n (%)
1. Did your participation in the study help you better understand Lewy Body Dementia?	
Not at all	0 (0)
Some	3 (25)
A great deal	9 (75)
2. Did your participation in the study help you feel more confident in dealing with difficult behavior of the care recipient?	
Not at all	1 (8)
Some	5 (42)
A great deal	6 (50)
3. Did your participation in the study help make your life easier?	
Not at all	2 (17)
Some	7 (58)
A great deal	3 (25)
4. Did your participation in the study help your ability to care for care recipient?	
Not at all	1 (8)
Some	7 (58)
A great deal	4 (33)

Discussion

Principal Findings

The study generated promising preliminary feasibility and efficacy data for a fully remote intervention designed specifically for family caregivers of persons with LBD.

Enrollment and retention were successful, with the study experiencing only a 20% dropout rate. Our study showed retention rates similar to or better than those reported in other recent studies of digital interventions for family caregivers of persons with dementia [14]. A pooled estimate from recent studies that mainly recruited spousal caregivers [9-13] reported an average 66% retention rate, compared to the 80% retention

rate reported in this study. Moreover, in the exit interviews, participants confirmed that the experience of participating in the study was valuable and motivated them to continue participating. As the study was not powered for statistical significance, we observed nominal average and net improvements in important psychological outcomes. Additionally, many caregivers reported that study participation helped them better understand the disease, feel more confident in dealing with difficult behaviors of the care recipient, and improve their ability to care for the care recipient. These encouraging results concerning improvement in psychological measures are on par with those of the hallmark REACH II trial [35], which, according to the recent AHRQ [36] and NASEM [37] reports, meets the threshold for an evidence-based intervention for family caregivers of a person with dementia. Given that VOCALE-LBD and the REACH II protocol share similar elements, such as the provision of information, didactic instruction, role-playing, problem-solving, and skills training, in this era of increased demand for fully remote interventions, this pilot program seems well suited for further research and evaluation.

In this pilot study, we found nominal average and net improvements in important psychological outcomes, similar to changes observed in the hallmark REACH II trial. Specifically using the same approach to calculate clinically significant net improvements, the REACH II trial reported an approximately 30% improvement in depression and 10% in burden in a comparable intervention subgroup in terms of race and ethnicity. Moreover, in terms of benefits of participation, 58% of the participants in the White/Caucasian REACH II intervention subgroup asserted that the intervention helped them understand memory loss a great deal, and similarly, 59% of them asserted that the intervention helped them to some extent to feel more confident in dealing with the care recipient. Our results of 50% and 30% net improvement in depression and burden, respectively, and 75% and 50% endorsements in benefits for participation fall within the upper bound of the REACH II results. As such, pending further research, one cautious interpretation is that the VOCALE-LBD remote intervention for family caregivers of persons with LBD holds promise for further development and evaluations.

Despite the full-time caregiving demands of our study participants, all but 3 participants completed the 8-week intervention (9/12, 80%). The platform is designed to promote convenience and accessibility, allowing the user to engage within the weekly interval at times of day and frequencies based on their own preferences. We are aware of only 5 web-based intervention studies since 2015 in the dementia caregiving context that recruited mostly spousal caregivers. A study by Pot et al [9] included approximately 60% spousal caregivers and had a 44% retention rate. A study by Gustafson et al [10] included approximately 90% spousal caregivers and had an 84% retention rate. A study by Boots et al [11] included

approximately 98% spousal caregivers and had a 61% retention rate. A study by Blom et al [12] included approximately 58% spousal caregivers and had a 70% retention rate. A study by Griffiths et al [13] included approximately 73% spousal caregivers and had a 73% retention rate. There may be various factors accounting for the 80% retention rate and engagement throughout this study. At the outset, because participants were recruited from a study registry, they are likely to demonstrate greater motivation and desire to participate. However, participants also commented that they appreciated the sense of community and connection among their peers, as well as the local context of the intervention (all participants were from the Pacific Northwest, with almost all from Washington state). On several occasions, participants discussed local resources and programs and even suggested plans to meet after the end of the study.

Limitations

This study has some limitations, which also suggest potential future directions. The effects of the intervention, although promising, must be interpreted with caution as the study was not powered for significance and did not include a control group. Moreover, the study focused on immediate health benefits without evaluating whether the changes were sustained over time. Eligible participants were part of a research registry and needed to have access to the internet. Although today, almost 70% of older adults have access to the internet [38], those who do not may respond differently to the intervention. A lack of racial or ethnic and gender diversity is a notable limitation, and there is a need to explore how caregivers of persons with LBD with other racial or ethnic and gender characteristics might experience VOCALE-LBD. Some participants had trouble relating to the personas and expressed a desire for skill enactment to be more focused on their real-life experiences, suggesting a need in future work to incorporate skill enactment activities more into participants' own lives. Finally, this study was subject to the common limitations of research involving self-report.

Conclusions

In this study, we performed a pilot evaluation of an innovative digital intervention that empowers caregivers of persons with LBD by providing a support network and enabling them to develop and improve problem-solving skills that they can use for daily challenges. If validated in future studies, the intervention could be an accessible, on-demand resource for caregivers to engage in moderated remote discussions with their peers at their own convenience in terms of location, time of the day, and frequency. The intervention could be used in conjunction with caregiver usual care and as a stand-alone module in circumstances, such as current and future pandemic emergencies when routine professional interventions might not be readily available.

Abstract

Background: There is an ongoing discussion about possible differences between insulin degludec (IDeg-100) and glargine U300 (IGlar-300). There is little data and head-to-head comparison of IDeg-100 and IGlar-300 regarding their simultaneous impact on glycemic variability and oxidative stress in patients with type 2 diabetes mellitus (T2DM).

Objective: In our randomized, open-label, crossover study, we compared the impact of IDeg-100 and IGlar-300 on glycemic variability and oxidative stress in insulin-naive patients with T2DM.

Methods: We recruited a total of 25 adult patients with T2DM (7 females) whose diabetes was uncontrolled ($HbA_{1c} \geq 7.5\%$) on two or more oral glucose-lowering drugs; a total of 22 completed the study. Mean age was 57.3 (SD 6.99) years and duration of diabetes was 9.94 (SD 5.01) years. After the washout period, they were randomized alternately to first receive either IDeg-100 or IGlar-300 along with metformin. Each insulin was administered for 12 weeks and then switched. At the beginning and end of each phase, biochemical and oxidative stress parameters were analyzed. On 3 consecutive days prior to each control point, patients performed a 7-point self-monitoring of blood glucose profile. Oxidative stress was assessed by measuring thiol groups and hydroperoxides (determination of reactive oxygen metabolites test) in serum.

Results: IGlar-300 reduced mean glucose by 0.02-0.13 mmol/L, and IDeg-100 reduced glucose by 0.10-0.16 mmol/L, with no significant difference. The reduction of the coefficient of glucose variation also did not show a statistically significant difference. IGlar-300 increased thiols by 0.08 $\mu\text{mol/L}$ and IDeg-100 increased thiols by 0.15 $\mu\text{mol/L}$, with no significant difference ($P=.07$) between them. IGlar-300 reduced hydroperoxides by 0.040 CARR U and IDeg-100 increased hydroperoxides by 0.034 CARR U, but the difference was not significant ($P=.12$).

Conclusions: The results of our study do not show a significant difference regarding glycemic variability between patients receiving either insulin IDeg-100 or IGlar-300, although IGlar-300 showed greater dispersion of data. No significant difference in oxidative stress was observed. In a larger study, doses of insulins should be higher to achieve significant impact on glycemic parameters and consequently on glycemic variability and oxidative stress.

Introduction

Background

Global diabetes prevalence in 2019 is estimated to be 9.3% (463 million people), rising to 10.2% (578 million) by 2030 and 10.9% (700 million) by 2045 [1].

The main feature of diabetes mellitus of all types is dysglycemia, which consists of two main components: chronic sustained hyperglycemia and acute glycemic fluctuations from peaks to nadirs. Although disputed by some authors [2], it is generally considered that both components contribute to diabetes complications through two main mechanisms—excessive protein glycation and activation of oxidative stress [3]—with glycemic variability being more specific in having an effect on oxidative stress than chronic sustained hyperglycemia [4], as both upward (postprandial glucose increments) and downward (interprandial glucose decrements) changes activate the oxidative stress pathway [5].

Glucose fluctuations gradually increase from normal glucose metabolism to impaired glucose regulation and diabetes mellitus. Intraday glucose variability occurs at the early stage of abnormal glucose tolerance. In addition to elevated intraday glucose fluctuations, newly diagnosed, drug-naive patients with type 2 diabetes mellitus (T2DM) also demonstrate increased postprandial glucose excursions, higher glucose levels overnight, and more interday fluctuations [6].

The main purpose of insulin therapy in diabetes mellitus is to control glucose—in other words, to combat dysglycemia. Long-acting basal insulin analogues (insulin glargine U100, insulin detemir) significantly improved diabetes management, providing longer duration, flatter profiles of action, lower risk of hypoglycemia, and less glycemic variability compared to NPH (Neutral Protamine Hagedorn) insulin [7,8].

The second generation of basal insulin analogues—insulin degludec 100 units/mL (IDeg-100) and insulin glargine 300 units/mL (IGlar-300)—have even smoother pharmacokinetic/pharmacodynamic profiles than insulin glargine U100, are longer acting, and further lower glycemic variability, at least in patients with T1DM [9,10].

Although several studies [11-13] have compared the impact of these two second-generation basal insulin analogues on glycemic variability in patients with type 1 diabetes mellitus (T1DM),

there is little data and head-to-head comparison of IDeg-100 and IGlar-300 regarding their simultaneous impact on glycemic variability and oxidative stress in patients with T2DM. In addition, the results from the T1DM studies are inconsistent [12,13].

Aim of the Study

In this initial study, we compared the impact of IDeg-100 and IGlar-300 on glucose variability and oxidative stress (represented through its surrogate markers) in insulin-naive patients with T2DM. The main research question was whether there is any difference between the two insulins regarding these parameters. The results of this study should inform a larger study comparing these two insulins.

Methods

Ethics Approval and Consent to Participate

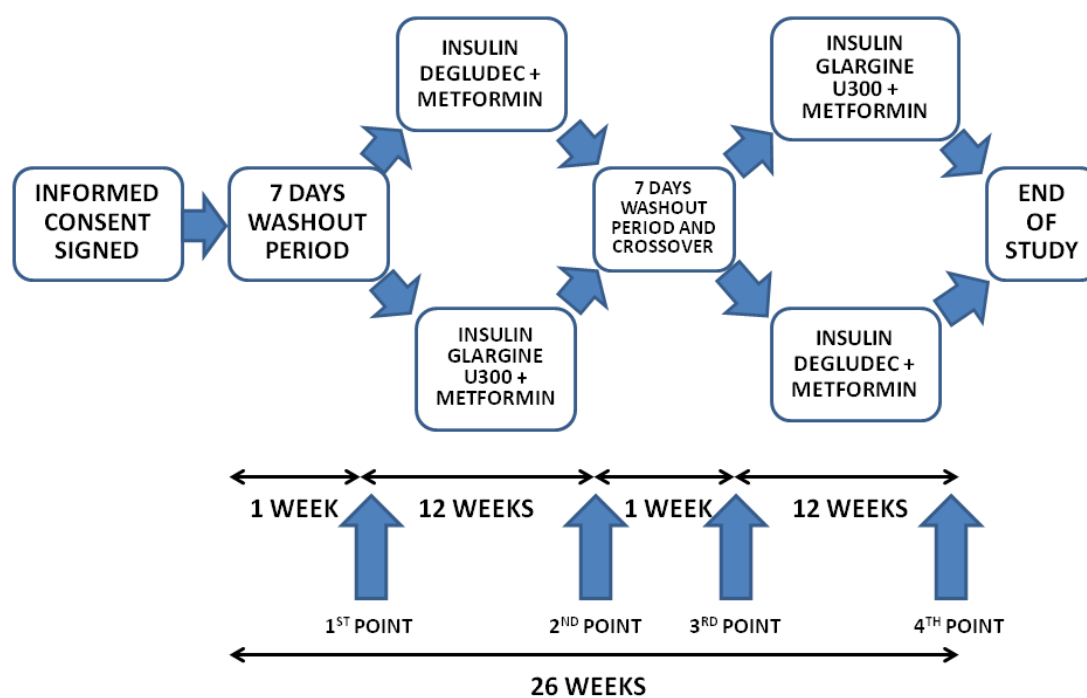

This randomized, open-label, crossover study was conducted in accordance with the Declaration of Helsinki and approved by the Ethics Committee of the University of Split School of Medicine (number 2181-198-03-04-17-0045). All subjects gave written consent prior to their participation in the study.

Study Protocol and Population

Between December 2018 and May 2019, we recruited 25 outpatient insulin-naive patients with uncontrolled T2DM (glycated hemoglobin [HbA_{1c}] \geq 7.5% on two or more oral glucose-lowering drugs) and assigned them to either degludec insulin or glargine U300 insulin combined with metformin. All patients were recruited and treated at University Hospital Split, Croatia. All patients finished the study, but only 22 were analyzed (3 patients were excluded from data analysis—one patient did not perform his 7-point self-monitoring of blood glucose (SMBG) profile 3 days prior to control points, one patient decided to continue with his oral glucose-lowering agents only, and one patient left the study for personal reasons). Basal characteristics of the participants studied are shown in [Table 1](#). The protocol of the study is shown in [Figure 1](#). The study adheres to CONSORT (Consolidated Standards of Reporting Trials) guidelines ([Multimedia Appendix 1](#) displays the CONSORT flow diagram). Patients and the public were not involved in the design, conduct, reporting, or dissemination plans of our research. The trial was retrospectively registered on ClinicalTrials.gov on December 31, 2020 (NCT04692415).

Table 1. Basal clinical characteristics of patients (N=25).

Parameter	Mean (SD)
Age (years)	56.23 (8.09)
Duration of diabetes (years)	8.90 (5.05)
Body weight (kg)	89.02 (13.82)
Body height (cm)	176.20 (10.03)
BMI (kg/m ²)	28.92 (3.89)
Waist circumference (cm)	102.84 (8.56)
Glycated hemoglobin (HbA _{1c}), %	9.66 (1.65)
Fasting glucose (mmol/L)	13.02 (4.47)
Serum creatinine (μmol/L)	68.24 (13.15)
Serum uric acid (μmol/L)	310.04 (60.75)
Total cholesterol (mmol/L)	5.28 (1.46)

Figure 1. The study protocol.

Patients who were eligible for the study fulfilled all of the following inclusion criteria: history of T2DM for at least 1 year, aged between 45 and 65 years (women obligatory in postmenopause and with no hormonal replacement), uncontrolled glycemia on two or more oral antidiabetic drugs, no prior use of insulin, HbA_{1c} ≥7.5%, receiving statins (if not on statins, they were put on it), not on antiaggregant therapy (if on antiaggregants, they were temporarily excluded from therapy).

Exclusion criteria were the following: the use of glitazones or anticoagulant therapy, renal impairment with creatinine clearance <60 mL/s, presence of malignant disease, chronic liver disease, severe cardiovascular disease and history of cardiovascular incidents (stroke, myocardial infarction, peripheral amputation), and rheumatic and autoimmune diseases.

All participants were asked to avoid the consumption of vitamin supplements, coffee, wine, and Coca-Cola and similar beverages, especially in the days before each control point. Patients were also asked to avoid intensive physical activity up to two days before each control point. All subjects were told to report any side effects immediately, and were given the telephone numbers of the study conductors for this purpose. At each control point, participants were asked about possible side effects.

At baseline, all patients discontinued their previous therapy and were given metformin alone (2 g/day) for 7 days (washout period). After the 7-day washout period, they were randomized alternately by investigators (1:1 ratio) to first receive either IDeg-100 or IGLar-300 subcutaneously according to the order they were included in the study. In phase one, they received either IDeg-100 or IGLar-300 combined with metformin for 12

weeks. Phase one was followed by a second washout period in which patients received metformin alone again for 7 days. Finally, in phase two, which also lasted for 12 weeks, patients were switched from IDeg-100 to IGlax-300 and vice versa (and metformin was continued). The initial dose of both insulins was 0.2 IU/kg. We did not change the dose of insulin during the study period to avoid hypoglycemia, which could significantly influence the results [14-16].

At the beginning and end of each phase, blood samples were collected for the analysis of standard biochemical and oxidative stress parameters (control points 1-4). On 3 consecutive days prior to each control point (at the beginning and the end of each phase), patients completed the 7-point SMBG profile. All patients were already experienced with the use of SMBG [17].

Glucose Measurement

To standardize results, all patients received a standard Bionime GM550 glucose meter. They were asked to regularly check their blood glucose 1-2 times per day during the entire study and, in the 3 consecutive days prior to each control point, to perform the 7-point SMBG profile. The 7-point blood glucose profile consisted of seven measurements: (1) before breakfast, (2) 2 hours after breakfast, (3) before lunch, (4) 2 hours after lunch, (5) before dinner, (6) 2 hours after dinner, and (7) before sleeping. Glucose variability was determined by calculating mean glycemia, SD, and coefficient of variation (CV) for each control point [17,18].

Standard Laboratory Measurement

Serum uric acid concentrations, serum creatinine, total cholesterol, serum bilirubin values, and other basic biochemical laboratory values were determined by Olympus AU 600 Chemistry Analyzer (Olympus Michima Co Ltd) and enzymatic laboratory kit.

Oxidative Stress Measurement

Thiol groups were assayed according to the Ellman assay [19], modified by Hu [20]. In detail, 100 μ L of plasma was diluted with 2 mL of Tris-EDTA buffer (0.1 mol/L Tris, 1 mmol/L EDTA, pH 8.2), and mixed with 100 μ L of 10 mM DTNB (5,5'-dithiobis(2-nitrobenzoic acid)), previously prepared in methanol. To subtract the absorbance of plasma and DTNB at 412 nm, two parallel blank samples were assembled. The first one ("blank sample") was prepared by mixing 2.1 mL of Tris-EDTA buffer with 100 μ L of plasma and the second one ("blank reagent") was prepared by mixing 2.1 mL of Tris-EDTA buffer with 100 μ L of DTNB. All measurements were performed in triplicate and blanks were run for each sample. Readings were taken spectrophotometrically (Lambda 25; Perkin Elmer) at 412 nm after 15 minutes of reaction at 25 °C. Results were compared with a standard curve prepared daily with different concentrations of glutathione and expressed as μ mol/L of glutathione.

The determination of reactive oxygen metabolites (d-ROM) assay measures the concentration of total hydroperoxides in serum or heparin plasma. The method was first described by Alberti et al in 1999 [21] and modified by Verde et al [22], and this modified assay was used to determine d-ROM values in plasma in this study. Each sample was prepared by mixing 2 mL of 0.1 M sodium acetate buffer (pH 4.8) and 20 μ L of 0.1 M DMPD (N,N-diethyl-p-phenylenediamine) with 10 μ L of plasma. After preparation, tubes with samples were vortexed for 15 seconds and incubated in a thermomixer (Thermomixer comfort, Eppendorf) at 37 °C and 1000 revolutions per minute for 75 minutes. All measurements were performed in triplicate and blanks were run for each sample. Readings were taken spectrophotometrically (Lambda 25; Perkin Elmer) at 505 nm after incubation. Results were compared with a standard curve prepared daily with different concentrations of H₂O₂. The results are expressed in CARR U (Carratelli units), where 1 CARR U corresponds to 0.08 mg/100 mL H₂O₂.

Statistical Analysis

The number of subjects to include in the protocol was selected according to previously published literature [4,23]. Statistical analyses were performed using Statistica 6.0 (StatSoft Inc). Two-way ANOVA for repeated measures was used to evaluate changes in plasma glucose levels, CV, plasma thiols, and hydroperoxides due to IDeg-100 and IGlax-300.

Results

Out of 25 randomized patients, 3 patients were excluded from data analysis—one patient did not perform his 7-point SMBG profile 3 days prior to control points, one patient decided to continue with his oral glucose-lowering agents only, and one patient left the study for personal reasons. No adverse reactions or unintended effects were noticed.

A total of 22 patients (7 females) successfully completed the trial, and their mean basal values were as follows: age, 57.3 (SD 6.99) years; duration of diabetes, 9.94 (SD 5.01) years; body weight, 88.25 (SD 13.57) kg; body height, 174.95 (SD 9.67) cm; BMI, 29.10 (SD 3.80) kg/m²; waist circumference, 102.73 (SD 8.02) cm; HbA_{1c}, 9.60% (SD 1.68%); fasting glucose, 13.20 (SD 4.48) mmol/L; serum creatinine, 66.0 (SD 2.09) μ mol/L; serum uric acid, 305.32 (SD 62.60) μ mol/L; total cholesterol, 5.05 (SD 1.12) mmol/L.

On the first of 3 consecutive days of 7-point SMBG, performed at the end of the observed period, IGlax-300 and IDeg-100 reduced mean glucose values by 0.02 and 0.16 mmol/L, respectively, which was statistically insignificant ($P=0.06$; 95% CI 0.003 to 0.28); there was also no significant difference between the two insulins ($P=0.17$; 95% CI -0.10 to 0.46) (Figure 2A).

Figure 2. Mean glucose change, SD, and CV on the first, second, and third day. CV: coefficient of variation; IDeg-100: insulin degludec; IGLar-300: insulin glargine U300. A) Mean glucose change on the first day. B) SD of glucose change on the first day. C) CV of glucose change on the first day. D) Mean glucose change on the second day. E) SD of glucose change on the second day. F) CV of glucose change on the second day. G) Mean glucose change on the third day. H) SD of glucose change on the third day. I) CV of glucose change on the third day.

The SD of glucose excursions was 0.36 for IGLar-300 and 0.06 for IDeg-100, which was not significant ($P=.20$; 95% CI -0.27 to 0.87); in addition, there was no statistically significant difference between the two insulins ($P=.07$; 95% CI -1.07 to 1.22) (Figure 2B).

The CV on the first day was 0.37 (37%) for IGLar-300 and 0.21 for IDeg-100, which was statistically insignificant ($P=.22$; 95% CI -0.30 to 0.63). When compared, CV for these two insulins was not significantly different ($P=.20$; 95% CI -0.73 to 1.15) (Figure 2C).

On the second of the 3 days of 7-point SMBG, performed at the end of the observed period, IGLar-300 and IDeg-100 reduced mean glucose by 0.03 and 0.10 mmol/L, respectively, which was statistically insignificant ($P=.08$; 95% CI -0.09 to 0.24); there was also no significant difference between the two insulins ($P=.07$; 95% CI -0.41 to 0.26) (Figure 2D).

The SD of glucose excursions on the second day was 0.12 for IGLar-300 and -0.05 for IDeg-100, which was insignificant ($P=.19$; 95% CI -0.23 to 0.59); when we compared the SD of the two insulins, there was no significant difference ($P=.17$; 95% CI -1.00 to 0.65) (Figure 2E).

The CV for the second day was 0.24 (24%) for IGLar-300 and 0.04 for IDeg-100 and that was statistically insignificant ($P=.20$; 95% CI -0.24 to 0.63). When compared, CV for the two insulins was not significantly different ($P=.08$; 95% CI -0.96 to 0.78) (Figure 2F).

On the third (last) day of the SMBG, the insulins reduced mean glucose levels by 0.04 (IGlar-300) and 0.11 mmol/L (IDeg-100), which was statistically insignificant ($P=.08$; 95% CI -0.10 to 0.24), again without a significant difference between the two insulins ($P=.20$; 95% CI -0.55 to 0.14) (Figure 2G).

The SD of glucose concentrations on the third day was 0.13 for IGLar-300 and -0.09 for IDeg-100, which was insignificant ($P=.18$; 95% CI -0.15 to 0.61), and comparison of the SD of the two insulins revealed no statistical difference ($P=.14$; 95% CI -0.62 to 0.91) (Figure 2H).

The CV on the third day was 0.19 for IGLar-300 and -0.01 for IDeg-100, which was statistically insignificant ($P=.16$; 95% CI -0.14 to 0.55). When compared, CV for these two insulins was not statistically different ($P=.54$; 95% CI -1.23 to 0.14) (Figure 2I).

Figure 3. Changes in plasma thiols and hydroperoxides. GSH: glutathione; IDeg-100: insulin degludec; IGLar-300: insulin glargine U300. A) Changes in plasma thiols. B) Changes in plasma hydroperoxides.

Discussion

Principal Findings

Since the new generation of insulin analogues, degludec and glargine U300, appeared on the market, there has been an ongoing discussion about the possible advantages of one insulin over the other. The majority of comparisons related to the incidence of hypoglycemia [7,19,21-23], as well as the absorption stability and profile flatness, as possible causes of differences in hypoglycemia tendency were compared [7,13,24].

Absorption stability and profile flatness, if different, should lead to a difference in glycemic variability between the two insulins as variability in insulin absorption represents an important source of glucose variability in these subjects. Variability can relate to the insulin preparation, the injection technique, and the individual [25].

Glycemic variability and the incidence of hypoglycemia are the elements that “upgraded” the diabetological paradigm from the “diabetic triad” (HbA_{1c}, fasting glycemia, and postprandial glycemia) to the “diabetic pentad” (HbA_{1c}, fasting glycemia, postprandial glycemia, hypoglycemia, and glycemic variability) or even “hexad,” if quality of life is included [26].

The final consequences of increased glycemic variability and long-lasting hyperglycemia, as mentioned in the Introduction section, are diabetic complications, both micro- and macrovascular. As glycemic variability contributes to an increase in oxidative stress (one of two main mechanisms leading to the development of diabetic complications) to a greater extent, the need for the comparison of glycemic

IGlar-300 increased thiol levels by 0.08 μmol/L and IDeg-100 increased thiol levels by 0.15 μmol/L ($P=.07$; 95% CI -0.21 to 0.08). No significant difference was found between the two insulins regarding the increase of thiols ($P=.14$; 95% CI -0.15 to 0.44) (Figure 3A).

Although IGLar-300 decreased hydroperoxides by 0.04 CARR U, and IDeg-100 increased hydroperoxides by 0.034 CARR U ($P=.06$; 95% CI -0.19 to 0.05), this impact was not statistically significant, and there was no significant difference between the two insulins ($P=.12$; 95% CI -0.13 to 0.37) (Figure 3B).

variability measures and oxidative stress markers in patients exposed to IDeg-100 and IGLar-300 emerges.

Two large, recently published studies (BRIGHT and DELIVER D+), although different in design, found “more similarities than differences” using IDeg-100 and IGLar-300. On the other hand, another large study (CONFIRM) attributed some advantages to IDeg-100. However, these studies, with the exception of the BRIGHT study, focused primarily on hypoglycemia rate and HbA_{1c} outcomes [27-29]. In this study, we wanted to associate glycemic variability with its ultimate consequence—oxidative stress.

Oxidative stress causes the development of diabetic complications through 5 main molecular mechanisms: the polyol pathway, the hexosamine pathway, increased formation of advanced glycation end products, increased expression of the receptors for advanced glycation end products and their activating ligands, and activation of protein kinase C isoforms. In addition, oxidative stress negatively influences the antiatherosclerotic endothelial enzymes: endothelial nitric oxide synthase and prostacyclin synthase. The intracellular reactive oxygen species increase by these mechanisms, then lead to defective angiogenesis in response to ischemia, and activate proinflammatory and epigenetic mechanisms after the normalization of glycemia (“hyperglycemic memory”) [30].

We used a basal-supported oral therapy variant in this study to emphasize the impact of the insulins studied. However, the results of this initial study did not show statistically significant differences both in glycemic variability and in the expression of oxidative stress in our patients. The primary reason for this was that the decrease in glycemic parameters was too small and,

consequently, the impact on glycemic variability and oxidative stress was too weak. The too-small decrease in glycemic parameters was a consequence of using a low dose of insulin. Namely, we administered both insulins at a dose of 0.2 IU per kg of body weight, and we did not titrate the dose for two reasons: to avoid hypoglycemia, which could significantly influence the oxidative stress and glycemic variability results, and to eschew the difference in dosing of two insulins, which could also affect the results. Many studies have shown that hypoglycemia can worsen oxidative stress through, among other mechanisms, a decrease in nitric oxide and a “reperfusion-like” effect [14-16]. If an examinee has experienced hypoglycemia, he or she should be excluded from the study. Nevertheless, in future studies, the dose of insulins administered must be higher. The question is if “treat-to-target” is the best therapy approach, as treating to target inevitably lowers blood sugar toward hypoglycemia. We think that an initial dose of 0.4 IU/kg with very careful titration of the dose will achieve a more desirable glucose level, but still far from the hypoglycemic zone. A smaller-scale titration study to optimize the dose of insulin and the optimal time for oxidative marker readout would be a good in-between step.

Some studies showed a lower incidence of hypoglycemia with IDeg-100 versus IGLar-300, and that also could contribute to the lower levels of variability and oxidative stress observed with degludec [27], although other studies showed no difference between IDeg-100 and IGLar-300 in that regard [28,29]. Previous research has also suggested a somewhat greater potency of IDeg-100, thus titration to target would probably lead to differences in the final doses used and, consequently, make the comparison more difficult [24,28].

A longer exposure period (longer than 12 weeks) would allow for a more expressed impact of each insulin, presumed positive, although some studies showed a negative effect of chronic insulin therapy on oxidative stress [31]. The longer exposure would possibly explain the difference in the simultaneous increase in thiols and hydroperoxides produced by IDeg-100. The increase in thiol group concentrations represents protein oxidative stress reduction and d-ROM gives insight into the acute changes of lipid peroxide oxidation. This should be considered in the context of the negative effect of chronic insulin treatment on oxidative stress, as mentioned above.

We assessed within-day glycemic variability through changes in average glucose levels, SD of glycemic excursions, and the CV, derived from the SD. The 7-point SMBG profile represents the standard method of glucose monitoring, and we used it for the assessment of glycemic variability [17,32]. Diagnostic CGMS (continuous glucose monitoring systems) and the Libre Flash monitoring system would be more precise tools for glycemic variability measurement but, unfortunately, at the time, due to financial reasons, they could not be employed in this initial study. CGMS or the Flash monitoring system would allow the detection of a greater number of daily peaks and nadirs and give a better insight into glycemic variability [33]. Using CGMS, it would be possible to use the mean amplitude of glucose excursions (MAGE) index as an assessment tool for glycemic variability as well. Hence, in future studies, we highly recommend the use of CGMS.

In this study, we recruited insulin-naive patients who experienced the failure of oral glucose-lowering therapy and needed insulin introduction. We excluded those who were previously on pioglitazone therapy because of the prolonged action of this drug (which was impossible to remove during the 7-day washout period) and its possible influence on the results. Moreover, we standardized the concomitant therapy by introducing the same dose of atorvastatin in all patients and by temporarily removing salicylic acid from the therapy.

Conclusion

The results of this study do not show a statistically significant difference in glycemic variability between IDeg-100 and IGLar-300. An insufficient dose of insulin was the main reason for the lack of impact on glycemic parameters and, consecutively, on glycemic variability. Probably due to the absence of a difference in glycemic variability, no difference in the oxidative stress level was noticed. A full-scale study should use larger doses of insulins (at least 0.4 IU/kg), and an optimized and adjusted “treat-to-target” algorithm. CGMS should be used instead of the 7-point SMBG profile. The MAGE index derived from the CGMS should be used for the assessment of glycemic variability. Another small titration study could be performed for optimization of the insulin dose and calculation of the sample size for the main study.

Acknowledgments

This research received no specific grant from any funding agency in the public, commercial, or not-for-profit sectors. The authors wish to thank Salvus d.o.o. Croatia for financial support and donation of glucose meters and test strips. The authors also thank Ms Tanja Vrebalov Cindro for language review.

Data Availability Statement

The data sets used and/or analyzed in this study are available from the corresponding author on reasonable request.

Authors' Contributions

MK contributed to study concept and design. PVC, MK, and TTK contributed to the acquisition of data. DM, DR, ASP, and JB contributed to laboratory analysis. MK, DM, PVC, and JV contributed to analysis and interpretation of data. MK, DM, and PVC contributed to drafting of the manuscript. MK, PVC, DM, and JV critically revised the manuscript for important intellectual

content. GK, DM, and JV contributed to statistical analysis. MK supervised the study. All authors have read and approved the final manuscript.

Conflicts of Interest

MK received honoraria from Sanofi, NovoNordisk, Eli Lilly, Abbott, MSD, Takeda, Novartis, Boehringer Ingelheim, Servier, Lifescan, and AstraZeneca as a speaker and for attendance at advisory boards. MK author has no conflicts of interest associated with this research.

TTK received honoraria from Sanofi, NovoNordisk, Eli Lilly, Abbott, MSD, Takeda, Novartis, Boehringer Ingelheim, Servier, Lifescan, and AstraZeneca as a speaker and for attendance at advisory boards. TTK author has no conflicts of interest associated with this research.

PVC received honoraria from Abbott, Teva, and Takeda as a speaker and a case presenter. PVC author has no conflicts of interest associated with this research.

JV, DM, GK, DR, ASP, and JB declare no conflicts of interest associated with this research.

Abstract

Background: The COVID-19 pandemic has triggered stigmatic attitudes against health care workers. Some forms of social media may play a role in disseminating stigmatizing messages.

Objective: We aimed to investigate the association between COVID-19 information sources and stigma against health care workers among college students during the pandemic.

Methods: A cross-sectional, observational study was conducted using a web-based platform in the Tohoku region of Japan. College students aged ≥ 20 years were asked to complete the questionnaire between August 18 and October 31, 2020. Stigma against health care workers was evaluated using a modified Japanese version of the Social Distance Scale. Participants were also asked to rate their perceived vulnerability to infection using the Japanese version of the Perceived Vulnerability to Disease scale.

Results: A total of 281 students from 8 colleges completed the web-based survey. There were 139 (49.5%) participants who used Twitter, 187 (66.5%) who used news websites, and 46 (16.4%) who used the websites of public health agencies as COVID-19 information sources. After adjusting for age, sex, department, and Perceived Vulnerability to Disease scores, the level of stigma did not differ between students who used Twitter and those who did not. Students who used the websites of public health agencies showed a significantly less stigmatic attitude than those who did not.

Conclusions: Fact-checking and directing visitors to credible information sources from public health agencies may have prevented the formation of stigmatic attitudes toward health care workers. An effective strategy to enable easy access to information provided by public agencies should be integrated into widespread web-based platforms.

Introduction

The COVID-19 pandemic is a serious threat to public health. Moreover, it is characterized by widespread fear, worry, and uncertainty, as many COVID-19 infections are contracted through presymptomatic and asymptomatic transmissions [1]. This health emergency has triggered discriminatory behavior and stigma against health care workers, despite their vital role in caring for people with COVID-19 [2,3]. Stigma is defined as an undesirable characteristic that results in discrimination against an individual [4]. Several incidents of stigmatization of health care workers have been reported; these include avoidance by family members or their community, being denied access to public transport, and even being subjected to physical assault [3,5]. The psychological challenges entailing stigmatization may amplify the negative consequences, such as emotional burnout [6], posttraumatic stress disorder [7], and turnover [8] of working with COVID-19 patients as frontline care providers. A reduction of stigma against health care workers is thus warranted during the COVID-19 pandemic.

The use of unreliable forms of social media as information sources for COVID-19 can lead to the spread of misinformation and increased stigma against health care workers. This is especially true because various COVID-19-related rumors, stigma, and conspiracy theories have been circulating on the internet [9]. Most people rely on the internet for COVID-19 information [10,11]. Particularly, Twitter conversations pertaining to COVID-19 are characterized by the dissemination of stigmatizing messages [12,13]. Although the media, including newspapers, television, and websites, are important sources that can be used to promote health education and literacy, mass media and even health agencies have contributed to the spread of health misinformation that could circulate stigma on the internet [14]. In addition to the media, Twitter allows users to post short messages (tweets), “retweet” messages (reposts), send replies, and “like” messages by other users. Therefore, Twitter users are more likely to be exposed to misinformation and stigmatizing messages, which in turn may exacerbate fear and anxiety and result in the further circulation of such messages [9]. Adolescents and young adults have been using social networking services more frequently since the COVID-19 pandemic, as pandemic-related restrictions have substantially changed their social lives due to school closures [15]. A previous study indicated that the level of anxiety about COVID-19 differed according to the type of preferred news source [16]. However, no studies have examined the association between the types of COVID-19 information sources and stigma against health care workers. An understanding of this association will provide a basis for developing strategies aimed at reducing stigma.

This study, thus, investigated the association between COVID-19 information sources and stigma against health care workers among college students during the pandemic. We hypothesized that college students who used Twitter as a COVID-19 information source would show a more stigmatic attitude toward health care workers than those who do not use Twitter.

Methods

Study Design

This cross-sectional, observational study was conducted using Google Forms, which is a web-based tool that allows data collection through personalized surveys. An anonymous questionnaire was uploaded and shared through an invitation email to potential participants.

Setting

On August 18, 2020, the survey link was shared with teachers from 8 colleges in the Tohoku region of Japan. The link provided a detailed explanation of the study purpose instructions. Subsequently, the teachers emailed the invitation link with the explanatory documents to the students. Participants aged ≥ 20 years were requested to complete the questionnaire on October 31, 2020.

The first page of the website contained details on the voluntary nature of the participation and protection of personal information. After reading the introduction, students indicated their consent to participate by clicking on the link to start the survey. The “Limit to 1 response” function of Google Forms was enabled to prevent respondents from completing the form more than once.

Participants

We used purposive and convenience sampling to select colleges and departments with (1) nursing students who underwent on-the-job training in hospitals and (2) students from other departments. The other departments were selected to ensure gender ratios similar to those of students in the nursing departments.

Nursing and other students were recruited to compare the level of stigma against health care workers. We assumed that nursing students would show less stigmatic attitudes than other students, because they are expected to become professional nurses and, therefore, have more psychological proximity with other health care workers.

Measurements

The questionnaire included questions regarding stigmatic attitudes against health care workers, COVID-19 information sources, perceived vulnerability to infection, department, age, sex, and contact with COVID-19 patients. The questions and response options of stigma against health care workers were developed for this study (Table S1 in [Multimedia Appendix 1](#)).

Stigma against health care workers was evaluated using a modified version of the Japanese version of the Social Distance Scale (SDSJ) [17]. The original Social Distance Scale was developed based on the Keyed Favorable Response and Ego-Involvement Ratings of Scale [18], which is used to assess the level of stigmatic attitude toward patients with schizophrenia. It contains 8 stigma-related items, which are rated on a 4-point Likert scale, and the scale has good reliability and validity [17]. For this study, we replaced “patients with schizophrenia” in each item with “health care workers and their families who are performing infectious disease management with an unestablished

treatment regimen.” The total score on the 8 items ranged from 0 to 24; higher scores indicated more stigmatic attitudes.

The 8 types of COVID-19 information sources were listed in the questionnaire. Participants were asked to check any source, if applicable. The list was developed by a research panel to contain a range of social media platforms, including newspapers, television news streams, television tabloid talk shows, news websites, Twitter, the websites of public health agencies (eg, Ministry of Health, Labour and Welfare), Instagram, and Facebook.

Perceived vulnerability to infection was evaluated using the Perceived Vulnerability to Disease (PVD) scale [19]. The PVD contains 15 items, which are rated on a 7-point Likert scale from 1 to 7. It comprises 2 subscales: Perceived Infectability and Germ Aversion. Perceived Infectability refers to beliefs about immunological functioning and personal susceptibility to infectious diseases. Germ Aversion refers to aversive affective responses to situations that connote a relatively high likelihood of pathogen transmission. The Japanese version of the PVD is reported to have good reliability and validity [20]. In this study, the Cronbach α coefficient was .78 (95% CI .74-.82) for Perceived Infectability and .65 (95% CI .58-.71) for Germ Aversion. Although Perceived Infectability refers to one’s susceptibility to infection, Germ Aversion covers behaviors exerting emotional discomfort in a high-pathogen context, which in turn deters from the source of infection. Therefore, we assumed that stigma against health care workers would show a moderate positive correlation with Germ Aversion but not with Perceived Infectability.

Participants also answered items pertaining to their age, sex, department, and contact with COVID-19 patients. The presence of contact was assessed if (1) the respondent or their family members or friends had been infected with COVID-19; and if (2) the respondent or their family members or friends had close contact with infected persons. Based on the contact hypothesis [21,22], we assumed that individuals who directly interacted with COVID-19 patients would be less likely to hold stigmatic attitudes against health care workers. However, the number of individuals with direct contact was small ($n=18$). Therefore, we used the presence of contact for sensitivity analysis instead of including it in bivariate and multivariate analyses.

Study Size

The required sample size was calculated using G*Power (version 3.1.9.7; Faul et al [23,24]). Based on a recent report on the use of Twitter among Japanese college students [25], we assumed the prevalence of Twitter as a COVID-19 information source to be 50% in this study. Assuming an α level of 5%, 95% power, and medium effect size (Cohen $d=0.5$) for a 2-tailed test, the minimum sample size was determined to be 210.

Statistical Analysis

The validity and reliability of the modified SDSJ were examined. To test concurrent validity, the mean difference

between nursing and other students was examined. The normality of distribution was assumed for total SDSJ score (Table S2 in [Multimedia Appendix 1](#)). The equality of variances between the 2 groups was also assumed (Table S3 in [Multimedia Appendix 1](#)). Therefore, 2-sided testing using 2-tailed students’ t test was used. To test convergent validity, Pearson correlation coefficient was calculated between the total SDSJ score and the subscales scores of the PVD. To test internal reliability, the Cronbach α coefficient and 95% CI [26] were calculated for the total SDSJ score.

Within the types of COVID-19 information sources, overlaps between Twitter and other major web-based platforms (news websites and the websites of public health agencies) were examined. To investigate the association between Twitter use and stigma against health care workers, the mean difference in SDSJ scores was examined by performing a 2-tailed t tests between participants who used Twitter as a COVID-19 information source and those who did not. Furthermore, a multiple Ordinary Least Square (OLS) regression analysis was performed using the SDSJ scores as the dependent variable and the types of information sources as independent variables. Participant characteristics, including age, sex, department, and PVD scores, were included as covariates. Diagnostic tests were conducted to test the assumptions of OLS regression, including the normality of the residuals, homoskedasticity, the absence of outliers, and low multicollinearity (Table S4 in [Multimedia Appendix 1](#)). Since some potential outliers were found, a sensitivity analysis of the multivariate model was performed by excluding them. Another sensitivity analysis was also conducted by excluding individuals with social contacts.

All analyses were conducted using Stata statistical software (version 17.0; StataCorp). The significance level was set at low ($\alpha=.1$), medium ($\alpha=.05$), and high ($\alpha=.01$) [27]. As our primary endpoint was to assess the association between use of Twitter and SDSJ under multiple regression analysis adjusting for covariates, we did not apply P value adjustments for multiple hypothesis testing [28].

Ethics Approval

The study protocol was approved by the Ethics Board of Tohoku University (2021-1-733) and was conducted in accordance with the Helsinki Declaration of 1975 (as revised in 2013).

Results

Participant Characteristics

A total of 281 participants completed the survey and were included in the final sample. The majority (86.7%, $n=238$) were women and the most frequent (50.9%, $n=143$) age was 21 years. There were 18 participants who reported coming into contact with COVID-19 ([Table 1](#)).

Table 1. Participant characteristics.

Variable, category	Participant (N=281), n (%)
Sex	
Female	238 (86.7)
Age (year)	
20	86 (30.6)
21	143 (50.9)
≥22	52 (18.5)
Department	
Nursing	104 (37)
Rehabilitation	70 (24.9)
Psychology	63 (22.4)
Other	44 (15.7)
Contact with COVID-19	
Any of the experiences below	18 (6.4)
Family members or friends had close contact with an infected person	13 (4.6)
I had close contact with an infected person	1 (0.4)
Family members or friends had been infected with COVID-19	5 (1.8)
I had been infected with COVID-19	0 (0)

Stigma Against Health Care Workers

The mean total SDSJ score in overall sample was 7.9 (SD 4.7). Nursing students had a significantly lower mean total score (mean 6.0, SD 4.5) than other students (mean 8.9, SD 4.5; $t_{218.48}=5.18$, $P<.001$). The mean total SDSJ score did not differ between participants with social contact (mean 8.6, SD 1.0) and those without (mean 7.8, SD 0.3; $t_{20.16}=0.73$, $P=.47$).

Pearson correlation coefficients were -0.03 ($P=.62$) between the SDSJ and PVD Perceived Vulnerability scores and 0.33 ($P<.001$) between the SDSJ and PVD Germ Aversion scores. The Cronbach α coefficient of the SDSJ score was high ($\alpha=.83$; 95% CI .80-.86). In summary, the modified SDSJ demonstrated satisfactory concurrent, convergent, and internal validity.

COVID-19 Information Sources

Half (49.5%, 139/281) of the participants used Twitter as a COVID-19 information source (Table 2). Since less than 10% of participants used newspapers (8.5%, $n=24$), Instagram (3.2%, $n=9$), or Facebook (0.4%, $n=1$), we excluded these sources from the following multivariate analysis.

In total, 89 participants reported using both Twitter and news websites, of which 16 participants also used the websites of public health agencies. Further, 44 participants used Twitter, but not news websites or the websites of public health agencies (Figure 1).

The total SDSJ score did not differ between Twitter users (mean 8.1, SD 4.4) and those who did not use Twitter (mean 7.6, SD 5.0; $t_{276.63}=0.97$, $P=.33$).

Table 2. Prevalence of COVID-19 information sources.

Type, category	Participant (N=281), n (%)
Newspaper	24 (8.5)
Television	
News stream	218 (77.6)
Tabloid talk show	71 (25.3)
Web-based source	
News website	187 (66.5)
Twitter	139 (49.5)
Website of public health agencies (eg, Ministry of Health, Labour and Welfare)	46 (16.4)
Instagram	9 (3.2)
Facebook	1 (0.4)
Other social networking services	13 (4.6)

Figure 1. Venn diagram of overlaps between Twitter and other major web-based platforms (news websites and the websites of public health agencies).

Association Between Stigma and Information Sources

A multiple regression analysis showed that the total SDSJ scores were lower among participants using the websites of public health agencies ($P=.008$), nursing students ($P<.001$), and those with lower Germ Aversion scores ($P<.001$; [Table 3](#)). The use of Twitter was not associated with SDSJ scores ($P=.58$).

The results of OLS diagnostic tests showed that the following assumptions were met: the normality of the residuals,

homoskedasticity, and low multicollinearity ([Table S4 in Multimedia Appendix 1](#)). However, there were 2 potential outliers ([Table S4 in Multimedia Appendix 1](#)). A sensitivity analysis that excluded the 2 individuals did not change the results ([Table S5 in Multimedia Appendix 1](#)).

Another sensitivity analysis that excluded individuals ($n=18$) who came into close contact with a patient with COVID-19 did not alter the results ([Table S5 in Multimedia Appendix 1](#)).

Table 3. Multiple linear regression analysis of stigma against health care workers^{a,b}.

Variable, category	Coefficient (95% CI)	P value
COVID-19 information source		
Television news stream	0.86 (–0.40 to 2.12)	.18
Television tabloid show	0.51 (–0.70 to 1.72)	.41
News website	0.60 (–0.45 to 1.66)	.26
Twitter	0.29 (–0.74 to 1.31)	.58
Websites of public health agencies	–1.84 (–3.20 to –0.49)	.008
Sex		
Male	1.07 (–0.38 to 2.52)	.15
Age (year)		
20	0.33 (–1.21 to 1.88)	.67
21	–0.25 (–1.64 to 1.14)	.72
≥22	reference	reference
Department		
Nursing	–3.04 (–4.11 to –1.98)	<.001
Perceived vulnerability to infection		
Perceived Infectability	–0.13 (–0.63 to 0.37)	.61
Germ Aversion	1.85 (1.31–2.39)	<.001

^aStigma against health care workers was evaluated using the modified Japanese language version of the Social Distance Scale; the total score ranges from 0 to 24.

^bPerceived vulnerability to infection was evaluated using the Japanese version of the Perceived Vulnerability to Disease scale; total scores range from 1 to 7 for both Perceived Infectability and Germ Aversion.

Discussion

With increasing concerns about the stigma against health care workers during the COVID-19 pandemic, strategies to reduce stigma are the need of the hour, considering the prevalence of Twitter and other information sources for information related to COVID-19. Thus, this study examined the association between the types of information source and stigma against health care workers among college students.

Principal Findings

Contrary to our hypothesis, Twitter use was not associated with the stigma against health care workers. The survey was conducted between August and October 2020 when the daily number of new COVID-19 cases in Japan ranged from 219 to 1178. This period is a few months after the onset of the outbreak, and our participants may have had a lower level of fear than that from February to April 2020 [9,12,13]. In the acute phase of the psychological response to a crisis, such as the Great East Japan Earthquake on March 11, 2011, Twitter messages diffused rumors and misinformation [29]. However, the level of anxiety expressed in Twitter messages appears to return to normal over time [30]. This shift to Twitter for content has also been observed for COVID-19 [31]. In addition, several students aged ≥20 years in the Tohoku region might have experienced the March 11 earthquake when they were children, resulting in their learned mindset to treat Twitter messages with caution.

College students who used the websites of public health agencies as information sources reported significantly less stigmatic attitudes than those who did not ($P=.008$) in the multiple regression analysis. Fact-checking and directing users to credible information sources from the websites of public health agencies can prevent the further spread of misinformation [32]. News websites also disseminate official announcements from public health agencies. In this study, substantial overlaps were observed between the users of the websites of public health agencies, news websites, and Twitter. This finding is consistent with a previous study [10]. Furthermore, public health agencies also have Twitter accounts, and each message is limited to 140 Japanese characters. Their messages usually include a URL to official website pages that contain longer texts. The accuracy of the information held by Twitter users may vary between those who only read the message and those who click on the link to access the website. Adequate communication strategies should be embedded in reliable information from trusted sources [31,33]. Considering that Twitter was a popular COVID-19 information source, access to information curated by public agencies may help reduce exposure to misinformation and stigma against health care workers. In addition to accurate information, “hero” messaging [34] should be reserved for health care workers in public policy. Health care workers were deemed essential frontline heroes during the COVID-19 crisis. Such perceptions can mitigate stigmatic attitudes toward health care workers. Furthermore, positive video messages embedded in tweets may enable young people to engage in parasocial interactions with health care workers, which in turn may help

change their negative beliefs about health care workers based on the parasocial contact hypothesis [22,35].

Stigma against health care workers, as measured by the modified SDSJ, was significantly lower among nursing students ($P<.001$) and students with lower germ aversion ($P<.001$). Unlike Germ Aversion, we found very little statistical evidence that Perceived Infectability was associated with stigma against health care workers using the total SDSJ score. These associations were consistent with our assumption that the modified scale is valid.

Strengths and Limitations

The strength of this study lies in the examination of stigma against health care workers in the context of COVID-19 and social media, thus addressing a gap in the literature. A limitation was the lack of information accuracy and limited data on the intensity of social media use among participants. In addition, the cross-sectional design precludes causal inferences between

stigma and the types of information sources. The use of websites of public health agencies might indicate the high health literacy and low stigmatic attitudes of students.

Conclusions

A few months after the onset of the COVID-19 pandemic, nearly half of the college student population used Twitter as an information source. Our findings showed that the level of stigma against health care workers did not differ according to Twitter use. Students who used the websites of public health agencies reported less stigmatic attitudes than those who did not. These results imply that directing people to credible COVID-19 information sources from public agencies may prevent the formation of stigmatic attitudes against health care workers. An effective strategy for the induction of access to credible information sources should be explored for integration into Twitter and other widespread web-based platforms.

Abstract

Background: The term “telemedicine” refers to the use of communication technology to deliver health care remotely. The COVID-19 pandemic had substantial impacts on health care delivery from 2020 onward, and it was necessary to adapt high-quality care in a manner that limited the potential for viral exposure of both patients and health care workers. Physicians employed video, phone, and electronic written (e-consultation) visits, all of which provided quality of care comparable to that of face-to-face visits while reducing barriers of adopting telemedicine.

Objective: This study sought to assess physicians' perspectives and attitudes regarding the use of telemedicine in Riyadh hospitals during the COVID-19 pandemic. The main objects of assessment were as follows: (1) physicians' experience using telemedicine, (2) physicians' willingness to use telemedicine in the future, (3) physicians' perceptions of patient experiences, and (4) the influence of telemedicine on burnout.

Methods: This study employed SurveyMonkey to develop and distribute an anonymous 28-question cross-sectional survey among physicians across all specialty disciplines in Riyadh hospitals. A chi-square test was used to determine the level of association between variables, with significance set to $P < .05$.

Results: The survey was distributed among 500 physicians who experienced telemedicine between October 2021 and December 2021. A total of 362 doctors were included, of whom 28.7% (n=104) were consultants, 30.4% (n=110) were specialists, and 40.9% (n=148) were residents. Male doctors formed the majority 56.1% (n=203), and female doctors accounted for 43.9% (n=159). Overall, 34% (n=228) agreed or somewhat agreed that the “quality of care during telemedicine is comparable with that of face-to-face visits.” Approximately 70% (n=254) believed that telemedicine consultation is cost-effective. Regarding burnout, 4.1% (n=15), 7.5% (n=27), and 27.3% (n=99) of the doctors reported feeling burnout every day, a few times a week, and a few times per month, respectively.

Conclusions: The physicians had generally favorable attitudes toward telemedicine, believing that its quality of health care delivery is comparable to that of in-person care. However, further research is necessary to determine how physicians' attitudes toward telemedicine have changed since the pandemic and how this virtual technology can be used to improve physicians' professional and personal well-being.

burnout; COVID-19; patient experience; perception; physicians; telemedicine; virtual

Introduction

Background

“Telemedicine” refers to the use of IT in the provision of health care via electronic devices [1]. COVID-19, a highly infectious virus causing respiratory illness, has caused an ongoing global pandemic. Saudi Arabia experienced more than half a million infections and more than 7000 fatalities by June 2021 [1]. This outbreak has led to innovative practices such as Telemedicine among health providers. Thus, physicians have often opted to use telemedicine as an alternative to provide fast and safe care away from outpatient clinics, which require physical contact [2]. This research investigates physicians’ perceptions of telemedicine during the COVID-19 pandemic in Riyadh, Saudi Arabia.

Although various forms of telemedicine such as phone calls and electronic messaging have been used in Saudi Arabia for years, COVID-19 has led to the implementation and successful use of audiovisual technologies for patients across the country.

Previous limited evidence suggested that telemedicine could provide generally effective, comparable, and satisfactory quality of care as well as improvements in clinical outcomes [3]. However, there is a lack of larger studies of perception and attitude regarding patient-physician interactions, satisfaction with services and convenience of using telemedicine, preference for face-to-face communication, and support for technology infrastructure [4].

Furthermore, few studies have assessed whether the use of telemedicine affects physician well-being and burnout, as telemedicine theoretically provides more flexibility in terms of physician time and geographical location while performing virtual visits [5]. This paper is organized as follows: first, the research team examined the literature for studies related to physician perceptions of telemedicine; second, the method and the survey design were explained; third, the statistical analysis and results were presented; and finally, discussion, limitations, and conclusions and recommendations are presented.

Physicians’ Experience Using Telemedicine

The United Kingdom’s National Health Service immediately implemented telemedicine as a substitute for face-to-face consultations during the COVID-19 pandemic [6]. Despite widespread unfamiliarity with telemedicine prior to the pandemic, there was a rapid rise in its usage among health care providers [6,7]. Moreover, web-based platforms became indispensable for boosting public health awareness and disseminating information about the pandemic [8].

The implementation of telemedicine, however, has encountered various barriers in Saudi Arabia. These issues include bureaucracy, lack of expertise, inadequate IT infrastructure, absence of guidelines, and insufficient institutional support [9]. Therefore, Saudi Arabia’s Ministry of Health must assess health care workers’ knowledge and perceptions of telemedicine to

facilitate its future implementation while considering patient privacy and confidentiality concerns [10]. To the best of the authors’ knowledge, this is the first study to do so.

Perceptions of Patient Experience

The success of any health care delivery system, including telemedicine, is heavily reliant on patient perceptions and satisfaction. Patients are the primary source of information that tells us whether health care is being delivered properly and whether the care they receive meets their expectations [11]. A study conducted by Power [12] on health care consumer satisfaction indicates that 66% of patients are either generally unaware that they can use telemedicine for consultations, or else it is not available to them. Among those who are aware, however, male patients, particularly those aged 18-59 years, are often satisfied with their telemedicine experiences [13]. Female patients, interestingly, are more likely to feel rather neutral toward telemedicine, that is, neither satisfied nor dissatisfied [13]. It is worth noting that almost half of the study’s respondents opined that the quality of telemedicine will never be on par with that of traditional in-person care [13]. Many telemedicine applications are available; however, due to a lack of knowledge about telemedicine technology, patients feel uncomfortable using and adapting to it. Therefore, user-friendly telemedicine apps should be developed to improve favorability among patients who feel that in-person care cannot be matched. Additionally, apps should be available in local languages to ensure that patients both learn about telemedicine and experience it in a positive and comfortable manner [14]. Moreover, policy makers around the world should work to boost patients’ awareness of telemedicine to ensure correct care during this pandemic and those to come [15].

In one study, most patients who had used telemedicine noted that the practice’s convenience and effectiveness helped them to seek treatment from remote areas and optimize their management of type 2 diabetes mellitus [15]. Another study found that the vast majority of patients believe that telemedicine had optimized their type 2 diabetes mellitus management; however, most of these patients noted that improvements could be made to aspects such as user-friendliness, interaction with medical team, and time required for recording or transferring data [16].

Willingness to Use Telemedicine in the Future

Technological advancements have improved existing practices and paved the way for the expansion of telemedicine in the future. Such advancements in telemedicine have increased dependability, lowered costs, improved audiovisual quality, and emulated clinical settings more successfully (eg, by implementing virtual waiting rooms) [17]. There is significant potential in the scalability of telemedicine visits [18]. However, Florea et al [17] revealed that approximately 77% of professionals believe that continual training is essential for health care providers to stay up-to-date with advancements in telemedicine.

Of course, health care institutions are likely to face new ethical challenges arising from the use of telemedicine. For example, they must be capable of protecting patients' private information against potential cyberattacks [17]. Telemedicine could also lead to a rise in malpractice claims stemming from a lack of appropriate guidelines and, in turn, problems with reimbursement [17]. Evidently, significant changes are necessary to fully incorporate telemedicine services into the health care landscape and to fully reap its benefits in advance of future pandemics [17].

Through technological advancements and appropriately oriented policy developments, telemedicine could become a sustainable mainstream solution for both public health emergencies and routine care [9]. Telemedicine may be a reasonable choice for physicians in the future if properly used by patients and if legal guidelines for telemedicine are implemented to address the aforementioned concerns [18].

Effects of Telemedicine on Burnout

Burnout has been defined as a psychological syndrome involving emotional exhaustion, depersonalization, and a sense of reduced personal accomplishment [19]. A 2020 study conducted by Jha et al [19] assessed how COVID-19 has placed several physical and emotional stressors on physicians, which increased physician burnout. The demanding role of primary care physicians (PCPs) in pandemic mitigation measures has made them susceptible to psychological distress. Some PCPs fear being infected by COVID-19; this fear is exacerbated by a lack of personal protective equipment and extended shifts on the front line. All of these issues are in addition to PCPs' existing anxiety stemming from a fast-paced, efficiency-oriented work environment. Many are concerned about errors of omissions and complaints of community residents. Additionally, the documentation process for reporting instances of COVID-19, which is perceived as time-consuming and not conducive to delivering high-quality care, is a source of frustration for most PCPs [20].

Methods

Ethics Approval

This study was approved by the institutional ethical committee of the King Fahad Medical City (IRB log:21-458).

Study Design and Population

This paper presents a cross-sectional study conducted between October and November 2021 among physicians in Riyadh hospitals. A web link survey conducted through SurveyMonkey distributed an anonymous 28-question survey to 500 physicians. After obtaining institutional ethical committee approval, the questionnaire was sent through social media platforms such as WhatsApp, Twitter, and LinkedIn. A total of 362 participants returned the questionnaire, yielding a response rate of 60%. The questionnaire consisted of the following five sections: (1) demographic characteristics; (2) familiarity with telemedicine; (3) perceptions of patients' experiences; (4) willingness to use telemedicine in the future; and (5) the effects of telemedicine on burnout. The responses were measured using a Likert scale. Each respondent's current academic position (consultant,

specialist, or intern), specialty, years of postresidency experience, age, sex, frequency of telemedicine use prior to the COVID-19 pandemic, and length of time using telemedicine were all variables of interest.

Survey Design

The instrument tool used in this study was inspired by Malouff et al [21]. The tool was developed to evaluate the perception of physician perceptions and attitudes toward telemedicine. The anonymous survey consisted of 38 questions. The survey was developed in consultation with an expert panel with a consensus informed by elements from existing evidence and models, including the unified theory of acceptance and use of technology, Technology Acceptance Model 2, and diffusion of innovation frameworks [21].

Statistical Analysis

The data were checked for completeness, and all errors were corrected. All of the variables were categorical; therefore, they are presented as frequencies and percentages. The responses of consultants, specialists, and residents—as well as those of men and women—were compared using chi-square tests. The analyses were performed at a 95% confidence interval using SPSS (v.23.0, IBM Corp). Physicians completed the survey including 28 items (sample item: "I find telemedicine has been easy to navigate and use"). The items were rated on a 5-point scale ranging from 1 (strongly agree) to 5 (strongly disagree). The Cronbach alpha for this study was .82, which is considered a good indication for internal consistency [22].

Results

The survey was sent to physicians who experienced telemedicine between October 2021 and December 2021. A total of 362 doctors were included, of whom 28.7% (n=104) were consultants, 30.4% (n=110) were specialists, and 40.9% (n=148) were residents. Male doctors formed the majority 56.1% (n=203), and female doctors accounted for 43.9% (n=159). When asked about the frequency with which they use telemedicine during the pandemic, 41.4% (n=150) answered "frequently," 26% (n=49) responded "occasionally," and 32.6% (n=118) said "never" (Table 1). Only 25% (n=89) of doctors specified their specialty. Figure 1 shows the specialty distribution; although the physicians were from almost all specialties, they were most frequently from emergency medicine (n=10, 12%) and pediatrics (n=10, 12%).

Moreover, 34% (n=228) agreed or somewhat agreed that the "quality of care during telemedicine is comparable with that of face-to-face visits." Approximately 70% (n=254) believed that telemedicine consultation is a cost-effective means of providing care relative to traditional face-to-face visits. Most of the doctors were skilled at delivering telemedicine 70% (n=163) and capable of independently solving technological issues during telemedicine visits 54% (n=195). Overall, the physicians felt that their patients view telemedicine positively; 68% (n=246) said that their patients felt comfortable using telemedicine, and 76% (n=273) stated that their patients would assert that telemedicine saves time. Regarding burnout, 4.1% (n=15), 7.5% (n=27), and 27.3% (n=99) of the doctors reported feeling

burnout every day, a few times a week, and a few times per month, respectively.

The physicians' responses to the Likert scale prompts are presented in [Multimedia Appendix 1](#). In all, 31% (113/362) of the physicians agreed or somewhat agreed that "telemedicine's quality of care is generally comparable to that which I deliver during face-to-face visits." Approximately 55% (199/362) believed that telemedicine consultations are cost-effective relative to in-person visits. Moreover, 74% (268/362) believed that telemedicine gives them more flexibility or control over how they deliver patient care ([Multimedia Appendix 1](#)). Most of the physicians (254/362, 70%) asserted that they are skilled at telemedicine, and are capable of independently solving technological issues during telemedicine visits (195/362, 54%). Furthermore, most of the physicians felt that their patients view telemedicine in a positive manner; 68% (246/362) said that their patients felt comfortable using telemedicine, and 76% (275/362) said that their patients would assert that telemedicine saves time ([Figures 2 and 3](#)).

Regarding burnout, 4.1% (n=15), 7.5% (n=27), and 27.3% (n=99) of the physicians felt it every day, a few times per week, and a few times per month, respectively. When asked about the role of telemedicine in burnout, 23.5% (n=85) of physicians said that it alleviated their burnout symptoms. However, 11.6% (n=42) believed that telemedicine contributed to their burnout, and an additional 6.6% (n=24) thought that it substantially contributed to their burnout ([Figures 4 and 5](#)).

This study found no statistically significant difference between the burnout frequencies of men and women ($P=.57$). However, there was a statistically significant difference in burnout frequency between those in different academic positions ($P=.002$). Whereas 6.1% (9/148) of residents felt burnout every day, only 2.7% (3/110) of specialists and 2.9% (3/104) of consultants felt the same. Interestingly, 18.3% (19/104) of consultants asserted that telemedicine alleviated their burnout symptoms to a sizable degree, whereas only 7.3% (8/110) of specialists and 8.1% (12/148) of residents felt the same ($P=.001$).

Table 1. Distribution of all physicians by their characteristics and previous experiences with telemedicine.

Characteristics	Values, n (%)
Current position	
Consultant	104 (28.7)
Specialist	110 (30.4)
Resident	148 (40.9)
Clinical experience following residency training (years)	
<5	142 (39.2)
5-10	114 (31.5)
11-20	77 (21.3)
21-30	25 (6.9)
>30	4 (1.1)
Current age (years)	
<30	114 (31.5)
31-40	140 (38.7)
41-50	85 (23.5)
51-60	23 (6.4)
Gender	
Male	203 (56.1)
Female	159 (43.9)
Frequency of telemedicine use before the COVID-19 pandemic	
Frequently (>1 time per month or >12 times per year)	150 (41.4)
Occasionally (1-12 times per year)	94 (26.0)
Never	118 (32.6)
Time spent using telemedicine in any medical capacity (years)	
<1	154 (42.5)
2-3	106 (29.3)
>3	102 (28.2)

Discussion

Principal Findings

Our data suggest that physicians in Riyadh have adapted to the implementation of telemedicine. Most of the physicians assessed in this study, regardless of their specialty, considered telemedicine to be easy to navigate and use. Furthermore, almost all respondents were open to using telemedicine for routine consultations and follow-ups even after the pandemic ends; in fact, more than half of them actively preferred telemedicine to in-person visits. The findings of this work align with those of previous studies. For example, Gillman-Wells et al [6] found that 70% of plastic surgeons surveyed in the United Kingdom have embraced the use of telemedicine. A survey by Srinivasan et al [7] found that personnel at Stanford University's primary care clinics strongly believe that telemedicine visits should be an ongoing element of health care delivery after the pandemic.

There are several potential reasons for why physicians are willing to adapt to this new technology, including cost-effectiveness, time efficiency for physicians and patients alike, as well as flexibility in scheduling telemedicine visits, all of which may improve physicians' quality of life [21]. These advantages balance out concerns over lower quality of care. According to a study conducted during the first year of the pandemic, one major shortfall of telemedicine that physicians should be aware of is the absence of physical examination [23].

As mentioned in the literature review, the cost-effectiveness of telemedicine relative to traditional in-person care is a significant driver of positive attitudes toward telemedicine; in this study, 70% (254/362) of the physicians agreed that it is a cost-effective way to deliver health care (in a study by the Mayo Clinic, 80% of the respondents agreed with this sentiment) [21]. To assess the verity of this perception, a study evaluated postoperative visit costs and found that patients who used telemedicine services saved an average of US \$888 per return visit (increasing to US \$1501 when accounting for travel and accommodation costs). The authors reported savings of US \$256 per visit, even for patients who did not require accommodation [24]. Furthermore, the Pediatric Cardiology Service at the Coimbra University Hospital Center analyzed telemedicine use in Portugal since 1998 and found that it had saved the country's health care system about EUR €1.1 million (US \$1.3 million) overall, equating to savings of approximately EUR €119 (US \$500) per patient [25].

Telemedicine also offers considerable efficiency for both physicians and patients. In this study, nearly three-quarters of the respondents agreed that telemedicine enhanced flexibility. Telemedicine visits can be conducted anywhere (including from home), and this ability helps physicians to balance their professional and personal needs, particularly during the COVID-19 pandemic. According to a study conducted by Chaudhry et al [26], telemedicine visits may also reduce some time-consuming activities that are common at clinics, such as waiting for rooms to become available, checking patients in, and moving patients from one room to another. Orthopedic patients reported that telemedicine saved them time, both when including (180 minutes) and excluding (17 minutes) travel time.

Regardless of the benefits that many physicians derive from telemedicine, more than one-third of this survey's respondents did not agree that telemedicine is equivalent to in-person visits in terms of quality of care. This finding aligns with those of previous studies. Although telemedicine can be efficient and cost-effective, physicians lose the ability to conduct physical examinations, which are often crucial in order to meet patients' needs and deliver appropriate preventative care. Furthermore, the patient-physician relationship largely depends on face-to-face visits. However, because telemedicine is even more common at the time of writing this paper compared to when this study was conducted, further surveys are necessary to understand physicians' concerns and their relative importance.

Indeed, the most common concerns over telemedicine pertained to an inability to provide care on the same level as traditional in-person care. Zhang et al [5] considered this concern when examining the Memorial Sloan Kettering Cancer Center during the COVID-19 pandemic. They found that 92% of the center's radiation oncology visits were conducted via telemedicine at the peak of the pandemic [5]. Overall, 71% of the providers reported no difference in their ability to treat cancer appropriately, and 55% of the patients reported no difference in their overall visit quality [5].

Although our study did not directly examine patients' experiences of differences between virtual and in-person consultations regarding lab tests, imaging exams, and prescribed medications, a study on Stanford's ClickWell Care clinic evaluated practice patterns for both telemedicine and in-person visits. It found no difference in laboratory tests, imaging tests, or prescriptions ordered between virtual and in-person visits for 17 of the most common diagnoses. However, overall, there were more laboratory and imaging tests ordered following in-person visits for all diagnoses; this increase may have affected general medical examinations [27].

Another widely reported concern when using telemedicine was the absence of a physical evaluation, which remains an essential element of follow-up care, mainly when assessing adverse posttherapy events for patients with physical disabilities [28]. To counter this limitation, some physicians are working to develop evaluations that can function via telemedicine, such as a neurosurgical spine examination that can be conducted remotely [29]. Early evidence on the feasibility and comparability of such examinations is promising. In addition, Laskowski et al [28] developed a specific set of guidelines to enhance evaluations of the musculoskeletal system when performing virtual examination.

Physical examinations are also correlated with patient satisfaction, which is critical in telemedicine because cost and time savings are meaningless if patients do not believe that they are receiving high-quality care [21]. Although this study did not directly survey patients, approximately 75% of the physicians felt that their patients were at ease communicating with them via telemedicine, with half agreeing that their patients found the technology easy to use and comparable in quality of care with face-to-face visits. These findings align with those of previous studies. For example, a study by Elawady et al [30] found that 73% of the physician respondents felt that their

patients understood their medical conditions and the corresponding recommendations given to them over the phone. In addition, physicians were asked whether videoconference consultation would improve patient care over telephone consultation alone, and 70% of the respondents agreed that it would [30]. Moreover, according to a meta-analysis conducted by Chaudhry et al [26], there were no differences in surgeon satisfaction or patient-reported outcome measurements when comparing telemedicine visits with in-person visits [26].

Although patient satisfaction with telemedicine is critical, reduction of burnout among physicians by boosting flexibility in care delivery is one potential benefit of telemedicine. Telemedicine may reduce transportation time, granting physicians more time for sleep, family life, and social activities, all of which are key factors in avoiding burnout [21]. This study found that more than one-third of the surveyed physicians' burnout symptoms were alleviated or substantially alleviated due to telemedicine. However, it is important to note that these figures may have been influenced by other stress factors related to the COVID-19 pandemic [21]. Further studies may be needed to evaluate whether—and to what degree—burnout can be mitigated through the postpandemic use of telemedicine.

According to Malouff et al [21], looking ahead, telemedicine will be an essential element of post-COVID-19 crises. Virtual reality has been proposed as a means of improving feelings of physical presence during examinations to compensate for the lack of physical presence during virtual visits [21]. In addition, telemedicine may be beneficial for people who are fearful of

visiting clinics or hospitals; patients with anxiety or depression may prefer telemedicine to in-person visits. Finally, telemedicine may offer an opportunity for underrepresented populations to participate in clinical trials because follow-ups and toxicity supervision can be conducted virtually [27].

Limitations

Despite this study's finding that physicians' perceptions of telemedicine are generally favorable, it comes with certain limitations. For instance, this was a survey-based study, meaning that it is subject to the typical limitations of survey-based evaluations, including incomplete responses and a low response rate. It was unable to precisely determine response rates because the survey link was partially distributed through social media platforms. Another major limitation of this study is that it does not directly survey patients. Furthermore, the results of this study are not generalizable to a wider health care population, given its small sample size and the sample size of the subgroups that were examined when comparing survey responses.

Conclusions and Recommendations

This study shows that physicians in Riyadh, Saudi Arabia, have generally favorable attitudes toward the adoption of telemedicine because they believe that the quality of care delivered using telemedicine is comparable to that delivered using traditional methods. However, further research is necessary to correctly assess how the COVID-19 pandemic influenced physicians' attitudes toward telemedicine and how telemedicine can be used to advance care delivery and improve patient outcomes in the future.

Abstract

Background: The COVID-19 pandemic has wreaked havoc on health care systems and governments worldwide. Although eHealth literacy is acknowledged as a critical component of public health, it was overlooked during the pandemic. To assist patients and their families, health professionals should be knowledgeable about online health information resources and capable of evaluating relevant online information. In a resource-constrained situation, the level of eHealth literacy among health professionals is not well documented.

Objective: The aim of this study was to assess the eHealth literacy level and its associated factors among health professionals working in Amhara regional state teaching hospitals, Ethiopia.

Methods: A self-administered questionnaire was used in an institutional-based cross-sectional study design. Descriptive statistics were calculated to describe eHealth literacy statements and key variables using SPSS v.24. Bivariable and multivariable logistic regression models were fit to identify factors related to eHealth literacy. Variables with $P < .05$ were declared to be statistically significant predictors.

Results: A total of 383 participants completed and returned the questionnaire with a response rate of 90.5%. Health professionals demonstrated a moderate level of eHealth literacy (mean 29.21). Most of the professionals were aware of the available health resources located on the internet, and know how to search and locate these resources. However, they lack the ability to distinguish high-quality health resources from low-quality resources. Factors that were significantly associated with eHealth literacy were computer access, computer knowledge, perceived ease of use, and perceived usefulness of eHealth information resources.

Conclusions: It is crucial to provide training and support to health care workers on how to find, interpret, and, most importantly, evaluate the quality of health information found on the internet to improve their eHealth literacy level. Further research is needed to explore the role of eHealth literacy in mitigating pandemics in developing countries.

KEYWORDS

eHealth literacy; COVID-19; health information; health literacy

Introduction

The internet is currently one of the most widely used tools for obtaining information about health care and medical conditions [1], providing health professionals with unprecedented access to a massive volume of relevant and high-quality current health care information [2]. Moreover, the internet has a significant impact on health and health care since it can improve health care delivery and help decision-making for health care workers [3]. For modern health care recipients, the internet provides a useful and accessible source of health-related information [4].

Health literacy is vital for people who interact with the digital world, with its diverse information and sources [5], and plays an important role in evaluating online health information [6], especially during pandemics such as COVID-19, the disease caused by infection with the novel coronavirus SARS-CoV-2, which has posed unprecedented challenges worldwide [7,8]. The COVID-19 pandemic has been accompanied by the rapid spread of disinformation or fake news via social media platforms and other outlets. The dissemination of this misinformation could lead to people acting inappropriately, thereby jeopardizing governments' and health authorities' efforts to manage the pandemic [9]. To control this worldwide health catastrophe, eHealth literacy is recommended among the interdisciplinary and multidimensional techniques [9]. Individuals with adequate eHealth literacy are more likely to utilize the internet to obtain health-related information and believe they are capable of applying web-based knowledge to improve their health [10].

eHealth literacy is defined as the ability to seek out, find, interpret, evaluate, and appraise health information from electronic sources, as well as apply that knowledge to address or solve a health problem. This composite skill necessitates the ability to interact with technology, think critically about media and science concerns, and navigate a large assortment of information tools and sources to obtain the information needed to make decisions [5].

The eHealth Literacy Scale (eHEALS) was developed in response to the need to assess eHealth literacy in a variety of populations and settings. The eHEALS is a self-report tool that can be administered by a health professional and is based on a person's perception of their skills and knowledge in each of the measured domains. The test is intended to offer a broad estimate of consumer eHealth abilities that can be used to guide clinical decision-making and health-promotion planning with individuals or groups. The eHEALS has potential to be used in a clinical setting to identify individuals who may or may not benefit from referrals to an eHealth intervention or resource [1,5].

Controlling pandemics requires strong enabling environments as well as modern and digitized health information systems. Beyond the COVID-19 pandemic, it is critical to promote digital solutions [11]. Countries with health information systems that combine data from the health and long-term care sectors are likely to be better prepared to deal with this challenge [12]. The use of online consultations from hospitals and health care centers has been found to be a safe and effective way to mitigate the pandemic's negative effects [13].

The outbreak of COVID-19 has made eHealth literacy more vital than ever [9]. However, this has been an underestimated issue during the pandemic [14]. eHealth literacy has a direct effect on health-promoting behaviors by improving health information-seeking behavior, which can ultimately lead to health-promoting behavior and health outcomes [15]. eHealth literacy has the potential to increase adherence to infection prevention and control measures, promote healthy habits, and maintain health care workers' health. This would help contain the COVID-19 pandemic and further mitigate its impacts [16]. The world learned via COVID-19 that eHealth is not an optional or excessive approach to health care but rather a crucial, safer, and effective means of providing health care to both individuals with underlying problems and others during such periods. Because it is critical to obtain accurate information from reputable sources when self-managing diseases, individuals' health perceptions and behaviors are negatively influenced by misinformation [17,18].

Aside from having a basic understanding of how to utilize the internet and eHealth literacy, health care practitioners should be knowledgeable on how to evaluate sources of information as reputable sources of information [19]. According to a study conducted at the University of Gondar (UOG) specialized hospital, patients have a poor level of eHealth literacy, implying that there is a need to bridge the skill gap [20]. This study could imply that this is where health care professionals can help patients make health-related decisions, specifically to assist patients and families in getting up-to-date, reliable, and quality health information, and identifying and analyzing suitable web sources for such decisions. However, health care practitioners must be eHealth literate to provide this assistance [21]. The potential predictor variables of this study were identified based on the review of findings from other related literature. Previous studies showed that variables such as age, sex, professional background, work experience, training about information retrieval techniques, computer knowledge, perception toward web resources, and computer accessibility were significantly associated with eHealth literacy [16,22-26].

The expansion of smartphone penetrations, the growing number of internet users, and information needs in developing nations are the most compelling reasons for assessing eHealth literacy and its associated factors among health care professionals to maximize eHealth benefits. However, there is limited information on eHealth literacy among health care workers in Ethiopia. Therefore, the aim of this study was to assess eHealth literacy among health professionals at Amhara regional state teaching hospitals, as well as to identify factors that influence eHealth literacy. We postulated the following three key hypotheses.

Hypothesis 1: computer knowledge positively correlates with eHealth literacy.

Hypothesis 2: there is a significant positive association between eHealth literacy and perception (perceived usefulness and perceived ease of use).

Hypothesis 3: The accessibility of computers is positively linked with eHealth literacy.

Methods

Study Area, Design, and Period

The study was conducted among health professionals working at Amhara regional state teaching hospitals in Ethiopia from February 23 to May 10, 2020, using an institutional-based cross-sectional study design. Ethiopia is divided into nine regions and two city administrations. The Amhara region is the country's second-largest and most populous among these regions [27]. The Tibebe Ghion specialized teaching hospital in Bahir Dar city and UOG specialized teaching hospital in the town of Gondar are the two specialized teaching hospitals in the region. At the time of the survey, the UOG specialized teaching hospital had 1076 permanent employees, whereas the Tibebe Ghion specialized teaching hospital had 738 permanent employees.

Study Procedure

The study's sample size was calculated using the following single-population proportion formula by assuming that 50% of health professionals have a high degree of eHealth literacy and a 10% nonresponse rate.

$$[Z_{\alpha/2} \times p(1-p)]/d^2 = [(1.96)^2 \times 0.5(1-0.5)]/0.05^2 = 384.4 + 38.4 = 423$$

Where $Z_{\alpha/2}$ is the Z statistic (value of the standard normal distribution) at 95% confidence, d is the margin of error at 5%, and p is the single-population proportion.

Participants of the study were selected from the UOG and Tibebe Ghion specialized teaching hospitals. To guarantee a fair distribution of the entire sample, health care workers from each hospital were stratified based on profession and then study participants were chosen using a simple random sampling technique.

Measures

eHealth Literacy

eHealth literacy was measured using the eHEALS, which was introduced by Norman and Skinner [5] to determine consumers' combined knowledge and perceived skill in finding, evaluating, and applying eHealth information to health problems. The eHEALS has eight items that are scored on a 5-point Likert scale ranging from 1 (strongly disagree) to 5 (strongly agree), and the total score ranges between 5 and 40. This scale was reported as a reliable tool with a Cronbach α coefficient of .88 in the original study [5] and had a Cronbach α of .847 in this study. A high eHEALS score indicates a high eHealth literacy level, whereas a low eHEALS score indicates low eHealth literacy.

Computer Access

Computer access was measured by a yes-or-no question; health professionals were asked whether they can access computers in their working area/hospital or not.

Perceived Usefulness

Perceived usefulness was measured using five closed questions, and study participants who scored the mean and above on the 5-point Likert scale questions were categorized according to

whether they considered that using eHealth information resources to be useful or not useful.

Perceived Ease of Use

Perceived ease of use refers to the degree to which a person believes that using eHealth information resources is free of effort, which was measured using four closed questions. Study participants who scored the mean and above on the 5-point Likert scale questions were categorized as to whether or not they considered that using eHealth information resources is easy.

Computer Knowledge

Computer knowledge was assessed based on participants' self-perceived reports; respondents were asked to rate their level of computer knowledge according to five categories (none, beginner, below average, average, above average) with respect to basic computer skills and internet navigation. According to these responses, the participants were dichotomized as having poor or good computer knowledge for further analysis.

Data Collection

Self-administered questionnaires were used to collect the data. The questionnaire included 29 questions divided into four sections: sociodemographic characteristics (six items), the eHEALS (eight items), perceived usefulness of eHealth information resources (five items), and perceived ease of use (four items).

Data collectors received training on data collection techniques, maintaining the confidentiality of health professionals' information, obtaining informed consent, study participants' rights, and all study protocols. Before the actual data collection, a pretest was performed among 5% of the entire sample population outside the study area, and any required corrections and revisions to the questionnaire were implemented. The completeness of the questionnaire was checked daily.

Data Processing and Analysis

Epi-info version 7 was used for data entry. Data cleaning and coding were performed before any statistical analysis. Data analysis was performed with SPSS version 20 software. To describe the participant characteristics and study objectives, key variables are summarized in terms of descriptive frequencies and mean (SD).

Model fit was checked using the Hosmer and Lemeshow goodness-of-fit test. Bivariate analysis was then used to examine the relationship between individual independent variables and the dependent variable. Variables with $P \leq .20$ in the bivariate analysis were then entered into a multivariable logistic regression model to examine the relationship between selected independent variables and the outcome variable. In the multivariate analysis, variables with $P < .05$ according to the odds ratio were determined to be statistically significant independent predictors.

Ethical Statement

On behalf of the UOG College of Medicine and Health Sciences, ethical approval was secured from the Institute of Public Health (number IPH/840/02/2020). Written consent was obtained from

each study participant. The data were collected anonymously and participants' privacy was respected. Privacy of all of the information gathered was maintained and the data were solely utilized for research purposes.

Results

Characteristics of the Study Participants

With a response rate of 90.5%, 383 of the total disseminated questionnaires were returned. The majority of the 383 study

participants were male (Table 1). The mean age of the participants was 28.3 (SD 3.37) years. Nurses accounted for the highest proportion of professionals, followed by medical doctors and midwives. Less than 30% of the participants had received information-retrieval training on eHealth information sources (Table 1).

Table 1. Sociodemographic characteristics of the study participants (N=383).

Variables	Participants, n (%)
Sex	
Male	239 (62.4)
Female	144 (37.6)

eHealth Literacy

The overall mean score for eHealth literacy was 29.21 (SD 7.08), which is considered to be moderate; among the 383 health professionals surveyed, 225 (58.7%) had high eHealth literacy and the other 41.3% (n=158) had low eHealth literacy, defined as those scoring above and below the mean on the eHEALS, respectively. As shown in Table 2, 240 (62.7%) of the total survey participants reported knowing what health resources are available on the internet and 235 (61.3%) of the 383 participants agreed with the statement "I know where to find helpful health resources on the internet."

Only 221 (57.7%) of the 383 participants claimed that they could identify high-quality health resources from low-quality resources, indicating that almost half of the health professionals have trouble distinguishing quality health resources on the internet; 231 (60.3%) of the participants reported that they have the skills to evaluate health resources they found on the internet (Table 2).

Based on the participants' background characteristics, the majority of both the male and female participants had a high level of eHealth literacy. By contrast, nearly half of the nurses and one-third of medical doctors had a lower level of eHealth literacy (Table 3).

Table 2. Distribution of eHealth Literacy Scale (eHEALS) responses (N=383).

eHEALS statements	Rating scale, n (%)					Mean score
	Strongly disagree	Disagree	Unsure	Agree	Strongly agree	
I know what health resources are available on the internet	7 (1.8)	47 (12.3)	89 (23.2)	196 (51.2)	44 (11.5)	3.58
I know where to find helpful health resources on the internet	11 (2.9)	50 (13.1)	87 (22.7)	161 (42.0)	74 (19.3)	3.62
I know how to find helpful health resources on the internet	8 (2.1)	30 (7.8)	111 (29.0)	171 (44.6)	63 (16.4)	3.66
I know how to use the health information I find on the internet to help me	13 (3.4)	31 (8.1)	94 (24.5)	163 (42.6)	82 (21.4)	3.70
I know how to use the internet to answer my questions about health	14 (3.7)	30 (7.8)	87 (22.7)	191 (49.9)	61 (15.9)	3.67
I have the skills I need to evaluate the health resources I find on the internet	12 (3.1)	49 (12.8)	91 (23.8)	165 (43.1)	66 (17.2)	3.58
I can tell high-quality health resources from low-quality resources	17 (4.4)	36 (9.4)	109 (28.5)	157 (41.0)	64 (16.7)	3.56
I feel confident in using information from the internet to make health decisions	7 (1.8)	34 (8.9)	64 (16.7)	187 (48.8)	91 (23.8)	3.84

Table 3. eHealth literacy level by background characteristics.

Variables	Low eHealth literacy, n (%)	High eHealth literacy, n (%)

≥7 (n=38)	16 (42.1)	22 (57.9)

Computer Knowledge, Information Retrieval Training Need, and Perception Toward eHealth Information Resources

The majority of the study participants (314/383, 82.0%) stated that they require training in retrieving information from eHealth information sources. Approximately one-third of the participants (131/383, 34.2%) had poor computer knowledge. The majority of the participants (268/383, 70.0%) agreed that eHealth information resources are a useful tool in supporting them in making health-related decisions, and 57.7% (221/383) of the

participants also perceived that retrieving information from these sources is easy.

Factors Associated With eHealth Literacy

Bivariable and multivariable logistic regression analyses were used to discover potential predictor variables linked with eHealth literacy. Variables with $P < .20$ in the bivariable analysis were further considered in the multivariable logistic regression analysis. Finally, the multivariable logistic regression analysis revealed that the variables perceived usefulness, computer access, perceived ease of use of eHealth information resources,

and computer knowledge were significantly associated with health professionals' eHealth literacy; thus, all three hypotheses were supported.

Perceived usefulness was significantly associated with eHealth literacy. Health professionals who perceived using health information resources located on the internet as useful were approximately 2-times more eHealth literate than their counterparts who perceived using eHealth information resources

as not useful. Respondents who had computer access were also more than 2-times more likely to be eHealth literate than those who did not have computer access (Table 4).

The computer knowledge of health professionals was also significantly associated with eHealth literacy. Study participants who had good computer knowledge were 2.3-times more eHealth literate than those who had poor computer knowledge (Table 4).

Table 4. Multivariable logistic regression analysis of factors associated with eHealth literacy.

Variables	Adjusted odds ratio (95% CI)	P value

Discussion

Principal Findings

Higher levels of eHealth literacy may help people make better health-related decisions, resulting in better health outcomes [28]. This study found that the higher the eHealth literacy, the more it will promote social media use for health information, health information-seeking behaviors, and self-care agency. This will lead to better health-promoting behavior by raising the motivation and intention for health promotion [29]. The main purpose of this study was to estimate the level of eHealth literacy and identify its potential predictors among health care providers working in Amhara regional state teaching hospitals

in Ethiopia during the COVID-19 pandemic. Our results showed that health professionals in Amhara regional state teaching hospitals have a moderate level of eHealth literacy (mean 29.21). The findings also revealed that computer access, perceived usefulness of eHealth information resources, perceived ease of use of eHealth information resources, and computer knowledge were significantly associated with health professionals' eHealth literacy level.

Comparison With Prior Work

In a study on Iranian medical and health science university students, the mean eHEALS score was 28.21 [30]. However, health professionals in Germany have higher eHealth literacy levels [31]. The possible reason for this discrepancy might be

due to the variation of internet penetration between these countries, which is 19% in Ethiopia [32] and 93% in Germany [33]. Additionally, due to the limited availability of health-related information in languages other than English, geographical location, cultural, and language barriers may have an impact on eHEALS scores [34,35].

The majority of participants agreed that the internet assisted them in making health-related decisions, and while they believe they know where to find helpful health resources on the internet and how to use them, nearly two-fifth of participants were not confident in their ability to evaluate the information they have retrieved. In particular, the participants' inability to distinguish between high- and low-quality health resources on the internet suggests a potential weakness in their ability to recognize crucial characteristics that would aid in determining which website may be reliable. Despite the increasing availability of eHealth information and increased acceptance of this mode of communication, all populations, including health professionals, may lack the skills to keep up with this dynamic and changing medium [36].

In terms of professional background, we found that nurses and medical doctors had greater eHealth literacy levels than midwives, pharmacists, and other health professionals. This finding is consistent with a previous study conducted among health care workers in Vietnam [16]. This might be due to the fact that doctors have more professional training than other health professionals, and they have been identified as the group with the greatest capacity for finding, analyzing, justifying, and using health care-related information [37]. Furthermore, because nurses and doctors are the primary caregivers responsible for educating and directing patients, health literacy has been identified as a strategic approach for improving patient-health care worker communication [38].

This study also investigated the factors that can influence eHealth literacy. Computer access, perceived usefulness of eHealth information resources, perceived ease of use, and computer knowledge were identified as significant predictors. Participants who had computer access in their working area were more likely to be eHealth literate than those who did not. Low access to technologies could be the main reason behind the low access to eHealth services [39].

The participants' eHealth literacy score was associated with their computer knowledge. This finding is consistent with studies that showed a positive association between technology literacy and eHealth literacy [26,40]. A Bangladeshi study also revealed a significant association between eHealth literacy and computer knowledge among university students [25]. Participants who had computer expertise had higher eHealth literacy levels than those who had poor computer knowledge. Because of Ethiopia's status as a developing country, computer access is limited, literacy skills are insufficient, and health professionals consequently do not have equal access to eHealth resources.

In contrast to other studies [16], demographic variables such as the participants' sex and age were not found to be significantly

associated with eHealth literacy in this study. In a study conducted in Jordan, a nonsignificant association was found between sex, age, and eHealth literacy [22]. Similarly, no significant association was found between gender and eHealth literacy in an Italian study, whereas there was a significant association between age and eHealth literacy [23]. Further studies are needed to investigate the associations between gender, age, and eHealth literacy.

eHealth literacy was also significantly associated with the perceived usefulness of eHealth information sources. Participants who perceived eHealth information resources to be useful for making decisions were more eHealth literate than those who perceived these resources as not being as useful. These findings are supported by studies conducted among nursing students in Jordan [22] and Nepal [24].

It has been suggested that eHealth should be integrated into the health care system, as it can provide certain benefits for improving the quality of health care received [41]. Health professionals should be informed on the latest information and skills to acquire competency in using eHealth resources for patient care and clinical decision-making. According to a preliminary situation assessment, eHealth initiatives in Ethiopia are characterized as being of small scale and unable to effectively communicate with each other (ie, low interoperability). Accordingly, the Ethiopian government developed and formulated a national eHealth strategy for coordinating and streamlining the eHealth initiatives underway in the country as well as for establishing a foundation for sustainable eHealth implementation [42]. When promoting eHealth literacy among health professionals, perceived usefulness and ease of use of eHealth information sources, along with training on information retrieval, computer knowledge, and access should be considered.

Conclusions

This study provides an overview of health professionals' eHealth literacy levels in the Amhara regional state, Ethiopia, revealing that more than half of these professionals have a high degree of eHealth literacy. Additionally, the factors associated with eHealth literacy were explored, with the results suggesting significant associations of perceived usefulness, perceived ease of use, computer access, and computer knowledge. To improve health professionals' eHealth literacy, which could help them assist in decision-making, multidisciplinary approaches are needed. This would help to minimize the risk of infectious diseases such as COVID-19 and further mitigate its impacts. Health professionals also require eHealth literacy to assist their patients in obtaining more up-to-date, reliable, and high-quality information. It is crucial to provide training and support to health care workers on how to find, interpret, and, most importantly, evaluate the quality of health information found on the internet to improve their eHealth literacy level. Further research is needed to explore the role of eHealth literacy for mitigating pandemics in developing countries.

Acknowledgments

We would like to express our gratitude to the study participants for their willingness to participate. We also express gratitude to the data collectors and supervisors for their time and effort.

Authors' Contributions

All authors made a substantial contribution to the study's conception, design, methodology, and data analysis. GAT drafted the manuscript. All authors read the manuscript, revised it critically for important intellectual content, and approved the final version.

Conflicts of Interest

None declared.

Abstract

Background: The COVID-19 pandemic has required restrictive measures to mitigate transmission of the virus. Evidence has demonstrated increased generalized anxiety and depression among young adults due to the COVID-19 pandemic. However, minimal research has examined the longitudinal effect of COVID-19 over the course of time and its impact on anxiety and depression. Additionally, age and gender have been found to play a significant role on individuals' mental health, with young adults and women particularly at risk.

Objective: The aim of this study was to examine the impact of the COVID-19 pandemic on anxiety and depression upon admissions to treatment.

Methods: This was an observational study that was completed longitudinally in which the grouping variable split the time interval into five equal groups for assessments over each period of time. A total of 112 young adults (aged 18-25 years) were recruited for the study. Participants completed assessments online through a Qualtrics link.

Results: Psychometric properties of the admission assessments were uniformly highly statistically significant. There was a significant difference in generalized anxiety between the group-1 and group-3 time intervals. No significant difference was found across the time intervals for depression. Differences in predicting the impact of the psychometrics scores were found with respect to gender. Only the ability to participate and the quality-of-life subfactor of the Functional Assessment of Chronic Illness Therapy (FACIT) assessment were significant.

Conclusions: This study sought to understand the impact that COVID-19 has had on young adults seeking mental health services during the pandemic. Gender emerged as a clear significant factor contributing to increased anxiety in young adults seeking mental health services during the pandemic. These findings have critical importance to ensuring the potential treatment success rate of clients, while providing an overarching understanding of the impact of the pandemic and establishing clinical recommendations for the treatment of individuals who are seeking out treatment.

Introduction

On March 11, 2020, the World Health Organization declared the coronavirus SARS-CoV-2 (COVID-19) outbreak as a pandemic. To mitigate transmission, restrictive measures were imposed across the United States, including the closure and modification of businesses and mandates for the use of face masks and vaccinations, which have had an immediate and unprecedented impact on psychological health [1-9]. Incidences of depression and anxiety, among other struggles such as substance use, posttraumatic stress disorder (PTSD), eating disorders, and suicidality, have increased as a result of pandemic-related stressors such as lockdowns, exposure to infected people, loss of loved ones, and economic hardship [10,11]. Age and gender have been found to play significant predictive roles on the impact that COVID-19 stressors have had on individuals' mental health, with young adults and women identified to be particularly at risk [5,6].

Several studies have demonstrated an increased incidence of depression and anxiety during the COVID-19 pandemic among adults [6,12-17]. One US study found that in states that had more than 50 COVID-19 cases since March 10, 2020, each additional day resulted in an 11% increase in the probability of ascending into a higher incidence of mental health crises [18]. Quantitative studies conducted in other countries echo these findings. Ammerman et al [19] investigated the association between COVID-19 and the prevalence of suicidal thoughts and behaviors, showing that 45% of those who endorsed past-month suicidal ideation reported that their thoughts were directly related to COVID-19. Moreover, 9% of the sample reported intentionally exposing themselves to COVID-19, with 50% of these individuals intending to kill themselves through willfully contracting the COVID-19 virus [19]. Taken together, these findings suggest a significant predictive relationship between COVID-19 stressors and the prevalence and severity of individuals' mental health, including anxiety and depression. However, there is a lack of research examining the impact of COVID-19 over the prolonged course of the pandemic.

Predictive factors related to the impact of COVID-19 stressors have also begun to emerge in the current literature. Age has been found to play a significant predictive role in the impact of COVID-19 on mental health. Evidence from several recent studies suggests that young adults are particularly at risk for experiencing mental health problems during the pandemic [12,14,20-24]. Studies have reported high levels of depression and anxiety symptoms in college students and young adults as a result of COVID-19 pandemic-related stressors [3,5,6,14,16,23,25]. More specifically, researchers evaluating the impacts of the COVID-19 quarantine in France among 69,054 university students found a high prevalence of suicidal ideation (11.4%), severe distress (22.4%), heightened perceived stress (24.7%), severe depression (16.1%), and high levels of anxiety (27.5%) [23]. Researchers also examined the prevalence of PTSD, depression, and psychological risk factors in 2485 home-quarantined college students, finding that PTSD had a prevalence of 2.7% and depression had a prevalence of 9.0% [25]. García-Portilla et al [26] examined the psychological

effects of the pandemic across age groups and found that those under 60 years old were at greatest risk. One potential related factor contributing to this finding is lack of resilience, as younger individuals have less years of experience in coping with hardship, which is a developmentally acquired skill [26,27]. These findings suggest that age has the potential to be a strong predictive factor of interest in the relative impact of COVID-19 stressors on key facets of mental health.

Gender has also been found to play a significant predictive role in the relative impact of COVID-19 on mental health. Turna et al [28] examined the effects of the COVID-19 pandemic on multiple facets of mental well-being. Anxiety and depression were assessed using the General Anxiety Disorder (GAD-7), Patient Health Questionnaire (PHQ-9), and Perceived Stress Scale among 632 participants, 82% of whom identified as female. The results showed that nearly one-third (31%) of participants met the criteria for generalized anxiety disorder and 29% met the criteria for major depressive disorder. Female gender was significantly predictive of psychiatric symptoms at a 99% CI. These findings are also supported by evidence found in a study by Emery et al [29] that looked at how COVID-19 impacted the mental health and behaviors of young adults in the United States: female gender, prepandemic mental illness symptoms, and self-reported stress were found to be emergent risk factors for mental illness. Kecojevic et al [30] obtained similar findings when examining the impact of COVID-19 on the mental health of college students, in which female students reported higher anxiety than male students. Collectively, these results suggest that female gender is a risk factor for COVID-19-related anxiety [28-30].

Emerging adulthood is a time of uncertainty and exploration, and the COVID-19 pandemic has had a compounding effect on this process, resulting in a significant decline in life satisfaction and a significant increase in mental health problems [31]. The aim of this study was therefore to examine the longitudinal impact of the COVID-19 pandemic on anxiety and depression upon admissions to treatment at a long-term and intensive outpatient mental health program for young adults (The Dorm). Specifically, this study examined the prevalence and acuity levels of generalized anxiety and depression diagnoses upon admissions in the first 15 months of the COVID-19 epidemic. Particular attention was paid to how gender identity was associated with acuity levels of anxiety and/or depression. We anticipated that as the pandemic continued over time, so would depression and generalized anxiety among young adults.

Methods

Participants

We attempted to recruit 133 individuals for this study, 112 of whom ultimately volunteered. The 21 individuals who did not complete the study cited lack of interest for not participating. Among the 112 young adults that agreed to participate (mean age 22.3, SD 3.2 years), 53 (47.3%) self-identified as female. Inclusion criteria were: (1) admitted to The Dorm, (2) provided informed consent, and (3) at least 18 years of age. Exclusion criteria were: (1) unfit to complete the survey due to medical

or psychological constraint and (2) not fluent in the English language.

Setting

The Dorm is an intensive outpatient program for young adults aged 18-35 years operating in New York City and Washington, DC. Empirically supported behavioral psychosocial methodologies are implemented to serve a variety of mental health illnesses and co-occurring disorders over the course of a phased treatment, which is typically a 1-year admittance (on average). In addition, holistic approaches such as exercise, yoga, Reiki, horticulture, community service, meditation, and mindfulness are an integral part of the treatment model. All clients participate in family programming, including weekly parent coaching, parent groups, and family groups. Clients work with both a therapist and a clinical coach, and participate in 3-30 hours a week of group therapy depending on the treatment phase.

Assessments

Generalized Anxiety Disorder

The GAD-7 is a 7-item, self-rated scale developed in correspondence with the Diagnostic and Statistical Manual and updated for the 5th Edition, which is used as a screening tool and severity indicator for generalized anxiety disorder. Reliability of this assessment demonstrated a Cronbach α of .92 [32].

Patient Health Questionnaire

The PHQ-9 is a 9-item self-report scale that is used for screening, diagnosing, monitoring, and measuring the severity of depression (mild, scores of 5-9; moderate, scores of 10-14; moderately severe, scores of 15-19; severe, scores of 20-21) [33]. Reliability of this assessment demonstrated a Cronbach α of .89.

Barratt Impulsivity Scale

The Barratt Impulsivity Scale (BIS-11) is a 4-point Likert scale from “rarely/never” (score=1) to “almost always/always” (score=4), where 4 indicates the most impulsive response [34,35]. However, there is no standard BIS-11 score that is consistently used to designate an individual as “highly impulsive.”

Functional Assessment of Chronic Illness Therapy Measurement System

The Functional Assessment of Chronic Illness Therapy (FACIT) Measurement System is a 27-item questionnaire that focuses on the domains of physical well-being, social/family well-being, emotional well-being, and functional well-being. Items are scored on a 5-point Likert scale, where participants endorse “not at all” to “very much” as the statement applies over the past 7 days [36].

Patient-Reported Outcomes Measurement Information System Scales

Ability to Participate in Social Roles and Activities

The Patient-Reported Outcomes Measurement Information System (PROMIS) Ability to Participate in Social Roles and

Activities is an 8-item self-report questionnaire that assesses the perceived ability to perform one’s usual social roles and activities. Items are worded negatively in terms of perceived limitations and responses are reverse-coded, where 5 indicates “never” and 1 indicates “always”; thus, higher scores represent fewer limitations (better abilities). The item bank does not use a time frame (eg, over the past 7 days) when assessing the ability to participate in social roles and activities.

General Self-Efficacy

PROMIS General Self-Efficacy is a 10-item measure used to assess a person’s belief in their capacity to manage daily stressors and have control over meaningful events [33]. This measure was derived from the National Institutes of Health Toolbox Self-Efficacy Item Bank by creating new “confidence” response options that mirrored the same response options as in the PROMIS measures of the Self-Efficacy for Managing Chronic Conditions scale: “I am not at all confident,” “I am a little confident,” “I am somewhat confident,” “I am quite confident,” “I am very confident” [37].

Friendship (Ages 18+) Fixed Form

PROMIS Friendship (Ages 18+) Fixed Form is an 8-item scale evaluating the perceptions of the respondent on their availability of friends or companions with whom to interact or affiliate with in the past month on a 5-point Likert scale (1=never, 5=always).

Perceived Rejection (Ages 18+)

PROMIS Perceived Rejection (Ages 18+) is an 8-item scale evaluating how often people perceive others to be arguing/yelling at them and the perceived insensitivity over the past month on a 5-point Likert scale (1=never, 5=always).

Sleep-Related Impairment Questionnaire

The PROMIS Sleep-Related Impairment Questionnaire is an 8-item questionnaire that measures self-reported alertness, sleepiness, tiredness, and functional impairments associated with sleep problems during waking hours within the past 7 days [38]. This measure uses a 5-point Likert scale (1=not at all, 5=very much).

Procedure

All potential participants were consented either through a private meeting using Zoom virtual conference software or in person under standardized COVID-19 protocols. Consent forms were read orally, and any questions were answered by the investigator or research assistant before asking the participant to electronically sign their name on the tablet. By electronically signing their name, the participant was assigned a random 6-digit number generated by Qualtrics survey management tools. All consented individuals were tracked and followed through a password-protected Microsoft Access file. Each participant was asked to complete the assessments online through the Qualtrics link. The research assistant stayed with the participants and provided assistance as needed until the completion of the survey. The total length of time required to complete the survey did not exceed 40 minutes.

Ethical Considerations

The study was approved by Yale School of Medicine's institutional review board prior to participant recruitment (IRES number 2000026514). This research was performed in alignment with the World Medical Association Declaration of Helsinki (2018).

Data Analysis

Data were analyzed using SPSS for Windows, version 26.0. The grouping variable split the time interval into five equal phases (1=March 2020 through May 2020; 2=June 2020 through August 2020; 3=September 2020 through November 2020; 4=December 2020 through February 2021; 5=March 2021 through May 2021).

Mean group and overall differences were analyzed using one-way analysis of variance, whereas dichotomous variables (eg, age, gender, location) were analyzed using Fisher-exact or χ^2 tests. Strengths of association between variables were examined by the Pearson correlation coefficient and by linear regression analyses with generation of odds ratios and accompanying 95% CIs. All statistical tests were two-tailed with an α level of .05. Additionally, linear regression was used with gender (male, female, transgender, and other) as the dependent variable to evaluate its impact on psychometric assessments.

Results

The demographic characteristics of the participants are summarized in [Table 1](#). Over 98% of participants were single

at admission and the majority either had some college or a high school/equivalent education when combined. The majority of participants were white, with equal representation of self-identified males and females at admission, along with individuals identifying as transgender and other represented. The highest percentage of admissions were unemployed 45%, and nearly 60% of those admitted had experienced at least a singular traumatic event in their lifetime.

[Table 2](#) presents a correlation matrix of the psychometric properties of the admission assessments, which were uniformly highly statistically significant. [Figure 1](#) presents the participants' average acuity of primary diagnosis of generalized anxiety and/or depression across the time intervals, along with the range of scores within each grouping. There was a significant difference in generalized anxiety levels between the group-1 and group-3 time intervals. No significant difference was noted across the time intervals for the depression assessment.

Additionally, the findings from the linear regression demonstrated differences across gender and the admission psychometrics. Significant findings were noted ($F_{101}=2.025$, $P=.04$) to predict the impact of the psychometrics scores on gender. However, as noted in the coefficients subtable, only ability to participate ($P=.002$) and the quality-of-life subfactor of the FACIT ($P=.02$) assessments were significant with other values being not significant. In contrast to initial indications, depression and anxiety were not significant factors across gender at admission to this program.

Table 1. Demographics of admission intakes (N=112).

Characteristic	Value	P value

Figure 1. Aggregate differences of anxiety and depression across the past five consecutive quarters.

Discussion

Principal Findings

Restrictive measures put in place to mitigate transmission of the coronavirus SARS-CoV-2 (COVID-19) have had an immediate and unprecedented impact on people's psychological health and well-being, especially as they relate to the incidences and severity of depression and anxiety. This study sought to understand the impact that COVID-19 has had on young adults seeking mental health services at an outpatient program during the pandemic. The results indicated a significant increase in anxiety in young adults across the measured time periods of the

pandemic, in particular between March and November of 2020, or phases 1-3 as defined in this study. This increase in anxiety coincides with a rising number of cases and COVID-19 becoming the third leading cause of death in the world, as death tolls were hitting their highest peak since 2015 (15.9% increase) [39]. The American Psychiatric Association issued a public opinion poll in 2020, which found that 80% of participants were either somewhat or extremely anxious about keeping themselves and their families safe in 2020, while 75% were worried about COVID-19 specifically.

The results also demonstrated that self-identified gender was a significant predictor of mental health. Female clients scored

lower than their male counterparts on measures of “quality of life” and “ability to participate in daily activities,” both of which are subscores that are reliably indicative of broader mental well-being. This is consistent with the literature, which suggests that female-identified individuals are more significantly impacted by psychological distress than their male-identified counterparts [40-42]. In particular, female-identified individuals between the ages of 26-35 years are most at risk in terms of vulnerability to stress [40]. Future research should consider the biological, social, and cognitive mechanisms underlying these gender differences.

Comparison With Prior Work

Mental health conditions account for 16% of the global burden of disease and injury in people aged 10-19 years. Young adulthood is a critical time of interpersonal, intrapersonal, social, educational, and vocational development [43]. Research shows that the brain does not fully develop until the age of 25, and risk factors for mental health may be of increased concern for the developing brain [8]. Half of all mental health disorders in adulthood start by age 14 [44]. Furthermore, COVID-19 has only exacerbated these statistics, heightening the public health urgency [12,14,20-23]. While young adults were at lower risk for the direct health effects of hospitalization or death due to COVID-19, research is needed to understand any long-lasting mental health effects that may be detrimental to development. The findings of this study echo the need to understand the long-term public health impact on young adult mental well-being. Future research should continue to evaluate the public health impact of COVID-19 on young adults in a systematic manner.

The findings emphasize the importance of secondary mental health concerns among young adults, especially female clients in this case. While this study demonstrated that young adults experienced a significant increase in anxiety during the pandemic and that gender was a significant factor in the compromised mental well-being of young adults, it will be necessary to continue to study the lasting and secondary impact of anxiety to prepare for and provide successful treatment to young adults. Anxiety is correlated with and can exacerbate secondary mental health concerns and symptoms such as substance use, PTSD, and suicidality. For instance, the prevalence of PTSD in 2485 home-quarantined college students was reported to be 2.7% [25]. In a study that looked at the association between COVID-19 and the prevalence of suicidal thoughts and behaviors, researchers found that 45% of those who demonstrated past-month suicidal ideation reported that their thoughts were directly related to COVID-19 [19]. Finally, substance use may have increased significantly during COVID-19, especially among those who already had preexisting mental health conditions such as anxiety and depression [45,46].

These secondary mental health concerns have the potential to compromise young adults beyond their psychological and emotional well-being. Secondary mental health concerns can lead to reduced productivity at home, school, and in the labor market. Special attention to the secondary effects of heightened anxiety in young adults because of COVID-19-associated stressors is vital to ensure the critical need for mental health preparedness from a global perspective.

Limitations

There are several limitations of this study. The longitudinal research design limits the generalizability of the findings due to not having a repeated measurement. Future research should evaluate the long-term impact of similar findings in a more systematic manner that includes a more rigorous research design methodology. Additionally, the sample size is relatively small, thus providing an initial understanding of the acuity of anxiety and depression in young adults seeking intensive outpatient programming during the pandemic. Another limitation is the lack of racial and socioeconomic diversity within the sample. A majority of the sample were white individuals. Additionally, research has demonstrated that marginalized populations such as non-white Hispanic and Asian populations experienced higher levels of the subjective perception of distress, worry, and fear [47]. Further research is needed to explore the impact of COVID-19 on racially and ethnically diverse populations as well as those with different socioeconomic statuses. Additionally, we did not collect information on the socioeconomic status of the participants. Future research is needed to understand if this is a covariate for increased anxiety and depression. While we recognize this as a contributing limitation within the manuscript, it should be noted that longitudinal data discussing the impact of COVID-19 on mental health are currently lacking. Lastly, due to restrictions put in place by COVID-19 and the corresponding state regulations, treatment for individuals within the first quarter was primarily conducted virtually instead of in person. While this deviates from the current protocol in place, all attempts were made to make the virtual sessions as equally representative as the in-person interactions.

Conclusion

This study attempted to understand the impact of COVID-19 on the admissions of an outpatient program for young adults. It was apparent that COVID-19 had a larger impact on the quality of life for women than for men. Additionally, it was apparent that there was a significant difference in generalized anxiety between the first and third intervals during the COVID-19 pandemic. These findings highlight the need to better understand the mental health impact of the COVID-19 pandemic.

Authors' Contributions

AF wrote the majority of the manuscript and provided editing of the manuscript. AC conducted the literature review, wrote a portion of the manuscript, and edited the manuscript. BC edited the manuscript, formatted the manuscript, and wrote portions of the manuscript. KJ edited the manuscript and wrote portions of the manuscript. FB obtained the consent, designed the research study, conducted the analyses, wrote a portion of the manuscript, edited the manuscript, and provided mentorship.

Conflicts of Interest

AF, BC, AC, and KJ are employed by The Dorm; however, they were not responsible for the data management or analysis. FB has no potential conflicts of interest to disclose.

Abstract

Background: Respiratory sounds have been recognized as a possible indicator of behavior and health. Computer analysis of these sounds can indicate characteristic sound changes caused by COVID-19 and can be used for diagnostics of this illness.

Objective: The aim of the study is to develop 2 fast, remote computer-assisted diagnostic methods for specific acoustic phenomena associated with COVID-19 based on analysis of respiratory sounds.

Methods: Fast Fourier transform (FFT) was applied for computer analysis of respiratory sound recordings produced by hospital doctors near the mouths of 14 patients with COVID-19 (aged 18-80 years) and 17 healthy volunteers (aged 5-48 years). Recordings for 30 patients and 26 healthy persons (aged 11-67 years, 34, 60%, women), who agreed to be tested at home, were made by the individuals themselves using a mobile telephone; the records were passed for analysis using WhatsApp. For hospitalized patients, the illness was diagnosed using a set of medical methods; for outpatients, polymerase chain reaction (PCR) was used. The sampling rate of the recordings was from 44 to 96 kHz. Unlike usual computer-assisted diagnostic methods for illnesses based on respiratory sound analysis, we proposed to test the high-frequency part of the FFT spectrum (2000-6000 Hz).

Results: Comparing the FFT spectra of the respiratory sounds of patients and volunteers, we developed 2 computer-assisted methods of COVID-19 diagnostics and determined numerical healthy-ill criteria. These criteria were independent of gender and age of the tested person.

Conclusions: The 2 proposed computer-assisted diagnostic methods, based on the analysis of the respiratory sound FFT spectra of patients and volunteers, allow one to automatically diagnose specific acoustic phenomena associated with COVID-19 with sufficiently high diagnostic values. These methods can be applied to develop noninvasive screening self-testing kits for COVID-19.

Introduction

The World Health Organization (WHO) reported that till October 16, 2021, about 241 million people were infected with the novel coronavirus (COVID-19) worldwide and about 18 million people currently have the disease [1]. COVID-19 is a public health problem in all countries regardless of their level of development.

It is known that SARS-CoV-2 causes a severe lower respiratory disease with high mortality and evidence of systemic spread [2]. The virus is able to actively multiply in the epithelium of the airways. Intense cough is 1 of the main symptoms of COVID-19. It is known that the highest density of cough receptors is in the larynx [3]. Anatomically, a dry cough can be associated with the effect of the virus on the cough receptors of the larynx due to infection with COVID-19. SARS-CoV-2 can penetrate into the smallest airways, where it infects cells and causes bilateral pneumonia, often with respiratory failure [4-7]. The damage of various airways, caused by SARS-CoV-2, alters sound formation in the patient and changes the characteristics of respiratory sounds. Detection of characteristic respiratory sounds (cough, wheezes, asthma wheezing, shortness of breath, etc) is a widely used way of diagnostics of pulmonary diseases, which is applied to develop new computer-assisted diagnostic methods (eg, [8-12] and references therein).

At present, diagnostics of COVID-19 is based on clinical symptoms, chest X-ray/computed tomography (CT), and coronavirus tests (polymerase chain reaction [PCR]), molecular tests, antigen tests, and specific antibodies to SARS-CoV-2 [6,7,13]. New and more contagious COVID-19 virus strains are appearing in the United Kingdom, the Republic of South Africa, Vietnam, and some other countries; in India, the daily number of new infected persons was up to 300,000 in May 2021. Therefore, it is desirable to develop vast, cheap, and widely available remote methods of COVID-19 diagnostics. One of these methods can be based on computer-assisted analysis of respiratory sounds of the patient and on comparison of the sound characteristics between a patient and a healthy volunteer.

The objectivity of auscultatory diagnostics can be significantly enhanced by using digitized audio signals and computer processing of these signals. Automated adventitious sound detection or classification is a promising solution to overcome the limitations of conventional auscultation and to assist in the monitoring of relevant diseases, such as asthma, chronic obstructive pulmonary disease (COPD), and pneumonia [14]. Olvera-Montes et al [15] used the detection of respiratory crackle sounds through an Android smartphone-based system for the diagnostics of pneumonia and monitoring of the patient's state.

Reyes et al [16] used a smartphone-based system for automated bedside detection of crackle sounds in patients with diffuse interstitial pneumonia. The performance of automated detection was analyzed using (1) synthetic fine and coarse crackle sounds randomly inserted into basal respiratory sounds acquired from healthy subjects with different signal-to-noise ratios and (2) real bedside-acquired respiratory sounds from patients with interstitial diffuse pneumonia. In simulated scenarios, for fine

crackles, an accuracy ranging from 84.86% to 89.16%, a sensitivity ranging from 93.45% to 97.65%, and a specificity ranging from 99.82% to 99.84% were found. The detection of coarse crackles was found to be a more challenging task in the simulated scenarios. In the case of real data, the results show the feasibility of using the developed mobile health system in a clinical noncontrolled environment to help the expert in evaluating the pulmonary state of a subject.

The overview concerns the potential for computer audition (CA), that is, the use of speech and sound analysis by artificial intelligence to help in COVID-19 diagnostics [17]. Automatic recognition and monitoring of breathing, dry and wet coughing or sneezing sounds, speech under cold, eating behavior, sleepiness, or pain are used. Schuller et al [17] concluded that CA appears to be ready for implementation of (pre-) diagnosis and monitoring tools.

It was considered that the acquired breathing sounds can be analyzed using advanced signal processing and in tandem with new deep machine learning and pattern recognition techniques to separate the breathing phases, estimate the lung volume, estimate oxygenation, and further classify the breathing data input into healthy or unhealthy cases [18]. Computer analysis of breath sounds can be important for identification of specific changes in these sounds, caused by COVID-19.

Brown et al [19] used the exploring automatic diagnostics of COVID-19 from crowdsourced respiratory sound data. The results of early works [16-19] and references therein allow one to suggest that respiratory sounds can be useful in COVID-19 diagnostics.

The purpose of this study is to 2 develop fast, remote methods of diagnostics of specific acoustic phenomena associated with COVID-19 based on computer-assisted analysis of respiratory sounds. The developed methods are based on analysis of fast Fourier transform (FFT) spectra of respiratory sounds recorded near the mouth. We proposed to use a personal computer, a modern mobile telephone, or a smartphone for registration, recording of respiratory sounds, and their analysis. The developed methods can be applied as additional screening methods of COVID-19 diagnostics and as personalized screening self-testing kits for COVID-19. Such self-tests would serve as an early step before further procedures ordered by a doctor (PCR test, lung CT, X-ray, etc). We restricted our work to consideration of breathing sounds (and not cough and voice samples). Lung diseases, such as asthma, COPD, and pneumonia, cause specific changes in the FFT spectra of respiratory sounds in the frequency range from 100 to 2500 Hz, and this range is usually considered during development of computer-assisted diagnostic methods (eg, [8-12,20-22] and references therein). We considered the larger frequency range up to 6000 Hz, and it was shown that for diagnostics of COVID-19, the frequency range from 2000 to 6000 Hz is significant. This allows us to diagnose specific acoustic phenomena associated with COVID-19 for patients with other lung diseases as well.

Methods

Patients

In this study, 14 patients with COVID-19 and 17 healthy volunteers participated. COVID-19 in the patients was diagnosed using medical methods, such as analysis of clinical symptoms, chest X-ray and CT, coronavirus tests (PCR test for SARS-CoV-2 RNA [the main method], specific antibody test for SARS-CoV-2). The clinical examination of the patients and the recording of their respiratory sounds were carried out at Perm Infectious Hospital, and the volunteers' respiratory sounds were recorded at Perm State Medical University (Perm, Russia).

Ethical Considerations

This study complied with the Declaration of Helsinki (adopted in June 1964, Helsinki, Finland), revised in October 2000 (Edinburg, Scotland) and was overseen by the independent ethics committee of Perm State Medical University (approval code: 5/21). Written agreements from the patients and volunteers were obtained.

Methods of Recording Respiratory Sounds

Doctors performed all the recordings, and patients and volunteers were instructed to remain calm and to breathe easily. No special measures to reduce ambient noise were applied. The respiratory sounds of patients were recorded in m4a format using a Honor dua-1 22 smartphone at a distance of 2 cm from the mouth for about 20 s; the sampling rate was 48 kHz. The respiratory sounds of volunteers were recorded near the mouth using a mobile telephone (the sampling rate was 44.1 kHz, mp3 format) and a computer-based recording system (the sampling rate was 96 kHz, wav format) [20-25]. Our comparison of the records carried out with the help of various devices showed that although the mp3 and m4a formats compress a signal, the FFT spectra of a sound recorded in the wav, mp3, and m4a formats are practically the same. To analyze respiratory sounds, we proposed to consider the normalized FFT spectra that largely decrease the influence of the recording format.

Simultaneous recordings of respiratory sounds in the same point of a patient in different formats were made. The normalized integral characteristics of the FFT spectra used for diagnostics differed by less than 3% for different formats.

The beginnings and ends of the recordings made using the smartphone and the mobile telephone contained temporal parts, in which respiratory sounds are not recorded. In these parts, there are short impulses, the amplitudes of which can be much larger than the respiratory sound maximum. The impulses do not reflect the processes in the airways. The applied preliminary processing removed these parts.

Diagnostic Methods

The 2 proposed diagnostic methods were based on the fact that lung diseases cause changes in the airways and these changes are reflected in the spectra of respiratory sounds. This approach has been applied in the development of computer-assisted methods of diagnostics of various lung diseases [8-12,20-26]. These developed methods were based on the analysis of the

FFT spectra of respiratory sounds in the frequency range from 100 to 2500 Hz and the comparison of the spectra of patients and healthy volunteers.

We proposed to compare different parts of the FFT spectrum of a patient with COVID-19 in a higher frequency range from 2000 to 6000 Hz. Examples of the amplitude-frequency dependences (spectra) of FFT for a patient with COVID-19 and a healthy volunteer are presented in Figure 1. In many cases, the FFT spectra of volunteers do not possess well-defined maximums and minimums, as shown in Figure 1a. One can see several differences (Table 1) in the spectra for a volunteer and a patient: the maxima and minima of their spectra are located in various frequency ranges; these differences could be used to formulate potential healthy-ill criteria, which are presented in Table 2. Similar locations of the maxima and minima were observed, for example, in the spectra for the first, third, and ninth patients. The clearly seen amplitude increase in the frequency range from 1000 to 1500 Hz in the spectrum for the first patient (Figure 1b) can be a result of concomitant disease (upper respiratory tract infection).

In Table 2:

where f_a is the frequency of the extremum, $A(f)$ is the harmonic amplitude at frequency f , and Δf is the half of the frequency range, chosen equal to 300 Hz. In the program, the integral is replaced by a sum of harmonic amplitudes with a frequency in the range from $(f_a - \Delta f)$ to $(f_a + \Delta f)$.

The criteria under test were formulated as ratios of the integrals of the harmonic amplitudes over various frequency ranges (Table 2 and Equation 1). So, the criteria values were independent of the breathing intensity.

Adventitious sounds caused by an illness change not only the amplitude-frequency dependence of the respiratory sound FFT spectrum but also the frequency-amplitude dependence. The second proposed method is based on analysis of differences between the frequency-amplitude dependences of FFT spectra for patients and volunteers.

The moments of the frequency (MF) distribution can be considered as potential healthy-ill criteria:

and

where i_{\min} and i_{\max} are the harmonic numbers corresponding to the minimal ($f_{\min}=2000$ Hz) and maximal ($f_{\max}=5900$ Hz) frequencies, respectively, and f_i is the frequency of the i -th harmonic.

The MF distribution was also independent of the breathing intensity.

Figure 1. Amplitudes of FFT harmonics for the first healthy volunteer (a) and the first patient with COVID-19 (b). The amplitudes are given in arbitrary units. FFT: fast Fourier transform.

Table 1. Comparison of the FFT^a spectra of a volunteer and a patient with COVID-19.

Volunteer	Patient
Minimum at about 2300 Hz	No extremum in the frequency range
Maximum at 3100 Hz	Minimum at 3300 Hz
Minimum at 4100 Hz	Maximum at 3900 Hz
Maximum at 4900 Hz	Minimum at 5000 Hz
No extremum at a frequency above 5300 Hz	Maximum at 5600 Hz

^aFFT: fast Fourier transform.

Table 2. Healthy-ill criteria.

Criteria	Healthy	Ill
$k_1 = I(2300)/I(3200)$	$k_1 < 1$	$k_1 > 1$
$k_2 = I(3200)/I(4000)$	$k_2 > 1$	$k_2 < 1$
$k_3 = I(4000)/I(5000)$	$k_3 < 1$	$k_3 > 1$
$k_4 = I(5000)/I(5600)$	$k_4 > 1$	$k_4 < 1$

Results

The First Method

The results of the calculation of potential healthy-ill criteria k_1 , k_2 , k_3 , and k_4 are presented in Tables 3 and 4.

For the reader’s convenience, Figure 2 presents the distribution of the criteria through patients with COVID-19 and volunteers. Comparing the results presented in Tables 3 and 4 and Figure 2, one can see that the most reliable result is given by the high-frequency criterion k_4 .

For healthy volunteers, the criterion should be >1 ; this was correct in $T_N=15$ (88.2%) of 17 cases and incorrect in $F_N=2$ (11.8%) cases. For patients with COVID-19, the criterion should be <1 ; this was observed in $T_p=11$ (78.6%) of 14 cases. COVID-19 was not diagnosed in $F_p=3$ (21.4%) cases.

The criterion for the 12th patient was close to the boundary value of 1. The second proposed method also had the healthy-ill criterion close to the boundary value (Figure 3). Analysis of the recording for the patient showed that the outside noise was high, and this can cause incorrect diagnostics.

Additionally, we applied the proposed method for diagnostics of COVID-19 using the respiratory sound recordings of 30 patients and 26 healthy persons (ages 11-67 years, 34, 60%, women). None of them reported that they had other lung diseases. These recordings were made by the persons themselves, who agreed to be tested at home, using a mobile telephone. The sound recordings were passed to us through WhatsApp. The cases of COVID-19 illness were confirmed by PCR tests, and in all cases, the illness was asymptomatic or mild. The proposed method gave the correct diagnosis for 26 (86.7%) of 30 patients and 22 (84.6%) of 26 healthy ones. The

PCR tests for persons who were incorrectly diagnosed as ill gave negative results.

Several patients made a few recordings during the process of the disease. Development of a spectrum of a patient is presented in Figure 3. Though the spectrum varied noticeably, the k_4

criterion was less than 1 during the illness. The pathological process was characterized by a clearly seen increase in harmonic amplitudes in a wide frequency range. The third-day spectrum corresponded to the most severe condition of the person (according to their message).

Table 3. Criteria k_1 , k_2 , k_3 , and k_4 for patients with COVID-19.

Patient number	Age (years), gender (F=female, M=male)	Diagnosis	k_1	k_2	k_3	k_4
1	18, F	COVID-19, upper respiratory tract infection	>1	<1	>1	<1
2	80, F	COVID-19, unilateral pneumonia	>1	>1	>1	<1
3	47, F	COVID-19, bilateral pneumonia	>1	<1	>1	<1

Figure 2. Healthy-ill criteria according to Tables 3 and 4: blue circles for volunteers and red squares for patients.

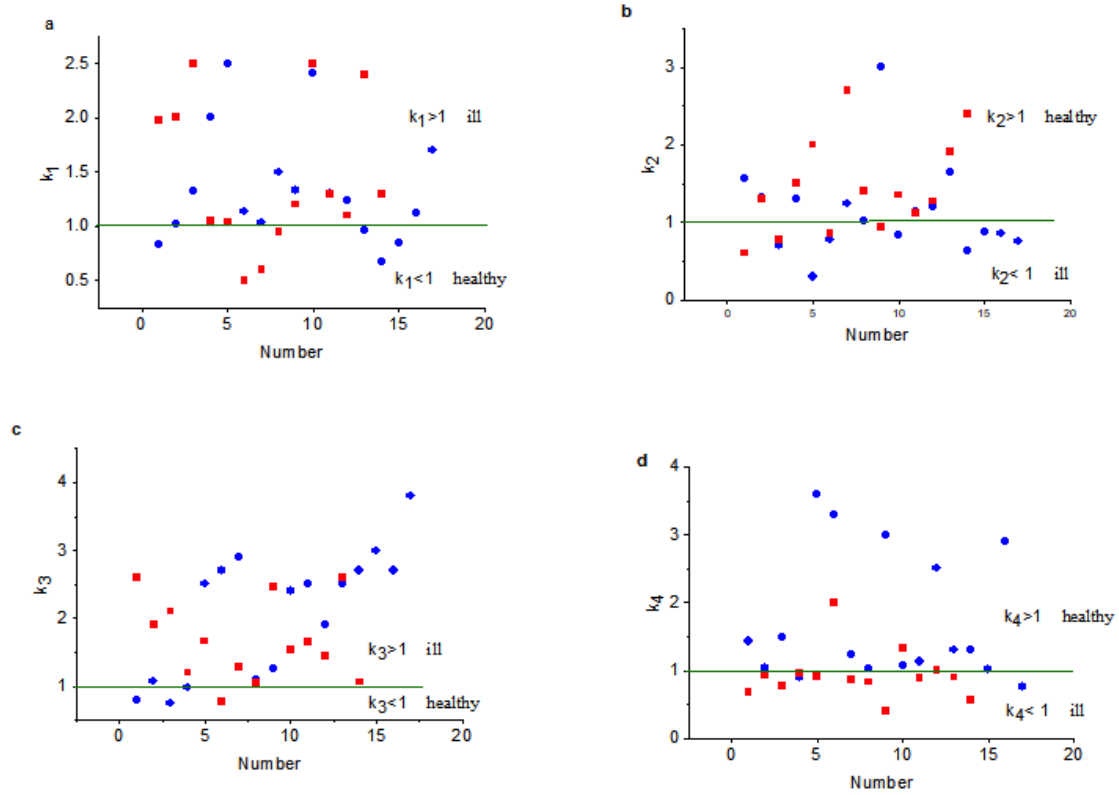

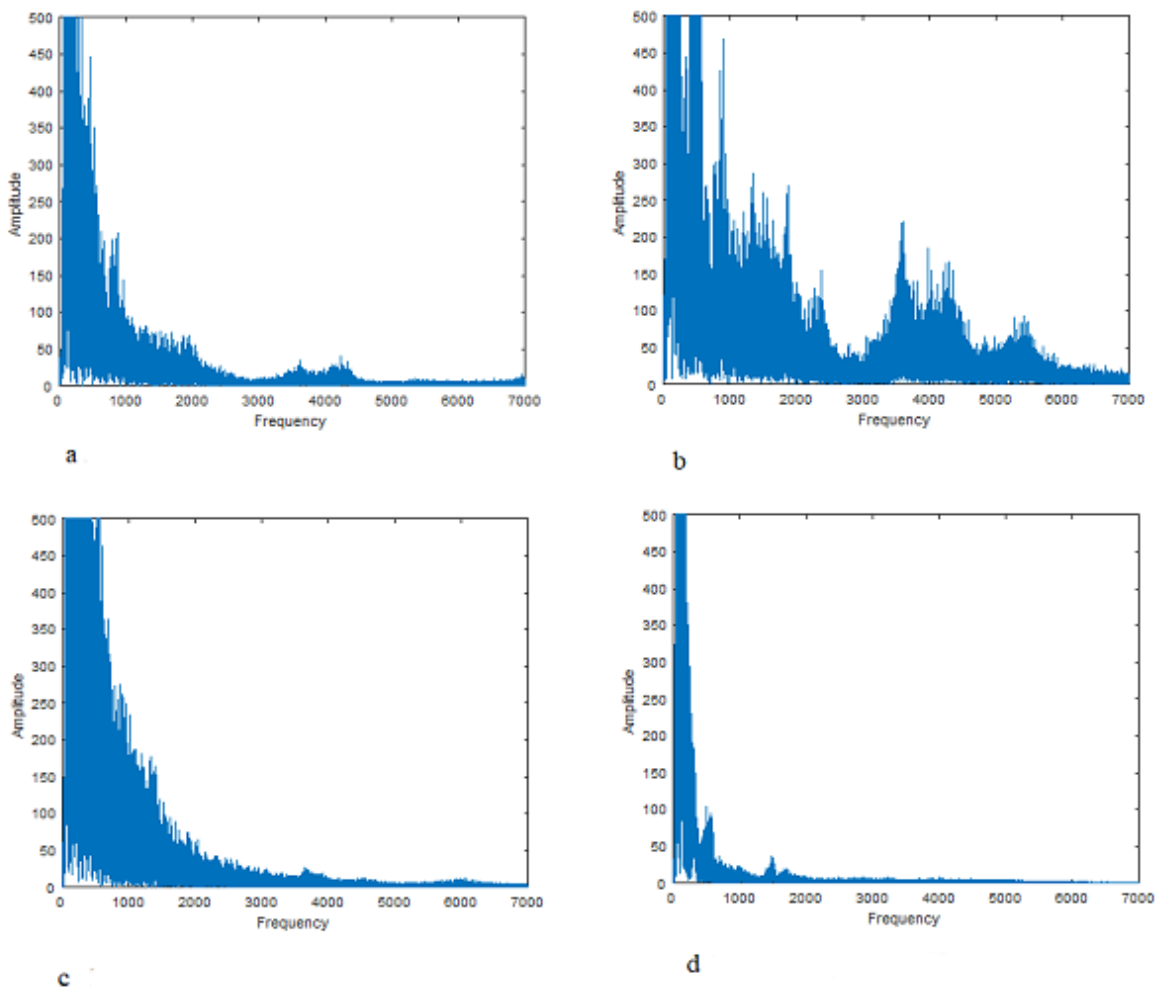

Figure 3. Change in the respiratory sound FFT spectrum of a patient with COVID-19 in the disease process. On the first day, the illness was diagnosed using the PCR test; on the last (11th) day, the person was diagnosed as healthy. The amplitudes are given in arbitrary units. FFT: fast Fourier transform; PCR: polymerase chain reaction.

The Second Method

We compared the values of MF and MF_n (n=2, 3, and 4) as well as MF_n/MF and MF_n/MF₂. The best result was obtained for MF₄/MF (Figure 4). In this figure, the blue line corresponds to the boundary value, which was selected by us as equal to 0.8: If (MF₄/MF)×10⁻⁹ is >0.8, the examined person is ill; if it is <0.8, the person is healthy. The second method, like the first one, gave incorrect diagnostics for the sixth patient and overdiagnosis for the fourth volunteer. The respiratory sound recording for this volunteer was characterized by a relatively low level of a signal and high noise. The overdiagnosis for the fourth volunteer could be the result of low quality of the recorded signal.

The second method correctly diagnosed patients as sick in T_p=13 (92.8%) of 14 cases and volunteers as healthy in T_N=14 (82.3%) of 17 cases. The method misdiagnosed patients as healthy only once, F_p=1 (7.2%), and healthy volunteers as sick in F_N=3 (17.7%) cases.

The second method applied to the respiratory sounds recorded by persons at home demonstrated a diagnostics effectivity that was close to that of the first method.

The results allow us to assess the main characteristics of the 2 proposed methods. Here, for characterization of the proposed methods, we used sensitivity, specificity, and the Youden index. The sensitivity of a method is determined by the formula [27]

$$S_e = \frac{TP}{TP + FN}$$

and its specificity as

$$S_p = \frac{TN}{TN + FP}$$

The sensitivity and specificity of the first method from Tables 1 and 2 were estimated as S_e=0.786 and S_p=0.882, respectively, and for the second method as (Figure 2) as S_e=0.93 and S_p=0.824. Here, we considered the results obtained only for people who were tested at the hospital.

The Youden index is calculated using the following formula:

$$YI = S_e + S_p - 1$$

The Youden index for the first method was about 0.67 and for the second was 0.754.

For the reader's convenience, these results and the sensitivity, specificity, and Youden index for both methods are presented in Table 5.

Figure 4. Healthy-ill criterion $(MF_4/MF) \times 10^{-9}$: blue circles for volunteers and red squares for patients. Each number on the horizontal axis indicates the number of a patient or a volunteer according to Tables 3 and 4, respectively. The blue line corresponds to the boundary value of 0.8. MF: moments of the frequency.

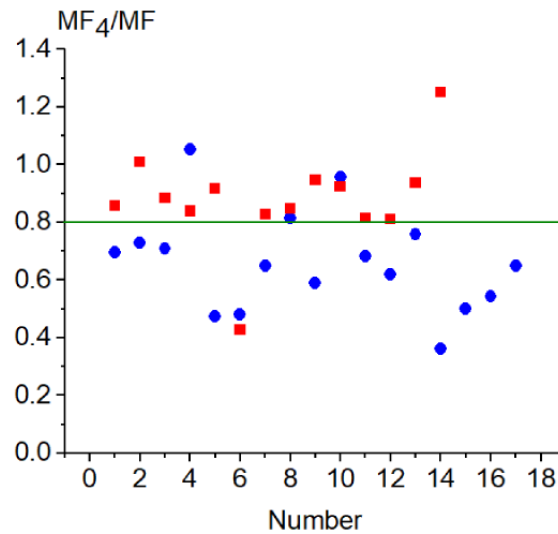

Table 5. Comparison of the 2 proposed methods.

Method	T_p	F_p	T_N	F_N	S_e	S_p	J
First	11	3	15	2	0.786	0.882	0.67
Second	13	1	14	3	0.93	0.824	0.754

Discussion

Principal Findings

The proposed computer-assisted diagnostic methods for COVID-19, which are based on analysis of respiratory sounds recorded near the mouth, demonstrated high diagnostic accuracy. For people tested at the hospital, the second method demonstrated better characteristics (sensitivity of 0.93, specificity of 0.824, and Youden index of 0.754) than the first one.

Both methods demonstrated close diagnostic characteristics when analyzing respiratory sound recordings made by persons themselves using a mobile telephone at home and submitted to us through WhatsApp. The proposed methods correctly diagnosed 86.7% of patients and 84.6% of healthy ones. These results demonstrate the possible application of the proposed methods for remote diagnostics.

Although a relatively low number (due to pandemic limitations) of the examined patients with COVID-19 and healthy volunteers did not allow estimating the method characteristics with high accuracy, the proposed methods correctly diagnose patients with COVID-19 in a wide age range, and the proposed criteria of healthy/ill are independent of the patient's age, sex, etc, as well as concomitant diseases, such as upper respiratory tract infection, pneumonia, exacerbation of COPD, and bilateral pneumonia (Table 3).

The patient and volunteer groups contained members of various genders and ages (from 5 to 80 years).

High diagnostic characteristics of the proposed methods independent of age were achieved due to comparison of various parts of the respiratory sound FFT spectrum. For example, in the first method, the ratio k_4 of integrals over various frequency ranges was determined and compared with the boundary value: If $k_4 > 1$, the examined person is healthy, and if $k_4 < 1$, the person is ill. The ratio is independent of the recording devices and sampling rate, and as our results showed, the boundary value does not depend on the individual patient characteristics and even on concomitant diseases (Table 3).

Comparison With Prior Work

Each lung disease is characterized by specific changes in the airways or lungs. These changes cause abnormal (adventitious) sounds, which can be separated into several types (wheezing, stridor, crackles, etc). These abnormal sounds are characterized by their durations and specific frequency ranges being below 2500 Hz [8,10,12]. For example, bronchial asthma is characterized by airway obstruction and inflammatory process, which covers all airways, from the central to the peripheral parts of the tracheobronchial tree (small bronchi) [21]. Asthmatic changes in the lungs cause typical respiratory sounds, with the main frequency in low-frequency ranges between 100 and 1000 Hz [12,28,29] and between 400 and 1600 Hz [12,30] (Figure 5). For analysis of respiratory sounds of patients with pulmonary diseases (asthma, pneumonia, HIV infection, etc) and

development of computer-assisted diagnostic methods, the frequency range from 100 to 2500 Hz is usually considered.

Figure 5. FFT spectra of sound signals for an asthmatic patient. The amplitudes are given in arbitrary units. FFT: fast Fourier transform.

For diagnostics of specific acoustic phenomena associated with COVID-19, we proposed to consider the high-frequency range of respiratory sound FFT spectra. It can be assumed that an upper respiratory tract injury leads to the appearance of changes in a higher-frequency part of the spectrum; it can be associated with COVID-19 [31]. Severe forms of tracheobronchitis were consistently present in 88% of COVID-19 cases [32-34]. This assumption is confirmed by our results: the most reliable criterion is the k_4 criterion, which is determined for the high-frequency range of the FFT spectrum, from 4700 to 5900 Hz (the first proposed method).

A decrease in the diagnostic value of the k_1 , k_2 , and k_3 criteria can be the result of concomitant diseases, which cause changes in the respiratory sounds in the lower-frequency range [8,10,12]. Another reason of the low accuracy of diagnostics based on the k_1 , k_2 , and k_3 criteria can be a higher sensitivity of the parameters f_a and Δf at low frequencies to individual characteristics of patients (age, sex, weight, etc) and also to fatigue and anxiety.

The second proposed method of computer-assisted diagnostics of COVID-19 is also based on the consideration of the high-frequency range of the FFT spectrum, from 2000 to 6000 Hz.

The high diagnostic accuracy is achieved in both methods due to our offer to compare various parts of the FFT spectrum of a patient (volunteer). This allows us to minimize the influence of the breathing intensity as well as the gender and age dependences of the FFT spectrum.

One of the ways to increase the diagnostic values of the proposed computer-assisted methods is to create a big database and determine the parameters (f_a and Δf for the first method and f_{\min} and f_{\max} for the second one) using machine learning.

The proposed methods for COVID-19 diagnostics are based on the consideration of the high-frequency ranges of FFT spectra. The most reliable result is given by the high-frequency criterion k_4 for the frequency range above 4700 Hz. Other lung illnesses do not cause abnormal respiratory sounds (adventitious sounds) in the considered frequency range; changes caused by them are between 50 and 2500 Hz (see Figure 5 and [8,10,12,28,35]). This fact and the independence of the proposed criteria of the concomitant diseases allow us to assume that the criteria can be used for diagnostics of COVID-19. We analyzed FFT spectra for several patients with other lung diseases (without COVID-19), such as asthma (Figure 5), bilateral pneumonia, pneumonia, and upper respiratory tract infection, and did not find these specific changes in the high-frequency range above 4700 Hz.

Limitations

The proposed screening self-tests would serve as a preliminary step before further procedures are ordered by a doctor. The results of the screening self-tests should be confirmed by other diagnostic methods (chest X-ray/CT and coronavirus tests, such as PCR test, antigen test, and specific SARS-CoV-2 antibody test).

Conclusion

The high-frequency range of the respiratory sound FFT spectrum contains information about the health state of the examined person. The proposed computer-assisted methods based on analysis of this spectrum part can be applied as fast, remote additional screening methods (telemedicine) for specific acoustic phenomena associated with COVID-19. The methods demonstrate sufficiently high diagnostic values. The methods can be a basis for the development of noninvasive screening self-testing kits for COVID-19. To increase the accuracy and

reliability of the methods, a big database of respiratory sounds of patients with COVID-19 and volunteers should be created.

Abstract

Background: It is expected that personal health information collected through mobile information terminals will be used to develop health strategies that benefit the public. Against this background, several countries have actively attempted to use mobile phones to control infectious diseases. These collected data, such as activity logs and contact history, are countermeasures against diseases such as COVID-19. In Japan, the Ministry of Health, Labor, and Welfare has developed and disseminated a contact-confirming app (COVID-19 Contact-Confirming Application [COCOA]) to the public, which detects and notifies individuals whether they have been near someone who had subsequently tested positive for COVID-19. However, there are concerns about leakage and misuse of the personal information collected by such information terminals.

Objective: This study aimed to investigate the possible trade-off between effectiveness in preventing infectious diseases and infringement of personal privacy in COCOA. In addition, we analyzed whether resistance to COCOA would reduce if the app contributed to public health or if a discount was provided on mobile phone charges.

Methods: A cross-sectional, quantitative survey of Japanese citizens was conducted using *Survey Monkey*, a general-purpose web-based survey platform. When developing the questions for the questionnaire, we included the installation status of COCOA and recorded the anxiety stemming from the potential leakage or misuse of personal information collected for COVID-19 infection control. The respondents were asked to rate various factors to determine their perceptions on a 5-point scale.

Results: In total, 1058 participants were included in the final analysis. In response to the question of whether the spread of the disease was being controlled by the infection control measures taken by the government, 25.71% (272/1058) of the respondents answered that they strongly agreed or agreed. One-quarter of the respondents indicated that they had already installed COCOA. This study found that the sense of resistance to government intervention was not alleviated by the benefits provided to individuals when using the app. The only factors that were positively associated with the response *absolutely opposed to use* of the app, even with a discount on mobile phone use charges, were those regarding leaks and misuse of personal information, which was true for all functions (function A: odds ratio [OR] 1.8, 95% CI 1.3-2.4; function B: OR 1.9, 95% CI 1.5-2.6; function C: OR 1.8, 95% CI 1.4-2.4).

Conclusions: Public organizations need to emphasize the general benefits of allowing them to manage personal information and assure users that this information is being managed safely rather than offering incentives to individuals to provide such personal information. When collecting and using citizens' health information, it is essential that governments and other entities focus on contributing to the public good and ensuring safety rather than returning benefits to individual citizens.

Introduction

Background

With the development of information technology, the use of big data has become more common. Indeed, there are many examples where big data have been successfully used to promote general public health by referring to the personal information collected via the data terminals of smartphones, as smartphones are carried around by people everywhere and form a part of their lives [1,2].

Against this background, several countries have actively attempted to use mobile phones for infectious disease control by launching, as well as promoting the download of, apps to collect data, such as activity logs and contact history, as a countermeasure against COVID-19. Each country has unique methods for doing so [3,4]. For example, in South Korea and Singapore, the government has taken the lead in developing and disseminating contact-tracing apps that track the history of individuals who are infected and established the necessary system to rapidly share data with municipalities and medical institutions [5-7].

Although the situation in early 2022—in which unlimited personal information could be uploaded to a specific information cloud or similar means for secondary use—might have been convenient, it involved various ethical, legal, and social problems [8-10]. For example, many contact-tracing apps developed to prevent the spread of COVID-19 have GPS-tracking capabilities, and the information collected by these apps includes detailed movement records of individuals. If this information were to be leaked or used for purposes other than as intended, an individual's privacy would be severely compromised. Moreover, because of the nature of the information, the purpose for which it is to be used must be communicated, along with details about the agencies managing the information and the scope of information use [11]. Wacksman [12] warned that the unprecedented demands stemming from the response to the spread of COVID-19 pose new risks, such as the collection of vast amounts of data and the risk of increasing demands for data sharing that go beyond the intended purpose.

In Japan, the Ministry of Health, Labor, and Welfare has developed and disseminated a contact-confirming app (COVID-19 Contact-Confirming Application [COCOA]) to the public, which notifies individuals whether they have been near an individual who has tested positive for COVID-19. The Ministry of Health, Labor, and Welfare explains the purpose of COCOA on its website as follows:

With knowledge of the possibility that an individual was in contact with a “positive” individual, users can receive early support from public health centers, such as by undergoing a test. As the number of users

increases, it is hoped that this initiative will help prevent the spread of infection.

As of April 2022, there have been >32.5 million downloads of COCOA, and it is thought that approximately 1 in 5 people living in Japan have installed the app on their mobile device or devices. In Japan, COCOA is the most widely used contact verification app, and citizens have only 2 choices: installing or not installing COCOA.

COCOA was developed as a Bluetooth-based exposure notification app rather than a contact-tracing app. Thus, current COCOA functions do not have the ability to track moving individuals through GPS or collect personal movement logs. If users who have installed this app on their mobile device come into close contact (within 1 m for ≥ 15 minutes) with an individual who is COVID-19 positive (positive registration is confirmed by self-report), the Bluetooth communication function detects this and informs the person that they have been in high-risk contact with an individual who is COVID-19 positive.

The information delivered through the notification does not include the location information of the app user who is infected—only a contact code is exchanged when a user contacts another app user's smartphone. Owing to the nature of COCOA's functions, there is very little risk of personal information being shared with government authorities, and the possibility of private information being externally leaked or used for other purposes is also considered to be extremely low [13].

However, whether COCOA functions effectively as an infection control measure against COVID-19 warrants further investigation, as there appear to be 3 reasons for its likely dysfunction. First, the app involves a double opt-in by users in terms of positive result registration through COCOA, which requires both the installation of COCOA on mobile devices and the proactive registration of a positive result (as sharing test results is not mandatory). Consequently, it is assumed that there are many undetected cases for which no alerts are issued, even when a person has actually been in contact with an individual who is COVID-19 positive [13,14]. Second, the app cannot collect data on people's movements, which makes it almost impossible for authorities to intervene directly or implement specific strategies, such as infection control, using the log data. Third, even for an alert indicating such contact, there is no function to suggest specific actions to be taken afterward; thus, the app cannot facilitate effective behavioral changes at the individual level to prevent further infections [13,14]. Several empirical investigations into the attitudes of actual users (citizens) of contact-tracing apps and exposure notifications toward the future use of such apps (regarding the balance between risks related to the leakage of private information, the use of such apps for other purposes, and the benefits to public health and individuals) have been conducted since the start of

the COVID-19 pandemic [15-19]. In a survey aimed at examining why some Australian citizens had not downloaded the app launched by their government, Thomas et al [18] reported that citizens were concerned about the app's technical functionalities and privacy and were distrusting of the government. According to a citizen survey on COCOA conducted by Machida et al [15], the main concerns that inhibited app use were identified as *lack of knowledge on how to use it, privacy concerns, doubts about the effectiveness of the app, and concerns about battery consumption and communication costs*. By contrast, there is a lack of international evidence on citizens' acceptance of apps when there is a trade-off between the app's features and the associated personal and public health benefits.

Objectives

In this study, we conducted a quantitative survey of Japanese citizens to identify the extent to which they were resistant to features that could be implemented in contact-confirming apps. This study investigates the possible trade-off between the effective prevention of infectious diseases and infringements of personal privacy. In addition, we analyzed whether this resistance would decrease if users perceived a contribution in terms of public health or if they received a discount on their mobile phone charges in exchange for app use.

Methods

Study Design and Participants

In this study, we conducted a cross-sectional web-based survey using *Survey Monkey*, a general-purpose web-based survey platform [20]. The target population was set as the general population, aged ≥ 18 years, living in Japan, and having their own mobile devices. We recruited participants with a target of 1000 respondents. For this, we invited a sample of residents who fit the general target population requirements from among the survey monitors of the contracted research company, Asmarq.co.jp [21]. A sample of 1300 respondents was initially recruited, and if the final number of respondents did not reach 1000, additional samples were added. This process ended when the number of respondents exceeded 1000. The survey was anonymous as the researcher could track neither the respondents nor the nonrespondents. The researcher did not pay any incentives directly to the respondents; however, a sampling fee was paid to the research company. Participants were required to check the details and overview of the survey presented on the website. The actual survey commenced once they provided informed consent. The survey was conducted in June 2021.

Instruments

A set of multiple-choice questions was developed to accomplish the objectives of this study through a cross-sectional survey on the internet. The specific survey items are listed in [Multimedia Appendix 1](#).

As independent variables were assumed to be associated with dependent variables, we asked about the respondents' characteristics, frequency of use of social networking sites (SNSs), COVID-19 infection history, fears related to COVID-19 infection, level of adherence to infection prevention behaviors

(behavioral restrictions and mask wearing), and their assessment of government agencies and hospital responsibility for infectious disease prevention.

As dependent variables, we tried to include the installation status of COCOA, as well as record respondents' anxiety regarding potential leakage or misuse of personal information collected for COVID-19 infection control. Respondents were asked about their anxiety on a 5-point scale from *strongly agree* to *strongly disagree*, with *neutral* as their neutral option. In addition, respondents were asked about their degree of resistance to the use of the app if the following 3 functions (that COCOA does not currently have) were added:

- Function A: If a respondent is found to have COVID-19, information on the respondent's infection would be provided to the authorities via a medical institution and reflected in COCOA notifications.
- Function B: In addition to function A, this function would use the location information function of smartphones to track and prompt individuals to take specific actions, such as requesting a medical examination.
- Function C: All movement data of people who have installed the app would be recorded through their mobile devices and aggregated by the government; these data would be used by the government to plan and implement specific infection prevention measures.

The respondents were asked to indicate their level of resistance to the use of the app if the various functions were added on a 5-point scale: *absolutely opposed to use, significant resistance to use, some resistance to use, not much resistance to use, and no resistance to use*. Finally, we asked about the resistance to each function when it was understood that the addition of functions A, B, or C would bring about a trade-off in benefits to individuals versus the public. Specifically, participants were asked about their resistance to each feature in the following cases:

- Condition 1: if 50% of the population uses the app with each feature added, the degree of spread of the infection would be halved compared with nonuse of the app.
- Condition 2: if installing the app with each feature resulted in a discount on their monthly mobile phone bill; the options were set as approximately ¥200 (US \$1.48) per month, ¥500 (US \$3.70) per month, ¥1000 (US \$7.29) per month, ¥2000 (US \$14.78) per month, ¥3000 (US \$22.17) per month, ¥5000 (US \$36.95) per month, and would not want to use it irrespective of the discount.

Data Collection

Participants sampled by the survey company visited Survey Monkey's website to take the survey we created. Thereafter, respondents were informed via the web about the purpose of the survey and the advantages and disadvantages of participating; only those who agreed to participate became respondents. The survey ended when the number of respondents exceeded 1000. Responses to the web-based survey were collected in the cloud, and the individual forms were downloaded by the principal investigator.

Statistical Analysis

SPSS (version 27; IBM Corp) was used for statistical analysis. All data entered for the survey, including age, were categorical. Descriptive statistics included descriptions of all independent and dependent variables, including patient characteristics. Logistic regression analysis was performed to analyze the factors that could explain the dependent variables. In performing the logistic regression analysis, we attempted to dichotomize the dependent variables into 0 and 1. As a criterion for dichotomization, we categorized anxiety regarding leakage or misuse of personal information collected for COVID-19 countermeasures between *agree* and *neither*. In addition, resistance to the proposed newly added functions was dichotomized between *absolutely opposed to use* and *significantly resistant to use*. The former option was dichotomized to determine whether a person had a small amount of anxiety. For the latter, we considered the presence of a clear and strong refusal to use the service as an important threshold for attitude. All statistical tests were 2-tailed, and $P \leq .05$ was set as the threshold for statistical significance.

Ethics Approval

This study was reviewed and approved by the Biomedical Research Ethics Committee of the National Hospital Organization Tokyo Medical Center in May 2021 (approval number R21-030).

Results

Participants' Sociodemographic Information

We recruited 1300 people through a research company, of whom 1191 (91.62%) accessed the survey website. The eligibility criteria were being aged ≥ 18 years, living in Japan, and having their own mobile phones. Of the 1191 individuals, 1096 (92.02%) met the eligibility criteria, and after excluding those who did not give consent or dropped out, 1058 (88.83%) participants were included in the analysis.

The basic characteristics and frequency of SNS use by the respondents are presented in Table 1. Regarding respondents' age, 8.82% (93/1058) were aged ≤ 34 years, 71.73% (759/1058) were aged 35 to 64 years, and 19.48% (206/1058) were aged ≥ 65 years. Regarding gender, 43.37% (459/1058) were female; regarding marital status, 66.6% (705/1058) were married; and regarding the number of people living together, 16.41% (174/1058) lived alone. The proportion of respondents who had personally contracted COVID-19 was 1.12% (12/1058), whereas the proportion of respondents whose family or close friends had been infected was 3.2% (34/1058). The frequency of SNS use (ie, Twitter, Facebook, and Instagram) was as follows (in the order *not used*, *used several times per month or less*, and *used several times per week or more*): 46.34% (487/1058), 20.6% (218/1058), 33.41% (353/1058) for Twitter; 52.32% (553/1058), 26.59% (281/1058), 21.1% (223/1058) for Facebook; and 58.78% (622/1058), 16.91% (179/1058), and 24.3% (257/1058) for Instagram.

^bCOCOA: COVID-19 Contact-Confirming Application.

Awareness of COVID-19 and Infectious Disease Control

The respondents' attitudes toward COVID-19 and infection control measures are shown in [Table 1](#). Respondents were asked how strictly they adhered to the government's requests to wear a mask when going out and restrict their activities, such as attending meetings in person. Approximately 93.21% (986/1058) and 88.59% (937/1058) of respondents said that they strictly adhered to or adhered to the requests with some exceptions for

wearing masks and for restricting activities such as meetings, respectively.

In response to the question of whether the spread of the disease was being controlled by the infection control measures taken by the government and various prefectures, 25.8% (273/1058) of respondents answered that they *strongly agreed* or *agreed*. When asked if the government and prefectures were conducting infection control measures with a strong sense of responsibility, 31.41% (332/1058) of respondents answered that they strongly agreed or agreed. When asked how fearful they were of harm

to their own health, the transmission of the disease to their family and friends, or transmission to others if they were to contract COVID-19, the respondents answered that they either *strongly agree* or *agree* with these 3 scenarios at 77.28% (818/1058), 79.43% (840/1058), and 75.5% (799/1058), respectively. When asked whether they were concerned that personal information and other data collected as part of the countermeasures against COVID-19 by the national and prefectural governments would be leaked or misused for other purposes, 41.17% (436/1058) of respondents answered that they *strongly agree* or *agree*.

One-quarter of the respondents indicated that they had already installed COCOA. They were given an overview of the functions of the current COCOA. Once each of the 3 aforementioned functions (A, B, and C) were added, the percentage of respondents who said that they would be absolutely opposed to its use or had significant resistance to its use was 27.31% (289/1058) for function A and 31.4% (332/1058) for function B. The difference compared with when only function A was added was not significant. With the addition of function C, this percentage was 33.63% (355/1058).

Respondents' Resistance to the Additional Functions, Even With Benefits and Trade-offs

The percentage of respondents who said they were *absolutely opposed to use* of the app even if half of the population used it with functions A, B, and C (enabling the degree of spread to be reduced to half of what it would be if the app were not used) was 11.6% (123/1058) for function A, 13.33% (141/1058) for function B, and 13.71% (145/1058) for function C. The percentage of respondents who said that they were *absolutely opposed to use* of the app, even if the effect of using it was to halve the spread of infections, was 10.36% (110/1058) for function A, 12.21% (129/1058) for function B, and 12.43% (131/1058) for function C. In response to the question "Would you accept the use of the app with each of the functions added, if the following reductions in mobile phone usage charges were applied?" the respondents who selected "I would not want to use the app irrespective of the discount" was 34.62% (366/1058) for function A, 36.77% (389/1058) for function B, and 37.3% (395/1058) for function C (Table 2).

Table 2. Resistance to using the COVID-19 Contact-Confirming Application under various conditions when functions are added to the current version (N=1058).

Condition and response option	Function A (responses), n (%)	Function B (responses), n (%)	Function C (responses), n (%)
Feature addition only			
No resistance to use	141 (13.5)	123 (11.9)	124 (12)
Not much resistance to use	282 (27.1)	251 (24.2)	243 (23.4)
Some resistance to use	334 (32.1)	337 (32.5)	321 (31)
Significant resistance to use	164 (15.7)	187 (18.1)	206 (19.9)
Absolutely opposed to use	121 (11.6)	138 (13.3)	142 (13.7)
A function is added, thereby halving the spread of infections			
No resistance to use	140 (13.4)	118 (11.3)	120 (11.5)
Not much resistance to use	304 (29.1)	259 (24.9)	256 (24.7)
Some resistance to use	339 (32.5)	369 (35.5)	354 (34.1)
Significant resistance to use	152 (14.6)	168 (16.1)	180 (17.3)
Absolutely opposed to use	108 (10.4)	127 (12.2)	129 (12.4)
Feature additions mean reduced charges for device use			
Would accept at a discount of about ¥200 (US \$1.48) a month	112 (10.7)	83 (8.0)	88 (8.5)
Would accept at a discount of about ¥500 (US \$3.70) per month	147 (14.0)	112 (10.7)	97 (9.3)
Would accept at a discount of about ¥1000 (US \$7.29) per month	154 (14.7)	150 (14.4)	147 (14.1)
Would accept at a discount of about ¥2000 (US \$14.78) per month	87 (8.3)	123 (11.8)	110 (10.6)
Would accept at a discount of about ¥3000 (US \$22.17) per month	52 (5)	53 (5.1)	65 (6.3)
Would accept at a discount of about ¥5000 (US \$36.95) per month	133 (12.7)	138 (13.2)	145 (13.9)
I would not want to use it regardless of the discount	362 (34.6)	384 (36.8)	388 (37.3)

Factors Associated With the Dependent Variables

The results of the logistic regression of the relationship between those who installed COCOA and the basic characteristics of the respondents are shown in Table 3. There was no significant difference in terms of gender or age groups; regarding the frequency of SNS use, those who used Facebook at least several times per week were more likely to have COCOA installed (odds ratio [OR] 1.5, 95% CI 1.0-2.2). Although there was no significant difference in terms of their own or family members' history of COVID-19 infection, those who answered *strongly agree* or *agree* to the question of whether they feared they might infect others if they contracted COVID-19 were more likely to have installed COCOA (OR 2.2, 95% CI 1.1-4.7). In addition, those who reported adhering to government-mandated behavioral guidelines for infection control were more likely to have installed the app (OR 2.0, 95% CI 1.0-4.0).

The association between the response *absolutely opposed to use* of the contact-confirming app with added functions A, B,

and C and the independent variables of the respondents are provided in Table 4. The respondents' basic characteristics, frequency of SNS use, history of COVID-19 infection, fear of the consequences of being infected themselves, and the degree of adherence to infection control behaviors were not significantly associated with the dependent variables for any of the functions A, B, and C. However, when all functions were added, those who were concerned about leaks or misuse of their personal information were more likely to respond that they were *absolutely opposed to use* of a contact app with more functions added than those who were not concerned (function A: OR 2.1, 95% CI 1.4-3.3; function B: OR 2.3, 95% CI 1.5-3.5; function C: OR 2.5, 95% CI 1.7-3.7). For function B, there was a negative correlation between the answers of *strongly agree* and *agree* in response to the question of whether the national and prefectural governments were controlling the spread of infections with a strong sense of responsibility and the response of *absolutely opposed to use* with the new functions (OR 0.5, 95% CI 0.2-0.9).

Table 3. Factors related to COVID-19 Contact-Confirming Application installation.

Independent variables	Odds ratio (95% CI)
Female (reference: male)	0.7 (0.5-1.0)

Respondent has a history of COVID-19	1.5 (0.7-3.4)	1.5 (0.7-3.4)	1.2 (0.5-3.0)
Respondent's family has a history of COVID-19	0.9 (0.6-1.6)	0.9 (0.5-1.5)	0.8 (0.5-1.4)
Respondent fears COVID-19 infection (reference: disagree)			
Fear of health deterioration to oneself	0.9 (0.5-1.8)	0.9 (0.5-1.7)	0.8 (0.4-1.6)
Fear of transmission to one's family and friends	0.7 (0.3-1.7)	0.8 (0.3-2.0)	0.7 (0.3-1.6)
Fear of transmission to people other than family members or friends	0.9 (0.4-2.2)	0.7 (0.3-1.6)	1.0 (0.4-2.3)
Compliance with preventative behaviors (reference: I do not do this)			
Wearing masks when going out	0.8 (0.3-1.8)	0.8 (0.3-1.8)	0.9 (0.4-2.0)
Restrictions on activities such as meetings	0.5 (0.3-1.0)	0.5 (0.3-1.0)	0.5 (0.3-1.0)
Assessment of authorities (reference: disagree)			
Infection is being controlled through countermeasures conducted by authorities	1.2 (0.6-2.4)	1.3 (0.6-2.6)	1.0 (0.5-2.0)
Authorities are controlling the infection with a sense of responsibility	0.6 (0.3-1.1)	0.5 (0.2-0.9)	0.6 (0.3-1.2)
I am concerned that my personal information collected by the authorities might be leaked or misused for other purposes	2.1 (1.4-3.3)	2.3 (1.5-3.5)	2.5 (1.7-3.7)

^aSNS: social networking site.

We also identified the factors associated with the response *absolutely opposed to use*, even when users were presented with trade-offs between privacy on the one hand and public health benefits from each feature's addition and the personal benefits of the feature additions in the form of discounted mobile phone use charges on the other hand (Tables 5 and 6, respectively). Even if the addition of each function reduced the spread of infection by half, the factors that were significantly associated with the response *absolutely opposed to use* of the app were the same for all functions (A, B, and C). One of the factors was positively correlated, and two were negatively correlated. The factor that was positively correlated was the respondents who were concerned about data leaks and misuse of personal information (function A: OR 2.2, 95% CI 1.4-3.5; function B: OR 2.2, 95% CI 1.4-3.3; function C: OR 2.5, 95% CI 1.6-3.8). Conversely, the factors that presented negative correlations were adherence to the government-imposed restrictions on activities (function A: OR 0.4, 95% CI 0.2-0.8; function B: OR 0.4, 95% CI 0.2-0.7; function C: OR 0.4, 95% CI 0.2-0.8) and agreement

that the national and local governments were conducting infection control with a sense of responsibility (function A: OR 0.4, 95% CI 0.2-0.8; function B: OR 0.5, 95% CI 0.2-1.0; function C: OR 0.5, 95% CI 0.2-0.9).

The only factor that was positively associated with the response *absolutely opposed to use*, even if there was a discount on mobile phone use charges, was concern about leaks and misuse of the collected personal information, which was true for all functions (function A: OR 1.8, 95% CI 1.3-2.4; function B: OR 1.9, 95% CI 1.5-2.6; function C: OR 1.8, 95% CI 1.4-2.4). In contrast, adhering to government restrictions on activities had a negative correlation with the dependent variables for all functional additions (function A: OR 0.5, 95% CI 0.3-0.8; function B: OR 0.5, 95% CI 0.3-0.9; function C OR 0.6, 95% CI 0.3-0.9). Fear of transmission to family members if respondents became infected was negatively correlated with functions A and C (function A: OR 0.5, 95% CI 0.2-0.9; function C: OR 0.5, 95% CI 0.3-0.9).

Table 5. Factors associated with the response “I am absolutely opposed to the use of the app” if it is assumed that the spread of infections will be halved by the addition of functions A to C.

Independent variables	Function A, odds ratio (95% CI)	Function B, odds ratio (95% CI)	Function C, odds ratio (95% CI)
Female (reference: male)	0.6 (0.4-1.0)	0.7 (0.5-1.1)	0.7 (0.4-1.0)
Age (years) group (reference: aged <34 years)

Discussion

Principal Findings

In formulating the hypotheses for this study, we were interested in the public's attitude toward privacy risks as an inadvertent side effect of the convenience offered by information technology. As Yuan et al [22] suggested, privacy risk strategies are socially implemented after taking into account 2 types of trade-offs that affect individuals' disclosure behavior: those between the expected benefits of privacy disclosure and the effectiveness of risk-management methods. The contact-tracing app or contact notification app that was developed and used in many countries to prevent the spread of the COVID-19 pandemic epitomizes this theory. The contact notification app (COCOA) in operation in Japan was developed to minimize privacy risks to the public; however, its effectiveness in preventing infection was lower than expected. Therefore, the addition of functions that cannot be performed by the current COCOA, such as the collection of mobile logs and secondary

use of the collected data, raises concerns about the increased risk to privacy and the functions themselves. The core objective of our research was to identify how the general public perceives the trade-offs between additional personal and public interest. We also wanted to investigate the extent to which people trade personal privacy risks for economic incentives, as noted by Hann et al [23]. This study was conducted on the assumption that when the administrative body of a country plans to develop and disseminate a contact-confirming app that is more effective in preventing the spread of infectious diseases, citizens who use the app may have some resistance to the government's collection of activity logs and provision of individual interventions for people with confirmed infections. We also hypothesized that this resistance might be mitigated by emphasizing the public health benefits of an effective contact-confirming app or through a discount on mobile phone use charges for individuals using the app [24,25].

The results of the logistic regression of factors associated with COCOA installation showed a positive correlation with fear of

transmission of infection to others in the event of oneself becoming infected; a reasonable interpretation of this result is possible. However, the positive correlation was not significant; rather, the proportion of citizens living in Japan who feel obligated to install COCOA, or who have a high assessment of the app's usefulness, is considered low.

The survey then introduced functions A, B, and C, which are expected to increase the risk of personal privacy violations concerning the current COCOA, and asked about the resistance to using the app when each of these functions was added. Approximately one-third of all respondents for functions A, B, and C indicated that they felt uncomfortable using the app. This result was more generous than expected at the beginning of the survey. Our initial assumption was that more than half of the survey respondents would react with at least moderate resistance to each of the additional functions. This result would suggest that the public is likely to be more receptive to the use of privacy-related information by the authorities for maintaining public health than we had expected.

Even when function B (ie, location tracking and specific encouragement of activities) were added to function A, there was no significant difference, suggesting that the additional fear and resistance to individual interventions are not necessarily significant. Similarly, there was no significant difference for function C, indicating that the resistance to the collection of personal information for infection prevention measures was not particularly high.

The percentage of respondents who answered *absolutely opposed to use or significant resistance to use* of the app decreased slightly when the addition of functions A, B, and C was known to reduce the degree of spread of infectious disease. This finding suggests that increased public health benefits can be traded against personal privacy risks. This result may be more characteristic of the trade-offs of interests in the somewhat special domain of health rather than the general market society principle [26,27]. Surprisingly, when presented with the condition that the addition of a feature would result in a discount on the cell phone bill, one-third of respondents stated that "I would not want to use it regardless of the discount" for all functions A, B, and C. Although it is difficult to explain this result via a literature review, we argue that this result was influenced by the health-related agenda and the fact that the project was a national government agency. When personal privacy is given up, the motivation behind it may not be to make money but to work together to help prevent the spread of infectious diseases. If so, we believe that bringing in financial incentives when promoting such behavior might inadvertently upset citizens' sentiments.

We also deem our interpretation of the results presented in Tables 4-6 to be relevant. Resistance to using apps was not associated with respondents' basic characteristics, an affinity for SNS, or history of COVID-19 but was negatively correlated with their evaluation of the executive branch regarding infection prevention activities and compliance concerning infection prevention behaviors. We interpreted this result as suggesting that the behavior of using exposure notification apps has an element of altruistic behavior that seeks the public good [28,29].

In contrast, as mentioned many times in previous literature, the sense of risk regarding information leakage had the highest contribution rate among the factors related to resistance to app use [16-18,30-32].

Generalizability

It may be acceptable for society to allow public organizations, such as national government agencies, to collect and use individuals' private information for specific purposes as part of nationwide efforts to control infectious diseases. However, such interventions must be balanced by the resistance felt by the public regarding the provision of private information [33]. In addition, it is necessary to have a continuous discussion between administrative agencies and the public regarding the conditions that would enable the formation of a social consensus on the collection and use of private information for administrative purposes. In this study, we presented a hypothetical basis for this discussion. The current COCOA in Japan is one of the weakest interventions for the collection and use of private information; however, the public response is that certain prerequisites must be in place, such as a clear purpose of use and a robust security environment. If these factors are satisfactorily explained to the public, the intervention will be stronger; however, even if this occurs, the possibility that the intervention will be accepted is still low [34]. For example, it may be possible to actively consider the collection of activity logs using the GPS function on people's phones [35,36]. However, these activities are tolerated by the public as they are aware of the greater public health risks posed by a global crisis such as the COVID-19 pandemic; a more cautious attitude is necessary when considering other general administration purposes [37,38].

An important interpretation to note is that there is no trade-off between the permissibility of government interventions and the provision of special incentives to individuals, such as discounts on mobile phone bills. This study revealed that such simplistic benefits may upset public sentiments and increase suspicion of the government. In a future society where personal health records are widely distributed, public organizations will increasingly require access to private information on the cloud. In such a case, it is more important for public organizations to increase the general benefits of managing personal information and provide assurance that this is being done safely rather than providing incentives to individuals who provide such personal information.

Study Limitations

This survey involved a representative sample of the Japanese population. The response rate was >10/13. The results could potentially be a decision resource for the government when considering whether to add more functions to the app.

However, 4 limitations must be noted. First, it is possible that the public did not understand the functions of the current COCOA. The questions asked in the survey assumed that additional functions would be added to the current COCOA, which may have been difficult for respondents to envision, along with the advantages and disadvantages that would result for themselves and the public. Second, as this was a quantitative

survey based on a specific hypothesis, it was not possible to set out the specific functions that the public would expect from COCOA. A survey with a qualitative approach would be necessary to explore the functions. Third, we were unable to examine the psychometric properties of the attitudes measured in this study. Usually, when attitudes are measured using questionnaires, their reliability and validity must be ensured. However, in this study, the lack of existing general-purpose scales and insufficient time for scale development created major limitations in interpreting the results. The existing literature identifies the main element of the public's resistance to the use of contact-tracing apps as a feeling of insecurity regarding the leakage of information or its use for purposes other than as intended [39,40]. As such an attitude is a very important concept for the future *Ethical, Legal, and Social Issues in Science and Technology* agenda in information technology, it may be necessary to develop a common rating scale with guaranteed psychometric validity [41,42]. Fourth, when interpreting the results of the survey, the impact of the *privacy paradox* along with clinical relevance must be considered. The privacy paradox is a situation in which people express concerns about privacy through their attitudes but do not hesitate to take actions that pose a significant risk in terms of revealing their private information in real life [43,44]. To avoid this paradox, we asked about respondents' attitudes regarding their actual behaviors rather than their conceptual concerns. However, when reflecting on the results of this study for policy recommendations, it must be stated that the evidence is influenced by this paradox.

Conclusions

In this study, we investigated the public's attitude toward the addition of several functions to COCOA, an app used to confirm COVID-19 contact distributed by the Japanese government. Although there was some resistance to its official and governmental release and use, there was little change in the public's resistance, as depicted in this study, regardless of the added functions' content. However, the sense of resistance to the government's intervention was not ameliorated by the incentives provided to individuals. On the basis of the results of this study, we believe that it is acceptable for citizens to implement functions that involve a certain degree of privacy risk when digitally processed personal privacy information is used primarily to promote health benefits, such as preventing the spread of infectious diseases, provided that the entities in charge of such projects, such as government agencies, are fully accountable for their actions. Furthermore, at least with respect to projects such as health policy, citizens will set aside their privacy concerns in view of broader public health interests rather than individual economic incentives. Thus, this study offers insights into potential strategies for governmental use of private information through mobile devices. Further social research and empirical evidence are needed on this topic to form an *ecosystem* of information and people, which is still expanding daily.

Acknowledgments

This research was part of this study, *Comprehensive Practical Research and Development Program to Address Ethical, Legal, and Social Issues in Science and Technology*, and it received funding from Research Institute of Science and Technology for Society, which is an initiative of the Japan Science and Technology Agency to promote research and development. The authors would like to thank Editage for their writing support in the *Abstract* section.

Authors' Contributions

SB was responsible for conceiving and designing the experiments, collecting and analyzing the data, and writing and revising the manuscript. SB, YH, and TF were responsible for data interpretation. All authors have read and approved the final version of the manuscript. All authors have agreed to its publication.

Conflicts of Interest

None declared.

Abstract

Background: Despite the worldwide growth in using COVID-19 contact tracing apps (CTAs) and the potential benefits for citizens, governments, health care professionals, businesses, and other organizations, only a few studies have examined the factors affecting the levels of willingness to download a CTA.

Objective: This study aimed to investigate individuals' preferences in the willingness to download a health app.

Methods: We conducted an experimental study in 2 countries, the Netherlands (N=62) and Turkey (N=83), using 4 different vignettes (ie, data protection, manufacturer, reward, and gaming models) with different attributes. Participants were randomly assigned to 1 of the conditions within the vignettes.

Results: The results showed that data protection and gaming elements are factors that influence the willingness to download a COVID-19 CTA. More specifically, we see that data protection is an important factor explaining the willingness to download the app in Turkey, whereas including gaming elements significantly affects the willingness to download the app in the Netherlands.

Conclusions: COVID-19 CTAs are highly promising to reduce the spread of the virus and make it easier to open up society faster, especially because they can be used quickly and share information rapidly. COVID-19 CTA developers must ensure that their apps satisfactorily and sufficiently address ethical considerations, even in times of crisis. Furthermore, integrating gaming elements in the CTA could enhance the willingness to download the CTA.

Introduction

Background

The COVID-19 pandemic affected human health tremendously, as well as social and economic life, increasing the urge to find effective measures to start reviving public life as soon as possible while minimizing the risk of infection and

hospitalization of patients [1]. Current developments across the world show that one strategy might be through technology, accompanied by mobile apps [2,3]. Considering that COVID-19 has proven to be highly contagious, especially newer variants such as Delta and Omicron [4]—sometimes without the carrier experiencing symptoms and infecting several others before actually testing positive—it is important to trace contacts and identify individuals who had close contact with the carrier.

Normally, this tracking is accomplished through a personal interview with the infected individual, establishing the people who have been in (close) contact with the carrier, and subsequently developing strategies to mitigate further spreading. However, it is difficult for people to accurately remember all the persons that they have been in close contact with, including those who cannot be identified because they are unknown to the carrier. Moreover, considering the rapidly increasing numbers of infected people in a majority of the countries worldwide at the moment, conducting the interviews manually would require a considerable workforce of trained individuals to hold the interviews effectively, which is a highly costly exercise and has shown to be ineffective in times of high infection rates [5].

Research has shown that COVID-19 contact tracings apps (CTAs) could mitigate the current pandemic by informing people instantly when they have been in close contact with an infected individual [5-9]. CTAs have been implemented in nearly all countries for the identification of pandemic hot spots, supporting collaborative information processes between the public and health authorities about critical contacts with infectious citizens. One of the main goals is to initiate knowledge circulation between the 5 systems of the Quintuple Helix [10], which includes the decision processes of policy makers. According to Oldeweme et al [6], the willingness to download processes of CTAs are fostered by the reduction of uncertainties—perceived privacy and performance risks—through trust in governments and public participation but do not reduce social risks and health-related COVID-19 concerns. Although these new possibilities promise several benefits for mitigating the pandemic, the actual willingness to download and the long-term use of mobile health (mHealth) apps is rather low and lags behind their potential [11]. As a result, despite the promising effects of the CTAs to mitigate the pandemic, there is insufficient evidence supporting the willingness to download preferences for these apps, although willingness to download is the first, and therefore important, step. This lack of evidence urges us to take a step back to better understand which factors influence the willingness to download CTAs [12,13].

A first step in this endeavor is to understand which factors affect people's willingness to download CTAs. Considering the limited understanding of the general cognitive motivators that trigger people's willingness to download health apps, especially in times of crisis, it is important to examine which attributes of health apps are preferred when downloading CTAs. An extensive systematic literature review [14] has shown that, in support of the Technology Acceptance Model, 8 key themes can be categorized for clinicians' adoption of mHealth tools: usefulness, ease of use, design, compatibility, technical issues, content, personalization, and convenience. In addition, from a patient's perspective [15], usefulness, ease of use, data-related factors, monetary factors, technical issues, and user experience were considered to be important factors for the adoption of an mHealth app.

Furthermore, intrinsic motivation to use such a health app is considered a strong predictor of actual willingness to download and use [16]. In addition, Salomoni et al [17] point out that

rethinking how the users receive and interact with a health app is important to better understand the role of diegetic interfaces, which should also be taken into account when developing a CTA. Without the proper comprehension of the cognitive motivators that explain the willingness to download and use mHealth apps, it would be very difficult to establish the effectiveness of mHealth apps and fully understand individuals' use of such apps.

Attributes Explaining Preferences in the Willingness to Download CTAs

The rising use of mHealth apps threatens to change the way substantial amounts of health data will be managed, with a paradigm shift from mainframe systems located in the facilities of health care providers to apps on mobile phones and data stored in shared cloud services [18,19]. According to Klar and Lanzerath [20], besides the challenges of effectiveness, technological problems and the risks of privacy and equity have to be considered. Ryan [21] has, for example, evaluated South Korea's digital tracing app through the lens of 4 human rights principles to determine if this response was ethically justifiable (ie, necessary, proportional, scientifically valid, and time-bounded) and concluded that the Korean digital CTA was scientifically valid and proportionate—meeting the necessity requirement—but it was too vaguely defined to meet the time-boundedness requirement. More specifically, the prerequisite of an ethical deployment of CTAs is voluntariness, starting with deciding to carry a smartphone, choosing to download and install a CTA, leaving the CTA operating in the background all the times, and finally, sharing contact logs when tested positive. Peschke et al [22] discussed the voluntariness of CTA deployment in different countries. Based on an analysis of more than 35 CTAs worldwide [23], 2 main categories of CTA deployment could be identified. First, for the participation of the public life, such as entering university campuses and shopping malls in Turkey, an individual Hayat Eve Sığar (Turkish for “life fits into home”) code has to be generated and presented to the gatekeepers. In these apps, the data of the users are collected in a central place and sometimes shared with other state institutions. If COVID-19 is detected within the passengers of the same vehicle or at the same location within the next 14 days, everyone at that place, family doctors, and the filiation team are informed [24]. Second, Google and Apple have developed a system called Exposure Notifications System to bring out anonymized identity information to the users' environment via Bluetooth. The importance of data protection and privacy issues regarded by potential users of the CTAs have not been sufficiently understood yet.

A recent study has shown that privacy perceptions are related to the use of mHealth apps, in which people with more concerns about the secondary use of their personal data were less likely to use certain mHealth apps [25]. In addition, the manufacturer of a health app can be considered a heuristic in the consumers' willingness to download a CTA. There is reason to assume that this factor may be an important, as the industry has struggled with its public image over the past few decades. Companies need to negotiate a tension between, on the one hand, striving for optimal health care and, on the other hand, striving for profit [26]. In the eyes of the public, it is not always clear that the

industry has the patients' interests at heart [27]. Therefore, people would probably prefer if an mHealth app is manufactured by the government than by a company.

By contrast, the Edelman Trust Barometer [28] reveals that business is the only institution that is understood to be competent and ethical by the public in 18 of the 27 countries evaluated. The public is more likely to trust in business as it acts as the guardian of information quality, embraces sustainable practices, and provides robust COVID-19 health and safety response [28]. However, the Netherlands noticed an increase of trust in both business and government [28]. The Edelman Trust Barometer did not capture data from Turkey, but the result of 2 studies conducted in 2020 show that the pandemic crisis revealed 2 different results. Bostan et al [29] conclude that the public trusts the authorities and the accuracy of the decisions taken by the state to combat the pandemic. However, Tanca et al [30] perceive the ambiguity and capriciousness of the public's reactions as a result of the uncertainty of both the government and national economy. A special report about trust and coronavirus published by Edelman Trust Barometer [31] reveals that 85% of the respondent want to hear more from scientists and less from politicians.

Lastly, it is worth emphasizing the importance of the design of the CTA when participants are downloading apps. Web-based gaming studies have shown that elements and features with clear goals at every step [32], immediate feedback [33-35], and balance between challenge and skill [36] grounded in the flow theory [37] are considered key elements of the willingness to download apps.

Finally, since last year, the majority of the public has prioritized increasing their own media and information literacy as well as science literacy, but only 26% of the respondents have good information hygiene—considering news engagement, avoiding information echo chambers, verifying information, and not amplifying unvetted information [28].

Hypotheses

In this study, we conducted 4 small experimental studies based on vignettes in 2 different countries (the Netherlands and Turkey). In the vignette study, we manipulated the manufacturer (government vs company), data protection (data protection vs no information), reward (no reward vs voucher as a reward), and gaming (no gaming elements vs gaming elements) variables and assessed the likelihood of downloading a COVID-19 CTA to test the following hypothesis:

1. Participants who are exposed to a COVID-19 CTA developed by a government will be more willing to download the app than participants who were exposed to a COVID-19 CTA that is developed by a company (Hypothesis [H]1).
2. Participants who are exposed to a COVID-19 CTA whereby there was communication that the data is protected by law will be more willing to download the app than participants who are exposed to a COVID-19 CTA whereby no information was given about the data protection (H2).
3. Participants who are exposed to a COVID-19 CTA and will receive a reward based on scientific evidence will be more

willing to download the app than participants who are exposed to a COVID-19 CTA and will receive no rewards (H3).

4. Participants who are exposed to a COVID-19 CTA that includes gaming elements will be more willing to download the app than participants who are exposed to a COVID-19 CTA without any gaming elements (H4).

Methods

Design

In this study, we conducted 4 small experimental studies through a web-based questionnaire using vignettes to simulate real-life situations. The use of a web-based questionnaire provided completion time data to support the internal validity checks and enabled an accurate record of the time taken to complete the surveys. There were 2 rounds of cognitive testing (N=12) undertaken in the Netherlands to check the participants' comprehension of information when making choices. These pretests confirmed that a study based on the questionnaire was acceptable and understandable for participants, after some minor revisions in the explanation of the task.

Procedure

All survey participants were informed about the overall study goals and procedures. First, participants were asked to provide sociodemographic information, including their age group, gender, education, and employment status. Subsequently, an introduction to the vignette studies provided an explanation of what was expected from the participants. One example of the vignette is the following, whereby the last sentence is the part of the script that varied among the conditions.

Imagine that an app is presented to you to mitigate the pandemic, by providing you detailed information about the people that you have been around with, how close, and for how long, that are infected by the COVID virus, or not. Based on the collected data, the app will provide tailored advice to improve your health. We will present you some pairs of options and will ask you to select the one that you would prefer to use the app or not. Importantly, the app is developed by the government.

Subsequently, participants were asked to score the likelihood that they would download the app and whether they would download the app. The other vignettes entailed exactly the same text, except the last sentence was replaced by the specific condition the participant was randomly allocated to (government vs company, data protection vs no information, no reward vs voucher as a reward, or no gaming elements vs gaming elements).

Ethics Approval

Only those who agreed to participate in the study gained access to the web-based survey. The approval of the Ethical Committee of the Tilburg School of Humanities and Digital Sciences to conduct the experiment was obtained (REDC 2021.73). Through signing informed consent, participants were ensured that their data would remain confidential, and they were told that they

could cease participation at any moment. All participants participated anonymously, and the collected data was stored in a dark archive at the Tilburg University.

Participants

For this study, we used data collected from 2 different countries (Turkey and the Netherlands). This study was part of a larger

project, whereby multiple experiments were conducted. After the participants finished the discrete choice experiment, they also participated in a separate experiment that is reported in a separate paper. The data in the Netherlands (N=62) and Turkey (N=83) were collected through a web-based survey administered through Qualtrics (SAP America Inc). Participant characteristics are shown in [Table 1](#).

Table 1. Descriptive information about the participants per country.

Characteristic	Netherlands (N=62)	Turkey (N=83)
Gender, women, n (%)	31 (50)	43 (52)
Age (year), mean (SD)	23.92 (7.45)	21.87 (2.46)
Educational level, n (%)		
Primary education	3 (5)	0 (0)
High school diploma	3 (5)	10 (12)
Some years of university	28 (45)	61 (73)
University degree	18 (29)	10 (12)
Post-graduate degree	10 (16)	2 (2)
Employment status, n (%)		
Employed/self-employed	11 (18)	12 (14)
Unemployed	7 (11)	0 (0)
Student	44 (71)	71 (86)
Retired	0 (0)	0 (0)
Not working due to illness or disability	0 (0)	0 (0)
Another reason for not being in the labor force	0 (0)	0 (0)
Health app use, n (%)		
No use	27 (44)	30 (36)
1 time	8 (13)	18 (22)
2 times	11 (18)	18 (22)
3 times	7 (11)	6 (7)
4 times	3 (5)	4 (5)
5 times	0 (0)	3 (4)
>5 times	6 (10)	4 (5)
Health consciousness, mean (SD)	3.77 (0.68)	3.93 (0.83)
Health information orientation, mean (SD)	2.99 (0.82)	3.48 (0.92)
eHealth literacy, mean (SD)	2.85 (0.96)	3.09 (1.00)

Measures

Dependent Variables

Willingness to download the app was measured through the question “Please indicate on a scale of 1 to 10 how likely it is that you would download the app. Please place yourself at a point on this scale where ‘0’ indicates that you would ‘definitely not download the app,’ ‘10’ indicates that you would ‘definitely download the app,’ and the remaining numbers indicate something in between these 2 positions.” whereby participants could answer on a visual analog scale.

Intention to download the app was measured through the question “Would you download the app?” whereby participants could answer yes or no.

Intrapersonal Factors

Health app use was measured by asking how often the participant used a health app, varying from 0 (never) to 6 (more than 5 times), and how much time the participant spent using a health app in the last week, varying from 0 (0 hours) to 6 (more than 1 hour).

Health consciousness was measured using 5 statements that were rated on a 5-point scale (from 1 representing strongly

disagree to 5 representing strongly agree) [38]. The reliability of the scale was high ($\alpha=.82$).

Health information orientation was measured using 8 statements rated on a 5-point scale (from 1 representing strongly disagree to 5 representing strongly agree) [38]. The reliability of the scale was high ($\alpha=.87$).

eHealth literacy was measured using 8 statements rated on a 5-point scale (from 1 representing strongly disagree to 5 representing strongly agree) [39]. The reliability of the scale was high ($\alpha=.95$).

Statistical Analyses

Several analyses of covariance (ANCOVAs) were conducted to assess the participants' likelihood to download the app—first, for all participants and subsequently, for each country. Next, we conducted logistic regression analyses to assess the participants' probability to download the app.

Results

Developer Models

The first ANCOVA tested if participants who were exposed to a COVID-19 CTA developed by a government were more willing to download the app than participants who were exposed to a COVID-19 CTA developed by a company, whereby age, gender, education, health consciousness, health information orientation, and eHealth literacy were included as covariates in the analysis. No effects were found for the developer ($F_{7,137}=1.307$; $P=.26$). For age ($F_{1,137}=9.848$; $P=.002$) and eHealth literacy ($F_{1,137}=7.047$; $P=.009$), we found significant relationships. For the other factors, we found no significant differences.

Next, the logistic regression analysis showed that there was no effect of the developer on whether the participants would download the app ($P=.32$). For age ($P<.001$) and education ($P=.02$), we found significant relations to whether the participants would download the app.

A separate ANCOVA for the Netherlands showed that no effects were found for the developer ($F_{7,54}=1.638$; $P=.21$). We found a significant relationship for age ($P=.01$). For the other factors, we found no significant differences. In addition, the logistic regression analysis showed that there was no effect of the developer on whether the participants would download the app ($P=.46$). For age ($P=.01$) and education ($P=.008$), we found significant relations to whether the participants would download the app.

In Turkey, an ANCOVA showed that no effects were found for the developer as well ($F_{7,75}=0.094$; $P=.76$). For the other factors, we found no significant differences. Furthermore, the logistic regression analysis showed that there was no effect of the developer on whether the participants would download the app ($P=.49$). For age ($P=.02$) and eHealth literacy ($P=.01$), we found significant relations to whether the participants would download the app.

Data Protection Models

The second ANCOVA tested if participants who were exposed to a COVID-19 CTA developed whereby data was protected by European legislation were more willing to download the app than participants who were exposed to a COVID-19 CTA whereby no information was given about the data protection, whereby age, gender, education, health consciousness, health information orientation, and eHealth literacy were included as covariates in the analysis. The results showed that participants who were exposed to a COVID-19 CTA developed whereby data was protected by law (mean 6.93, SD 2.44) were significantly more willing to download the app than participants who were exposed to a COVID-19 CTA whereby no information was given about the data protection (mean 6.93, SD 2.44; $F_{7,137}=19.125$; $P>.001$). For the other factors, we found no significant differences. The logistic regression analysis showed that there was a significant effect of data protection on whether the participants would download the app ($P<.001$). The probability that a participant would download the app would be 3.886 times greater when the data was protected by EU legislation than when no information was provided about what would be done with the data. For the other factors, we found no significant relations.

Separate analyses for the Netherlands showed that participants who were exposed to a COVID-19 CTA developed whereby data was protected by law were not more likely to download the app than participants who were exposed to a COVID-19 CTA whereby no information was given about the data protection ($F_{7,54}=1.130$; $P=.29$). For the other factors, we found no significant differences. The logistic regression analysis showed that there was a significant effect of data protection on whether the participants would download the app ($P=.03$). The probability that a participant would download the app would be 3.327 times greater when the data was protected by law than when no information was provided about what would be done with the data. For the other factors, we found no significant relations.

In Turkey, participants who were exposed to a COVID-19 CTA developed whereby data was protected by law were significantly more willing to download the app (mean 7.27, SD 2.52) than participants who were exposed to a COVID-19 CTA whereby no information was given about the data protection (mean 4.17, SD 3.09; $F_{7,75}=24.584$; $P>.001$). For the other factors, we found no significant differences. The logistic regression analysis showed that there was a significant effect of data protection on whether the participants would download the app ($P=.007$). The probability that a participant would download the app would be 3.847 times greater when the data was protected by law than when no information was provided about what would be done with the data. For the other factors, we found no significant relations.

Reward Models

The next ANCOVA tested if participants who were exposed to a COVID-19 CTA and would receive a reward if they adopted the app were more willing to download the app than participants who were exposed to a COVID-19 CTA and would receive no

rewards, whereby age, gender, education, health consciousness, health information orientation, and eHealth literacy were included as covariates in the analysis. The results showed that participants who were exposed to a COVID-19 CTA and would receive a reward if they adopted the app were not more willing to download the app than participants who were exposed to a COVID-19 CTA and would receive no rewards ($F_{7,137}=0.324$; $P=.57$). For the other factors, we found no significant differences. In addition, the logistic regression analysis showed that there was no effect of reward on whether the participants would download the app ($P=.93$). For age ($P=.002$), health consciousness ($P=.04$), health information orientation ($P<.001$), and eHealth literacy ($P=.003$), we found significant relations to whether the participants would download the app.

Separate analyses for the Netherlands showed that participants who were exposed to a COVID-19 CTA and would receive a reward if they adopted the app were not more willing to download the app than participants who were exposed to a COVID-19 CTA and would receive no rewards ($F_{7,54}=0.322$; $P=.57$). For the other factors, we found no significant differences. The logistic regression analysis showed that there was no effect of reward on whether the participants would download the app ($P=.24$). For gender ($P=.05$), age ($P=.003$), health consciousness ($P=.006$), health information orientation ($P=.004$), and eHealth literacy ($P=.003$), we found significant relationships to whether the participants would download the app. In Turkey, we found similar results for the reward ($P=.74$) and no other significant relations.

Gaming Models

The next ANCOVA tested if participants who were exposed to a COVID-19 CTA that included gaming elements were more willing to download the app than participants who were exposed to a COVID-19 CTA without any gaming elements, whereby age, gender, education, health consciousness, health information orientation, and eHealth literacy were included as covariates in the analysis. The results showed that participants who were exposed to a COVID-19 CTA where gaming elements were included (mean 6.46, SD 2.28) were significantly more willing to download the app than participants who were exposed to a COVID-19 CTA without any gaming elements (mean 5.46, SD 2.73; $F_{7,137}=6.603$; $P=.01$). We found a significant relationship for age ($F_{1,137}=6.008$; $P=.02$). For the other factors, we found no significant differences. Next, the logistic regression analysis showed that there was no effect of gaming on whether the participants would download the app ($P=.15$). For education ($P=.03$) and health information orientation ($P=.02$), we found significant relations to whether the participants would download the app.

Separate analyses for the Netherlands showed that participants who were exposed to a COVID-19 CTA where gaming elements were included (mean 6.51, SD 2.07) were significantly more willing to download the app than participants who were exposed to a COVID-19 CTA without any gaming elements (mean 4.87, SD 2.27; $F_{7,54}=26.755$; $P<.001$). Furthermore, we found a significant relationship for age ($F_{1,54}=13.399$; $P<.001$). For the other factors, we found no significant differences. Next, the

logistic regression analysis showed that there was a significant effect of gaming on whether the participant would download the app ($P=.006$). Participants who were exposed to a COVID-19 CTA with gaming elements were 20.516 times more likely to download the app than participants who were exposed to a COVID-19 CTA without gaming elements. For age ($P=.03$), education ($P=.02$), health consciousness ($P=.04$), and eHealth literacy ($P=.03$), we found significant relations to whether the participants would download the app. In Turkey, we found no significant differences between the gaming conditions ($F_{7,75}=2.380$; $P=.57$) and for the other factors. The logistic regression analysis showed that there was no effect of gaming on whether the participants would download the app ($P=.62$). No other factors were significantly related to whether the participants would download the app.

Discussion

Principal Findings

The results showed that data protection and gaming elements are important factors that affect the willingness to download a COVID-19 CTA, thereby supporting H2 and H4. For the developer and reward, we found no significant differences between the participants, thus rejecting H1 and H3. Governments might not have a second chance to get an intervention right, especially because in times of crises, trust in politicians is an important factor to mitigate the crisis at stake. Governments, developers, and deployers must ensure that COVID-19 CTAs satisfactorily address the ethical questions that were set out [3]. According to the Organisation for Economic Cooperation and Development [40], citizens expect integrity, openness, and fairness in communication and knowledge transfer, where responsiveness and reliability are crucial factors. As a result, a positive perception of comprehension leads to an increase in acceptance and cooperative engagement.

Comparison With Prior Work

Despite the worldwide growth in using COVID-19 CTAs and the potential benefits for all the actors within the Quintuple Helix to mitigate the pandemic more effectively and make us able to open up society sooner, only a few studies have examined the factors affecting the levels of willingness to download the apps. In this study, we investigated individuals' preferences in the willingness to download a health app. Digital contact tracing via smartphone apps was established as a new public health intervention in many countries in 2020. Most of these apps are now at a stage where they need to be evaluated as public health tools, especially because this could provide us with important lessons for future events such as the current pandemic [3,41].

Limitations

One of the limitations of the study is that we used a convenience sampling, whereby most of the participants were students from only 2 countries, thus reducing the generalizability of the outcomes. Considering that this study is part of a larger study where we will develop an actual CTA that will be tested among a larger and more representative study in 5 different countries

(Spain, the Netherlands, Finland, Germany, and Turkey), the generalizability will improve. Finally, gamification elements might have been judged differently if they were actually displayed or could be tried out in the experiment, increasing its effectiveness, which unfortunately was not possible. In the next phase of the study, we will test gaming elements in more detail.

Conclusions

Simply rolling out a CTA without ethical considerations is not acceptable and does not support the knowledge circulation in the Quintuple Helix. Even in a crisis, a “try everything” approach is dangerous when it ignores the real costs, including serious and long-lasting harms to fundamental rights and freedoms and the opportunity costs of not devoting resources to something else. As this pilot study shows, reassuring people that data protection regulations are put in place is an essential element for increasing the levels of willingness to download CTAs.

During the last few decades, mHealth initiatives have emerged at an accelerating pace; some have seen widespread willingness

to download, whereas others have failed to provide sustained value [42]. These failings can be attributed to their design and implementation efforts that were initiated without a good understanding of the interdependencies between technology, societal and cultural values, and user experience in a health care setting, which has become highly apparent during the current pandemic and health care crisis. Many conceptual frameworks based on implementation science have been developed to evaluate and orient mHealth delivery. These frameworks highlight key factors that predict successful and sustainable mHealth technologies, although there is still limited understanding of the factors influencing the willingness to download these technologies. The urgency of the ongoing public health crisis stimulated the rapid development of CTAs and other mHealth innovations, and this generated a substantial number of related publications. Their coverage of the essential design and implementation characteristics for eHealth innovation remains under investigated and needs to be further researched in future studies [41].

Abstract

Background: During the COVID-19 pandemic, several home monitoring programs have described the success of reducing hospital admissions, but only a few studies have investigated the experiences of patients and health care professionals.

Objective: The objective of our study was to determine patients' and health care professionals' experiences and satisfaction with employing the COVID-box.

Methods: In this single-center, retrospective, observational study, patients and health care professionals were asked to anonymously fill out multiple-choice questionnaires with questions on a 5-point or 10-point Likert scale. The themes addressed by patients were the sense of reassurance and safety, experiences with teleconsultations, their appreciation for staying at home, and the instructions for using the COVID-box. The themes addressed by health care professionals who treated patients with the COVID-box were the characteristics of the COVID-box, the technical support service and general satisfaction, and their expectations and support for this telemonitoring concept. Scores were interpreted as *insufficient* (≤ 2 or ≤ 5 , respectively), *sufficient* (3 or 6-7, respectively), or *good* (≥ 4 or ≥ 8 , respectively) on a 5-point or 10-point Likert scale.

Results: A total of 117 patients and 25 health care professionals filled out the questionnaires. The median score was 4 (IQR 4-5) for the sense of safety, the appreciation for staying at home, and experiences with teleconsultations, with good scores from 76.5% (88/115), 86% (56/65), and 83.6% (92/110) of the patients, respectively. Further, 74.4% (87/117) of the patients scored the home monitoring program with a score of ≥ 8 . Health care professionals scored the COVID-box with a minimum median score of 7 (IQR 7-10) on a 10-point scale for all domains (ie, the characteristics of the COVID-box and the technical support service and general satisfaction). For the sense of safety, user-friendliness, and additional value of the COVID-box, the median scores were 8 (IQR 8-10), 8 (IQR 7-9), and 10 (IQR 8-10), respectively, with good scores from 86% (19/22), 75% (15/20), and 96% (24/25) of the health care professionals, respectively. All health care professionals (25/25, 100%) gave a score of ≥ 8 for supporting this home monitoring concept, with a median score of 10 (IQR 10-10).

Conclusions: The positive experiences and satisfaction of involved users are key factors for the successful implementation of a novel eHealth solution. In our study, patients, as well as health care professionals, were highly satisfied with the use of the home monitoring program—the COVID-box project. Remote home monitoring may be an effective approach in cases of increased demand for hospital care and high pressure on health care systems.

KEYWORDS

COVID-19; digital health; eHealth; telemedicine; telemonitoring; hospital admission; health care professional; thematic analysis; user satisfaction; usability; home monitoring; health care system

Introduction

The COVID-19 pandemic resulted in an increased demand for hospital care. To keep up with this surging demand, home monitoring was implemented in many countries to avoid unnecessary hospital admissions and detect clinical deterioration in patients at an earlier stage to allow for timely admission and readmission [1].

At the Leiden University Medical Center (LUMC), the Netherlands, we developed the COVID-box project, which is a home monitoring program for patients with (suspected) COVID-19. After a hospital or emergency department visit, patients with (suspected) COVID-19 receive Bluetooth-connected devices (blood pressure monitor, pulse oximeter, and thermometer) and instructions for monitoring their vital parameters 3 times per day, combined with daily teleconsultations carried out by a health care professional. Once the patients get home, the COVID-box team calls the patients to help with the installation of devices and answer questions. The COVID-box team is reachable during office hours for solving logistics issues and answering questions from patients and health care professionals. A detailed description of the telemonitoring program was published previously [2].

The implementation of several home monitoring programs has resulted in a reduction in hospital admissions by allowing for the safe survey of clinical symptoms and vitals [3-9]. Although many observational studies have studied the effectiveness of home monitoring, few studies have reported on patients' and doctors' experiences with telemonitoring [5,10-13]. We focused on the COVID-box experiences of patients and health care professionals.

Methods

Ethics Approval

Central ethical approval was obtained for this study from the medical ethics committee of the LUMC.

Study Design

This retrospective observational study was conducted as part of the COVID-box project, which was initiated at the LUMC in May 2020 upon the first wave of the pandemic. A detailed operational description of the COVID-box project was previously reported [2]. In this study, we evaluated patients with COVID-19 and their experiences with telemonitoring by surveying patients after the completion of the telemonitoring phase and full recovery. Patients were asked to anonymously

fill out questionnaires regarding the sense of reassurance and safety, experiences with teleconsultations, their appreciation for staying at home, and the instructions for the COVID-box. Health care professionals who treated patients with the COVID-box were given separate questionnaires regarding the characteristics of the COVID-box, the technical support service and general satisfaction (estimated patient satisfaction), and their expectations and support for this telemonitoring concept. All questions were multiple-choice questions on a 5-point or 10-point Likert scale. For this study, scores were interpreted as follows: on a 5-point Likert scale, scores of ≤ 2 were *insufficient* scores, scores of 3 were *sufficient* scores, and scores of ≥ 5 were *good* scores; on a 10-point scale, scores of ≤ 5 were marked as *insufficient*, scores of 6 to 7 were marked as *sufficient*, and scores of ≥ 8 were marked as *good*. Unvalidated questionnaires were developed by members of the Department of the Directorate of Quality and Patient Safety and clinicians from the Department of Internal Medicine. The questionnaires were web-based and anonymous.

Statistics

Descriptive statistics were used to summarize the results. The scores given by patients and health care professionals are presented as medians with IQRs, and the number of patients and health care professionals are presented as absolute numbers and percentages. We used IBM SPSS Statistics Version 25 (IBM Corporation).

Results

Patients

Of the first 300 patients who were monitored in the COVID-box project from June 2020 to March 2021, a total of 117 (39%) responded to a web-based survey (Multimedia Appendix 1). All of these patients underwent actual telemonitoring with at least 1 contact with a health care professional by using the COVID-box as a home monitoring tool. The results are summarized in Figure 1.

The median score for the sense of reassurance and for the instructions of the COVID-box was 4 (IQR 3-5), with good scores from 67.6% (75/111) and 70% (80/115) of patients, respectively. For the sense of safety, experiences with teleconsultations, the appreciation for staying at home, and the ability to ask questions about the disease and disease course, the median score was 4 (IQR 4-5); good scores were given by 76.5% (88/115), 83.6% (92/110), 86% (56/65), and 91.2% (104/114) of patients, respectively. Overall, 74.4% (87/117) of

patients scored the home monitoring program with the COVID-box as *good*, with a score of 8 or higher.

Figure 1. Patients' valuation. *"Information provision" ratings; **"Grade" ratings.

Health Care Professionals

Overview

Of the 60 health care professionals approached, 25 (42%) filled out the questionnaire (Multimedia Appendix 2). Of these, 6

(24%) were specialists who worked at the emergency department, 5 (20%) were specialists from the Department of Internal Medicine (20%), 12 (48%) were residents, and 2 (8%) were nurse practitioners. The results are summarized in Figure 2.

Figure 2. Health care professionals' valuation.

Characteristics of the COVID-box

The median score for the sense of safety, reliability, and more self-management/control in patients was 8 (IQR 8-10), with good scores from 86% (19/22), 89% (8/9), and 92% (22/24) of health care professionals, respectively. For user-friendliness, data presentation, and time efficiency, the median scores were 8 (IQR 7-9), 7 (IQR 7-10), and 8 (IQR 6-9), respectively; good scores were given by 75% (15/20), 44% (4/9), and 55% (6/11) of health care professionals, respectively. The additional value of the COVID-box had a median score of 10 (IQR 8-10), with good scores from 96% (24/25) of health care professionals.

Technical Support Service (COVID-box Team)

For information provision and technical support for problems, the median scores were 7 (IQR 7-8) and 8 (IQR 7.5-8), respectively, with good scores from 37% (8/22) and 76% (13/17) of health care professionals, respectively. The median scores for the assessment of a patient's ability and motivation were 8 (IQR 6-8) and 8 (IQR 7-9), respectively. A total of 57% (13/23) and 76% (16/21) of health care professionals, respectively, scored these items as *good*.

General Satisfaction

The general satisfaction of health care professionals and estimated patient satisfaction had a median score of 8 (IQR 7-8), and 60% (15/25) and 95% (18/19) of health care professionals scored these items as *good*, respectively. With regard to meeting the expectations for this home monitoring concept, good scores were given by 92% (22/24) of health care professionals, with a median score of 8 (IQR 8-10). With regard to supporting this home monitoring concept, the median score was 10 (IQR 10-10), with good scores from all health care professionals (25/25, 100%).

Discussion

Principal Findings

Our study demonstrates that the home monitoring of patients with COVID-19 is well appreciated by patients as well as health care professionals. Previous observational studies have shown the safety of the remote telemonitoring of patients with (suspected) COVID-19 and its efficacy in reducing hospitalization. Few studies have addressed user experience and patients' and health care professionals' satisfaction with telemonitoring. It is well established that the successful implementation of novel eHealth solutions is critically dependent on the positive experiences and satisfaction of involved users.

Comparison With Prior Work

During the extraordinary situation of the COVID-19 pandemic, remote telemonitoring has been quickly implemented in different ways [5-7,10-13]. In general, many patients and health care

professionals are very positive about this concept. Remote telemonitoring is used for conducting disease triage; reducing hospital admissions; and providing reassurance, disease and disease course information, and psychological support to clinically stable patients at home. Several studies have reported that patients appreciate all forms of remote telemonitoring (eg, the measuring of vital parameters, symptom recording, and daily teleconsultations) in various settings (eg, in primary care and after an emergency department visit or hospital admission) [5-7,10-13]. The important aspects are easy access to the program, good information provision, and the good quality of the service for the onboarding process. Importantly, older age does not seem to be a problem, as different studies have successfully included patients aged >50 years [5,7,11]. Patients have pointed out that video consultations are also highly appreciated. Self-evidently, the adherence of patients to telemonitoring is critical to its success. Nonadherence to telemonitoring among patients with COVID-19 has been reported when they feel too sick, forget to measure vital parameters, feel insufficiently informed, or experience quick improvements in disease symptoms [13]. Health care professionals are largely convinced of the benefits of remote telemonitoring, as long as a program is easy to use and it is possible to receive patient data correctly.

Limitations

Given the observational and retrospective nature of our study, which was conducted during the COVID-19 pandemic, our study has several limitations that are noteworthy. First, the patient-reported experience measure questionnaires on telemonitoring a new disease, such as COVID-19, were not validated, and a formal validation of these questionnaires was out of the scope of this study. Second, the questionnaires were completed anonymously; therefore, internal consistency could not be reliably assessed. Lastly, the relatively low response rates (patients: 117/300, 39%; health care professionals: 25/60, 42%) could have introduced unwanted bias to the results of this study.

Conclusion

In conclusion, the home monitoring of patients with COVID-19 is well appreciated by patients as well as health care professionals. This study demonstrated that patients felt safe and reassured with the home monitoring and daily teleconsultations in the COVID-box project. Additionally, health care professionals were satisfied with the safety and user-friendliness of the COVID-box. The acceptance of the COVID-box is critical for the successful implementation and expansion of home monitoring for patients with COVID-19 to relieve the burden on health care systems. Our findings could be especially relevant to the current perspectives on oral antiviral agents for the out-of-hospital treatment of patients with COVID-19.

Correction of: <https://formative.jmir.org/2022/1/e32126>

(*JMIR Form Res* 2022;6(7):e41121) doi:[10.2196/41121](https://doi.org/10.2196/41121)

In “Evaluating the Quality of Asynchronous Versus Synchronous Virtual Care in Patients With Erectile Dysfunction: Retrospective Cohort Study” (*JMIR Form Res* 2022;6(1):e32126), the authors noted the following corrections:

1. In [Table 1](#), the values for each side effect - headache, dizziness, flushing, congestion, dyspepsia, back pain, and blurry vision - were mislabeled. Values categorized as ‘asynchronous’ should have been labeled ‘synchronous’ and vice versa. No values were incorrectly referenced in the text of the article and this error does not impact the overall interpretation of results.

2. In the original paper, the following sentence was present in the *Discussion* section:

The recent widespread adoption of telehealth as an acceptable treatment modality and the exploration for potential expansion of traditional methods outside the scope of synchronous care have prompted deeper exploration of the downstream effects of these approaches to care distribution.

This has been changed to:

The recent widespread adoption of telehealth as an acceptable treatment modality and the potential expansion of asynchronous care have prompted deeper exploration of the downstream effects.

3. The phone number of the corresponding author, Lauren Broffman, has been updated to 1 888 798 8686.

Table 1. Rates of reported side effects by modality.

Side effects	Synchronous (n=2150)	Asynchronous (n=7850)
Any side effect, n (%)	24 (1.12)	113 (1.44)
Headache, n (%)	10 (0.47)	56 (0.71)
Dizziness, n (%)	0 (0)	3 (0.04)
Flushing, n (%)	2 (0.09)	31 (0.39)
Congestion, n (%)	12 (0.56)	17 (0.22)
Dyspepsia, n (%)	7 (0.33)	10 (0.13)
Back pain, n (%)	0 (0)	6 (0.08)
Blurry vision, n (%)	2 (0.09)	8 (0.10)
Other, n (%)	2 (0.09)	7 (0.09)

The correction will appear in the online version of the paper on the JMIR Publications website on July 27, 2022, together with

the publication of this correction notice. Because this was made after submission to PubMed, PubMed Central, and other full-text

repositories, the corrected article has also been resubmitted to those repositories.

Abstract

Background: Dental care expenses are reported to present higher financial barriers than any other type of health care service in the United States. Social media platforms such as Twitter have become a source of public health communication and surveillance. Previous studies have demonstrated the usefulness of Twitter in exploring public opinion on aspects of dental care. To date, no studies have leveraged Twitter to examine public sentiments regarding dental care affordability in the United States.

Objective: The aim of this study is to understand public perceptions of dental care affordability in the United States on the social media site, Twitter.

Methods: Tweets posted between September 1, 2017, and September 30, 2021, were collected using the Snsrape application. Query terms were selected a priori to represent dentistry and financial aspects associated with dental treatment. Data were analyzed qualitatively using both deductive and inductive approaches. In total, 8% (440/5500) of all included tweets were coded to identify prominent themes and subthemes. The entire sample of included tweets were then independently coded into thematic categories. Quantitative data analyses included geographic distribution of tweets by state, volume analysis of tweets over time, and distribution of tweets by content theme.

Results: A final sample of 5314 tweets were included in the study. Thematic analysis identified the following prominent themes: (1) general sentiments (1614 tweets, 30.4%); (2) delaying or forgoing dental care (1190 tweets, 22.4%); (3) payment strategies (1019 tweets, 19.2%); (4) insurance (767 tweets, 14.4%); and (5) policy statements (724 tweets, 13.6%). Geographic distributions of the tweets established California, Texas, Florida, and New York as the states with the most tweets. Qualitative analysis revealed barriers faced by individuals to accessing dental care, strategies taken to cope with dental pain, and public perceptions on aspects of dental care policy. The volume and thematic trends of the tweets corresponded to relevant societal events, including the COVID-19 pandemic and debates on health care policy resulting from the election of President Joseph R. Biden.

Conclusions: The findings illustrate the real-time sentiment of social media users toward the cost of dental treatment and suggest shortcomings in funding that may be representative of greater systemic failures in the provision of dental care. Thus, this study provides insights for policy makers and dental professionals who strive to increase access to dental care.

dentistry; oral health; social media; access to care; healthcare reform; COVID-19; dental care; health care service; twitter; public health; health communication; dental treatment; health policy; dental professional; thematic analysis

Introduction

A lack of access to dental care can lead to lower levels of systemic health, quality of life, and economic outcomes [1]. Yet, those who are most in need of dental care are often the least likely to receive it [2]. Low-income, working-age adults report the highest levels of financial barriers to needed dental care [3]. In the United States, the financial barriers to accessing dental care are higher than any other type of health care service [3-5]. The percentage of the population without dental insurance is more than twice that of those who are medically uninsured [6]. Spending on dental care results in a high percentage of out-of-pocket expenses because of a lack of insurance or high insurance deductibles and copayments [7].

While comprehensive dental coverage for children is an essential benefit under the Affordable Care Act, dental coverage for adults remains optional [7]. At the time of this study, 3 states provide no dental coverage, and 12 states provide emergency-only dental services to Medicaid beneficiaries [8]. In a comparison of public dental coverage for older adults in high-income countries, the United States had the shallowest dental coverage for older adults [9]. In an effort to mitigate access inequalities, there was a recent push in the US federal government to provide for Medicare coverage of dental and oral health services. In January of 2021, the Medicare Dental Benefit Act of 2021 (H.R.502 and S.97) was introduced into Congress, and President Biden's budget-reconciliation package proposed funding for a Medicare dental benefit. In August 2021, the Centers for Medicare and Medicaid Services appointed a chief dental officer to guide it in advancing oral health in Medicare [10]. To best develop a policy to address financial barriers to dental care, perspectives at the individual level are needed.

Social media is increasingly becoming an essential tool for public health communication [11]. Twitter is a free social media service where people communicate their daily thoughts and behaviors in short, 280-character messages called "tweets." With over 68 million active monthly users in the United States, Twitter offers rich, population-based data for tracking concerns of public health significance [12]. Twitter data emerge from real-world social environments, which encompass a large and diverse range of people, without any prompting from researchers. This contrasts with traditional approaches of public surveillance where responses are elicited in the form of semistructured interviews and web-based surveys with open-ended questions [13]. In addition, Twitter is a compelling data source for public health researchers because of the real-time nature of the content and high level of correlation with user sentiment and consumer confidence indices [14]. These qualities have contributed to a growing number of studies examining the use of Twitter for public health research [15-21], including the investigation of aspects of oral health [22-26]. Several studies have aimed to assess the influence of societal events on Twitter content related to oral health [27,28].

This study aims to explore the sentiments of Twitter users in the United States on dental care affordability in order to summarize trends and perceptions that describe how the cost of dental treatment impacts access to dental care. To date, no

studies have leveraged Twitter to examine public sentiments regarding dental care affordability in the United States.

Methods

Ethical Considerations

This infodemiological study used a convergent mixed methods approach [29,30] to analyze publicly available Twitter content related to dental care affordability. This study was submitted to the Institutional Review Boards of New York University (IRB-FY2021-5634) and the University of Washington (STUDY00013725). In alignment with federal regulations regarding the use of publicly available data for research, both institutional reviews determined that the study did not meet the criteria for research involving human subjects and that no further review was required.

Data Collection and Preprocessing

Data were obtained from Twitter, a free social media website created in 2006. Tweets can remain visible to the public or can be made visible only to approved followers, at the discretion of the user. Only publicly available tweets were used in this study, and usernames were removed for privacy protection.

Search terms were generated to identify tweets that discussed financial considerations associated with dental treatment. These search terms were tested and expanded through pilot queries and assessments until they were refined to the following word stems: "dental," "dentist," "tooth," "teeth," "root canal" AND "expensive," "pay," "afford," and "money."

Using a newly created account on Twitter, tweets were collected between September 1, 2017, and September 17, 2021, using Snsraper [31-33], an open-source web scraper written in Python (Python Software Foundation). The data collection script included a specific query that consisted of any combination of the search terms. Duplicate tweets, foreign language tweets, and retweets were then excluded. In addition to the tweets, metadata was collected as follows: "url," "date," "renderedContent," "user," "replyCount," "retweetCount," "likeCount," "quoteCount," "retweetedTweet," "quotedTweet," "mentionedUsers," "coordinates," "place," "hashtags," and "cashtags."

Metadata related to the users' location were used in order to limit the included tweets to those in the United States. Content was excluded from the data set of tweets for any of the following reasons: (1) content was unrelated to dental-treatment needs or experiences; (2) content was determined to be an advertisement; (3) content pertained to purely cosmetic or orthodontic dental procedures; (4) content pertained to veterinary dentistry; (5) content was classified as a joke or sarcasm; and (6) content was in reference to dental policies outside of the United States.

Data Analysis

Data were analyzed qualitatively using both deductive and inductive approaches. Two members of the research team with clinical dental knowledge (SY and LB) co-coded all of the tweets. In total, 8% (440/5500) of all of the included tweets were coded in order to identify prominent themes and subthemes. A final codebook was developed through consensus

among the members of the research team. The themes identified for the codebook included (1) general sentiments; (2) delaying or forgoing dental care; (3) payment strategies; (4) insurance; and (5) policy statements. Using the codebook, the entire sample of the included tweets was independently coded by the aforementioned researchers. In instances where the coders disagreed, they reached a consensus through discussion.

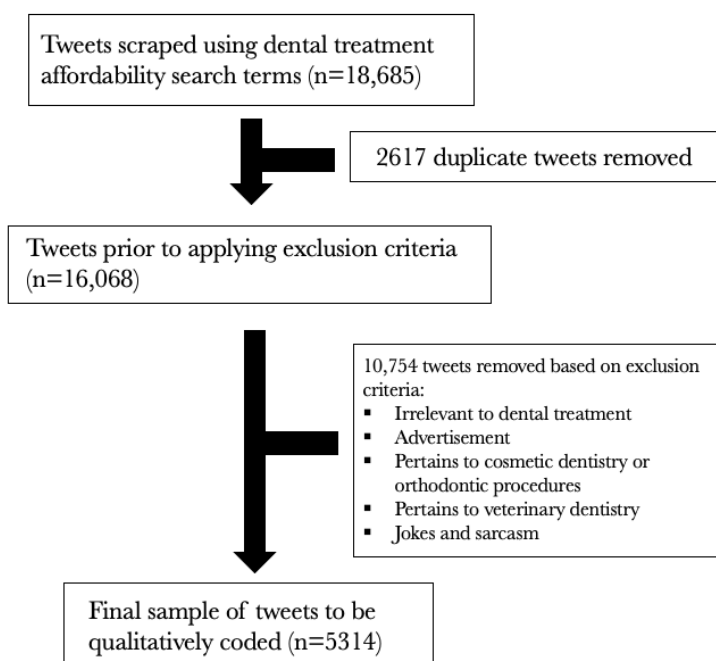

Quantitative data analysis included geographic distribution of tweets by state, volume analysis of tweets over time, and distribution of tweets by content theme. The tweets were mapped to an individual state within the United States, and the volume of tweets over time were depicted using Tableau (Tableau Software Inc), a data visualization software.

Results

Data Collection

Using the search terms, we collected a total of 18,685 tweets from September 1, 2017, to September 30, 2021. Of these tweets, 2617 (14%) were removed as duplicates, and 10,754 (57.6%) were removed based on preestablished exclusion criteria. A final sample of 5314 (28.4%) tweets (from 4963 unique users) were included in the study (Figure 1). The top 5 pairs of search terms were as follows: dental_afford (520/5314, 9.8% tweets); teeth_pay (461/5314, 8.7% tweets); dentist_pay (436/5314, 8.2% tweets); dental_money (356/5314, 6.7% tweets); and dental_expensive (353/5314, 6.6% tweets).

Figure 1. Data collection flow chart. Tweets about dental care affordability.

Thematic Distribution of Tweets

Thematic analysis identified the following prominent themes (Table 1): (1) general sentiments (1614/5314 tweets, 30.4%); (2) delaying or forgoing dental care (1190/5314 tweets, 22.4%);

(3) payment strategies (1019/5314 tweets, 19.2%); (4) insurance (767/5314 tweets, 14.4%); and (5) policy statements (724/5314 tweets, 13.6%). The identified subthemes and illustrative quotes from the data are presented below and in Table 2.

Table 1. Volume of tweets over time by thematic category.

Main category	Overall (n=5314), n (%)	2017 (n=277), n (%)	2018 (n=1227), n (%)	2019 (n=1341), n (%)	2020 (n=1090), n (%)	2021 (n=1379), n (%)
General sentiments	1614 (30.4)	110 (39.2)	399 (32.5)	405 (30.2)	320 (29.4)	380 (27.6)
Delaying or forgoing care	1190 (22.4)	64 (23.1)	304 (24.8)	286 (21.3)	266 (24.4)	270 (19.6)
Payment strategies	1019 (19.2)	34 (12.3)	206 (16.8)	298 (22.2)	249 (22.8)	232 (16.8)
Insurance	767 (14.4)	44 (15.9)	173 (14.1)	187 (13.9)	155 (14.2)	208 (15.1)
Policy statements	724 (13.6)	25 (9.0)	145 (11.8)	165 (12.3)	100 (9.2)	289 (21.0)

Table 2. Representative tweets for theme or subtheme as described in the codebook.

Theme and subtheme	Tweet
Insurance	<ul style="list-style-type: none"> “My dental insurance deductible was so high, I couldn't have dental work done last year. And my knee surgery got cancelled as a result. Damn shame. Still can't afford it. [URL]” “And... 19's root canal and crown cost more than the annual dental insurance max. There go \$837 of tuition money. I'm really just over this whole century.” “According to most health insurance companies teeth and eyes are luxury items that I must pay more to continue enjoying because they're a cosmetic privilege.”
Payment strategies	<ul style="list-style-type: none"> “@username @username hey. I know it's a long shot but I just had to use my rent money to have a very badly infected tooth removed and now I don't know how I'm doing to pay rent. PLEASE help if you can  God bless ya'll doing God's work”^a “Nervous to get my tooth pulled tomorrow but mainly because I'm afraid it's gonna cost more than what I have left on the credit card I'm using to pay for it....”
Delaying or foregoing care	<ul style="list-style-type: none"> “I canceled my root canal that was supposed to be Monday because my tooth quit hurting but here we are in ridiculous pain again and my husband has no job so no money to spend on it right now . “@username Yes it is I have several teeth I need to get pulled/ worked on but can't afford it..and also take pain meds that don't seem to help much of anything...”^a “@username Do you live near a dental school? When I didn't have dental insurance, I did an expensive project at a dental school for about 1/5 the cost. It took more time, but it was worth paying less.”^a
General sentiments	
Dentist mistrust	<ul style="list-style-type: none"> “I'm positive the dentist doesn't really find cavities in my teeth they just want to get my money and torture me. How do I brush every day and floss and still get cavities every time”
Dentistry is expensive	<ul style="list-style-type: none"> “@username Dental work is horribly expensive. I have had my very last \$1700 root canal.”^a
General statements	<ul style="list-style-type: none"> “@username @username This is why I never want to hear another American make fun of British teeth again. People in this country cannot afford the astronomical prices charged by dentists for dental care. So they just go without dental care at all.”^a
Positive sentiments	<ul style="list-style-type: none"> “i spent a lotta money on my teeth and it was worth it .
Policy statements	<ul style="list-style-type: none"> “@DeptVetAffairs @SenateGOP @HouseGOP I cannot afford regular dental coverage as a disabled veteran with a \$200 a month income.” “My mom doesn't have insurance for dental care...now, she has an infection in her tooth... now she needs to pay \$1504 before seeing the specialist... we don't have \$1504 in the bank... This is why we need Medicare For All!!! I'm angry because of this greedy corruption #Bernie2020” “@username @username When someone has a dental problem serious enough for a root canal, they are in pain and it will be an emergency treatment. But only people with money or dental insurance can get one. Most states' Medicaid doesn't cover adult dental care, and if it does, they pull the tooth.”^a

^aUsername was removed to maintain the privacy of the Twitter user.

General Sentiments

The most prominent theme included tweets containing general sentiments that expressed that dental care was expensive or not affordable but did not additionally suggest the cost that prohibited the user from accessing needed dental care. The overwhelming majority of these tweets expressed negative sentiments. Tweets in this thematic category were subcoded into the following subthemes: mistrust of dentists, expressions that dental care is expensive for the tweeting individual or a personal acquaintance (eg, a family member), impersonal statements about the affordability of dental care, and positive sentiments about accessing dental care.

The most prevalent subtheme was “expensive dental care,” representing 70.3% (n=1135) of the tweets in this theme.

Individuals frequently expressed displeasure related to the direct cost of dental care and surcharges related to administrative costs.

The consultation alone was \$250... out of pocket at that ...why the dentist gotta be so expensive?? I just want to be beautiful and healthy for the low [URL].
[User #677]

Tweets about “dentist mistrust” represented the second most prevalent subtheme of general sentiments. Users expressed sentiments of being financially duped or perceptions of dentists prioritizing financial gain over the patient's health.

@username @username Another common practice to make more money, is to remove all of the wisdom teeth, when often times patients do not need all of

them removed. It's just like, we're in there, so let's do them all. [User #1106]

Delaying or Forgoing Dental Care

Tweets about delaying or forgoing dental care due to an inability to afford treatment were categorized into the second most prominent theme. Strategies resulting from delaying or forgoing dental care mentioned within this theme included dental tourism, visits to the emergency room, visits to free clinics or dental schools, and self-treatment.

Users tweeted about not being able to afford the upfront cost of care and as a result delaying care despite being in pain. In some cases, users shared experiences of death resulting from an inability to access dental care.

@username I had a friend who didn't get treated, he died from sepsis. I don't want to scare you but it can be infected and that can spread really fast. No dentist should refuse someone because they can't pay when it comes to infection. I wish her well. [User #1126]

Users reported visiting the emergency room to address dental pain or infection when they could not afford treatment by a dentist. They often expressed dissatisfaction with their experience, which often left them with palliative care such as pain killers and antibiotics rather than treatment. In some cases, visits to the emergency room resulted in unexpected costs when medical insurances denied claims for dental-related conditions.

@username will not cover the ER visit because dental related, and I will have to pay close to \$2000 hospital bill. All they did was examine me and prescribe painkiller and antibiotics. How is this right? Everything needs to change. [User #4995]

Travel to countries with lower-cost dental care was expressed as a way to access care when dental treatment in the United States was considered to be too expensive. Domestically, users considered going to dental schools or public dental clinics when they could not afford the cost of a private dentist.

The fact that I'm driving three hours into Mexico tomorrow to get my teeth done at an 1/8 of the price I was going to pay at a "nonprofit" dentist in America is fucking ridiculous. [User #1990]

Payment Strategies

The theme about "payment strategies" for needed dental care most frequently included tweets asking for donations from others. Certain twitter accounts were frequently referenced in donation requests including @pulte, @TeamPulte, and @JefferyStar. Twitter users often asked for funds to be sent to them via PayPal, Venmo, GoFundMe, and CashApp.

I'm raising money to have my teeth pulled. Click to Donate: [URL] via @gofundme. [User #241]

A limited number of tweets indicated having to make sacrifices, such as foregoing groceries or rent, to afford dental care. Other payment strategies included going into debt and using stimulus checks or tax refunds to pay for care.

Really hoping I get stimulus money. I have teeth that hurt and dentists are expensive. [User #1091]

Insurance

Tweets discussing experiences with private-payer dental insurance were included in this less prominent theme. Many tweets discussed dental insurance as an employee benefit, and some expressed gratitude for occupation-granted insurance facilitating access to dental care.

However, tweets about insurance for dental care expressed negative sentiments more frequently, including a fear of losing coverage or not being able to afford care despite having insurance. In certain instances, individuals expressed displeasure with the complexity of the insurance system and dissatisfaction for having to pay for a portion of dental care in addition to their monthly insurance premium. Some users also expressed displeasure with dental care being excluded from medical insurance.

@username I have fancy employee dental insurance, but still have to pay a bunch for crowns and root canals with the added bonus of being really limited in dentists who accept the insurance. Instead of paying \$1,000 for a crown I pay \$300. So basically paying \$30/month for a discount card. [User #4934]

Policy Statements

Tweets categorized as "policy statements" were the least prominent theme. The included tweets were those that mentioned Medicaid or Medicare, health care reform, were directed at politicians, or were about veterans. The content of these tweets was often related to the desired policy changes related to dental coverage.

Time and Geographic Distribution of Tweets

Overall, 5314 tweets about dental affordability were collected (Table 1), with 277 (5.2%) in 2017, 1227 (23.1%) in 2018, 1341 (25.2%) in 2019, 1090 (20%) in 2020, and 1379 (26%) in 2021. The period of data collection was less than a year in 2017 (September 1 to December 31; 4 months) and 2021 (January 1 to September 30; 9 months).

The volume of tweets over the study period is depicted in Figure 2. There was a monthly average of 116 included tweets. The lowest number of tweets was observed in April 2020 (58 tweets, 1.1%), and the highest number of tweets was observed in September 2021 (673 tweets, 12.7%). Overall and across each year of collection, "general sentiments" was the most prevalent thematic category (Table 1). "Delaying or foregoing care" was the second most prevalent thematic category, except in 2019 and 2021, when "payment strategies" and "policy statements," respectively, were the more frequently observed categories. "Policy statements" was consistently the least frequently observed thematic category, except for a significant increase in 2021.

The geographic location of tweets was determined and mapped in Figure 3. Tweets originated the most from the most populous states in the United States, which are California, Texas, Florida, and New York [34].

Figure 2. Volume of tweets by month and year.

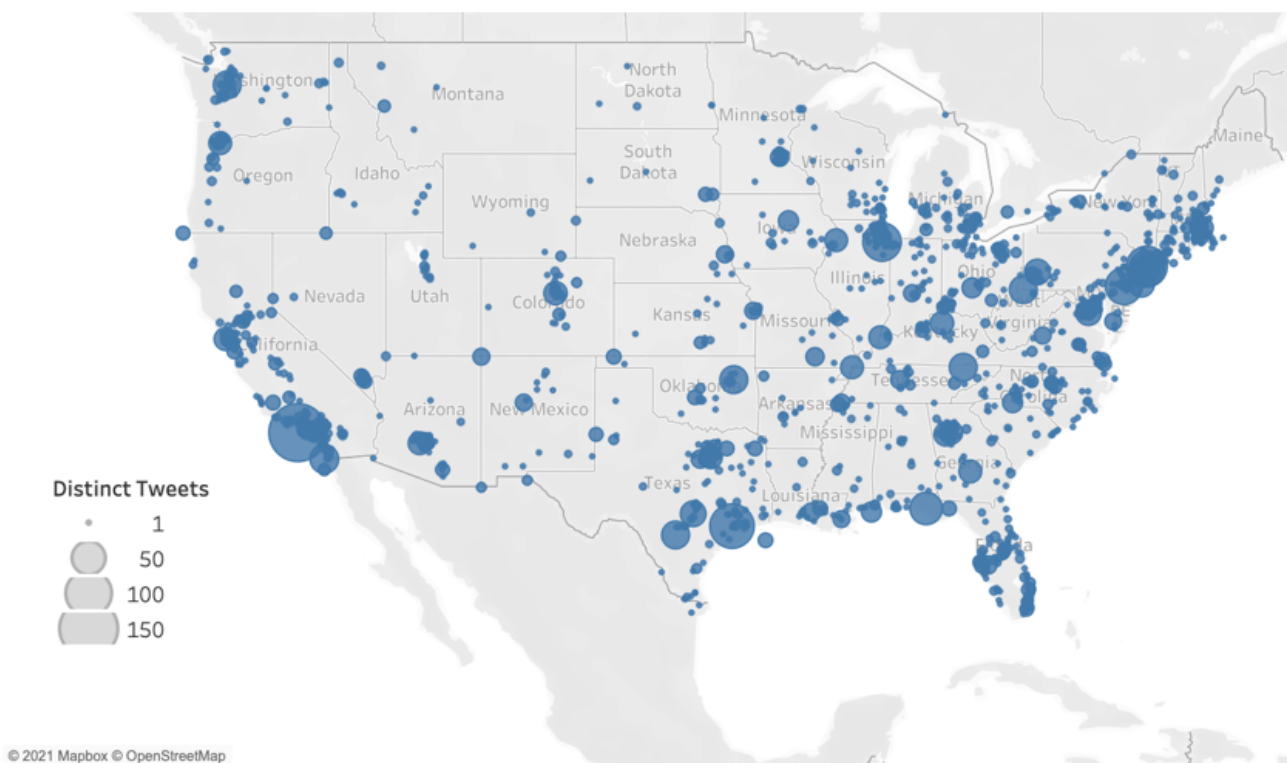

Figure 3. Map of tweet geolocations. Size of the dot represents the volume of tweets at a given latitude-longitude pair.

Discussion

Principal Results and Comparisons With Prior Work

This study leveraged Twitter to examine public sentiments toward dental care affordability in the United States. Twitter

users expressed dissatisfaction with the cost of dental treatment and the ability to access dental care. The overwhelmingly negative sentiments found in this study provide insight into how individuals are coping with financial barriers, including delaying or foregoing care and pursuing various payment strategies. Our

study findings support the conclusions of the existing dental literature on dental care affordability [2-5,7]. In the 2019 National Health Interview Survey, it was found that 19.2% of women and 15.6% of men did not access their needed dental care because of cost in the prior 12 months [35]. Rates of forgoing dental care are particularly high for uninsured adults, where 1 in 2 had not seen a dentist because of costs [36].

Moreover, our study findings highlight the fact that financial barriers to accessing dental care are prevalent even among those with dental insurance. The expressed sentiments of discontent with dental insurance payment structures echoed those of the existing reports in the literature. In a study on US health care spending, among 154 conditions examined, oral disorders requiring dental care had the highest out-of-pocket costs [37]. Another study that supports the sentiments of insured tweeters in this study reported that among individuals who were insured all year, US adults were significantly more likely than adults in other developed countries to go without care because of costs, the possibility of facing high out-of-pocket spending, or the financial burden of medical bills [36].

In an effort to come up with the money required to be paid out of pocket, users reported a variety of payment strategies that included credit cards, loans, stimulus checks, tax refunds, and donations. Crowdfunding, the web-based solicitation of public donations, has become a major financier of health care-related costs [38-41]. This trend was reflected in our study findings and reinforces sentiments that the use of crowdfunding to cover direct health care expenses may be a sign of a failing system [42]. Future research may explore crowdfunding for dental procedures.

Two relevant societal events occurred during the study period, which were the COVID-19 pandemic and the election of President Biden. COVID-19 resulted in dental office closures across the country in the spring and summer of 2020, with the greatest decline in weekly visits compared with 2019 observed in the week of April 12, 2020 [43]. This trend corresponds with the quantitative findings of this study, in which the lowest number of tweets were observed in April 2020. Further, COVID-19 had an economic impact that appeared to exacerbate financial barriers to accessing dental care for some people. One user tweeted, "...I can't wait to get an eye exam and new glasses, not to mention long overdue dental care! Or just not because I can't afford it ... because of #COVID19". For others, economic

stimulus checks distributed during the COVID-19 pandemic helped reduce financial barriers to dental care; for example, "@politico Got my stimulus money today. Thinking of getting much-needed dental work. Several teeth fell out when I had COVID in Dec. and Jan. Thank you President Joe!" Lastly, once dental offices reopened after COVID-19-related closures, there were tweets expressing displeasure with increased costs of care due to safety measures; for example, "...Had to pay an up charge for PPE for a dental appointment over the summer. Was told insurance was not likely to cover that aspect of the cleaning..." The election of President Biden in 2021 renewed conversations about health care reform, and the volume of tweets coded as "policy statements" increased in correspondence. In September 2021, there were 3.4 times the monthly average number of tweets. We hypothesize that this increase is a reaction to the announcement in August 2021 that President Joe Biden's budget-reconciliation package included funding for a standard Medicare dental benefit [44-46]. Ultimately, the Medicare dental benefit was not included in the House of Representatives' passed legislation.

Limitations

The trends in the volume of tweets over time as well as the geographic distribution of the tweets support the generalizability and transferability of the findings of this study. However, this study is not without limitations. While all demographic categories have been shown to engage with social media to varying extents in the United States, Twitter users are not necessarily representative of the US population [47]. On average, Twitter users are younger, are more likely to identify as Democrats, are more highly educated, and have higher incomes than US adults overall [48]. Further, the sample of tweets collected may have some sampling bias, as the data set was not necessarily limited to a single tweet per unique user.

Conclusions

The findings illustrate the real-time sentiment of Twitter users toward the cost of dental treatment and suggest shortcomings in funding, which may be representative of a greater systemic failure in the provision of dental care. Thus, this study provides insights for policy makers and dental professionals who strive to increase access to dental care. Limitations of dental insurance payment models, both public and private, are one such area that may be explored.

Abstract

Background: The COVID-19 pandemic has drawn attention to various inequalities in global societies, highlighting discrepancies in terms of safety, accessibility, and overall health. In particular, sex workers are disproportionately at risk due to the nature of their work and the social stigma that comes alongside it.

Objective: This study examines how public social media can be used as a tool of professional and personal expression by sex workers during the COVID-19 pandemic. We aimed to explore an underresearched topic by focusing on sex workers' experiences with the ongoing COVID-19 pandemic on the social media platform Twitter. In particular, we aimed to find the main issues that sex workers discuss on social media in relation to the COVID-19 pandemic.

Methods: A literature review followed by a qualitative analysis of 1458 (re)tweets from 22 sex worker Twitter accounts was used for this study. The tweets were qualitatively coded by theme through the use of intercoder reliability. Empirical, experimental, and observational studies were included in this review to provide context and support for our findings.

Results: In total, 5 major categories were identified as a result of the content analysis used for this study: concerns (n=542, 37.2%), solicitation (n=336, 23.0%), herd mentality (n=231, 15.8%), humor (n=190, 13.0%), and blame (n=146, 10.0%). The concerns category was the most prominent category, which could be due to its multifaceted nature of including individual concerns, health issues, concerns for essential workers and businesses, as well as concerns about inequalities or intersectionality. When using gender as a control factor, the majority of the results were not noteworthy, save for the blame category, in which sexual and gender minorities (SGMs) were more likely to post content.

Conclusions: Though there has been an increase in the literature related to the experiences of sex workers, this paper recommends that future studies could benefit from further examining these 5 major categories through mixed methods research. Examining this phenomenon could recognize the challenges unique to this working community during the COVID-19 pandemic and potentially reduce the widespread stigma associated with sex work in general.

sex work; social media; COVID-19; pandemic; Twitter; infodemiology; social stigma; sex worker; risk; public health

Introduction

Background

There is some ethnographic research discussing the relationship between the COVID-19 pandemic and female sex workers' experience as a marginalized group in society, but there is a clear lack of literature discussing how public social media can

be used as a tool of professional and personal expression amongst sex workers. We focus here on public social media in contrast to closed or restricted social media sites, such as OnlyFans. Though sex workers are a vulnerable group, social media provides people with vocal autonomy and advocacy, while also finding a sense of belonging and community [1]. Thus, social media is an important tool for drawing attention to some of the major concerns and issues experienced by sex

workers during the COVID-19 pandemic. Though there are studies that have focused on the challenges experienced by sex workers more generally, there is a lack of literature examining the ways that sex workers use social media.

This gap in academia reinforces the argument that sex workers are both vulnerable and devalued and fails to acknowledge how social media can act as an important tool for developing an online community, encouraging safety, and developing a dialogue between vulnerable groups, such as sex workers, and the public. It is important to note that most of the literature focuses on female sex workers, but some studies have examined the implications and stigma associated with male sex workers [2-4]. Regardless of the gender of participants, it is undeniable that the stigma associated with sex work reinforces the vulnerability of this group before the pandemic and continues to render them even more vulnerable today.

Despite the ground that existing research has covered, there is still a lack of studies exploring how sex workers use social media to amplify their voices, discuss their personal experiences, and demonstrate support for other vulnerable groups. As a result, this study aims at filling some of these gaps by exploring how sex workers use social media to disseminate information about COVID-19 and their experiences while working during the pandemic.

Literature Review

In general, existing academic studies concerning sex workers' use of social media platforms have not fully explored the implications of social media usage during precarious times, such as during the ongoing COVID-19 pandemic. Although several available studies have examined the implications of sex workers' use of social media [1,2,4-6], there is a limited number of academic studies that have empirically explored and analyzed existing social media posts from sex workers themselves to determine how social media platforms function as important sites for self-identified sex workers in a multitude of ways during the COVID-19 pandemic.

The available studies highlight the importance of ensuring that sex workers have adequate access to health care resources, particularly during the COVID-19 pandemic. Indeed, almost all types of sex work remain highly stigmatized [7], which has led to the creation of various organizations that fight for sex workers' basic rights to ensure that their positions are seen not only as work but also as essential work [1,8]. In fact, some studies and reports concluded with calls of action that specifically identified the discrepancies between work that is, on the one hand, considered essential and, on the other hand, considered sex work, thus drawing attention to the stigma associated with the latter [3,7,9]. Many sex workers are unable to access their health care needs due to government restrictions, long wait times, and limitations on social gatherings [8]. Though the demand for sex work during the pandemic remains strong, sex workers are not granted the same precautions that workers in other industries are, especially with regard to economic and labor support [10], a lack of available and accessible COVID-19 testing [7], and a higher risk for the spread of sexually transmitted diseases [8]. Due to inadequate resources and health

care, many sex workers have to rely on their own strategies for their safety and advocacy.

Several published academic studies concerning the implications of COVID-19 and sex workers have been explored worldwide. In Ghana and Kenya, sex work itself is not deemed illegal, though it is not considered essential work [3,11]. The Kenyan and Ghanaian governments have put several regulations in place to prevent the spread of the virus. Though this has reduced the spread of the virus, it has threatened many sex workers' stability and only added to their vulnerability [3,11]. Through various social media channels, sex workers in Kenya are able to share information with one another and discuss safety strategies [3]. The instability of work for sex workers is not limited to the West; thus, it is a reality for sex workers worldwide that can be somewhat mitigated through the use of social media channels. This highlights that although the nature of sex work has depended on being in close physical contact with others, the integration of social media platforms provides sex workers with alternative and safer options for their line of work.

Several studies have highlighted the various purposes social media usage can serve for sex workers, sex work organizations, and other vulnerable groups. One recent study found that social media can function as a tool for advocacy amongst the sex worker community [1]. In the study, the authors highlighted the many benefits of encouraging sex workers to use social media, as well as the potential risks involved with using these platforms [1]. Though activities that are both online and offline have similar characteristics, it is worth noting that not all digital spaces are accessible to all sex workers, even if there has been an influx of sex workers relying on these online spaces [12,13]. In addition, another study found that social media advocacy can increase the efficiency of moving between offline and online spaces, enhance safety, and strengthen communication between sex workers [1]. In particular, the authors found that sex workers who were engaged in dialogue with one another would have many more positive encounters with clientele, as they could exchange information about potential clients and discuss problems concerning specific clientele [1]. In the past, sex workers have been limited to who they encounter in the streets [4], but now, given the ubiquity of social media, sex workers can instantly connect with one another and transmit information in a much more efficient, safe, and effective manner.

In general, the advent of social media has changed how sex workers engage with and meet their clients, promote their services, and explore their agency online. A different study found that online spaces provide extensive opportunities for sex workers to explore and curate their online identities to collaborate with one another, to avoid conflict, and to develop a stronger role of agency [6]. Although social media has proven to have many benefits for sex workers, its use is not without risks. One study found that sex workers struggle with receiving payment, especially since social media can act as a transparent space where content, such as photos and videos, is already visible on one's profile for free [4]. Although social media offers many benefits for sex workers, these sites call for a lot more emotional and mental labor to maintain and manage one's online profile.

One of the challenges not mentioned in these aforementioned studies is that of shadowbanning, which is a phenomenon vital to understanding how sex workers navigate online spaces. Shadowbanning is a process that reduces and limits the visibility of a user's social media platform, even to their followers [14,15]. Shadowbanning has become a lot more prominent for sex workers on social media platforms with an audio-visual focus, such as Instagram, OnlyFans, TikTok, and Facebook. According to 1 sex worker who identifies as a camgirl who has worked in the industry for over 10 years, most social media platforms frequently discriminate against sex workers' persons, work, and jobs, rather than their content [14]. This is believed to be in relation to the US Fight Online Sex Trafficking Act–Stop Enabling Sex Traffickers Act (FOSTA-SESTA) bill, which was enacted to prevent online sex trafficking, though sex work is consensual and legal for many sex workers online. This bill has increased social stigma toward sex work as it does not differentiate between consensual and nonconsensual sex work sectors [14]. However, Twitter has proven to be much less extreme in shadowbanning sex workers, whereas Instagram has made it extremely difficult for users to search for sex workers' accounts through the search function, as well as limiting the visibility of posts and stories of sex workers, even for their followers [15,16]. Thus, the shadowbanning techniques implemented by Twitter appear to be less unrelenting compared to other social media platforms, but the platform is still not completely accepting and inclusive of sex workers.

What is largely missing in these studies is an empirical examination of sex workers' social media posts referencing the pandemic. Therefore, this study attempts to answer the following main research question: *What are the main issues that sex workers discuss on social media in relation to the COVID-19 pandemic?*

Methods

Data Collection

Social media data for this study were collected from December 29, 2019, until July 7, 2021, which is when the study was conducted. The data collection began in late 2019 because this is when coronavirus emerged. Using convenience sampling, 2 researchers examined the Twitter profiles of 22 sex workers, which were identified using several English search terms, such as “sexwork” and “sex workers.” The identified users included 15 (68.2%) women; 5 (22.7%) sexual and gender minorities (SGMs), including 1 (20%) individual who is openly transgender; and 2 (9.1%) men. For this study, SGMs should be understood as those who identify as being part of the two-spirit, lesbian, gay, bisexual, transgender, queer or questioning, intersex, asexual (2SLGBTQIA+) community, those who identify as nonbinary, and those who are not cisgender. Most of the sex workers have self-identified their gender on their Twitter profiles. Interestingly, 9 (40.9%) sex workers on our list publicly declared on their Twitter profiles that they are vaccinated.

In this respect, we cannot claim that we managed to map all the available sex workers on Twitter, as this is a prodigious if not an impossible task, but we believe that the number of users was

adequate to conduct this study. We used convenience sampling for this study, where users were selected based on their availability; the chosen profiles have identified that they are sex workers in their descriptions, and their profiles are public, in which their posts are available to all users and viewers. We chose to use Twitter for this study due to the higher prominence of shadowbanning on different social media platforms and its higher level of accessibility for sex workers. Though not without controversy, Twitter acts as a more accessible and less problematic platform for sex workers as it is one of the few that does not censor users solely based on their career, and the guidelines are much easier to navigate [15,17].

Data Extraction

To extract the data, we used Twitter application programming interface (API) v2, which allows full data extraction, except for deleted posts or private accounts. In total, 134,025 tweets were downloaded, representing all the available messages posted on the accounts of the 22 sex workers, including what they retweeted. We included the retweets in our analysis because they also represent what the sex workers intended to highlight, such as violations or work restrictions. On average, each sex worker posted 6092 (re)tweets during the study period; the highest number of (re)tweets was 31,802 by 1 (4.5%) sex worker, and the lowest was only 3 (re)tweets. [Multimedia Appendix 1](#) shows that March 14, 2021, had the highest number of (re)tweets.

As the collected data were rather substantial for a manual content analysis, we used a Python script [18] to extract tweets that referenced 33 terms related to the pandemic: “coronavirus,” “pandemic,” “coronapocalypse,” “COVID,” “COVID-19,” “COVID19,” “vaccin*,” “vaxxed,” “mRNA,” “Pfizer,” “Moderna,” “Johnson & Johnson,” “Johnson&Johnson,” “Astra-Zeneca,” “Covidiot,” “essential worker,” “frontline worker,” “herd immunity,” “virus,” “quarantine,” “epidemic,” “asymptomatic,” “personal protective equipment,” “PPE,” “contact tracing,” “lockdown,” “new normal,” “social distancing,” “social distance,” and “N95.” Another Python script was used to extract the most referenced hashtags in the overall data set. Once again, these search terms do not represent all the available terms that are related to the pandemic, but they cover the main issues concerning COVID-19. The filtered data comprised 1458 (re)tweets that received 11,035 likes, 960 replies, and 10,517,689 retweets. To design the codebook, 2 coders examined a sample data set using emergent coding [19,20] to identify the major categories in the social media posts. In total, 6 main categories were identified as follows:

- **Blame:** Tweets that blame and criticize the government, rich people, and those in positions of power, such as health authorities, for how the virus is being handled, how the vaccine is being distributed, etc.
- **Humor:** This is generally used as a coping mechanism or to increase people's ability to relate to what others are feeling. Many people will use the retweet or like function to show that they agree with it or to share these tweets with their followers to make others laugh about some unique circumstances occurring during the pandemic.

- **Concerns:** Tweets that express health concerns or concerns about their loved ones or people they know, as well as concerns about fake news, media reliability, race, class, and gender—intersectionality—across social groups, including concerns about essential workers, etc.
- **Solicitation:** Tweets that promote sex workers' availability, vaccine status, times that they will be online or available for meetings, or cities that they will be traveling to. This category also includes when users post photos of themselves.
- **Herd mentality:** This category refers to the way people will try to create an emotional plea or rational argument to conform to mainstream ideas and policy guidelines; tweets will normally say “retweet if you're still social distancing” or “have you taken the vaccine yet?”. This is similar to shaming but is based on being socially desirable by following public health regulations.
- **Other:** Any other minor issues that are not listed in the previous categories.

To test the codebook, 2 coders examined over 10% (n=150) of the total data set, and in the second attempt after a few rounds of deliberation and discussion, intercoder reliability was measured using Krippendorff $\alpha \geq 0.78$, which was acceptable [21].

Ethical Considerations

As mentioned, sex workers are a highly vulnerable group that is also highly stigmatized. When researching such a population, it should be ensured that the privacy and confidentiality of the participants are protected. Given that the data for this study were collected through users' public profiles on social media, ethics clearance was not needed from our university. That being said, though these users have their profiles set to “public,” that does not mean that it is any less incriminating if their identities are revealed [22]. To address this ethical concern, this study did not provide any personal details about any of the participants, where names, locations, and specific details from their profiles were all omitted. The method for this study was broad enough that others using similar search terms in the Twitter search bar may not receive the same results—due to algorithms or other factors. To further protect the identities of the participants, our method included both original tweets and retweeted posts, so it is impossible to identify the sex workers examined in this study as the increased number of posts further protects the participants.

Results

Main Findings

As mentioned before, this study aims to identify the major themes and topics sex workers discuss on the social media platform Twitter. From the 1458 tweets and retweets, 6 main categories emerged: blame, humor, concerns, solicitation, herd mentality, and other. These categories are exhaustive and mutually exclusive, and the coders identified the most dominant underlying message in each tweet, especially due to the brevity of tweets. To ensure the validity of the codebook, 2 coders

examined a sample and the intercoder reliability test using Krippendorff $\alpha \geq 0.78$ was acceptable [21].

Blame

Blaming others is a reactionary retort that can address one's frustration. For this study, the blame category is understood as posts that explicitly and critically identify an actor responsible for the cause of concern. These actors are criticized and can include government representatives, political parties, the elite, police departments, and others in positions of authority. Although the rationale behind blaming or criticizing others may vary, it can be agreed that blaming others in times of uncertainty is a common reaction, especially if individuals are experiencing a heightened level of fear and anxiety [23,24]. This category came as the fifth-most frequent one, with only 146 (10%) of the social media posts referencing it (Multimedia Appendix 2). Some examples of the blame category include statements resembling criticism, such as:

How ICE helped Spread the Coronavirus...

Rich people did not experience the same pandemic as working class people and now they get the vaccine first. It's actually twisted.

In terms of gender, we found that SGM sex workers had the highest percentage of tweets that blame and criticize other parties (n=62, 11.2%), followed by female sex workers (n=83, 9.3%), denoting the urgent issues these groups discuss. Twitter audiences did not show active engagement with messages that contained blame, for this category came fifth, with 1,790,953 (17%) of the most retweeted posts.

Humor

Humor is a powerful coping mechanism that takes on multiple forms on social media and is especially prominent in times of crisis, such as during a global pandemic. With this in mind, humor is understood as the way that users rely on funny posts in their many forms—including sarcasm, satire, and irony—as a coping mechanism and to produce relatable content. Humor is a vital tool for bringing hope to people while they are experiencing times of crisis; humor is also understood as 1 of the only “available option[s]” for openly criticizing others, releasing one's frustration, and providing a narrative for living through a pandemic [25,26]. This category came in fourth at 13%, with 190 of the social media posts referencing it (Multimedia Appendix 2), and male sex workers (n=4, 28.5%) seem to rely on this category more often than other gender groups (Table 1); however, the data on men are extremely low, so definite conclusions cannot be reached. Some examples of humor in this data set include:

Feel bad for people who got fit in quarantine but now have to STAY fit for like 7 more months before anyone sees. Shoulda paced yourselves

Whoever smoked mid from a soda can as a teenager is immune to coronavirus

Interestingly, social media audiences found this category more appealing than other ones for they mostly retweeted posts in the humor category, at 3,205,669 (30.4%) of the most retweeted posts.

Table 1. Major categories (N=6) discussed by sex workers by gender.

Category	Women (N=886), n (%)	Men (N=14), n (%)	SGM ^a (N=558), n (%)
Blame	83 (9.3)	0	63 (11.2)
Humor	120 (13.5)	4 (28.5)	66 (11.8)
Concerns	302 (34.0)	6 (42.8)	234 (41.9)
Solicitation	221 (24.9)	3 (21.4)	112 (20.0)
Herd mentality	155 (17.4)	0	76 (13.6)
Other	5 (0.5)	1 (7.1)	7 (1.2)

^aSGM: sexual and gender minority.

Concerns

The number of concerns that have emerged since the outbreak of coronavirus have been multifaceted and expansive. Thus, for the purposes of research, concerns are understood as being associated with individuals' worries about their loved ones, health issues, essential workers and businesses, and intersectionality [27]. The latter refers to how the lived experiences of someone's life can impact one's "social determinants of health" due to their identity [28]. This category of concerns therefore also refers to those whose identities render them marginal, such as those who are immunocompromised or racialized. Concerns not only refer to fears associated with contracting or spreading coronavirus but also include concerns about public safety, public health, and those who are especially vulnerable to the virus.

The findings showed that this is the top category in the whole data set, constituting 542 (37.2%) of the posts ([Multimedia Appendix 2](#)). It is also the highest category across all gender groups (men: n=6, 42.8%; SGMs: n=234, 41.9%; and women: n=302, 34.0%; see [Table 1](#)). One example is:

in the 8 days since the first COVID-19 case on the navajo nation, our nation now has 49 cases. that number is growing every day. i'm starting a thread of all the ways you can support the navajo nation during the COVID-19 pandemic.

Another example states:

The Covid-19 pandemic particularly has demonstrated how so many people who already face marginalisation are excluded from vital financial resources - government schemes, access to bank accounts and cards. Denying people access to these denies them access to society as a whole.

In terms of the most referenced hashtags, we found that sex workers used relevant terms to express different types of legal, safety, and health concerns, such as #covid19 (n=52), which is ranked amongst the top 10 most used hashtags, as well as other ones, such as #sexworkerdemands (n=18); #antittrafficking (n=15); #sextrafficking (n=15); #coronavirus (n=14); #decriminal (n=12), used in relation to decriminalizing sex work in Queensland, Australia; and #antiprostitution (n=6). Some of the other concerns expressed by sex workers were related to their online safety, for a few of them mentioned the importance of avoiding doxxing, which is the online disclosure of personal

information, such as sex workers' phone numbers and addresses. For example, 1 (4.5%) sex worker retweeted:

Harm Reduction: Doxxing Prevention Tips for Sex Workers and Protesters is now live!

In terms of the audience's reaction, this category came second in relation to the retweeted posts, comprising 2,787,188 (26.5%) of the retweeted posts.

Solicitation

The COVID-19 pandemic has presented sex workers with many challenges, which include the way that they promote and solicit their work. Although there were some sex workers who had already moved to online platforms, the accessibility of Twitter provides sex workers with an online platform where they can solicit online clients by promoting their services or performing their gender in a specific way [6,29]. This category of promotion and solicitation, therefore, includes content that promotes the availability of sex workers' services, such as photographs of the worker in question, information about their vaccine status, cities that they will be traveling to, and specific dates and times that they will be available for meetings. This is an expansive and comprehensive category that not only includes sex workers promoting themselves but could also include the promotion of other organizations that need financial or social support that aligns with sex workers' individual values. This is the second-most frequent category, with 336 (23%) posts ([Multimedia Appendix 2](#)), and female sex workers posted more tweets around this issue (n=221, 24.9%; see [Table 1](#)). Some examples of this include:

Finally, this category of posts received the least amount of attention from Twitter audiences, with 32,047 (0.3%) retweeted posts.

Herd Mentality

As mentioned before, herd mentality refers to how the actions and behaviors of a group can influence other individuals. During the COVID-19 pandemic, herd mentality has often been associated with promoting messages that align with government recommendations and public health authorities' guidelines to reduce the number of cases of COVID-19 among the population. Those on social media will often promote government restrictions, information about how to social distance at protests, or promote getting vaccinated. Although there is no central

authority or specified leader to herd mentality, this kind of behavior and its associated actions are transmitted to local networks with the help of others who explicitly promote this way of thinking [30,31]. In this case, the local actions can refer to social media posts, such as in the form of (re)tweets, to promote these messages. This category came third, with 231 (15.8%) posts, as the most important issue discussed by sex workers (Multimedia Appendix 2), and female sex workers are ahead of other groups in referencing it (n=154, 17.4%), followed by SGMs (n=76, 13.6%; see Table 1. Some examples of herd mentality include:

In terms of audience engagement with these types of tweets, this category only came third, with 2,653,060 (25.2%) of the retweeted posts.

Finally, the other category is not discussed here, because it deals with only minor issues that are mostly personal or irrelevant to this study, comprising 13 (0.8%) of the retweeted posts.

Discussion

Principal Findings

As described in this paper, most tweets in our sample align with the issue of concerns. The ongoing COVID-19 pandemic has drawn significant attention to the inequitable structures in society that disproportionately impact vulnerable groups. As a result, the pandemic has influenced how sex workers advocate for themselves on social media platforms, as they are more likely to express concerns about how COVID-19 has impacted their own work and other communities worldwide. Although the concerns have been localized to certain national contexts, such as the United States and Australia, the nature of this online community through the digitization of advocacy has highlighted how COVID-19 is a global phenomenon, thus causing sex workers to advocate for themselves and their own work alongside other disparate groups worldwide. For example, we found that the hashtag #blacklivesmatter was mentioned 50 times by sex workers, together with #BLM (n=31) and #blacklivesmatteraustralia (n=19), to express solidarity with the movement. Though this could be due to the large wave of support for the Black Lives Matter movement following the murder of George Floyd, this highlights that sex workers, as a marginalized community, will not only use social media as a site to discuss their own difficulties but also draw attention to how other social groups have been impacted [28]. The same point applies to intersectional issues and politics.

Given that concerns are closely associated with protecting vulnerable populations, we found that herd mentality was the third-most frequent category. The implicit part of addressing concerns about the vulnerability of certain groups is ensuring that one is taking the necessary steps to protect themselves and others from contracting and spreading the virus. By following the official COVID-19 guidelines, sex workers examined in this study are highlighting the importance of following restrictions to keep others safe and, by showing that they are taking part in this behavior, others should too. Since this

category was the third-most frequent one, it is closely associated with the most recurrent category of concerns because, to protect those who are more vulnerable, everyone needs to follow the official health guidelines.

Solicitation was the second-most frequent category. Given that COVID-19 is highly contagious and sex work is a profession that often requires close physical contact between parties, sex workers are at a much higher risk for contracting COVID-19. The codebook sample provided insight into how sex workers were struggling to find work during the pandemic, especially since sex work is not decriminalized or legalized in some countries [11]. Thus, the high frequency of tweets that were coded as solicitation demonstrates how sex workers are using social media platforms to promote their services and have an income to rely on.

The category of humor was not only used by sex workers during the COVID-19 pandemic but also relied upon by many individuals as a coping mechanism [25,26]. Through the use of humor, the severity of the pandemic can be momentarily forgotten as users share relatable information in order to make light of the situation. Though humor was the fourth-most frequent category, its presence shows that the sex workers from this sample engaged with these posts during times of crisis, though there was a much stronger presence of other serious themes.

Finally, the blame category was the least frequent, where those in positions of power are criticized or identified as the cause of concern. During a global health crisis, it is only natural that vulnerable populations will point out further issues of inequity with regard to the specific challenges faced by their community (as is the case with the concerns category) or through the identification of a single actor or representative engaging in activities that are a cause for concern. By identifying different actors that are believed to be responsible for social inequalities or, at the very least, perpetrating them, sex workers are drawing specific attention to the root causes of inequity and how it is manifested in the society during the COVID-19 pandemic.

Limitations

One of the limitations of this study is that we only used posts and retweets that were in the English language. It is likely that there are many other sex workers' accounts on Twitter that are not written in English, but they were not included in this study. This was not the only factor that limited our scope: While conducting our search, we used a limited number of search terms and only used Twitter, while some sex workers might prefer to use other online platforms, such as OnlyFans and Instagram. That being said, Twitter was the most reliable platform for this study because other social media platforms are a lot stricter with shadowbanning content, thereby making it more difficult to find and identify sex workers on those platforms.

Though the authors believed that they reached saturation with 22 sex workers' accounts for this study, it is likely not representative of the sex worker community as a whole. There are many unique challenges that sex workers in different countries experience, which may not be summed up in only 280 characters. Furthermore, there are sex workers who may not

feel comfortable disclosing their profession on their Twitter account for personal or safety reasons, just as there are likely sex workers who do not use Twitter at all.

Conclusion

Although the existing literature vaguely highlights how sex workers use public social media as tools of advocacy, education, and community support in this community, this study used a selected sample of tweets to examine the specific issues that arise from the content of tweets on sex workers' public accounts. The 6 main issues of blame, humor, concerns, solicitation, herd mentality, and other discerned from this sample highlight how Twitter functions as an uncensored space for sex workers to openly discuss their lived experiences while working in an essential, yet high-risk, career throughout the pandemic. These issues, some of which are pressing ones, do not only highlight sex workers' individual concerns but demonstrate that sex

workers are advocating for and supporting other vulnerable communities through retweets and likes and posting their own content about other essential workers and those with marginal identities.

Future research on the topic of sex workers' online advocacy could benefit from examining these issues in detail through mixed methods research, such as through online surveys, interviews, or focus groups that explicitly seek answers to questions about sex workers' online advocacy strategies. Examining this phenomenon is not only significant for recognizing the challenges unique to this community during the COVID-19 pandemic but can also highlight how online spaces function as alternative locations of inclusion without the normally ubiquitous stigma attached to sex work. Indeed, social media can be effectively used as a tool for advocacy, education, and community support.

Data Availability

The data set and the coded posts are available with the researchers and can be shared with the reviewers upon request. However, we cannot post them online in a public data repository in order to protect the identity of sex workers.

Conflicts of Interest

None declared.
