Abstract

Background: Physical inactivity remains a leading risk factor for mortality worldwide. Owing to increasing sedentary behavior (activities in a reclining, seated, or lying position with low-energy expenditures), vehicle-based transport, and insufficient physical workload, the prevalence of physical activity decreases significantly with age. To promote sufficient levels of participation in physical activities, the research prototype *Fit-mit-ILSE* was developed with the goal of making adults aged ≥ 55 years physically fit and fit for the use of assistive technologies. The system combines active and assisted living technologies and smart services in the *ILSE* app.

Objective: The clustering of health and fitness app user types, especially in the context of active and assisted living projects, has been mainly defined by experts through 1D cluster thresholds based on app usage frequency. We aimed to investigate and present data-driven methods for clustering app user types and to identify usage patterns based on the *ILSE* app function *Fit at home*.

Methods: During the 2 phases of the field trials, *ILSE* app log data were collected from 165 participants. Using this data set, 2 data-driven approaches were applied for clustering to group app users who were similar to each other. First, the common approach of user-type clustering based on expert-defined thresholds was replaced by a data-driven derivation of the cluster thresholds using the Jenks natural breaks algorithm. Second, a multidimensional clustering approach using the Partitioning Around Medoids algorithm was explored to consider the detailed app usage pattern data.

Results: Applying the Jenks clustering algorithm to the mean usage per day and clustering the users into 4 groups showed that most of the users (63/165, 38.2%) used the *Fit at home* function between once a week and every second day. More men were in the *low* usage group than women. In addition, the younger users were more often identified as *moderate* or *high* users than the older users, who were mainly classified as *low* users; moreover, the regional differences between Vienna and Salzburg were identified. In addition, the multidimensional approach identified 4 different user groups that differed mainly in terms of time of use, gender, and region. Overall, the younger women living in Salzburg were the users with highest average app usage.

Conclusions: The application of different clustering approaches showed that data-driven calculations of user groups can complement expert-based definitions, provide objective thresholds for the analysis of app usage data, and identify groups that can be targeted individually based on their specific group characteristics.

Introduction

Background

Around 1.65 million people ≥ 65 years old were living in Austria in 2018. This number will increase to 2.5 million in 2040 according to the 2018 population forecast of the Austrian Conference on Spatial Planning [1]. The increasing number of older adults highlights the need for health-promoting measures to prevent immobility and ensure a good quality of life for this growing segment of society.

To date, the recommended physical activity dosage for healthy insufficiently active adults consists of 150 minutes of moderate to vigorous physical activity per week [2,3]. In addition, according to the World Health Organization (WHO) [4], people ≥ 65 years old with poor mobility should be physically active for ≥ 3 days per week, focusing on functional balance to prevent falls. However, every exercise session, whether short (seconds to minutes) or long (minutes to hours), counts toward reducing the risk of cardiometabolic morbidity and mortality [5].

To promote physical activity, the fitness program *Fit-mit-ILSE* was introduced as part of the Austrian Active and Assisted Living (AAL) research project, *fit4AAL*. The project aimed to make the increasingly technology-familiar generation of ≥ 55 years fit and *fit for the use of assistive technologies*. Within the program, an app called *ILSE* was developed to support and encourage the older adult population to exercise at home or outdoors through videos and courses on a tablet or 3D camera system.

In particular, the analysis of app usage is of interest in determining the acceptance of apps in general and fitness apps. Actual app usage can be monitored by analyzing the questionnaire or app usage log data, which may include exercise frequency tracking. App usage and reasons for fitness and health apps have been addressed in various studies. For example, the study by Dadaczynski [6] analyzed the user experience and the actual use of the web-based intervention *Healingo Fit* with a user experience questionnaire and usage data. The results showed particularly high satisfaction values for the dimensions of attractiveness, stimulation, and originality. Analysis of the log data revealed that the app was visited on average 65 times a day within 6 weeks [6]. The study by Schneider et al [7] discussed the use of the AAL prototype CARIMO and found from the analysis of the log data that the use of the CARIMO app remained quite stable during the test months. The study by Meyer et al [8] analyzed the use of activity trackers and described their general use, changes over time, and characteristic patterns of activity tracker usage in the long term.

The definition of app usage groups characterizes users and can be used as a grouping variable in statistical tests. From an exercise prescription perspective, identifying user types is important for creating a personalized fitness training program. Such personalization aims to engage in health-promoting physical activity, improve physical fitness levels, and maintain users' exercise fidelity [9]. A wrongly tailored exercise program, that is, if the exercises are too difficult and too intense, will not be adopted by the user [9,10]. By analyzing app usage and

identifying the types of usage, app limitations can be identified. For example, it is possible to investigate which user groups are using the app and which groups may not yet be addressed and therefore may need other engagement strategies.

Thus far, different approaches have been used to identify and group app usage groups. Meyer et al [8] and Schneider et al [7] used expert or predefined categorization limits to define different use patterns or user types. Data-driven clustering of users was performed by Lim et al [11], who used daily step counts from activity trackers of 140,000 individuals and clustered them into 16 user segments.

However, to the best of our knowledge, no common definition exists for classifying fitness app users into user groups. Groups of app users can be clustered based on either expert knowledge [7,8] or data-driven methods [11], which offers a less subjective grouping option and can help experts identify an objective classification.

Objective

This paper proposes 2 data-driven usage-type clustering approaches that can be used to characterize the users of the training module of the *ILSE* program. We aimed to answer the following 2 research questions: How can *ILSE* app user types be defined in a data-driven manner? How are these user types characterized?

Log data from the *ILSE* app's *Fit at Home* training module were used for the analysis, and users were categorized in 2 different ways. The 1D clustering approach was based on usage frequency, and the classes were defined using the Jenks natural breaks (Jenks NB) [12] algorithm, with the number of groups and the lower bound set manually. The second multidimensional clustering approach was based on multiple features of app usage, and the Partitioning Around Medoids (PAM) [13] clustering algorithm was applied to identify app usage patterns.

Methods

Overview

The analysis was based on *ILSE* app usage data from the AAL project *fit4AAL*. The *ILSE* system combines smart home components and smart services such as the *ILSE* fitness app. The fitness app aimed to encourage and support elderly exercise at home or outdoors via prerecorded videos and courses on a tablet or 3D camera computer. Participants in the program used the *ILSE* app in a field study for several weeks. There were 2 field trial phases in the Austrian cities of Vienna and Salzburg as well as in the surrounding area of Salzburg. The participants were able to use the system for 13 consecutive weeks before they returned the systems in either trial phase 1 or trial phase 2. The first trial phase was from April to September 2019. The second phase began in September 2019 and ended in March 2020.

Study Design

Overview

A prospective controlled trial using a wait-list protocol was conducted. To analyze the usage of the *ILSE* app, usage data from the first and second field tests were collected.

The developed system included 2 *ILSE* app versions (1 for the tablet and 1 for the 3D camera system). The app received physical activity data from a fitness tracker (eg, steps, duration, and type of activity) and additional smart home components. The *ILSE* app consisted of 4 different modules for German-speaking participants (see Figure 1 for an overview of the system).

Figure 1. The *ILSE* app and its modules provided on the tablet version and the 3D camera system version. e-Learning: electronic learning.

Exercise Module

In *Fit zu Hause* (translated as *Fit at home*), the users could access their training plan tailored to their fitness level. Each day, a different workout session of 10, 20, or 30 minutes could be selected, which consisted of exercises to improve strength and balance.

The *ILSE* app version on the 3D camera system, namely the Orbbec Persee [14], supported an overview of the training sessions performed and an advanced exercise module by using skeletal tracking to detect starting positions, counting repetitions, and notifying the trainees when unfavorable positions for selected exercises occurred.

Before the participants received the system, the *ILSE* coaches, who were specifically trained sports scientists, assessed the functional fitness of each participant and configured the functional training plan tailored to the fitness level of the participants.

Physical Activity Module

Within *Fit unterwegs* (translated as *Fit on the move*), users could keep an outdoor activity diary by entering their activities manually or by wearing the fitness tracker using the integrated activity recording. Furthermore, a connection to the outdoor platform *outdooractive* [15] enabled users to plan their next outdoor activities (such as hiking or cycling).

e-Learning Module

The module *Fit durch Wissen* (translated as *Fit by knowledge*) offered a total of 24 e-learning topics that focused on health- and fitness-promoting exercise training and physical activity for adults ≥ 55 years old.

Motivation Module

The *Erreichtes* (translated as *Achievements*) module displayed the activities performed and the goals achieved in terms of

physical activity engagement. The exercise module allowed users to check how much exercise they had performed and the duration of training sessions. In terms of behavior change concepts, all engagements were summarized, and users received weekly medals.

For the following analyses, only those participants who used the *ILSE* app at least once during the field study were included in the analysis. In total, 79% (79/100) of participants from the first test phase and 79% (86/109) of participants in the second test phase used the system. As there were no notable differences in *ILSE* app usage and demographic characteristics between the 2 field test phases [16], the 2 phases were analyzed together to obtain a larger sample size of 165 users.

For each participant, the test week was defined as the week beginning with the day of the week in which they received the system. For example, if they received the system on a Thursday, their test weeks started on Thursdays and ended on Wednesdays. The first test week was assumed to be the familiarization phase for participants; therefore, the first test week was excluded for all. The subsequent analysis of app usage was based on 12 continuous test weeks (test weeks 2-13) for each participant. For the analysis, visits were aggregated per test week and participant.

Data Collection and Aggregation

Usage data of the *ILSE* app were collected via *Matomo*, an open-source web analytics tool [17]. Usage data describe the log data of the *ILSE* app visits, such as date, time, and visit duration. The main metric of interest for *ILSE* app usage is a *visit*. A visit is defined as the access of a webpage (in our case, the *ILSE* app) by a visitor more than 30 minutes after their last opening of *ILSE* (see the glossary of *Matomo* for detailed descriptions [17]). For the analysis, this definition of a visit was further narrowed so that it consisted of at least 2 actions within

30 minutes; that is, if someone only opened the app, the visit would not be counted.

To identify the *ILSE* app user types, the analysis focused on those visits that opened the exercise module *Fit at home*. Visits that contained only the other 3 modules were not considered in the following analyses.

Apart from usage data, demographics (age, region, gender, education, and household size) were added to describe app users and find usage patterns. For the analysis, Austrian education levels were grouped according to the International Standard Classification of Education classification [18].

Furthermore, information on fitness level and subjective stated amount of daily exercise and sports was collected at the

beginning of the field test to include participants' previous experience in relation to movement in the analyses. The fitness level as a score between 1 (not fit) and 4 (very fit) was assessed by sports scientists at the beginning of the field test. In addition, participants indicated how much time they spent on average during a typical exercise session. They also indicated how many days per week, on average, they do fitness exercises and how many days they ride a bicycle. Furthermore, the self-reported number of hours they sat on an average day was included in the analysis. As demographic- and exercise-related variables were not available for all participants, Table 1 provides an overview of these variables and the availability of given information based on the number of observations.

Table 1. Overview of the demographic- and sports-related variables included in the analysis (N=165).

Characteristics	Observations, n (%)
Variables	
Region	165 (100)
Age (years)	165 (100)
Gender	165 (100)
Household size	165 (100)
Education level	165 (100)
Fitness level	129 (78.2)
Subjective variables	
Sports duration	138 (83.6)
Number of days with fitness exercises performed	163 (98.8)
Hours in sitting position	163 (98.8)
Number of days on which they ride a bicycle	78 (47.3)

Ethics Approval

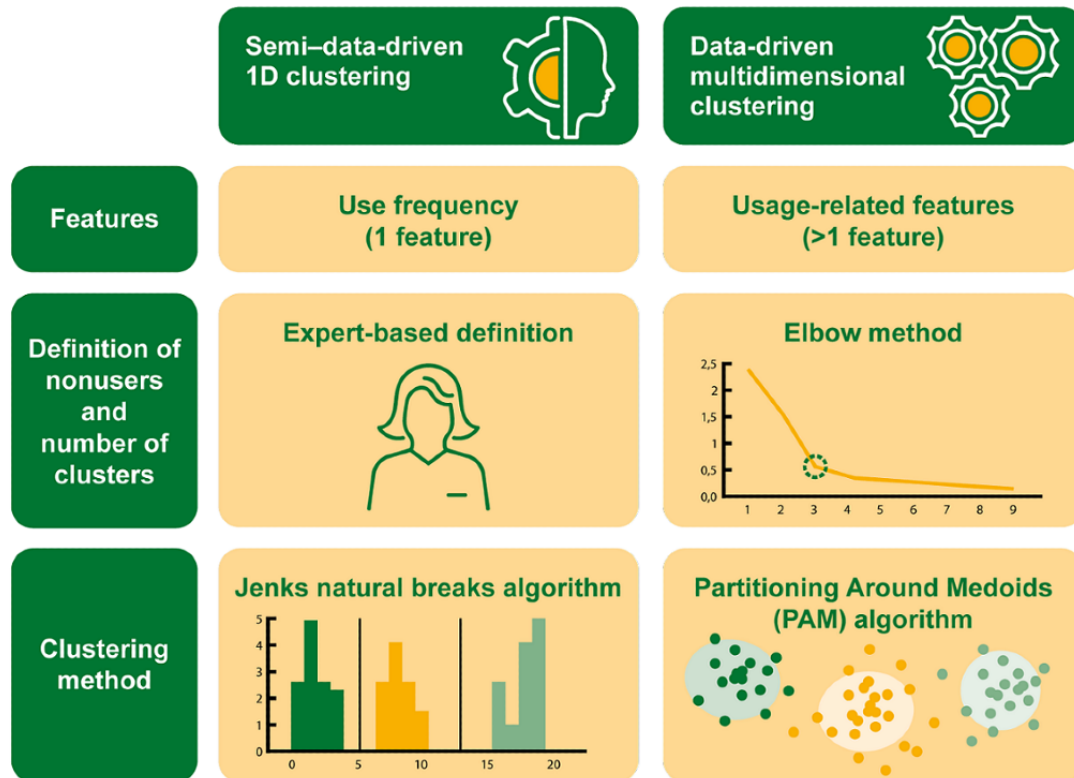

All participants provided written informed consent before their participation in the study. The study was conducted in accordance with the guidelines of the Declaration of Helsinki and was approved by the ethics committee of the University of Salzburg (protocol code EK-GZ:09/2018).

Data Analysis

Statistical analysis was performed using R (R Foundation for Statistical Computing; version 4.1.0) [19]. The clusters based

on the 1D algorithm were calculated using the package `classInt` [20], the multidimensional clustering algorithm with the package `cluster` [21]. For the generation of plots and data preparation, several packages [22-27] were applied. To test the statistical relationship between app usage types and demographic- and sports-related variables, a chi-square test was applied for categorical variables and a Kruskal-Wallis test was applied for numerical variables. The significance level was set at .05 in both cases. To determine app usage types, 2 data-driven approaches were presented and explored. Figure 2 presents an overview of the 2 clustering approaches.

Figure 2. Overview of the 2 user-type clustering approaches.

Semi-data-Driven Usage Frequency-Based Clustering Approach

This 1D approach is similar to the usual clustering approach for user types, where experts use the usage frequency as a basis to categorize user groups by means of thresholds and, hence, identify subgroups, called clusters, that have cases that are similar to each other but different from other groups in a data set [28]. As in the work of Schneider et al [7], we defined a total of 4 groups but calculated the cutoff points in a data-driven manner with nonequal length based on the Jenks NB [12] clustering algorithm, which identifies the interval thresholds of the groups in a data-driven manner. Jenks NB was developed for the analysis of geographic data and has the additional requirement of a predefined number of clusters [29]. It is similar to the k-means algorithm as it minimizes the within sum of squares of the classes [30].

Furthermore, in the first approach, the lower threshold that defined *low* was set manually. *Low* users were defined as those that did not use the app at least once per week. A single visit was assumed to equate to a training frequency of once per week. There are indications that positive health results can already be expected from a frequency of once per week in the target group of >65 years old [31,32].

Data-Driven Multidimensional Clustering Approach

As *ILSE* app usage is not only characterized by the pure usage frequency, the second approach took several features into account. The app users were clustered not only by the frequency of the *ILSE* app usage but also by app usage patterns such as *When did they use ILSE?*, *For how many days did they use ILSE?*, *Did they use the tablet or the camera system?*. Furthermore, at the beginning of the field test, subjective stated

number of days per week with fitness exercises performed and the hours in sitting position were included in the multidimensional clustering, as these 2 variables were available for almost all (163/165, 98.8%) users. In total, 14 features were used for the calculations of the multidimensional clusters of 165 users.

As Jenks NB only works for 1D data, a different clustering algorithm needed to be used. We focused on a partitioning clustering method because it is easier to interpret and implement than hierarchical approaches [33].

The cluster group size was determined using the Elbow method, and the PAM algorithm (see the study by Kaufman and Rousseeuw [13] for the idea and details of PAM) was applied for cluster calculation as the PAM algorithm is less sensitive to outliers and the sequence of input data compared with k-means [34].

User Statistics

For the analysis, we included 77% (127/165) women and 23% (38/165) men (compiled from field tests 1 and 2) who used the *Fit at home* function on the tablet or on Orbbec Persee at least once between test weeks 2 and 13. The participants were located in Vienna (79/165, 47.9%) and Salzburg (86/165, 52.1%). They were born between 1946 and 1957 (mean 1952.6, SD 2.36; age ranged from 62-73 years in 2019) and used the *ILSE* app on the tablet, on Orbbec Persee, or on both devices.

Results

User Clusters

In the following section, the derived number of cluster groups and cluster thresholds for each approach are presented.

Semi-data-Driven Usage Frequency-Based Clustering Approach: Jenks NB

Table 2 lists the cluster thresholds of the 4 user groups based on the application of the Jenks NB algorithm. Applying the expert-based lower threshold for *low* users and the manually set number of 4 groups, 38.2% (63/165) of the participants used the *ILSE* once a week up to every second day. About 30% (49/165) visited the *ILSE* app between once a day and every second day (*moderate* use), and 4% (7/165) used *ILSE* ≥ 2 times per day (*high* use) on average over the 12 test weeks. Analyzing the descriptive statistics in **Table 2** showed that although almost all of the oldest group were *low* or *light* users, the younger users, aged between 62 and 65 years in 2019, generally fell into the *moderate* and *high* user types. In addition, although more than three-fourths (66/86, 77%) of the users from Salzburg were in the *light* or *moderate* group, more than three-fourths (62/79, 78%) of the users living in Vienna were part of the *low* and *light* group. Statistically significant associations were found between the *ILSE* app user-type group and gender ($\chi^2_3=9.9$; $P=.02$), region ($\chi^2_3=13.1$; $P=.004$), and age class ($\chi^2_6=23.7$; $P<.001$). In terms of household size and education, there was no

significant relationship between usage group and household size ($\chi^2_9=3.1$; $P=.96$), as well as education ($\chi^2_{33}=379$; $P=.26$).

Table 3 analyzes the app user types with regard to user experience and amount of daily movement. Although 40% (10/24) of the users who were rated as less fit (level 2) are in the *low* usage groups, 19% (7/37) of the very fit participants (level 4) are in the *low* usage group. Furthermore, more users rated as very fit (level 4) or fit (level 3) are in the *moderate* and *high* usage groups than those rated as less fit (level 2). Regarding the self-reported average duration of a training session, it can be shown that those who do <30 minutes of sports activities are in the *low* and *light* usage groups. In addition, at almost 60% (10/17), more people who said they never ride a bicycle are in the *moderate* or *high* usage group than those who said they ride a bicycle frequently (>3 times per week; 5/17, 29%). However, no significant associations between these variables and the app usage group were found (fitness level: $\chi^2_6=4.8$, $P=.56$; sports duration: $\chi^2_9=13.9$, $P=.13$; fitness exercises days per week: $H_3=2.1$, $P=.55$; sitting hours per week: $H_3=2.8$, $P=.42$; days riding a bicycle per week: $H_3=1.9$, $P=.60$).

Table 2. Demographics of the cluster groups of *ILSE* app users applying Jenks natural breaks in the semi-data-driven approach. Apart from the birth year, the age reached in 2019 is given in parenthesis (N=165).

Data-Driven Multidimensional Clustering Approach: PAM

After calculating a number of clusters of size 1 to 10, a total of 4 groups were also used for multidimensional clustering, analogous to the 1D clustering (Figure 3).

Applying the PAM algorithm to the 14 features resulted in 4 clusters of 60 (cluster A), 30 (cluster B), 42 (cluster C), and 33 (cluster D) users. Examination of the clusters showed that cluster B included those users who used the app the most, with a mean use of 50.5 (SD 13.6) total days compared with 8.2 days (SD 5.9) in cluster D (Figure 4).

Figure 3. Elbow plot of the multidimensional clustering approach. PAM: Partitioning Around Medoids.

Figure 4. Number of total days of app use in the 4 cluster groups.

Table 4 shows the descriptive statistics of the clusters, and Table 5 lists the sports- and fitness-related variables. A detailed analysis of the 4 multidimensional cluster groups revealed the following characteristics.

- Cluster A was formed by users who mainly used the devices in the morning. A total of 80% (48/60) were women, and 55% (33/60) lived in Salzburg.
- Cluster B had the highest number of average app visits and consisted of 90% (27/30) of female users. Two-thirds (20/30, 66%) of users in this cluster lived in Salzburg. *ILSE* app users in this group also made greater use of other features of the *ILSE* app and were younger than those in the other clusters.
- Cluster C was formed by users who used the devices mainly in the evening. A total of 50% (21/42) lived in Vienna, and 50% (21/42) lived in Salzburg.
- Cluster D had the lowest number of average app visits and was formed by 63% (21/33) of users who lived in Vienna and by users who reported doing fitness exercises 4 days per week or less but not more than 4 days. In addition, this cluster was disproportionately formed by men.

Table 4. Demographics of the 4 cluster groups derived by the Partitioning Around Medoids algorithm (N=165).

	Cluster A (n=60)	Cluster B (n=30)	Cluster C (n=42)	Cluster D (n=33)

Discussion

Principal Findings

This study aimed to define *ILSE* app user types and calculate thresholds in a data-driven manner to identify usage patterns. For this purpose, 2 approaches were applied to the usage data of *Fit-mit-ILSE*'s exercise module *Fit at home*. The calculated thresholds within this work were calculated for the specific case of *Fit-mit-ILSE*; therefore, the comparison of the resulting thresholds with other works is impractical. However, the cluster thresholds were compared with the WHO recommendations for functional balance and strength training for adults ≥ 65 years old (3 or more days per week at moderate or greater intensity) indicates that the *moderate* and *high* user types accomplished the WHO-recommended training frequency. From 1D clustering, 33.9% (56/165) of all users fell into these groups.

Applying the Jenks NB clustering algorithm to the mean app usage per day showed that most of the users of the *Fit-mit-ILSE* program were *light* users of the *ILSE Fit at Home* module, using the module between once a week and every other day with a manual definition of the lowest threshold. The proportion of men in the *low* user group was higher than that of women. In general, male users of the *Fit at home* module were mainly found in the *low* and *light* usage groups. This finding is in

contrast to the analysis of Lee [35], who studied 276 older adults from senior centers based on self-administered questionnaire data and found that, in this sample, men engaged in significantly higher amounts of leisure time physical activity than women. Thus, it could be that the *ILSE* app and its functions mainly addressed women, which could be because of several reasons. One assumption could be that the design of the system and the indoor training modules is more likely to motivate women than men, who may prefer to train with physical coaches or independently, without instructions from web-based coaches. As described in the user statistics, 77% (127/165) of the participants were women. This unbalanced sample could influence the analysis of app user groups, as women were more likely to use the app than men, on average. Therefore, future research should include a more gender-balanced sample by, for example, using needs assessments and questionnaires to address men's expectations related to fitness apps.

Analysis of app user groups in terms of age also showed that older users were disproportionately more likely to be assigned to the *low* and *light* usage groups than younger users, who were more often identified as *moderate* or *high* users. This could be because they are less technology-savvy than younger app users. In the work of Gitlow [36], lack of knowledge, fine motor difficulties, negative attitudes, and age-related physical changes, for example, hearing loss, were identified as barriers for older

adults in using technology. To increase older adults' app usage, additional support could be offered to older participants in the future, particularly concerning technical questions.

In addition, the analysis revealed regional differences in app use, and users living in Salzburg had higher average app use than users from Vienna, suggesting that there may be regional differences between the city of Vienna and the state of Salzburg. Users from these 2 different regions may need to be addressed and motivated differently, which could also be addressed through participatory approaches in the design and development phase of future projects. These results go well with the analysis of Cleland et al [37], who found in their study that adults in rural areas reported significantly more physical activity than adults in urban areas.

As part of the multidimensional clustering approach of *ILSE* app users, 4 different user groups were identified, which differed mainly by the total number of app visits, gender, region, and the time of app use during the day.

Limitations and Future Research

The analysis of *ILSE* app usage data is subject to some limitations that suggest ideas for future research. Although there was a support team to help with technical and *ILSE* app-orientated questions, some of the users experienced difficulties in using and setting up *ILSE*, especially at the beginning of the field test phases [38]. Therefore, a support team should be planned in future studies, focusing more on supporting older people, as the analysis showed that this group was less likely to use the app.

In addition, there were 3 system issues where the server was shut down for several hours and the *ILSE* app was unavailable during this time, during which use data may be lost. However, as app usage for several weeks was investigated, the shutdown of some hours did not affect the analysis.

Furthermore, as described in the Methods section, the 2 phases of the field test were combined for this analysis. It should be considered that the 2 field tests were conducted in different seasons and that the app was slightly modified (with adapted functions) in the second field test phase. Therefore, the use of the *ILSE* app may be influenced by seasonal effects or seasonal variations. However, as previously reported, there were no remarkable differences in app usage between the 2 phases.

App user types were clustered based on app usage frequency within the study period of 12 weeks. Therefore, changes in usage frequencies over time were not considered and could be interesting for further research.

Participants used *ILSE* in their homes and were instructed to use the app only by themselves. However, owing to the unsupervised setting, other people could theoretically have used the *ILSE* app, which would have increased the number of app visits.

This work focused on analyzing the overall use of the *ILSE* app and focused mainly on the number of visits to the app, as this metric is easy to interpret and comparable with, for example, the WHO recommendations. The correlation between the number of app visits and visit duration per user showed a significantly strong positive Pearson correlation ($r=0.87$). For further studies, however, other data, such as visit duration, should be investigated in detail.

Future research could also investigate the effect of and change in app use frequency on fitness status. A detailed analysis of participants' dropout reasons and dropouts could also provide relevant insights.

Finally, clustering involves some challenges, such as the definition of the clustering method [39,40]. Another disadvantage of clustering is that different algorithms often result in different partitions [39]. Moreover, determining the number of clusters using the Elbow method is not always clear if the graph has no unique elbow or more than one elbow [41]. Therefore, future work could investigate clustering algorithms other than the Jenks NB and PAM algorithms.

Conclusions

Applying the Jenks NB and PAM algorithms to the example of *ILSE* app usage data showed that data-driven calculations of user groups can replace expert-based definitions and provide objective thresholds for the analysis of app usage data.

For example, when evaluating a new fitness app, statistical methods and data-driven clustering techniques could help identify the impact of this newly developed app on subgroups of a particular population, describe usage patterns and users, and draw conclusions about which groups of people may not yet be addressed. Using these insights, groups that have not yet been targeted can be specifically addressed and supported.

The cluster analysis of the *Fit at home* module of the *ILSE* app revealed differences in app use by gender, age, region, and time of app use. On average, higher app use was observed among women, younger users, and app users living in Salzburg.

In general, from determining the number of cluster groups to identifying cluster thresholds and ranges, data science offers a variety of alternative methods and algorithms to identify patterns in data.

Acknowledgments

The project "Fit in einen neuen Lebensabschnitt mit neuen Technologien—AAL-Testregion Salzburg/Wien (fit4AAL)" was partly funded by the Austrian Federal Ministry Republic of Austria for Climate Action, Environment, Energy, Mobility, Innovation and Technology under grant 862035 in the research program benefit. Salzburg Research, MyBodyCoach, and the Department of Sport and Exercise Science of the Paris Lodron Universität Salzburg would like to thank Wirtschaftsuniversität Wien (Forschungsinstitut für Altersökonomie) for providing the demographic data. The authors would also like to thank the additional

consortium partners, bit media e-solutions GmbH, SMART ASSETS Development GmbH, 50plus GmbH, Salzburg AG, Care Consulting (Sonja Schiff), and all users in Salzburg and Vienna for their participation.

Abstract

Background: Some attempts have been made to detect atrial fibrillation (AF) with a wearable device equipped with photoelectric volumetric pulse wave technology, and it is expected to be applied under real clinical conditions.

Objective: This study is the second part of a 2-phase study aimed at developing a method for immediate detection of paroxysmal AF, using a wearable device with built-in photoplethysmography (PPG). The objective of this study is to develop an algorithm to immediately diagnose AF by an Apple Watch equipped with a PPG sensor that is worn by patients undergoing cardiac surgery and to use machine learning on the pulse data output from the device.

Methods: A total of 80 patients who underwent cardiac surgery at a single institution between June 2020 and March 2021 were monitored for postoperative AF, using a telemetry-monitored electrocardiogram (ECG) and an Apple Watch. AF was diagnosed by qualified physicians from telemetry-monitored ECGs and 12-lead ECGs; a diagnostic algorithm was developed using machine learning on the pulse rate data output from the Apple Watch.

Results: One of the 80 patients was excluded from the analysis due to redness caused by wearing the Apple Watch. Of 79 patients, 27 (34.2%) developed AF, and 199 events of AF including brief AF were observed. Of them, 18 events of AF lasting longer than 1 hour were observed, and cross-correlation analysis showed that pulse rate measured by Apple Watch was strongly correlated (cross-correlation functions [CCF]: 0.6-0.8) with 8 events and very strongly correlated (CCF>0.8) with 3 events. The diagnostic accuracy by machine learning was 0.9416 (sensitivity 0.909 and specificity 0.838 at the point closest to the top left) for the area under the receiver operating characteristic curve.

Conclusions: We were able to safely monitor pulse rate in patients who wore an Apple Watch after cardiac surgery. Although the pulse rate measured by the PPG sensor does not follow the heart rate recorded by telemetry-monitored ECGs in some parts, which may reduce the accuracy of AF diagnosis by machine learning, we have shown the possibility of clinical application of using only the pulse rate collected by the PPG sensor for the early detection of AF.

Introduction

Atrial fibrillation (AF) is the most common, persistent arrhythmia in adults, with a lifetime risk of 25%-33%, and it is associated with heart failure, stroke, dementia, and death [1,2]. However, approximately one-third of patients with paroxysmal AF are asymptomatic, making it difficult to diagnose an arrhythmia without symptoms unless an ECG monitoring is performed in a medical facility [1,3-5]. In fact, up to 50% of patients who have a stroke due to AF are diagnosed with AF after the stroke has occurred [6-9].

The European Society of Cardiology guidelines recommends opportunistic screening for AF using pulse checks or ECG rhythm strips in patients over 65 years of age [10]. With the recent advent of mobile devices and wearable sensors, it has become possible to continuously monitor health status in daily life. The number of connected wearable devices worldwide has more than doubled in 3 years, from 325 million in 2016 to 722 million in 2019; by 2022, the number of devices is expected to reach more than 1 billion. In addition, their sales are expected to grow from US \$14.93 billion in 2020 to US \$17.35 billion in 2021, at a compound annual growth rate of 16.2%, making wearable devices increasingly popular [11,12].

Recent smartwatches are equipped with photoplethysmography (PPG) that uses infrared light-emitting diode optical sensors to monitor changes in microvascular blood volume, making it possible to continuously monitor pulse rate in daily life. The clinical applicability of PPG has been addressed in several studies, one of the most famous is the Apple Heart Study [13]. Of the participants who received arrhythmia notifications from their Apple Watch, more than one-third had AF confirmed by a subsequently worn ECG patch monitoring, and of the arrhythmia notifiers who returned their ECG patches, 84% (72/86) had a positive ECG patch (ie, positive for AF). Positive notifications were consistent with AF 84% of the time (95% CI 76-92) [13].

We previously measured pulse rate in patients after cardiac surgery wearing 2 wearable devices and showed that heart rate in sinus rhythm correlated well with pulse rate measured by wearable devices; however, during AF, the accuracy was slightly lower, but the pulse rate tracking was accurate enough for clinical applications [14].

Further innovations in wearable devices have led to the technology of single-lead ECG collection. By touching the wearable device with the contralateral finger for about 30 seconds, a single-lead ECG can be taken, and the ECG data can be used to diagnose AF. Although this method is by a single lead, it has been shown to have a higher sensitivity and specificity due to the ECG information such as P waves and QRS waves [9,15-17].

However, many patients with AF are older people, and it is difficult to have them voluntarily perform the task of touching

the wearable device with the contralateral finger for 30 seconds to collect a single-lead ECG when they are notified of an arrhythmia.

There have been many attempts to detect arrhythmias using wearable devices, but most of these studies have been based on brief observations and data collection under ideal conditions in selected patients. In this study, we conducted long-term pulse rate monitoring during hospitalization of patients undergoing cardiac surgery to collect data under real clinical conditions.

This is the second part of a 2-phase study aimed at developing a method for the immediate detection and diagnosis of paroxysmal AF using a wearable device with a PPG sensor. We investigated the possibility of clinical application of heart rate monitoring by wearable devices in the special environment post cardiac surgery.

Methods**Ethics Approval**

In accordance with all applicable regulations, this study was approved by the Clinical Research Ethics Committee of Chiba University Hospital (Clinical Research Protocol jRCTs032200032) on October 23, 2020. We obtained written informed consent from all study participants to allow data monitoring as well as data registration and management to be performed by the Chiba University Hospital Clinical Trials Data Center. In addition, an independent Data Monitoring Committee has been established within the Department of Clinical Trials at Chiba University.

Participants

Between June 2020 and March 2021, 80 patients scheduled for cardiovascular surgery at a single institution were recruited for this study. The exclusion criteria were the following: a history of permanent pacemaker implantation, skin disorders at the wristband site, and past hypersensitivity to wristbands (or rubber products); in addition, patients with chronic AF who did not undergo arrhythmia surgery and patients who were unfit for the safe conduct of this study according to the principal investigator or subinvestigator were also excluded.

After written informed consent was obtained, 80 subjects were given an Apple Watch (series 4) and asked to wear it on one forearm. A spare, fully charged smartwatch was always available to measure their pulse for 24 hours continuously. The Apple Watch was removed on the day the patient underwent surgery; the Apple Watch was reapplied when the patient was discharged from the intensive care unit (ICU) to the general ward after cardiac surgery (ie, usually the day after the surgery); all Apple Watch wearing was done under the supervision of a physician. Apple Watch was worn continuously until discharge or for up to 14 days after discharge from the ICU unless the study was interrupted for clinical or personal reasons.

A publicly available HeartWatch mobile app (Tantsissa) was used to access data from a standard commercially available Apple Watch.

Apple Watch has 2 functional modes for measuring pulse rate: standby mode and workout mode. In standby mode, the pulse rate is measured once every few minutes, resulting in less data. Therefore, all participants' Apple Watches were set to workout mode during wear.

Central ECG monitoring using a telemetry system (VitalSignTelemater GZ-130P; Nihon Kohden) was continued in all patients until hospital discharge. If AF was suspected, a 12-lead ECG monitoring was performed, whenever possible, for confirmation.

AF was diagnosed based on the guided diagnostic criteria by 2 qualified physicians [10].

When an arrhythmia was identified, the telemetry data were checked, and the time of the onset and cessation of arrhythmia was recorded. These procedures were repeated each time an arrhythmia was suspected on the central monitor.

Heart Rate and Pulse Rate Measurements

Heart rate data were obtained from a telemetry electrocardiograph that calculates the heart rate every 3 seconds based on the previous RR interval.

Pulse rate data were obtained from an Apple Watch with built-in PPG; in Apple Watch workout mode, the pulse rate is calculated every 5-6 seconds. The time interval of each pulse rate calculation on the Apple Watch may vary depending on the conditions (eg, low perfusion conditions and dark skin color) because the Apple Watch has an automatic optimization function that increases the brightness of the light-emitting diodes and the sampling rate to compensate for low signal levels [18].

Cross-Correlation Analysis

Using the same technique as in part 1 of this study [14], we created time series pulse rate trends and heart rate trends and analyzed the similarity of the trend patterns.

Events in patients with brief AF or bouncing between AF and atrial flutter have negative impacts on correlation analysis; therefore, cross-correlation analysis was performed on AF events lasting longer than 60 minutes that transitioned from sinus rhythm to AF and from AF back to sinus rhythm, as measured by central ECG monitoring and the Apple Watch. The complete pulse rate data measured by the central ECG and Apple Watch were included in the analysis.

We then used the trend data to check the accuracy of PPG-based pulse rate measurement with reference to ECG-based heart rate measurement during AF.

Machine Learning Model for AF Diagnosis

We used a gradient boosting decision tree (GBDT) [19] to diagnose AF based on pulse rate data from the Apple Watch and patient background information summarized in Table S1 in [Multimedia Appendix 1](#). We computed features of the pulse rate data every minute and treated them as a single record for training and validation of the GBDT model. As pulse rate features, the mean and SD of pulse rate per minute within 10 minutes of the timing for the AF diagnosis were calculated. The median value of the mean and SD of heart rate up to the time of diagnosis was used as the baseline. GBDT is a kind of ensemble learning that can handle missing values without complementation and is known to provide high prediction accuracy by boosting technology. The Python package LightGBM (version 3.3.2; Python Software foundation) was used for the GBDT implementation, and hyperparameter was tuned by Bayesian optimization with cross-validation, using the Optuna framework [20]. The data of 79 patients were first split into a training cohort of 59 patients and a test cohort of 20 patients; only the training cohort was used for hyperparameter tuning, variable selection, and training of the machine learning model. The variable importance of the GBDT model was calculated for the training cohort by the "permutation importance" function implemented in the Python package eli5 (version 0.11.0; Python Software foundation). To evaluate the performance of the machine learning model for AF diagnosis, a receiver operating characteristic (ROC) analysis was performed. The ROC analysis plots the change in sensitivity and specificity, as the threshold for the probability of AF is varied. The ROC analysis was performed using the R package pROC (version 1.18.0; Xavier Robin).

Other Statistical Analysis

Summary of statistics are presented as frequency and percentage for categorical data, mean (SD) for continuous variables, and frequency and percentage for categorical variables.

All statistical analyses were performed using SAS (version 9.4 for Windows; SAS Institute Inc).

Results

Patient Background

Of the 80 patients, 1 had redness on the area the Apple Watch was worn, and we stopped the study before she underwent surgery. The demographics of the 79 patients are shown in [Table 1](#).

Table 1. Characteristics of study participants (N=79).

Demographics	Values
Age (years), mean (SD)	65.8 (13.4)
Sex (male), n (%)	57 (72.2)
Left ventricular ejection fraction, mean (SD)	58.9 (8.8)
Off-pump coronary artery bypass grafting, n (%)	18 (21.5)
Valve surgery, n (%) ^a	57 (72.2)
Other surgery, n (%) ^b	4 (5.1)
Minimally invasive cardiac surgery, n (%)	7 (8.9)
Monitoring period (days), mean (SD)	13.3 (2.5)
Use of antiarrhythmic drugs before the event, n (%) ^c	30 (38.0)

^aIncluded multiple surgeries.

^bIncluded 2 thoracic surgeries, 1 atrial septal defect closure, and 1 ventricular septal myectomy, and on-pump coronary-artery bypass grafting.

^cTypes of antiarrhythmic drugs included pilsicainide, flecainide, amiodarone, verapamil, digoxin cibenzoline, sotalol, bepridil, and β -blockers.

Arrhythmias

The mean number of days of smartwatch wear per patient was 13.3 (SD 2.5) days, and the median number of days of wear was 14 (IQR 11-15) days. Of 79 patients, 69 had a good postoperative course and were discharged within 14 days after transfer from ICUs to the general ward; 10 patients required

more time for treatment of complications or postoperative rehabilitation, so pulse rate measurement with the Apple Watch was ended 14 days after leaving the ICU as per protocol.

The total number of arrhythmia events diagnosed in the 79 patients included in the analysis was 429 in 31 patients. The total number of AF events was 199 in 27 patients (Table 2).

Table 2. Arrhythmia events in patients (N=79).

Event	Patients, n (%)	Events, n	Total time (h)
Atrial fibrillation	27 (34.2)	199	713.7
Atrial fibrillation and atrial flutter ^a	1 (1.3)	13	4.2
Atrial flutter	7 (8.9)	37	163.8
Atrial flutter and premature atrial contractions ^b	1 (1.3)	3	5.4
Atrial tachycardia	6 (7.6)	97	114.9
Paroxysmal supraventricular tachycardia	1 (1.3)	10	0.8
Ventricular tachycardia	1 (1.3)	67	0.6
Other ^c	1 (1.3)	3	61.7

^aAtrial fibrillation and atrial flutter are mixed.

^bAtrial flutter and premature atrial contractions are mixed.

^cIncluded sinus arrest and unidentified arrhythmias.

Cross-Correlation Analysis of Pulse Rate Accuracy Based on PPG Sensor During AF

Table 3 shows the results of the CCF analysis of the 1-minute moving average of the central monitor ECG heart rate and Apple Watch pulse rate in the 18 AF events lasting more than 1 hour used in the analysis.

Of the 18 events, 8 events had a strong correlation (CCF: 0.6-0.8), and 3 events had a very strong correlation (CCF>0.8) [21].

Figure 1 shows 2 time series curves (one for heart rate trend and the other for pulse rate trend) for one event that showed a very strong correlation (Event 12), and Figure 2 presents another event that showed a weak correlation (Event 11). In Figure 1, the Apple Watch pulse rate follows the central monitor ECG heart rate very well, but in Figure 2, the Apple Watch pulse rate does not follow the central monitor ECG heart rate after the heart rate exceeds about 120 per minute and is measured as a low value.

Table 3. Time series correlation of pulse change in paroxysmal atrial fibrillation.

Event number	Cross-correlation function ^a	P value
1	.69869	<.001
2	.06296	.33
3	.17394	.001
4	.35918	<.001
5	.81694	<.001
6	.76119	<.001
7	-.19029	.07
8	.64214	<.001
9	.77215	<.001
10	.76217	<.001
11	.02752	.64
12	.88082	<.001
13	.60062	<.001
14	.84744	<.001

17	.17998	.14
18	.75319	<.001

^aFor reference, the strength of correlation [20] can be classified in the literature as follows: <0.19 as very weak; 0.2-0.39 as weak; 0.4-0.59 as moderate; 0.6-0.79 as strong; and >0.8 as very strong.

Figure 1. Time series trend curves during atrial fibrillation (AF) (event 12). The figure compares the trend curve of the Apple Watch (red curve) with central monitor heart rate (blue curve). The green curve shows the time trend of AF diagnosis prediction rate by machine learning. The purple dotted line indicates the diagnostic threshold for AF (0.018). BPM: beats per minute.

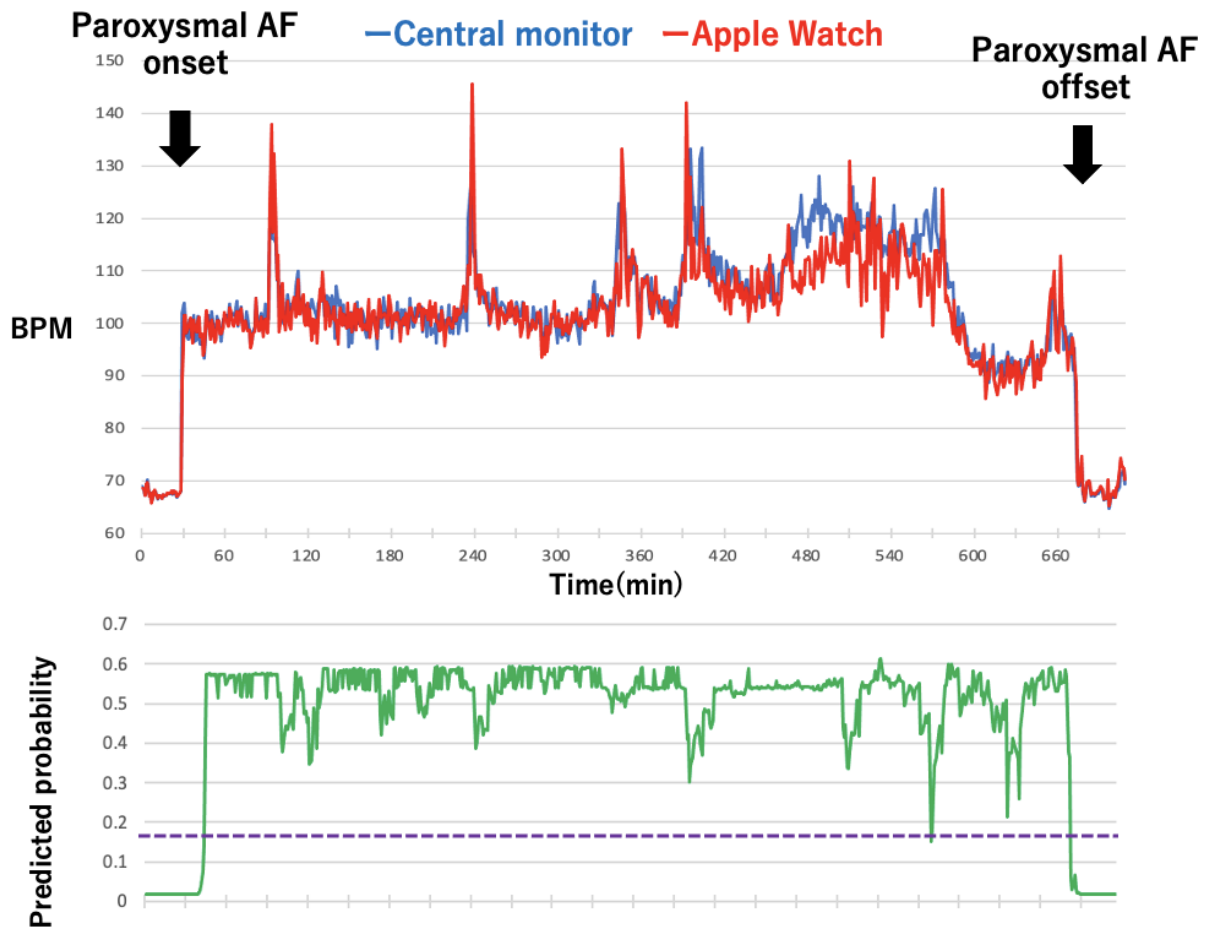

Figure 2. Time series trend curves during atrial fibrillation (AF) for event 11. The figure compares the trend curve of the Apple Watch (red curve) with central monitor heart rate (blue curve). The green curve shows the time trend of AF diagnosis prediction rate by machine learning. The purple dotted line indicates the diagnostic threshold for AF (0.018). BPM: beats per minute.

Diagnosis of AF by Machine Learning

In this study, the area under the ROC curve for the diagnosis of AF with the GBDT model was 0.9416, with a sensitivity of 0.909 and a specificity of 0.838 at the point closest to the top left (Figure 3; Table 4). The importance of the GBDT model is

shown in Figure 4. The importance of age and baseline SD was high. In Figure 1 and Figure 2, the diagnostic predictive rate of AF is plotted as time series, and in Figure 2, where the Apple Watch pulse rate did not track the actual heart rate, the diagnostic rate dropped notably at that site.

Figure 3. Receiver operating characteristic curve of atrial fibrillation diagnosis rate.**Table 4.** The sensitivity and specificity of the gradient boosting decision tree (GBDT) atrial fibrillation (AF) prediction.

	Gold standard diagnosis		Total
	AF positive	AF negative	
GBDT AF prediction			
AF positive	8113	25,622	33,735
AF negative	816	132,515	133,331
Total	8929	158,137	167,066
Sensitivity (%)	90.9	— ^a	—
Specificity (%)	83.8	—	—

Figure 4. Factors contributing to the diagnosis of atrial fibrillation. DM: diabetes mellitus; HL: hyperlipidemia; HT: hypertension; TM01_mean: mean heart rate 1 minute before the timing; TM02_mean: mean heart rate 2 minutes before the timing; TM03_mean: mean heart rate 3 minutes before the timing; TM10_mean: mean heart rate 10 minutes before the timing; baseline_mean: mean heart rate at the timing; TM01_std: SD 1 minute before the timing; TM02_std: SD 2 minutes before the timing; TM03_std: SD 3 minutes before the timing; TM10_std: SD 10 minutes before the timing.

Discussion

Principal Findings

In this study, we measured the pulse rate of 79 patients undergoing cardiac surgery by a wearable device on their forearm for 24 hours during hospitalization and continuously until discharge (for a maximum of 14 days after discharge from the ICU). The pulse rate data obtained were used in a machine learning model to create a diagnostic algorithm for AF. The diagnostic accuracy of this algorithm was 0.9416 (sensitivity 0.909 and specificity 0.838 at the point closest to the top left) for the area under the ROC curve. Some authors have reported that the diagnostic accuracy of AF by wearable devices is high with an area under the ROC curve of 0.9 or higher [22-24]. However, these are based on data sampling in a limited ideal environment (eg, at rest, or when data collection time is only a few hours) and with a preselected group of patients with a history of AF. For patients after cardiac surgery who are prone to various arrhythmias other than AF, these studies have a large proof-of-concept aspect, and it is desirable to conduct research and development for practical use in the real world of patients with cardiac diseases.

In this study, we measured pulse rates under real clinical conditions and were able to diagnose AF with high accuracy, using only time series pulse rate data and patient background information. The Apple Watch with a silicon band was worn by patients, and although 1 patient complained of an itchy sensation with redness at the site of wearing, no other adverse events caused by the Apple Watch occurred. Some patients, after coronary artery bypass surgery, had radial artery grafts and forearm wounds extending to the wrist, which limited the use of the watch in some cases; however, the watch could be worn and monitored for a long time in clinical practice. In the perioperative period, various arrhythmias other than AF occur,

as well as circulatory conditions such as water overflow and dehydration. To the best of our knowledge, no study has attempted continuous and prolonged monitoring and machine learning for AF diagnosis using a wearable device in such an environment.

In this study, the cross-correlation coefficient between the heart rate obtained from central ECG monitoring and the pulse rate data obtained from the Apple Watch for AF lasting more than 1 hour showed a strong correlation in 11 out of 18 events. As shown in Figure 2, there were cases where the Apple Watch pulse rate did not follow the timing of the faster heart rate. Al-Kaisey et al [25] also reported that pulse rate during AF is underestimated compared to sinus rhythm. Since the PPG sensor is a pulse pressure waveform that originates from heart contraction and propagates through the cardiovascular system, as shown in our previous study [14], depending on pathophysiological conditions such as intravascular volume, heart rate, and heart condition, sufficient pulse pressure may not be generated [14,26-28]. For the above reasons, pulse rate data obtained from PPG sensors may not accurately represent the heart rate, especially in patients with cardiac disease or after cardiac surgery, making it difficult to diagnose AF. In this study, as shown in Figure 2, the diagnostic accuracy dropped where the Apple Watch pulse rate did not track the actual heart rate.

The main factors contributing to the AF diagnosis with GBDT were age and baseline SD. There have been many attempts to use machine learning to diagnose AF; however, to our knowledge, there have not been studies that have identified the factors contributing to its diagnosis. Although the machine learning in this study was not able to achieve a high diagnostic accuracy that could be immediately applied in actual clinical practices, it suggests the possibility that a wearable device can be used to monitor pulse rate for a long period of time and diagnose AF in the special environment after cardiac surgery.

Limitations

There are several limitations to this study, one of which is the small sample size. We believe that we sampled a relatively large number of patients in a study of long-term monitoring under real clinical conditions, but the sample size is still too small for machine learning. Second, the Apple Watch wearing process was done entirely by a physician, and when the patient removed the watch by himself, the heart rate measurement stopped, and some data were missing. The data collected from the Apple Watch were synchronized each time the Apple Watch was charged and were stored in the iPhone, but there were times when data were not transferred to the iPhone for some unknown reason, resulting in missing data.

Clinical Outlook

In this study, we developed an algorithm to immediately diagnose AF, using machine learning on the collected data; however, there are reports indicating that analysis using deep learning as an artificial intelligence technology can diagnose AF with higher accuracy [29].

We are planning to create a classifier with higher accuracy and diagnostic performance by using a new diagnostic algorithm

based on deep learning. Once a classifier with enough accuracy to withstand clinical use is completed, patients will be able to know their own arrhythmia in real time, and heart rhythms can be monitored safely with a very simple wristwatch device. It is said that potential AF is involved in the development of cerebral infarction and stroke, but there is little evidence on the threshold for developing cerebral infarction, which remains controversial [30]. If it becomes possible to accurately record AF at all stages, this is expected to become an extremely useful tool to determine the threshold for stroke onset and may lead to the introduction of anticoagulation therapy in appropriate patient groups to prevent stroke.

Conclusions

In the second phase of the 2-phase study, the Apple Watch was safely worn for a long period of time even in the special environment post heart surgery. Furthermore, the findings of this study showed that the Apple Watch could potentially detect AF with a machine learning classifier during the recovery period after heart surgery. The next step will be to improve the accuracy of immediate diagnosis of AF by deep learning.

Acknowledgments

The authors deeply thank Hideyuki Akashi, MD, the chief executive officer of MEDCARE Corporation for providing the monitoring equipment necessary for this study. The study equipment was borrowed from MEDCARE Corporation for clinical monitoring purposes only. This work was supported by JSPS KAKENHI Grant Number 20K17709.

Abstract

Background: The transformative storytelling technique is an innovative top-down approach to narrative therapy that aims to provide building blocks for creating flourishing narratives for target groups or populations. This approach acts as a facilitator for implementing the human-centered design in developing digital self-help tools for larger samples or target groups.

Objective: This study applied the transformative storytelling technique, as a new approach in mental health, to develop empowering audio narratives for informal caregivers.

Methods: A narrative inquiry was conducted with 17 informal caregivers (16 women and 1 man) who completed a semistructured interview, “Caregiver Life Story,” acquiring information about the beginning of the role, rising action, and critical point of the role. The participants’ ages ranged from 41 to 84 years, with all participants providing care for at least a 6-month period. This inquiry was guided by the transformative storytelling technique, and aimed to collect data relevant to creating fictional stories based on real-life themes.

Results: Twenty-five overall themes were distinguished across three a priori-set categories, providing narrative building blocks for the informal caregiver life stories. The final empowering caregiver life story was created as an example for this study, demonstrating the application of the transformative storytelling technique in an informal care context.

Conclusions: The creation of empowering stories for populations or target groups in mental health care requires a unified and guided approach that will follow clear guidelines and storytelling principles. The transformative storytelling technique is a first of its kind in the mental health context, representing an initial step in enabling and supporting the creation of meaningful stories and the development of relatable, but productive, narratives. Such narratives have the potential to serve across media and digital platforms for supporting and improving well-being, and potentially triggering self-change in the target group or population.

Introduction

The narrative approach in therapy is a technique grounded in feminist, anthropological, and multicultural theories, offering a collaborative narrative journey and honoring the life experiences of the client [1]. Following this approach, a narrative therapist assists a client to reauthor the problematic experience into a more constructive personal story by relying on the notion of “multiple truths” within the story rather than the client’s subjective stance.

The therapist works with the “problem-saturated” story the client holds about his/her life or some aspect of life, and collaboratively engages in the process of “unpacking” and “reauthoring” the story. This bottom-up approach aims to mutually arrive at the preferred narrative of the story, deconstructing the experience to emphasize the disregarded but helpful aspects and to reconstruct it into a more positive self-story.

Some of the common applications of the narrative approach can be seen in counseling for depression; recovery from abuse; addiction; posttraumatic reactions; and in therapeutic work with couples, adults, and children [2-4]. However, a significant limitation of the highly personal nature of narrative therapy is the challenge to implement it for a target group or population. More concretely, a target group or population is here defined as a large group of people sharing a common issue (eg, alcohol abuse), difficulty, or mental health problem (eg, posttraumatic stress disorder).

Guided by the idea of expanding narrative therapy principles to the individuals belonging to wider groups and populations, we developed the transformative storytelling technique (TST) [5] as a top-down approach to traditional narrative therapy.

Unlike the bottom-up approach where the clients work on creating a productive self-narrative following various narrative techniques (eg, narration, journaling, mapping the influence of the problem, outcome questions, counterviewing questions), the top-down approach starts from a ready story to be delivered to a specific group (eg, informal caregivers).

In this manner, the ready TST narrative acts as a template and a pathway for assisting with self-story restructure for the individual, with no additional knowledge of narrative techniques needed. Concretely, the TST-structured fictional stories act in a 2D manner. The primary dimension is to assist end users (eg, informal caregivers) to create a more productive self-story within the context (eg, caregiving) by using the fictional TST story as a template. The second dimension facilitates and enables users to anticipate and intercept the potential role-related issues and prepare appropriate coping strategies.

However, outside of the mental health context, the fundamental of storytelling is both art and craft. While art is an instinct-driven process, the crafting part of storytelling requires a technique in the form of a guided approach that builds the story. Some traditional storytelling techniques include Monomyth, also known as the Hero’s Journey; Rags to Riches; The Mountain, or the Freytag pyramid; Nested Loops; Sparklines; In Medias Res; False Start; and Converging Ideas [6]. These techniques provide a cohesive structure for the narrative in literature and allow a writer to set a proper stage for telling the story. For example, the Monomyth, like Joseph Campbell’s Hero Journey, sets the storytelling in a circular plot where the protagonist leaves the known and sets out on a journey [6]. Throughout this journey, the protagonists experience difficulties, despair, and lessons, or encounter teachers that help them move on and return to the starting point as a better and improved version of the self (ie, Hero).

Conversely, the Nested Loops approach enables the core message to be communicated through several narratives delivered within one story. Similarly, the Mountain, which is also known as the Freytag pyramid, allows the storytelling formation in a rising line that marks the dramatic points and resolution of the difficulties [6]. In fact, the Freytag pyramid is one of the oldest and most classic techniques, which is easily utilized and simply structured, allowing even amateur writers to set their story appropriately. Therefore, we adopted this approach in developing our TST.

Unlike the traditional approaches serving the literature structure, the TST provides clear guidelines in creating and structuring empowering digital stories. This technique relies on the narrative approach to therapy and storytelling principles in the narrative, allowing the implementation of narrative therapy principles (eg, narration, storytelling; nonlinear, linear, or chronological narrative formation) to larger groups or members of a target population simultaneously through audio or video stories.

Specifically, with the TST, we aim to address the narrative identity needs (ie, understanding the self in the story) of a group or target population. The TST provides clearly structured digital narratives that act as a cue for triggering self-restructuring within the narrative identity of “the self.” In such a manner, with the TST, we strive to empower end users by giving them a tool that will facilitate the adaptation of adverse or unexpected life circumstances (eg, caregiving) into the productive story of “the self.”

The TST facilitates the process of human-centered design in the creation of digital therapeutic narration for larger groups and populations, and is currently the only existing technique that provides clear guidelines in creating digital stories for mental health. In line with this concept, the TST differs from the traditional storytelling techniques mentioned above because

it focuses on structuring the experiences of target groups to produce building blocks for the creation of productive template stories that trigger self-restructure. Moreover, unlike the real-life accounts of individuals, the TST allows integration of multiple experiences within a given context, resulting in richer and more representative storytelling content.

In this study, we focus on informal caregivers as a target population for developing a healing story guided by the TST. Informal caregivers are considered a backbone of the health care systems across Europe, and we define this population as long-term unpaid primary care providers who assist a family member or a close other in need (eg, spouse, parent, cousin, in-law, close neighbor) with daily life activities over a course of an illness or chronic condition.

Informal caregivers of older adults and individuals living with dementia have been reported to experience depressive symptoms, anxiety, and increased levels of stress throughout their role when compared to noncaregivers [7]. Moreover, numerous adverse health outcomes for informal caregivers have been noted across the literature [8-10]. Reflecting on the Italian caregiving context, long-term care provision in Italy as well as other Mediterranean countries has been labeled as “familialist” or family-run [11]. This type of care regime puts the responsibility of providing long-term care for a loved one in need on the family members, who often reach out for additional support mostly from migrant care workers and less frequently from the social and health systems [11].

A closer look at the existing mental health support and interventions for informal caregivers indicates respite care, psychosocial interventions, and information and communication technology support as the most common therapeutic options used by mental health experts [12]. Although numerous studies recognize the existing narrative-identity issues within the caregiving role [13-16], there is no study available that explored the potential of applying or adapting the narrative approach to accommodate shifts in self-identity of informal caregivers. Informal caregivers often place caregiving activities into primary

focus within their lives, while personal life and needs become secondary [17]. In this manner, caregivers take the responsibility of providing care for a loved one in need while negotiating newly formed and unfamiliar roles within the relationship and neglecting other aspects of life [17].

In fact, this all-consuming nature of caregiving inevitably interferes with social and relational roles, resulting in identity disruptions [18]. These disruptions mostly occur when personal experiences do not align with the preconceived “self,” ultimately causing distress and loss of meaning in life [18].

Interestingly, informal caregivers report a loss of self as an outcome of the caregiving role, and as the caregiving role becomes more prominent, informal caregivers require meaning-making in the context of their caregiving identity [17,19]. In line with this situation, the ability to reconcile the discrepancy between self-identity and caregiving identity is detrimental in productive adoption of the caregiving role into the narrative identity of self [20].

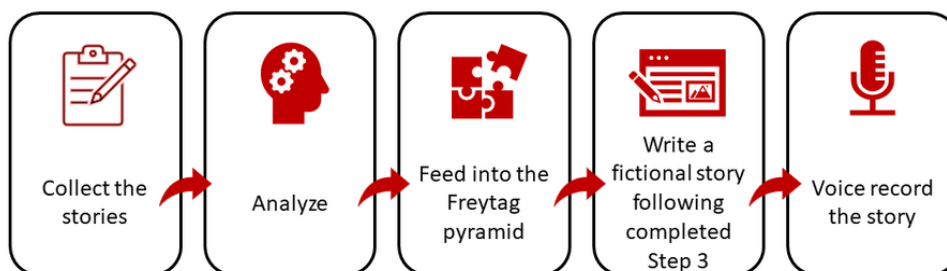

Accordingly, the aim of this study was to provide a step-by-step demonstration of application of the TST for creating a productive and empowering story in the informal care context. Such a story can then be used as a cue for triggering self-restructuring within the narrative identity of an informal caregiver, and serve as a guide to facilitate familiarization and understanding of the caregiving experience for the caregivers early in the role.

Methods

Overview of the TST

The TST is a top-down approach to traditional narrative therapy that we developed to create ready stories with flourishing narratives for larger groups or target populations. In this study, we used the TST for the creation of audio stories, built through a series of five consecutive steps (see Figure 1), acting as a concrete guideline that we follow in developing the empowering digital story for an informal caregiver sample.

Figure 1. Steps of the transformative storytelling technique.

The therapeutic aspect of the TST is based on narrative principles in therapy and draws from the theory of narrative identity [21], which poses the identity of “the self” as a construct based on an internalized and evolving story required for the meaning-making about the self and others. The storytelling aspect of the TST is based on the Freytag pyramid, which was introduced in 1894 for developing engaging and dramatic story plots in literature [22]. This pyramid is a mountain type of storytelling technique, commonly used in narratives owing to

its simplicity, which allows use by individuals who are not experienced writers.

By applying the TST, we (1) collected the stories of the target population (ie, informal caregivers) through structured interviews; (2) thematically analyzed the stories in search for themes; (3) fed the obtained themes into the Freytag pyramid structure, which enabled visualization of the key elements for (4) writing the fictional story that will be (5) audio-recorded with voice actors, and used as a blueprint of a flourishing

narrative and a cue for triggering self-restructuring within the narrative identity of the target population. The fictional story is freely constructed, while strictly following the building blocks retrieved in step 3. Therefore, the obtained story is just a sample of numerous potential fictional stories that can be created following the step-3 building blocks. This paper complies with Standards for Reporting Qualitative Research, as recommended by O'Brien and colleagues [23].

Ethical Statement

The study was approved by the Commissione Etica della Ricerca in Psicologia (CERPS) Ethical Committee of Università Cattolica del Sacro Cuore (UCSC) under protocol number 20-21, and was conducted in compliance with the latest version of the Declaration of Helsinki. Informed consent, provided to the participants in a written version, included a page containing an information sheet about the study and a page addressing the General Data Protection Regulation, as well as the participant's right to withdraw from the study at any point with no penalties. The informed consent followed the template provided by the CERPS of UCSC and was additionally adapted to include the specific information about the study.

Participants and Procedure

The participants were long-term primary caregivers (eg, spouse, daughter, daughter-in-law) of an elderly family member or close other who requires care due to a chronic condition, advanced age, or age-related illness (N=17; 16 women, 1 man). They were recruited on a voluntary basis through a nonprofit caregiver association in Italy. The participants had to be providing primary care at the point of recruitment for at least a 6-month period regardless of the living conditions (living with the care recipient or living outside of the care recipient's home). Several recruitment strategies were employed, including posting an information sheet about the study on the information corner in the association, telephone calls to the members of the association who indicated they would like to take part in future studies, and through announcements by the self-help group facilitators who disseminated the study and referred interested caregivers to the information corner where the information sheet was available.

Participants received a link for the online interview through email or during their visit to the caregiving association by the group facilitator or researcher (SB), depending on their presence within the association. The structured interview was available via the Type Form platform, with an average completion time of 10 minutes. Some of the participants who expressed the desire to participate in the study but did not feel comfortable due to the ongoing pandemic or were not sure of how to use the Type Form website were assisted by the researcher in charge of data collection (SB). Furthermore, due to COVID-19 restrictions at the time of data collection, most caregivers chose to be contacted via telephone to prevent potential contagion of virus transmission to the care recipient. The researcher performed the interview and filled in the data in Type Form on behalf of the

participant. The telephone interviews were audio-recorded (at the researcher's request and upon participants approval) and then transcribed into Type Form by the researcher. All participants agreed to be recorded. The duration of the structured interview varied (10-30 minutes) depending on the amount of information shared by the participants, and each participant was interviewed only once.

Interviews

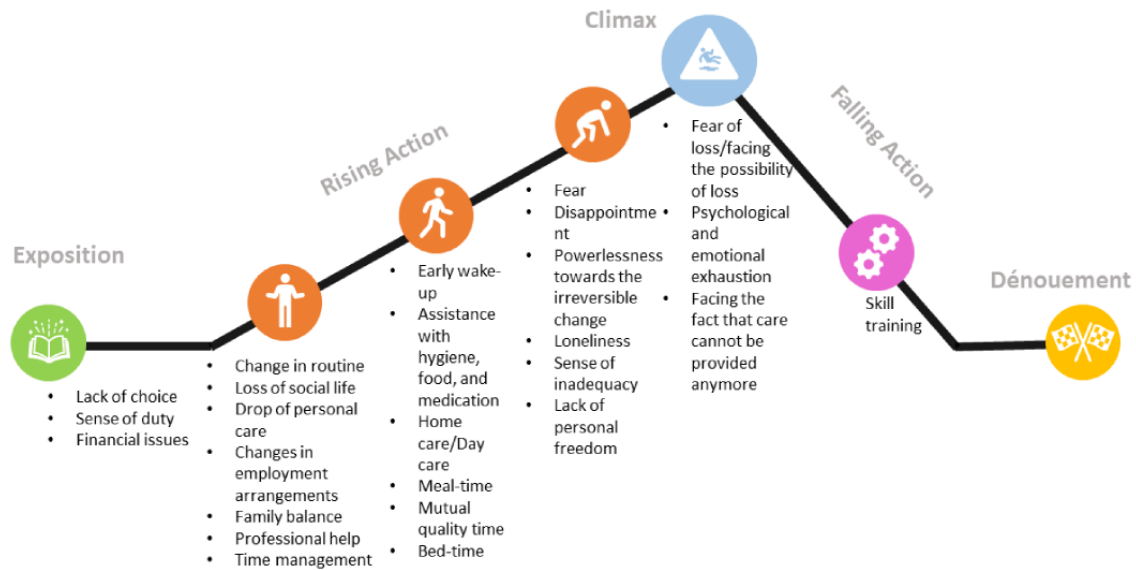

A structured interview, named "Caregiver Life Story," was created for the purpose of this research. Following the general form suggested by the TST, the interview questions inquired about (1) the beginning of the caregiving role/issue/event, (2) changes that took place, (3) the new routine/outcome, (4) psychological and emotional challenges of the caregiving role/issue/event, and a (5) a critical/climax point of the issue/role/event.

In addition, the interview assessed demographic (ie, age, gender) and care recipient illness-related (ie, age and health condition of the care recipient, relationship with the care recipient) information.

Analysis

Thematic analysis was performed following an inductive approach and the six-phase guidelines proposed by Braun and Clarke [24]. The phases included (1) familiarization with the text, (2) initial coding, (3) search for themes, (4) revision of themes, (5) definition of themes, and (6) final output (see [Multimedia Appendix 1](#)). Within the TST, each question acts as an a priori category derived from the Freytag pyramid. In essence, each category collects the data for a specific part of the story plot (deductive) of the Freytag pyramid (see [Figure 2](#)). To ensure the extraction of relevant data, we performed the initial coding, which was then refined with more specific and narrowed codes that allowed for an easier search for themes and definition of themes. The data were analyzed by two researchers independently. Namely, a large amount of interview data contained particularly emotional responses and confessions from the everyday life of informal caregivers that could potentially influence the interpretation. To mitigate the potential effects that highly personal and emotional recollections shared by the participants could have on the objectivity of the analysis, independent analyses were performed by two researchers (MP and ML) and the findings were then jointly compared and discussed until potential disagreements were resolved. The final codes and themes were established by noting and sorting the overlapping codes from the researchers' analysis. The third researcher (GA) supervised this process of distinguishing the themes independently and establishing the final themes jointly. In instances where the researchers disagreed, the points of disagreement within data were marked and blindly validated by the third researcher (GA) without prior knowledge on the specifics of the disagreement.

Figure 2. Themes inserted into the Freytag pyramid serving as building blocks for a story.

Results

Participants

The sample consisted of 16 female informal caregivers and one male informal caregiver (see Table 1). This number generally reflects the unequal gender distribution in informal care, pointing to women as the usual primary caregivers [25]. The most common illness among care recipients was Alzheimer disease,

often associated with other chronic conditions. Interestingly, the gender distribution among care recipients was quite homogenous in contrast to the caregivers being predominantly women. Participants provided care mostly for a parent or both parents at once, while there were also some participants providing care for a mother-in-law.

The following results are presented in line with the steps of the TST (see Figure 1 and Multimedia Appendix 1 for the detailed coding procedure).

Table 1. Characteristics of the study population.^a

Participant ID	Gender	Age (years)	Gender of the care recipient	Age of the care recipient (years)	Relationship to the care recipient
P1	Female	41	Male	70	Father
P2	Female	62	Male	67	Husband
P3	Female	46	Female	82	Husband's aunt
P4	Female	55	Female	77	Mother-in-law
P5	Female	57	Female	80	Mother-in-law
P6	Female	61	Female	NA ^b	Mother
P7	Female	78	Male	79	Husband
P8	Female	55	Male	81	Father
P9	Female	63	Male	68	Husband
P10	Female	73	Male	78	Husband
P11	Female	47	Male and female	80 and 80	Parents
P12	Female	64	Female	85	Mother
P13	Male	84	Female	NA	Wife
P14	Female	65	Male and female	91 and NA	Parents
P15	Female	74	Male	80	Husband
P16	Female	57	Female	84	Mother
P17	Female	59	Female	82	Mother

^aIllness-related data are removed to respect the privacy of the participants.

^bNA: not available; information not shared or recipient recently deceased.

Step 2: Analysis of the Stories

Overview of Themes

The thematic analysis resulted in 25 overall themes. A full list of initial coding, refined coding, and theme formation within each category is available in [Multimedia Appendix 1](#). The 25 final themes were sorted into a priori categories of the TST. Each interview question collected data for a specific category: (1) the beginning, belonging to the category of *exposition/the beginning*; (2) life changes, daily life, and psychological and emotional challenges, belonging to the category *rising action*; and (3) critical point, belonging to the category *climax/critical point*.

Exposition/The Beginning Category

The themes retrieved in the first category reflect the role onset/exposition, which include *the lack of choice, sense of duty, and financial issues*. The role onset has been marked with a *lack of choice* in accepting the caregiving duty either due to the living condition (eg, spouse), or the lack of another caregiver available or willing to provide care (eg, other siblings denied caregiving, children living across the country), often imposing the caregiving role upon the only available family member.

The *sense of duty* in providing care was the second noted theme. The sense of duty appeared due to a personal understanding of the relationship, family ties, marital responsibility, or being the only child that is willing to assume care, hence feeling as the last resort available, which is in essence closely related to the first theme of a lack of choice. The caregivers described the sense of duty with statements such as “I have to, she is my mother”; “I am the wife”; or “I am the daughter it’s my duty.”

The third theme of the first category, *financial issues*, appeared at the beginning of the role. In line with the theme lack of choice, caregivers also reported that the financial aspect has been an important factor in their decision to become a caregiver. There was a noted lack of financial resources for care homes as well as in-home formal caregiver support, which also seemed to further add to the prolonged care even when the caregiver was not willing to continue the care provision.

Rising Action Category

Main Category

This category explores the rising action through reported daily changes that occur in individuals’ lives due to the caregiving role, average daily life after the changes occurred, and finally psychological and emotional challenges of the role. The category *rising action* constitutes the following three subcategories.

Daily Changes Subcategory

Seven themes were noted within the daily changes subcategory. Caregivers reported that a *change in routine* took place after the role was assumed, which forced them into giving up numerous habits and adjust to the new way of living. The caregivers expressed this through statements such as “I lost my routine,” “the day was organized in the service of her,” “I gave up my personal time,” and “had to be more present for my parents.”

The following theme within the subcategory daily changes was the *loss of social life*. Caregivers noted this as a relevant aspect of the daily changes that took place through shared statements such as “loss of friends”; “lack of social life”; “gave up my social life”; “all activities we had together stopped, hence our friends drifted apart”; and “my social life doesn’t exist anymore.”

The third theme, the *drop of personal care*, was evident through the lack of sleep or sleep disruption, limited sleeping hours, strict waking-up hours, loss of freedom for personal time and activities with family and friends, as well as lack of time to visit the doctor for personal health reasons. This theme was reflected in statements such as “I cannot take care of my own health issue, nor make the time to visit the doctor”; “I have to monitor her during the night because she already fell once”; and “my mother remains my priority.”

The fourth theme of the daily changes subcategory was *changes in employment arrangements*, which appeared in all cases where employment existed prior to the caregiving role. Some of the statements supporting this theme included “full-time to part-time work,” “I had to quit my job,” “I was waking up at 4:30 AM going to work and returning home at 8:30 AM.”

The fifth theme in the subcategory daily changes was *family balance* disruptions, which reflects internal family problems that informal caregivers experienced in different contexts due to their role. Disrupted family time or activities were reported among spouses, parents and children, and siblings. The disruptions involved changes in the usual weekend-routine patterns of a family, the amount of time spent together, vacation routine, free time among parents and children, and free time for spouses. Moreover, the family balance was also affected among spousal caregivers reporting that what used to be regular mutual activities have now ended. Additionally, the family balance has also been affected over a course of caregiving due to lack of involvement of other family members who were considered obliged to caretake (eg, brothers not assisting with caregiving to sister, daughters not assisting with caregiving activities to mother), resulting in the deterioration of the overall family relationship.

The sixth theme, *professional help*, was noted when caregivers addressed the professional help either in the form of day care or professional/semiprofessional caregivers who were hired for in-home assistance. The caregivers who had the financial resources to cover the in-home professional/semiprofessional care expenses hired help regardless of the living arrangements or their full-time presence in the home. Some of the statements the caregivers made regarding professional help included “I paid the woman to help me,” “I had to send him to day care against his will so that I can work,” and “I had 24-hour home assistance.”

The seventh theme of *time management* within the rising action subcategory of daily changes included all the relevant issues regarding the daily organization of time and changes that took place within the personal schedule. For instance, caregivers reported “all day revolved around the care recipient,” “the day was organized in the service of the care recipient,” and “I had to give up my personal time.”

Average Day Subcategory

The average day subcategory explores a day in the life of an informal caregiver, including all of the relevant activities concerning care after the initial routine has been shifted and caregiving became a part of life. We noted six emerging themes within this subcategory pointing to *early waking hours*; *assistance with hygiene, food, and medication*; *daycare center/home*; *meal time*; *mutual quality time*; and *bed time*.

Informal caregivers reported *early waking hours* as the beginning of each day, followed by *assistance with hygiene, food, and medication*. These two themes were reported by all caregivers regardless of the living arrangements (eg, living together or separately). The caregivers reported that the first activity in the morning involved assistance with showering, cleaning, dressing, breakfast, medications, and therapy. This assistance was provided alone or, in a few cases, together with the professional/semiprofessional in-home caregiver. Caregivers also noted that the assistance with personal hygiene was the most uncomfortable aspect of the caregiving role and the aspect that was also seen as repulsive in the beginning of the caregiving role.

The third theme was *home care/day care*. Care recipients either visited the daycare center for a couple of hours, or home care continued with the existing daily routine such as brief walks, grocery shopping, and reading newspapers. Caregivers who had the opportunity to spend some time away from the care recipient noted that they felt good about these hours even though they were still occupied with the caring obligations.

The *meal time* theme followed the home care/day care theme. The care recipient would usually return from the daycare center or the late-afternoon home care would continue with early dinner. The *mutual quality time* theme was noted as a small period existing after dinner where the care recipient and caregiver spent quality time together, such as listening to music, talking, reading, or watching TV. These moments were also marked with the occasional efforts of informal caregivers to reminiscence with the care recipient about the past and good moments lived together.

Bed time was the final theme within the average daily life subcategory, in which caregivers prepared the care recipient for sleep, distributed the medication, assisted with other care needs, and helped the care recipient go to bed. The caregivers mostly reported going to bed sometime later, after small house chores were complete.

Psychological and Emotional Challenges Subcategory

Psychological and emotional challenges of the role were identified through six emerging themes, including *fear*, *disappointment*, *powerlessness*, *loneliness*, *sense of inadequacy*, and *lack of personal freedom*.

The theme *fear* was noted as an important aspect of the subcategory emotional and psychological challenges. Fear experienced by caregivers was related to the care recipients' health and possible deteriorations of their health. In instances where the care recipient was ill, or the condition suddenly worsened, the caregivers reported fearing the possible outcomes and/or that they will not be able to appropriately assess the

seriousness of the condition, which might have severe or lethal consequences on the care recipient.

Following the theme of fear, the *disappointment* theme emerged in the subcategory of emotional and psychological challenges as caregivers described daily events that affected them the most. It was noted that caregivers were disappointed with the disease progression and the outcomes, stating that related events are particularly difficult since they are taking place right in front of the caregivers. Some of the statements portraying these themes include "seeing your mother not recognizing you and not knowing anymore," "becoming a mother of my parents," and "I have always seen my parents as pillars and instead I discovered all their weaknesses."

The *powerlessness* theme appeared as an outcome of the irreversible change in the disease progression, when, despite the care provided, the condition was still deteriorating/not improving. Caregivers reported "the inability to do something against the disease/the sense of powerlessness caused by the disease weighted the most," "maintain a normal relationship when you are overwhelmed by the suffering that involves seeing the decline due to the disease," and "I feel so angry and I feel lonely."

Loneliness was noted as a fourth theme of the psychological and emotional challenges subcategory, overlapping with the loss of social life theme noted in the subcategory of daily changes. Loneliness was identified by statements such as "I feel lonely," "I find it hard to be the only one who has to follow him," and "she is refusing other caregivers' presence."

Sense of inadequacy was the fifth theme noted when the care recipient condition worsened or difficult symptoms occurred. Caregivers reported feeling as if they were not sufficiently or adequately prepared to manage caregiving duties, or being in need of time to adapt to new circumstances/worsening of the condition. The examples were noted through a variety of statements such as "the moments of aggression that he had"; "feeling inadequately equipped to provide assistance"; "my movement had to be exactly the same as hers and this cannot happen overnight, you have to adapt"; "she once grabbed my neck"; and "she was waking up at night and ran."

Finally, *lack of personal freedom* was the sixth theme caregivers repeatedly noted in the subcategory of psychological and emotional challenges. This theme was reflected in planning out private time, going out alone, socializing, organizing weekends with family, or simply managing to spend time with people other than the care recipient. Furthermore, caregivers reported a lack of personal freedom in statements such as "lack of freedom is what oppresses me," "inability to spend time with children," and "sense of guilt for not having the time for everyone."

Climax/Critical Point Category

The climax point in the TST is the peak moment where the story begins to unravel since it reached the moment of the greatest tension. The climax/critical point category reflects the peak point for informal caregivers, where the provision of care has reached its peak in terms of difficulty, burden, and negative experiences, and hence must change or terminate. This category

explores the themes emerging from the experiences of the most critical moments in the role of caregiving.

The initial theme recognized within the critical point category was the *fear of loss/facing the possibility of loss*. Caregivers reported that the critical points occurred when they were confronted with the further/serious health deterioration of the care recipient that implied the possibility of a lethal outcome. This theme appeared in the later phases of caregiving and could be potentially related to the following theme of *psychological and emotional exhaustion*. Concretely, when the caregiver had the resilience and strength to carry the role-related burden, the fear was less present/obvious. Some of the caregivers' statements shedding light on the theme of fear of loss/facing the possibility of loss include "when he gets ill/does not feel well I am scared because I believe it is serious"; "while my father was still having a driving license, since he was a danger to himself and others"; "when he is ill I do not know what the outcome will be"; and "the most critical moment is the last days when you know that nothing else could be done." This fear appeared to surface after the first encounter with the critical situation where the life of a care recipient was jeopardized.

The theme *psychological and emotional exhaustion* was reflected through numerous examples of negative emotions experienced, tiredness within the role, and the concern about the continuation of the caregiving activity. Furthermore, a few caregivers reported that due to psychological and physical fatigue—which could, in turn, be the consequence of psychological exhaustion—they were concerned if caregiving could last any longer. Caregivers expressed this through statements such as "I have experienced all the feelings of this world, anger, frustration, resentment, loneliness"; "I feel alone and criticized by my siblings while they are not truly aware of the situation"; "yes, there are mornings when I'm more tired and hearing the same things over and over again is heavy"; and "physical fatigue that prevented me from seeing the situation clearly/the worst moment was when I realized I cannot bear the caregiving for much longer."

The final theme noted within the category of climax/critical points was *facing the fact that care cannot be provided anymore*. It seems that such confrontation with the reality of the situation comes after first experiencing physical, psychological, and emotional exhaustion. Such a conclusion could also be related to the previous argument about the themes of fear, disappointment, and powerlessness, argued as early indicators that imply the caregiver is reaching a critical point within the role.

Step 3: Arranging Themes Into the Freytag Pyramid

The obtained themes were used as building blocks for development of a fictional story guided by the real-life experiences common to the target population (ie, informal caregivers). The real-life experiences are reflected in the obtained themes, while the TST is used for incorporating these real-life experiences into a flourishing narrative. Following the third step of the TST, the obtained building blocks/themes were fed into the Freytag pyramid (Figure 2) and used for the creation of numerous stories and different narratives for informal caregivers.

Step 4: Creation of the Final Story

The fourth step of the TST consists of writing a fictional story using the obtained figure from step 3 (see Figure 2). The created fictional story provides the viewer/listener an identification with the protagonist who experiences similar challenges throughout the role (ie, identification is supported by the building blocks/themes) but also an emotional distance that allows taking an objective stance toward the caregiving experience through a third-person perspective (ie, the narrator telling the story to the caregiver, or the protagonist). A sample of a fictional story created as step 4 of the TST is included in Textbox 1 (see Multimedia Appendix 2 for the full story).

Once the final step of the TST is completed and the written story is audio-recorded using a voice actor, the audio will be available on the Voice Me Out platform we designed for the informal caregivers (the platform is not yet publicly available).

Textbox 1. Final fictional caregiver stories created. Words in italics are the retrieved themes incorporated into the fictional story.

- Excerpt from the category “The beginning”

I think I can describe it simply; I *did not have a choice*, but to take her with me that night. “*It is my duty*”—I said to myself—because she is my family. Besides, I *cannot afford anyone* to take care of her. As the days were going by, I had to change so many things in my life, one after another. I had never expected all of it to happen that way. I had to reorganize the space in my house and empty a room for her.

- Excerpt from the category “Rising action”

My entire morning routine had to adapt to her from day one. I had to *change my working hours* and shift to *part-time work* because I couldn’t get to work by 9 any longer and stay there until 5. It is difficult sometimes to follow my own schedule.

My spouse often complains, and I do understand him, but I don’t see what else I can do. I can’t put her into a nursing home. My children didn’t seem bothered at the beginning. In fact, they were excited to have Grandma home, but there comes a time when they try to make plans for us to go to the park on the weekend, as we used to, but I can’t promise anything because I do not know if she will be in her good mood that weekend and able to leave the house. My *family balance* is completely disturbed.

- Excerpt from the category “Climax/critical point”

Fear, this is how I can describe such moments. I did not know what to do. I was scared for her, for my children. It was fear that didn’t let me think for a moment. I felt *powerless* because she wasn’t getting any better; she was either the same or getting worse. I couldn’t make her get better and I think I was making her worse by not knowing what to do exactly. I was *completely alone*. No one could truly understand what I was going through. I didn’t know what to do and I had no one to call. Everyone I knew had already advised me many times to consider a nursing home. I couldn’t just take a break to have a *moment for myself* to think. It had been like that for months. I had lost my *personal freedom*. I felt trapped.

I took the phone and called an ambulance.

Discussion

Principal Findings

This study implemented the TST [5] for developing empowering narratives in an informal care context. We demonstrated how to use the TST to obtain and categorize building blocks of a universal informal caregiver life story to develop an empowering fictional story. The final 25 themes have been distinguished across three a priori categories (ie, the beginning/exposition, rising action, critical point), covering a wide range of experiential, practical, and emotional changes, along with experiences throughout the role.

Numerous obtained themes (eg, within the beginning, and psychological and emotional challenges categories/subcategories) are in line with the past literature and reflect the important aspects of the informal care experience. Although some of the themes such as those within the subcategory of daily life constitute a major part of informal caregiver life and activities, they have been rather neglected in the literature to date (see Figure 2). It can be suggested that some of these themes also have an important role in the caregiver burden.

Interestingly, following the TST, we obtained qualitative data that have already been reported in the literature, but never gathered in one study. Namely, the TST enabled an all-encompassing approach to collecting, structuring, and grouping these findings chronologically. In other words, the TST enabled and facilitated gaining a magnified overview of the detailed caregiving experience.

Findings in the beginning/exposition category, which reflects on the early experiences in the role, indicate that informal care is often taken because of personal beliefs about family duties and obligations. This theme is also in line with prior research noting that informal caregivers consistently report this sense of

duty across different cultures [26-28]. Additionally, when several children were available to provide care for a parent, other siblings commonly expected the female child or the oldest child to assume the caregiving role.

Therefore, the sense of duty is arguably not equally present in all potential caregivers, but rather formed by certain expectations for the specific family member to assume care (eg, the female sibling or the oldest sibling). It could be suggested that the sense of duty or the internal perception of duty is one of the distinctions between those that will assume care in the future and those that will refuse it. However, no current data are available comparing the sense of duty among siblings when more than one child is available to assume the role. Furthermore, it can be added that the existing perception of the feminine nurturing role additionally disadvantages female family members when the caregiving arrangements are being determined [29].

The financial aspect/lack of resources for formal or institutional care appeared as an important theme in the role assumption. Informal caregivers that had resources to support formal care or financially cover the placement into the nursing home/daycare center reported such actions early in the role. Moreover, caregivers who were able to afford assistance of any kind reported fewer caregiving tasks, ultimately allowing more personal freedom and time for other activities.

In line with this argument, findings from a recent study across 12 European countries assessing existing care policies and health of informal caregivers point to a significantly lower health status of informal caregivers who provide home-based care [30]. Similarly, our results indicate that in instances where informal caregivers were not able to afford any type of help, the emotional experiences in the subcategory of psychological and emotional challenge within the rising action category were described to a greater extent, with vivid examples and recollections of numerous difficult situations. Another

interesting finding is that caregivers who provide only home care reported more severe emotional responses toward the care recipient and frustration toward the caring situation, which was reflected in the rising action category exploring the psychological and emotional challenges concretely. This insight can also be related to the past literature pointing to psychologically and physically abusive behaviors occurring in the informal caregiving context [31-33], suggesting that the type of care (in-home only vs shared care with respite/or a day center) could be related to more severe reactions.

Informal caregivers noted the loss of social life and personal time early in the role, describing these experiences as part of the changes that took place due to the role. A similar theme reemerged as loneliness in the category of psychological and emotional challenges, described mostly as “lack of friends,” “lack of support group,” and “lack of people that can serve as a reference point or companion during the difficulties.” Interestingly, these findings are consistent with a previous study noting the presence of similar experiences of social isolation and lack of support [34].

The relevance of the theme *drop of personal care* can also be aligned with the existing literature pointing to the gradual decrease in the physical health of informal caregivers who provide care for a longer period [35]. Arguably, the drop of personal care can be attributed to the maladaptation to two other themes, *loss of social life* and *changes in the routine*, ultimately occurring as an unconscious process in the caregiver. Moreover, a drop in personal care may act as a potential mediating factor in the decrease of physical health noted in the literature. The past literature exploring personal self-care in informal caregivers underlines the strong association between self-care and emotional well-being, pain, perceived stress, and general health [36].

Changes in employment arrangements is another theme in line with numerous studies, pointing either to the lack of social policy that will provide flexible working hours for informal caregivers or inadequate long-term financial support for the hours missed from work (see [30,37,38]).

Caregiver fear, discovered as another theme, has also been noted in the literature in the context of specific illnesses such as pulmonary fibrosis, amyotrophic lateral sclerosis, and heart failure (see [39-41]), where caregivers did not know how to manage specific illness-related aspects of care. However, the role of an overall fear in informal caregivers about assuming and providing caregiving has been rather neglected.

Another interesting theme discovered in this study is the sense of powerlessness. This theme emerged right before the critical/climax point category. In fact, the themes of fear, disappointment, and powerlessness toward irreversible change could be argued as early indicators that the caregiver is reaching a critical point in adverse experiences within the role, where the care provision either needs to be terminated, restructured, or shared to avoid critical situations.

Sense of loneliness and social abandonment/isolation are present from the early stages of taking up the role and seemed to be most strongly expressed in the emotional and psychological

challenges subcategory. These themes are also consistent with the literature, pointing to the reported sense of isolation and abandonment in caregivers (see [42-44]).

The aforementioned themes within the psychological and emotional challenges subcategory could be argued as a set of early indicators leading to the confrontation with the fact that care can no longer be provided, as a part of the critical point category. Following such a perspective, if the early indicators are not appropriately addressed, the critical point follows or can be avoided by perpetual therapeutic work on fear, disappointment, and powerlessness within the role.

Following the categorization of the building blocks (Figure 2) and the creation of the empowering informal caregiver fictional story, these findings demonstrate how the TST can act on two levels. First, the categorization of building blocks with the TST can serve as an informative pathway for further research and interventions. Concretely, building blocks provide a path of the informal caregiver life experience from the beginning of the role until the critical point, and as such, proper steps can be developed to prevent, intercept, or manage problematic experiences in practice.

Second, the value of the created story and the potential effects of this story on informal caregiver well-being need to be assessed in a pilot trial, ensuring that informal caregivers benefit from such stories. The stories serve as a sample of a productive caregiving narrative to be used as a template in self-restructuring of the personal caregiving life stories. If TST stories show positive outcomes for informal caregivers in the currently ongoing pilot testing, we can further explore the development of flourishing gender-adapted narratives through digital health tools. This approach would further facilitate human-centered design in eHealth tools for informal caregivers, and provide a new method of exploring adverse experiences while offering a path for creating flourishing and empowering digital narratives.

Limitations

Unlike the traditional storytelling approaches, the TST allows for the collection of universal building blocks for target groups or populations rather than individuals. In this sense, the technique enables in-depth exploration of the dominant/repetitive themes in the concrete categories of experience, acting as building blocks of an individual narrative within the target population.

Such collection and representation of the building blocks provide (1) an informative template for research and practice, (2) a pathway in the design and development of tools and interventions, (3) an overview of the narrative of the experience, (4) a blueprint for self-restructuring within the personal story of “the self,” and (5) a top-down approach to narrative therapy (ie, providing ready empowering narratives linked to personal experience).

Several limitations of this study must be considered. Further work on gathering and comparing themes in informal care following the TST is required to verify the universality of the retrieved themes in acting as building blocks for informal care narratives. Therefore, although our focus was on distinguishing universal caregiving experiences through the TST, we cannot

assume the generalizability of our findings until the ongoing pilot trial data are retrieved and until the retrieved themes are reproduced by using the TST in further studies. The majority of our sample was predominantly female informal caregivers, leading to possible perspective bias. The male experiences need to be collected and compared against the obtained themes to ensure the generalization of themes as building blocks for informal care narratives. In this sense, minimizing bias in future studies would strengthen the scientific rigor for obtaining universal themes of the informal care experience. Another consideration regarding the scientific rigor that must be acknowledged is that all the participants had already taken part in self-help group meetings of the association, which might have prepared them and facilitated their capacity for self-reflection but likely also contributed to preconception of the emotional difficulties. In this sense, some experiences shared with our researcher (SB) might have already been predefined and conceived in self-help groups rather than reflected on for the purpose of our interview. This might ultimately affect the validity of the reported experiences, since they might have been reassessed and adapted in a self-help meeting to better resonate with the support group members rather than resonating with the general informal care experience.

Moreover, it must be noted that this study did not define an upper age limit for informal caregivers, allowing even elderly

caregivers to take part in the study. The age difference among informal caregivers raises a question about the universality of the experiences across generations.

Finally, our sample consisted of informal caregivers who provided care for family members with concrete illnesses such as Alzheimer disease, Parkinson disease, or dementia. Therefore, the obtained experiences in this study could be potentially biased or formed by the specific illness presented in the care recipient. A larger sample of informal caregivers including other chronic conditions would be desirable in better exploring and creating universal themes of the informal caregiving experience.

Conclusions

The rapid expansion of storytelling applications in mental health calls for structured and tested techniques that will provide consistent narrative structures with clearly defined purpose and goals. The TST is the result of our effort to create a technique for developing structured, meaningful, and empowering narratives for larger groups or populations that can be easily adapted and applied to a digital format. The translation of personal narratives into empowering digital stories is one of our next goals in implementing the human-centered design in digital health development for informal caregivers, where the value of every individual is recognized in the overall process of the group experience.

Abstract

Background: Due to an increase in life expectancy, the prevalence of chronic diseases is also on the rise. Clinical practice guidelines (CPGs) provide recommendations for suitable interventions regarding different chronic diseases, but a deficiency in the implementation of these CPGs has been identified. The PITeS-TiSS (Telemedicine and eHealth Innovation Platform: Information Communications Technology for Research and Information Challenges in Health Services) tool, a personalized ontology-based clinical decision support system (CDSS), aims to reduce variability, prevent errors, and consider interactions between different CPG recommendations, among other benefits.

Objective: The aim of this study is to design, develop, and validate an ontology-based CDSS that provides personalized recommendations related to drug prescription. The target population is older adult patients with chronic diseases and polypharmacy, and the goal is to reduce complications related to these types of conditions while offering integrated care.

Methods: A study scenario about atrial fibrillation and treatment with anticoagulants was selected to validate the tool. After this, a series of knowledge sources were identified, including CPGs, PROFUND index, LESS/CHRON criteria, and STOPP/START criteria, to extract the information. Modeling was carried out using an ontology, and mapping was done with Health Level 7 Fast Healthcare Interoperability Resources (HL7 FHIR) and Systematized Nomenclature of Medicine Clinical Terms (SNOMED CT; International Health Terminology Standards Development Organisation). Once the CDSS was developed, validation was carried out by using a retrospective case study.

Results: This project was funded in January 2015 and approved by the Virgen del Rocío University Hospital ethics committee on November 24, 2015. Two different tasks were carried out to test the functioning of the tool. First, retrospective data from a real patient who met the inclusion criteria were used. Second, the analysis of an adoption model was performed through the study of the requirements and characteristics that a CDSS must meet in order to be well accepted and used by health professionals. The results are favorable and allow the proposed research to continue to the next phase.

Conclusions: An ontology-based CDSS was successfully designed, developed, and validated. However, in future work, validation in a real environment should be performed to ensure the tool is usable and reliable.

adherence; ontology; clinical decision support system; CDSS; complex chronic patients; functional validation; multimorbidity; polypharmacy; atrial fibrillation; anticoagulants

Introduction

Chronic Diseases and Multimorbidity

Due to an increase in life expectancy, the prevalence of chronic diseases is also rising [1]. According to the World Health Organization (WHO), chronic diseases are health problems requiring treatment over years or decades [2]. The diagnosis of 2 or more chronic conditions in a patient at the same time is called multimorbidity [3]. Patients with multimorbidity, called complex chronic patients (CCPs), are characterized by being fragile, with polypharmacy, of older age, in emergency departments frequently, and having a higher rate of hospital readmissions [4]. CCPs also constitute a challenge for the health system, particularly for health professionals, as there are few specific guidelines for providing integrated health care [5].

Polypharmacy

The increase in the number of CCPs is linked to a higher incidence of polypharmacy [6], defined as a patient taking 5 or more drugs [7]. The drugs offer clinical benefits and risks, but the complexity of CCPs makes this group more susceptible to errors [8].

Polypharmacy is associated with increased adverse reactions, reduced adherence to treatment, and increased demand for health care resources [9]. Currently, clinical practice guidelines (CPGs) recommend drugs for disease management based on clinical trials for specific diseases. However, CPGs do not consider the complications that can arise in a CCP due to interactions between different drugs for different diseases [10].

All this highlights the need for personalization of care and prescriptions due to each patient's specific situation [11].

Clinical Guidelines

CPGs are defined as “systematically developed statements to assist practitioner and patient decisions about appropriate health care for specific clinical circumstances” [12]. Some CPGs provide recommendations for good interventions regarding different chronic diseases. However, there is lack of implementation of these CPGs in clinical practice due to different factors, such as subjective interpretation by health care professionals, the lack of time for health care professionals to read these CPGs [13], and clinical inertia [14], among others. In addition, a study carried out by the National Institute of Health and Care Excellence (NICE) compared 12 CPGs and detected numerous dangerous interactions between the different recommendations given by each CPG [15].

Today, health care systems face the challenge of providing a new care model integrating all the CPGs [10] that do the

following: take into account the individual situation of each patient; identify possible interactions between drugs prescribed to the same patient to avoid complications; consider the patients' life expectancy as, in some situations, prescribing the drug will not provide significant benefit to the patient; and if life expectancy is low, recommend beneficial and effective but less aggressive treatments.

Clinical Decision Support Systems

Clinical decision support systems (CDSSs) are handy tools in the health framework and have 3 requirements [16]: (1) computable biomedical knowledge, (2) information about the specific situation of each patient, and (3) reasoning mechanisms to be able to provide personalized recommendations to each patient.

However, even with years of research in this field, health care professionals' acceptance of CDSSs is not satisfactory. This is one of the reasons why 95% of CDSSs are discarded [17]. Different studies have been conducted to determine what needs to be fulfilled during the development of the CDSS to be well accepted in the health care environment and especially by health care professionals. Shortlife et al [18] reported that biomedical informaticians had identified the following characteristics necessary to achieve good acceptance of a CDSS: users, in this case, health care professionals, must understand the basis and reasoning behind the CDSS recommendations; the CDSS developed in the health care environment should be intuitive and easy to use; the CDSS should support the health care professional by providing advice but always respecting their experience and knowledge; and the recommendations provided by the CDSS should be evidence-based and offer resources (scientific papers, CPGs, studies, etc) to review the validity of those recommendations.

Trinkley, Blakeslee, et al [19] explored the beneficial features of a CDSS for primary care from the health professional's perspective. They concluded that the design of the CDSS should be user-centered and take into account the user's needs in terms of content, presentation, and functionality and that the CDSS should be personalized to the health professional's needs, providing relevant information and optimizing the workflows.

Trinkley, Kahn, et al [17] highlighted the importance of reducing alerts to a minimum to minimize health professional fatigue, including all health care team members in the workflow, and encouraging health professionals to follow the recommendations. The latter point focuses on time savings during health care, such as ordering a test directly from the CDSS or updating the medical record with the data entered in the CDSS automatically.

Ontology-Based Systems

Studies such as that by Van de Velde et al [20] demonstrate that integrating the knowledge contained in CPGs and other knowledge sources into a CDSS improves clinical practice. To carry out this integration, it is necessary to make an intermediate step that models this information's content [21]. One way to perform this intermediate step and, in this way, to infer the specific clinical knowledge, is by designing an ontology.

An ontology is an excellent way to organize existing knowledge in CPGs [22]. These kinds of resources define a common vocabulary that allows researchers to share information about the same field [23]. Borst [24] defines ontology as “an explicit and formal specification of a shared conceptualization.” According to Lekhchine [25], each element of the definition of ontology provided by Borst should be understood as follows: explicit specification—each ontology concept and associated features are defined in a declarative form; formal—this allows ontologies to be interpretable by a machine; shared—here, the knowledge that is shared in the ontology is consensual; and conceptualization—this involves linking to the abstraction of a phenomenon by identifying concepts related to that phenomenon.

Konaté et al [22] identified the most critical needs for the decision to develop an ontology to be the following: a shared understanding between different software developers; reuse of knowledge in a particular domain; helping the different actors in a domain to understand each other better and increase their knowledge; distinguishing 2 types of knowledge, operational knowledge and domain-focused knowledge; and analyzing existing knowledge about a domain.

With consideration to all the characteristics analyzed in this section and to provide personalized and integrated care to CCPs, the PITeS-TIiSS (Telemedicine and eHealth Innovation Platform: Information Communications Technology for Research and Information Challenges in Health Services) tool has been designed, developed, and validated.

The main objective of the PITeS-TIiSS project is to improve evidence-based decision-making capacity and reduce variability in clinical practice in the domain of integrated care of CCPs through the use of advanced semantic interoperability and clinical decision support methods and tools.

Methods

Ethics Approval

This study obtained authorization from Virgen del Rocío University Hospital (VRUH) review board chaired by Victor Margalet on November 24, 2015 (number PI15/01213).

Selecting the Study Scenario

For the development and clinical validation of the PITeS-TIiSS tool, a specific study scenario was defined.

To design this study scenario, the prevalence of chronic diseases was taken into account in the health area where this clinical validation was carried out. This ensured the recruitment of

patients for the study and the high availability of information recorded in the electronic health record (EHR).

The ultimately chosen scenario focused on treatment with anticoagulant drugs in patients with atrial fibrillation. This pathology has a high prevalence, and an early treatment protocol needs to be established due to the complications it can cause [26].

The study was conducted in the Andalusian Health Service in Andalusia, a Spanish region with more than 8 million inhabitants. Specifically, the study area was located at the VRUH in Seville and the Primary Care Center in Camas (Seville).

Study, Analysis, and Selection of Knowledge Bases

Selection Criteria

Once the study setting was defined, the clinical researchers analyzed the evidence-based knowledge bases most commonly used in clinical practice concerning atrial fibrillation, care of CCPs, and oral anticoagulant therapy. More than 20 clinical documents with relevant information were identified. Several criteria were also considered in the selection of clinical records to be used for knowledge extraction: the frequency of application in clinical practice of the information included in the document; the level of updating of the clinical data; the level of consensus of the clinical data; and the clinical documents included in the clinical action protocols of the VRUH and its affiliated centers, where the PITeS-TIiSS tool was to be validated.

After the analysis of the identified clinical documents, it was decided to select the following sources of knowledge.

STOPP/START Criteria

These criteria were first published in Ireland in 2008 and were updated in 2014 [27]. This knowledge base focuses on describing the most common errors in drug prescription. One of their most important features is that these criteria can be integrated into computer systems [28]. This knowledge base is used at the European level to analyze drugs prescribed to older adult patients. These criteria aim to control the polypharmacy to which this type of patient is usually subjected in order to optimize the drugs prescribed and prevent side effects that cause major complications. This document makes it possible to study each patient's individual and specific situations and obtain personalized recommendations for these situations. Moreover, it provides 2 types of recommendations: (1) prescription of drugs necessary for each patient according to the patient's condition; and (2) deprescription of drugs whose effect, due to the particular situation of each patient, may be more harmful than beneficial. These criteria have been demonstrated to detect potentially dangerous and inappropriate prescriptions and improve the quality of prescriptions.

LESS-CHRON Criteria

These criteria guide the optimization of drug prescription in patients with chronic diseases and have been developed using the Delphi method. This document analyzes different pharmacological characteristics, including the indications for which the drug is prescribed, conditions that recommend

deprescribing the drug, health variables to monitor the behavior of the drug, and the time that should elapse between different follow-ups. Based on these characteristics, a list of 27 criteria has been compiled [29].

PROFUND Index

The PROFUND Index is a scale designed by Spanish physicians and is widely used in Spain. It is a prognostic index for CCPs. It includes different types of variables: demographic, clinical, laboratory, functional, socio-familial, and care [30].

Clinical Practice Guidelines

CPGs are systematically developed guidelines to assist health professionals in developing care to provide personalized care for individual patients in specific clinical circumstances [13]. Clinical researchers recommended using a CPG on the diagnosis and treatment of atrial fibrillation [31].

Knowledge Extraction and Decision Rule Design

After selecting the knowledge bases, 2 researchers (ERV and CAV) specializing in medical informatics extracted the relevant information for the defined study scenario. Due to the length of some of the documents, information was searched using keywords related to anticoagulant and antiplatelet drugs, such as “oral anticoagulants,” “anticoagulation,” “anticoagulants,” “vitamin K antagonists,” “antiaggregants,” “antiaggregation,” “acetylsalicylic acid,” and “clopidogrel.”

The information extracted from the selected documents was collected in a tabulated record in the form of rules. The clinical researchers (BBF, MJGL, and LMG) validated these before continuing with the procedure.

The extracted rules have a specific structure. Clinical concepts are the variables that are associated with the values (numeric, Boolean, and others), for example, age, atrial fibrillation, antiaggregants, etc. Premises are the values and features that are associated with clinical concepts, for example, greater than or less than, true or false, and number.

Clinical statements include the text that makes the recommendation to be shown to the health professional, for example “Deprescribe in any case.”

Likewise, 2 types of rules have been defined: mini-rules are rules that relate to a single clinical concept and a single premise

associated with a clinical statement, for example “IF Treatment with Ticlopidine THEN Deprescribe in any case”; super-rules are those that relate to several clinical concepts and their premises to a clinical statement. for example “IF Atrial Fibrillation AND (Mitral Stenosis OR Mechanical Heart Valve) THEN Do Not Prescribe New Oral Anticoagulants (Apixaban, Dabigatran, Edoxaban, and Rivaroxaban).”

A total of 59 clinical recommendations related to the prescription and deprescription of drugs were extracted in the clinical setting of patients with atrial fibrillation. The clinical recommendations were displayed in a personalized way in the CDSS developed based on the information collected for each patient.

Information Modeling and Mapping

With all the necessary information collected in the tabulated document, the ontology was defined. To implement the clinical concepts, the premises, clinical statements, and the relationships between them, Protégé software was used.

Initially, the clinical concepts were added and mapped through annotations with the Health Level 7 Fast Healthcare Interoperability Resources (HL7 FHIR) standard [32] to facilitate syntactic interoperability and with Systematized Nomenclature of Medicine Clinical Terms (SNOMED CT) [33] to facilitate semantic interoperability (Figure 1).

Specifically, Figure 1 is about the drug acetylsalicylic acid. Overall, 100% of the ontology concepts were mapped with FHIR, and 52% of the concepts were mapped with SNOMED CT. It was not possible to map all the concepts with SNOMED CT, as some of these concepts do not exist within that terminology.

Once the clinical concepts were introduced, the premises and clinical statements were implemented. The ontology's internal logic was established through the use of object properties, data properties, and the relationships between the concepts.

The establishment of the relationships between the clinical concepts and the premises to design the mini-rules was carried out through a propositional logic system (true or false, less than or greater than, etc). For the super-rules' design (Figure 2), the logical relationships between the different clinical concepts and premises (and/or) was also established.

Figure 1. Systematized Nomenclature of Medicine Clinical Terms (SNOMED CT) and Health Level 7 Fast Healthcare Interoperability Resources (HL7 FHIR) mappings.

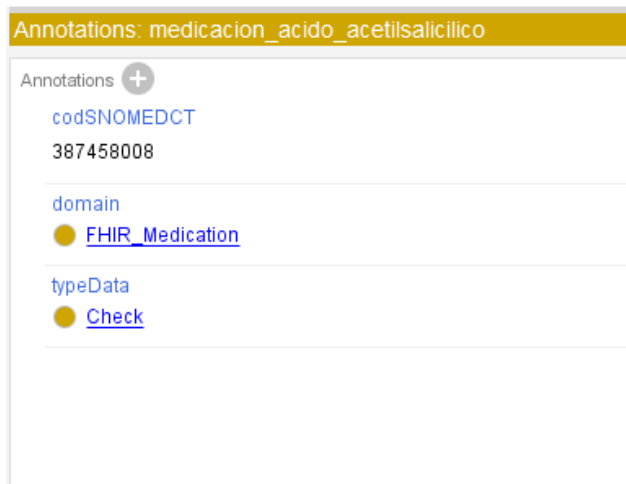

Figure 2. Super-rule example. HAS: Hypertension, Abnormal Renal/Liver Function, Stroke; HAS-BLED: Hypertension, Abnormal Renal/Liver Function, Stroke, Bleeding History or Predisposition, Labile INR, Elderly, Drugs/Alcohol Concomitantly.

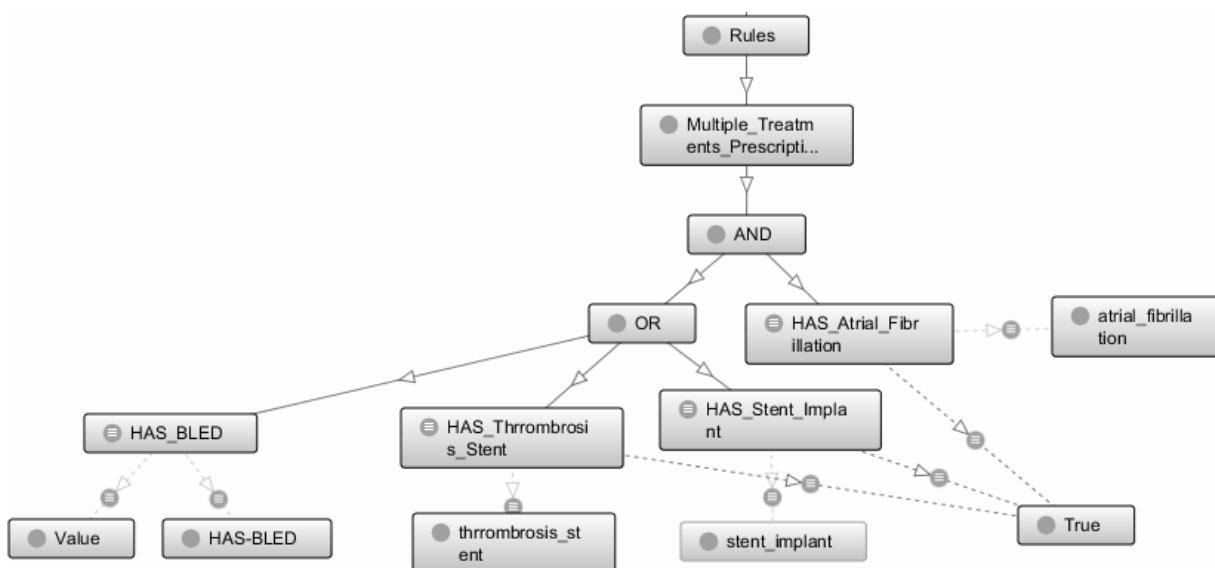

Figure 2 shows an example of the super-rule related to the National Institute of Health Stroke Scale (NIHSS). In this case, for the rule to be fulfilled, the patient must necessarily have multiple prescribed treatments and atrial fibrillation and additionally have 1 or more of the following characteristics: a certain value on the HAS-BLED (Hypertension, Abnormal Renal/Liver Function, Stroke, Bleeding History or Predisposition, Labile INR, Elderly, Drugs/Alcohol Concomitantly) score on bleeding risk, an implanted stent, or a thrombosis in a stent.

Design and Development of the CDSS

For the design and development of the CDSS, including the user interface, the ITCBio (Infrastructure for Translational and Clinical Research based on Standardization, Integration, Advanced Analytics) infrastructure [34] was used. This is a computer tool based on free software that has been developed to provide support for research in Andalusia (Spain).

First, the technical developer technicians (JMC, JARG, and GAER), together with the researchers specializing in medical

informatics (ERV and CAR), completed the user interface design. Based on the tabulated document, the questions that are shown to the health professionals to collect information on each patient were formulated. In order to make the tool usable and speed up the collection of information, the questions are distributed in different sections related to the patient's anamnesis, exploration, complementary tests, and treatment (Figure 3). Based on each premise, a question is formulated and presented to the health professionals through the tool's interface. Thus, depending on the answers selected by the health professionals, the premises may or may not be fulfilled, and the recommendations whose premises are fulfilled are then executed.

Second, for the integration of the ontology containing the ITCBio infrastructure rules, the free software integration engine Mirth Connect was used, whose function is focused on the integration of tools in the health care field. One of this integration engine's most important functions is that it natively provides the following HL7 messaging standards. This

integration engine allows interoperating with the clinical information of the recruited patients present in the EHR through the development of specific channels.

Once the health professional enters the information into the CDSS, ontology queries are made, rules are executed, and recommendations related to the pharmacological prescription are generated all through the Mirth Connect integration engine.

Figure 4 shows an example of the information used by the Mirth Connect integration engine after querying the ontology. In this case, it is a mini-rule in which the clinical concept corresponds to the attribute “name_bd” and is “Ticlopidine treatment.” The Premise corresponds to the attribute “values” and, in this case, has the value “TRUE.” The Clinical Statement corresponds to the attribute “recommendation,” and its value in this example is “Deprescribe in any case.”

Figure 3. Tool interface.

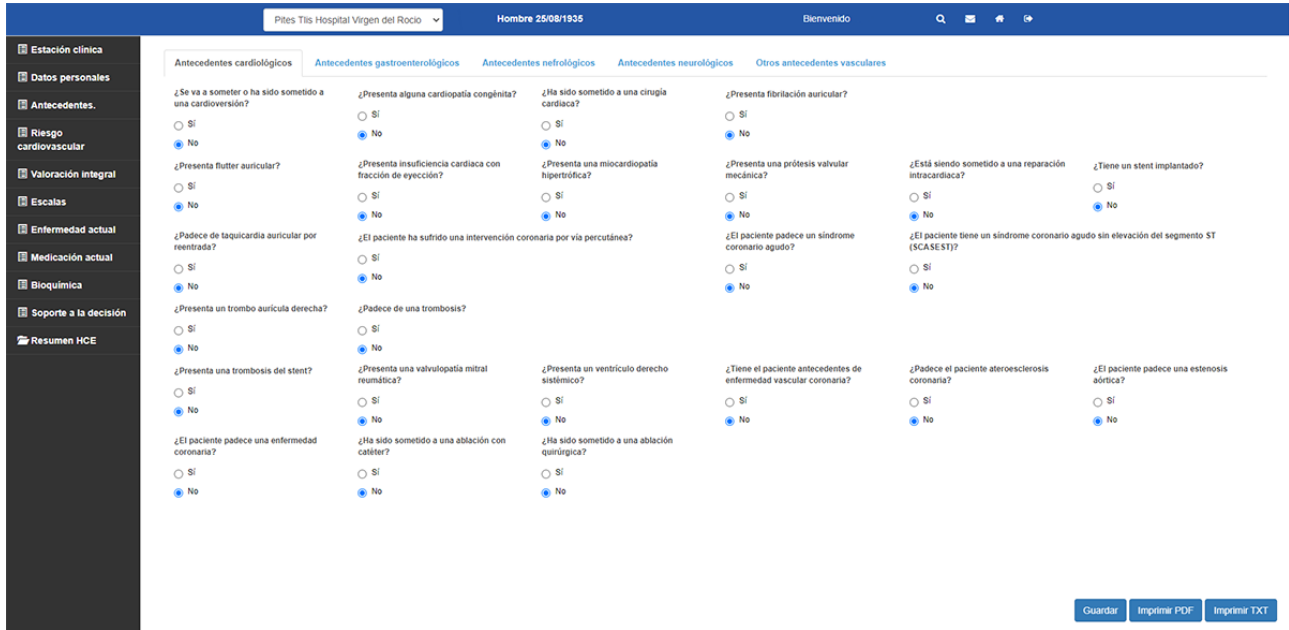

Figure 4. Mini-rule.

```

"rule-0": {
  id: "rule-0",
  logicalType: "AND",
  type: "rule",
  children: {
    "condition-0": {
      id: "cond-0",
      type: "condition",
      logicalType: "AND",
      operator: "equal",
      itemToEvaluate: {
        item_id: "6142",
        nombre_bd: "Tratamiento con Ticlopidina",
        nombre_formulario: "¿Se está medicando con Ticlopidina?",
        values: [
          { text: "Sí", value: "True" },
          { text: "No", value: "False" },
        ],
      },
      conditionalValue: { text: "Sí", value: "True" },
    },
  },
  recommendation: "Deprescribir en cualquier caso",
};
    
```

Figure 5 shows an example of the information used by Mirth Connect concerning a super-rule. In this case, 3 clinical concepts can be observed. One of them must have the value “TRUE,” and the other 2 are nested, and only 1 of them must have the value “TRUE” for the recommendation to be presented.

In this way, 3 types of information are shown to health professionals: (1) recommendations on prescribing, (2) recommendations on deprescription, and (3) recommendations that have not been implemented due to a lack of information.

To check that the rules have been executed correctly, each recommendation contains a drop-down list showing the assumptions that have been taken into account to execute the rule. Additionally, health professionals are shown information on the clinical concepts and premises that have been fulfilled to execute the rule and display the recommendation, the CPG from which the recommendation has been extracted, the page

and section of the CPG where the recommendation appears, and the level of evidence of the recommendation.

Moreover, for those rules that are not executed due to a lack of information, the CDSS simulates the result that would be generated if that value had been completed, fulfilling the premise and not fulfilling it. In this way, the tool analyzes whether the result would be affected by fulfilling these 2 hypotheses, and the rule would be executed.

Figure 5. Super-rule.

```

"rule-0": {
  id: "rule-0",
  logicalType: "AND",
  type: "rule",

Clinical Validation

For patient recruitment and subsequent clinical validation, a number of inclusion criteria were defined: 65 years old or older, polypharmacy (5 or more drugs daily [7]), multimorbidity (with at least 2 chronic diseases or comorbidities in the multimorbidity classification [4]), with atrial fibrillation, and undergoing oral anticoagulants treatment. Meanwhile, the exclusion criterion was as follows: patients at the end of life with a short-term prognosis of less than six 6 months.

Results

Once the PITeS-TiSS tool was designed and developed, 2 different tasks were carried out to test the functioning of the tool. First, retrospective data from a real patient who met the inclusion criteria were used. Second, the analysis of an adoption model was performed through the study of the requirements and characteristics that a CDSS must meet in order to be well accepted and used by health professionals.

Functional Validation

For the functional validation, a patient was identified from the Camas Health Center in Seville, Spain, who met the inclusion criteria.

After this, the process of extracting knowledge from the EHR and generating personalized recommendations was carried out. This process of extracting clinical information consisted of 3 phases: (1) In the first stage, patient's identification data were included in the ITCBio platform; once the patient was included, the ITCBio platform extracted the information on hospitalizations, prescriptions, and other patient data useful for the study. (2) In the second stage, the tool had not been tested in a real environment, and retrospective data were used for functional validation; these data were extracted from the EHR of the patient chosen by a clinical researcher (ERV) and entered

into the PITeS-TiSS tool; this was obtained from the date on which the patient was diagnosed with atrial fibrillation and prescribed medication. (3) In the third phase, based on the data entered into the PITeS-TiSS tool, the rules whose assumptions were met were executed, and personalized recommendations on the prescription of medicines were generated.

As seen in [Textbox 1](#), patient 0 meets the first, third, and fourth inclusion criteria, as he is over 65 years old, has multimorbidity, and has been diagnosed with atrial fibrillation.

He also met the inclusion criteria related to polypharmacy and prescription anticoagulants ([Textbox 2](#)).

Once this patient's information was entered into the PITeS-TiSS tool, including the results of the Pfeiffer Questionnaire, PROFUND Index, and CHA₂DS₂-VASc (congestive heart failure, hypertension, age ≥ 75 years, diabetes, stroke, vascular disease, age 65 to 74 years, and sex category), 9 personalized recommendations were displayed ([Textbox 3](#)).

For each recommendation shown for this clinical case ([Textbox 3](#)), the following assumptions have been met: recommendation 1, the patient has atrial fibrillation and is prescribed a vitamin k antagonist; recommendation 2, the patient has atrial fibrillation and is prescribed antiaggregants and oral anticoagulants; recommendation 3, the patient has atrial fibrillation; recommendation 4, the patient has atrial fibrillation and arterial hypertension and is prescribed oral anticoagulants; recommendation 5, the patient has atrial fibrillation and is prescribed oral anticoagulants; recommendation 6, the patient has atrial fibrillation and is prescribed oral anticoagulants; recommendation 7, the patient has atrial fibrillation and is prescribed oral anticoagulants; recommendation 8, the patient is prescribed a vitamin k antagonist; recommendation 9: the patient has atrial fibrillation and is prescribed antiaggregants and oral anticoagulants.

Textbox 1. Patient 0.

<p>Patient 0</p> <p>Gender: Male</p> <p>Age: 70 years</p> <p>Pathologies:</p> <ul style="list-style-type: none"> • Dyslipidemia • Obesity • Arterial hypertension • Diabetes Mellitus 2 • Atrial fibrillation • Asthma • Chronic obstructive pulmonary disease • Mild nonproliferative retinopathy • Prostatic adenocarcinoma.
--

Textbox 2. Prescribed drugs.**Prescribed drugs**

- Treatment for type 2 diabetes mellitus: rapid and mixed insulin and metformin
- Treatment for arterial hypertension: irbesartan, hydrochlorothiazide and amlodipine
- Analgesic treatment with paracetamol
- Treatment for prostate cancer with decapeptyl, tamsulosin hydrochloride, and bicalutamide
- Antiaggregant treatment with acetylsalicylic acid
- Anticoagulant treatment with aldocumar
- Lipid-lowering treatment with atorvastatin
- Omeprazole stomach protector

Textbox 3. Personalized recommendations for patient 0.**Personalized recommendations displayed by the PITeS-TIiSS tool**

1. “It is recommended to keep the therapeutic range time (TRT) as high as possible.”
2. “It is recommended to avoid the combination of antiaggregants and anticoagulants if there is no other indication for platelet inhibition.”
3. “Antiplatelet therapy in monotherapy is not recommended for the prevention of stroke in patients with atrial fibrillation.”
4. “Blood pressure should be monitored closely in this patient.”
5. “Moderate alcohol consumption is recommended, as there is a risk of bleeding.”
6. “It is recommended that renal function be evaluated once a year.”
7. “It is recommended to thoroughly review the prescription, eliminating drugs that may cause bleeding and shortening prescription times.”
8. “It is recommended to reduce the dose of vitamin K antagonists if the patient is taking amiodarone.”
9. “It is recommended to deprescribe ASA [acetylsalicylic acid] as it is of no benefit.”

Following the retrospective validation of the tool, a health professional from a primary care center performed a thorough analysis of the results.

First, the health professional reviewed the EHR of the selected patient and checked that the data entered in the PITeS-TIiSS tool were correct.

Subsequently, the recommendations displayed for this patient were reviewed. As indicated in the section on the development methodology of the tool, the assumptions that execute each rule and show each recommendation can be checked by reviewing a drop-down that shows them.

After reviewing the assumptions, the health professional reviewed the displayed recommendations and the additional information in the CPGs that support each recommendation.

The health professional concluded that she would comply with all the recommendations provided.

Adoption Model

Taking into account the analysis of the needs that a CDSS must meet to be well accepted that was carried out in the Introduction section, an adoption model was designed, consisting of an analysis of the 8 requirements that the PITeS-TIiSS tool must meet and how it can do so:

1. Health professionals need to understand the basis and reasons why the CDSS makes the relevant recommendations: the tool

provides below each recommendation the premises fulfilled for that recommendation to be displayed. Thus, the health professional can quickly recognize which items are related to each recommendation and why it is displayed.

2. CDSS should be intuitive and easy to use (usability). For the design and development of the PITeS-TIiSS tool, the ISO 13407:1999 standard has been followed. Human-centered design processes are required for interactive systems, as this complies with the 4 following principles of user-centered design contemplated in this standard: (1) active involvement of users as specified in point 5; (2) appropriate assignment of roles to the PITeS-TIiSS tool and the user—different roles have been established to access other tool modules, such as the developer role and health professional role; (3) iterative design solutions—during the tool's design and development stage, meetings were held between the development team and the health professionals to achieve a tool adapted to their needs, and the rules were also revalidated by presenting different clinical cases in these meetings; (4) multidisciplinary design—the PITeS-TIiSS tool has been designed and developed by technical developers and clinical informatics researchers (JMC, JARG, GAER, ERV, and CAR) who have provides their clinical and informatics vision.

3. The CDSS should support the health professional and offer advice while respecting his or her experience and knowledge: the PITeS-TIiSS tool's recommendations are not presented as mandatory. In the interface where the recommendations are

displayed, the health professional can indicate which rules will be followed and which rules are considered not to be followed. In turn, the health professional can justify why he or she has decided not to follow a specific recommendation. The latter allows the CPGs to be compared with actual clinical practice and to include changes in the CPGs that can improve clinical practice.

4. Recommendations should be evidence-based and provide resources to review the validity of these recommendations: in this case, the PITEs-TIiS tool offers the option of displaying in a PDF format the reasons why the recommendation has been shown. It shows the clinical concepts, the premises that have been met, the CPG from which this information has been extracted, the text in which the recommendation is found, the page and section where the recommendation is located, and the level of evidence of the recommendation.

5. The CDSS should be user-centered, taking into account the user's needs. Numerous meetings were held with the team of hospital and primary care health professionals throughout the design and development process. In these meetings, in addition to validating the content of the rules and recommendations, the health professionals' needs in terms of the development of the tool's interface were taken into account.

6. Fatigue-inducing alerts should be minimized. The PITEs-TIiSS tool does not display alerts or pop-up windows. Once the workflow has been completed and all the necessary patient information has been entered, the tool displays the personalized and justified recommendations.

7. All team members and workflow should be included in the tool's use. In this case, the PITEs-TIiSS tool focuses on health professionals—mainly internists, primary care physicians, and nurses.

8. Health professionals should be encouraged to use the tool. This feature is mainly about facilitating health professionals' work. It focuses on the need for a CDSS to connect to the EHR and primarily share information. The PITEs-TIiSS tool does not have a connection to the EHR. However, in the new Smart-PITEs project grant (#PI18/00700; Learning Health System for the Integrated Care and Adherence Management of Complex Chronic Patients), which is a continuation of the PITEs-TIiSS project, it is intended to connect with the EHR.

Discussion

Principal Findings

A personalized ontology-based CDSS called PITEs-TIiSS tool was designed and developed. A first functional validation was carried out to test and evaluate the proper functioning of this tool. A basic model for adopting the technology was designed by analyzing the needs of a CDSS to encourage its successful adoption in the health care field. These needs were extracted from different scientific publications that deal with this subject in-depth and have been added as references in this paper in the Introduction section.

The PITEs-TIiSS project is the third phase of a network of collaborative research projects whose overall objective is to

provide a secure, open, and interoperable digital ecosystem to facilitate the design, development, validation, and implementation of telehealth service innovations. Specifically, this third phase aims to incorporate advanced semantic interoperability and clinical decision support tools into clinical practice to provide integrated and personalized care to CCPs.

Concerning functional validation, the results have been favorable and allow the research proposed for the fourth phase of this network of research collaboratives projects, called Smart-PITEs, to continue.

Moreover, a new front is emerging concerning different CPGs. This is because there may be inconsistencies between each CPG's recommendations, and, thanks to the information provided by health professionals on the reasons why they choose not to follow a specific recommendation, changes in the CPGs based on health care can be considered.

Limitations

Although the research results are favorable, we intend to address several limitations during the completion of the Smart-PITEs project. Regarding the knowledge bases, those used to design the decision rules are those most commonly used in the VRUH health care area. It may happen that, in any other health care area, other CPGs are used. However, the established methodology can be applied to the design of new decision rules.

Due to many existing drugs and pathologies, to facilitate development and clinical validation, it was decided to study a specific scenario. In this case, it was CCPs with atrial fibrillation and prescribed oral anticoagulants. However, it is necessary to broaden the study of pathologies and drugs to provide real integrated care. In addition, the validation was carried out with a single clinical case, which does not conclusively ensure that the tool works correctly. Moreover, the validation of the PITEs-TIiSS tool was carried out with retrospective data. However, this potential limitation to prospective validation is expected to be addressed by the Smart-PITEs project currently underway and continuing this research approach. Finally, a lack of integration with the EHR has been identified, which means that one of the needs for the successful adoption of the health care field tool is not being met. One of the objectives of the Smart-PITEs project is to remedy this limitation.

Comparison With Prior Work

CDSS are useful tools for clinical practice. This is why there is a wide variety of proposals for such tools.

In Velickovski et al's [35] work in the field of CDSS for CCPs, they propose a CDSS focused on diagnosis and prevention in patients with chronic obstructive pulmonary disease. However, in this research, they did not use ontology as information modeling. Furthermore, they focused on a single pathology. Böttiger et al [36] also did not use ontology for the development of their CDSS. Instead, they focused on preventing and avoiding drug-drug interactions and adverse effects. Zhang et al [37] did use ontology as the main element of development. Their proposal focused on the diagnosis, assessment, and treatment of patients with type 2 diabetes mellitus. The difference between this proposal and the PITEs-TIiSS tool is that the first focuses

on a single chronic disease, while the proposed tool aims to address numerous chronic pathologies. Beyond this, PITeS-TiSS reports the assumptions that have been met for the personalized recommendations to be displayed. Konaté et al [22] proposed the development of a decision support system using an ontology. However, the field of development was not health care. The CDSSs proposed by Chen et al [38] and Madhusanka et al [39] were also based on an ontology. However, they again focused on a single pathology, such as type 2 diabetes mellitus 2. Bouaud et al [40] also proposed a CDSS and relied on an ontology for development. In this case, the researchers focused only on primary breast cancer patients. Finally, Miñarro-Giménez et al [41] developed an ontology-based CDSS focused on decision support for health professionals by providing pharmacological data to both

professionals and patients. This tool is specifically focused on patients with genetic disorders to prevent adverse reactions or drug interactions in these patients. They concluded that this tool could be useful for personalized medicine.

Conclusions

An ontology-based CDSS was successfully designed, developed, and validated. However, it has only been validated with retrospective information from 1 case study, so a more robust validation would be necessary to ensure that the tool is usable and reliable.

The next phase, the Smart-PITeS project, aims to overcome the limitations found in this project and also to ensure that the tool performs automatic learning and predictive models in relation to care and adherence to treatment of CCPs.

Acknowledgments

This research was partly funded by the Innovation in Medical Technologies and Health (ITEMAS; platform for the dynamization and innovation of the industrial capacities of the National Health System) platform (code #PT13/0006/0036 and #PT17/0005/0036) and by the PITeS-TiSS project (code #PI15/01213) and Smart-PITeS project (code #PI18/00700) from the Carlos III National Health Institute, both cofunded by the European Regional Development Fund (ERDF). We would like to thank Dr Rosario Villarán Martínez for the help during the validation phase of the PITeS-TiSS tool.

Abstract

Background: Pathways to mental health services for youth are generally complex and often involve numerous contact points and lengthy delays. When starting treatment, there are a host of barriers that contribute to low rates of therapeutic engagement. Automated text messages offer a convenient, low-cost option for information sharing and skill building, and they can potentially activate positive behaviors in youth and caregivers prior to beginning formal therapy. To date, there is little evidence for the feasibility of initiating transdiagnostic text messages during the early stages of youth and caregiver contact with community outpatient mental health services.

Objective: To develop and test the feasibility of implementing 2 novel text messaging campaigns aimed at youth clients and their caregivers during the early stages of engaging with outpatient mental health services.

Methods: A multidisciplinary panel of experts developed two 12-message interventions with youth and caregivers prior to deployment. Each message included a link to an external interactive or multimedia resource to extend skill development. Enrollment of youth aged 13 to 18 years, their caregivers, or both occurred at 2 early treatment timepoints. At both time points, text messages were delivered automatically 2 times a week for 6 weeks. Analytics and survey data were collected in 2 phases, between January and March 2020 and between January and May 2021. Enrollment, willingness to persist in using the intervention, engagement, satisfaction, perceived value, and impact were measured. Descriptive statistics were used to summarize youth and caregiver outcomes.

Results: A total of 41 caregivers and 36 youth consented to participate. Follow-up survey response rates were 54% (22/41) and 44%, (16/36) respectively. Over 1500 text messages were sent throughout the study. More than three-quarters (14/16, 88%) of youth reported that they learned something new and noticed a change in themselves due to receiving the texts; the same proportion (14/16, 88%) of youth said they would recommend the text messages to others. Youth ranked the first text message, related to coping with difficult emotions, as the most helpful of the series. Caregivers reported acting differently due to receiving the texts. Over two-thirds of caregivers were satisfied with the texts (16/22, 73%) and would recommend them to others (16/22, 73%). Caregivers perceived diverse levels of value in the text topics, with 9 of the 12 caregiver texts rated by at least one caregiver as the most helpful.

Conclusions: Results are preliminary but show that brief, core skill-focused text messages for youth clients and caregivers in community outpatient mental health services are feasible. Both youth and caregivers reported promising knowledge and behavior change with exposure to only 12 messages over 6 weeks. A larger study with statistical power to detect changes in both perceived helpfulness and engagement is required to confirm the effectiveness of this type of transdiagnostic intervention.

Introduction

Successfully addressing the mental health concerns of youth depends not only on timely help-seeking behavior, but also on a rapid and appropriate response by the mental health system [1,2]. Pathways to mental health services for youth are generally complex and often involve numerous contact points and delays [3]. Initial assessment does not guarantee referral to treatment, and many of those referred do not attend their first scheduled appointment [4]. It is increasingly clear that planned early interventions across initial system contact points, including preclinical contact, can help avoid downstream negative impacts (ie, worsening symptoms, lower treatment satisfaction, and no-shows) and build momentum for sustained engagement [5-7]. Even a single early destigmatizing experience may be sufficient to promote future help-seeking behavior in youth and even delay illness progression [8].

Transforming reluctance into investment in treatment requires establishing mutual understanding among clinicians, youth, and their caregivers about the purpose, goals, and actions needed by all involved for positive change in the client's life [9]. With a growing body of literature showing that the constituent "practice elements" of evidence-based interventions can be relevant to a wide variety of child and youth mental health conditions (ie, they are not restricted to treatments for a specific type of problem or disorder) [10-13], there is an opportunity to automate universal low-intensity supports and make them part of routine service initiation pathways. Socializing youth and caregivers to help them learn transdiagnostic skills that target core-skill mechanisms (eg, strategies for emotional regulation, skills for dealing with positive and negative valence systems, problem solving, sleep regulation, self-identity, and communication skills) [14] could have significant positive individual and system level outcomes [15].

A recent scoping review of youth and family engagement research found that facilitating early access to complementary and digital mental health services is particularly desirable when wait times cannot be avoided, or when community conditions and geographic constraints prohibit routine engagement with outpatient services [16]. Short messaging service (SMS) or text messages offer a convenient, low-cost communication channel with which to establish connections with youth and their caregivers and activate transdiagnostic mental wellness strategies and skills. A scoping review by our team [17] showed that text messaging interventions are now used in many areas of child and youth mental health, including mild to moderate anxiety [18], bipolar disorder [19], appointment reminders [20], medication adherence [21], and mood disorders [22].

The literature shows high rates of acceptability among youth [23,24], with only a small percentage of users unsubscribing from therapeutic text messages [25] when given the opportunity.

Thematic analysis of interviews with youth who presented to the emergency department for mental health treatment indicated that cognitive behavioral therapy-based messages resonated with them, as did emotional regulation messages [26]. In some instances, text message interventions have led to significant behavior change [27] and a decrease in symptoms [28]. Exploring the feasibility of using text messages to deliver transdiagnostic supportive messages to both caregivers and youth during early interactions with outpatient services is a novel contribution to this evolving field.

The intention of this study was to develop and assess a text messaging campaign to engage youth clients and their caregivers while initiating outpatient service pathways. Through sharing tips, self-care ideas, and skill-building strategies and promoting new behaviors, the text messages were viewed as an opportunity to empower youth and caregivers to activate self-management skills prior to initiation of formal therapy.

The specific questions guiding the study were: (1) How many youth clients and caregivers want to receive text messages to support their general wellness when initially offered? (2) Once signed up to receive the text messages, do youth or caregiver clients choose to stop receiving text messages? (3) Which topics or types of resources being communicated through text messages are youth and caregivers most interested in? (4) In what ways do youth and caregivers feel that the text messages are or are not helpful in supporting behavioral change and in preparing them for their next appointment?

Methods

Study Design

A multimethod, descriptive research design was used for formative feasibility testing. Web analytics and survey data were collected in 2 phases between January 2020 and May 2021.

Text Message Development

The text message intervention was informed by an earlier cross-sector knowledge mobilization project involving several of the authors. That project sought to address local gaps in youth mental health supports using technologies such as text messaging [29]. In particular, the intervention aimed to focus on patient activation, which was defined as creating a common language for patients to share their concerns with health care providers; to learn about their condition to enable informed future decisions about treatment; to set expectations that they would take an active role in their own care; and to learn basic coping skills to manage symptoms [30]. Development and deployment of the text message intervention for youth and caregivers occurred in 5 steps, described in the following sections.

Step 1

Prioritization of content for the text messages was identified through the results of the team's scoping review [17] and a team activity completed by community mental health and addictions team clinicians at IWK Health. Clinicians were asked to come up with a list of the most important core skills in working with local clients and families. To the degree that a given skill or activity (eg, relaxation techniques, facing fears, and sleep hygiene) targeted multiple disorders (eg, anxiety, depression, and conduct problems) the text messages were viewed as potentially transdiagnostic.

Step 2

A panel was created with 5 members who had a broad range of expertise, including clinical psychology, psychotherapeutic competencies, behavior change, digital health, and implementation science. The panel achieved early consensus on several key aspects of the text message interventions to be created: (1) include a web link to an outside resource for each text message topic, (2) minimize the burden on users by presenting a brief and engaging topical prompt for each text message, and (3) establish a time-limited messaging period with no more than twice-weekly messages being sent.

Step 3

Taking the list of important core skills identified in step 1, the panel engaged in a collaborative process to draft prototype versions of the text message intervention for youth and

caregivers. The panel aimed to create messages appropriate for a broad spectrum of individual youth and caregiver experiences and needs. Each text message contained a short topical statement and a link to a further resource to deepen understanding, build skills, or reinforce concepts through interactive multimedia. The linked resources were all publicly available online and were vetted by the panel for clinical and developmental appropriateness and to ensure a variety of modalities (ie, not all videos or not all PDFs). Many of the links were resources familiar to clinicians on the team and already in use as informational resources that youth and caregivers might be directed to as part of treatment sessions.

Step 4

Drafts of the text messages and links were checked for face validity with 6 youth and 5 caregivers. The testers suggested rewording, deleting some proposed content areas, noted links that they did not like, and suggested resources and links. Each tester also ranked a series of text message topics to determine which 12 topics were the most salient to them. Feedback was incorporated, and the final list of messages was completed (Table 1). Examples of the text messages included: (1) (for teens) "Sometimes it feels good to let your feelings out. But don't let yourself get overwhelmed by the ones you don't want, like fear and rejection. Learning to control feelings can help a lot. Here's some ideas on how to do that" and (2) (for caregivers) "Is your teen's fear controlling your family? When worry starts to take control you need to coach your teen to face it: one step at a time."

Table 1. Youth and caregiver message themes and description of resources.

Message number	Topic	Linked resources for youth	Linked resources for caregivers
1	Difficult emotions	Animated YouTube video about anxiety	Animated YouTube video about empathy
2	Facing fears	Handout on building a plan to face your fears	Activity on how to build a fear ladder

11	Values	Animated YouTube video on finding your own happiness	Animated YouTube video on finding your own happiness
12	Social media	Infographic on how to hold a "digital detox"	Blog post on being a digital mentor to your teen

Step 5

The text messages were set up for automated delivery using an SMS platform (SimplyCast) [31]. The platform provided a user-friendly interface to build text message campaigns, embed study surveys, and track user engagement. SimplyCast utilizes

firewalls, cryptography, and access-control procedures to protect information from unauthorized access. SimplyCast is ISO 27001, 27017, and 27018 certified. All information within the SimplyCast platform is stored on servers located in Canada. Text messages were set up to be automatically sent out at 6:00 PM, 2 times per week (3 days apart), for 6 weeks. This time of

delivery was chosen because youth and caregivers were more likely to be out of school or work at that time, thus increasing the probability that they could engage with the linked resource. Participants could text “STOP” at any time to opt out of receiving the text messages. After the participant received their 12th therapeutic text message, a final message provided an embedded direct link to a brief web-based follow-up survey.

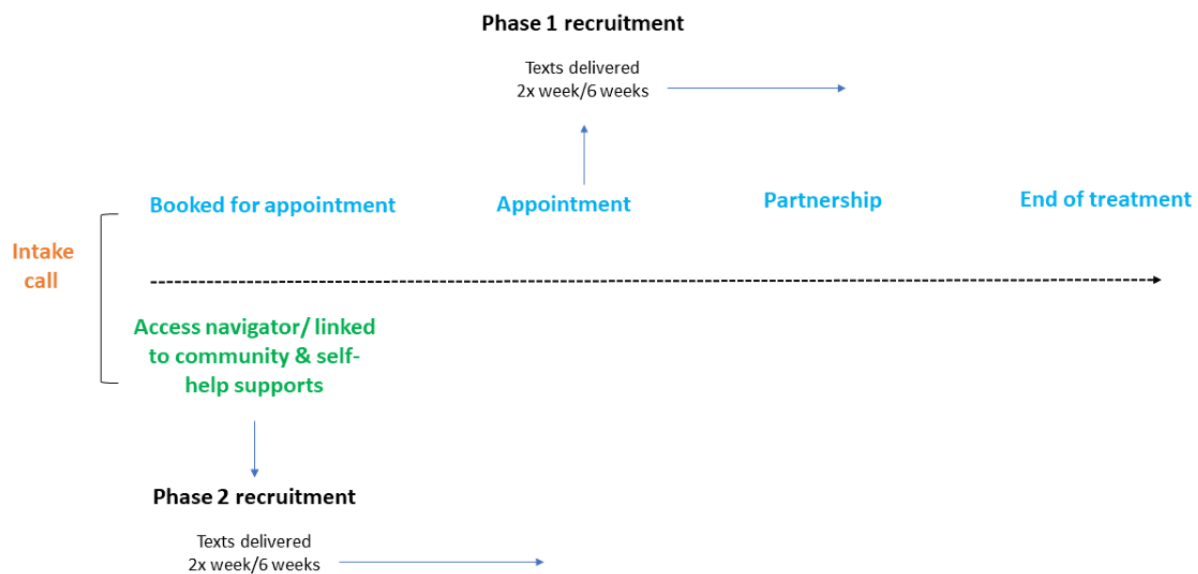

Setting

The IWK community mental health and addictions teams use the choice and partnership approach (CAPA) to outpatient child and youth mental health and addictions treatment. CAPA is a service transformation model that includes active collaboration with clients and families, lean thinking concepts, and therapeutic engagement tasks [32]. After an initial intake call, the family is either booked for a choice appointment with a clinician or receives support from an access navigator to connect directly with community resources appropriate to meet their mental wellness needs (Figure 1). The choice appointment is a time for collaboratively developing a plan with the youth, family, and clinician for next steps that could be helpful to meet their mental health goals, regardless of whether returning for clinical

treatment sessions is part of that plan. Based on the identified goals, options for next steps may include self-help information or helping the youth and family to access relevant supports within or external to the outpatient community mental health services. A fundamental stance of the CAPA way of working is to value the expertise of the youth and family and engage them in actively participating in goal setting and decision-making. Administrative data from 2019 show that approximately 1987 youth were referred for a choice appointment after their intake call that year. Youth who have mental health treatment needs are offered an opportunity to book for treatment (partnership) after the choice appointment.

The 2-phase recruitment plan for this study was partially driven by real-time data monitoring. Initially, in 2019, the wait time between the choice appointment and the partnership ranged from 15 to 76 days (Figure 1); this presented an important window, where contact via text message could help bridge the lapse in contact with outpatient clinicians. In the second phase, during the early months of 2021 (January to March) we anticipated a potential influx of referrals due to the pandemic; data showed that the wait for choice appointments ranged from 36 to 39 days.

Figure 1. Process flow diagram for text message delivery within the treatment pathway.

Population

Census data related to the IWK catchment area show that the community from which the study participants were recruited could be characterized as urban, predominantly English speaking, and White; 17% of the population are in households considered to have low incomes [33]. Participants were youth, aged 13 to 18 years, and their caregivers, who had inquired about services from the IWK community mental health and addictions program. Participants did not have to sign up as a youth-caregiver dyad, to ensure access to anyone who was interested. In this way, youth could still participate even if a caregiver did not attend the appointment. Youth clients and caregivers were eligible if they spoke English, had a cell phone, could read text messages, and were willing to receive up to 12 messages over a 6-week period.

Recruitment and Informed Consent

Recruitment occurred in 2 phases. In phase 1 (January to March 2020), clinicians described the study to families while they were facilitating a choice appointment and helped those interested to sign up while in the office, before going home. If youth came to appointments without a caregiver, only the youth was offered the service. Clients and caregivers signed up by texting a short code (ie, IWKTEEN or IWKCAREGIVER) to a specific number. Following the short code, an automated welcome text message with an embedded web-based consent form was sent. In phase 2 (January 2021 to May 2021), access navigators on the intake team described the study to the youth or caregivers at the end of their intake phone call and offered to assist those interested in signing up during the call. A welcome text message with an embedded web-based consent form was sent, as in phase 1. No remuneration was offered to those participating.

Measures

By reviewing the existing literature on outcomes associated with text messaging interventions for youth mental health [17], discussing what outcomes were of interest to local decision-makers, and aligning the outcome measures to the purpose of a pilot study (ie, to identify potential effects and associations to explore in a larger study) we selected a range of exploratory engagement, impact, and satisfaction measures.

Uptake

In phase 1 only, clinicians in 3 outpatient clinics tracked the number of youth and caregivers who were offered and subsequently enrolled in the text messaging service. We calculated the percentage of those who accepted as a preliminary measure of uptake.

Willingness to Use the Service

In addition to the data tracked about participant recruitment and enrollment, we tracked instances when participants did not desire to continue using the service. Dropouts (ie, those who texted “STOP”) were recorded.

Engagement

To measure engagement with the text messages, we calculated the total overall number of times each link within a message was clicked or relicked.

Satisfaction

A 10-item follow-up survey was used that included 2 satisfaction questions. A global measure was ascertained by asking users to rate their level of satisfaction with the text messages on a 5-point Likert scale: “very dissatisfied,” “slightly dissatisfied,” “neutral,” “slightly satisfied,” and “very satisfied” (item # 1). A second question asked about satisfaction with the text message frequency (item #2).

Value

Four survey questions assessed perceived value. A global measure was assessed by asking users to rate the text message intervention on a 5-point Likert scale of helpfulness: “not helpful at all,” “somewhat helpful,” “neutral,” “helpful,” and “very helpful” (item #3). In addition, participants were asked to identify which 1 of the 12 text messages was the most helpful (item #4) and which was the least helpful (item #5). One additional question asked respondents if they would recommend the text messages to someone they knew (item #7).

Impact

Four questions on the survey measured impact. One asked about changes in knowledge; in other words, if the user learned anything from receiving the text messages (item # 8). Another asked if the user found themselves acting differently or changing their behavior after receiving the text messages (item #9) or noticed any changes in themselves as a result of receiving the text messages (item #6). Lastly, during phase 1, we asked the users if the text messages helped ready them for their next step

in the therapeutic pathway (ie, attending their partnership appointment) (item #10).

Analysis

As the underlying parameters of the interventions were the same across recruitment phases (same messages, delivery schedule, and links), data from both phases of recruitment were pooled. Descriptive statistics appropriate for the level of measurement were conducted using Jeffrey’s Amazing Statistics Program (JASP) [34]. Frequency counts and percentages were used to summarize the results. Graphs were used to examine engagement over time.

Ethics Approval

Institutional review board approval was obtained from the IWK Health Research Ethics Board (1024462) and all participants provided informed consent.

Results

Across both phases of recruitment, a total of 41 caregivers and 36 youth consented to participate. Of the 77 users enrolled, 54% (22/41) of caregivers and 44% (16/36) of youth completed the post-study survey. Over 1500 text messages were sent in total during the study.

Uptake and Willingness

Enrollment data during phase 1 showed that 63% (33/52) of youth approached about the study in the clinics agreed to participate. Reported reasons for declining included not being interested (7/19, 37%), not having a data plan or a cell phone (5/19, 26%), and caregivers not providing consent for participation (1/19, 5%). Reasons were not provided by 32% (6/19) of youth who declined. Among caregivers approached, 78% (29/37) agreed to participate in the study. Only 2 caregivers gave reasons for declining: one was not interested, and one did not have a data plan. Willingness to use the text service was 97% (75/77), with only 2 participants texting “STOP” before the end of the 6-week intervention period.

Engagement and Satisfaction

Overall, youth and caregivers opened links to resources and supports 551 times. Figure 2 shows the text message links clicked the most by youth, which were related to coping with difficult emotions (49 clicks; text message #1) and facing fears (34 clicks; text message #2). The linked resources clicked the most overall by caregivers were related to coping with difficult emotions (34 clicks; text message #1) and facing fears (26 clicks; text message #2). Overall, satisfaction with the text messages was positive, with 75% (12/16) of youth and 73% (16/22) of caregivers reporting they were “very satisfied” or “slightly satisfied” (Table 2). Message frequency was highly satisfactory for both groups, with 81% (13/16) of youth and 86% (19/22) of caregivers saying that 2 messages a week worked well. Of the 16 youth, 2 (13%) thought it would have been better to receive more than 2 text messages a week.

Figure 2. Total number of text message clicks by youth and caregivers across topics.

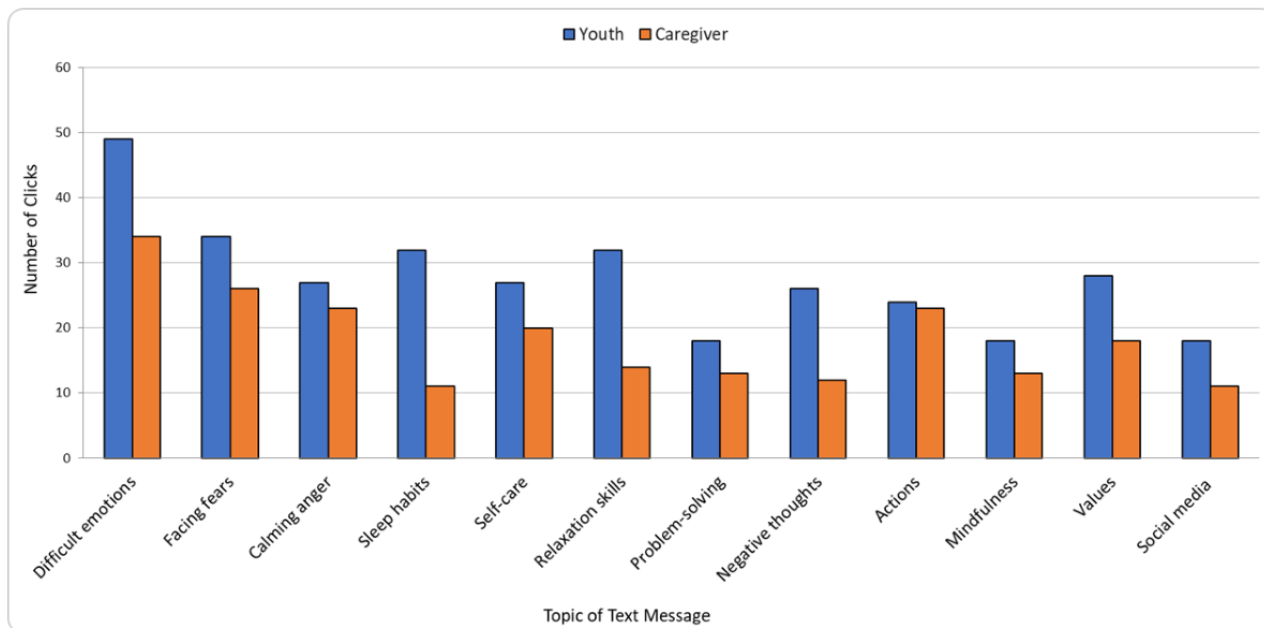

Table 2. Comparison of youth and caregiver experiences with text messages.

Survey item	Number of responses by youth (N=16), n (%)	Number of responses by caregivers (N=22), n (%)
Satisfaction

Value and Impact

Among youth completing the follow-up survey, 50% (8/16) indicated that the most helpful text message was the one related to coping with difficult emotions (text message #1). Three text messages were identified as the least helpful: healthy use of

social media (4/16, 25%; text message #12), facing fears (4/16, 25%; text message #2), and personal values (4/16, 25%; text message #11). Fifty-six percent (9/16) of youth said the messages were “helpful” or “slightly helpful,” with an additional 44% (7/16) reporting a neutral response on helpfulness (Table 2). At the same time, 94% (15/16) of youth noticed at least some

degree of change since receiving the text messages; 88% (14/16) indicated they had learned something new from the text messages, and 88% (14/16) would recommend it to someone they knew. Only one youth (1/16) provided an example when prompted to describe what they found themselves doing differently. The youth wrote “I was being more aware of myself and others. The timing of the text messages and my current life lined up exactly.”

Among caregivers completing the follow-up survey, there was less consensus as to the most helpful message. Nine of the 12 caregiver text messages were rated by at least one caregiver as the most helpful. The message focused on coping with difficult emotions (text message #1) was rated as the most helpful by 18% (4/22) of caregivers. The least helpful text messages, according to caregivers, were the ones about healthy social media use (6/22; 27%; text message #12) and sleep hygiene (4/22; 18%, text message #4). Among caregivers, 45% (10/22) reported acting differently since receiving the text messages, 63% (14/22) noticed at least some degree of change in themselves, and 63% (14/22) indicated they had learned something new from the text messages. When prompted to provide examples of the observed changes since receiving the text messages, caregivers pointed to a range of impacts. For example, “having more engaging conversations” with their teen, “keeping even tones when having difficult discussions,” “processing negative thoughts differently,” “managing anger,” and learning to “take a break from the conflict.” Seventy-three percent of caregivers (16/22) indicated they would recommend the text messages to people they knew. No youth or caregiver reported that the text messages were “very helpful,” but conversely, no youth or caregiver reported that the messages were “not helpful at all.”

When asked if the text messages had helped them feel ready for the next step in their treatment journey, 44% (7/16) of youth answered “yes,” and an additional 44% (7/16) answered “maybe.” Twenty-three percent of caregivers (5/22) said the text messages had helped them feel ready for their youth’s next step in the treatment journey, and 32% (7/22) answered “maybe.”

Discussion

Principal Findings

The intention of this pilot study was to develop and assess the feasibility of delivering a novel text-message campaign to engage youth clients and their caregivers during early stages of the mental health treatment pathway. As pilot testing is an almost essential prerequisite for a full-scale controlled study, this study helped test methods, learn more about the sample population, investigate recruitment strategies, and identify potential effects and associations that should be explored in a larger study [35].

Unlike other text-message interventions that have targeted a single clinical subpopulation (eg, those experiencing early psychosis) or desired behavior (eg, medication adherence), this study focused on transdiagnostic mental wellness and patient activation strategies for both youth and their caregivers. Our

results suggest that for youth and caregivers new to outpatient mental health care and who are interested in gaining insights into mental wellness skills and strategies, a brief, time-limited text message intervention may be viable. These results bolster ongoing efforts to distill and integrate core mental wellness strategies that may be helpful across a variety of clinical conditions [36]. Theorizing about why certain text messages or linked resources were engaged with more than others was outside the scope of this pilot study but will be an important direction for future research to optimize and tailor the intervention to the needs and interests of the population. In the future, other avenues (eg, social media) for promoting and introducing transdiagnostic strategies, skills, and techniques could be explored.

The major finding of this study was that most youth and caregivers reported experiencing positive knowledge and personal change because of the intervention and found the text messages satisfactory. Enrollment rates and willingness to use the intervention were consistent with other text-messaging studies [37,38]. More than two-thirds of the youth (14/16, 88%) answered “yes” to questions asking if they learned something new from receiving the text messages, noticed a change due to receiving the text messages, and would recommend the text messages to others. Almost half (10/22, 45%) of the caregivers reported acting differently due to receiving the text messages. More than two-thirds (14/22, 63%) said they learned something new and would recommend the text messages to others. For a low-intensity intervention, these are not inconsequential real-life impacts. However, considerable work remains in the field of text-message interventions in general to refine and validate outcome measures that are sufficiently sensitive to changes (long-term and short-term) resulting from microinterventions like the brief series of text messages used here. Considering the minimal human resources required to deliver the automated services and the range of real-world changes participants reported (eg, managing anger better and having more engaging conversations between youth and caregivers), there is a significant opportunity to refine the intervention, refine the outcomes of interest, and leverage this modality in routine outpatient pathways in the future. Future research could examine whether early text-message support helps socialize youth and caregivers moving on to formal psychotherapy to the fact that therapeutic treatment requires active practice and application of skills, as opposed to something they passively receive. Text messages could even be trialed with individuals looking at e-mental health options online who choose not to enter the mental health system at that time.

Our findings may serve as a caution to future developers to avoid oversaturating youth and caregivers with too-frequent text messages. Two text messages a week over 6 weeks, a relatively brief campaign, was described as “timing worked for me” by 81% (13/16) of youth and 86% (19/22) of caregivers. The considerable variation in text messages identified as most and least useful suggests that technological capabilities would be useful to allow greater tailoring based on end-user preferences and concerns. While this study leveraged preexisting free online content, there could be advantages to cocreating locally relevant content that aligns with and reflects the preferences of the local

community. Additionally, as we observed some downward trends in engagement over time, future studies could compare the order of the messages and the timing of delivery as features that could be optimized to promote ongoing engagement.

An unexpected finding, to be interpreted with caution given the small sample size, was that 45% of caregivers felt the text messages were not helpful for getting them ready for the next step of treatment. This may be because caregivers do not always perceive themselves to be part of the treatment and instead focus on their youth as the primary client. Caregivers may not have viewed their role in a mental health treatment journey as vital or something they needed to prepare for. It is also important to note that we did not measure which youth or caregivers would be coming back for further treatment (partnership appointments) and which had collaboratively decided that no further treatment was needed after the choice appointment. Future work could explore caregivers' expectations of treatment pathways and how text messages could support transitions or further socialize caregivers to their vital role in the treatment success of youth. Collecting and analyzing data in caregiver-youth dyads could also help uncover important effects, interactions, and associations unique to particular family dynamics.

The study recruitment occurred in 2 time-limited phases during complex service and social changes due to COVID-19. It is unclear how that complexity may have impacted uptake, sense of helpfulness, views on which text messages were most valuable, or the ability of youth and caregivers to act on suggestions offered in the text messages (ie, suggested self-care strategies may have been impacted by physical distancing requirements or closures). In addition, phase 1 recruitment required clinicians to remember to introduce and enroll consenting youth and caregivers during a session. Future research may help illuminate the barriers to and enablers of clinician versus self-referral pathways and potential impacts on clinical workflow (eg, time and administration support needs).

It is also important for future research to explore the possible mediating effects of clients' personal clinicians introducing or promoting a text message intervention (phase 1) as opposed to individuals receiving a generic offer to enroll (phase 2).

Limitations

Several limitations should be mentioned. First, although our follow-up survey response rate was consistent with the mean response rate of other youth mental health studies [39,40] a larger study, with statistical power to detect changes in both helpfulness and engagement, is required to confirm the effectiveness of the intervention. The small sample size, nonexperimental design, and short follow-up period prevent conclusions about any sustained behavior changes or the detection of significant differences between youth and caregivers' usage and experiences. Second, to reduce the data entry burden on youth and caregivers, no baseline demographic data (eg, gender, symptom severity, or mental health literacy level) were collected, which limits our understanding of possible covariates. Third, youth and caregivers were sampled from an urban, community outpatient service and therefore may not represent broader youth and caregiver experiences. Finally, most outcome data were self-reported and subject to possible bias.

Conclusions

Transdiagnostic mental wellness text messages for youth clients and caregiver engagement in community outpatient treatment are feasible. Although the sample size was small, the participants who followed through with the intervention had favorable impressions and reported promising changes in knowledge and behavior. Brief, skill-focused text messages may support youth and caregivers in experimenting with new ideas that could be helpful in making changes related to their mental health as a possible first step in community outpatient mental health services.

Acknowledgments

SJ received a small, short-term reduction in clinical workload from IWK Health to support coordinating the research. We wish to thank Sylvie Euale for contributions to study planning and administration.

Abstract

Background: COVID-19 restrictions severely curtailed empirical endeavors that involved in-person interaction, such as usability testing sessions for technology development. Researchers and developers found themselves using web-based moderation for usability testing. Skilled remote moderators and observers are fundamental in this approach. However, to date, more empirical work is needed that captures the perceptions and support needs of moderators and observers in testing situations.

Objective: The aim of this paper was to identify remote moderator and observer participant experiences and their use of certain tools to capture feedback of users as they interact with the web browser application.

Methods: This research is part of a broader study on an educational web browser application for nursing students to learn perspective taking and enhance their perceptual understanding of a dialogue partner's thoughts and feelings. The broader study used a quantitative and think-aloud qualitative problem-discovery usability study design. This case study explored written accounts of the remote moderator and observer participants regarding their roles, experiences, and reactions to the testing protocol and their suggestions for improved techniques and strategies for conducting remote usability testing. Content analysis was used to analyze participants' experiences in the usability testing sessions.

Results: We collected data from 1 remote moderator and 2 remote observers. Five themes were identified: dealing with personal stressors, dealing with user anxiety, maintaining social presence, ethical response to the study protocol, and communication during sessions. The participants offered recommendations for the design of future remote testing activities as well as evidence-informed training materials for usability project personnel.

Conclusions: This study's findings contribute to a growing body of endeavors to understand human-computer interaction and its impact on remote moderator and observer roles. As technology rapidly advances, more remote usability testing will occur where the knowledge gleaned in this study can have an impact. Recommendations based on moderator and observer participant perspectives identify the need for more evidence-informed training materials for their roles that focus on web-based interpersonal communication skills, execution of user testing protocols, troubleshooting technology and test user issues, proficiency in web conferencing platforms, behavior analysis and feedback technologies, and time management.

Introduction

Background

Moving Toward Remote Usability Testing

Usability testing is a fundamental step for evaluating and developing quality technologies, products, or services [1]. Usability testing involves the systematic evaluation of how effective, efficient, and satisfactory a product or service is when a user interacts with it [2]. This testing helps developers identify and refine the product or service before full-scale uptake by potential future users or implementation in the marketplace. Since the COVID-19 pandemic, in-person testing sessions for technology development have been curtailed. Remote usability testing has become the default approach to maintain advancements in technology evaluation or research [3]. Many system developers, usability personnel, and researchers have resorted to web-based moderation for remote usability testing, which is the focal context of this paper.

Remote usability testing was introduced 20 years ago as a means of conducting usability assessments of participants or users who were in separate locations or separated by time from the researchers or practitioners [4,5]. Since that time, a range of web conferencing platforms have emerged, and an array of features and functions are now available that can advance remote usability testing (eg, Microsoft Teams, Zoom, Skype, and Cisco Webex). Hill et al [5] provided an overview of the different types of remote usability testing methods and a summary of key findings about their use with users. Across these different methods, skilled remote moderators and observers are essential.

The literature on remote usability testing is evolving in an emerging field [5]. Gaps in knowledge still exist regarding the method. Wozney et al [6] were among the first authors to highlight the empirical gap in the influence of moderators and observers on remote web-based usability testing. The empirical literature has instead tended to focus on the feasibility, logistics, and pros and cons of the method. The rapid review of studies by Hill et al [5] found benefits to remote usability testing, such as facility attendance not being required and being more convenient and affordable for research personnel and participant users, the ability to more easily recruit a broad and diverse participant sample, and the opportunity to use technology more realistically in the participant user's own environment. The disadvantages were the loss of contextual information, challenges in detecting nonverbal cues, and dealing with technology network issues [5]. Other factors that can influence the efficiency, validity, and reliability of remote usability testing and are difficult to control include user characteristics, internet speed, devices used, pace of the testing session, technical skills of participant users, and unforeseeable disruptions or interruptions [5].

Of note, Molich et al [7] explained that best practices or guidelines for remote moderation and observation are often derived from experiential evidence that is published in books

and websites. However, *human factors* associated with the moderator and observer role are receiving increasing attention as salient influences on the “quality” of usability testing results. Such factors can include the moderator's cognitive load, communication challenges, and handling of multiple technical issues that affect their role and social presence and, thus, participant users' performance outcomes [6]. Wozney et al [6] identified these as “sociotechnical human factors,” including the attentional divide between auditory, textual, and visual stimuli. In testing sessions, these factors are dynamic and put cognitive demands on remote moderators and observers. In an earlier article, the impact of social context on performance outcomes was reviewed by Trivedi and Khanum [8]. These authors identified the social context or social environment as comprising people (eg, participant users, research personnel such as evaluators, and other people) whose presence during testing can have a substantial role in usability evaluations. However, to date, social context and human factors linked to the moderator and observer roles have not received the same attention as the physical context (ie, laboratory and field settings) as potential moderators or mediators of usability testing outcomes [6,8].

The Remote Moderator Role

The remote moderator is pivotal in usability testing. This role requires skilled, simultaneous execution of the following tasks: knowledge and use of technology and its features or functions; observation skills in watching the user interact with the product; careful documentation of usability issues; good communication skills that include ad hoc questioning, probing for clarity, and verbal and nonverbal communication; careful listening to the user's spoken-out-loud thoughts and feedback; and knowing when to take the lead in asking the participant to perform tasks and when to stay quiet as the user engages in the tasks. The goal is to build trust with the user and obtain honest feedback about the product or service and the user's experiences as well as foster user motivation to complete the assigned tasks. Wozney et al [6] explained that these skills are similar to those used by qualitative researchers. Others have stated that these skills affect the quality of the usability testing findings and user feedback [7].

The Remote Observer Role

Most of the time, the literature tends to focus on the moderator role [7]. However, considering the multitude of simultaneous tasks required of the moderator, it makes sense to include a “silent” observer or note-taker in the testing sessions. The observer or note-taker can serve as a vital second pair of eyes and ears in witnessing how the user interacts with the technology, product, or service. Tullis and Albert [9] described how the observer or note-taker has better “behind the scenes” opportunities than the moderator does to observe participants directly (eg, what they are doing, where they struggle, and how they succeed) and quickly record the user's performance (eg, recording the time to complete tasks). The early stages of the design and development process often involve small sample

sizes (eg, 5 to 6 participants) to identify issues with the design and administer fixes to those issues. Regardless of sample size, it is plausible that involving both an observer and a moderator could help lessen the odds of missing major usability issues in comparison with when the busy moderator needs to observe alone.

In summary, while conducting a review of the remote usability testing literature for the broader project, we discovered studies that reported on “how to” support the moderator and observer roles [7,10,11]. Other authors [5,6] made a call to action to better comprehend complex linkages among human factors (eg, social context or environment or “who” is present at testing), human-computer interaction, and web-based technology and tools to advance the remote usability testing approach. More peer-reviewed research needs to focus on moderator and observer subjective viewpoints regarding their influence and related factors for successful usability testing efforts (eg, motivating users to engage with tasks, obtaining quality feedback from users, and efficient decision-making about priority design refinements).

Study Aim and Research Question

Our broader project involved usability testing of an educational web browser application (called In Your Shoes) for nursing students to learn perspective taking and enhance their perceptual understanding of a dialogue partner’s thoughts and feelings. The aim of this study was to present an adjunct component of this broader project, where the experiences of 1 moderator and 2 silent observer participants during remote usability testing sessions were uncovered. The qualitative research question was “What are the perceived experiences of the lead remote moderator and 2 silent remote observers using web conferencing and various tools to capture user feedback on the empathy application during remote usability testing?”

Methods

Research Design and Usability Testing Context

A single-case methodology was used as an adjunct to a broader study that used a quantitative and think-aloud qualitative

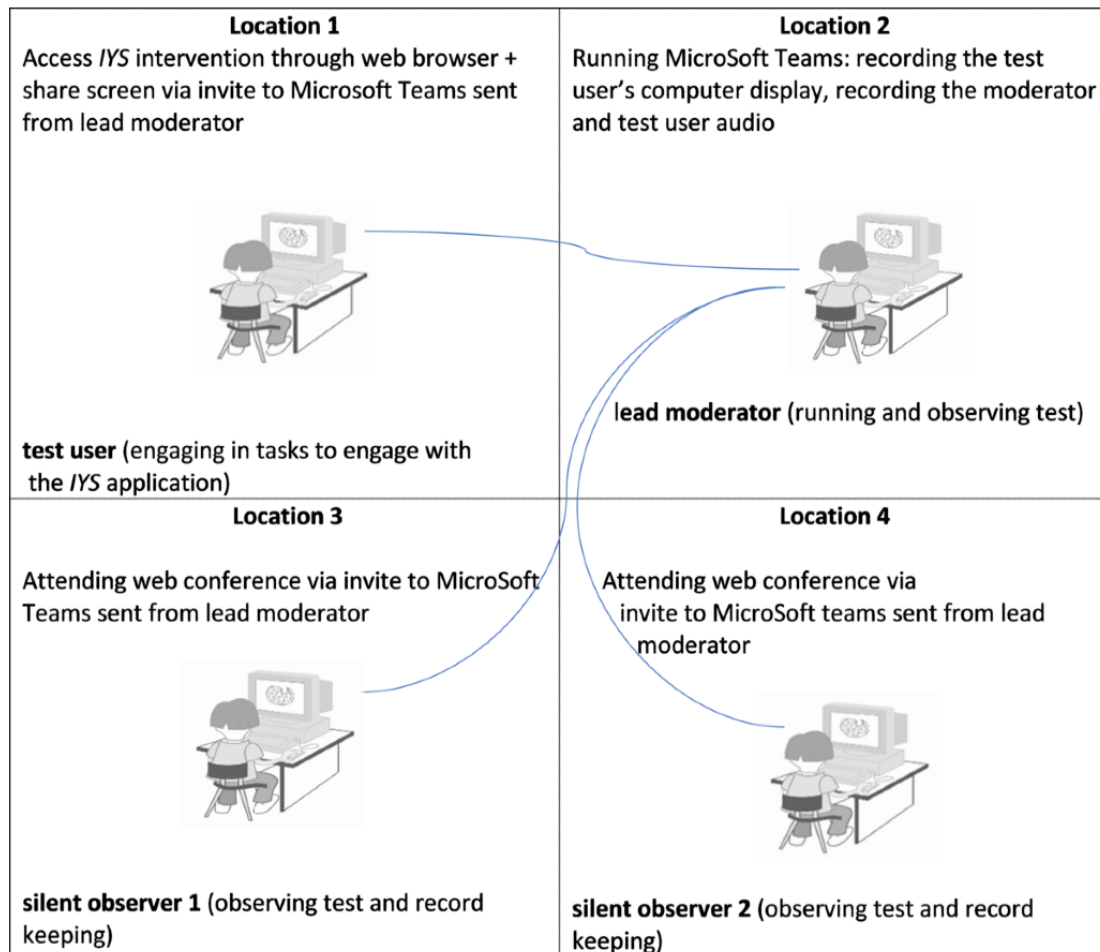

problem-discovery usability study design. A report on the quantitative and qualitative user feedback will be provided elsewhere. In this paper, we report only the experiences of the remote moderator and remote observers. The case method approach allowed us to closely explore the experiences of the lead remote moderator and 2 silent remote observers using a web conferencing platform during their remote testing of the empathy web training portal with nursing student users [12]. The “case” was the lived experience of “how” the remote moderator and remote observers executed the study protocol and “why” they had responses to certain “live” events. The “context” of the lived experiences was the protocol-driven usability testing sessions [13]. We collected and content-analyzed their written responses to a list of questions about their experiences in their roles and reactions to the usability testing protocol.

Ethics Approval

This study was conducted remotely with participant users in a midprairie province city in Canada. This study received ethics approval HS24965 (R1-2021-082) from the University of Manitoba Research Ethics Board and access approval from the College of Nursing. The remote moderator obtained informed consent from users before commencing the study protocols with them.

The broader study consisted of 3 consecutive phases. Each phase was interspersed with elements of data analysis and iterative design refinements for application prototype redevelopment [9,14]. A summary of the usability testing setup is provided in [Multimedia Appendix 1](#). [Figure 1](#) depicts the usability testing session scenarios for phases 1 and 2 and the roles. Phases 1 and 2 entailed a 1-hour video recording as moderated by the remote moderator. The remote moderator guided users to engage in tasks followed by immediate content analysis by the principal investigator (ML), the remote moderator, and the remote observers of the transcriptions of the users’ speak-aloud responses and video-recorded “performance” of tasks. Before starting our usability testing protocol, ethics approval was obtained from our institutional research ethics board, and access approval was obtained from the College of Nursing.

Figure 1. Web conferencing test environment set up for phases 1 and 2.

Characteristics of the User Sample

Undergraduate Nursing Students

We aimed to recruit 12 undergraduate nursing students from 1 university. The sample size was based on sampling and recruitment for usability studies to maximize the expected level of problem discovery [9,14]. Owing to the small number of student volunteers (n=8) with constrained schedules to participate freely, random assignment to each phase was not feasible. Instead, the remote moderator selected a combination of second- to fourth-year male and female students from the undergraduate baccalaureate program in nursing who owned or had access to a PC desktop computer, an Apple desktop computer, or a tablet device for 3 cohorts of a total of 8 students (phase 1: n=3, 38% of students; phase 2: n=3, 38% of students; and phase 3: n=2, 25% of students).

Recruitment

All second- to fourth-year students received an initial email invitation from our unit's research office on behalf of ML that was followed by 2 email reminder invitations. Interested students contacted the remote moderator, who emailed them an information package about the usability testing sessions. At a convenient time, the remote moderator conducted a video or phone call with potential users to further explain the study and expectations during the testing sessions. The remote moderator's script was as follows: "We are testing the application to get user

feedback, so we will have a video call where I will be joined by 2 other research assistants. They will be silent observers, so they will have their cameras and microphones off. During the call, I will get you to share your screen and see how you interact with the application; I will prompt you to answer questions and ask you to do tasks on occasion. We really want to get insight into the user experience, so we want honest feedback about the thoughts and feelings of the users. The video call will be about an hour long, give or take 15 minutes."

Setting, Access, and Preparation for the Usability Testing Sessions

Overview

An undergraduate research assistant from the computer sciences served as the lead remote moderator from her isolated setting with no distractions. The remote moderator facilitated the testing sessions using a functioning microphone and the institutionally adopted Microsoft Teams screen- and audio-sharing tool that allowed student users to share their screens. Remote observation via screen sharing, aided by Microsoft Teams and video files viewable in Microsoft Teams, helped the team capture and review behaviors and narrations as the users performed the tasks. In total, 2 undergraduate research assistants in computer sciences and computer engineering served as silent remote observers who watched and recorded user behaviors during tasks from their respective isolated settings. The remote

observers also performed application refinements based on user input.

A member of our investigative team (Yumiko Sakamoto) was an expert in human-computer interaction who trained the remote moderator and remote observers on how to conduct a 1:1 session with users. The training included how to observe and keep records in Microsoft Excel, prompt users to speak aloud to explain the actions they were taking, and conduct user exit interviews. The users were not provided with the task list to review before the scheduled session. Instead, at scheduled sessions, the remote moderator provided users with realistic task scenarios to interact with the application interface and perform tasks in the sequence of steps that they would need to carry out if they were using the application in a real-life setting (ie, set up an account, open training documents, upload an mp4 video, engage in video tagging, and obtain their perceptual understanding score) [15].

Pilot Test

The first step was to conduct pilot-testing sessions using Microsoft Teams that were remotely moderated with 2 nursing student users at the end of June 2021 and the beginning of July 2021. The pilot sessions helped the remote moderator and remote observers become acquainted with each other, determine the best approach to conduct the testing sessions collaboratively, and identify issues related to moderating sessions (eg, avoiding asking leading questions and the need to send participants a video to upload in advance of the testing session). The remote observers also identified that the performance metrics tool required reformatting based on the anticipated order of the user tasks to be performed. On the basis of pilot test user feedback, the remote observers made application refinements (eg, provided clearer explanations of key features directly on the application pages, inserted colored text to delineate application “taggers,” and fixed glitches with log-in and sign-out functions). Commencing in mid-July 2021 until the end of August 2021, 3 phases of user testing sessions were successfully executed at the College of Nursing.

Description of the Web Browser Application

We developed and tested the first prototype of an empathy-related video feedback intervention (*In Your Shoes*) to improve perspective-taking skills and perceptual understanding by clinicians of their clients (or accurate understanding of another person’s thoughts and feelings) that requires attendance in a laboratory setting plus a desktop, a stationary camera, and a commercial video analysis software program [16,17]. Our *In Your Shoes* intervention was adapted from the award-winning research in social psychology on empathic accuracy (or the extent to which an individual’s inferences of the content of another person’s thoughts and feelings are accurate) by Dr William Ickes et al [18,19]. The work by Ickes provided us with a practical, reliable, and objective method for measuring an individual’s ability to accurately infer another person’s thoughts and feelings during a video-recorded interaction.

To enhance accessibility and ease of use, our investigative team and the Red River College Polytechnic ACE Project Space

students transformed the existing in-laboratory desktop approach into a unique web browser application version to learn perspective taking on any computer or tablet device. The development process consisted of the front end, server, database, and cloud storage system as the 4 key interconnected system components required to deploy the *In Your Shoes* web application. The front end retains the user’s interface (ie, everything that the user sees is rendered here) and was developed using the React framework (Meta). The data displayed on the front end are stored mainly in MongoDB (MongoDB Inc), which houses data including user information, tags, and video data. The videos are stored on Amazon Web Services using an S3 bucket, whereas links to the videos are stored in MongoDB. For the front end to use and display the data from the database and cloud storage system, the Django Representational State Transfer framework (Django Software Foundation) is used on the server to structure the data in a way that is easily accessible from the front end. Essentially, the data are taken from storage, structured on the server, and rendered on the front end so that the user can interact with them (see [Multimedia Appendix 2](#) for the system components). The application was developed to replicate the existing in-laboratory process with no special requirements for hardware. The only hardware needed is a computer, laptop, or mobile device with a functioning browser and internet access. To secure evidence on prospective users’ experiences with the *In Your Shoes* application features and functions and to obtain feedback for further application refinements, we conducted a usability testing project with the remote moderator and silent observers who were the focus of this case study.

Study Procedure

Remote Moderator Role, Responsibilities, and Recommendations for the Broader Study

The remote moderator was responsible for facilitating the remote testing sessions, answering user questions during testing sessions, managing the virtual video recording and transcription platform, and editing the transcripts, as well as for data collection, data analysis, and data management via the Qualtrics (Qualtrics International Inc) and Microsoft Teams platforms. After the study’s expectations were explained, the remote moderator sent users the Qualtrics link to the informed consent and demographic data form for phases 1 and 2. Users in phase 3 were sent the Qualtrics link to the consent form and demographic data form plus the usability tool. A total of 24 hours before the scheduled session, the remote moderator sent instructions to download the Microsoft Teams application and an mp4 video to upload during the testing session. Once the consent and demographic forms were signed, the remote moderator sent a Microsoft Teams calendar invitation to the user and remote observers for the testing session. Approximately 5 minutes before the video call, users were sent the link to the *In Your Shoes* application. There was 1 participant who did not attend the initial or rescheduled sessions. In addition, 2 other students signed their consent forms but never responded to the remote moderator’s email requests to schedule a testing session. A recommendation is for future users to send out several

reminders (ie, 48 and 24 hours in advance of the scheduled testing session).

Once the user was logged into the session, the remote moderator immediately thanked them for participating. A repeated explanation of the study expectations was provided. The remote moderator encouraged users to be honest with their feedback. Despite having sent students a reminder to download the Microsoft Teams application in advance of the session, most students used the browser application instead. Regarding users' computer technology skill level and experience with Microsoft Teams, some had used it before, but most had not. This lack of experience resulted in the remote moderator needing to explain to them how to share their screens. During the testing session, the remote moderator learned that the desktop and browser versions of the Microsoft Teams functions and features were different. This became an issue when the remote moderator would explain how a user could share their screen and the user was using the browser instead of the desktop version. In that case, the remote moderator was challenged to help them as the user did not have access to the same buttons as the remote moderator, who used the desktop version. For the few users who had a very slow internet connection, the video quality of the call was fine, but it would take a while to upload a video to the application for the video-tagging exercise. While they were uploading the video, the remote moderator would either perform another task with the users or just wait for the video to be uploaded. Otherwise, the remote moderator and remote observers found Microsoft Teams intuitive to use. The recording and transcription facilities were extremely helpful in capturing session data, which allowed them to quickly rewatch the sessions to ensure the accuracy of the data that they had collected.

During phase 1 and phase 2 sessions, the remote moderator encouraged the user to engage with the application as if they were alone with it. Allowing the user to figure things out on their own was the most useful approach. The most information about user interaction with the application came from observing the user and asking them questions about their actions instead of telling them how to perform the task. The strategy used was to wait for the user to interact with the web application and remind them to speak out loud while they were doing an activity. Asking the user to speak aloud was helpful when editing the transcripts wherever users were unclear and when adding context to the testing session. It was easier to determine what was happening when the user described the webpage they were interacting with during the session.

For phase 3, users engaged with the application in their own environments for 1 week, and they were not observed. The remote moderator sent them detailed instructions about the purpose of the study and specific tasks for them to complete. The users emailed the remote moderator to express their confusion about uploading a video that they were asked to create based on a conversation they were asked to have with a family member or friend. Owing to pandemic restrictions, both users explained that they could not locate a family member or friend that they felt comfortable with to do a video-recorded dialogue and then upload and analyze this video recording in the application. Testing the independent use of these tasks (ie, the main functions of the application) was not possible.

Once the users had engaged with the application for 1 week, a scheduled 60-minute video-recorded and scripted interview was led by the remote moderator, who administered the usability tool to capture user "satisfaction" with the *In Your Shoes* application [20]. A total of 3 questions were added to capture language understandability, visual-interactive appeal, and whether use expectations were met. A think-aloud process was used where the remote moderator asked users to speak aloud their thoughts as they completed each statement on the usability tool [21]. The remote moderator used probes such as "I would like to hear what you were thinking when you answered this question." Users also provided information on the type, brand, and operating system of the device used; the number of times they accessed the application; and the amount of time they spent on the application each time they accessed it over the previous week.

Remote Observer Roles, Responsibilities, and Recommendations for the Broader Study

Silent remote observation was an important aspect of phases 1 and 2. In total, 2 remote observers monitored how each of the participants traversed through the application and maintained a record of (1) the user's test environment, (2) paths that users navigated to perform a task, and (3) temporal and cognitive resources each user spent when performing a task. Once the remote observers had reviewed the data collected in the usability testing session, they performed refinements to the application to make the user experience better for the subsequent phase.

For phases 1 and 2, the remote observers developed a predefined protocol, as guided by Tullis and Albert [9] and Nielsen [14], to capture performance metrics on predefined tasks that the users had to perform. The performance metrics were recorded by the remote observers as they monitored an ongoing testing session. The remote observers used 2 electronic forms with Google Forms that supported a wide range of inputs ([Multimedia Appendix 3](#)). The think-aloud method used by the remote moderator with the users helped the remote observers identify technical issues and required refinements to the application [22]. One remote observer recorded the success of the user in completing predefined tasks and some remarks regarding how well they completed the tasks. The other remote observer recorded the number of mouse clicks required for the user to complete each task. This proved to be challenging at times depending on the device used by the user. Some users had mouse devices that were inaudible, which made it difficult for the remote observer to see and hear the clicks to capture them in the performance metrics. In addition, there were occasional issues with choppy video depending on the user's internet connection. Hotjar (Hotjar Ltd) with heat maps was also used as a behavior analytics and feedback data tool (see [Figure 2](#) for scrolling activity and [Figure 3](#) for clicking activity). This tool helped the project team understand what the users were doing on the website pages (eg, where they clicked or scrolled and what they looked at or ignored) and then identify priority application refinements. The performance metrics spreadsheets were stored on Google Drive, which made it easy for the team to manage access and collaborate in evaluating the results. Overall, there was great benefit to having the remote observers directly monitor and record the impact of their implemented

changes when different users interacted with the application across the phases.

The remote observers were also the “application fixers” who were able to quickly and accurately identify required application refinements by directly communicating with the users at the end of the usability testing sessions. This dialogue summarized how well the remote observers felt the user did during the session and allowed the remote observers to ask the user about further suggestions for application refinements. The remote observers participated in testing sessions at their physically distanced work stations in remote settings where external disturbances were limited; this fostered their focused observation and accurate data collection. Unforeseen disruptions did arise

occasionally during remote testing sessions in the form of network disruptions or user and researcher computer malfunctions. When such situations arose, the team prioritized the user’s comfort by reassuring the user and worked through solutions. This approach by the remote observers was essential to prevent users from being influenced by negative experiences that could bias their reactions toward the application.

At weekly meetings, the remote moderator and remote observers reported on user feedback to ML. Priority application refinements that would influence the design iteration before advancing to the next phase were identified for attention within 1 week.

Figure 2. Hotjar (Hotjar Ltd)—scrolling activity (on the application’s Training Portal for a sample of 282 scrolling activities; red indicates that all or almost all users have seen this part of the page).

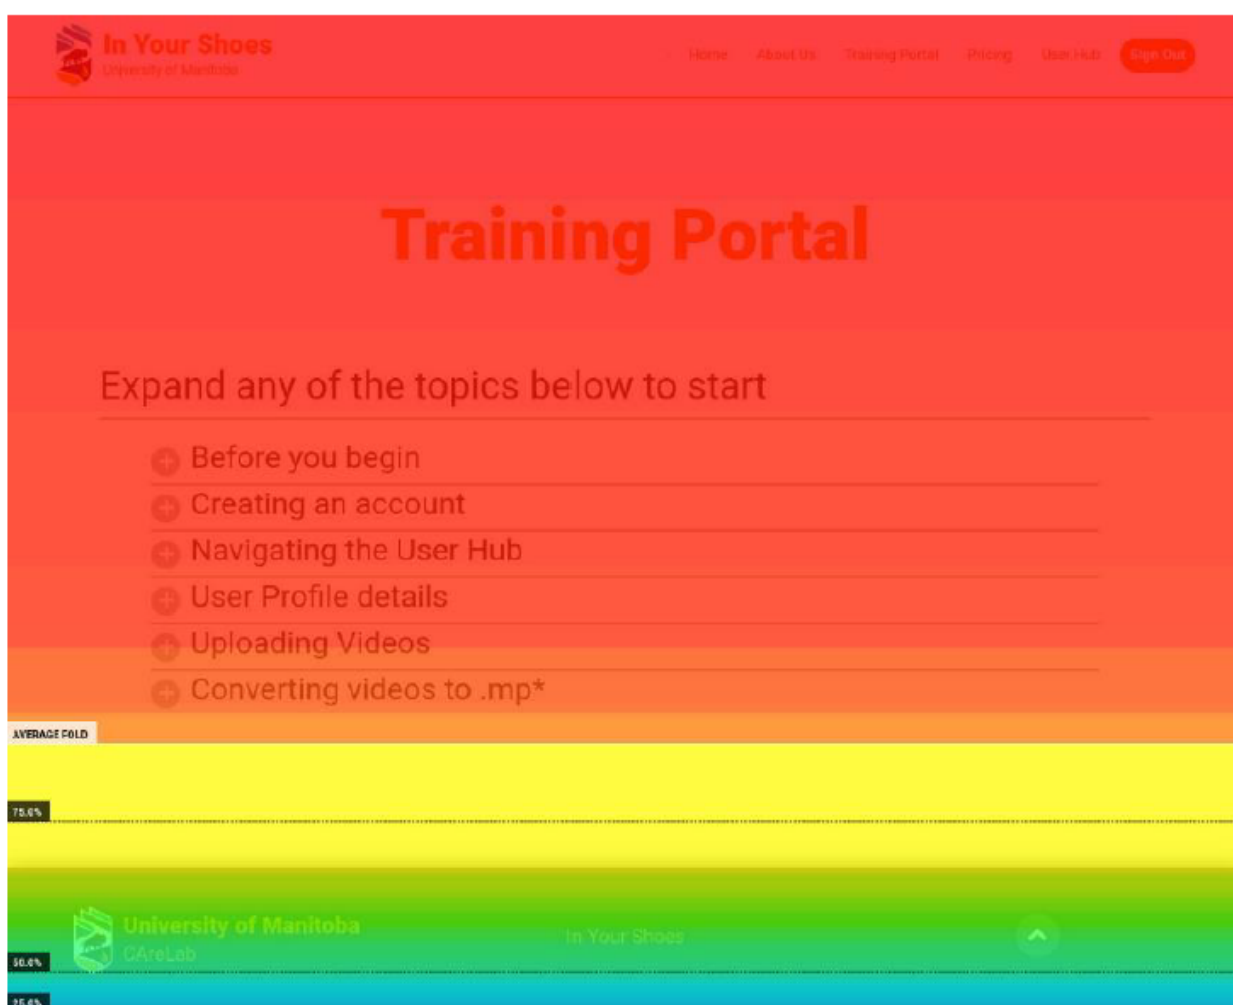

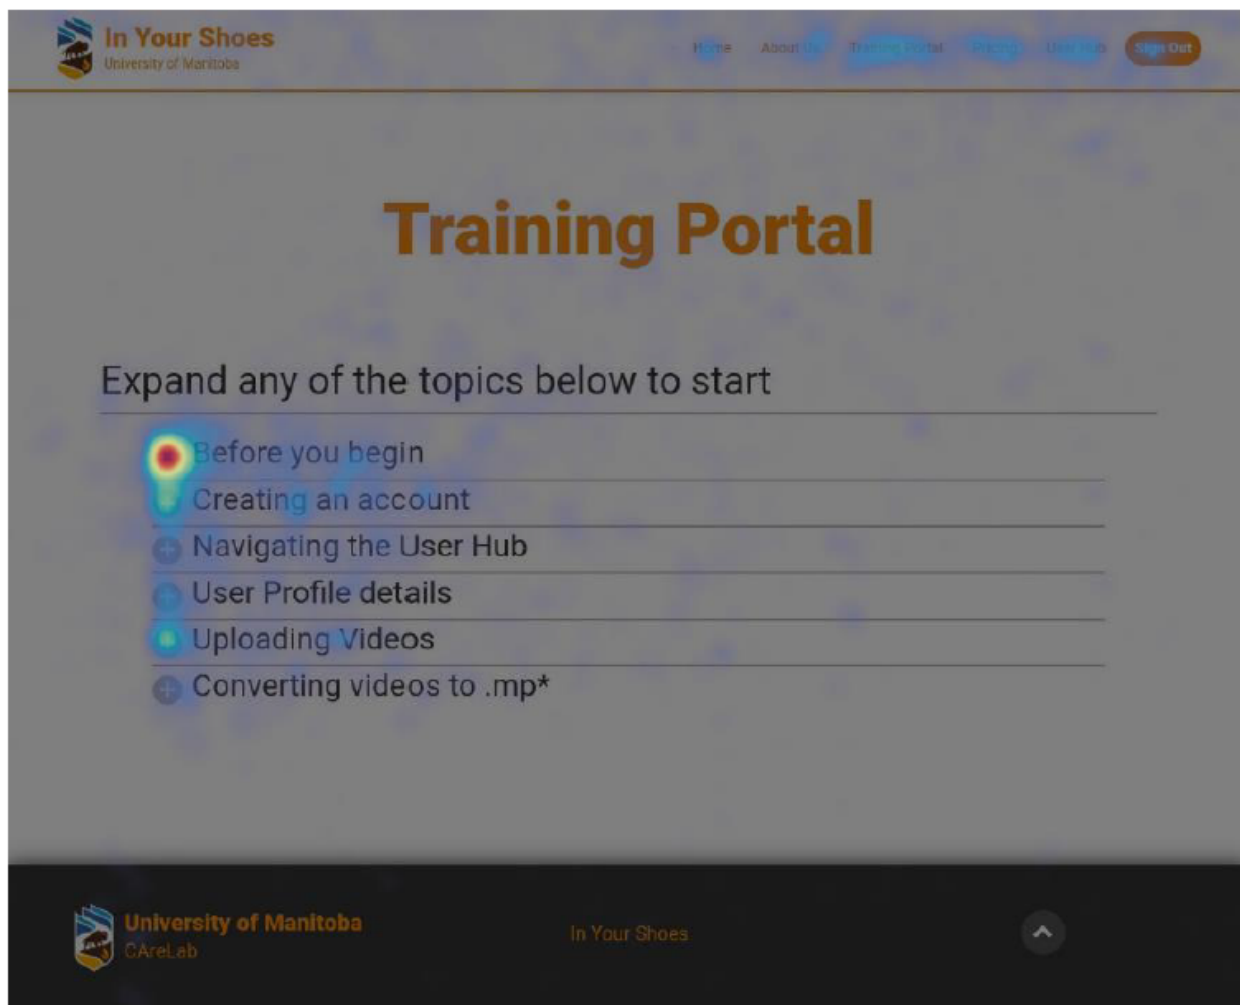

Figure 3. Hotjar (Hotjar Ltd)—clicking activity (on the application’s Training Portal for a sample of 175 clicks).

Data Management by the Remote Moderator and Silent Observers in the Broader Study

Once the testing session was done, the remote moderator immediately edited the Microsoft Teams transcripts and replaced the user’s name with a code number. Although the video quality for the recordings in Microsoft Teams was very good, the automatic transcription was challenging to work with in terms of occasionally getting wrong the order of who spoke, at times breaking up sentences in a way that was nonsensical, not always accurately capturing what the user was saying, and adding words not said or inserting odd words; for example, every time the user said “tag,” the transcription would show they said “take.” The remote moderator relied heavily on listening to the video-recorded session to decipher what the user was saying or referring to during the session. For example, if a user said, “I will click this button” in the transcript, the remote moderator was able to look back on the video and put an annotation in the transcript as to the exact button they clicked. The edited transcripts from the testing sessions were downloaded as a docx file and saved in the Microsoft Teams folder.

Some time was required by the remote moderator to become familiar with how to use the Qualtrics platform to capture project data. Creating the forms in Qualtrics was easy, as was editing them. However, linking separate forms proved to be challenging

with the loss of consent forms and demographic data forms in phase 3. Both users in phase 3 had to complete the 2 forms again. The demographic data form and the usability tool were exported to respective csv files with the names and email addresses of the users removed. These csv files and consent forms (downloaded from Qualtrics) were uploaded for secure storage on ML’s system drive folder.

After each session, similar to the remote moderator, the remote observers relied on Microsoft Teams video recordings and transcripts to confirm their recorded values (eg, number of mouse clicks) on the performance metrics tool. The performance metrics tool was stored on Google Forms, and the videos were accessed by the remote observers from Microsoft Teams. Upon completion of the analysis, the performance metrics tool was uploaded and securely stored in ML’s system drive folder. Video recordings of the Microsoft Teams meetings were deleted after the transcripts had been edited, and the remote observers cross-checked their record keeping against the video-recorded sessions.

Data Collection for This Case Study

ML circulated a written list of questions about the personal accounts and experiences of the lead remote moderator and 2 remote observers while executing their roles and responsibilities during the usability testing sessions ([Multimedia Appendix 4](#)

[6]). The list of questions was adapted from the questions by Wozney et al [6] used with moderators in their remotely moderated study. The remote moderator and remote observers submitted their written accounts to ML in response to each of the questions posed on the list.

Results

Overview

In response to the research question, the following is a narrative account of the respective role experiences of the remote moderator and the remote observers during the usability testing sessions. Their personal accounts are accompanied by reflections on their assigned tasks plus recommendations for the design of future usability testing sessions. ML collated and analyzed their written accounts. Content analysis was conducted, and the coded data that emerged were organized, synthesized, and interpreted as themes by ML [13]. ML's analysis of the data was shared with the remote moderator and remote observers, who read the interpretation and contributed correct information or additional perspectives about their experiences.

The following are emerging themes from the analyses of the written accounts of the remote moderator and the remote observers: (1) dealing with personal stressors, (2) dealing with user anxiety, (3) maintaining social presence, (4) ethical response to the study protocol, and (5) communication during sessions.

Themes

Dealing With Personal Stressors

The remote moderator experienced anxiety during the first few sessions that was greatly reduced in subsequent sessions. The initial anxiety was mainly due to having not yet established a comfortable flow of tasks; for example, it seemed that the initial users took too much time to read the training documents, which caused a sense of urgency in the remote moderator. However, the anxiety dissipated when the remote moderator grew to appreciate that, realistically, engaging with the educational training application and documents could take between 1 and 1.5 hours. She also found that working with Qualtrics was anxiety-provoking because of her limited experience and learning curve with the program. One mishap involved the loss of 2 signed consent forms because of the way the remote moderator set up the consent form in Qualtrics.

Cognitive overload for the remote moderator also occurred most often in the first few sessions. The remote moderator struggled to pay attention not only to what the users were doing but also to how to guide them when they became reliant on her for direction while also concentrating on their think-aloud responses. Future remote moderators should be well rested to better focus on conducting the interviews. It is also good to follow a script of user tasks with possible responses to anticipated user questions.

Dealing With User Anxiety

The remote moderator would start most sessions by chatting with and asking the user how their day was going, talking about a topic other than the testing session, or laughing at a shared

joke. The occasional sidebar conversation occurred, which helped the users feel more comfortable during the testing session. During the course of the testing sessions, if the remote moderator detected that the user was feeling anxious, she would usually ask them about how they were feeling in that moment, and common user responses were "I am confused," "I want to do good on this," or "This is a lot of reading and I am a bit overwhelmed." In addition to providing reassurance, the remote moderator made it clear that the users were not being tested but rather being asked to provide honest feedback about the application.

The early testing sessions involved users who would pause during the task without explanation. The remote moderator assumed that they were just resting and did not ask if they were confused. After the first 2 interviews, the remote moderator took a different, more validating approach that entailed instructing the user to explain what was on their mind or asking a specific question to clarify the user's thoughts. The remote moderator would interject if the user was clearly not understanding how to complete a task (eg, when they tried to complete the tag multiple times, read the error message, and still did not understand how to tag instances in the timeline). Prompts by the remote moderator would be "What on this page do you want to click on?," "Is there anything you are confused about on this page?," or "What do you think you should do next?" Other times, it seemed that the user wanted direction from the remote moderator when they would say things such as "How do I do..." before engaging with the application on their own. In these situations, the remote moderator would try to remain impartial and respond with "What would you do if you were on your own right now and you had to figure that out?" Additional usual responses by the remote moderator were "What page on this website have you been to that might have that?" or "Maybe go read the documents again" instead of just directly telling them how to do it. However, if the user was struggling hard to figure something out, the moderator would tell them how to do it. This happened most frequently when users did not understand how to annotate ("tag") the video when attempting to capture their inference of the dialogue partner's thoughts or feelings.

Maintaining Social Presence

The remote moderator and remote observers found no ill effects in not being able to draw on in-person visual cues (eg, full body language) to provide expressive guidance to the user or for the remote moderator to gauge users' responses to the application. Other visual cues were noticeable with screen sharing, especially the user's facial reactions such as confusion with certain aspects of the application. Getting the user to think aloud was very helpful as they would narrate what action they were performing and the reasons behind it. The remote moderator consciously used her hands and facial expressions as visual cues for the user. By contrast, being in person could have made it easier for the remote moderator to explain where to locate something (eg, physically pointing and saying, "It is in the top left corner under the other button...no up a bit more"). Overall, there was no evidence of a negative impact of being physically distanced on the performance of the user.

The remote observers had limited social interaction with the users. However, toward the end of the testing sessions, the remote moderator would invite the remote observers to make some remarks to the user (eg, thank them for participating and share their appreciation for helpful feedback). This was important for rapport building, helped the user see how well they did during the session, and provided a last chance to offer added suggestions for application refinements to the remote observers. Otherwise, the remote moderator asked the remote observers to interject amid the testing session only if needed (eg, assistance with a task). A remote observer described that being remote allowed him to focus on record keeping without being distracted by the presence or actions of another person. This remote observer felt that, if user testing sessions were done in person, his own reactions or behaviors could potentially pose an undue influence on the user's responses to interacting with the application.

Ethical Response to the Study Protocol

The remote moderator described how her virtual interaction with the users was likely different than it would have been if she had engaged in person with the users. The remote moderator felt obligated to work hard at making the user feel comfortable by consciously using verbal cues versus having a wide range of bodily cues to better express herself at her disposal. Users also required a lot of reassurance as they were conscious of their appearance and other visual cues (eg, facial expressions and body movement) while being video recorded. This might have made them more reticent to share their thoughts and feelings about the application. To foster user trust in the remote moderator and testing process, the remote moderator explained to the users before the scheduled session that 2 remote observers would be present who would have their cameras and microphones turned off while they took notes throughout the session. The remote observers would be invited to interact with the users before the end of the testing session.

Communication During Sessions

During the sessions, the remote moderator and remote observers used the private chat function in Microsoft Teams for impromptu requests such as requesting the remote moderator to ask the user to add questions or give feedback to one another without distracting the user. The remote observers would send the remote moderator a message if she forgot to do something, such as not starting the recording or forgetting to tell the user to do something. The chat function also helped the remote observers engage with the remote moderator in troubleshooting issues that arose during the testing sessions. At first, the remote moderator found the communication features in Microsoft Teams folders to be confusing. Sometimes, she would receive a notification from one of the remote observers and she would not know if it came from the chat box or a different communication channel in Microsoft Teams. Overall, the remote moderator and remote observers found that Microsoft Teams was a comprehensive platform with built-in features that fostered discrete and timely communication with each other during the testing sessions. After each testing session, Microsoft Teams made transcriptions readily accessible for the team to quickly

analyze and then communicate in a timely manner to make joint decisions about priority application refinements.

Tangled conversations were common when the remote moderator and the user would speak over or interrupt each other. Other users would mumble or speak to themselves when using the application or reading the training documents. This caused issues for the remote moderator, particularly when she attempted to accurately discern their user experiences while editing the transcriptions. The users were simply asked to repeat themselves in live sessions whenever tangled or interrupted speech occurred. Overall, the remote moderator and remote observers felt that these issues were unique to remotely moderated testing sessions and required careful attention to promote clarity in user communication for quality audio capture and transcription.

Discussion

Principal Findings and Research Implications

Wozney et al [6] described that real-time usability testing involves human impact factors—often unpredictable—that can influence the quality of the testing session results. Extant literature provides only a rare glimpse into the influence of test environments on moderator and test user performances, which warrants further attention. Therefore, our aim was to contribute to the literature by providing further qualitative information for consideration in the design of future remote usability testing sessions. In this section, we discuss the main experiences encountered by the remote moderator and remote observers related to triangulating methods of data collection and using unfamiliar technology and software as well as managing personal stressors and user anxiety, maintaining social presence, and ensuring good lines of team communication during testing sessions. The recommendations identified in this section describe how the remote moderator and remote observers felt that emerging issues could be better addressed during testing sessions.

The usability methods used in this study were comparable with those used in related studies. In their recent scoping review, Maramba et al [23] found that 6 different usability methods were often used: quantitative methods using questionnaires and task completion and qualitative methods using think-aloud, interviews, focus groups, and heuristic methods. Our broader study saw that the remote moderator and remote observers used 4 of the 6 methods: a questionnaire, task completion, think-aloud, and interviews. The efforts of the remote moderator and remote observers corroborate those described by Maramba et al [23], where the use of the think-aloud protocol by developers led to further iterative application development (in comparison with the use of questionnaires, task completion, interviews, and focus groups). In total, 3 iterations of the application were informed by user feedback obtained in our pilot tests and from each phase of usability testing. In their review, Maramba et al [23] found that only 31.3% of the included papers reported having done at least one further iteration of the application. Although the think-aloud method might slow the process, it does not have a negative impact on the flow of user thoughts [22]. Tiriticco [24] described this method as simple, flexible, and affordable as well as not needing

“special skills” or equipment. As in this and related studies, evidence suggests that the think-aloud process is an optimal method to garner user feedback for application refinement and ought to be the focus of training for remote moderators and observers.

When they described positive experiences, the remote moderator and remote observers said that they were primarily enabled by the functionality and features of the Microsoft Teams web conferencing technology and software with screen-sharing, video recording, and transcription features. Despite the initial lack of familiarity with the Microsoft Teams platform, the team quickly learned the technology because of their respective backgrounds in computer science and technology. Wozney et al [6] described that having to learn new web conferencing software can create a “cognitively demanding environment.” The team could have benefited from viewing demonstration videos or web-based tutorials about Microsoft Teams features (eg, chat and channel communication and the use of desktop and browser versions of the software) [7]. This would be in addition to running pilot sessions intended to clarify protocol steps and enable the coordination of team members in preparation for “real” testing sessions.

Technology also eased the cross-checking of the accuracy of record keeping as performed by the remote observers, who accessed the video-recorded sessions and transcriptions provided by Microsoft Teams. Furthermore, the use of Hotjar aided the remote observers in making more objective observations of how the user engaged with the application’s webpages (eg, user clicks, taps, scrolling behavior, and mouse movements) and identifying usability issues more easily. The triangulation of methods to capture user experiences (ie, video recordings, written transcriptions, and visualization of how the user maneuvered on the webpages) strengthened the reliability of the remote observers’ interpretation of user behavior [1]. This, in turn, led to their optimal decision-making regarding priority application refinements and rapid resolution of how to make application refinements before advancing to the next phase.

Regarding cognitive challenges, the remote moderator especially described her experience as stress-evoking. She needed to “take in” textual stimuli as well as auditory and visual stimuli while relying on her memory and interpretation skills as part of encouraging users to provide useful feedback for the remote observers and their application refinements [6]. Remote observers were less affected by cognitive overload and felt more efficient in their tasks. The lead remote moderator role was expected to not only learn the features and proficiently manage the functionality of Microsoft Teams in a short period (ie, during brief testing sessions) but also respond to anxious users’ questions, needs, and behaviors and to private chat room communication with remote observers during sessions. These expectations existed for the remote user who also needed to create a warm, inviting environment for users to provide honest responses to their experiences with the application. A recommendation to reduce the cognitive load for the lead moderator is to conduct pilot sessions with sufficient time for personnel to become familiar with testing demands and jointly strategize how to reduce anticipated cognitive challenges [22]. This would entail practice time to (1) learn advanced features

in Microsoft Teams, such as the private chat function, to communicate with other team members; and (2) engage in rapport building with other team members (eg, silent observers) who will serve as a reassuring pair of added eyes and ears to address emerging issues during testing sessions. The other option is to hire experienced moderators and silent observers with advanced skills and knowledge of remote usability testing to efficiently deal with cognitive demands during sessions.

There were differences in opinion between the remote moderator and the remote observers regarding the benefits of in-person versus remote or virtual testing sessions in promoting social presence. Although the remote moderator had a larger role in interacting with the user, it is understandable that she felt constrained in not being able to provide more expressive instructions to the users—especially to users who were anxious when performing tasks. The remote observers did not feel hindered doing remote sessions. Rather, they felt that their use of screen sharing was sufficient for them to conduct silent observation and record keeping and not bias the user’s responses to the application. To overcome constrained communication with users, the remote moderator used the camera and audio features to maintain social presence (eg, with eye contact and body language) without feeling a need to talk more than necessary with the user. As described by Wozney et al [6], establishing and maintaining a social presence entails a combination of technical and interpersonal communication skills in the lead moderator. Practice exercises in virtual communication using technology and obtaining feedback from dialogue partners would be helpful in training research personnel in social presence.

Communication was an essential element that the team was keen to focus on to attain successful testing outcomes as fostered by technology. For instance, the private chat function in Microsoft Teams allowed for timely in-session communication and impromptu problem solving between the remote moderator and the 2 remote observers as required during the sessions. Being sensitive to the potential ill effects of physical distancing saw the team engage in careful efforts to create a friendly and accommodating environment for users [22]. For example, the remote observers were sensitive to their method of secretly communicating with the remote moderator during testing sessions and making themselves known to the user at the end of the session. The remote observers appreciated the opportunity to debrief with the user, express their gratitude, compliment the user for their efforts, and invite further user feedback. It is believed that these actions promoted trustworthiness in the testing experience and in the research personnel. Drawing on emerging evidence on establishing good web-based communication [22] would also be helpful in training remote moderators and silent observers.

Limitations

A limitation related to “how” and “when” we captured the remote moderator’s and remote observers’ perceived experiences. First, the remote moderator’s and remote observers’ responses were based on their experiences with a small sample of nursing student participants from 1 setting, which poses a caveat to generalizing these findings to a wider student

population. Second, their feedback was not solicited until after all usability testing sessions were completed and during a time when their student commitments were heavy. Furthermore, their narrative accounts may have been negatively affected by memory biases. A more reliable approach to capturing trustworthy accounts would have been to record a debriefing session individually with the remote moderator and remote observers immediately after each testing session. A focus group approach involving the remote moderator and remote observers could have also stimulated rich and more in-depth responses to their joint experiences in the testing sessions. The remote moderator and remote observers would need to feel comfortable enough with each other to honestly share how their collaborative efforts unfolded and were affected by each other's behaviors.

This study's main findings revealed a wealth of learning experiences by the remote moderator and remote observers in their respective roles when executing the usability testing protocol. Their use of web conferencing and survey technologies enabled adequate remote communication with users, good collaboration among research team members, the capture of user feedback, automatic transcription with immediate access for quick analysis, and easy remote administration of questionnaires. See [Multimedia Appendix 5](#) for the remote moderator's and remote observers' recommendations relating to future usability testing sessions and a training protocol for research personnel.

Conclusions

With the growing availability of web conferencing platforms, application developers are no longer restricted to in-person

testing sessions. We anticipate a rising use of remote usability testing sessions as applications, services, technology, and software platforms continue to evolve and grow [23]. Usability testing is a relatively young science. This work contributes to the scarce literature on remote usability testing with web browser applications developed in academia, especially in health sciences [23]. "Best practice standards" are emerging where developers are required to publish evidence of user involvement and user satisfaction when seeking uptake of their application in the real world (eg, in clinical practice [25]).

Our results suggest that remotely moderated usability testing can serve as a valid substitute for traditional in-person usability testing. However, there remains a great need for more rigorous research to better comprehend the influence of remote moderator and silent remote observer characteristics, their previous experiences, and team collaboration on user responses. We also need more research that contributes evidence as a foundation for training remote moderators and remote observers in web-based interpersonal communication skills, the execution of usability testing protocols in virtual environments, team decision-making (eg, joint troubleshooting of emerging technical and user issues in "live" testing sessions), and technology and web conferencing technology skill proficiency. Finally, ongoing development and testing of reliable and valid methods to capture data remotely and record-keeping tools are warranted to ensure that rigorous studies are performed and outcomes are being captured to advance the science in usability testing. With such evidence in hand, videoconferencing software and technology developers can continue to create sound tools and methods for uptake by usability testing personnel.

Acknowledgments

Financial support was provided by the University Research Grants Program, University of Manitoba, Project 55126. A Mitacs Globalink Research Internship, Project ID 22156, was awarded to PRB. Dr Marcia Friesen, Dean, Price Faculty of Engineering, University of Manitoba, provided student stipend support for AA.

Authors' Contributions

ML conceived the study; acquired funding; and participated in design, coordination, and supervision of research personnel. She was the lead author of the manuscript. PRB, AA, and AL participated in revising the study protocol, data collection, data analysis, and made significant contributions to the manuscript. All authors have read and approved the final manuscript.

Abstract

Background: Bullying is a significant problem for youth associated with wide-ranging negative consequences. Providing students who witness bullying with intervention strategies to act as *defenders* can reduce bullying and negative associated outcomes for both targets and bystanders. Educating teachers about bullying and training them to support students to intervene as *defenders* may increase the efficacy of bystander programs as teachers' attitudes and responses to bullying relate to bystander behavior. This is particularly important in middle school, when bullying peaks and rates of reporting bullying to teachers begin to decline. Reducing implementation barriers, including limited time and resources, must also be considered, particularly for schools in low-income and rural areas. Technology-based programs can increase access and scalability but require participant buy-in for adoption.

Objective: We used a mixed methods design to inform the development of the STAC teacher module, a companion training to a brief bullying bystander intervention. STAC stands for the four bystander intervention strategies: *Stealing the Show*, *Turning it Over*, *Accompanying Others*, and *Coaching Compassion*. Objectives included examining the effectiveness of the STAC teacher module and informing the translation of the training into a technology-based format that can be used as a companion to the technology-based STAC.

Methods: A sample of 17 teachers recruited from 1 middle school in a rural, low-income community completed pre- and posttraining surveys assessing immediate outcomes (ie, knowledge, confidence, comfort, and self-efficacy), intention to use program strategies, and program acceptability and relevance, followed by a qualitative focus group obtaining feedback regarding program appropriateness, feasibility, content, perception of need, and desire for web-based training. Descriptive statistics, 2-tailed independent-sample *t* tests, and thematic analyses were used to analyze the data.

Results: Assessment of pre- and posttraining surveys indicated that teachers reported an increase in knowledge and confidence to support *defenders*, confidence and comfort in managing bullying, and bullying self-efficacy. Furthermore, most participants reported that they were likely or very likely to use STAC strategies to support students who intervene in bullying. Quantitative and qualitative data revealed that participants found the training easy to use, useful, relevant, and appropriate. Qualitative data provided feedback on ways of improving the program, including revising role-plays and guidance on understanding student behavior. Participants shared positive perceptions regarding program feasibility and need for bullying-specific prevention, the most significant barriers being cost and parent buy-in, suggesting the importance of including parents in the prevention process. Finally, participants shared the strengths of a web-based program, including ease of implementation and time efficiency, while indicating the importance of participant engagement and administration buy-in.

Conclusions: This study demonstrates the effectiveness of the STAC teacher module in increasing knowledge and bullying self-efficacy and provides support for developing the module, including key information regarding considerations for web-based translation.

KEYWORDS

teacher bullying interventions; technology-based bullying intervention; STAC; middle school

Introduction

Background

Bullying is a significant problem for youth, which is associated with a wide range of socioemotional consequences in childhood and adolescence [1] that extend into adulthood [2]. Bullying peaks in middle school, with 28% and 33% of students in the United States reporting being bullied at school and cyberbullied, respectively [3]. Among middle school students, being a target of bullying is associated with poor academic performance [4,5], absenteeism [5,6], somatic symptoms [7], anxiety [1,7], depression [1,7,8], suicidal ideation, and suicide attempts [1]. A growing body of literature demonstrates that students who witness school bullying as bystanders also report negative outcomes, including an increased risk of depression, anxiety [9-11], and somatic symptoms [12]. Similar trends are also emerging for middle school students who witness cyberbullying [13-15].

Bystanders as Defenders

Most students (ie, up to 80%) report witnessing school bullying as bystanders [11], and approximately 50% report witnessing cyberbullying [16]. However, only 20% to 30% of students report intervening in school bullying [17], and as few as 10% report intervening in cyberbullying [18]. When bystanders interrupt a bullying situation by telling the bully to stop or by reporting bullying to an adult, bullying decreases [19] and bystanders report improved emotional adjustment [20]. However, often, bystanders do not intervene as they lack the knowledge or skills to act as *defenders* [21,22]. Therefore, equipping bystanders with strategies that they can use when they witness bullying can reduce both bullying and the negative associated consequences for both targets and students who witness bullying.

The STAC Intervention

Researchers developed the STAC intervention [23] to train middle school students to act as *defenders* on behalf of targets of bullying using the following four intervention strategies: (1) *Stealing the Show* (using humor or distraction to interrupt a bullying situation and remove the attention from the target), (2) *Turning it Over* (identifying a trusted adult at school, reporting, and asking for help during a bullying incident), (3) *Accompanying Others* (befriending or providing support to a peer who was a target of bullying), and (4) *Coaching Compassion* (gently confronting the perpetrator and increasing empathy for the target). STAC is a brief bystander intervention comprising a 75-minute training that includes didactic and experiential components. In the didactic portion, students learn about the definition of bullying, types of bullying, negative

associated consequences, bystander roles, and the 4 STAC strategies. The experiential component comprises role-plays during which students practice using the STAC strategies and receive feedback from the trainers. After the training, students participate in two 15-minute booster sessions to reinforce learning and skills. Boosters include check-in, support, and brainstorming of how to use the STAC strategies more effectively.

Research conducted with middle school students has shown that students report posttraining increases in knowledge of bullying and the STAC strategies, as well as the confidence to intervene on behalf of targets [23-26]. The findings also indicate that the STAC intervention is effective in reducing bullying victimization [24,27] and perpetration [24], as well as improving bystander mental health, including reducing anxiety [24,28], depression [24,29], and suicidal ideation [29], and increasing self-esteem [30].

Use of STAC Strategies to Act as a Defender

Although $\geq 90\%$ of middle school students report using at least one of the four STAC strategies to intervene in bullying situations after training [24,26,31], middle school students report using *Turning it Over* less frequently than elementary school students. Specifically, the prevalence rates of using “Turning it Over” declined from 78% in elementary school [31] to 69.1% in middle school [26]. Interestingly, this is not the case for the other 3 strategies, with prevalence rates increasing from 50.9% to 69.1% for *Stealing the Show*, from 76.4% to 90% for *Accompanying Others*, and from 44.4% to 69.1% for *Coaching Compassion* among elementary school students [31] and middle school students [26], respectively. A possible explanation for the lower rates of using “Turning it Over” in middle school is that middle school students may believe that teachers do not care enough about bullying to take action and perceive bullying as a less significant problem than students do [25]. Therefore, providing education to teachers about bullying and training them on how to support students when they report bullying or ask for help may be important additions to the STAC intervention at the middle school level.

Equipping Teachers to Support Student Defenders

Middle school students indicate that school bullying occurs most often in the classroom, accounting for 42.3% of all school bullying incidences [32]. However, national data indicate that only approximately half (51.7%) of middle school students report bullying to an adult at school, with report prevalence declining from sixth grade (57.2%) to eighth grade (47%) [32]. Although students report bullying to teachers more often than to any other adult at school [33], reporting behavior is influenced by a student’s perception of teachers’ responses to bullying.

Students are more likely to report when they believe teachers will intervene [34], effectively handle the situation [35], and reward students' efforts when they report or intervene in bullying [36]. In addition, students' future reporting behavior is influenced by how teachers respond to students' initial reporting [37]. Students are less likely to report bullying [33] and rates of bullying are higher in the classroom [38] when students perceive that teachers have low self-efficacy in handling bullying situations. As such, it is important for teachers to demonstrate comfort with and confidence in handling bullying situations. Training teachers to effectively respond to bullying and to encourage and support students who report and intervene in bullying are important components of bullying programs aimed at increasing student bystander intervention.

Reducing Barriers to Access and Implementation

Successful implementation of bullying prevention programs requires key stakeholder buy-in that can be enhanced by reducing barriers through the reduction of time and cost while increasing training flexibility [39]. We are in the process of translating the in-person STAC intervention into a technology-based format (STAC-T) [40,41] to increase accessibility, particularly for schools in low-income and rural communities. Developing a technology-based teacher module has the potential to enhance program efficacy, reduce implementation barriers [42], and increase program scalability [43]. Although web-based training outcomes (eg, increased knowledge, self-efficacy, and behavioral intentions) are equivalent to in-person training outcomes [42], perceived usefulness [44] and participant buy-in [39] are both important factors that contribute to program acceptability. Therefore, it is important to understand the perspectives of teachers regarding the strengths and barriers related to a technology-based format.

Initial Development of the STAC Teacher Module

The purpose of the development of the STAC teacher module was to enhance intervention outcomes by equipping teachers with knowledge and skills to appropriately address bullying and support students who witness bullying to intervene as "defenders." The content of the STAC teacher module was originally developed through focus groups conducted with high school teachers [45] and then adapted for the middle school level through focus groups conducted with middle school personnel, including teachers, an administrator, and a school counselor [46]. Preliminary research with high school teachers indicates that the training was effective in increasing teachers' knowledge; confidence in supporting student bystanders to intervene as *defenders*; and comfort, confidence, and self-efficacy in intervening in bullying situations [45]. Qualitative data from focus groups conducted with middle school personnel suggest that the content of the STAC teacher module is useful, relevant to, and appropriate for middle school settings [46]. In addition, middle school personnel indicated a need for the program and identified barriers to implementation, including cost, time, and teacher buy-in. Participants also provided feedback on delivering the program in a technology-based format, appreciating the flexibility of a technology-based program while expressing concerns regarding participant engagement.

Study Objectives

The purpose of this study was to build on our prior research on developing the STAC teacher module, examining the effectiveness of the training, as well as providing data to inform the translation of the training into a technology-based format that can be used as a companion module to the STAC-T program. To date, we have collected posttraining data from high school teachers and qualitative data from middle school teachers and other school personnel. This study represents the next step in the development of the STAC teacher module for middle schools. Specifically, we aimed to evaluate immediate posttraining outcomes (eg, changes in knowledge, confidence, self-efficacy, and teachers' intention to use the STAC strategies) among middle school teachers and obtain additional feedback from a new group of middle school teachers recruited from a different school district regarding program content, acceptability, need, and delivery via a technology-based format. To achieve these aims, we used a mixed methods research design to answer the following research questions: (1) Do the trained teachers report increases in knowledge and confidence to support students who act as *defenders* and increases in confidence, comfort, and self-efficacy in managing and handling bullying? (2) Do teachers indicate behavioral intentions to use the STAC strategies after training? (3) Is the STAC teacher module acceptable and relevant to middle schools? (4) What was the teachers' feedback regarding program appropriateness, feasibility, content, perception of need, and desire for web-based training?

Methods

Participants

Participants were teachers (N=18) recruited from 1 public middle school in a rural, low-income community in the northwestern United States. We selected the school based on a prior and ongoing research partnership. The school was a Title I school located in a rural community, with 89.1% (304/341) of the student population qualifying for reduced or free lunch. The race or ethnicity of the student body included 64.5% (220/341) Hispanic, 34.3% (117/341) White, and 1.2% (4/341) other. Of the 18 participants who completed the pretest survey, 17 (94%) completed the immediate posttest survey. The final sample comprised 76% (13/17) women and 24% (4/17) men. Among the participants, ages ranged from 25 to 62 (mean 44.76, SD 12.16) years, and years of experience as a middle school teacher ranged from 1 to 26 (mean 10.24, SD 7.82) years. Most of the teachers in the sample were female (13/17, 76%) and identified as White (16/17, 94%). Of the 17 teachers who completed the immediate posttest survey, 6 (35%) signed up and participated in the focus group. The sample comprised 35% (6/17) women who identified as White. A series of chi-square analyses and 2-tailed independent-sample *t* tests revealed no statistically significant demographic differences between those who participated in the focus group and those who did not participate.

STAC Teacher Module for Middle School

Overview

The STAC teacher module is a 50-minute module that includes (1) normative feedback regarding the prevalence of bullying to engage teachers; (2) didactic information about bullying, including the definition and types of bullying and the associated negative consequences; (3) a review of the student STAC strategies and corresponding strategies that teachers can use to support students who act as “defenders,” followed by role-plays to reinforce skill acquisition; and (4) information about “perceptions vs. facts” about bullying that can influence how teachers shift the school climate and demonstrations of how teachers can apply research-based strategies to positively influence and shift the school climate.

Normative Feedback

The normative feedback module begins with teachers estimating the local and national prevalence rates related to bullying among middle school students. Example questions include the following: (1) What percentage of middle school students say that they have been bullied in the past year? (2) What percentage of middle school students say that they have been cyberbullied in the past year? (3) Rank the order of the location middle school students are most frequently bullied (ie, hall/stairwell, classroom, cafeteria, outside of school grounds, and bathrooms/locker rooms), and (4) Among middle school students, what percentage of students report bullying to an adult?

After the teachers indicate their estimates, trainers provide actual prevalence data in comparison with their responses and facilitate a brief discussion regarding discrepancies.

Bullying Education

Teachers are presented with the definition of bullying, including examples of behaviors that would not be considered bullying (eg, what is not bullying). Trainers also discuss different types of bullying (ie, physical, verbal, relationship, and cyberbullying), negative associated consequences for students who are targets or bystanders, and positive outcomes for students who are trained and intervene as “defenders.” This information is presented in a manner that parallels the STAC training for students.

STAC Strategies and Role-plays

Overview

Trainers present the 4 STAC strategies (ie, *Stealing the Show*, *Turning it Over*, *Accompanying Others*, and *Coaching Compassion*) that students are taught to use to intervene as *defenders* when they witness bullying at school. Next, trainers discuss the skills that teachers can use to support students using each of the 4 STAC strategies. After each strategy is presented, trainers ask for teacher volunteers to engage in a role-play to practice the skills the teachers can use to support students acting as “defenders.” The 4 STAC strategies with the corresponding teacher strategies are outlined in the following sections.

Stealing the Show

Students are taught to use humor or distraction to interrupt a bullying situation. Teachers can support students using this

strategy by approaching the situation, joining in the conversation, or laughing at a joke that appropriately interrupts the bullying situation. Teachers are encouraged to disperse the peer group so that the perpetrator or perpetrators do not have access to a peer audience. Teachers are also encouraged to reinforce the *defender* with positive feedback, check in on the target, and report the situation to the administration when appropriate.

Turning It Over

Students are taught to use *Turning it Over* or reporting the bullying situation to an adult at school, and they are encouraged to always use this strategy if they witness physical or cyberbullying. Teachers can support students who report bullying by assuring them that they did the right thing. Trainers encourage teachers to reinforce to students that bullying is not acceptable and that it requires maturity and strength to report bullying and ask for help. As students generally believe that their peers will perceive them as a “Snitch” if they report bullying to adults [47], teachers are also encouraged to share with *defenders* that research shows that students are generally supportive of their peers who report bullying. In addition, trainers instruct teachers to share with students that it often requires continued documentation for adults to be able to take significant action and that a process may be occurring outside of a student’s awareness because of issues related to confidentiality. As such, teachers should encourage *defenders* to continue reporting and, in the case of cyberbullying, documenting by taking immediate screenshots or pictures. Teachers should also follow up and report bullying to their administration when appropriate.

Accompanying Others

Students are taught to use *Accompanying Others* to befriend or support peers whom they witness being a target of bullying. Student *defenders* can use this strategy without calling attention to the situation by inviting students who were targeted to sit with them at lunch or walk with them to class. Depending on the nature of their relationship, *defenders* can share with the target that they witnessed what happened, state that the perpetrator’s behavior was unacceptable, and ask whether they would like to talk about it. Teachers are encouraged to let students who use this strategy know that they are being a good friend and positively affecting their peer’s experience at school. Trainers also encourage teachers to reinforce to *defenders* that by befriending targets, they are communicating to their peers that they care about them and that they are not alone at school. Furthermore, teachers are instructed to encourage *defenders* to check back in with their peers who were targeted the day following the incident to build an acquaintanceship or friendship, as well as to follow up with the targets themselves or report the bullying incident if appropriate.

Coaching Compassion

Students are taught to use *Coaching Compassion* to gently confront students who perpetrate bullying behaviors during or after a bullying incident. Only students who are older, have a higher social status, or are good friends with the perpetrators are encouraged to use this strategy. The goal is to raise the awareness of students who bully that bullying is unacceptable

while fostering empathy toward the target. Trainers instruct teachers to support students using this strategy by paying close attention to the situation and becoming involved if necessary to ensure safety. In addition, teachers are encouraged to reinforce to *defenders* that they did the right thing in intervening and that bullying is unacceptable and share that research indicates that for students who bully infrequently, increasing awareness and empathy often decreases bullying [48].

Perceptions Versus Facts About Bullying and Teachers' Role in Shaping the School Climate

Trainers present statements related to bullying and school climate, and teachers are asked whether these statements are true or false. Trainers then discuss the correct answers and supporting research. For example, teachers are asked (1) whether most students have negative attitudes toward peers who report bullying to teachers; (2) whether students perceive that teachers think bullying is developmentally appropriate and that teachers do not care enough about bullying; and (3) in schools where teachers appear to be less judgmental of bullying, whether students are bullied more often. The training concludes with a demonstration of a teacher intervening in a classroom bullying situation reinforcing strategies that research supports are effective in positively shifting the school climate.

Procedures

Participant recruitment and data collection occurred during the spring of 2022. The inclusion criterion was being a middle school teacher at the participating school. The exclusion criterion was being a staff member other than a teacher. The team worked with the school principal to recruit all teachers from 1 middle school to be trained on the STAC teacher module. The first author (AM) and a Master's student conducted study recruitment, data collection, and the STAC teacher module training in person at the school during a professional development day. The researchers conducted the informed consent process immediately before collecting the baseline data, which was then followed by the STAC teacher module and postintervention data collection. The pre- and postintervention data collection took 15 to 20 minutes to complete, and the training lasted 50 minutes. After postintervention data collection, the researchers invited all study participants to sign up for a follow-up focus group that occurred within a week of the training and was conducted on the web. A doctoral student and a master's student conducted the focus group, which lasted approximately 45 minutes and was recorded for verbatim transcription. Participants received a US \$50 Amazon gift card as an incentive to participate in the STAC teacher module and complete pre- and posttraining surveys. Participants also received a US \$50 Amazon gift card as an incentive to participate in the follow-up focus group.

Ethics Approval

We used active informed consent for this study. The researchers provided the participants with an informed consent form that contained information about the study, including purpose and background, procedures, risks or discomforts, extent of confidentiality, benefits, payment, and how to contact the primary investigator and the institutional review board of the

university. All study procedures were approved by the institutional review board of the university (101-SB21-051) and by the school district. Although the principal recruited teachers to participate in the training, the research team members conducted study recruitment. Teachers were informed that their participation in the study procedures (ie, completing surveys or participating in a focus group) was voluntary and that they could choose not to participate or withdraw from the study at any time without penalty. We believe that this procedure minimized any pressure teachers may have felt to participate in the research because of the principal's role in recruiting teachers to participate in the training.

Measures

Demographic Survey

The teachers completed a brief demographic questionnaire that included questions about age, gender, race or ethnicity, and years of experience teaching.

Knowledge and Confidence to Support Defenders

The Teacher-Advocates Pre and Post Scale [45] was used to measure knowledge and confidence in supporting "defenders." The questionnaire comprises 11 items that measure knowledge of bullying behaviors, knowledge of how to support students using the STAC strategies, and confidence in supporting students who intervene in bullying situations. Examples of items include "I know what verbal bullying looks like," "I know how to support students who reach out to students who are targets of bullying," and "I feel confident in my ability to do something helpful to support students who report bullying to me." Items are rated on a 4-point Likert scale ranging from 1 (*totally disagree*) to 4 (*totally agree*). All the items are summed to compute the total scale score. Possible scores range from 11 to 44. Higher scores reflect higher levels of knowledge and confidence. The Teacher-Advocates Pre and Post Scale has established internal consistency, with Cronbach α ranging from .72 to .95 [45]. The Cronbach α was .71 for this study.

Confidence in Managing Bullying

The Teacher's Attitudes about Bullying Questionnaire [49] is a 22-item questionnaire that contains 5 subscales. We used the 3-item Confidence in Managing Bullying Subscale, which includes the items "I am confident that I will know what bullying is when I see it," "I am confident that I will know how to respond if one of my students is being victimized by a peer," and "I am confident that I will put my knowledge into practice and actively respond in bullying situations." Items are rated on a 5-point Likert scale ranging from 1 (*strongly disagree*) to 5 (*strongly agree*). All the items are summed to compute the total scale score. Possible scores range from 3 to 15. Higher scores reflect higher levels of confidence in managing bullying. The Cronbach α was .67 for this study.

Comfort With Managing Bullying

The teachers' comfort with managing bullying was measured using items from the National Education Association Bullying Survey [50]. The teachers were asked the question "How comfortable would you feel intervening when you see the following bullying behaviors?" followed by four types of

bullying and their definitions: (1) physical (hitting, pushing, or kicking), (2) verbal (general teasing or name calling), (3) relational (rumor spreading or excluding someone from a group), and (4) cyberbullying (sending or posting harmful material or engaging in other forms of social aggression using the internet or other digital devices, such as mobile phones). Items are rated on a 4-point Likert scale ranging from 1 (*very uncomfortable*) to 4 (*very comfortable*). All the items are summed to compute the total scale score. Possible scores range from 4 to 16. Higher scores reflect higher levels of comfort with managing bullying. Items were summed to create the scale. The Cronbach α was .71 for this study.

Bullying Self-efficacy

The teachers' self-efficacy in handling bullying situations was measured using 2 items from the National Education Association Bullying Survey [50]. The items "I have effective strategies for handling bullying" and "I have effective strategies for supporting students to intervene in a bullying situation" are rated on a 4-point Likert scale ranging from 1 (*strongly disagree*) to 4 (*strongly agree*). All the items are summed to create the scale. Possible scores range from 2 to 8. Higher scores reflect higher levels of self-efficacy. The Cronbach α was .81 for this study.

Intention to Use Teacher STAC Strategies

The intention to use teacher STAC strategies was measured using an adapted version of the Use of STAC Strategies [28] for students. The items were adapted from the student version to be appropriate for teachers. The 4-item measure asks teachers the following: "How likely are you to support students using these strategies to intervene in bullying in the future?: a) Stealing the Show—support students using humor or distraction to get the attention away from the bullying situation, b) Turning it Over—support a student who reported bullying to you or supporting students to report to a principal or SRO, c) Accompanying Others—support students who reach out to the student who was the target of bullying, or d) Coaching Compassion—support students who help the student who bullied develop empathy for the target." Items are rated on a 5-point Likert scale ranging from 1 (*very unlikely*) to 5 (*very likely*), with higher scores reflecting higher levels of intention to use the strategies.

Acceptability and Relevance of the Teacher STAC Training

Acceptability (ie, ease of use or utility) and relevance of the STAC training were assessed using a social validity survey comprising 8 items. Items were ranked on a 4-point scale from 1 (*strongly disagree*) to 4 (*strongly agree*), with higher scores reflecting higher levels of acceptability and relevance. The survey was based on social validity surveys used to assess the appropriateness of interventions adapted for a new population with demonstrated reliability and validity [51,52]. The Cronbach α was .97 for this study.

Interview Questions

Within a week of being trained and completing the posttraining survey, a subset of teachers (6/17, 35%) participated in a focus group. Participants were asked semi-open-ended questions about the relevance and appropriateness of the training.

Participants were asked (1) what they liked and did not like about the training; (2) what information was missing from the training to equip teachers to support students to act as *defenders* in a bullying situation; (3) how useful they perceived the training was to prepare teachers to address the problem of bullying at school; (4) whether the content of the program was relevant to and appropriate for their students and community; (5) what was the practicality and workability of the training for their school setting; (6) what types of similar training they had received, including training specifically about bullying; (7) whether they thought there was a need and whether they would use this training at their school; (8) what barriers may prevent their school from adopting or implementing a bullying intervention program; (9) what were the strengths or barriers to implementing this program as a web-based program; and (10) what was the usefulness of web-based training.

Data Analysis

Quantitative

Quantitative data from the questionnaires were analyzed using SPSS (version 28.0; IBM Corp). Before conducting the statistical analyses, the data were examined for outliers and normality, and all variables were within the normal range for skewness and kurtosis. We computed descriptive statistics for all variables at pre- and posttest measurements. We conducted a series of paired-sample *t* tests to evaluate changes from pre- to posttest measurements. All analyses were considered significant at $P < .05$. The Cohen *d* was used to measure effect size, with the magnitude of effects interpreted as follows: small ($d = 0.20$), medium ($d = 0.50$), and large ($d = 0.80$) [53].

Qualitative

One team member, who facilitated the focus group, transcribed the data verbatim. The data analysis team comprised 2 faculty members with expertise in qualitative data analysis and a doctoral student. The lead analyst developed an analysis plan. First, analysts wrote an individual precoding memo reflecting on potential biases and assumptions about the research questions. Subsequently, they participated in a preanalysis meeting where they discussed initial memos and coordination for the analysis process. Team members used thematic analysis, which is a phenomenological approach focusing on participants' experiences, and an inductive approach to coding the transcript and interpreting the data [54,55]. Analysts coded the focus group transcript individually, wrote a postcoding memo, and met twice to achieve a consensus on themes and finalize the results. The team used the participants' quotes to resolve disagreements. An external auditor reviewed the results and provided the team with feedback through email correspondence. No identifying information was included in the interview transcripts.

Results

Quantitative Analysis

Posttraining Outcomes

Means, SDs, and statistical contrasts for pre- to posttest training outcomes are presented in Table 1. The teachers reported an increase in knowledge and confidence to support *defenders*

($P<.001$), confidence in intervening in bullying situations ($P<.001$), comfort with intervening in bullying situations ($P<.001$), and bullying self-efficacy ($P<.001$). All the effect sizes were large. The results support the effectiveness of the

teacher training in increasing knowledge and confidence in both working with student bystanders and intervening directly in bullying situations from before the training to after the training.

Table 1. Means, SDs, and statistical contrasts for paired-sample t tests.

Item	Pretest time point, mean (SD)		Posttest time point, mean (SD)		
	Values, mean (SD)	Values, mean (SD)	t test (df)	P value	Cohen d
Knowledge and confidence in supporting <i>defenders</i>	30.71 (2.95)	37.34 (3.90)	8.31 (16)	<.001	2.02
Confidence in intervening in bullying	10.47 (1.70)	13.12 (1.54)	7.09 (16)	<.001	1.72
Comfort with intervening in bullying	11.42 (1.62)	13.06 (1.95)	4.20 (16)	<.001	1.02
Bullying self-efficacy	4.65 (0.86)	6.82 (1.01)	9.44 (16)	<.001	2.29

Intention to Use Teacher STAC Strategies

The teachers' ratings of their intention to use teacher STAC strategies are reported in Table 2. As seen in Table 2, most teachers indicated that they were likely or very likely to use the STAC strategies to support students who intervene in bullying in the future. For specific strategies, >90% (16/17, 94%) reported that they would be likely or very likely to support

students using *Stealing the Show*, >90% (16/17, 94%) reported that they would be likely or very likely to support students using *Turning it Over*, 100% (17/17) reported that they would be likely or very likely to support students using *Accompanying Others*, and >85% (15/17, 88%) reported that they would be likely or very likely to support students using *Coaching Compassion*.

Table 2. Intention to support students using STAC strategies in the future (N=17).

Strategy	Agreement, n (%)				
	Very likely	Likely	Not sure	Unlikely	Very unlikely
Stealing the Show	7 (41)	9 (53)	1 (6)	0 (0)	0 (0)
Turning it Over	8 (47)	8 (47)	1 (6)	0 (0)	0 (0)
Accompanying Others	6 (35)	11 (65)	0 (0)	0 (0)	0 (0)
Coaching Compassion	5 (31)	9 (56)	2 (13)	0 (0)	0 (0)

Acceptability and Relevance of the Teacher STAC Training

The percentage of agreement for the social validity survey items is reported in Table 3. Overall, the scores suggest a very high level of program acceptability and relevance. Most teachers

found the STAC teacher module to be easy to understand (16/17, 94%), useful (16/17, 94%), interesting (15/17, 88%), and relevant (16/17, 94%) to middle school teachers. Most teachers also indicated that they had learned something from the program (16/17, 94%) and would recommend it to other teachers at their school (16/17, 94%).

Table 3. Participants reporting agreement with social validity items (N=17).

Item	Agreement, n (%)			
	Strongly agree	Agree	Disagree	Strongly disagree
The STAC teacher training was easy to understand.	11 (65)	5 (29)	0 (0)	1 (6)
The STAC teacher training was useful.	11 (65)	5 (29)	0 (0)	1 (6)
The STAC teacher training was interesting.	9 (53)	6 (35)	0 (0)	2 (12)
The STAC teacher training information was relevant to middle school teachers.	14 (82)	1 (6)	1 (6)	1 (6)
The STAC teacher training examples of bullying were relevant to middle school teachers.	11 (65)	5 (29)	0 (0)	1 (6)
The STAC teacher training strategy role-plays were relevant to middle school teachers.	11 (65)	5 (29)	0 (0)	1 (6)
I learned something from the STAC teacher training.	12 (71)	4 (24)	0 (0)	1 (6)
I would recommend the STAC teacher training to other teachers at my school.	13 (77)	3 (18)	0 (0)	1 (6)

Qualitative Analysis

Overview

Qualitative feedback for the STAC teacher module supported the quantitative findings and was positive overall, with participants sharing the perception that the STAC teacher module was useful, relevant, and appropriate, as well as sharing ways of improving the program. In addition, teachers shared positive thoughts about program feasibility, the need for bullying-specific training for teachers, and strengths of and implementation barriers to a web-based program. The results are presented in the following sections, organized according to the following themes: (1) positive program attributes; (2) relevance and appropriateness; (3) program feedback; (4) feasibility, need, and current program offerings; (5) potential barriers; and (6) web-based offering.

Positive Program Attributes

Participants spoke positively about the STAC teacher module, including liking the teacher strategies to support students who report bullying, finding the strategies easy to implement, and finding the role-plays useful. Participants also liked that the STAC program provides students with the knowledge and skills to intervene in bullying situations. A participant shared the following:

You know there are so many things to be concerned about in a classroom and a lot of bullying, I think, is pretty under the radar. So, having the tools to know what to look for and maybe how to interpret some of the things we see. I think it's really beneficial.

When talking about the strategies they had learned, a teacher added the following:

These are just simple easy things, it is not something that is super difficult or a lot of steps you have to remember to be able to implement some of those strategies so that is really helpful.

Another participant indicated the following:

...the role-playing did help. It just lets you know, yeah, it's okay to say this and you know gives you something to fall back on.

When discussing the value of empowering students, a participant stated the following:

You know just to be able to have those tools, so they [students] can be empowered to help other kids or to help themselves.

Relevance and Appropriateness

When asked whether the STAC teacher module was relevant to and appropriate for their school and community, all participants expressed agreement. A teacher stated the following:

I guess if we see it in our schools it's happening in our community too. If we can deal with it here hopefully that will bleed out into the community and have an effect, there too.

Another teacher indicated the following:

I think there is a need [for the STAC Teacher Module] and I think, you know, there is some staff that are attuned to it. So, I think there would be definitely some teachers that would use it more than others, which is probably good because we need lots of personalities to connect with different student personalities. My guess is that it is really hard to say we are all going to do this and have it really be effective, but I think given the training and the tools there would be more teachers that would implement it.

Program Feedback

When participants were asked for feedback regarding areas that were missing from the training, a few participants indicated the need for role-plays with more realistic scenarios; additional guidance to discern whether students were genuinely acting as defenders or being disingenuous, especially when using humor; and concern about the impact of labeling a student as a bully. A participant indicated the following:

Maybe some scenarios of things that actually might occur, so we have a better idea of what to look for because sometimes they look like they are playing and maybe that is okay. But, then other times, they really are not playing, you know, and so what are some, you know, different scenarios that would help us to identify or see some of the things that really affect middle schoolers that we could kind of tune in on.

Another participant added the following:

Yeah, characteristics to look for because it is hard to know what is genuine and what's not especially when they are in middle school because everything is a joke. Which I like, I use humor as a tool all of the time, but everything is a joke and sometimes a kid will interpret someone's humor as bullying.

In terms of concerns about labeling students, a teacher stated the following:

The issue that I struggle with is labeling somebody as a bully because once us, as teachers, identify that behavior as bullying, then all of the sudden other students look at that student differently. When it could be that they just needed to learn. I don't know I struggle with that as well because once you label them as a bully then it is kind of stuck with them and other students look at them differently. And then all of the sudden the bullying actually shifts and they start to look at that kid negatively.

However, another participant responded as follows:

On the other hand sometimes we don't acknowledge when somebody is a bully. And we just keep justifying their behavior and it makes the kids that are being bullied like victimized more and so I think it is important that we get that conversation going...

Feasibility, Need, and Current Offerings

Participants indicated agreement on the program being practical and workable. Participants also spoke about the need for training

and support in addition to the current offerings on social-emotional learning and identifying a need for bullying-specific training for teachers. When asked if the program seemed practical and workable, a participant indicated the following: “Yeah, I think that would be great.” Another participant added that “I think it would be a feasible thing to do...” In terms of current offerings, a participant stated the following:

As a district we also have a 21st Century program that serves our elementary school and our middle school kids and they have a huge focus on the social emotional learning.

When asked about training that teachers received specifically about bullying, a participant indicated the following: “Uh, no not enough... We have a little, you know.”

Potential Barriers

Participants spoke about concerns regarding cost, potential pushback from parents, and maintaining an open mind. For example, a teacher stated that “Cost, if there is a cost to it—there is going to be one [barrier] there.” Another teacher shared the following:

Yeah, and I think even some kind of pushback from parents, you know, because we’ve seen that kids that you would think are perfect kids, they are the actual ones that are bullying, and their parents can’t believe it.

Finally, a teacher shared the following:

It’s hard to redefine people that you think you know. So, if you think of them as a perfect student and then you hear that they’re a bully as well, well is that really true or is it you know so having that open-mindedness to just say oh I guess what I thought was wrong.

Web-Based Programs

When addressing completing the STAC teacher module as a web-based program, participants talked about strengths such as ease of implementation and time efficiency, as well as challenges, including less engagement and missing the in-person connection. Participants also spoke about inherent issues related to technology and the importance of administration buy-in. For example, when speaking about strengths, participants indicated the following:

...you can go back and review it. So, if I’m thinking, okay, what did we say about that, or whatever or the kids need a refresher or those kinds of things. Technology does give us access to that as well as consistency.

Another participant added the following:

Technology would make it really easy to do a follow up with this kind of course...a refresher using technology and a quick setting.

A third participant added the following:

One thing is nice with web-based because you don’t have to have a sub and you don’t have to miss class

and that’s really valuable because we spend a lot of time doing sub plans and different things.

However, this participant went on to say the following:

But it’s just not as engaging [to complete the program online]

Another participant added the following:

When you’re trying to implement bullying strategies, how to deal and handle and cope, there is something to be said with the interpersonal relationship having someone in person teaching it versus online...

Another teacher stated the following:

...sometimes that removed, that technology piece, you don’t engage the same way as if you’re in person...

Participants also mentioned technology issues as barriers; for example, a teacher stated that “Access to technology, yep.” Finally, a participant shared the following about the importance of buy-in:

Yeah, I think there is buy-in and if there is buy-in from our administration then it’s a go. You know, and I think you kind of need a little bit of our administration to push it out and teachers that really see a need for it to buy-it and to push it out to the other teachers. I think a lot of us do different things as situations arise, we talk about it in our classrooms, that’s—we don’t have anything like whole school [programming]

Discussion

Principal Findings

The purpose of this study was to build on our prior research on developing the STAC teacher module, examining the effectiveness and acceptability of the training, as well as providing data to inform the translation of the training into a technology-based format that can be used as a companion model to the STAC-T student bystander bullying intervention. Quantitative findings indicated that teachers reported increases in knowledge and confidence to support students who intervene as *defenders* and to directly intervene in bullying situations from before training to after training. The teachers also reported behavioral intentions to use the STAC teacher strategies. Furthermore, the participants’ responses demonstrated high levels of program acceptability and relevance to middle school teachers. Qualitative findings were consistent with the quantitative results and revealed the following themes: (1) positive program attributes; (2) relevance and appropriateness; (3) program feedback; (4) feasibility, need, and current program offerings; (5) potential barriers; and (6) web-based offering.

Comparison With Prior Work

Consistent with prior research conducted with high school teachers trained in the STAC teacher module [45], quantitative data demonstrated increases in knowledge and confidence to support *defenders* as well as increases in confidence, comfort, and self-efficacy in managing and handling bullying from before training to after training. In addition, the teachers reported that they would use all 4 strategies to support students who act as

defenders on behalf of targets. Qualitative data supported these findings, indicating that the teachers liked the strategies and found them easy to implement. These findings are important as increases in teacher knowledge and bullying self-efficacy have been associated with directly intervening in bullying [33], which, in turn, could lead to students being more likely to report bullying behavior [34]. By rewarding students' efforts when they report or intervene in bullying [36], teachers are also likely to reinforce and increase bystander intervention, which has been shown to decrease bullying behaviors [48].

In terms of program acceptability and relevance, quantitative data indicated that most participants (16/17, 94%) reported that the STAC teacher module was easy to understand, useful, and relevant to middle school teachers. Furthermore, most participants (16/17, 94%) indicated that they learned something from the training and would recommend it to others. Consistent with our prior research with middle school personnel [46], the teachers reported that the training was useful, relevant to, and appropriate for middle school settings. Qualitative data supported these findings, with all teachers indicating agreement about the training being relevant. As program adoption and implementation are associated with acceptability and relevance [56], these findings are particularly promising.

The teachers also provided feedback on program feasibility and perception of program need. Although they confirmed the need for bullying programs that equip teachers to intervene and to support students who act as "defenders," the teachers also spoke about barriers, including cost, as well as the importance of considering parents in bullying programs. These findings are consistent with our previous studies concerning the implementation of both the STAC teacher module [46] and the student STAC-T program [40,41], suggesting that there is a need for a cost-effective STAC teacher module that incorporates parental participation.

Regarding program content, the teachers provided feedback indicating that the role-plays corresponding to the 4 STAC teacher strategies were helpful; however, a few participants expressed a desire for more realistic scenarios to further improve the training. In addition, although a few teachers stated concern about the impact of labeling a student as a bully, they also acknowledged the importance of recognizing bullying behavior. This reluctance to acknowledge bullying is similar to findings from previous studies in which teachers indicated a desire to remain neutral [45]. However, it is important for teachers to be willing to communicate that bullying behaviors are unacceptable, reinforce students who intervene as *defenders* [36], and discipline students who perpetrate bullying [37] to establish a school climate that does not condone or promote bullying.

Finally, when asked about their perspectives on web-based programs, the teachers pointed out strengths, such as ease of implementation and time efficiency, as well as challenges, including less engagement and missing the in-person connection. Participants also suggested that these barriers could be mitigated by administrative buy-in. These findings are similar to prior research conducted with school personnel emphasizing the importance of flexibility while expressing concerns about

participant engagement [46]. As training acceptability is related to stakeholder buy-in [39], it may be important to emphasize that web-based training decreases program costs and allows for training schedule flexibility [42]. Designing the training to include web-based assessment and personalized feedback components to individualize the user experience [57] can be integrated to maintain engagement.

Limitations

Although this study contributes to the literature, certain limitations must be considered. First, we only collected data from teachers in 1 rural, low-income middle school in the northwestern United States. We chose to use only 1 school as this study represents one of a series of studies conducted as formative research on the development of the STAC teacher module. Our prior research included teachers from 2 middle schools. This sample represents teachers from a third middle school.

Furthermore, because of the small sample size and lack of a control group for the quantitative portion of the study, we cannot make causal attributions or generalize our findings to the larger middle school teacher population. Therefore, it would be helpful for future studies to include middle schools from different regions in the country with greater racial or ethnic diversity and to conduct a randomized trial to assess training efficacy. In addition, as most of the sample was female, the interpretation of the results for men should be made cautiously. Formative research conducted during the development of the prototype application of the STAC teacher module should use purposeful sampling to ensure that men are included. Finally, our findings were based on self-reported data. It is possible that the teachers' responses to the survey questions and the focus group interview were influenced by their desire to please the researchers. They may have been particularly influenced as team members who trained the teachers were present during both quantitative and qualitative data collection. Future research in which team members who act as trainers are different from those who conduct data collection would be helpful in reducing participants' potential desirability effects.

Implications

This study has important implications for the development of the STAC teacher module and the translation of the training into a technology-based format that can be used as a companion module to the STAC-T program. First, the teachers reported increased immediate posttraining outcomes (ie, knowledge, confidence, comfort, and self-efficacy) in managing and handling bullying and supporting student bystanders to intervene in bullying situations. Furthermore, the teachers indicated behavioral intentions to use the STAC strategies after the training and reported that the training was feasible as long as the program was cost-effective. In addition, although the response to the training was very positive, a few teachers indicated a desire for more realistic scenarios for role-plays; as such, it may be beneficial for researchers to conduct additional focus groups with both teachers and students to further investigate student reporting behavior and teachers' responses. Furthermore, participants identified potential parent pushback as a barrier. Therefore, the development of a parent training

intervention to educate parents about the STAC program by providing information that parallels the STAC teacher module may be an important next step in program development.

The findings of this study also support the initial prototype development and testing of a technology-based version of the STAC teacher module. The teachers pointed out that the benefits associated with web-based training included ease of implementation and time efficiency. However, the teachers cautioned that maintaining engagement in web-based training is important. The teachers talked about the importance of administrator buy-in for successful adoption and implementation. Thus, when designing an internet-based program to maximize teacher engagement, integrating feedback from both teachers and administrators will be an essential element in developing a technology-based version of the STAC teacher module.

Conclusions

Bullying is a significant problem for youth in the United States, reaching its peak in middle school. Although training students in the STAC program to act as *defenders* is a promising approach to bullying interventions, equipping teachers to support students who intervene may increase the effectiveness of the program. Findings from this study demonstrate immediate posttraining outcomes, including increased knowledge, confidence, comfort, and self-efficacy, as well as teachers' behavioral intentions to use the STAC strategies. Furthermore, this study demonstrates program acceptability, relevance, feasibility, and the need for a teacher training intervention, as well as interest in a web-based translation. This study provides support for the effectiveness of the STAC teacher module and provides data to inform the translation of the training into a technology-based format that can be used as a companion model to the STAC-T bystander bullying intervention.

Abstract

Background: Population aging and multimorbidity has led to increasing chronic care needs associated with new challenges in managing growing costs, rising health care professional workloads, and the adoption of rigorous guidelines. These issues could all benefit from greater digitalization and a more patient-centered approach to chronic care, a situation brought to the fore by the COVID-19 pandemic. Little is known about real-life use in primary care.

Objective: This study aimed to explore the views, thoughts, usability, and experiences concerning a recently introduced digital self-care platform for chronic conditions in 3 Dutch primary care practices.

Methods: We conducted an explorative study combining questionnaires and interviews among patients and general practitioners from 3 general practices that used the digital platform. Questionnaires were sent to patients in each practice to seek the views and experiences of both patient nonusers (n=20) and patient users (n=58) of the platform, together with standardized questionnaires about illness perception and quality of life. In addition, patients (n=15) and general practitioners (n=4) who used the platform took part in semistructured interviews. We transcribed interviews verbatim and performed qualitative content analysis using a deductive approach. The results of the questionnaires were analyzed with descriptive analysis.

Results: Among patients who had not actively used the platform but had received an explanation, only 35% (7/20) would recommend its use due to concerns over communication and handling. However, this percentage increased to 76.3% (45/59) among the people who actively used the platform. Interviews with patients and general practitioners who used the platform uncovered several key benefits, including reduced time requirements, reduced workload, improved care quality, and improved accessibility due to the greater patient-centeredness and use of different communication tools. In addition, the self-management tool led to greater patient autonomy and empowerment. Although users considered the platform feasible, usable, and easy to use, some technical issues remained and some patients expressed concerns about the reduction in human contact and feedback.

Conclusions: The overall experience and usability of the platform was good. Support for the online self-management platform for chronic care increased when patients actively used the tool and could experience or identify important advantages. However, patients still noted several areas for improvement that need to be tackled in future iterations. To ensure benefit in the wider population, we must also evaluate this platform in cohorts with lower digital and health literacy.

Introduction

Western health care systems are facing challenges due to population aging and the rising number of chronic diseases [1,2]. Crucially, these chronic diseases are costly for individuals and the health care system, representing an important limiter of life quality [3,4], and are responsible for increased workloads experienced by general practitioners (GPs) [5]. Traditional clinical pathways offer standardized care that can be seen as rigid when physicians make decisions for their patients based on strict guidelines, and this can result in poor adherence and ownership by patients [5-7]. However, this approach contradicts modern views that patients should be responsible for their health and lifestyle [7]. Health care systems require a shift toward patient-centered care, with prevention and health lead by patients themselves [8].

Patient-centered care considers the individual preferences, needs, and values necessary to guide all clinical decisions [9] to improve quality of life for patients [10]. To achieve patient-centered care, patients must also engage in self-management and shared decision-making. Self-management requires that patients with chronic disease manage their own symptoms, treatment, lifestyle changes, and any consequences [6]. This can empower patients by increasing their autonomy [11], and it benefits by offering direct feedback via the required self-monitoring of vital signs [12]. Shared decision-making is a process through which health care providers make important decisions with patients regarding disease management or a lifestyle change [13].

Digital health can facilitate the change to patient-centered care by offering web-based information programs, remote monitoring, teleconsultations, and home care supported by mobile devices [14]. Health outcomes when comparing these services with in-person consults to date have either been similar [9,15] or have shown improvement [16]. Digital health can also improve health care effectiveness, efficiency, and accessibility in the context of population aging and greater disease chronicity [12], helping to manage increased GP workloads [17] while still offering patient-centered care [18]. The COVID-19 pandemic led to a marked increase in digital health implementations [19], consistent with models that predict health behavior and acceptance of technology, such as the health belief model [20] and the unified theory of acceptance and use of technology (UTUAT) model [21], respectively.

We implemented an online self-management platform for patients living with chronic illness in 3 Dutch primary care facilities. In this study, we aim to describe this innovative approach and evaluate (1) views on care digitalization and intention to use the new platform among patients who did not use the platform questionnaires, (2) experiences with the platform and thoughts about illness and quality of life among

patients who used the platform questionnaires, and (3) experiences of GPs and patients who used the platform.

Methods

Online Platform

Three Dutch primary care practices (Westerdokters, Veendokters, and Wouwe Markt), all members of the Flexdokters Cooperative, introduced a digitally supported self-care platform in April 2020. Designed by GPs from Flexdokters as a tailor-made service for patients with chronic illness, it used the online Viduet platform (Medicine Men), an independent tool to monitor chronic diseases that is partly integrated with the electronic health information system of the GP. It does not contain all medical information of the patient, only data that are relevant for chronic diseases like, for example, blood pressure and glucose levels. The costs are mainly covered by health insurance and offered for free to participating patients. GPs can recommend the platform to eligible patients and offer an initial explanation via video call or in-person contact. Shared decision-making is then used to select appropriate measuring devices, symptom questionnaires, contact options, and measurement frequency. If they agree, patients receive the necessary devices and user manuals at their home address and a link by email to create a platform account. Patients can then use validated questionnaires to monitor asthma, chronic obstructive pulmonary disease, cardiovascular risk, diabetes, depression, or other chronic diseases. Available devices include blood pressure monitors, glucose meters, oxygen saturation meters, smartwatches, fitness trackers, thermometers, and weighing scales, which are sent if needed.

Data are input manually or automatically (via Bluetooth). The platform offers access to a technical help desk for health care professionals and patients that refers any medical questions from patients to the health care provider. The GP retains control over a given patient's participation, but that patient has full autonomy over their care. Patients must grant permission for GPs to access their data via a viewer in the electronic patient record, which can also give alerts if measurements are above or below certain predetermined thresholds or if data collection stops.

Study Design

This explorative study comprised 3 elements (see Table 1). All patients with known chronic care needs, irrespective of platform use, received an email invitation from their GP asking if they would participate in the study, and if agreeable, to return an included questionnaire and informed consent form. Thereafter, nonusers received a combined questionnaire covering their disease status and thoughts about the platform, while users received a Dutch revised version of the Illness Perception Questionnaire-Short (IPQ-K) [22,23], the 12-Item Short Form

Survey (SF-12) [24] for quality of life, and the System Usability Scale (SUS) [25].

We used convenience sampling to include participants based on time and availability to respond during a 2-month period. Participants also needed to be able to speak Dutch or English and could have no disability that might limit their ability to

answer questions. The research team included 2 GPs, one epidemiologist/psychologist, 2 information technology (IT) experts, and 3 research assistants. Two master's in business administration in health students (research assistants) at the University of Groningen received training in qualitative research and performed the interviews.

Table 1. Study design.

Element	Sample, n	Participants and methods	Aim
1	20	Patients in the practice who do not use the platform questionnaire	Evaluation of views on digitalization of care and intention to use the new platform
2	61 partly 58 fully	Patients who use the platform questionnaires (IPQ-K ^a for illness perception, SF-12 ^b for quality of life, and SUS ^c for usability)	Evaluation of their experiences with the platform and their thoughts toward illness and quality of life
3	19	Semistructured interviews with patients (n=15) and general practitioners (n=4) who used the platform	Evaluation of their experiences with the platform

^aIPQ-K: Illness Perception Questionnaire–Short.

^bSF-12: Short Form Survey–12 Item.

^cSUS: System Usability Scale.

Ethics Approval

The University of Groningen approved this research (20200060047). Each participant completed an informed consent form that included their rights and what to expect prior to inclusion. Participation was voluntary and data were anonymized during collection. Identifiable information were kept to a minimum, stored on a safe drive at the university, and only used for this study.

Data Collection

Questionnaires

Questionnaires were sent by GPs via the Qualtrics system for online questionnaires from December 2020 to January 2021, and participants could complete and upload them online.

To understand how relative outsiders viewed the platform, patients who had not used it were asked about their digital activity in daily life and their opinion of the platform after receiving information about its aims and content ([Multimedia Appendix 1](#)). We used multiple choice and 7-point Likert scales and recorded their age, sex, and chronic disease to enable comparison with users.

To clarify the practical aspects of the platform, users were asked to provide an evaluation by completing the SUS. In addition, the IPQ-K and SF-12 standardized questionnaires were completed, and we obtained data on age, sex, chronic disease, and health-related quality of life.

Interviews

Patients and GPs who used the platform were interviewed by phone until saturation (15 patients) or until no additional participants were available (4 GPs). The interviews included general questions about IT and digital health, personal experiences with the platform, effort expectancy, user intentions, barriers, and facilitators. Factors were chosen based on the health

belief model and the UTUAT model. Quotes from interviews are used to illustrate the study findings.

Data Analysis

Questionnaire data were analyzed descriptively using proportions and numbers. All interviews were recorded and transcribed verbatim. Thematic and axial coding were used to analyze the qualitative data, starting with the main interview themes, before performing deductive coding to look for patterns in the transcripts. ATLAS.ti (ATLAS.ti Scientific Software Development GmbH) was used for coding.

Results

Element 1: Questionnaire Responses of Platform Nonusers

In total, 20 patients (55% female, average age 69 [SD 9] years) completed the questionnaire. The main chronic diseases were hypertension/cardiovascular disease, chronic respiratory disease, and a few individual cases of thyroid disease and prostate hypertrophy. Age, sex, and chronic disease characteristics were comparable with users.

All respondents had access to the internet at home, with 85% (17/20) using laptops or smartphones, 60% (12/20) using tablets, and 50% (10/20) using desktop computers at least weekly. When asked about their digital skills, one considered computer use and two considered smartphone use a bit difficult, while the remaining 85% (17/20) considered themselves digitally skilled. Two respondents considered technology a bad development for health care because they wanted “to be treated as individual and not as robot” or “to have a GP in front of me to spar together.” Those who thought it was a good development liked the speed and efficiency of the process for patients and GPs, stating “it can be practical and reduce time to have digital consultations.”

According to 35% (7/20) of respondents, they expected that communication with the health care professional would change

when using the platform. One did not expect that the information provided would be treated confidentially, while 40% (8/20) wanted to share their data in the platform with other health care professionals. The following free-text comment was made regarding data exchange:

I have reservations. Not so much about the app itself, but...about the handling, data processing, and follow-up. Treatment and cure is more than collecting data. [Patient]

Overall, however, slightly more than a third (35%) would recommend the platform after they received an explanation of its functions.

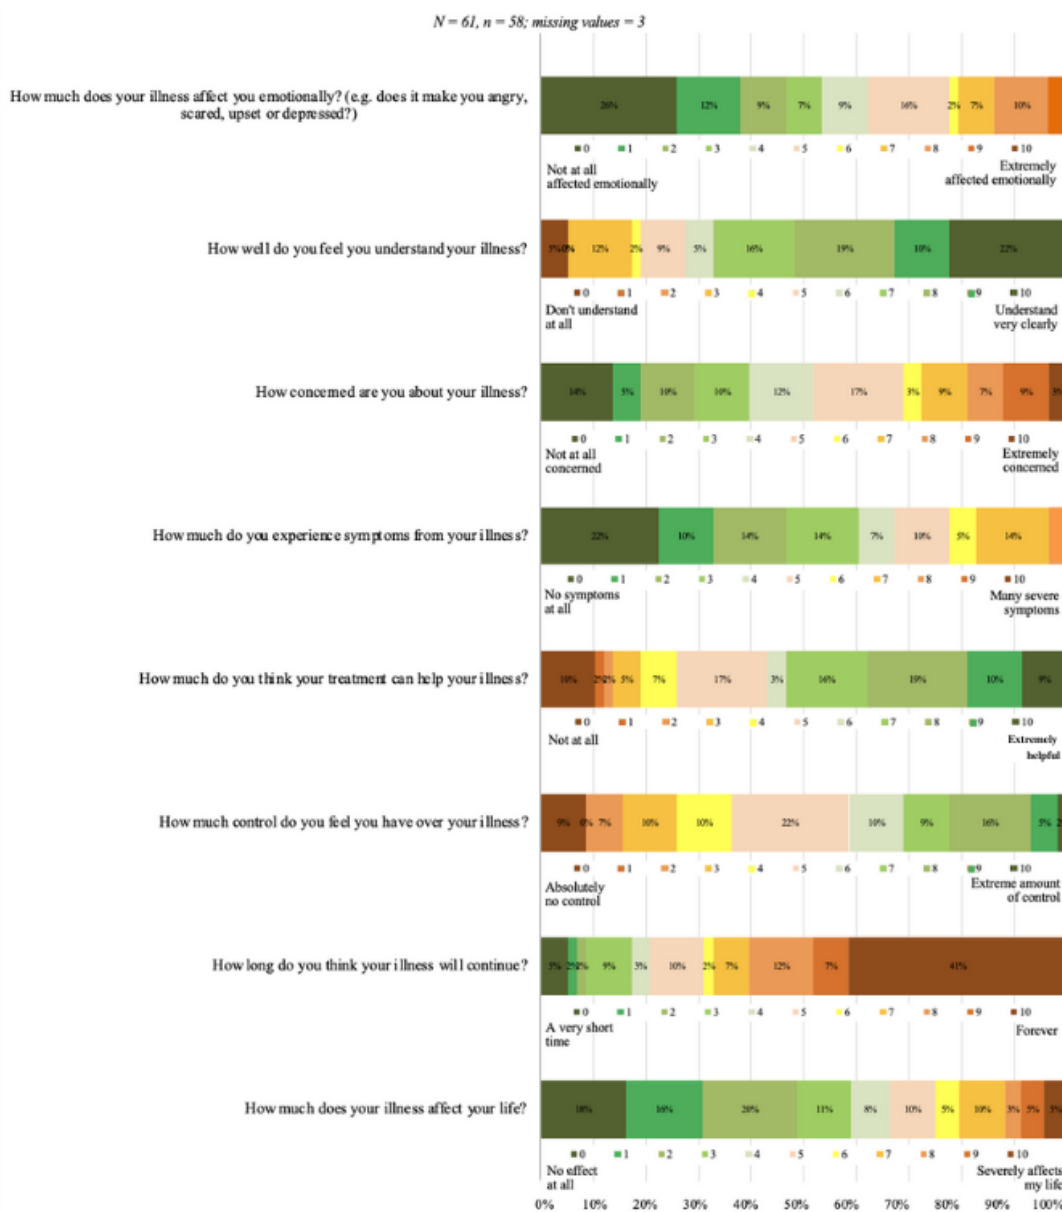

Element 2: Questionnaire Responses of Platform Users

Among the patients who used the platform, 61 partially completed and 58 fully completed the 3 questionnaires (33/61, 54.1% female, average age 62 [SD 8] years).

IPQ-K Instrument

Users more often reported that they are largely unaffected by symptoms, will have them for life, have some control over them, know that treatment helps, and that they cause only moderate worry (Figure 1). They typically reported having a good understanding of their complaints and that these did not severely influence their mood. In general, the complaints had a relatively minor impact on patients. The 3 most frequently mentioned causes of their complaints were stress, heredity/genes, and lifestyle habits (eg, overeating, alcohol, and lack of exercise), while events (eg, COVID-19 or an accident) or mental/physical conditions were mentioned less often.

Figure 1. Results of Illness Perception Questionnaire–Short.

SF-12 Instrument

Figure 2 summarizes the questions and responses concerning health-related quality of life among platform users. Patients who used the platform rated their health from poor to excellent, with most considering it fair or good. Over half (30/59, 50.8%) indicated that they were not limited at all when engaging in moderate levels of exertion, with most users considering themselves somewhat or not limited by their symptoms.

Regarding how health affected work and other daily activities, the distribution varied from sometimes to never being affected. Moreover, users were typically never or rarely bothered by their mental health, while most were not hindered at all and none were hindered very much by pain. In the 4 weeks preceding the questionnaire, users typically reported that they felt calm and content, had a lot of energy, did not feel gloomy or dejected, and were rarely or never hindered by their physical or emotional health during social activities.

Figure 2. Short Form Survey–12 Item: summary of responses for health-related quality of life among platform users.

SUS Instrument

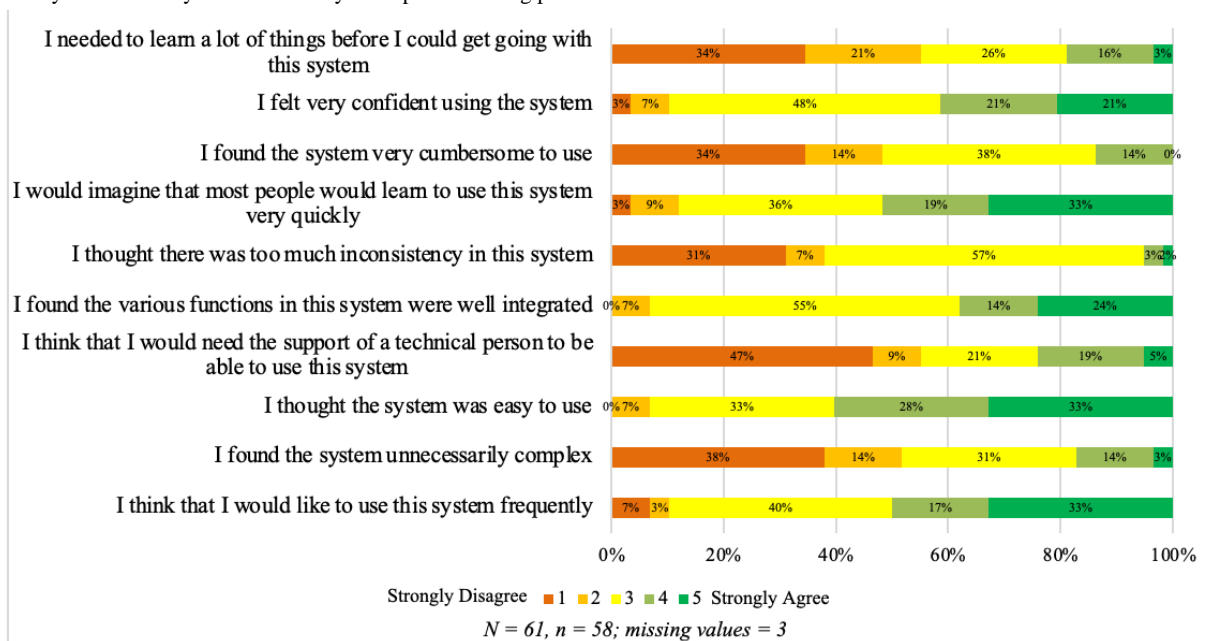

Users indicated the extent to which they agreed or disagreed with each of 10 statements (Figure 3). Only 10.1% (6/59) of

users stated that they will not use the platform regularly, with 6.8% (4/59) answering that it was not easy to use. Almost a quarter (14/59, 23.7%) of users mentioned that they would like to receive external support while using the platform. Users were

neutral on the statements regarding how well functions were integrated (33/60, 55.0%), the presence of inconsistencies (34/60, 56.7%), whether most people will learn to use the platform quickly (21/59, 35.6%), whether the platform is too cumbersome (23/60, 38.3%), and whether they felt confident using the platform (29/60, 48.3%). However, users typically disagreed completely with the statements that the platform was

unnecessarily complicated (23/60, 38.3%), that they needed technical support (28/59, 47.4%), or that they had to learn a lot before they could use the platform (21/66, 35.0%). The total SUS value was 66.55 (on a scale of 0-100), which is below the threshold of 68 for acceptability [26]. However, most of the users (45/59, 76.3%) positively recommended the platform with various degrees of enthusiasm.

Figure 3. System Usability Scale: summary of responses among platform users.

Element 3: Interviews With Users (GPs and Patients)

Participants

All participating GPs from the 3 practices that use the platform took part in the interviews (n=4; average age 46 years; 3 females; average interview duration 53 minutes) together with

their patients who use the platform (n=15; average age 63 years; 9 females; average interview duration 32 minutes). The chronic conditions of users were similar to those of nonusers, with most suffering from cardiovascular and pulmonary chronic conditions. Some had more than one chronic disease. Interview results are described by topic and summarized in Table 2.

Table 2. Overview of topics and themes concerning the platform, as identified by questionnaire and interview.

Interview topics and themes	Examples
Overall opinions	
Factors that may influence use	Viewpoint of GP ^a
Recommendation to other patients	Not hypochondriac and must be digitally literate
Recommendations for the platform	Personal health environment and need to expand before it is efficient
User experience and needs	
Use of other features	Interest in other features (eg, scale, Fitbit, and glucose meter)
Learning process for using the platform	Learning how to use the platform
User friendliness	Easy interface
Satisfaction measuring tool	Three easy-to-use measurements
Continued use of the platform	Intent to continue using the platform
Advantages	
Time and task efficient	Workload reductions
Increased quality	More insight and involvement
Increased accessibility	Lower threshold for consultation
Self-management	More autonomy and empowerment
Limitations	
Fixed time	Felt rigid and strict
Technical questions	Difficulty using Bluetooth
Lack of communication	Sometimes a bit impersonal
Lack of feedback	Difficult to be motivated without a reaction

^aGP: general practitioner.

Time and Workload for Patients and GPs

A GP indicated that patient-centered care led to more efficient care and could be supported by digital health. This can improve quality and accessibility, moving patients from a passive role to active self-management. All participating GPs indicated that the traditional model was no longer feasible due to high workloads, with one stating that the platform increased efficiency.

I think it is also quite easy for the doctor because all is arranged. ...they automatically receive a message about how the week went, and [if needed] they can call the patients or intervene. [GP]

One reason for the decreased workload was that improved self-management by patients can save time for GPs.

...it takes less time, so you can do more. Yes, you can do it with fewer people. How many exactly? Yes, that needs to be determined by experience. Time will tell that, but this does relieve the workload; that is obvious. [GP]

Of course, it saves a lot of time. You know the great thing about this way of working? You let the patient do a lot themselves and you lose the 'noise' from having to perform routine checks...which if it is done well...actually takes 5 minutes. [GP]

Although digital health saves on travel time and expenses for GPs and patients, its implementation requires an initial time investment to become familiar with the system. However, patients did state that GPs responded faster and could be contacted more easily.

I much prefer that I can reach my doctor with an e-consultation, or [that] when I call, I can schedule a call-back time. This is better than when I am on hold for half an hour. [Patient]

When I have finished a weekly measurement, it goes right to the GP...[and they]...see it...immediately. So, it is a lot faster. You need fewer steps to get to the goal. So, I think that's a very big advantage. [Patient]

Despite these positive experiences, some GPs warned that the system can increase workload. The contact options for patients can generate reminders and administrative actions. For example, one explained that she was unable to answer all the messages generated by patients. Some patients also used the platform more than needed, which GPs thought could increase workloads.

People check very often, so we may have to do something with that...because of course...you don't have to measure your blood pressure every day. [GP]

Personalized Care

Where time was saved by GPs using the platform, it could be used to improve patient-centered health care by allowing GPs to afford patients additional support.

Performing a hypertension check is of course not interesting...for the patient [or] the doctor. So that does not contribute much to your...relationship. But if you have a difficult period in your life, for whatever reason, and you just had several conversations and contacts with your doctor during that period, then you build a bond. [Patient]

Although most patients and GPs experienced the advantages of personalized care through the platform, there were also a few who experienced the tool and digital health in general as more impersonal than traditional care.

The human dimension is becoming less and less important in health care. People must justify everything. A person is a person...not a machine. So yes, the interaction is also lessening...deteriorating. [Patient]

Quality of Care

Opinions regarding care quality varied, with both positive and negative effects mentioned. Repeated monitoring by patients can help them feel seen by their GP, creating a sense of safety when GPs intervene because values indicate poor disease control. Patients with chronic illness who require support but never visit the practice can also be reached more easily because the platform is more accessible. Measurements are also more accurate because they are taken frequently, over a longer period, and at home, minimizing the potential stress and inconvenience of testing in a clinical setting. Prevention is another advantage of digital health. GP visits can become more efficient because evaluation has already started.

My doctor can monitor me without me noticing. You can have a precautionary look with each other, based on numbers, before having an appointment. I think that's a big advantage. [Patient]

Accessibility of Health Care

Patients and GPs were generally positive about the digital platform, viewing it as the future of health care. Having the support of GPs was crucial to implementing change because all patients initially started to use the platform based on a GP's recommendation. When patients were actively involved with their GP, they tended to be enthusiastic about the platform. Patients felt the platform improved accessibility.

Because it's just a lot easier. It's fast, simple, and works well. [Patient]

I can start using those questionnaires...I find it useful that it can be done remotely, even in a non-Corona era; I think it is just practical. [Patient]

The digital skills of patients also affected accessibility, but patients typically had no problems.

Once you have it installed on your phone...it is not that difficult. [Patient]

Physicians added that frail patients may not be able to take full control, but that monitoring should be possible in all cases. Technical problems could also affect accessibility to digital health services. For example, patients had difficulty using Bluetooth and synchronizing with the blood pressure monitor. They indicated that it sometimes worked and sometimes did not.

When I switch on my iPad, it synchronizes to the blood pressure monitor. Then it indicates that synchronization was successful and includes the result in a graph. [The last few times]...something has gone wrong in that process. [Patient]

Most agreed that the platform was very user-friendly, with an interface that was clear and easy to use.

What I have used was quite simple, I must say. [Patient]

I think it is very good. I can quickly look up patient data. [GP]

However, patients wanted better instruction and communication about services, with some not knowing why a device was being used or who to approach with queries.

Self-management by Patients With Chronic Illness

It was noted that the platform requires that patients take an active role in managing their disease, which can represent an important change.

The patient starts to work on his own health, hopefully. That's the idea. I really hope that it will give patients more insight into their disease and perhaps improve control. [GP]

It is demanding for the patient [who] must understand what it is about and that it is best if he is also in charge of it himself. It is no longer what you [the GP] are going to do about it, but what [he] can do about it [him]self? [GP]

GPs believed that patients could take this role but that some do not want to and will not benefit from the platform. Therefore, patients must show enthusiasm to be deemed eligible. Care must also be taken to exclude patients considered vulnerable, known to be illiterate, or with intellectual/cognitive limitations who lack the skills needed for self-management, specifically through a digital platform.

Patients generally agreed on the importance of self-management and empowerment.

You do get a picture of how you are doing. Especially if your blood contains too much sugar...it is very good to be able to check that yourself. Yes, I think that is important...it is very good if you can control that yourself. I always say you are responsible for your own health. [Patient]

Discussion

Principal Findings

There was general agreement that the digital platform offered benefit from reducing time commitments and workloads for

patients and GPs when used with appropriately selected patients. The quality and accessibility of care improved through greater patient-centeredness and a lower threshold for contact through different channels, respectively. Importantly, the self-management required by the tool increased patient autonomy and empowerment, and users considered the platform to be feasible, being both usable and easy to learn to use. However, they reported some minor technical issues (eg, Bluetooth connectivity) and wondered if people with fewer digital skills could manage.

It was notable that patients who had not used the platform but who had received the explanation were least positive about this new approach to chronic care management. Although they were relatively experienced and skilled with digital media, only a minority of the nonusers would recommend the platform due to concerns over data security and handling. This might be explained by there being less trust in digital health interventions when they have not experienced the tool themselves [27]. Among platform users, the percentage who would recommend the platform increased to approximately 76%, although the SUS score of 66.55 was just below the score of 68 required to claim success [28]. Active patient involvement in new health initiatives can decrease hesitation toward innovations and contribute to higher acceptance and support of a digital tool that may offer new insights and introduce new elements [29].

From the results of the IPQ-K, it can be interpreted that the study participants typically had a good understanding of their complaints with the impression that treatment could affect their health although it would probably stay with them for the rest of their lives. Compared to other populations with chronic diseases, they score relatively high but this is probably related to the fact the study population has relatively limited levels of multimorbidity as they are still supervised in the primary care setting [30]. However, the results from the SF-12 show that around half of the population is prevented from accomplishing the work and activities they would like to due to their physical and emotional health. This also reflects that the majority expresses impact on their energy levels and mood, which is often a risk in populations with chronic diseases [31,32]. Most respondents reported being digitally literate, which is not surprising because this first version of the platform was considered unsuitable for highly vulnerable patients. As with most digital innovations, we first introduced it among people who are both digitally and health literate [33]. Although users did not know all the available functions, they did tend to find the platform easy to use. Further analysis of what these users require, possibly with better education about what is already included, could improve utility among IT literate populations with less severe chronic illness. This endeavor will hopefully lead to greater awareness of the needs of less digitally or health literate patients with chronic illness who are so often forgotten [34].

An important element to take into account is that the platform started in April 2020 when Covid stressed the relevance of distance monitoring of patients and worked as a catalyzer for health care organizations to implement digital health, and more specifically telemonitoring, among vulnerable and chronically

ill populations [35]. This definitely has positively influenced the uptake of the platform.

Opinions were divided regarding platform expansion. While GPs indicated that communication with other parties and improved data linkage to the GP information system was possible, patients were either neutral or had mixed opinions. Some patients wanted a personal patient environment, but others thought that the system was complicated enough. One GP agreed with this, elaborating to state that the platform should be simplified to have fewer functions and include less information, in line with the need for simplicity in use and scalability for digital health interventions in different settings [36]. This might also be further elaborated on when using the tool in populations with a lower digital literacy.

Patients saw that the digital platform brought many benefits, including improved efficiency, time savings, better care, and greater personal control over their illness. By contrast, GP opinions were more divided about whether the platform leads to preoccupation with illness and even restlessness, with some expressing concern that self-management changes the doctor-patient dynamic. This has been seen in similar interventions in neighboring countries [37]. It would be worthwhile to explore further what specific groups of patients with chronic illness are least and most suited for this type of platform.

Potential obstacles included the fixed time at which measurements were required, lack of communication and feedback, impersonal nature, and technical problems. Feedback was considered particularly necessary to ensure that patients know they are not measuring for nothing. Indeed, feedback is essential to achieve behavior change or ensure that patients take their medications and measurements [38]. Moreover, users were positive about the platform during this development phase, but they were neutral about whether they will use it regularly. This will depend not only on whether the platform is part of their treatment but also on the support and enthusiasm of the GP and their practice. While there is a responsibility for patients to use the platform, there is an equal responsibility for practitioners to keep the platform relevant. The role of the GP in these innovations should not be underestimated [39]. They also play an important role in influencing patients on the levels of perceived benefits and expected improvements in outcomes in the health belief model and UTUAT, which is also shown in other studies to be beneficial for adopting digital innovations [40].

GPs considered digital health to be the future, offering a good solution for organizing care more efficiently and positively influencing the doctor-patient relationship, as suggested elsewhere [41]. However, some patients considered the platform impersonal and were neutral about its impact on their relationship with the doctor. GPs thought that patients who avoid in-person care may have a lower threshold for using the platform than seeking in-person consultations and that any measurements will be more accurate. Although monitoring was considered possible for every disease group, it was mentioned that patients must be enthusiastic and have the necessary digital skills.

GPs were also concerned about the initial time investment and possible increased workload. This is an important consideration given that they need to be motivated. Similar studies have found that enthusiastic GPs can realize the extra impact on their work [42], but as in this study, they anticipate that benefits will come later. An important consideration in this is the tipping point at which an innovation used by a large group starts to become more efficient [43]. Current nonusers indicated that they would like to be notified when results are good, which could be a problem when a larger number of patients use the platform and are monitored. Handing control to patients could lead to the valid concern of actionable items increasing for GPs [42], with uncertainties about where to draw the line for blood pressure results and how to identify patients who are not completing the questionnaires correctly (or who do so too often). Another important element for motivation and reduction of perceived workload is that the integration of these kind of platforms with existing electronic health records should be very smooth [44].

Recommendations to Remove Barriers and Facilitate Implementation

Some barriers and potential facilitators related to implementation are detailed in Table 3. Patients need to understand how a given digital platform works. Information videos or clear and simple instructions could offer value, especially for patients who cannot see the potential benefits of the platform. Patients require a clear explanation of when they must measure, when they must stop, why it is necessary, when they have to contact the GP again, and whether the GP has access to their data. GPs and patients may be more likely to use the digital platform if they can add or remove features as needed. For example, a GP may wish to remove some features, while a patient may want to use different measuring instruments (eg, a Fitbit). Here, flexibility may be key.

Table 3. Recommendations to facilitate implementation and remove barriers.

Recommendation	Example
Ensure that there is sufficient information about the digital platform, its use, and the goals.	A manual or introductory video can help.
Be clear about what information the health care provider can view and when contact will occur.	Create standardized messages and discuss uncertainties before starting.
Avoid fixed measurement times.	This could be resolved by giving patients control over when to take measurements.
Make the platform adaptable to the users.	Certain functions could be added or removed from the user's personalized online environment.
Ensure balance between digital and in-person consultations to ensure that the platform is not experienced as impersonal.	Try to provide consultations at regular levels, either in person, by phone, or via the app, depending on the patient.
Start using the platform with patients who are less digitally and health literate to ensure that the whole population can benefit from the tool.	The population currently using the tool is clearly interested and equipped to work with such tools, but we must ensure applicability to all groups with additional research.

GPs indicated that it was useful to meet with a patient first to explain the process, but they also expressed concern that this can be time consuming. Both GPs and patients wanted medical questions to be resolved by the GP and technical questions to be resolved by the platform developer, requiring clarification on how the developer can be reached. Clear communication between the patient and GP also appears necessary, possibly with quarterly or yearly check-ups or a method to communicate when measurements are above or below that expected. Similarly, offering a standardized message when readings are within reference limits could prove beneficial, as has also been shown in the literature [44]. Functions must be adaptable to the patient, making it possible to take measurements on their own schedule to remove this obstacle and increase autonomy. Of course, measurement timings will still need to be specified (eg, 12 hours apart, every morning) based on clinical need and relevance, like measuring 1 week quarterly instead of daily the whole year round [45]. Given that patients in this study thought that digital health could appear impersonal, a balance will need to be struck with in-person consultations.

Strengths and Limitations

The major strength of this study is that various groups gave feedback on our digital platform for chronic care, with patient users and nonusers and GPs being involved in the implementation. This gives an interesting insight into how the attractiveness and interest for the digital health platform differs among the 3 groups. Another strength is that we used triangulation by evaluating experiences on the platform through questionnaires and interviews. However, there were some important limitations. First, there was the potential for bias in the questionnaires received from patients within the health care practice. It could be that both the patients and the participating GPs had greater motivation than their peers in the general population, an issue that could affect the generalizability of our findings. Second, the interviews took place early in the implementation, so they may need to be repeated to see if there have been any developments. This will also be needed because the intervention will be adjusted based on this feedback to improve not only the platform and its implementation but also the outcomes and experiences of all participants.

Conclusion

This study highlights the benefits of a digital platform for chronic illness in primary care along with the barriers and facilitators experienced by users. Both GPs and patients see this as an innovative tool that represents a good development improving care by offering time savings, greater efficiency, and greater patient-centeredness through improved autonomy and

empowerment. Users considered the fixed measurement schedules, impersonal nature, time investment in learning and use, and poor communication and feedback to be the main barriers. Based on these findings, several recommendations have been developed that might improve the implementation of this or similar platforms in the future. Research must now focus on how to ensure that all patients gain benefit.

Acknowledgments

We would like to thank Vladan Ilic, the inventor of this new model of care, for his support in conducting the research in his practice. We would also like to thank Oscar van Dijk, who has supported the Viduet platform technically and provided input and clarifications during the research. In addition, we would like to thank Femke Oomen for her support in drawing the figures. Finally, we thank Dr Robert Sykes [46] for providing technical editing in the final drafts of this manuscript.

Conflicts of Interest

OvD is founder and CEO of MedicineMen, and JC is technical assistant at MedicineMen. All other authors declare that they have no conflicts of interest.

Abstract

Background: Internet and mobile phones, widely available in Brazil, could be used to disseminate information about HIV prevention and to recruit gay, bisexual, and other cisgender men who have sex with men (MSM) to HIV prevention services. Data evaluating the characteristics of MSM recruited through different web-based strategies and estimating their cost and yield in the country are not available.

Objective: We aimed to describe a web-based recruitment cascade, compare the characteristics of MSM recruited to a large HIV prevention service in Rio de Janeiro according to web-based venues, and estimate the cost per participant for each strategy.

Methods: We promoted advertisements on geosocial networking (GSN) apps (Hornet and Grindr) and social media (Facebook and Instagram) from March 2018 to October 2019. The advertisements invited viewers to contact a peer educator to schedule a visit at the HIV prevention service. Performance of web-based recruitment cascade was based on how many MSM (1) were reached by the advertisement, (2) contacted the peer educator, and (3) attended the service. We used chi-square tests to compare MSM recruited through GSN apps and social media. The estimated advertisement cost to recruit a participant was calculated by dividing total advertisement costs by number of participants who attended the service or initiated preexposure prophylaxis (PrEP).

Results: Advertisement reached 1,477,344 individuals; 1270 MSM contacted the peer educator (86 contacts per 100,000 views)—564 (44.4%), 401 (31.6%) and 305 (24.0%)—through social media, Grindr, and Hornet. Among the 1270 individuals who contacted the peer educator, 36.3% (n=461) attended the service with similar proportion for each web-based strategy (social media: 203/564, 36.0%; Grindr: 152/401, 37.9%; and Hornet: 107/305, 35.1%). MSM recruited through GSN apps were older (mean age 30 years vs 26 years; $P<.001$), more frequently self-reported as White (111/247, 44.9% vs 62/191, 32.5%; $P=.03$), and had higher schooling level (postsecondary: 157/254, 61.8% vs 94/194, 48.5%; $P=.007$) than MSM recruited through social media. GSN apps recruited MSM with higher HIV risk as measured by PrEP eligibility (207/239, 86.6% vs 133/185, 71.9%; $P<.001$) compared with social media, but there was no difference in PrEP uptake between the two strategies ($P=.22$). The estimated advertisement costs per participant attending the HIV prevention service were US \$28.36 for GSN apps and US \$12.17 for social media. The estimated advertisement costs per participant engaging on PrEP were US \$58.77 for GSN apps and US \$27.75 for social media.

Conclusions: Social media and GSN app advertisements were useful to disseminate information on HIV prevention strategies and to recruit MSM to a large HIV prevention service in Brazil. Compared to GSN apps, social media advertisements were less expensive and reached more vulnerable and younger MSM. Digital marketing campaigns should use different and complementary web-based venues to reach a plurality of MSM.

KEYWORDS

social media; web-based recruitment strategies; men who have sex with men; pre-exposure prophylaxis; PrEP; HIV prevention; Brazil; Latin America; HIV

Introduction

Gay, bisexual, and other cisgender men who have sex with men (MSM) are disproportionately affected by HIV infection in Brazil [1], with HIV prevalence estimated at 18.4% [2]. Recent data point to increased prevalence of HIV among young MSM aged 18-24 years [3]. Since 2017, Brazil has been offering oral preexposure prophylaxis (PrEP) at no cost to individuals eligible for PrEP, including MSM [4]. However, increasing awareness of PrEP and other HIV prevention strategies among most vulnerable MSM, including young and those with lower income, remains a challenge [5].

Rio de Janeiro metropolitan area has more than 13 million inhabitants, the 16th largest urban area in the world [6]. Rio de Janeiro has a disproportionately large number of vulnerable individuals who live on the outskirts of the city. These social inequalities have great consequences for health access [7], including inadequate HIV care and prevention [8], which were intensified after the onset of the COVID-19 pandemic [9]. Among MSM from Rio de Janeiro, HIV prevalence was estimated at 15.3% in 2016 [2] and increased among those aged 18-24 years from 4.4% to 13.3% between 2009 and 2016 [3].

Internet and mobile phones are widely available in Brazil and could be used to disseminate information about HIV prevention services. Despite large inequalities, Brazil has a large number of internet users in all social strata: 74% of individuals receiving a minimum monthly wage (US \$220.00) have access to the internet [10]. In Southeast Brazil, where Rio de Janeiro is located, 91% of the population have a mobile phone [11], and 99% have access to internet or apps via mobile phones [12].

Social media and geosocial networking (GSN) apps for sexual encounters (eg, Grindr, Hornet, and Scruff) are popular among MSM in Brazil [5,9,13,14]. A meta-analysis including 25 studies conducted in Australia, China, India, Thailand, and the United States showed that app users may have a higher prevalence of sexually transmitted infections (STIs) than nonusers [15]. In a web-based survey enrolling 11,367 Brazilian MSM, 93% reported using apps to seek sex partners, 54% of them with daily use. Willingness to use PrEP was similar among different sources of web-based recruitment, including GSN apps (Grindr and Hornet) and social media (Facebook and Instagram) [13].

Although different web-based venues have been used to recruit MSM, there are no Brazilian data evaluating the characteristics of MSM recruited through these strategies and estimating their cost and yield in the country. In this paper, we aimed to (1) describe the web-based MSM recruitment cascade, (2) compare the characteristics of MSM recruited to a large HIV prevention service according to different web-based venues, and (3) estimate the cost per individual of each strategy.

Methods

Study Design

We performed a digital marketing campaign targeting MSM from March 2018 to October 2019 using advertisements on GSN apps (Hornet and Grindr) and social media (Facebook and Instagram) to increase HIV knowledge, HIV testing, and PrEP awareness. The Instituto Nacional de Infectologia Evandro Chagas, Fundação Oswaldo Cruz (INI-Fiocruz) study team designed and implemented the campaign [16]. INI-Fiocruz has the largest HIV prevention service for adults (18 years or older) in Rio de Janeiro city and its metropolitan area in Brazil. The service is part of the Brazilian Public Health System (*Sistema Único de Saúde* [SUS]) at no cost to the user.

Recruitment Strategies

Hornet and Grindr are popular among MSM in Brazil, and recruitment using these GSN apps has been used in previous cross-sectional studies conducted in the country [5,9,13,14,17,18]. We used direct inbox messages and banners to advertise on Hornet and Grindr, respectively. In addition, we created posts on social media (Facebook and Instagram), which were boosted and appeared at user's feeds. We targeted social media users interested in subjects related to LGBTQIA+ people (people of diverse genders and sexualities, inclusive of and not limited to lesbian, gay, bisexual, transgender, queer, intersex, asexual, questioning, and pansexual) communities. Advertisement messages were built during meetings with key members of MSM communities from different socioeconomic status and race. These advertisements had information about HIV prevention and invited viewers to contact a peer educator (via phone number, email, and WhatsApp) to schedule a visit at the HIV prevention service for HIV risk assessment, HIV testing and referral to PrEP or postexposure prophylaxis (PEP).

Variables

All MSM referred by the peer educator who attended the HIV prevention service answered semistructured interviews conducted by trained counselors. Covariables were age at the time of the visit (categorized in 18-24, 25-35, and >35 years); race (Black, Pardo or mixed, and White); schooling (elementary [≤ 9 years], secondary [10-12 years] and postsecondary [>12 years]) and Municipal Human Development Index, a 3-level dimension measure of human development (life expectancy, education, and income), dichotomized into very high (≥ 0.800) or other (< 0.800) [19].

HIV testing was offered to all individuals who attended the HIV prevention service. HIV status was dichotomized into negative and positive according to HIV rapid test results, following Brazilian recommendations [20]. Counselors evaluated all HIV-negative MSM for PEP and PrEP eligibility based on Brazilian National Guidelines. Individuals reporting condomless

sex in the previous 72 hours were referred for PEP [21]. MSM with at least one of the following criteria in the last 6 months were eligible for PrEP: (1) condomless receptive anal sex, (2) sex with partner living with HIV, (3) transactional sex (in exchange for money, goods, and benefits, among others), and (4) history of STI [22]. PrEP uptake was defined as the number of participants who initiated PrEP divided by the number of participants eligible for PrEP [23].

Data Analyses

We evaluated the web-based recruitment cascade for Hornet, Grindr, and social media based on the number of MSM who (1) viewed the advertisement; (2) contacted the peer educator; and (3) attended the HIV prevention service. Conversion rate was calculated dividing the number of MSM who contacted the peer educator by those reached by advertisements. We used chi-square test to compare the characteristics of MSM recruited through dating apps (Hornet and Grindr) with those of MSM recruited by social media (Facebook and Instagram). We estimated the advertisement costs (in US dollars) to recruit one participant to HIV prevention service by dividing total advertisement costs by the number of individuals who attended the service (GSN apps or social media). Lastly, we used the same rationale to estimate the cost per individuals engaging on PrEP. All analyses were conducted in R Studio, using R version 4.0.3 (R Foundation for Statistical Computing).

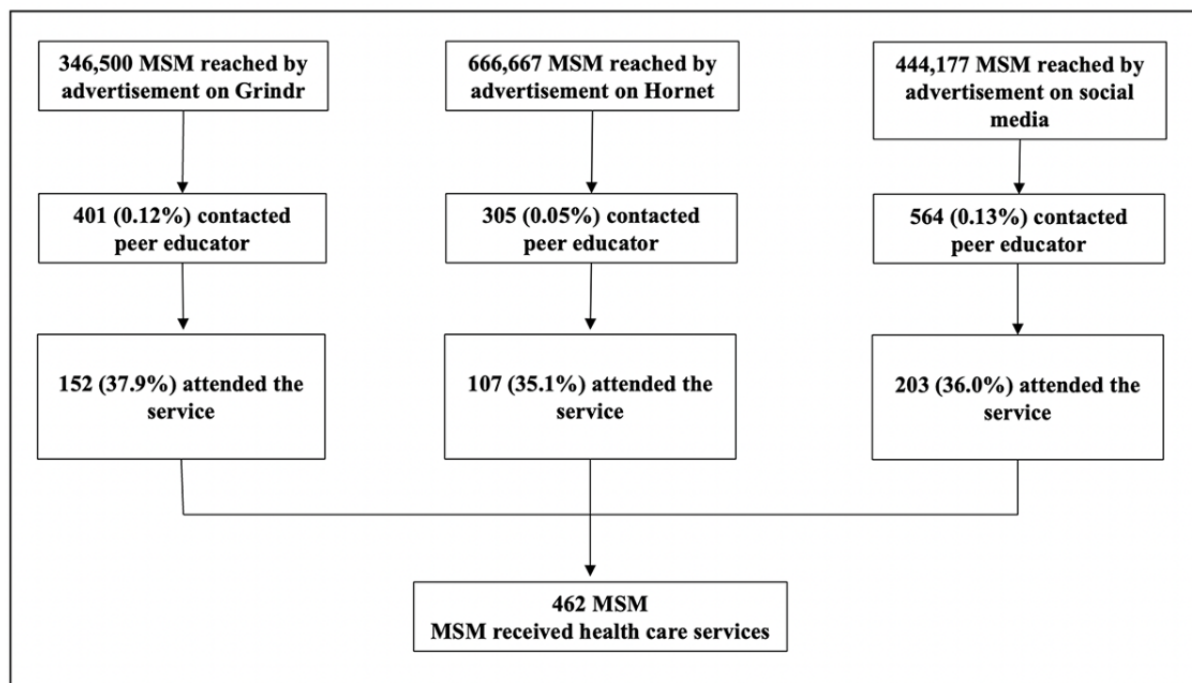

Ethical Considerations

This study was reviewed and approved by the INI-Fiocruz institutional review board (#CAAE 26095519.1.0000.5262). The board waived the informed consent as data were collected retrospectively from participants' charts and exams collected at INI-Fiocruz during HIV testing or prevention routine. Most participants attended the service only once, and personal information such as telephone number or address were nonexistent or outdated, avoiding collection of informed consent a posteriori.

Results

Our marketing campaign (all strategies combined) reached 1,477,344 individuals—346,500 (23.8%) from Grindr, 666,667 (45.7%) from Hornet, and 444,177 (30.5%) from social media (Figure 1). Overall, 1270 MSM contacted the peer educator (86.0 contacts per 100,000 views), with a higher conversion rate on social media (564/444,177, 0.13%) compared to Grindr (401/346,500, 0.12%) and Hornet (305/666,667, 0.05%). Among the 1270 MSM contacting the peer educator, 564 (44.4%), 401 (31.6%), and 305 (24.0%) were recruited on social media, Grindr, and Hornet, respectively. Of all 1270 MSM who contacted the peer educator, 36.3% (n=462) attended the HIV prevention service, with similar proportions for each web-based strategy (Grindr: 152/401, 37.9%; Hornet: 107/305, 35.1%; and social media: 203/564, 36.0%).

Figure 1. Web-based cascade to recruit gay, bisexual, and other cisgender men who have sex with men (MSM) for a large HIV prevention service at Rio de Janeiro, Brazil.

MSM attending the HIV prevention service (N=462) had a median age of 28 years (IQR 23-34), mostly self-identified as Black or Pardo (265/438, 60.5%), completed postsecondary schooling (251/448, 56.0%), and lived in very high Municipal Human Development Index neighborhood (301/461, 65.3%). A total of 38 (8.2%) MSM tested positive for HIV. Among the 424 HIV-negative MSM, 340 (80.2%) were eligible for PrEP;

PrEP uptake was 62.9% (214/340). Only 22 (5.2%) MSM were eligible for and initiated PEP.

MSM recruited by GSN apps were older (mean age 30 years vs 26 years; $P<.001$) and reported White race (111/247, 44.9% vs 62/191, 32.5%; $P=.03$) and higher schooling level (postsecondary: 157/254, 61.8% vs 94/194, 48.5%; $P=.007$)

than MSM from social media (Table 1). MSM from GSN apps reported higher HIV risk as measured by PrEP eligibility (207/239, 86.6% vs 133/185, 71.9%; $P < .001$) than MSM from social media, but there was no difference on PrEP uptake ($P = .22$).

The estimated advertisement cost per participant attending the HIV prevention service was US \$28.36 for GSN apps and US \$12.17 for social media. The estimated advertisement cost per participant engaging in PrEP was US \$58.77 for GSN apps and US \$27.75 for social media.

^dPrEP: preexposure prophylaxis.

Discussion

Principal Results

Our digital marketing campaign on different web-based venues was effective in recruiting MSM to a large HIV prevention

service in Brazil. We successfully reached and engaged diverse MSM of different ages and races and high PrEP eligibility. Nevertheless, MSM with lower education was the least accessed group, indicating that complementary recruitment strategies such as those on LGBTQIA+ venues or respondent-driven

sampling [24] may still be necessary to reach MSM at higher social vulnerability.

Social media recruited a larger proportion of young MSM, with lower income and schooling compared to those recruited via GSN apps. This underscores the importance of using social media to recruit MSM for HIV prevention services and to promote prevention campaigns targeting young MSM at HIV risk in Rio de Janeiro, Brazil. In addition, social media were more cost-effective to recruit individuals to attend the HIV prevention service and to use PrEP. Facebook was the most cost-effective web-based venue to recruit MSM to a qualitative study in Seattle [25] and was effective to recruit Latino gay couples in a study conducted in New York [26]. These findings confirm that social media platforms such as Facebook and Instagram could be used as an alternative option to reach and engage MSM in other HIV prevention services in resource-constrained settings such as Brazil.

By contrast, a study conducted in Philadelphia identified Grindr as the most effective strategy to recruit people for an HIV vaccine trial [27]. Although PrEP uptake did not differ between individuals recruited by different strategies, GSN apps were more effective in recruiting high-risk MSM, according to PrEP eligibility, compared to social media. As such, different web-based venues may be useful to recruit diverse MSM to HIV prevention services, especially young MSM, as shown in previous studies conducted in the United States [27,28].

Strengths

In addition to recruitment to the HIV prevention service, our campaign aimed to increase PrEP awareness, although the latter could not be measured in this study. Data from web-based surveys showed an increase in PrEP awareness in Rio de Janeiro, Brazil, from 2016 to 2018 [29], and 2020 national data indicated that 87% of sexual and gender minorities recruited on Hornet were aware of PrEP [9]. Moreover, HIV knowledge was associated with PrEP use among MSM eligible for PrEP in Brazil [17]. Digital campaigns are of utmost importance to promote information on HIV prevention, including PrEP and

other prevention technologies, among MSM. These results are particularly useful to develop public strategies and may contribute to designing campaigns to increase PrEP uptake in Brazil. Lastly, our study was conducted before the COVID-19 pandemic, and due to the increased use of digital recruitment for scientific studies [30], a more heterogeneous population would be expected to be reached nowadays.

Limitations

This study considered only MSM reached by a digital marketing campaign who contacted the peer educator. The advertisements may have reached other MSM who attended the HIV prevention service without contacting the peer educator or who attended other services in Rio de Janeiro, Brazil. Responses of web-based recruitment and PrEP or PEP eligibility were self-reported, thus introducing the possibility of recall, response, or social desirability bias. Participants reported sexual behavior during risk assessment for PrEP or PEP evaluation. However, data on sexual behavior practices have not been systematically collected, preventing further associations between web-based recruitment and sexual practices (eg, condomless receptive sex or transactional sex). This study helped to identify this issue, leading to modifications aiming to collect more detailed data on sexual behavior and other variables, such as substance use and previous STIs. Lastly, venue-based recruitment and peer referral may perform better than web-based recruitment for most vulnerable MSM (young, Black or Pardo, low-income, and low-educated individuals) [16], highlighting the importance of community networks.

Conclusions

Advertisements on social media and GSN apps were useful to disseminate information on HIV prevention strategies and to recruit MSM to an HIV prevention service in Brazil. Compared to GSN apps, social media advertisements were less expensive and reached more vulnerable and younger MSM. Our findings indicate that digital marketing campaigns should use different and complementary digital venues to reach diverse MSM.

Acknowledgments

The abstract for this manuscript was presented as a poster presentation at AIDS 2020: Virtual. 23rd International AIDS Conference, 6-10 July 2020 (abstract number PEC0557). We would like to thank all study participants and the Instituto Nacional de Infectologia Evandro Chagas, Fundação Oswaldo Cruz (INI-Fiocruz) HIV prevention service staff—Alexandre Nabor, Bianka Fernandes, Daniel Waite, Edilene Bastos, José Roberto Grangeiro, Luciana Kamel, Nilo M Fernandes, and Sandro Nazer.

Abstract

Background: The most common route to a diagnosis of cancer is through primary care. Delays in diagnosing cancer occur when an opportunity to make a timely diagnosis is missed and is evidenced by patients visiting the general practitioner (GP) on multiple occasions before referral to a specialist. Tools that minimize prolonged diagnostic intervals and reduce missed opportunities to investigate patients for cancer are therefore a priority.

Objective: This study aims to explore the usefulness and feasibility of a novel quality improvement (QI) tool in which algorithms flag abnormal test results that may be indicative of undiagnosed cancer. This study allows for the optimization of the cancer recommendations before testing the efficacy in a randomized controlled trial.

Methods: GPs, practice nurses, practice managers, and consumers were recruited to participate in individual interviews or focus groups. Participants were purposively sampled as part of a pilot and feasibility study, in which primary care practices were receiving recommendations relating to the follow-up of abnormal test results for prostate-specific antigen, thrombocytosis, and iron-deficiency anemia. The Clinical Performance Feedback Intervention Theory (CP-FIT) was applied to the analysis using a thematic approach.

Results: A total of 17 interviews and 3 focus groups (n=18) were completed. Participant themes were mapped to CP-FIT across the constructs of context, recipient, and feedback variables. The key facilitators to use were alignment with workflow, recognized need, the perceived importance of the clinical topic, and the GPs' perception that the recommendations were within their control. Barriers to use included competing priorities, usability and complexity of the recommendations, and knowledge of the clinical topic. There was consistency between consumer and practitioner perspectives, reporting language concerns associated with the word *cancer*, the need for more patient-facing resources, and time constraints of the consultation to address patients' worries.

Conclusions: There was a recognized need for the QI tool to support the diagnosis of cancer in primary care, but barriers were identified that hindered the usability and actionability of the recommendations in practice. In response, the tool has been refined and is currently being evaluated as part of a randomized controlled trial. Successful and effective implementation of this QI tool could support the detection of patients at risk of undiagnosed cancer in primary care and assist in preventing unnecessary delays.

Introduction

The diagnosis of cancer in primary care is complex, owing to the nonspecific nature of many presenting symptoms [1-3]. In particular, symptoms of cancer are often consistent with more common diagnoses [4-6]. This complexity can lead to delays in diagnosis and multiple visits to the general practitioner (GP) before cancer is considered [5], and significantly prolong the primary care interval (from a patient's first presentation to the GP up to specialist referral) [7,8].

While the factors that influence delays in diagnosis are multifaceted, a timely response to abnormal test results that may herald an underlying cancer can improve patient outcomes and reduce time to diagnosis [9-12]. In primary care, delays can be due to missed opportunities to consider a cancer diagnosis and arrange further investigations [13-15]. For example, over one-third of patients with iron-deficiency anemia are not investigated [16,17], and missed opportunities to investigate for gastrointestinal cancers in the presence of so-called *red flag* symptoms leads to delays [18]. While there is no population screening program for prostate cancer in Australia, rates of testing are high (close to 1.5 million prostate-specific antigen [PSA] tests were ordered in 2017) [19,20]. Controversy and confusion about PSA testing and changing guidelines, including altered thresholds for what is abnormal, all contribute to variable rates of follow-up in men with raised PSA levels [21-23]. Missed opportunities are also relevant in areas of new evidence [24]. Thrombocytosis has recently been identified as an important predictor in primary care for several cancers, including lung and colorectal, but many GPs may be unaware of this new evidence [25-27].

A previous systematic review of computerized decision support systems (CDSSs) to assist with the identification of patients at risk of an undiagnosed cancer found that they have the potential to minimize prolonged diagnostic intervals and reduce missed opportunities to diagnose cancer [28]. Quality improvement (QI) platforms involve a combination of interventions, which can include a CDSS with audit and feedback [29]. The evolution in technology allows for the use of the electronic medical record (EMR) to develop quality measures and to facilitate QI-based audit and feedback [30]. Practice population audit tools are complementary to CDSSs, in which algorithms are linked to a clinical knowledge base and produce patient-specific guideline-based recommendations or prompts for consideration at the point of care (PoC) [24,31].

While the development of QI tools is promising, challenges persist around implementation, especially when designed to identify patients who may be at risk of an undiagnosed cancer [28]. QI tools that are designed with continuous involvement and input from the end users are more likely to be effectively embedded in everyday practice [32]. This study explores the usefulness and feasibility of a novel QI tool using algorithms to identify inadequate follow-up of abnormal test results that could be indicative of an undiagnosed cancer and prompt further investigation.

Methods

Ethical Considerations

Ethical approval was granted by the University of Melbourne Human Research Ethics Committee and registered with the Medicine and Dentistry Human Ethics Sub-Committee (Ethics ID 1953614). Participation in the interviews and focus groups were voluntary, and informed consent was obtained from all study participants. Participants who completed an interview received gift vouchers (AU \$100) as a reimbursement for their time.

Participants and Study Design

The development of the QI tool Future Health Today (FHT) has been described elsewhere [33]. In summary, FHT consists of two primary components. The first, a PoC prompt, is a CDSS that provides guideline-based recommendations and is visible upon opening the patient's medical record ([Multimedia Appendix 1](#)). The second component is a web-based portal that contains an audit and recall tool, allowing practice staff to review the FHT recommendations at the practice population level and take steps for recall ([Multimedia Appendix 2](#)). Although FHT is designed to manage many different conditions, this study focused on the cancer recommendations. FHT uses EMR data to identify patients who may be at risk of an undiagnosed cancer using the results of abnormal tests (iron-deficiency anemia, raised PSA, and raised platelet counts) and patient information (age, sex, and previous cancer diagnoses). If no appropriate follow-up actions for these markers are identified, guideline-specific recommendations will prompt the GP to review relevant patient symptoms and guide further investigation.

FHT was implemented in 12 primary care practices in Melbourne, Australia as part of an optimization study prior to a cluster randomized controlled trial (RCT) [34]. GPs, general practice nurses (GPNs), and practice managers (PMs) were purposively sampled from 9 of the FHT pilot sites (3 sites did not receive the complete set of cancer algorithms due to limitations associated with pathology data in one EMR system). The PSA and platelet recommendations were released in December 2020, and the anemia recommendations were released in March 2021. Participants had been using FHT with recommendations for chronic kidney disease (CKD) for up to 3 months before the cancer algorithms were introduced. Interviews were conducted from February to May 2021; if the user had not seen the cancer recommendations via the PoC prompt during a consultation, the recommendations were shown using a demo of the tool over Zoom (Zoom Video Communications).

Data Collection

Semistructured interviews were carried out with GPs, GPNs, and PMs to explore their perspectives on the cancer module and recommendations for improving the tool. In addition, three focus groups were conducted, one with GPs and GPNs, and two with consumers. The general practice focus group explored the audit tool and barriers to use. Consumer focus groups explored

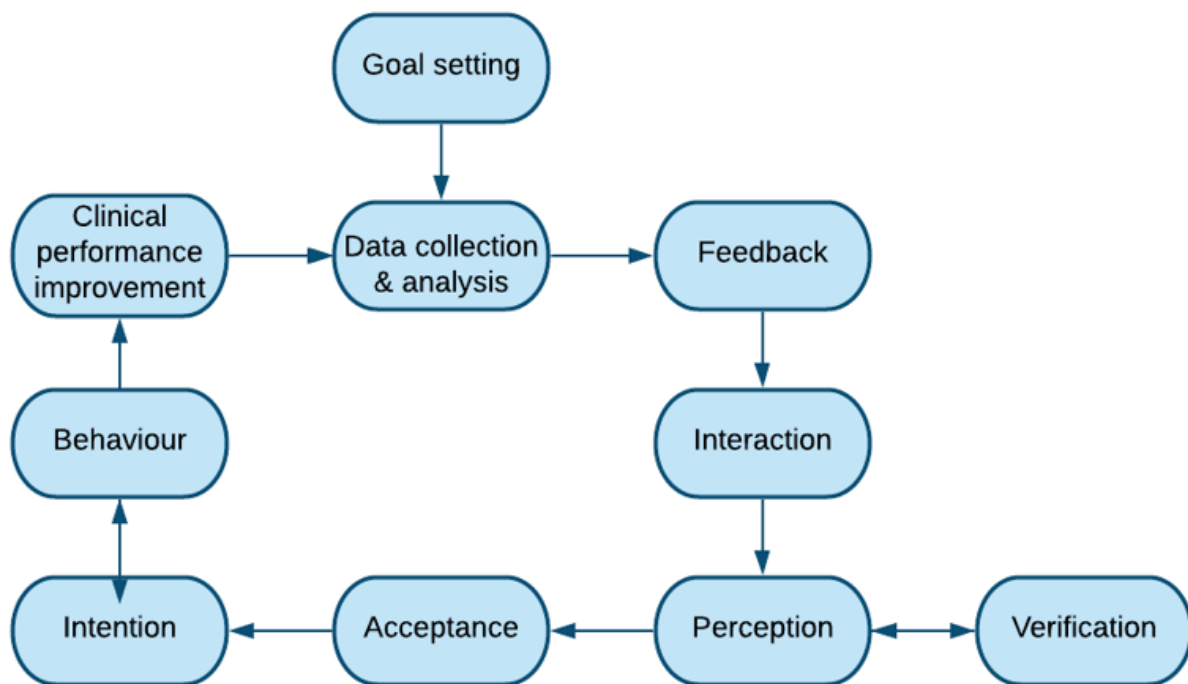

their perception of the cancer recommendations, barriers to uptake, and current priorities.

Data Analysis

We analyzed all interviews and focus groups using NVivo (version 12; QSR International). The transcripts were independently coded by two reviewers (SC and BH) using an inductive approach to identify themes in the data [35]. Discrepancies in the interpreted data were discussed by the two coders until a consensus was met. For the general practice data, we applied a deductive approach using the Clinical Performance Feedback Intervention Theory (CP-FIT) [36]. A number of frameworks were considered for this analysis. CP-FIT was chosen as it incorporates and builds upon 30 pre-existing theories and, unlike other frameworks, was developed specifically for health care to explain factors that influence feedback success. The theory posits that the feedback cycle

(Figure 1) is affected by feedback variables (eg, display and delivery), recipient variables (eg, knowledge of the clinical topic), and context variables (eg, the implementation process) [36]. It describes mechanisms such as compatibility and complexity, which explain how the variables influence the feedback cycle, and resulting clinical performance. In the context of FHT, guideline-based recommendations are communicated to GPs and GPNs. CP-FIT outlines the steps that the user moves through: algorithms are applied to the EMR (data collection and analysis); recommendations are delivered to GPs and GPNs (feedback); and the recommendation is received (interaction), interpreted (perception), and interrogated (verification). If there is acceptance of the recommendation, the user responds to the recommendation (intention and behavior), and ultimately, this leads to changes in patient care (clinical performance improvement) [36].

Figure 1. The Clinical Performance Feedback Intervention Theory feedback cycle.

Results

We conducted 14 interviews with participants from 6 general practice clinics. As not all participants had experienced the cancer recommendations in practice, follow-up interviews were

scheduled with 3 GPs (for a total of 17 interviews). Interviews ranged from 18 to 40 minutes. A total of 8 participants took part in the general practice focus group, of whom 4 had participated in individual interviews. There were 10 participants in the consumer focus groups. Participant characteristics are presented in Table 1.

Table 1. Characteristics of the participants and method of data collection

	Interview participants, n (%)	Focus group participants, n (%)
Role		
General practitioner	9 (64)	6 (33)
Practice nurse	4 (29)	2 (11)
Practice manager	1 (7)	0 (0)
Consumer	0 (0)	10 (56)
Gender		
Female	11 (79)	9 (50)
Male	3 (21)	9 (50)

CP-FIT

We mapped practice staff perspectives to CP-FIT. The resulting themes could be mapped across the three constructs: context, feedback, and recipient variables.

Context Variables

Organization and Team Characteristics: Workflow and Competing Priorities

Most participants reported using the CDSS either before or after the consultation; only 1 GP reported using it exclusively during the consultation. Opening the patient's file prior to the consultation aligned with the use of FHT, where participants could read, verify, or address the recommendation and, if needed, prepare and print off patient resources or investigation request forms.

In some ways I organise routine care for a consultation before I see the patient, because I won't remember once they've come in and told me all the medicines they need and those kinds of things. [GP2]

All practice staff reported competing priorities and an already busy schedule as a barrier to use for all components of the FHT tool.

I haven't had a lot of time to actually play around with the cohort and implement bringing people in. [PM1]

That was coupled with the priorities of the patient as a barrier to being able to address the recommendations during the consultation.

If time allows, I'll deal with it. It won't be the first thing because when the patient comes in, they're coming in because they want to come in. [GP8]

While most GPs felt that the recommendations were feasible, some discussed their limited ability to control the consultation and guide the patient to the issues raised by FHT because the patient comes in with their own agenda. This was also discussed in the context of being able to manage the prompts in a single

consultation because some recommendations may require long time-intensive conversations to address the patient's questions and potential worries.

But cancer's a huge thing - it was much easier to say, by the way, the kidney - this is bad therefore we should do this. Whereas the cancer one is much more nebulous and much more challenging and scary. [GP1]

For GPs who had seen the cancer recommendations in practice, half considered delegating some responsibility to either GPNs or medical students. This was driven by their ability to conduct longer consultations and focus on one specific issue raised by FHT.

Their [GPN] ability to engage patients at a level and to quickly put them at ease, I think is quite extraordinary [GP8]

Patient Population: Clinical Appropriateness and Choice Alignment

Participants were able to determine when the recommendation was not clinically appropriate for their patient. However, the balance of perceived risk (eg, patient distress or risks associated with further investigation) when deciding to investigate for cancer based on the platelet recommendation was raised by two GPs. This may be indicative of a knowledge gap on the association between raised platelets and undiagnosed cancer (see Recipient Variables section).

If you're going to do a CT of somebody's chest, you're clearly exposing them to radiation, what's the positive likelihood that you're going to find something if you're using platelets as a cancer marker? [GP2]

Participants frequently framed their reflections on FHT through the lens of their patient population. Some participants saw barriers to actioning the recommendations associated with the patient's health literacy, language skills, health complexity, and common anxieties associated with the word *cancer*. Others felt that their cohort of patients were well-prepared and responsive to recommendations from the GP.

Our patients are highly health literate. They're very interested in their health. They really are prepared to do something about it. We're very lucky. [GP6]

Implementation Process: Cost, Training, and Support

While the interviews focused primarily on the cancer module, there were themes around the implementation of the QI tool more broadly, which affected the uptake of the cancer recommendations. For all users, the perceived cost of the CDSS in relation to time was low. Overall, it was reported to be subtle and nondisruptive to the consultation, while the time and resource cost associated with using the audit tool was high and often described as a barrier to use.

I think really useful. It's all sitting behind in there if you want. It gives you options of having a quick look. It gives you options of re-skilling and it gives you the option of educating the patient as well. [GP3]

More than half of the participants reported perceived technical issues, which highlighted areas where more training was needed. For example, to access the audit tool, users needed training on the registration process and errors they may encounter from this process not being completed properly.

I haven't managed to get my head around exactly how it works [audit tool], so I'm only using the front [CDSS] which pops up on the patient. [GP2]

Feedback Variables

Goal: Importance, Controllability, and Relevance

The themes of importance, relevance, and perceived controllability were present in all participant interviews. The benefits of the intervention were visible to most recipients, and there was a recognized need for the recommendations, which included helpful reminders, reassurance, keeping up with changing guidelines, and ensuring timely action. There was also a recognized need for decision support tools in general.

So, I would be using these tools for re-educating me and ensuring I'm doing best practice because I'm getting older now and things change. [GP3]

However, exposure to the recommendations in practice highlighted a shift in priorities. Despite the recognized need for the recommendations, addressing the recommendation became less important and less relevant, as the GPs did not have enough information (see next section) or because of competing priorities.

Feedback Display: Usability and Framing

Significant barriers were identified relating to usability. This was due in part to the clarity, length, and language used in the recommendations, which required too much time to process in the time available. The way the recommendations were presented impacted the GP's ability or desire to engage with the recommendations and indicated a need to modify how we presented the information. Participants reported that the recommendations could be made more concise or were missing essential information (eg, appropriate next steps). Further, it was indicated that the wording of the platelet recommendation was too prescriptive, and therefore, the function of the

recommendation did not allow for the GP to exercise their clinical judgement.

In terms of the increased platelets, that's helpful. What it is though, it's a bit diffuse in terms of why. Most people are saying, what's the relationship with thrombocytosis. What cancers does that show, for instance? [GP8]

Feedback Delivery: Active Delivery, Frequency, and Function

The importance of active delivery was demonstrated in GPs primarily using the CDSS and not using the audit tool (ie, prompts are sent to the users as part of the CDSS, but the audit tool required participants to take steps to obtain the information).

It's not as if it's just not even there and you're never going to see it. When it comes up like that, you know, it might be worthwhile having a look at this and see what's there. It will be a good thing. [PN2]

Participants spoke of prompt fatigue in relation to other (non-FHT) prompts or reminders. Participants contrasted these systems with FHT, reporting that they did not find FHT to be an obstruction or an irritant, rather that it had a good balance of appearing when needed, drawing attention but not demanding it, and allowing for action or inaction as the clinician decides.

I do like just it's a subtle - it's not in your face that's coming up all the time as a reminder, because we've got so many flashes. [GP3]

The GP's perception of the function of the recommendations was to support them in providing quality care. Most talked about the recommendations as being helpful and beneficial given how much they need to be thinking about, and often framed it as a *suggestion* or *reminder*, indicating that they see it as a supportive rather than a correction or judgement.

I think just to be reminded that a raised platelet count is associated with cancer is a very good thing and I think a lot of GPs wouldn't be aware of it. [GP6]

Recipient Variables

Health Professional Characteristics: The Role and the Knowledge and Skills in the Clinical Topic

There was a difference in uptake of the CDSS and the audit tool by clinical role. Most GPs reported using the CDSS regularly, but only 1 GP reported accessing the audit tool. In comparison, all GPNs had used the audit tool in some capacity where they felt it aligned with their role in the facilitation of patients for recall. However, they did not consider it part of their role to address the cancer recommendations in the PoC. For GPNs, there was a lack of ownership around the content of the recommendations; most stated that the responsibility of doing something about an abnormal test result that a GP had ordered fell solely on the GP. This was an interesting finding, considering the suggestions by some GPs that they would delegate the responsibility of some recommendations to GPNs or medical students (see Context Variables section).

I might do the recalls, I might call people in but in the end, GPs need to be accountable for their work and not me. [PN1]

In general, the attitude toward the cancer recommendations was positive both before and after use. Most GPs felt confident acting on the iron-deficiency anemia and PSA recommendations. However, they identified the need for more education to act on the platelet recommendation given that it comes from relatively new evidence. Some GPs felt they did not have adequate knowledge and skills on the clinical topic, which influenced the credibility of these recommendations and the user’s trust in the tool.

I gather from Future Health Today I should be actively looking for occult cancers in this group. But I need – I need a bit more education about it. [GP1]

Consumer Perspectives

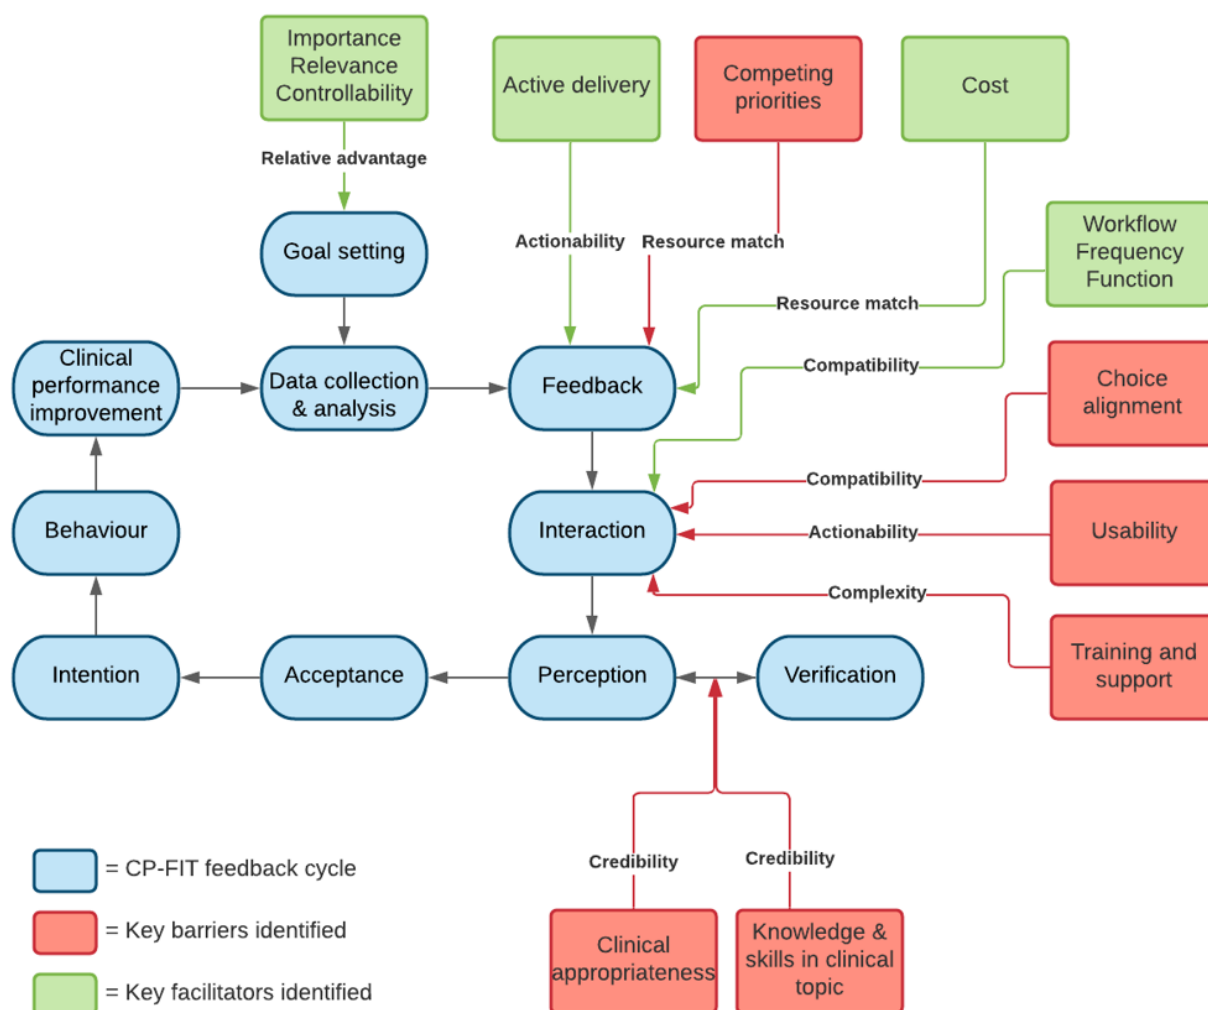

The consumer focus groups elicited key themes around language and innate concerns associated with the words *cancer* and *abnormal*. These themes aligned with those identified in the

general practice interviews and focus group. Consumers expressed concerns about the short time frame of most consultations coupled with their need to discuss and understand the issues raised by the GP or GPN. There was a consensus around the need for tailored patient resources to aid communication in the consultation and to give patients the ability to digest and review the information in their own time.

The Feedback Cycle: Which Variables Influence Implementation and How?

The themes identified as part of this qualitative study can be mapped onto the CP-FIT feedback cycle [36]. Further, the framework analysis allows for the identification of the underlying mechanisms, which provides information as to why and how the platform does, or does not, work as an effective feedback loop. As illustrated in Figure 2, the key components of the feedback cycle where participants were getting *stuck* is the interaction and verification stages. These findings provide an explanation for how FHT for cancer diagnosis in primary care can be improved and guides appropriate action in refining the tool.

Figure 2. How CP-FIT explains the effectiveness of the Future Health Today intervention. CP-FIT: Clinical Performance Feedback Intervention Theory.

Discussion

Principal Findings

In this optimization study, participants reported that FHT was easy to use and nondisruptive to the consultation. The cancer recommendations were seen to meet a need that participants recognized and, for most, did not require a change to their consultation style and workflow. However, with repeated exposure to FHT, participants highlighted the complexity that stemmed from the way the cancer recommendations were communicated to users. There was a need to improve the usability and clarity of the recommendations as well as to provide ways for the GP to verify the recommendations. Further, there were barriers when applying the recommendations in practice relating to patient worry, patient communication, and the patient group that the GP saw most often.

We also found that many of the concerns raised by the GP mirrored those raised by consumers. One of the most important although not surprising findings is the importance of language and communication. Both consumers and the GP expressed a need for tailored patient resources to explain why they had recommended further tests and concerns about the time constraints of consultations to address the patient's worry. The utility of the QI tool for cancer diagnosis relies in the ability to communicate all necessary information accurately, effectively, and concisely in a format that ensures brevity but comprehensiveness at the PoC [37].

By applying CP-FIT as a framework, we were able to illustrate the differences when comparing those who were shown the cancer recommendations at the time of interviewing (ie, a researcher-led simulation) to those who had experience with the recommendations in practice, including those who were reinterviewed after extended exposure. Although the sample size was small, it highlighted in the initial conceptual interviews (when asked to provide immediate feedback on the recommendations) the most prevalent and recurrent themes sat within the *goal* feedback variable at the start of the CP-FIT feedback cycle (ie, importance, relevance, and controllability). Because these variables were met, the response was overwhelmingly positive (there was both acceptance and intention, and the mechanisms indicated actionability and a relative advantage to the way they currently approached these processes). However, once the users had repeated exposure to the recommendations and the users began to move through the feedback cycle (ie, from goal setting to interaction), new barriers were identified (experiential feedback). Although all participants reported competing priorities, this was partially alleviated by ensuring the required time cost was low and the recommendations were actively delivered. However, barriers such as the user's knowledge of the clinical topic, the usability and clarity of the recommendations, and the need for training and support led to many participants getting stuck at this point in the feedback cycle.

Limitations

Given the complexities associated with the implementation of QI tools, this study provided an opportunity to evaluate and refine the QI tool for cancer diagnosis with end users. A novel

framework was chosen to support the analysis [36]. Participants were recruited from a range of practices, in both rural and metropolitan areas, to ensure a wide range of perspectives. There were, however, significantly more women than men in our sample. While this study targeted GPs and GPNs to explore the clinical appropriateness of the tool and to refine the cancer recommendations, we aim to capture a broader range of perspectives from the primary care workforce in the RCT.

Due to the low frequency with which GPs were exposed to the recommendations, some participants had not seen any cancer recommendations at the time of interviewing and were therefore providing feedback on their expectations of using FHT in practice rather than their actual experience, limiting the generalizability to the usual workflow in the consultation. To address this, we reinterviewed half of the GPs who had not initially seen the recommendations, and this allowed for comparisons of participants' perception of the recommendations before and after use. The iron-deficiency anemia recommendation was released 3 months after the other recommendations, potentially limiting the amount of feedback on this prompt.

The timing and environment in which this study was conducted is also important. This pilot and feasibility study was conducted during the COVID-19 pandemic, which caused a large disruption to the usual workflow of most primary care professionals. The effects of the pandemic seen in primary care are numerous, with an increase in telehealth appointments, a shift in health perceptions and priorities, and the resulting staff turnover in primary care [38]. We aim to explore how these ongoing changes to usual practice have impacted the use of FHT in the RCT.

Comparison With Prior Work

While QI tools for cancer diagnosis in primary care are posited to improve the quality of care for patients, reduce practitioner errors, and allow for efficiency in everyday practice, previous studies have reported a range of barriers to implementation and low acceptance in practice. Issues with CDSSs for cancer include tools that are underused [39], too complex [40], incompatible with the workflow [41], incompatible with GP software [42], or do not align with practitioner practice [43]. The results of this study align with the findings of a previous systematic review [28]. The ability to verify the recommendations by understanding the research underpinning the recommendation was not being met as part of FHT [28]. For the diagnosis of cancer, embedding tools in the workflow is often a key barrier [39]; however, the limited disruption caused by the tool and the timing of the prompt meant that FHT aligned with most participants workflow.

The use of a researcher-led simulation in the earlier interviews aligns with previous research that shows that simulations are not able to replicate the stress, workflow, and competing priorities of a usual busy general practice [44]. Nevertheless, they showed a recognized and potentially unmet need around the follow-up of abnormal test results that could be due to an underlying cancer. The later interviews indicated that the perceived usefulness did not translate to optimal usability, and refinements were necessary to address these barriers before

testing the efficacy in a large RCT [45]. In particular, changes were made to the language, phrasing, length, and clarity of the recommendations; tailored resources were created to address knowledge gaps; and custom resources were created to address patient communication barriers.

There are implications for further development of this tool. FHT has been developed for use across multiple disease types. The cancer module was implemented in practices after participants had used FHT for CKD. While the tool and its functionality remained constant, the recommendations for CKD showed progression through the feedback cycle (this may be due, in part, to familiarity with CKD guidelines). However, this indicates that the technology has the potential for effective

behavior change and improvement in clinical care but highlights that there is no *one size fits all* in the development and messaging of recommendations across disease types. Further work on how to develop, modify, embed, and prioritize these recommendations for use in primary care is needed, especially as the number of conditions within FHT is expanded.

Conclusions

QI interventions are difficult to implement. This study highlights the benefit of optimization and refinement before testing the efficacy and clinical utility in a large cluster RCT. Successful implementation of this QI tool could be used as a support system to detect patients at risk of an undiagnosed cancer in primary care and assist in reducing diagnostic delays.

Acknowledgments

The authors would like to acknowledge the contributions of the Future Health Today (FHT) project team and investigators. We would also like to acknowledge the time and commitment of all consumer focus group participants.

This project was supported by the Australian Government's Medical Research Future Fund Rapid Applied Research Translation program in conjunction with the Melbourne Academic Centre for Health. FHT is also supported by the CanTest Collaborative (funded by Cancer Research UK C8640/A23385) of which JE is an associate director. JE is supported by a National Health and Medical Research Council investigator grant (APP1195302). SC is supported by the Joan Alice Duncan PhD Scholarship.

Abstract

Background: Improving preconception health can benefit all women, their children, and their families regardless of their individual pregnancy intentions. Rapidly increasing access to information technology and online engagement have created opportunities to use digital health resources to engage with preconception women regarding lifestyle behaviors.

Objective: This study explores how preconception women engage with digital health resources and online platforms to inform the design and development of a digital health resource to support women to make positive behavior change for their preconception health.

Methods: This codesign research followed the Double Diamond process, which focuses on contextualization and explorative processes in phase 1 and ideation and development processes in phase 2. Phase 1 is reported on in this study and was undertaken via a series of 1-on-1 in-depth interviews with female participants (N=12) aged 18-45 years over 3 months. Interviews were designed to explore participants' lived experiences in relation to their health and desired supports for healthy lifestyle behaviors. The first interview focused on participants' perceptions of health and health behaviors, the second interview focused on social connections for health, and the third interview focused on digital health information and supports. Conversations from the first interview informed the development of the second interview, and conversations from the second interview informed the development of the third interview. Community advisors (N=8) met to provide feedback and advice to the researchers throughout the interview process. Qualitative analyses of transcripts from interviews were undertaken by 2 researchers before a deductive process identified themes mapped to the capability, opportunity, motivation, and behavior (COM-B) framework.

Results: In total, 9 themes and 8 subthemes were identified from 124 codes. In relation to digital health resources, specifically, participants were already engaging with a range of digital health resources and had high expectations of these. Digital health resources needed to be easy to access, make women's busy lives easier, be evidence based, and be reputable. Social connectedness was also highly important to our participants, with information and advice from peers with similar experiences being preferred over yet more online health information. Online communities facilitated these social interactions. Participants were open to the idea of chatbots and virtual assistants but acknowledged that they would not replace authentic social interactions.

Conclusions: Codesigned digital health resources should be evidence based, reputable, and easy to access. Social connections were considered highly important to women, and designers of digital health resources should consider how they can increase opportunities for women to connect and learn from each other to promote health behaviors.

Introduction

Optimal preconception health has benefits beyond fertility and pregnancy for mothers, children, and women who do not have children [1-3]. A public health view of the preconception period encompasses the months and even years prior to a potential pregnancy, when health behaviors may impact maternal health status at the critical weeks around conception [2,4]. Taking this broad view is useful when considering that the event of pregnancy is never certain, that a relatively large proportion of pregnancies are unplanned [5], and that some women remain nulliparous. Health behaviors in relation to nutrition, physical activity, and weight management can improve preconception health, prevent chronic disease across the life span [6-8], and assist with managing existing health conditions [9]. Positive health behaviors are often observed by others and can have a positive influence on children, families, and those in the broader community [10].

Women's awareness of the importance of their health behaviors during the preconception period is low [11]. This issue is exacerbated by social, economic, and physical environments that tend to promote or enable suboptimal health behaviors [12]. Globally, the most rapid increase in rates of overweight and obesity is in reproductive aged women [13,14], and approximately 40% of women conceive with a BMI that is considered unhealthy [15]. Preconception behavior change interventions tend to target women of a reproductive age who are planning a pregnancy [16]. These women have been labeled pregnancy "intenders" [17]. Intenders are identified by their goal to conceive and motivation to have a healthy pregnancy [17,18]. Women of a reproductive age who are not planning a pregnancy in the foreseeable future have been labeled "nonintenders" [17]. Their health behaviors are equally important as intenders' as they may eventually impact a future pregnancy, planned or unplanned, and the health of the women themselves [2,4]. Nonintenders are generally not motivated by the event or chance of a pregnancy, possibly far off in the future, to change health behaviors [17]. In fact, they tend not to resonate with the term "preconception" at all, considering it to be something that applies to those planning a pregnancy [19]. These women may have a range of other nonpregnancy-related motivators for behavior change [17]. Regardless of women's pregnancy intentions, optimizing health behaviors in the preconception period can improve every woman's health and, in the event of pregnancy, can improve the health of future generations.

Digital health is defined by the World Health Organization as knowledge and practice associated with the development and use of digital technologies to improve health [20]. Digital health is facilitated by a range of existing technologies, such as mobile and online platforms and devices, as well as emerging data science, artificial intelligence, and robotics technologies [20,21]. A range of commercial online digital health resources have engaged women from the general population to make health

behavior change, at least in the short term (eg, Michelle Bridges 12 Week Body Transformation [22], 28 by Sam Wood [23], Weight Watchers Digital [24]). However, cost is likely to be a barrier to access for some women. Online and social media platforms, such as Instagram and Facebook, are also highly influential in women's decision-making around health behaviors [25]. Globally, 2.7 billion people use Facebook [26] and 1.0 billion use Instagram every month [27]. In Australia, approximately 3.5 hours are spent on online digital devices daily [28] and the average time spent exclusively on social media is 1.48 hours daily [29]. Modes of online engagement, and technology to support digital health resources, and ease of access are expanding rapidly [21]. With approximately 6 billion smartphone subscribers worldwide [30], opportunities to engage with almost any target market to promote behavior change have never been so numerous.

Digital health resources can promote behavior change [21,31], including in preconception populations. For example, Jack and colleagues [32,33] developed a virtual health professional to provide African American women with preconception health information and advice via computer and internet access. In a national randomized controlled trial in the United States, women in the intervention group were supported to address 50% of their identified preconception risks, significantly more than the control group [33]. This technology was tested in Australia with a multicultural sample of women aged 18-45 years [19,34]. Participants in this study, who all identified as being nonintenders, acknowledged the importance of health behaviors for preconception health and considered the resource an acceptable way to provide preconception health information and advice. However, they ultimately were not motivated to engage with a digital health resource that promoted preconception health or pregnancy [19,34]. Participants were particular about what they liked and did not like. They called for digital health resources that are accessible on smartphones (the format tested with them via a computer), easy to navigate, and tailored to meet their individual preferences. Key considerations for those developing digital health interventions are the rapid evolution of information technology and possibilities in digital health [21], trends in user engagement, and keeping up with women's preferences and expectations [19,34]. Despite the opportunities afforded by digital health, the requirements for engaging and sustainable preconception health resources are not yet fully understood. This research aims to further explore how intender and nonintender women engage with digital health resources and other online platforms, including social media, to inform the design and development of a digital health resource (or resources) to support women, both intenders and nonintenders, to make positive behavior change in relation to their preconception health. This study reports on the first phase of a larger body of participatory design research to empower women to adopt and maintain healthy lifestyle behaviors that optimize their preconception health and overall health and well-being.

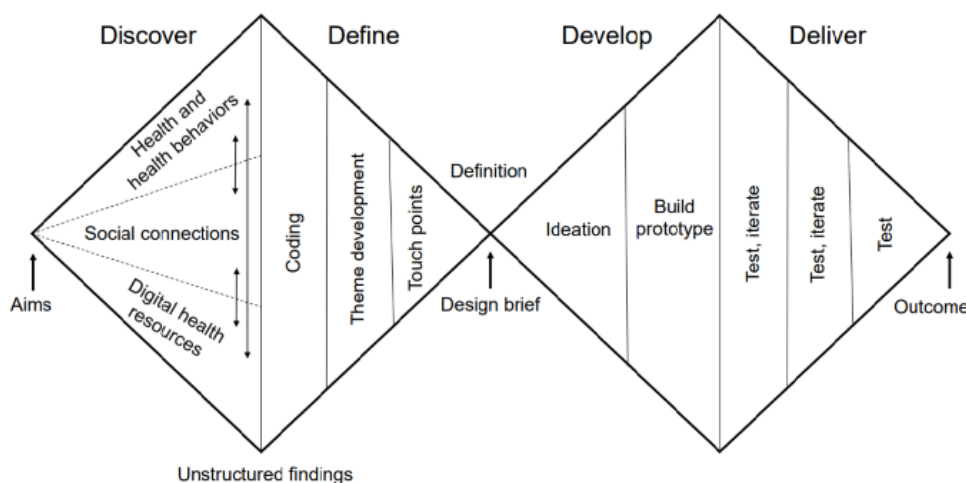

Methods

Study Design

Our experience-based codesign approach involving women and community advisors was based on the Double Diamond process, an integrated design process that focuses on contextualization and explorative processes in phase 1 and ideation and

development processes in phase 2 (Figure 1) [35]. Phase 1 is reported in this study, including a design brief with a range of considerations to scope the activities of phase 2. The anticipated output of phase 2 is a codesigned digital health resource (or resources) that engages women with knowledge and support in relation to their preconception health behaviors. Two community advisory committees guided this research from the outset.

Figure 1. Double Diamond process, adapted for use in this research.

Ethical Considerations

Ethics approval was obtained from the Monash University Human Research Ethics Committee (MUHREC reference: 28204). Participants provided informed consent via an online consent form. This full method is reported elsewhere (Walker et al, unpublished data, May 2022), and a summary is provided later.

Setting, Participants, and Community Advisors

Study participants and community advisors lived in Victoria, Australia, and were aged 18-45 years. To be eligible, they needed to identify as being an intender (planning a pregnancy in the next 2 years or had a child in the past 2 years) or as being a nonintender (not planning a pregnancy in the next 2 years, with or without children already).

Recruitment and Consent

Study participants and community advisors were recruited via advertisements sent to existing contacts at a range of women's health groups in metropolitan Melbourne and regional Victoria, Australia, and via Facebook and Twitter. Community advisors were recruited and screened for eligibility in February and March 2021. Following the first community advisor meeting, participants were recruited and screened in April and May 2021.

Data Collection

Community advisors were divided into intender and nonintenders groups based on whether they identified as being an intender or a nonintender. Four meetings for each group were held between March and October 2021. The meetings' overall objectives were to introduce the study aims, gather feedback regarding the study design and results, and seek nonbiased

guidance relating to how the interviews were conducted and phase 2 planning. The intender community advisors provided feedback in relation to the interviews being conducted with the intender participants, and the nonintender community advisors provided feedback in relation to the interviews being conducted with nonintender participants. These meetings were audio-recorded, transcribed, and added to the data set. Three in-depth interviews with each participant were conducted between June and September 2021. Interviews were designed to explore participants' lived experiences in relation to their health and desired supports for healthy lifestyle behaviors. The first interview focused on participants' perceptions of health and health behaviors, the second interview focused on social connections for health, and the third interview focused on digital health information and supports. COVID-19 restrictions meant that all meetings and interviews in this study had to be conducted online via Zoom. Meeting and interviews were audio-recorded using a Dictaphone, transcribed with the Descript transcription service, and then checked by 1 of the researchers. Community advisors and participants were de-identified with a unique participant number.

Data Analysis

Data collection and analysis occurred concurrently. This was because data collected in previous interviews informed the subsequent interviews. This process involved rapid coding to gain insights from the first interview, which informed the activities designed for the subsequent interview with a degree of personalization based on the individual responses provided by the participants. Two researchers (authors SQ, a female research assistant and dietitian, and RW, a postdoctoral research fellow and dietitian, both with expertise in women's health and

qualitative research methods) double-coded a subset of the interview 1 transcripts to develop the initial coding framework. The remaining interview 1 transcripts were coded and cross-checked intermittently for consistency. The same process was used for interviews 2 and 3, with new codes being added to the initial framework. The transcripts from community advisor meetings were double-coded using the same framework. The community advisors discussed similar topics to those discussed in the interviews, creating a situation where the same coding framework used for the interviews could be used for the community advisor transcripts. NVivo software (QSR International) supported the analyses.

A deductive process was used for theme development. Codes were mapped to 3 focus areas of the in-depth interviews (perceptions of health and health behaviors, social connection, digital health information and support) and to the 3 components of the capability, opportunity, motivation, and behavior (COM-B) framework [36]. The 2 researchers developed summary statements for each intersection between the focus areas and the COM-B system before “touch points” were identified. Touch points in experience-based codesign are positive or negative experiences that elicit an emotional response [37]. In this study, we applied the term “touch point” to crucial aspects of the product or service design that must be present for participants to initially like it, have a desire or motivation to engage with it, actually engage with it, and then allow it to be a trusted and ongoing support for behavior change. For example, a woman may initially be drawn to a digital health resource

because of its graphic design (eg, earthy tones, images of nature and well-being). She may like that the digital health resource has clear tabs for easy navigation and that the information provided is by a figure or person she relates to and trusts. Interacting with the resource may make her life easier, not harder. Touch points in this scenario may be labeled “calming,” “ease of use,” “reliability,” and “trust.” A degree of subjectivity may have been present in the identification of touch points for this study. Steps were taken to mitigate this by the 2 researchers (SQ and RW) discussing what touch points emerged as being most important to our participants with the rest of the research team. Repetition of some touch points across the intersections also indicated that they were important design considerations. The touch points generated the design brief that was scrutinized in the fourth round of community advisor meetings. Finally, themes and subthemes were derived from the summary statements and touch points.

Results

Community Advisor and Participant Characteristics

In total, 8 community advisors and 12 participants were included (Table 1), and 9 themes and 8 subthemes were derived from 124 codes, with overlap between themes (Table 2). Themes relating to digital health information and supports are reported here, while themes relating to health behaviors and social connections for health are reported elsewhere (Walker et al, unpublished data, May 2022).

Table 1. Community advisor and participant characteristics.

Characteristics	Community advisors (N=9) ^a	Participants (N=12)
Intender ^b , n (%)	3 (33.3)	6 (50.0)
Nonintender ^c , n (%)	6 (66.6)	6 (50.0)
Age (years), median (IQR)	29 (11)	31.5 (6)
Culturally and linguistically diverse, n (%)	4 (44.4)	3 (25.0)
Living with a disability ^d , n (%)	2 (22.2)	5 (41.7)
University educated, n (%)	8 (88.8)	10 (83.3)

^aOne of the community advisors only participated in 1 of the 4 group sessions.

^bIntender: planning a pregnancy in the next 2 years or had a child in the past 2 years.

^cNonintender: not planning a pregnancy in the next 2 years, with or without children already.

^dPosttraumatic stress, hearing impairment, mental health, severe endometriosis, attention deficit hyperactivity disorder.

Table 2. Summary statements, touch points, and themes (from participant and community advisor data).

	Perceptions of health and health behaviors ^a	Social connections for health ^a	Digital health information and supports
Capability for health behaviors			
Summary statement	Capability comes from a holistic understanding of health, health information, and feeling of empowerment.	Social connections and shared experiences are integral to capability.	Digital health information and supports increase capabilities for health behaviors.
Touch points	<ul style="list-style-type: none"> Health is valued. Trustworthy information. 	<ul style="list-style-type: none"> Relationships with friends and family Shared experiences Being listened to 	<ul style="list-style-type: none"> Trustworthy information Quality digital health information
Theme(s)	<ul style="list-style-type: none"> Health is multidimensional, and a few key health behaviors are valued over all others. 	<ul style="list-style-type: none"> Social connections and shared experiences build knowledge and increase confidence in decision-making. 	<ul style="list-style-type: none"> Digital health information and support need to be evidence based and reputable to increase capability.
Subtheme(s)	<ul style="list-style-type: none"> Health information can empower and disempower health behaviors. Everyday life can empower and disempower health behaviors. 	<ul style="list-style-type: none"> Looking to other sources of information when health professionals are not trusted 	N/A ^b
Opportunity for health behaviors			
Summary statement	A range of resources create opportunities for health behaviors.	Social connections are shared experiences are integral to opportunity.	Digital health information and supports increase opportunities for health behaviors.
Touch point(s)	<ul style="list-style-type: none"> Makes life easier 	<ul style="list-style-type: none"> Relationships with friends and family Shared experiences Being listened to 	<ul style="list-style-type: none"> Information and supports need to be timely and relevant. Online communities support social connections for health. Smartphone access is essential.
Theme(s)	<ul style="list-style-type: none"> Personal responsibilities prioritized over health behaviors 	<ul style="list-style-type: none"> Social connections and shared experiences increase opportunity for health behaviors. 	<ul style="list-style-type: none"> Digital health information and support need to be relevant and increase opportunity for social connection.
Subtheme(s)	<ul style="list-style-type: none"> Resources that make health behaviors easier 	<ul style="list-style-type: none"> Being listened to shared experiences are important. 	<ul style="list-style-type: none"> Ease of access and convenience are essential. Chatbots and virtual assistants may be useful but will not replace authentic social interactions.
Motivation for health behaviors			
Summary statement	A desire to feel well and live well motivates health behaviors.	We thrive when we are together.	Digital health information and supports have the potential to increase motivation for health behaviors.
Touch points	<ul style="list-style-type: none"> Pregnancy is a motivator when a pregnancy is planned or desired. Quality of life, including nature, rest, and relaxation. 	<ul style="list-style-type: none"> We learn from each other. We support each other. 	<ul style="list-style-type: none"> Clear and tailored information Variety and choice Privacy and trust Diversity and inclusion Aesthetically appealing Goal setting, tracking, and monitoring progress
Theme(s)	<ul style="list-style-type: none"> A range of factors motivate health behaviors. 	<ul style="list-style-type: none"> "We're not designed to be alone... We thrive when we're together." 	<ul style="list-style-type: none"> New digital health information and support need to be innovative to meet expectations of their target audience.

^bN/A: not applicable.

Theme: Digital Health Information and Support Need to Be Evidence Based and Reputable to Increase Capability

Participants engaged with a range of digital health resources to increase their capability, including apps, online classes, podcasts, websites, and social media. They had clear expectations of the digital health resources they engaged with, including evidence-based information, tailored advice, and the presence of a moderator on online forums. Due to an abundance of online information and “a lot of misinformation out there” (participant 3, nonintender), participants were aware of the importance of health literacy and discerning between trustworthy and unreliable information. Google was a starting point for health information searches, along with recommendations from social connections, online reviews, and a number of downloads. Participants wanted to know that other people respected and valued the information they were accessing.

In terms of resources...I did a lot of Googling. I would look up what's good, what's happening through the pregnancy cycle and what's good to be, you know, to be done during pregnancy...Um, so I did look up a few resources...I think specific applications like “Baby Centre” has some good resources, even the NHS Pregnancy Guide [National Health Service, UK]. [Participant 6, intender]

Theme: Digital Health Information and Supports Need to Be Relevant and Increase Opportunity for Social Connection

Digital health information and support on social media (mostly Facebook and Instagram) increased the participants’ opportunity to search for information, access online communities, and learn from others who had similar experiences to them. Online communities also facilitated opportunities for social connections that were considered of utmost importance to our participants. Despite many participants and community advisors being only passively involved in online discussions (eg, not posting and only reading) or engaging intermittently, these forums seemed to be highly valued.

I think for me, even though I don't post or comment, I like to be able to read other people, uh, their posts, uh, and the advice that other people provide...Yeah. So that's, that's my personality for someone who is like an introvert and doesn't talk...But it [online communities] also caters to someone who's an extrovert and likes to really ask questions and ask opinions and provide advice. [Community advisor 1]

Participants who valued online communities tended to be those most likely to experience barriers to meeting with people face to face (eg, had a chronic condition, caring for small children) or were at a time in life when their need for support was higher (eg, pregnancy).

I would definitely put an online community in my inner circle. When I fell pregnant with my oldest one, he's 6 now...I was holding on to the “What to expect when you are expecting” App...Like a lifeline, because I was terrified of what was going on. I was curious, I was all those things nervous, excited. [Community advisor 2; the term “inner circle” was used during the interviews to define those who participants relied on and trusted most.]

It's [online community] somewhere between inner circle and community, to be honest. Um, I feel like obviously a lot of [online community's] following it's my inner and broader community anyway. Um, but I feel like because we're discussing such vulnerable things and, um, people are coming back with responses saying, I understand, and I feel this, and I've been through this and everyone kind of feeling so comfortable and nurtured in that space that...I'm having conversations publicly on there that I wasn't having privately 2 years ago in my inner circle, which is really weird. But it's such a beautiful space, um, that I feel like that's kind of somewhere between inner and community. [Participant 3, nonintender]

Subtheme: Ease of Access and Convenience Are Essential

Factors that increased the participants’ opportunity to use digital health information and support were access to hardware (eg, smartphones, tablets, and computers) and cost. Participants mostly used their smartphones and were happy to pay for health apps and online programs if they were perceived to be valuable.

I tend to use the mobile phone a lot more. Um, like, you know, when I'm kind of done with work, um, I use the phone a lot more. [Participant 6, intender]

Like, I'm quite happy to pay for the, for apps or information if, if it was laid out to start with... [Participant 5, intender]

Subtheme: Chatbots and Virtual Assistants May Be Useful but Will Not Replace Authentic Social Interactions

Participants were asked about their experiences with chatbots and virtual assistants. Most had interacted with them for practical, non-health-related activities, such as booking appointments or product queries. Most reported that they would

be willing to interact with a chatbot or virtual assistant for health but described potential limitations. If participants used a chatbot or virtual assistant for health, they would need to trust they were receiving expert advice. Participants were less likely to interact with a chatbot or virtual assistant if it was not a person they were interacting with, if they did not receive timely responses, or if responses were not tailored to meet their needs.

I think you can tell when it [chatbot] is not a person...So I think that particularly from a health point of view, it maybe, sort of, needs to be very clear that's what it is. That it's not, there's not a person at the end of this chat. This is just a direction tool or something...If it was a robot, I don't think I'd use it. [Participant 2, intender]

Theme: New Digital Health Information and Support Need to Be Innovative to Meet Expectations of Their Target Audience

Participants had clear expectations of digital health information and supports they wanted. When asked about desirable features that would to motivate them to engage, the participants requested (1) resources with a clear purpose; (2) resources tailored to their needs; (3) privacy and opportunities to participate anonymously; (4) trust, openness, and honesty from other participants (fostering a sense of community); (5) diversity and inclusion; and (6) functionality that facilitates goal setting and data tracking to monitor their progress. Digital health resources also need to be visually appealing, easy to navigate, and accessible for those with hearing and visually impairments and should offer a variety of ways to engage (eg, Facebook groups, Instagram, Podcasts, and moderated forums).

I wouldn't want one resource to be all of general health, if that makes sense. Like, I would prefer it to be multiple or that resource to be more specific to women's health; or even that's very broad. Like reproductive health, for example, what would be helpful as a smaller area of the topic. [Participant 5, intender]

One of the successful things I think of these groups is that there is those multiple components. Like, you have the podcast and you have the community. Um, I don't know if either would be so successful without the other. [Community advisor 3]

In relation to preconception health, participants identified that tracking from preconception to pregnancy and birth would be helpful.

It would be cool to continue into pregnancy...So like especially spending money on an app. You don't really want to be like, "oh man, now I'm pregnant. Now I need a new app." It would be good to continue on the same thing that you can still be tracking... [Participant 4, intender]

Due to COVID-19 lockdowns, participants were working from home on their computers. The participants expressed wanting to get away from their computer screens at the end of the work day. If they were to engage with a digital health resource, they wanted to use one that seemed to be recreational.

Like it's, unfortunately it's [being online] just part of your whole day really...I just saw something on Twitter before...One of the people who has done some work with us is like, "Is anybody else just not interested in having Zoom parties?" Because by the end of a work day, I just, last thing I want to do is look at a screen... [Participant 2, intender]

Participants created a huge list of digital health information and supports that they had accessed. Some of this information and support was developed by governments (Better Health Channel, National Health Service [NHS], United Kingdom) and large organizations (Baby Centre, Royal Women's Hospital). Some of this information was developed to meet a perceived need and for commercial purposes (Keep it Cleaner, Chemical Maze, Noom), while some information and support were developed because of an unmet need and not for commercial purposes (Private Parts, Facebook groups). Participants did not list any resources that had been solely developed by health professionals or academics. In fact, some of their comments cautioned against this.

To me, um, it would need to be coming from like someone [a face or advocate] who opens the story. Like, "Hey, I'm 30 years old. I don't think I'm going to have kids. This is my situation." Um, I think that it would be quite interesting...Like, as SP was saying, like, um, there might be online forums out there, but you always search for someone who is in a very similar situation to you...I think that's why "She's on the Money" has been successful because it's run by young woman. Um, so, yeah. It just like, it cuts through a little bit more...Rather than like, "Hey, we're like, you know, from our Ivory Tower or institution..." in the messaging. Yeah. You know what I mean? [Community advisor 4]

Our community advisors also made some relevant comments in relation to the overall aims of this project to motivate women to engage with digital health resources for health behavior change.

I think that, that organic, um, like that organic genesis I think is really quite an important part. I think in terms of trust...I just like, I think that I've got a couple of friends who are involved with, um, a big breastfeeding group on Facebook called the Breastfeeding Cooperative...I think it started quite small and it's grown to be like, you know, over a hundred thousand members. And, um, you know, they've got this huge admin team now and it's massive. Um, and a lot of the women who moderate the group are doctors or nurses or like are professionals in some way, but it, it did happen very organically...It's a group that is really trusted among a lot of Australian women. But I think if it had started from like a health promotion, like deliberate, like "Let's, let's make a health promotion intervention!" I don't think it would have worked... [Community advisor 5]

What does a health promotion intervention that women trust and rely on and engage with look like?

I suppose it looks like something that you want to be a part of. Like, you want to actually be socially involved because you get something out of it...I like to feel how I give something back to that same community. And that's what makes it community rather than a classroom...I suppose, in order for them to be successful, I feel like there has to be a bit of learning, but also a bit of teaching taken on by everyone...I think you, you feel connected to them because of that shared experience. So if you create something that could generate that, that information-giving along with that social connectedness...I think you'd have a far greater buy-in from a lot of people. [Community advisor 2]

Our discussions with the community advisors and participants identified themes and touch points (Table 2) that informed the development of a design brief to inform phase 2 of this research (Multimedia Appendix 1).

Discussion

Principal Findings

Our pregnancy intender and nonintender participants were already engaging with a range of digital health resources, including social media, to optimize their preconception health, general health, and overall well-being. They actively sought health information that they considered to be evidence based, trustworthy, and relevant. Desirable attributes of digital health resources were related to convenience. Our participants were busy and wanted information and supports that made their lives easier. Online interactions that facilitated meaningful social connections for health were prioritized over simply having access to more health information. Our participants listed a range of preferences for designers to consider as they leverage off information technology, the internet, and social media to develop digital health resources that promote preconception health behaviors.

Limitations

This research had equal representation from pregnancy intender and nonintender participants who were interviewed 3 times over 3 months. This longer period of engagement allowed interviewers to delve more deeply into the participants' lived experiences, their health behaviors, and supports for health. Ongoing interaction over 3 months also facilitated trust and rapport between participants and the interviewers. Additionally, ongoing data analyses enabled the findings from one interview to inform the next interview, and interviews were tailored to individual participants. The age range of participants was a limitation of this study, with an absence of women aged from 18 to 26 years. However, this younger age group was represented in community advisor meetings, with 3 nonintender community advisors being aged less than 26 years.

Consideration needs to be given to the impact of COVID-19 in the interpretation of the results. Data collection occurred during 1 of several COVID-19 lockdowns in the state of Victoria, Australia, in 2021. The COVID-19 lockdowns impacted all health behaviors, including those considered most important by

our participants (food, exercise, and social connection) [38]. Potentially, the value participants placed on these health behaviors may have been magnified. Social connection is protective at times of stress, and perceived social support can buffer the negative impacts of isolation and loneliness [39]. Again, this may have magnified the importance participants placed on being socially connected with others. The final interview that explored participants' use of digital health information and supports occurred after many participants had been working from home or home-schooling children for approximately 18 months. This increased use of information technology for work and daily tasks may also have altered how some participants described their use of digital health resources.

Comparison With Prior Work

Digital health resources that promote health behaviors are plentiful, and women are engaging with them as it is expedient to them. This research highlighted women's dependence on commercial or perhaps less formal digital health resources, including social media, such as Facebook and Instagram. Our participants valued the opportunities these platforms created for sharing experiences and learning from others (Walker et al, unpublished data, May 2022). Individuals are increasingly turning to experience-based information and support as opposed to expertise-based information and support provided by health professionals [40]. This challenges how health promoters and designers approach the development of digital health resources that are competitive in this space [41].

Examples of the successful integration of health promotion with social media platforms can be found in the use of existing online communication platforms, such as Facebook, WhatsApp, and free online learning platforms designed specifically for laypeople [42,43]. For example, the *FeedFinder* mobile phone app supports breastfeeding women to identify, review, and share information around public breastfeeding spaces [44,45]. This digital health resource was developed in consultation with women by a multidisciplinary research team from Newcastle University, United Kingdom, highlighting the importance of user involvement in design and how some digital health interventions are more effective when targeted to communities where information is shared [44]. Another example is the use of Massive Open Online Courses (MOOCs) for learning and discussion regarding a range of topics, including health [46-48]. Developed by Monash University, Australia, the MOOC Food as Medicine provided learners with education around nutrition as well as a moderated question and discussion forum [43]. Between May 2016 and February 2018, the course attracted >81,000 learners [41]. The evaluation found that learners were open to nonexpert advice from other learners because this feedback was timely, easily accessible, and often with personal anecdotes [41]. A common feature of these examples with our research is the value users placed on opportunities to interact and learn from each other. Experience-based information and support were preferred over expertise-based information by our participants. This reinforces the need to consider the strengthening influence of online voices and the importance of sharing experiences when developing digital health resources for contemporary women [40].

Future resources to promote behavior change, digital or other, should be codesigned with target audiences to ensure they meet their specific needs and preferences and promote ongoing engagement [49]. Our particular audience targeted in this research was broad. Essentially, a public health view of the preconception period includes all reproductive-age women [2,4]. We noted more similarities than differences between our intender and nonintender participants. Social connections, including being listened to and hearing from the shared experiences of others, were paramount for all our participants' health and health behaviors (Walker et al, unpublished data, May 2022). In relation to digital health resources, participants primarily wanted resources that were easy to navigate and made their lives easier. This was confirmed with the feedback and oversight of our intender and nonintender community advisors who agreed that social connections should be integral to planning in phase 2. A systematic review of user engagement with digital health resources for mental health also found that social connections and customized content are enablers for engagement, while technical and navigation difficulties are a barrier [50]. The other touch points we identified, including privacy and the importance of images that represent quality of

life (eg, nature, rest, relaxation), were incorporated into a design brief format and shared with our community advisors for feedback. Slight but important alterations were made to the design brief after the final community advisor meeting, demonstrating the importance of community engagement throughout the research process to ensure that participant and community voices are represented accurately [51].

Conclusion

Women engage with digital health resources and other online platforms, including social media, to support their health behaviors and overall health and well-being. Women have clear expectations of what they want from digital health resources. These should be evidence based, reputable, and enable ease of access to fit in with busy lives. Social connections are paramount for women. Therefore, designers of digital health resources should consider how they can increase opportunities for women to connect and learn from each other to promote health behaviors. Codesigning digital health resources is important to successfully engage women with digital health information and support to increase their capability and create opportunities and motivation to support positive health behaviors.

Acknowledgments

Funding for this research was provided by the Australian government's Medical Research Future Fund (MRFF). The MRFF provides funding to support health and medical research and innovation, with the objective of improving the health and well-being of Australians. MRFF funding has been provided to the Australian Prevention Partnership Centre under the MRFF Boosting Preventive Health Research Program. The authors also acknowledge a Monash Institute of Medical Engineering grant (Monash University) to accelerate the development of new medical technologies to address unmet clinical needs.

Abstract

Background: Implementation of clinical guidelines into routine practice remains highly variable. Strategies to increase guideline uptake include developing digital tools and mobile apps for use in clinical practice. The National Heart Foundation of Australia in collaboration with the Cardiac Society of Australia and New Zealand published 3 key cardiac clinical guidelines, including the Australian clinical guidelines for the (1) prevention and detection of atrial fibrillation, (2) detection and management of heart failure, and (3) management of acute coronary syndromes. To improve access and uptake for health care providers, we developed the Smart Heart Guideline App.

Objective: This study aims to evaluate the acceptability, implementation, and usability of an Australian-specific cardiac guidelines mobile app.

Methods: We used an iterative multiple methods development and implementation approach. First, we conducted a cross-sectional web-based survey with end users (n=504 health professionals) in 2017 to determine the acceptability of an Australian-specific cardiac clinical guidelines mobile app. Second, the Smart Heart Guidelines app was created using a design, user testing, and revision process. The app includes interactive algorithms and flowcharts to inform diagnosis and management at the point of care. The freely available app was launched in October 2019 on iOS and Android operating systems and promoted and implemented using multiple methods. Third, data from 2 annual national cross-sectional general practitioner (GP) surveys in 2019 and 2020 were evaluated to understand the awareness and use of the clinical guidelines and the app. Fourth, data from the app stores were analyzed between October 1, 2019, and June 30, 2021, to evaluate usage.

Results: Most health professionals surveyed (447/504, 89%) reported accessing resources electronically, and most (318/504, 63%) reported that they would use an Australian-specific cardiac guidelines app. GPs surveyed in 2019 were aware of the heart failure (159/312, 51%) and atrial fibrillation (140/312, 45%) guidelines, and in 2020, a total of 34 of 189 (18%) reported that they were aware of the app. The app was downloaded 11,313 times (7483, 66% from the Apple App Store; 3830, 34% from Google Play) during the first 20-month period. Most downloads (6300/7483, 84%) were a result of searching for the app in the stores. Monthly download rates varied. App Store data showed that people used the app twice (on average 2.06 times) during the 20 months. Many (3256/3830, 85%) Android users deleted the app.

Conclusions: Health professionals supported the development of the Smart Heart Guidelines app. Although initial downloads were promising, the frequency of using the app was low and deletion rates were high. Further evaluation of users' experience of the most and least useful components of the app is needed.

Introduction

Cardiovascular disease is the leading cause of death in Australia and a nationwide priority for research [1]. National clinical guidelines have been developed to inform decision-making among health professionals in the diagnosis and management of cardiovascular disease. Implementation of clinical guidelines can prevent avoidable harm, improve resource use, and reduce variation in care [2]. Despite this, implementation of clinical guidelines into routine practice remains highly variable, suboptimal, and concerning, low in some areas of health care [3]. In Australia, the National Health and Medical Research Council advises improving access and uptake of clinical guidelines by presenting content in multiple formats that are tailored to users' needs [2].

Smartphone apps are a convenient way for health professionals to access health information in a timely manner. In recent years, international organizations including the European Society of Cardiology and the American Heart Association have developed mobile apps providing digital access to their guidelines and specific apps for interactive decision support tools for real-time use in clinical practice and cardiovascular risk calculation [4,5]. Similarly, other health disciplines including anesthesiology, pediatrics, and dermatology have developed apps to improve access and adherence to guideline recommendations in clinical practice [5-8]. With the advent of "living guidelines" and its methods of continuous evidence surveillance and recommendation updates, digital authoring, and web-based publication platforms such as Making Grade the Irresistible Choice (MAGICapp) have been developed, publishing over 190 living guidelines, including the Australian guidelines for care for people with COVID-19 [9]. These developments complement a trend toward greater utilization of digital platforms and smart phone use by doctors in Australia [10,11].

The National Heart Foundation of Australia (Heart Foundation) is an independent, not-for-profit organization that funds cardiovascular research and, in partnership with the Cardiac Society of Australia and New Zealand and other organizations, publishes clinical practice guidelines and position statements in areas where guidance will have the biggest impact.

The study aim was to evaluate the acceptability, implementation, and usage of an Australian-specific mobile app to improve the awareness and use of 3 Australian cardiac clinical guidelines for the (1) prevention and detection of atrial fibrillation 2018, (2) detection and management of heart failure 2018, and (3) Australian clinical guidelines for the management of acute coronary syndromes 2016 [12-14].

Methods

Overview

We used an iterative multiple methods approach, drawing on established methods in mobile app development,

implementation, and evaluation [15]. First, we conducted a cross-sectional web-based survey of end-users to determine the acceptability of an Australian-specific mobile app to access cardiac clinical guidelines. Second, the Smart Heart Guidelines app was developed and launched on Google Play and Apple App Store (App Store) and promoted using multiple methods. Third, the app was promoted and implemented. Fourth, data from 2 annual cross-sectional national general practitioner (GP) surveys in 2019 and 2020 were evaluated to assess awareness and use of the clinical guidelines and the app. Fifth, data from the app stores were collated to evaluate app use. Each of these steps are now described.

Health Professional Acceptability Survey

A web-based survey designed for health professionals likely to use a cardiology guidelines app was developed and distributed in 2017. The survey contained 10 questions including the frequency of searching for information about the prevention or management of cardiovascular disease, methods of searching, and the likelihood of using an Australian-specific mobile app to access cardiac clinical guidelines. The survey was distributed through the Heart Foundation's social media accounts and promotion in the organization's monthly newsletter (the mailing list comprised of approximately 15000 health professionals: average open rates of 21%, 3150/15000). Survey responses informed the development of the app.

Development of the Smart Heart Guidelines App

The Heart Foundation collaborated with a global app developer, experienced with international cardiology apps in Europe and the United States. The app was created in iOS (Apple) and Android formats.

Three clinical guidelines were converted from publication in a PDF format in a peer-reviewed journal into the app. The app included the guidelines for acute coronary syndromes, atrial fibrillation, and heart failure [12-14]. The app was organized into 3 sections for each clinical guidelines and contained a main page, table of contents, interactive tools and algorithms (to support clinical decision-making), and a table of key recommendations, as shown in [Multimedia Appendix 1](#). The app was created using a design, user testing, and revision process.

The app was registered as a class 1 software-based medical device with the Australian Register of Therapeutic Goods in 2019, in accordance with national legislation [16]. Registration requirements include ongoing monitoring of safety, quality, and performance. Users had to declare that they were a health professional to download the app. The freely available (no cost) Smart Heart Guidelines app was launched on both the App Store and Google Play in October 2019.

Promoting and Implementing the App

Implementation strategies used to promote the app included printed and electronic flyers, containing a quick response code

distributed at health professional educational meetings and events. Direct email and newsletters to multiple health professional groups and paid advertising in health professional journals was used. Promotion of the app on multiple webpages associated with the clinical guidelines was also undertaken.

Annual Cross-sectional Awareness Surveys to General Practitioners in 2019 and 2020

The Heart Foundation develops and distributes a nationwide cross-sectional survey to GPs annually since 2010. These surveys collect feedback about views, attitudes, awareness and the use of Heart Foundation resources and clinical guidelines. The 2019 and 2020 surveys were distributed to a sample of approximately 4000 GPs identified from the Medical Directory of Australia [17]. The 2019 annual survey contained 24 items and was distributed and open between October and November 2019. GPs could respond on the web, using the software platform Typeform or via a paper version [18]. In 2020, the 21-item survey was only available on the web and was open from October 2020 to November 2020 [18]. Both surveys contained a combination of closed-ended questions and Likert rating scales.

Evaluation of App Usage From the App Store and Google Play

Usage data for the app was retrieved from the App Store and Google Play during the period between October 1, 2019, and June 30, 2021. Data from both app stores showed the total number of downloads of the app and the conversion rate (number of downloads divided by the number of impressions) during this period. Data from Google Play showed the retention rate (percentage of users who had not uninstalled the app from their device). The App Store report provided the number of impressions (the number of times an app appears in an App Store search), product page views (the number of times a user viewed the apps product page in the App Store), and average use (number of sessions per device divided by the total number of users).

Ethical Considerations

Heart Foundation surveys are approved through routine governance organizational processes. Data collected from the surveys were anonymized and informed consent was assumed at the time of survey participation. Therefore, there was no ethical application made for this multi-methods study.

Data Handling and Statistical Analyses

Descriptive statistics were used to summarize the health professional acceptability survey from 2017 and the GP surveys in 2019 and 2020. Google Analytics was used to evaluate app data from the App Store and Google Play.

Results

Health Professional Acceptability Survey in 2017

There were 504 respondents, from all 6 states and 2 territories in Australia. Most were nurses (198/504, 39%), allied health professionals (132/504, 26%), GPs and cardiologists (45/504, 9%), researchers (11/504, 2%), or identified as other (118/504, 23%). Respondents were from a variety of disciplines including public health (131/504, 26%), private practice (121/504, 24%), community health (86/504, 17%), research institute (55/504, 11%), private hospital (35/504, 7%), health promotion (25/504, 5%), and others (50/504, 10%). Most (447/504, 89%) reported accessing the Heart Foundation's resources electronically. Most health professionals reported using Microsoft software (246/504, 63%) Apple iOS (162/504, 32%), or Android devices (63/504, 13%). The majority of health professionals (369/504, 73%) reported they would use a mobile device (a tablet or mobile phone) to access health professional resources, although the majority (465/504, 92%) currently did not. The majority (314/504, 62%) reported that they would be likely or very likely to use an Australian-specific mobile app to access the clinical guidelines and resources.

Promotion and Implementation the App

Implementation and promotional strategies for the app are summarized in Table 1. Promotion strategies had a potential reach to over 73,000 individuals.

Table 1. Methods used to promote and implement the Smart Heart Guidelines app.

Method	Dates promoted	Recipients

Annual Cross-sectional Awareness Surveys to General Practitioners in 2019 and 2020

From the 4000 GPs on the distribution list, 312 GPs responded in 2019, and 189 GPs responded in 2020. Respondents'

awareness of specific cardiac clinical guidelines and reported the use of guidelines and the Smart Heart Guideline app are presented in [Table 2](#).

Table 2. Frequencies of general practitioners (GPs) who reported being aware and frequently using specific guideline resources in the annual GP surveys in 2019 (n=312) and 2020 (n=189).

Surveys	Heart failure ^a , n (%)	Atrial fibrillation ^b , n (%)	App ^c , n (%)
GP survey 2019			
Aware of the resource	159 (51)	140 (45)	Not asked
Frequently uses the resource	9 (7)	19 (6)	Not asked
GP survey 2020			
Aware of the resource	113 (60)	102 (54)	34 (18)
Frequently uses the resource	11 (6)	11(6)	10 (5)

^cSmart Heart Guideline app.

Data From the App Store and Google Play

During the period from October 1, 2019, to June 30, 2021, the Smart Heart Guideline app had 11,313 downloads (n=7483, 66% from the App Store; n=3830, 34% from Google Play). Data from the App Store indicated over 59,900 impressions (the number of times the Smart Heart Guideline App appeared in an App Store search) with 9000 product page views (number

of times a user viewed the apps product page in the App Store), resulting in 7483 downloads. Of these downloads, the majority (6300/7483, 84%) were a direct result of searching for the Smart Heart Guideline app in the App Store. The remaining downloads resulted from accessing the app's product page via the organization's webpage (610/7483, 8%) from browsing the App Store (n=346, 5%) or from an app referrer (a link within another app; n=214, 3%). The app had consistent conversion rates

(number of downloads divided by the number of impressions) throughout this period in both the App Store and Google Play. Data from the App Store showed that most downloads were on a mobile device (6951/7483, 93%) with fewer downloads on a tablet (532/7483, 7%). The App Store data showed low average use of the app, with an average of 2.06 sessions per user during the 20-month period. Additionally, Google Play data showed that from the 3830 downloads, most (3260/3830, 85%) resulted in user losses (app deletion by users). Download data from the App stores are presented in [Multimedia Appendix 2](#).

Discussion

Principal Findings

Following a survey among end users, which revealed that approximately two-thirds (318/504, 63%) of health professional reported being “likely” or “very likely” to use an Australian-specific mobile app to access cardiology guidelines, the Smart Heart Guidelines app was launched in October 2019. Downloads of the app during the first 20 months from users deliberately searching for the Smart Heart Guideline app in the App Store and Google Play indicate that promotional and implementation activities were useful in raising awareness of the app. The total number of app downloads (>11,000), primarily in smartphones in the first 20 months from app launch, is encouraging. However, usage data show people tended to use the app only a couple of times and many deleted the app, indicating it may not be meeting users’ needs. Responses from the 2019 and 2020 GP surveys demonstrate a consistent lack of awareness and use of clinical guidelines, despite efforts to disseminate broadly and improve accessibility, including open access publishing. Although 18% (34/189) of GPs reported awareness of the Smart Heart Guidelines app in the 2020 GP survey, fewer (10/189, 5%) reported frequently using it.

Comparisons With Prior Work

Guideline implementation is notoriously challenging [3]. Internationally, there have been mixed experiences with the development and use of clinician-facing guideline apps. The National Institute for Health and Care Excellence, United Kingdom, a major developer of clinical guidelines, launched a guideline app in 2012 only to retire it in 2018 because app use stagnated and more people were directly accessing their website for information [19]. It is important to consider the purposes of a guideline app, and if it is created for voluntary download and passive access to guideline information, it may not be meaningful to clinicians and may have low impact on practice and behavioral change. Contrastingly, apps involving more interactive and specific decision support tools may be better in improving guideline adherence and changing patient outcomes. The European Society of Cardiology Atrial Fibrillation clinical guideline app has demonstrated the value of integrating novel digital technology into clinical practice, with potential for optimizing health care professionals’ adherence to recommendations of pharmacological and interventional therapy for patients with atrial fibrillation [4]. Our App included a combination of guideline information and interactive decision support tools.

In a literature review of medical smartphone apps in clinical decision support, Watson et al [20] identified 48 trials and one Cochrane review finding that while diagnostic accuracy studies are plentiful, studies to determine whether guideline apps improve adherence to guidelines are only beginning to emerge, usually in the form of before-and-after studies, often in global health. For example, in India, in a study of over 6000 participants, a nurse - facilitated smartphone - enabled hypertension and diabetes mellitus intervention in primary care was associated with significant improvements in blood pressure and blood glucose control over 18 months [21]. The nurse examined and entered patient parameters into a mobile phone-based clinical decision support system to generate a prescription, which was reviewed by a physician [21]. In contrast, in a small randomized controlled trial of pediatric doctors in the United States in a hospital simulation study, a guideline app developed to support and drive cardiopulmonary resuscitation in real time improved guideline adherence compared with other tools including pediatric advanced life support pocket cards. The app was associated with a shorter time to first and subsequent defibrillation attempts and fewer medication errors.

A reported barrier to health professionals’ uptake of guideline apps is the lack of an international regulatory framework to ensure that the apps are evidence-based and held to a quality standard [15,22]. In Australia, therapeutic goods including medical software must be entered in the Australian Register of Therapeutic Goods, and registration of the app as a class 1 medical device may have positively influenced the uptake of the app. Studies investigating if the investment in creating and maintaining a guideline app is superior to other guideline implementation strategies are lacking [20,23]. It was beyond the scope of this study to undertake a cost-benefit analysis of the app; however, reviews of cost-effectiveness of digital health interventions in the management of cardiovascular disease are generally promising [24].

Strengths and Limitations

A strength of this study is the use of multiple methods used to identify the acceptability of an Australian-specific cardiology clinical guidelines app and comparing App Store and Google Play usage data and GP experience survey data over 2 years (2019 and 2020). The app included both guideline information along with clinical decision support tools and interactive algorithms. However, this study has limitations. First, although the acceptability survey had over 500 respondents, only a small proportion of them were GPs and cardiologists, the main intended users of the app, potentially limiting the representativeness of this sample. Second, response rates to the 2019 and 2020 surveys were low, limiting the generalizability of the results. Third, comparisons between the app’s use across the App Store and Google Play was restricted as data capture is not consistent across these commercial platforms. Fourth, we were unable to comment on health professional behavior change resulting from app use, as it was beyond the scope of this study, and alternate methods are required to understand how access to the app influenced clinical practice healthcare service delivery.

Future Directions

This formative research provides a summary of why and how an Australian-specific cardiac guideline app was developed, launched, promoted, and initially used. Future research could involve qualitative interviews with app users to explore which aspects of the app they find most and least useful and to discover any unmet needs of health professionals using the app. More tailored research into the use of clinical decision aids and support tools in the app would help better understand whether the app changes health professional behaviors and improves patient outcomes.

Conclusions

The development of the Smart Heart Guideline app, a cardiology-specific guideline app in Australia, was indicated from surveying health professionals. The app incorporated guideline information and clinical support decision aids. Although downloads of the app from among >11,000 users in the first 20 months was a promising finding, the frequency of using the app was low and deletion of the app was high. Further evaluation of the app is needed to understand the most and least useful aspects and to understand if using the app improves guideline adherence and impacts patient outcomes.

Acknowledgments

Abstract

Background: After a serious knee injury, up to half of athletes do not return to competitive sport, despite recovering sufficient physical function. Athletes often desire psychological support for the return to sport, but rehabilitation clinicians feel ill-equipped to deliver adequate support.

Objective: We aimed to design and develop an internet-delivered psychological support program for athletes recovering from knee ligament surgery.

Methods: Our work for developing and designing the Back in the Game intervention was guided by a blend of theory-, evidence-, and target population-based strategies for developing complex interventions. We systematically searched for qualitative evidence related to athletes' experiences with, perspectives on, and needs for recovery and return to sport after anterior cruciate ligament (ACL) injury. Two reviewers coded and synthesized the results via thematic meta-synthesis. We systematically searched for randomized controlled trials reporting on psychological support interventions for improving ACL rehabilitation outcomes in athletes. One reviewer extracted the data, including effect estimates; a second reviewer checked the data for accuracy. The results were synthesized descriptively. We conducted feasibility testing in two phases—(1) technical assessment and (2) feasibility and usability testing. For phase 1, we recruited clinicians and people with lived experience of ACL injury. For phase 2, we recruited patients aged between 15 and 30 years who were within 8 weeks of ACL reconstruction surgery. Participants completed a 10-week version of the intervention and semistructured interviews for evaluating acceptability, demand, practicality, and integration. This project was approved by the Swedish Ethical Review Authority (approval number: 2018/45-31).

Results: The following three analytic themes emerged from the meta-synthesis (studies: n=16; participants: n=164): (1) tools or strategies for supporting rehabilitation progress, (2) barriers and facilitators for the physical readiness to return to sport, and (3) barriers and facilitators for the psychological readiness to return to sport. Coping strategies, relaxation, and goal setting may have a positive effect on rehabilitation outcomes after ACL reconstruction (randomized controlled trials: n=7; participants: n=430). There were no trials of psychological support interventions for improving the return to sport. Eleven people completed phase 1 of feasibility testing (technical assessment) and identified 4 types of software errors, which we fixed. Six participants completed the feasibility and usability testing phase. Their feedback suggested that the intervention was easy to access and addressed the

needs of athletes who want to return to sport after ACL reconstruction. We refined the intervention to include more multimedia content and support access to and the use of the intervention features.

Conclusions: The Back in the Game intervention is a 24-week, internet-delivered, self-guided program that comprises 7 modules that complement usual rehabilitation, changes focus as rehabilitation progresses, is easy to access and use, and includes different psychological support strategies.

Introduction

Background

After a serious knee injury, up to half of athletes do not return to competitive sport [1]. Athletes typically recover sufficient knee function for withstanding the physical demands of playing their sport, but an athlete's mental state is often the main hurdle to returning to sport [2]; the physical and psychological readiness to return to sport often do not coincide. The fear of reinjury is the most frequent reason reported by athletes who do not return to their preinjury sport or give up their sport after anterior cruciate ligament (ACL) injury or reconstruction [2,3]. Athletes of all ages at all participation levels can have problems with returning to sport after ACL reconstruction [1,4].

The objective of our work was to design and develop an internet-delivered psychological support program for nonprofessional athletes who are recovering from knee ligament (ACL) injury. The aim of the Back in the Game intervention is to deliver on-demand psychological support in parallel with

usual postoperative rehabilitation. The goal is to improve athletes' confidence to return to sport and subsequently improve the return to preinjury sport rate after ACL reconstruction.

Background Theory

This paper describes the processes for developing an internet-delivered program that provides psychological support for the return to sport to athletes recovering from knee ligament surgery (ACL reconstruction). *Development* refers to the entire process for arriving at an intervention to test in a randomized controlled trial. *Design* refers to the specific decisions we made about the intervention content, format, and delivery mode [5].

We adopted a blended approach [5,6] to developing and designing the Back in the Game intervention, which leaned heavily on theory- and evidence-based (United Kingdom Medical Research Council framework for developing and evaluating complex interventions [7]) approaches and target population-based (person-based [8]) approaches. O' Cathain et al's [5] taxonomy and synthesis guided the development of the eight building blocks that underpin our work (Figure 1).

Figure 1. The eight building blocks that underpin our work for developing the Back in the Game intervention.

Who Benefits From a Psychological Support Intervention?

Athletes with ACL injury expect and desire to return to sport [9-11]. Up to 9 in every 10 recreational athletes expect to return to their preinjury sport after ACL reconstruction [11,12]. Yet, fewer athletes than expected achieve their return to sport goals [1]. Psychological factors have large effects on return to sport outcomes after ACL reconstruction and larger effects on outcomes other than physical function [13,14]. Many psychological factors, including confidence, anxiety, and risk appraisal, are potentially modifiable [1,13]. Greater psychological readiness (a construct that incorporates confidence, emotions, and risk appraisal) is associated with a greater likelihood of returning to the preinjury sport [1]. Therefore, an effective intervention that provides psychological

support for the return to sport is likely to be relevant for a broad cross section of athletes.

Context of the Target Population

A biopsychosocial approach to health and rehabilitation is the dominant paradigm within which health care is delivered in the 21st century [15]. Clinicians recognize that different patients require different emphases on biological, psychological, and social elements and different emphases at different times during a course of treatment. Recovering physical function is vital for achieving return to sport goals; athletes require sufficient physical capacity for coping with the demands of playing their sport, executing their skills as desired, and staying injury-free [16].

The transition from rehabilitation to the resumption of sport after injury can be difficult. Young athletes undergoing rehabilitation get bored and lose motivation during the long

rehabilitation period [17,18]. They feel frustrated when rehabilitation does not focus on sports performance [19,20] and are concerned about their body's ability to cope with the demands of their sport [21]. Anxiety about the consequences of sustaining a knee injury again often besets athletes as they work toward returning to sport [22]. Adding to the challenge, athletes are often discharged from rehabilitation several months before attempting to return to sport. Critically, most athletes lack the support of a rehabilitation clinician during the transition back to sport.

High-quality rehabilitation aims to help athletes gradually regain knee function and physically and mentally prepare for returning to sport. The return to sport occurs along a continuum [23], beginning at injury diagnosis and concluding when the athlete is performing as desired in their chosen sport. Therefore, return to sport support should also be delivered along the same continuum.

Methods

Study Design

Our work for developing and designing the Back in the Game intervention involved systematically searching for and synthesizing available literature, designing and developing the intervention, and conducting feasibility testing. We synthesized information on the lived experiences, perspectives, and needs of active people with ACL reconstruction and the effects of psychological support interventions for improving ACL injury rehabilitation outcomes in athletes. After designing and developing the Back in the Game intervention, we conducted a 2-phase feasibility and usability study.

Lived Experiences, Perspectives, and Needs of Active People With ACL Reconstruction

To understand the issues to be addressed, based on the lived experiences, perspectives, and needs of active people with ACL reconstruction, we systematically searched electronic databases to identify qualitative research exploring the perceptions and experiences of active people with ACL reconstruction. We used the PerSPecTIF (Perspective, Setting, Phenomenon of Interest/Problem, Environment, Comparison, Time/Timing, Findings) framework [24] to construct the research question for a qualitative evidence synthesis, as follows: "From the perspective of an active person with ACL reconstruction, in the setting of completing or having completed rehabilitation, how does the phenomenon of biopsychosocial factors during recovery impact on a person's experiences and perceptions related to recovery and return to sport?" The meta-synthesis methods and results from 16 qualitative studies are outlined in [Multimedia Appendix 1](#) [9,10,17,18,25-36].

Effects of Psychological Support Interventions

To identify evidence of the effects of other psychological support interventions, we systematically searched for research addressing the following question: "What is the efficacy of psychological support interventions for improving ACL injury rehabilitation outcomes in athletes?" We identified and qualitatively summarized the major characteristics of psychological support for athletes and the consequences of

providing psychological support during rehabilitation after ACL reconstruction. The aim was to articulate a credible causal explanation for a psychological support intervention that improves the return to sport after ACL reconstruction. The review methods, as well as the specific results and quality assessments from the seven included randomized controlled trials, are outlined in [Multimedia Appendix 2](#).

Designing and Developing Back in the Game

By combining the results of qualitative and quantitative syntheses, we framed what a psychological support intervention should do and the target behaviors for achieving potential treatment outcomes. We established guiding principles to address key objectives of intervention design and important features that must be addressed to achieve the intervention objectives [8].

Ethics Approval

This project was approved by the Swedish Ethical Review Authority (approval number: 2018/45-31).

Feasibility and Usability Study

After designing the first iteration of the intervention, we completed a 2-phase feasibility testing project. Because Back in the Game was a new intervention, we wanted to ensure that it was appropriate and acceptable for athletes after ACL reconstruction. Detailed methods and results for the feasibility and usability study are in [Multimedia Appendix 3](#).

We used maximum variation sampling to recruit 11 participants for phase 1; these participants included physiotherapists, orthopedic surgeons, sports psychologists, researchers from the musculoskeletal rehabilitation field, and people with lived experience of ACL injury. For phase 2, we used strategic sampling to identify and recruit patients with recent ACL reconstruction who were aged between 15 and 30 years at the time of ACL injury, regularly played pivoting and/or cutting sports (eg, football, basketball, and floorball) prior to their injury, and intended to return to their sport. We invited 18 patients, and 7 consented to participate.

In phase 1 of feasibility testing, we focused on addressing practical issues. We sought feedback regarding technical problems with the platform that was used to deliver and display content (ie, feedback not specifically regarding the intervention content). In phase 2, we invited feedback via multiple rounds of interviews on the intervention content, look and feel of the user interface, flow and acceptability of content, frequency of content delivery, and value of the intervention.

Results

Lived Experiences, Perspectives, and Needs of Active People With ACL Reconstruction

A total of 16 descriptive themes emerged from the meta-synthesis, which we mapped to the following three analytic themes: (1) barriers and facilitators for the psychological readiness to return to sport, (2) barriers and facilitators for the physical readiness to return to sport, and (3) tools or strategies for supporting rehabilitation progress.

Athletes at all levels (ranging from amateur to professional) shared common perceptions and lived experiences of rehabilitation after ACL reconstruction (Table S1 in [Multimedia Appendix 1](#) [9,10,17,18,25-36]). Athletes wanted to play sports and saw playing sports as central to their self-identity [25,26]. They felt happy when they were playing sports [9]. However, the experience of ACL injury had often irrevocably changed how they thought of themselves and their capacity to contribute to society [27].

Anxiety and low confidence were dominant emotions. Athletes felt scared, uncertain, frustrated, and hopeless at different times during recovery and when returning to sport. Sometimes, athletes avoided tasks or activities (eg, sport-specific movements) because they lacked confidence in their knee

[9,10,17,18,26-34]. Athletes drew support, feedback, encouragement, and reassurance from people they trusted. Previous experiences of sports injury also helped athletes know what was required to recover and return to sport [17,18,25-33,35,36].

Athletes judged that quality rehabilitation programs included strategies that help build their physical and mental capacity for participating safely in sports again [9,10,17,28,29,32,34,36]. [Textbox 1](#) summarizes the key aspects of athletes' perspectives, lived experiences of rehabilitation, and needs after ACL reconstruction that informed the development and design of the intervention (Table S2 in [Multimedia Appendix 1](#) [9,10,17,18,25-36] provides a detailed summary).

Textbox 1. Evidence summary: athletes' lived experiences. Themes 1, 2, and 3 were barriers and facilitators for the psychological readiness to return to sport, barriers and facilitators for the physical readiness to return to sport, and tools or strategies for supporting rehabilitation progress, respectively.

Athletes' lived experiences

- Athletes wanted to play sports and felt happy when they were playing sports (theme 1).
- Athletes felt nervous and worried about sustaining another knee injury (theme 1).
- Athletes lacked self-confidence, self-efficacy, and self-esteem during rehabilitation (theme 1).
- Athletes knew there were risks associated with returning to sport and took active steps to manage the risk of new injury (theme 2).
- Injured athletes wanted the following (theme 3):
 - Strategies to help manage pain and injury risk
 - An understanding of their injury and what was required for recovery
 - Support from important people (eg, family, friends, physiotherapist, and coach)
 - Help with setting goals
 - Regular feedback

Effects of Psychological Support Interventions

We identified 7 randomized controlled trials for inclusion in the quantitative synthesis of the effects of psychological interventions in ACL rehabilitation (Figure S1 in [Multimedia Appendix 2](#)). The psychological support interventions with the most research attention were imagery, relaxation, and goal setting. Effect estimates are summarized in Table S1 in [Multimedia Appendix 2](#).

Textbox 2. Evidence summary: treatment approaches.

Treatment approaches

- Watching others who have experienced the injury and rehabilitation before completing rehabilitation exercises
- Learning about the ways people coped with the mental and physical challenges of rehabilitation
- Watching a carefully curated set of images designed to induce positive psychological responses toward injury and rehabilitation
- Guided relaxation
- Guided goal setting
- Guided imagery

Psychological skills training that targets coping strategies, relaxation, and goal setting might work for improving physical impairments and psychological outcomes after ACL reconstruction. It is uncertain whether imagery/visualization is helpful for injured athletes. [Textbox 2](#) outlines treatment approaches with the potential to improve health outcomes and the potential for inclusion in a new psychological support intervention.

Designing and Developing Back in the Game

A psychological support intervention for helping athletes return to sport after injury should deliver practical tools or strategies

that athletes can use to complement physical rehabilitation ([Textbox 3](#)). The intervention should (1) help injured athletes understand their injury and what is required for recovery; (2) support athletes in setting realistic goals and provide regular

feedback on progress toward athletes' goals; (3) teach athletes strategies for managing fear and anxiety, boosting low confidence and self-efficacy, and maintaining motivation and athlete identity; and (4) support athletes in establishing lifelong habits and staying healthy while playing sports. We established 5 guiding principles [8] for intervention design (Textbox 4).

Back in the Game delivers cognitive behavioral therapy plus motivational interviewing to help athletes identify negative

thoughts about the behavior of playing sports and reframe negative thoughts into positive thoughts to promote behavior change (Figure 2). The rationale for the content and delivery mode is that supporting athletes in achieving psychological readiness to return to sport while they complete usual postoperative rehabilitation helps them to more successfully transition back to the preinjury sport.

Textbox 3. Evidence summary: behaviors to target with a psychological support intervention for athletes with anterior cruciate ligament reconstruction.

Behaviors to target

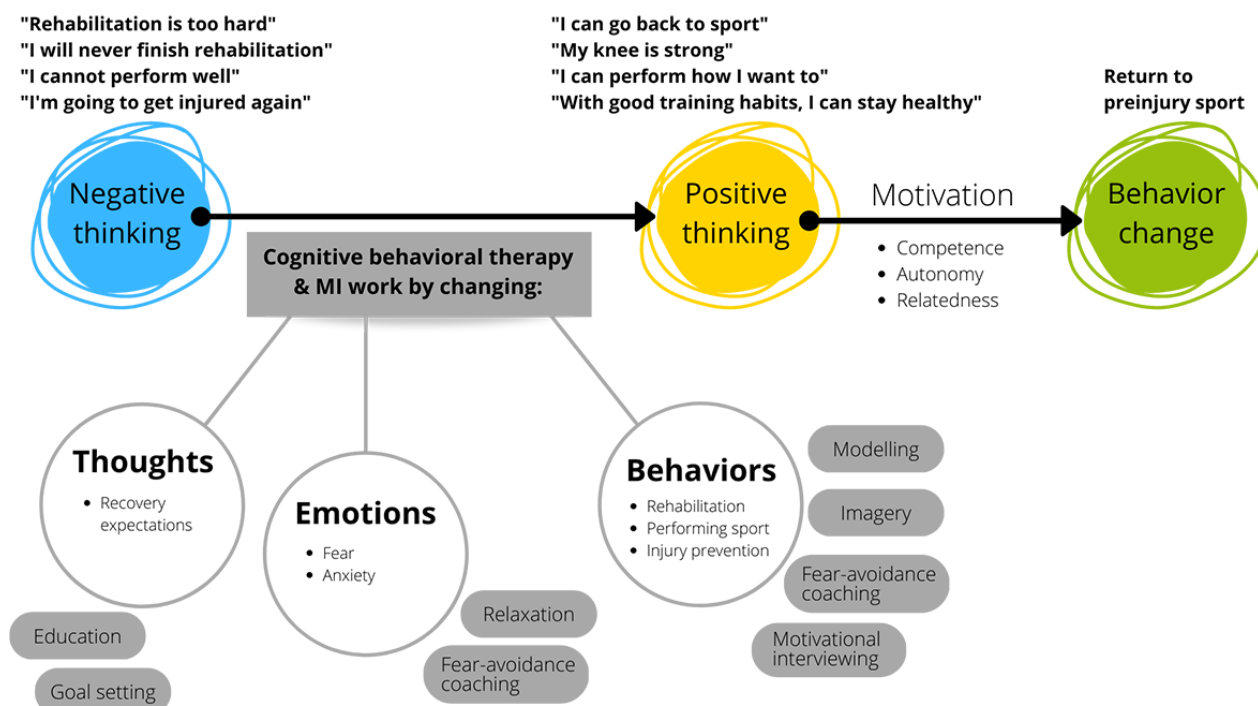

- Fear avoidance
- Setting goals
- Understanding how to recover well from injury
- Safely participating in sport
- Ongoing injury prevention
- Practicing psychological support skills (imagery/visualization, relaxation, etc)

Textbox 4. Evidence summary: guiding principles for the structure and delivery of the Back in the Game intervention.

Guiding principles

- Complement usual rehabilitation care
- Change focus as rehabilitation focus changes
- Self-guided and easy to access
- Unobtrusive and not burdensome to use
- Include a range of psychological techniques/strategies (something to meet everyone's needs)

Figure 2. Back in the Game is grounded in cognitive theory and self-determination theory and aims to facilitate return to sport behavior change. Topics that are listed in grey ovals (adjacent to "Thoughts," "Emotions, and "Behaviors") are the key contents of the intervention modules. MI: motivational interviewing.

Back in the Game is a 24-week intervention that commences in the first week following ACL reconstruction. A total of 7 modules (Figure 3) are delivered in parallel with usual rehabilitation care. The intervention mirrors the progression of rehabilitation, functions as a stand-alone eHealth intervention, and does not require monitoring or input from the clinician responsible for delivering rehabilitation. Tasks are delivered in a progressive fashion (ie, users receive a notification to log in and take action in the app every time there is new content available and up to two reminders to access the content each week) and are tailored to the stage of face-to-face rehabilitation.

Athletes choose, from a menu of different tasks, the task that best suits their needs during each intervention session.

The motivational interviewing delivered in Back in the Game focuses on athletes' confidence for recovering from their knee injury, returning to sport, returning to performance, and staying injury-free (Figure 4). Linked to each motivational interviewing question are strategies for building athletes' psychological skills in relaxation, mental imagery, education, and goal setting (Figure 4). The modules *Handling thoughts & emotions* and *Injury education* comprise tailored content that athletes can watch, read, and listen to (Figure 5).

Figure 3. Summary of the seven self-directed modules (covering psychological skills, psychoeducation, and principles of motivational interviewing) of the Back in the Game intervention. Each dot represents how often the user is prompted to complete a task in each module.

Figure 4. Overview of the "Recovery," "Return to sport," "Return to performance," and "Staying injury-free" modules plus linked cognitive behavioral therapy tasks (strategies). This screenshot is presented in the content overview video that accompanies the app introduction, which users receive when they register.

 **Building self-confidence**

Question: how confident are you about:

 Recovery?	 Return to sport?
 Return to performance?	 Staying injury-free?

Choose a strategy:

-   Relaxation
-  Mental training
-  Listen to other athletes
-  Set some goals

Figure 5. Overview of the "Handling thoughts & emotions" and "Injury education" modules. This screenshot is presented in the content overview video that accompanies the app introduction, which users receive when they register.

Feasibility and Usability Study

We worked with the content delivery platform vendor (Briteback AB, Norrköping, Sweden) to complete additional engineering tasks and implement bug fixes in response to the feedback we received in phase 1. Table S1 in [Multimedia Appendix 3](#) details the specific bugs and bug fixes. In phase 2, we identified aspects of the intervention that were satisfactory and did not require changes (Table S4 in [Multimedia Appendix 3](#)) and aspects that required specific changes/actions (Table S5 in [Multimedia Appendix 3](#)).

Users (1) thought that the intervention would add value to their physical rehabilitation, (2) found appealing content with appropriate flow, (3) appreciated receiving notifications and reminders to engage with the intervention, and (4) said that the goal-setting module was helpful. Users (1) wanted more support for starting the intervention, (2) wanted to better understand

what they had to do, and when and why they had to do certain tasks, and (3) wanted more feedback on their progress through the intervention. In response to the feasibility testing results, we added additional video and infographic content and strengthened the system for providing tailored progress reports and feedback.

Discussion

Principal Findings

Back in the Game employs a mix of psychological skills, psychoeducation, and motivational interviewing. Our blended approach to developing the intervention ensured that the content choices were informed by the prominent emotions that athletes said they felt (confidence and fear), the strategies that were tested in previous research (goal setting, imagery, relaxation, and behavior modeling), and what athletes said they needed

(support for setting goals, managing pain and injury risk, understanding their injury and what was required for physical and mental recovery, and receiving feedback on their recovery progress). A person-based approach [8] informed the decisions we made about the intervention content, format, and delivery mode (designing the intervention). This approach allows designers to understand what to do to design an attractive intervention that (1) addresses end users' needs and (2) is feasible to implement [8].

Internet-delivered psychological support works best when users feel engaged in their mental health support in real time, when the intervention employs a user-friendly interface that prioritizes multimedia, and when the intervention structure encourages users to engage in self-monitoring [37]. We embraced the recommendations for designing mental eHealth interventions and established key design principles for guiding our work.

We recommend that athletes use the Back in the Game intervention for a minimum of 30 minutes every week. It is rare for athletes to return to a pivoting sport before 6 postoperative months, and athletes are actively encouraged to delay returning to unrestricted participation in a pivoting sport for at least 9 months [16]. The intervention is designed to help athletes prepare for the return to sport; we do not expect athletes to return to their preinjury sport during the 24-week intervention period. However, we expect that some athletes will participate in a modified sport (eg, no contact and no direction changes) by the end of the intervention period.

People's beliefs, perceptions, plans, and interpretations influence their behaviors and emotions and determine how the world influences them [38,39]. Cognitive theory underpins cognitive behavioral therapy. The aim of cognitive behavioral therapy is to transform negative thoughts/thinking into positive thoughts/thinking by changing a person's thoughts, emotions, and behaviors. Cognitive behavioral therapy targets a person's interpretations and beliefs. Uncovering and changing negative thinking patterns boosts a person's self-motivation to engage in a health-promoting behavior [38]. This is the central theory underpinning the Back in the Game content. Based on the combination of cognitive theory and self-determination theory [40], we propose that when one has positive thoughts about a behavior, the motivation to engage in this behavior is enhanced, ultimately boosting the likelihood of engaging in and sustaining the behavior.

We recognized that motivation was highlighted in athletes' lived experiences of recovering from ACL reconstruction, and we incorporated self-determination theory into our framework for Back in the Game. The motivation to change one's behavior is strongest when one feels that the behavior is self-determined [40]. For the return to sport, an athlete's self-motivation to engage in a sport (ie, fulfilling return to sport goals) is driven by the following three key elements: a sense of personal control over what happens (autonomy), a belief that one has the skills and knowledge to succeed (competence), and support for achieving one's goals (relatedness) [40].

Real-world Issues

Back in the Game is a self-directed psychological support intervention that was designed to be available on-demand and be delivered via the internet (smartphone app or website). An intervention that complements physical (face-to-face) rehabilitation might be an effective tool for overcoming potential barriers to delivering effective psychological support to athletes during and after rehabilitation [37,41]. We speculate that geography, cost, and stigma are barriers that might prevent athletes from accessing the psychological support that they need to return to sport after injury. An eHealth intervention can deliver content to athletes, regardless of where they live or train, at low (or no) financial cost to the athletes, and the athletes do not need to disclose to anyone that they are accessing the psychological support content provided by an eHealth app.

For at least 2 decades, clinicians and health researchers have developed and delivered psychological treatments via the internet [42]. Digital interventions can be as effective as in-person visits to a psychologist, can deliver sustained benefits, and are probably cost-effective [43]. Using digital interventions to complement face-to-face sports injury rehabilitation is an area of growing research interest [44-46]. eHealth technology facilitates the low-cost, on-demand delivery of psychological support to injured athletes [41-43]. Smartphones are an accessible platform [47] that can be used to deliver evidence-based strategies for improving the confidence to return to sport that athletes can access anywhere at any time.

Conclusion

We describe a multifaceted approach to developing a complex eHealth intervention that considers an athlete's lived experience and context, previous work in the field, a theoretical rationale for the intervention, and input from end users to ensure an appropriate and acceptable final product.

The Back in the Game intervention is a 24-week, internet-delivered program that covers psychological skills, psychoeducation, and principles of motivational interviewing. The self-guided intervention complements usual rehabilitation, changes focus as rehabilitation progresses, is easy to access and use, and includes different psychological support strategies. End users suggested that the Back in the Game intervention met our objective of developing a psychological support intervention that was easy to access, focused on the return to sport, and complemented usual postoperative rehabilitation (ie, the intervention was appropriate and acceptable for the target population). End users had a generally positive attitude toward the intervention.

The results from the feasibility and usability testing phase confirmed that Back in the Game is an intervention that is worth testing in a definitive randomized controlled trial. The Back in the Game trial [48] commenced recruitment in 2019, and it aims to recruit 220 young athletes with ACL injury to test the effects of the Back in the Game intervention on the return to preinjury sport and level after ACL reconstruction.

Acknowledgments

We thank Professor Nicholas Taylor, who contributed to project planning, which included designing feasibility studies and planning the efficacy trial, and Professor Julian Feller, who helped secure funding to support content design and production. We also thank David Brohede, Linnéa Helfrich, Anna Wretman, and Dr Björn Paxling for their help during content design and production and David Brohede and Anna Wretman for conducting the feasibility study interviews. Dr Johan Åberg and the Briteback team provided technical support for the content delivery platform.

This project received financial support from the Swedish Research Council (grant 2015-03687), Swedish Research Council for Sport Science (grants 18-2016, D2018-0041, P2018-0180, and P2019-0174), Östergötland County (grant LIO-729161), Australian National Health & Medical Research Council (grant GNT1109779), and American Orthopaedic Society for Sports Medicine (grant SKG2015-1). The funding agencies did not and will not have any role in developing and designing the intervention; collecting, analyzing, and interpreting the data; or writing and approving the manuscript.

Authors' Contributions

CLA is the principal investigator and project leader. CLA was responsible for funds acquisition; intervention design, development, and production; database searching; article selection; data extraction and synthesis; the feasibility and usability study design; intervention administration; data collection, analysis, and synthesis; and the drafting, revision, and submission of the manuscript. NH was responsible for database searching, article selection, data extraction, data synthesis, and the review of the manuscript. PO and KEW were responsible for funds acquisition, project planning, intervention design and development, and the review of the manuscript. JK is the coprincipal investigator. JK was responsible for funds acquisition, project planning, intervention design and development, qualitative data extraction, the feasibility and usability study design, data synthesis, data storage, and the review of the manuscript. All authors read and approved the final version of the manuscript.

Abstract

Background: The Cognitive Behavioral Analysis System of Psychotherapy (CBASP) is an empirically supported psychotherapeutic treatment developed specifically for persistent depressive disorder. However, given the high rates of nonresponse and relapse, there is a need for optimization. Studies suggest that outcomes can be improved by increasing the treatment dose via, for example, the continuous web-based application of therapy strategies between sessions. The strong emphasis in CBASP on the therapeutic relationship, combined with limited therapeutic availabilities, encourages the addition of web-based interventions to face-to-face therapy in terms of blended therapy.

Objective: The aim of this study was to test an app-based intervention called *CBASPath*, which was designed to be used as a blended therapy tool. *CBASPath* offers 8 sequential modules with app-based exercises to facilitate additional engagement with the therapy content and a separate exercise to conduct situational analyses within the app at any time.

Methods: *CBASPath* was tested in an open pilot study as part of routine outpatient CBASP treatment. Participating patients were asked to report their use patterns and blended use (integrated use of the app as part of therapy sessions) at 3 assessment points over the 6-month test period and rate the usability and quality of and their satisfaction with *CBASPath*.

Results: The results of the pilot trial showed that 93% (12/13) of participants used *CBASPath* as a blended tool during their therapy and maintained this throughout the study period. Overall, they reported good usability and quality ratings along with high user satisfaction. All participants showed favorable engagement with *CBASPath*; however, the frequency of use differed widely among the participants and assessment points. Situational analysis was used by all participants, and the number of completed modules ranged from 1 to 7. All participants reported blended use, although the frequency of integration in the face-to-face sessions varied widely.

Conclusions: Our findings suggest that the digital augmentation of complex and highly interactive CBASP therapy in the form of blended therapy with *CBASPath* is feasible in routine outpatient care. Therapeutic guidance might contribute to high adherence and increase patient self-management. A few adjustments, such as saving entries directly in the app, could facilitate higher user engagement. A randomized controlled trial is now needed to investigate the efficacy and added value of this blended approach. In the long term, *CBASPath* could help optimize persistent depressive disorder treatment and reduce relapse by intensifying therapy and providing long-term patient support through the app.

Introduction

Background

Up to 30% of all depressive disorders take a chronic course [1,2]. Persistent depressive disorder (PDD) is, compared with nonchronic major depressive disorder, associated with an earlier onset, a longer duration of the disorder, higher comorbidity rates of axis 1 and axis 2 psychiatric disorders, higher rates of suicidal behavior, alexithymia [3], and more childhood maltreatment [4]. Not surprisingly, treatment outcomes—both pharmacological and psychotherapeutic—are poorer, and recurrences are higher [5], often resulting in a higher frequency of treatment seeking [3]. Specific challenges in the treatment of PDD include impaired interpersonal functioning (ie, a more submissive and hostile interpersonal style), behavioral and emotional avoidance, pronounced help and hopelessness, rigid behavioral patterns, and high personal distress [3,6,7].

The *Cognitive Behavioral Analysis System of Psychotherapy* (CBASP), originally developed by McCullough [8], is, to date, the only psychotherapeutic approach that specifically targets PDD. CBASP integrates cognitive behavioral therapy (CBT) with interpersonal and psychodynamic theories and strategies [9]. The central element of treatment [10] is CBASP-specific *situational analysis*, a highly structured, multi-step interpersonal problem-solving task through which patients learn that their behavior has consequences and how to relate functionally to others. Situational analysis includes behavioral training in the form of role-playing, and the Kiesler interpersonal circumplex model [11] is used as a supplemental interpersonal strategy. At the start of therapy, formative early learning experiences are collected by creating a list of *significant others' histories*. The significant others history is then related to current interpersonal problems, initially within the therapeutic relationship. To achieve this, therapists strive for a therapeutic alliance described by *disciplined personal involvement*. Therapists regularly reveal their own feelings and reactions to patients' behavior and thus provide the foundation for corrective, healing interpersonal experiences within the therapy setting. Differences between the therapists' responses and negative experiences with significant others of the patients are emphasized using the *interpersonal discrimination exercise* (IDE).

CBASP as an outpatient treatment is an empirically supported treatment [12-15]. It has been shown to be particularly beneficial for patients with early onset [12], childhood maltreatment [16,17], and in combination with medication [14]. CBASP has also been shown to be effective in inpatient settings in open pilot studies [18-20]. However, high rates of nonresponse (40%-60%), nonremission (60%-80%), and relapse (up to 50% after 2 years) indicate the need for optimization [13,15,18,21].

Studies have shown that (1) a larger number of therapy sessions (at least 18 sessions [22]); (2) a longer treatment duration [15,22,23]; and (3) an intensification of CBASP in the sense of a dose increase through, for example, additional group therapy

or another additional therapy program [18,20] might improve therapy outcomes.

Psychotherapy resources are limited, and as CBASP requires special training, few therapists offer this treatment in routine care. Increasing CBASP therapy sessions for patients during treatment would thus result in much longer waiting times for individuals seeking this treatment. Hence, this is neither practicable nor efficient, and solutions are needed to increase the treatment dose without increasing the number of treatment sessions. This solution could then also be useful in supporting patients to maintain their treatment gains in the long term.

Internet- and mobile-based interventions (IMIs) offer high potential for psychotherapy [24]. Desktop-based IMIs have been proven to be effective and cost-efficient in delivering mental health care in numerous trials [25-27]. Guided interventions are associated with better adherence and outcomes than unguided ones [27-30]. Smartphone- or app-based IMIs have been less researched but promise to yield small to moderate effects in the treatment of depression ($g=0.33$ and $g=0.56$ [31,32]).

Research findings suggest that IMIs may also improve face-to-face therapy. In *blended therapy*, face-to-face therapy is augmented with IMIs [33]. This option of increasing the effectiveness of conventional therapy has been shown to be feasible [33-36]. The superiority of blended therapy compared with standard psychotherapy has been shown in 2 studies for mild to moderate depression, also at the 6-month follow-up [36,37]. A web-based self-management program, in combination with care as usual, also showed promising results for recurrent depression [38]. A plausible explanation for this large effect may simply be that the treatment dose was increased by adding the IMI. Another explanation could be that the more specific effect of self-directed, between-session practice and application of therapy skills in daily life contributed a significant additional benefit to an already effective therapy [39].

When conceptualizing IMIs within CBASP, the highly structured nature of the treatment and the high relevance of the therapeutic relationship but the simultaneous limitation of therapeutic availabilities suggest a blended approach to meet the needs of PDD patients. Interpersonal strategies for shaping the therapeutic relationship and behavioral training can still be applied in face-to-face sessions, whereas an IMI could support patients to elaborate and continuously apply learned CBASP strategies (eg, situational analysis) in everyday life, thus increasing the therapy dose. A total of 2 case reports of internet-based situational analysis training after CBASP inpatient treatment indicated good acceptability and feasibility [40]. Both individuals found the training helpful in transferring therapy content to everyday life.

Objective

Building on these positive first experiences, we developed an app-based intervention called *CBASPath* to be used as part of a blended CBASP therapy. The aim of this paper is to introduce

the features of *CBASPath*, describe the blended approach, and present the results of a pilot study investigating the feasibility of *CBASPath* use in routine clinical care. We examine the participants' engagement with *CBASPath*, which was blended with face-to-face sessions. Usability, app quality, and user satisfaction are important factors influencing continuous use [41]. Therefore, an additional open research question targeted participants' perceived usability, quality ratings, and satisfaction. Depression severity was observed in an exploratory manner.

Methods

Overview

To examine the feasibility of the blended *CBASPath* intervention, a single-arm, open pilot study was conducted in a routine care setting. Data were collected over a 6-month period at 4 assessment points.

Ethics Approval

The ethics committee of the Philipps University of Marburg granted ethical approval for all study procedures (file number 2019-29k).

Procedures

CBASP-certified practitioners in Germany were invited by mail to integrate *CBASPath* in their ongoing CBASP treatments in the context of the pilot study. Interested therapists received information about *CBASPath* and were instructed on how to give their patients access to it. Participants were given a link to a web-based survey [42]. Before the start of the first survey, participants were informed about study participation and app use and signed an informed consent form. Invitations for subsequent assessments were sent via email. Data were collected pseudonymously using self-generated codes to allocate assessment points. Demographic variables, self-reported diagnoses, depression severity, and prior experience with psychotherapy, as well as information on participants' current therapy and participants' attitudes toward IMIs, were assessed at baseline. Participants' engagement in *CBASPath* and depression severity were assessed 6, 12, and 24 weeks after initial use. Usability, app quality, and satisfaction with the app were assessed at week 12. A raffle of web-based vouchers for participants who took part in all the surveys served as an incentive. Manuals for therapists and patients provided suggestions for incorporating the app into the therapy. Telephone consultations for therapists were offered as needed, primarily related to study procedures and technical difficulties.

Participants

German-speaking patients who were aged at least 18 years and who were currently undergoing outpatient CBASP therapy (regardless of the stage of therapy) were eligible to participate. Additional inclusion criteria were the possession of a smartphone with internet access (Android or iOS operating system) and sufficient skills to use it, a valid email address, and willingness to take part in the web-based survey.

The *CBASPath* Intervention and Its Use in Blended CBASP Therapy

CBASPath is a CBASP-specific mobile app course integrated into the *MindDoc* app (MindDoc Health GmbH). *MindDoc* is a certified class 1 medical device that includes an adaptive monitoring system, automated feedback about the user's mental health, and courses and exercises facilitating the self-management of mental health complaints.

For the study, a designated setup of the *MindDoc* app was created, including the *CBASPath* material and additional content depending on the individual symptoms (psychoeducation about depression, mindfulness, relaxation, rumination, self-compassion, and sleep). All content could be used at the user's discretion.

The *CBASPath* material was developed specifically for this study and was accessible only to the study participants. All contents were based on the McCullough [8] concept for outpatient CBASP therapy, related treatment manuals [43,44], and a self-help book for patients with PDD [45]. We also included both CBASP practitioners and patients in the development process.

We strived to make all content as app-friendly as possible; for example, by keeping reading times short, avoiding unnecessary typing, and using interactive features. *CBASPath* includes 8 sequential modules in line with CBASP therapy and an additional module comprising 4 different step-by-step exercises for conducting personal situational analysis (interpersonal, future, and internal focus) and IDE at any time (for a detailed description, see Table 1 and sample screenshots in Figure 1). Minor adjustments to the original situational analysis and IDE exercises were made to simplify their use on the smartphone (eg, describing the situation using a meaningful heading and using multiple-choice answer options where possible).

The *CBASPath* intervention serves as an augmentation to face-to-face CBASP therapy. Although the course is primarily designed for patients to use on their own between sessions, individual exercises are closely intertwined with the content of CBASP therapy. Patients are repeatedly encouraged to discuss difficulties, success, and results of exercises with their therapist in sessions, or therapy content are followed up with the help of specific exercises (eg, on transference hypothesis). The extent to which *CBASPath* is embedded into therapy sessions can be adapted according to individual needs and the therapy stage. Intensive therapeutic guidance at the beginning in the form of a detailed introduction, specific time for questions or doubts, and concrete suggestions for suitable exercises to work on between sessions might motivate patients and prevent early attrition. Although all 8 modules are designed to be completed between sessions without therapeutic help, not reviewing completed exercises, as with analog homework, could be demotivating and have a negative impact on future use [46]. Blended use might provide additional opportunities for disciplined personal involvement, IDE, and eventually corrective relationship experiences (eg, recognition through the promotion of completed exercises and dealing with problems and doubt). Over the course of therapy, *CBASPath* should become an integral part of therapy, and therapeutic guidance can be

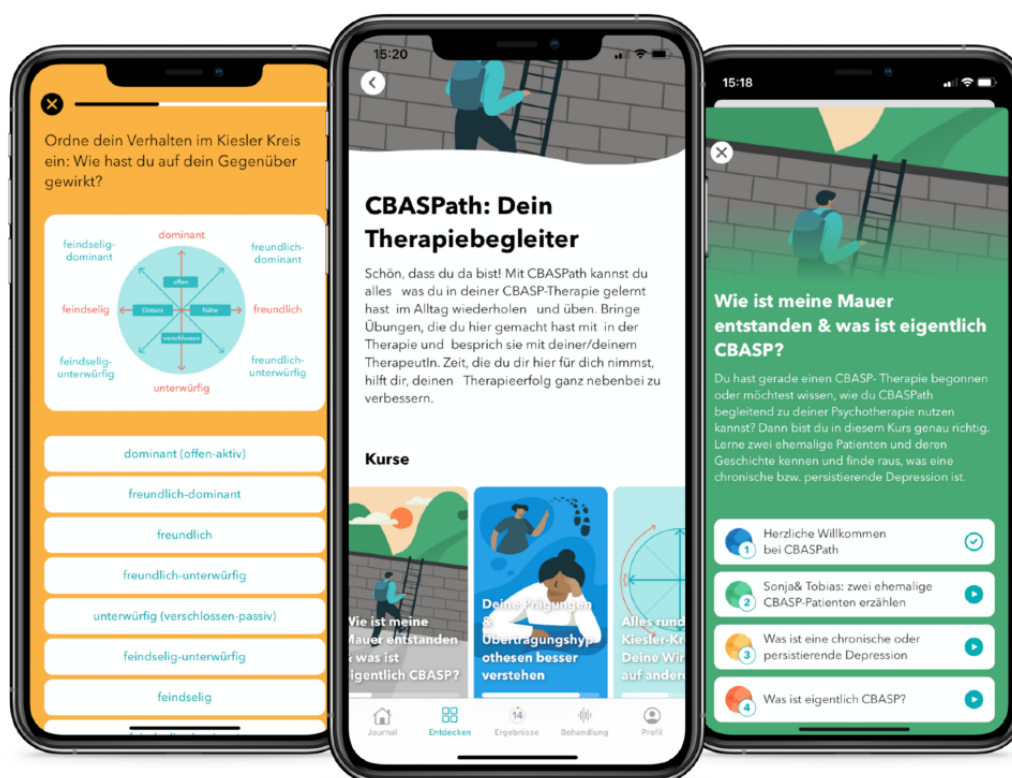

gradually faded out. After the therapy is completed, *CBASPath* can serve as a self-help tool to maintain therapeutic gains and prevent relapse. Ideally, the course is now a daily companion for the patient, which they can fall back on as needed and thus continue to incorporate CBASP skills into everyday life.

Table 1. Comparison of Cognitive Behavioral Analysis System of Psychotherapy (CBASP) components and their representation within *CBASPath*.

CBASP therapy components (disciplined personal involvement)	CBASPath content
Therapy start	<ul style="list-style-type: none"> Module 1: Information on the blended use of <i>CBASPath</i>; psychoeducation on persistent depressive disorder and CBASP; written and audio-based introduction of 2 prototype patients
Significant others history and transference hypotheses	<ul style="list-style-type: none"> Module 2: Psychoeducation on significant others history and transference hypotheses including examples of prototype patients; reflecting and journaling of personal significant others history and transference hypotheses developed in therapy
Kiesler circumplex model	<ul style="list-style-type: none"> Module 3: Psychoeducation; solidifying knowledge with interactive exercises (eg, experiencing different dimensions of the model through short videos or becoming familiar with the model by positioning celebrities in the model); hands-on exercise with reflection (eg, to try out different and unfamiliar behaviors in everyday life and to record the reaction of others in the app)
Situational analysis and training of interpersonal skills	<ul style="list-style-type: none"> Module 4: Psychoeducation on situational analysis; step-by-step training based on a prototype patient's situation presented via video and subsequent sample solutions. Module 6: Video-based empathy training; hands-on empathy exercise with reflection Situational analysis exercises: conducting personal situation analysis (3 different types of situation analysis with interpersonal, future, and internal focus)
IDE ^a	<ul style="list-style-type: none"> Module 5: Psychoeducation on IDE and "hot spot" situations; IDE training based on a prototype patient's situation and subsequent sample solutions; reflecting and journaling of personal hot spots. IDE exercise: conducting personal IDEs
Therapy completion	<ul style="list-style-type: none"> Module 7 and 8: Summarizing (and celebrating!) personal therapy successes; reflecting on helpful therapy skills as part of relapse prevention; planning further use of app as long-term support and maintenance

Measures

Participants' engagement in the *CBASPath* was measured using self-report items at weeks 6, 12, and 24. Participants specified their average duration per app use in minutes, frequency of use per week, whether they conducted situational analysis and IDE, and how often *CBASPath* was used during face-to-face sessions as an additional therapy tool or for prediscussion and follow-up discussion of completed content, all regarding the last measurement time. The usability of the *CBASPath* course was measured using the System Usability Scale (SUS) [47]. The scale, which has high validity and economy, was adapted to the app context for the purpose of this study, as recommended by the author [47]. Participants' global satisfaction with the blended use of *CBASPath* was assessed using the Client Satisfaction Questionnaire adapted for internet-based Interventions (CSQ-I) [41]. Good construct validity and high internal consistency have been demonstrated [41]. The Mobile App Rating Scale [48] is the most frequently used scale for evaluating the quality and content of mental health apps. The German translation of the user version of Mobile App Rating Scale (uMARS) [49] used in this study includes 4 objective subscales (engagement, functionality, aesthetics, and information quality) and one subjective quality scale. The uMARS has good internal consistency and test-retest reliability [49]. In addition, the 16-item Attitudes toward Psychological Online Interventions Questionnaire (APOI) [50], was used to assess the participants' general attitudes toward IMIs, including a total score and 4 subscales (skepticism and perception of risk, confidence in effectiveness, technologization threat, and anonymity benefits), with higher scores indicating a more positive attitude.

Depression severity was assessed using the Beck Depression Inventory–Second Edition [51].

Statistical Analysis

Owing to the small sample size, all data collected are presented and compared at the individual case level. Mean values and SDs were calculated for the expectations toward web-based interventions, usability and quality ratings, and user satisfaction. Analyses were performed using IBM SPSS Statistics (version 27.0; IBM Corporation) for Windows. Owing to the small sample size and the fact that data on use intensity varied greatly, participants' engagement in *CBASPath* use was categorized into high, medium, and low use. High use was rated as at least twice weekly app use with a duration of at least 15 minutes of situational analysis use and at least five completed modules. Medium use was rated as once or twice a week with at least 5 minutes of situational analysis use and at least one completed module. Below this level of use was classified as low. Individual values on depression severity were visualized in a scatter plot.

Results

Participants

A total of 18 participants registered for the pilot study at baseline, of whom 5 (28%) did not participate in any further measurement time point and were therefore handled as dropouts. Another participant was excluded from data analysis as he could not download the study version of the app and could therefore not use *CBASPath*. The final study sample included 12 participants, and the final survey in week 24 was completed by 11 (92%) participants. Table 2 summarizes the baseline

sociodemographic and clinical characteristics of all participants. The sample was heterogeneous in terms of age, gender, and level of education. All patients reported depressive disorder as the treatment diagnosis. Of the 12 participants, 9 (75%) reported at least one completed psychotherapeutic treatment. All participants were in different stages of outpatient CBASP therapy when they began using the app; 50% (6/12) received CBASP group therapy, and 67% (8/12) had been in ongoing therapy for more than a year. Of the 12 participants, 10 (83%) perceived their current treatment as helpful, and 2 (17%) were

unsure. At the end of the study period after 24 weeks, of the remaining 11 participants, 3 (27%) reported having completed their outpatient treatment, and the rest were still in treatment. None of the participants reported a self-help experience with IMIs; 33% (4/12) reported a self-help experience with books. Participants' general attitudes toward IMIs can be considered positive with an average APOI total score of 48.33 (SD 3.82, range 41.00-56.00). Participants' individual APOI total scores and subscale scores are listed in [Multimedia Appendix 1](#).

General Usability, Quality Ratings, and User Satisfaction of the CBASPath Course

CBASPath's overall usability was rated with a mean total SUS score of 85.21 (SD 10.74, range 57.50-97.50) on a 100-point scale. Of the 12 participants, 8 (67%) rated *CBASPath*'s usability as excellent (SUS ≥ 85.5), 3 (25%) as good (SUS ≥ 71.4), and 1 (8%) participant rated the usability as *ok* (SUS ≥ 50.9) [52]. Participants' average satisfaction with the *CBASPath* resulted in a mean CSQ-I score of 28.00 (SD 2.26, range 24-31) out of 32 scale points, indicating high user satisfaction [41]. Users' quality ratings of *CBASPath* resulted in an average uMARS total score of 3.99 (SD 0.30, range 3.51-4.56; 1=poor to 5=excellent), indicating good quality. Approximately equally high scores were found for the subscales *function* (mean 4.10, SD 0.55, range 3.00-5.00), *aesthetics* (mean 4.03, SD 0.30, range 3.33-4.33), and *information quality* (mean 4.04, SD 0.32, range 3.50-4.50). The engagement subscale was rated at 3.80 (SD 0.50, range 3.00-4.60), and subjective app quality was 3.67 (SD 0.29, range 3.00-4.00). The individual SUS, CSQ-I, and uMARS ratings of all participants are presented in detail in [Multimedia Appendix 2](#).

Participants' Engagement With the App and in the Blended App Use Setting

All 12 participants reported using the *CBASPath* throughout the study period. Of the 12 participants, 9 (75%) reported using situational analysis within the first 6 weeks of use; as the study progressed, all participants reported using situational analysis.

In an open response field at the end of the survey, 25% (3/12) of participants noted that they had found the situational analysis particularly helpful (participants 5, 6, and 7). None of the participants reported IDE use at 6 weeks; 8% (1/12) stated using it at week 12 (participant 1), and 42% (5/12) reported IDE use at 24 weeks (participants 1, 4, 5, 6, and 8). Participants reported using *CBASPath* at least once a week to daily for 1 to 50 minutes at a time, with wide variation between individual participants and within measurement time points (see [Table 3](#) for variation of frequency of use during the study period). The most intensive use was reported at week 12: 75% (9/12) reported using *CBASPath* at least three times a week. They completed between 1 and 7 out of the 8 available CBASP modules. Owing to the small sample size and the fact that participants' engagement in *CBASPath* and blended use varied greatly, the individual use patterns were categorized into low to high use; of the 12 participants, high use could be found in 7 (58%) participants (participants 1, 2, 4, 5, 8, 9, and 12), medium use was shown by 5 (42%) participants (participants 3, 6, 7, 10, and 11), and none showed low use. All participants reported some form of blended use during the 24-week study period; however, the frequency of integration into therapy varied widely between individual participants. For example, 17% (2/12) of participants (participants 1 and 10) reported blended use in nearly every session, whereas others reported consistent blended use (participants 4 and 6) or less frequent involvement, totaling approximately 2 to 4 times (participants 12 and 11). Individual engagement in *CBASPath* and the blended use of all participants can be found in detail in [Table 3](#).

Table 3. Participants' *CBASPath* use categorized as medium and high adherence and reported blended use^a.

Depression Severity

Figure 2 illustrates the Beck Depression Inventory–Second Edition total scores of the 12 patients at the start of *CBASPath* use and during the course of the study. The trajectories vary considerably. Of the 12 participants, 3 (25%; participants 3, 7, and 11) had very low depression scores at the beginning of the study, which also remained at a low level during the study

period. Participant 8 showed high depression scores throughout the study period, and the depression severity of participant 6 increased after a slight improvement in the sixth week. The remaining participants (1, 2, 4, 5, and 12) showed a slight improvement in symptoms over the course of the study. Owing to pseudonymous participation, the dropout reason for participant 9 is unclear.

Figure 2. Participants' individual BDI-II scores over the course of the study period. BDI-II: Beck Depression Inventory-Second Edition; W: week.

Discussion

Principal Findings

The purpose of this study was to outline the concept and feasibility of a blended CBASP treatment in a routine care setting and investigate the usability and quality of and satisfaction with the app-based *CBASPath* course.

Our findings suggest that the digital augmentation of rather complex and highly interactive CBASP therapy in the form of blended therapy is feasible in routine outpatient care. Participants reported continuous blended use over the course of the study, good usability and quality ratings, and high user satisfaction. The positive experiences of conducting situational analysis on the web reported in another pilot study by Brakemeier et al [40] can, therefore, be extended to the app context and blended setting in this pilot study.

Usability of, Quality of, and Satisfaction With *CBASPath*

The good to excellent usability ratings indicate that working with *CBASPath* content on a smartphone is feasible and that disadvantages compared with computer-based IMIs, such as the small screen and different use patterns (eg, lower rates of user engagement), could be well compensated for by an adapted design [31]. For example, the design of the exercises was adjusted to minimize typing by using a multiple-choice format instead of text entries. To assist users who are less technology savvy in getting started, all patients were provided with written instructions for using the app, suggesting possibilities for blended use and answers to frequently asked technical questions (eg, “how do I take a screenshot?”).

The quality rating underlines the high usability of *CBASPath*. The app's functionality (including performance, ease of use, navigation, and gestural design), aesthetics (layout, graphics, and visual appeal of the app), information provided via the app

(quality, quantity, visual information, and credibility of the source), and opportunities for participant engagement (entertainment, interest, customization, and target group) were unanimously rated positive, as was subjective app quality and user satisfaction. All 12 participants would continue to use *CBASPath* by themselves and would recommend it to others; however, almost all were hardly willing to pay for the app. Considering that psychotherapy is covered by health insurance in Germany, that some health apps can be prescribed by health professionals, and that participants perceived their current therapy as mainly helpful, their willingness to spend additional money might have been limited.

CBASPath was found to be helpful by most participants in dealing with their difficulties, and they would use it again if they needed help, which again underlines the high satisfaction. A benefit through the increase of self-management skills by having independent access to digital therapy content, as found in a former study on blended therapy acceptance [53], might apply to CBASP as well and foster patients' autonomy.

Participants' Engagement With *CBASPath* and Its Blended Use

Participants' medium to high engagement with *CBASPath* and the reported blended use support the feasibility and acceptance of the presented blended modification of CBASP therapy.

The patient who did not use *CBASPath* could not install the app because of an outdated operating system on his smartphone and was therefore excluded from further analysis. *CBASPath* was continuously used over a 6-month period by at least 92% (11/12) of participants. Another participant did not participate in the final survey at the end of the 6-month study period; thus, we could not specify his use at the end of the study.

The good acceptance of blended CBASP therapy among patients is further reinforced by the fact that none of the patients in this study reported previous IMI experience but nevertheless showed

sufficient user engagement, although prior experience with eHealth is associated with higher acceptance of digital applications [54]. Although the validity of the reported use data is reduced because of the small sample size and self-reported data, it supports previous findings that therapeutic guidance for IMIs can lead to high adherence and might even reduce the risk of treatment dropout [28,33,55].

It is particularly encouraging that all participants reported using the app-based situational analysis and considered it particularly helpful, as situational analysis is a central component of CBASP therapy [43,44]. Situational analyses created in the app can be reinforced by behavioral training during the session. Moreover, good situational analysis skills were associated with better treatment outcomes in a previous study [56]. The smartphone, as a daily object, seems to be a feasible device and therefore particularly promising for transferring central CBASP skills, such as situational analysis, to patients' everyday life.

The benefit of CBASP-specific modules remains unclear as their extent of use varied widely. Most participants (8/12, 67%) had completed at least half of the 8 available modules by the end of the study period. Participants were in different stages of therapy when they started using *CBASPath*, which is why some of the modules might not have suited the respective therapy stage so that they were no longer or not yet used (eg, experienced patients may already be very familiar with their significant other's history and transference hypothesis and therefore no longer need module 2). In addition, longer reading times of some exercises of up to 15 minutes might have been an additional barrier. Brief skill-based app content is related to high and long-lasting use [57], as it reflects the typical short but frequent use of smartphones. The first 2 *CBASPath* modules could be expanded by the inclusion of hands-on exercises that prioritize *getting into the action* in addition to journaling session content and psychoeducation at a minimum. Furthermore, the low blended use of the modules because of a very flexible approach on how to embed *CBASPath* into therapy may have led therapists to recommend the modules more for independent use than incorporating them into the session. For instance, the blended use of situational analysis was advised in the written information that patients and therapists received, and modules, by contrast, were designed as self-help to bridge sessions and might therefore be less integrated into sessions. It is plausible that, in some cases, only a few modules were completed, but situational analysis was still used regularly within the blended setting.

Therapists also did not receive training for blended therapy in addition to written information; the offered telephone support was used by only one of the therapists. Training for therapists could be another way of optimizing blended use and thus improving the uptake of modules [58]. It is also suggested that the effectiveness of IMIs depends on the long-term use of an app, which can be promoted through face-to-face sessions [59].

The participants' feedback on *CBASPath* revealed options for further technical improvements that could lead to higher engagement with the course material. For example, an option to save entries directly in the app for future reference (instead of taking screenshots) was mentioned by several users. The use

of voice input may have been additionally beneficial, especially for the frequently used situational analysis exercises.

Limitations

Several limitations should be considered. Data were available only for patients who used the app. Therefore, reasons for dropout or nonuse of *CBASPath* could not be assessed, and the present results could be positively biased. Considering that participants' overall attitudes toward IMIs was rather positive, there might be a selection bias, as patients with a high general acceptance of IMIs might have been interested in participating in the study and might therefore have been particularly motivated to use the app. However, none of the participants reported experiences with blended use, and participants' general attitudes toward IMIs were similar compared with a sample with mild to moderate depression (mean 48.33 compared with mean 48.3) [50]. In addition, an affinity for smartphone use was an inclusion criterion. For more patients who are skeptical or less technologically savvy, blended use could pose additional challenges.

Furthermore, the reliability and generalizability of the results were limited because of the small sample size. Results regarding engagement and adherence should be viewed with caution because of the self-reported nature of the data collected. Objective use data should be used in subsequent studies.

Finally, there was no control of how exactly *CBASPath* was embedded in face-to-face therapy; thus, the form of blended use can vary greatly between individuals. Therefore, a subsequent randomized controlled trial (RCT) should compare manualized blended therapy with *CBASPath* with therapy without app support.

Implications and Future Directions

Overall, good usability and quality ratings, high user satisfaction, and favorable adherence to user engagement and blended use are good prerequisites for further adaption, a subsequent RCT on the efficacy, and implementation of the blended CBASP therapy concept in different routine care settings such as CBASP outpatient therapy.

A recently published RCT comparing immediate and long-term effectiveness [36] found that blended therapy could have an additional positive effect on psychotherapy for depression in terms of symptom reduction, improved therapeutic processes, and higher health-related quality of life. As an increase in therapy dose and duration seems beneficial to further improve CBASP therapy [15,20,22,60], subsequent RCT studies should further investigate whether blended CBASP therapy is also beneficial and should therefore be implemented. Future studies should include long-term follow-up assessments to evaluate whether long-term stabilization of symptoms can be achieved.

The reported use patterns and concurrent blended use appeared to be contrary in some cases. For example, when comparing weeks 12 and 24, participants 2, 3, 5, 6, 7, and 12 reported an increase in blended use during face-to-face therapy, although their user engagement with the app decreased. Therefore, further research should investigate which frequency and intensity of blended use are most effective and efficacious for different

stages of CBASP therapy. On the basis of the participants' engagement in this pilot study, it should be examined whether strong therapeutic support at the beginning, as advised in the written information (eg, by planning which modules to be worked on between sessions), can improve IMI uptake and whether intensive blended use toward the end, as observed in this pilot study (especially high in participants 1, 3, 7, and 10), might foster the use of the app as a self-help maintenance treatment after therapy. Monitoring patients' symptoms could also be a useful feedback system for therapists in making clinical decisions [38] and should be investigated more in the context of blended therapy concepts.

The fact that half of the participants received CBASP group therapy indicates the feasibility of the blended treatment approach in this setting and is consistent with earlier findings of a blended CBT group therapy for depression [61]. Of 6 patients in the blended CBASP group therapy, 2 (33%) showed high use, which, in comparison with the individual setting (5/6, 83% of patients showed high use), could indicate that the blended group therapy may be less able to encourage continuous use. Given the relatively small number of CBASP therapists, blended group therapy could be especially relevant because of higher scalability.

Replacing up to two-thirds of the face-to-face contacts with IMIs use was found to be noninferior to standard CBT treatment [62]. Therefore, blended CBASP therapy might also be promising when it comes to counteracting the treatment gap by allowing therapists to treat a larger number of patients.

As CBASP is also offered in inpatient settings [20,60], blended use as part of inpatient treatment seems promising. The use of

CBASPath as a self-help tool after successful blended therapy or for bridging therapy breaks, especially after comparatively short inpatient stays, also seems useful and should be investigated in further studies.

During recruitment, we observed that only a few interested therapists were willing to test *CBASPath* with patients. Therefore, a therapist's assessment of the feasibility of blended therapy and satisfaction with *CBASPath* should be considered to prevent potential difficulties in future studies and subsequent implementation. Further acceptance-facilitating interventions (eg, informational videos) have been proven to be effective in increasing psychotherapists' acceptance of blended therapy [63] and might help attract therapists.

Conclusions

The novel treatment approach presented here could allow further optimization of an already effective CBASP treatment and provide patients with a feasible and assessable treatment program. The blended setting itself is particularly coherent with CBASP therapy, despite its highly interactional character. However, the right frequency and optimal embedding should be further investigated to combine the best of the analog and digital worlds. Randomized controlled studies are now vigorously needed to investigate the efficacy of blended CBASP therapy and the *CBASPath* tool, with a focus on long-term follow-up to examine long-term responses. If positive, *CBASPath* could help optimize CBASP treatment in the long term and reduce relapses by intensifying therapy and providing patients with PDD with long-term therapeutic support through the app.

Abstract

Background: Despite the numerous studies evaluating various rhythm control strategies for atrial fibrillation (AF), determination of the optimal strategy in a single patient is often based on trial and error, with no one-size-fits-all approach based on international guidelines/recommendations. The decision, therefore, remains personal and lends itself well to help from a clinical decision support system, specifically one guided by artificial intelligence (AI). QRhythm utilizes a 2-stage machine learning (ML) model to identify the optimal rhythm management strategy in a given patient based on a set of clinical factors, in which the model first uses supervised learning to predict the actions of an expert clinician and identifies the best strategy through reinforcement learning to obtain the best clinical outcome—a composite of symptomatic recurrence, hospitalization, and stroke.

Objective: We qualitatively evaluated a novel, AI-based, clinical decision support system (CDSS) for AF rhythm management, called QRhythm, which uses both supervised and reinforcement learning to recommend either a rate control or one of 3 types of rhythm control strategies—external cardioversion, antiarrhythmic medication, or ablation—based on individual patient characteristics.

Methods: Thirty-three clinicians, including cardiology attendings and fellows and internal medicine attendings and residents, performed an assessment of QRhythm, followed by a survey to assess relative comfort with automated CDSS in rhythm management and to examine areas for future development.

Results: The 33 providers were surveyed with training levels ranging from resident to fellow to attending. Of the characteristics of the app surveyed, safety was most important to providers, with an average importance rating of 4.7 out of 5 (SD 0.72). This priority was followed by clinical integrity (a desire for the advice provided to make clinical sense; importance rating 4.5, SD 0.9), backward interpretability (transparency in the population used to create the algorithm; importance rating 4.3, SD 0.65), transparency of the algorithm (reasoning underlying the decisions made; importance rating 4.3, SD 0.88), and provider autonomy (the ability to challenge the decisions made by the model; importance rating 3.85, SD 0.83). Providers who used the app ranked the integrity of recommendations as their highest concern with ongoing clinical use of the model, followed by efficacy of the application and patient data security. Trust in the app varied; 1 (17%) provider responded that they somewhat disagreed with the statement, “I trust the recommendations provided by the QRhythm app,” 2 (33%) providers responded with neutrality to the statement, and 3 (50%) somewhat agreed with the statement.

Conclusions: Safety of ML applications was the highest priority of the providers surveyed, and trust of such models remains varied. Widespread clinical acceptance of ML in health care is dependent on how much providers trust the algorithms. Building this trust involves ensuring transparency and interpretability of the model.

Clinical decision support system; machine learning; supervised learning; reinforcement learning; atrial fibrillation; rhythm strategy

Introduction

An estimated 2.3 million Americans harbor a diagnosis of atrial fibrillation (AF), and that number is expected to grow to 10 million by 2050 [1,2]. Reduction in mortality and morbidity in patients with AF is predominantly achieved by reducing stroke risk via anticoagulation (AC) [3]. However, AC does not contribute to treating the symptoms of AF or mitigating the long-term effects of living with AF, rather than affecting the sinus rhythm (SR), such as AF-induced cardiomyopathies [4]. Hence, a decision of rate control versus rhythm control must be made. Rate control involves increasing the ventricular filling time by decreasing the ventricular rate, whereas rhythm control involves re-establishment of the SR through some combination of external cardioversion, antiarrhythmic medications, or catheter ablation. The decision of rate versus rhythm control is one that has been studied for years. The data show us that there is no one-size-fits-all answer to this question, and the optimal strategy is highly reliant on individual characteristics and comorbidities of patients with AF [5-16]. The variability of these data and the differences in efficacy in various subsets of the population render the rhythm versus rate control decision a very individualized one and one that lends itself to the aid of clinical decision support systems (CDSSs).

CDSSs encompass a wide array of tools designed to augment and improve clinical outcomes [17]. These tools vary from broad aids such as literature databases [18], to decision trees that help with diagnosis [19-22], to risk stratification tools including the CHA₂DS₂Vasc and HEART scores, which estimate stroke risk in patients with AF and 6-week increase in adverse major cardiac events, respectively [23-28]. Although CHA₂DS₂Vasc and HAS-BLED (Hypertension, Abnormal renal/liver function, Stroke, Bleeding history or predisposition, Labile International Normalized Ratio, Elderly, Drugs/alcohol

concomitantly) [29] scores (the HAS-BLED score estimates risk of major bleeding for patients on AC) have been helpful in determining which patients with AF need AC, there is no CDSS to our knowledge that has been designed to help make the less straightforward AF decision concerning rate versus rhythm control. For more than a decade, the focus in CDSS has been on the development of computerized algorithms to aid in decision-making or development of computerized CDSSs (CCDSSs). A CCDSS harnesses the massive data pool, that is, the electronic health record (EHR), along with advanced computing to aid providers in making complex decisions. CCDSS development is an active field of research focusing on Bayesian networks (BN), machine learning (ML), and artificial neural networks (ANN), but clinical acceptance has lagged behind.

In this study, we introduce a novel ML framework used to create a CCDSS for rhythm management in patients with AF. The QRhythm application is a learning CCDSS that utilizes a 2-stage ML model to identify the optimal rhythm management strategy in a given patient on the basis of a set of clinical factors, in which the model first uses supervised learning (SL) to predict the actions of an expert clinician, and then applies reinforcement learning (RL) to identify the best strategy to obtain the best clinical outcome.

Providers are asked to input data pertaining to the patient in question, including age, duration of AF, history of heart failure, diagnosis of left atrial enlargement, resting heart rate, diagnosis of hypertension, BMI, and symptoms associated with their AF. Based on the answers to these questions, the algorithm predicts the frequency at which an expert would choose different rhythm control strategies including external cardioversion, antiarrhythmic medications, AF ablation, or rate control. Screenshots of the input and output screens of the application are provided in [Figures 1A](#) and [1B](#), respectively.

Both the SL and RL algorithms of the QRhythm application are based on linear regression models, in which the inputs are each weighted toward prediction of each of the 4 possible treatment options: rate control, external cardioversion, antiarrhythmic medication, and ablation. The SL model is trained using stochastic gradient descent, with back-propagation of the gradient of the error, which represents the difference between the predicted treatment and what is actually selected by a treating provider, adjusted by a learning rate of 0.1. The RL model uses an algorithm called Q learning, in which the model is trained in parallel for patients in whom outcome information related to hospitalizations, stroke, and symptomatic recurrence is available in follow-up. Within the Q learning framework, the reward is calculated as $-2 \times (\text{stroke}) - (\text{hospitalization}) - (\text{symptomatic recurrence})$, and is back-propagated across each treatment, after adjustment for a learning rate of 0.01. Owing to the preliminary nature of the RL algorithm, the learning rate is one order of magnitude lower than that used in the SL algorithm. Weight updates are delivered in batches of 8 patients. The QRhythm algorithm was initialized using a combination of big data mining and chart review in the University of Colorado Health system of 100 patients diagnosed with AF,

which were used to train the SL algorithm based on the action selected by the treatment provider. The QRhythm application is now being deployed in the clinical setting, where its recommendations are being used to guide rhythm strategy decisions in actual patients. Here, it can continue training of the SL algorithm and begin training the RL algorithm as additional patient information is included.

Over time, the model will use what it has learned in the SL phase as a scaffold to slowly transition from an SL algorithm to an RL one, driven by rewards and punishments based on defined outcomes of hospitalizations, symptoms, quality-of-life scores, and changes in rhythm strategies. Rather than predicting what strategy an expert is most likely to choose, the RL edition will have the ability to suggest actions that an expert may not realize as being beneficial for the patient. Therefore, the RL edition will have the capability to improve outcomes for patients with AF when compared to standard of care. This 2-staged method was utilized by the team at DeepLearning to develop a ML model with the ability to defeat world experts in the game Go [30,31].

We used the QRhythm application as a substrate to analyze the reasons underlying apprehension toward clinical acceptance of CCDSs in general.

Methods

Ethics Approval

This study was approved by the Colorado Multiple Institutional Review Board (#20-2192).

Qualitative Assessment

Residents, fellows, and attendings were first introduced to the QRhythm app via a brief written tutorial. The providers were asked to examine the app. They were encouraged to use the app in a clinical setting—that is, to help inform a rhythm/rate strategy for a real patient—but this was not required. They then were presented with a survey produced on REDCap. The survey was designed to assess how important the providers thought certain characteristics of the app were. They were asked to rate how important each category was on a scale of 1-5, with 1=unimportant, 2=slightly important, 3=moderately important, 4=important, and 5=very important. Other prompts asked the provider to report how firmly they agreed with a prompt, with 1=“strongly disagree,” 2=“somewhat disagree,” 3=“neutral,” 4=“somewhat agree,” and 5=“strongly agree.” Finally, those who used the app were asked to rank their areas of concern with using the app from 1=highest concern to 5=lowest concern. Data were collected on REDCap and exported to an Excel (Microsoft Inc) spreadsheet for further analysis.

Results

In total, 33 providers responded to the survey. Seven (21%) of them were attendings (postgraduate year>3), 2 (6%) were fellows, 21 (64%) were residents, and 3 (9%) chose not to identify their provider level. The providers were predominantly either internal medicine residents or attendings (n=27, 82%) with the remainder being either cardiology fellows or attendings (n=6, 18%). We feel that this mix of internists and cardiologists is valuable, as it importantly reflects providers involved in both early-stage (referrals—internists) and later-stage (treatment—cardiologists) management of AF.

Of the characteristics of the app surveyed, safety was most important to the providers, who reported an average importance rating of 4.7 out of 5 (SD 0.72) in response to the prompt “The model is not recommending anything unsafe or potentially harmful.” This was followed by an importance rating of 4.5 (SD 0.90) for clinical integrity corresponding to the prompt “The information the model is using to make predictions makes sense clinically,” 4.3 (SD 0.65) for backward interpretability (“I know the population in which the model was derived is the same as the one in which I am applying it,”), and 4.3 (SD 0.83) for application transparency (“I understand the reasoning with which the model made its recommendations”). Least important to the providers was provider autonomy with an average importance of 3.85 (SD 0.83) placed on the prompt “I am able to disagree with or challenge the recommendations of the model” (Figure 2).

Figure 2. Importance rated by survey respondents on a scale of 1-5, with 1=unimportant, 2=slightly important, 3=moderately important, 4=important, and 5=very important, with regard to safety, clinical integrity, backward interpretability, application transparency, and provider autonomy.

Of those who responded, 6 providers used the app at least once in the clinical setting; that is, they used the app to aid in developing rhythm control strategies for actual patients. Providers were not required to follow the specific recommendations of QRhythm, but merely to examine agreement and interpretability of the application, as formal testing toward hard clinical outcomes was beyond the scope of this pilot investigation. Apprehension concerning the use of the app clinically varied among these providers. In response to the prompt “I would feel apprehensive about using the QRhythm application,” 1 provider (17%) strongly disagreed, 2 (33%)

somewhat disagreed, 2 (33%) were neutral on the subject, and 1 (17%) somewhat agreed. Trust in the app similarly varied. To the prompt “I trust the recommendations provided by the QRhythm app,” 1 provider (17%) somewhat disagreed, 2 (33%) were neutral, and 3 (50%) somewhat agreed. For the most part, providers did not feel intimidated by the app. One provider (17%) strongly disagreed with the statement “the QRhythm application would be intimidating for me to use,” 4 (67%) somewhat disagreed with this statement and 1 (17%) was neutral. To the prompt, “Learning to use the QRhythm application would be easy for me,” 4 providers (67%) strongly

agreed, and 2 (17%) somewhat agreed. Finally, in general, providers felt that the QRhythm app would be helpful when taking care of patients with AF. To the prompt “Using the QRhythm application would enhance my effectiveness in patient care and AF management,” 1 provider (17%) strongly agreed, 3 (50%) somewhat agreed, and 2 (33%) were neutral.

These providers were also asked to rank their concerns regarding clinical use of the app from highest to least concern. Four providers (67%) ranked the clinical integrity of recommendations as their highest concern, 1 (17%) ranked ineffectiveness as their highest concern, and 1 (17%) ranked data security as their highest concern.

Discussion

Principal Findings

In this study, we examined the provider experience with a novel, AI-based CCDSS for rhythm management of AF. Providers generally found the application easy to use, though trust in the application was variable and apprehension toward its advice remains a concern. Our data show that safety of the recommendations provided by the app was most important to providers. This priority is followed closely by a desire for advice from a CCDSS to make sense clinically, for the provider to have knowledge of the population in which the algorithm was developed, and for transparency of the reasoning with which the app made its decision. Less important in the minds of the providers surveyed was the ability to challenge the decisions made by the app. Of those providers who used the app in the clinical setting, the accuracy of its recommendations ranked highest among their concerns.

Comparison With Prior Work

Although there are no existing CDSS for rhythm management of AF to our knowledge, there are numerous studies related to specific treatment approaches within the rate versus a rhythm control strategy decision for patients with AF. The AFFIRM trial, published in 2002, showed noninferiority in terms of mortality in rate-controlled patients compared to rhythm-controlled patients, with a trend toward increased mortality in the rhythm control group [5]. This trial subsequently guided rhythm control strategies away from the promise of improvement in mortality, and directed treatment toward improvement in symptoms alone. However, the paradigm for rhythm management may be shifting with the more recent data suggested by the EAST-AFNET 4 trial published in February 2021, which showed that early rhythm control (within a year of AF diagnosis) decreases stroke and cardiovascular mortality compared to a rate control strategy [6].

We surmise that declaring rate control as superior to rhythm control, or vice versa, however, is too sweeping a conclusion to make. Further evaluation of these data reveal that individual characteristics of patients with AF play a large role regarding the success or failure of a chosen strategy. Subsets of patients with AF, such as those with heart failure or left ventricular dysfunction, have been shown to have a mortality benefit from rhythm control [7]. Additionally, the severity of symptoms for patients with AF vary widely, and symptomatic patients

experience more relief with rhythm control than with rate control [8-12]. Conversely, factors such as atrial enlargement [13,14], age at onset of AF [15], and duration of AF (paroxysmal vs persistent vs permanent) [16] make rhythm control strategies more difficult to achieve. In other words, the decision about rate or rhythm control in patients is likely to be highly individualized, which raises the possibility that an automated CDSS could provide guidance with AI integration.

Within the category of rhythm control, various rhythm strategies exist including external cardioversion, various antiarrhythmic medications, and AF ablation. The EAST-AFNET 4 trial randomized patients into a rate or rhythm control strategy, but the protocol did not specify which rhythm control strategy was to be pursued. Patients either underwent AF ablation or were started on an antiarrhythmic agent with coincident external cardioversion, but the choice of antiarrhythmic agent was left to the provider [6]. In short, the variability in outcomes based on patient characteristics makes it difficult to generalize and extrapolate data from these studies. It does, however, lend itself to the aid of AI, which can quickly take all of these characteristics into account and provide recommendations accordingly.

The advent of EHR has brought a wealth of data to the fingertips of providers. However, the vastness of these data makes utilizing them time-consuming and clumsy for humans alone. With the aid of AI, CCDSSs aim to create interfaces that are easy to interact with, which condense this plethora of data into easily digestible visualizations to improve the quality of decisions made by providers. Multiple methods have been used to develop such technology, including BNs, ML, and ANNs. While BNs and ANNs are not presently used by QRhythm, these more sophisticated prediction algorithms could easily be incorporated in future versions to include additional types of data, such as electrocardiography (ECG) tracings, patient symptom reports, and clinic notes. The framework we have developed for QRhythm using stochastic gradient descent provides the opportunity for expansion to deep neural networks, for example, which could be used for image recognition or natural language processing to incorporate these additional data types.

ML can be broken down into 3 categories: unsupervised learning (UL), SL, and RL. UL is not used in QRhythm and will therefore not be discussed here.

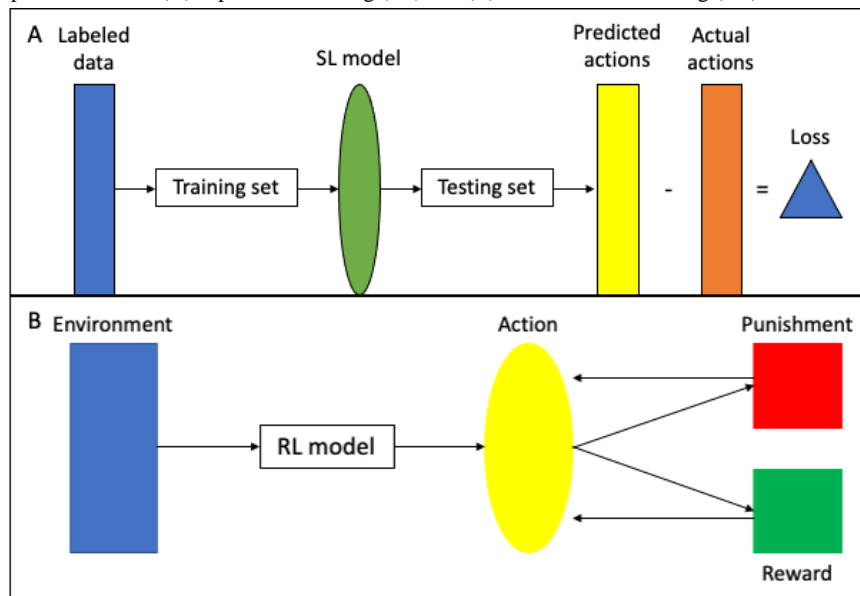

In SL, data are input to the model with associated labels; that is, data on patients who underwent a rate control strategy would be labeled as “rate control,” data for those who underwent external cardioversion would be labeled as “external cardioversion,” etc. Through application of various computer algorithms, a model is trained to recognize data associated with these labels in order to predict an outcome using a held-out “training set.” The algorithm is then applied to a second set of data known as the “testing set” or “validation set” to assess its out-of-sample generalizability and efficacy in predicting an outcome. SL comprises the initial strategy for the QRhythm application. Its learning set is a large set of charts of patients with AF. Based on these data, the model has been taught to predict the rhythm strategy most likely to be selected by an expert; for example, an electrophysiologist. SL is designed to

mimic the decisions or predictions that would be made by humans. Its efficacy is measured by the difference in the predictions made by the model compared to those made by human experts. This difference is known as the loss function. A loss of zero represents a “perfect” supervised learning model. Therefore, by definition, an SL model can only ever be as effective as the human experts against which it is compared [32-34]. SL models have been used to produce algorithms that accurately interpret ECGs [35,36]. A diagrammatic representation of SL is shown in Figure 3A.

Rather than comparing the model’s performance compared to that of a human expert as in SL, RL is driven by a system of punishments and rewards. RL is an iterative process in which

actions are made on the basis of the model’s environment. The results of each action are assessed on the basis of the outcomes of the action. Good outcomes harbor a positive value or “reward”; bad outcomes harbor a negative value or “punishment.” The model takes into account the reward or punishment that results from a certain action and uses this knowledge to inform its next action. RL models are designed to choose actions in order to maximize the reward, thus providing the best outcome possible. As the goal of RL is not merely to mimic humans, but rather to maximize outcomes, it has the potential to outperform human experts. Figure 3B shows a diagrammatic representation of an RL algorithm. An RL model has been used to aid in dosing decisions during dofetilide loading for patients with AF [37].

Figure 3. Diagrammatic representations of (A) supervised learning (SL) and (B) reinforcement learning (RL).

The advantage of ML in health care is clear; advanced computation allows for analysis of unfathomable amounts of data in infinitesimal amounts of time, which is something the most adept provider simply cannot physically achieve. More data lead to a more informed decision and, therefore, better outcomes [18,38-41]. However, the power and accuracy of ML models are irrelevant if their use is not widely adopted. AI in health care is a robust area of research, but its acceptance in everyday clinical practice lags behind. Two key obstacles standing between the development of AI for health care and its clinical use are model interpretability and trust in the technology.

Interpretability can be broken down into forward or mechanistic interpretability and backward or post hoc interpretability [42]. Forward interpretability represents the ability for a provider to walk through the input portion of the model (ie, its usability). All QRhythm users reported that using the app would be easy for them, indicating good forward interpretability. Backward interpretability represents the ability of a user to easily identify the reasoning behind the decision made by the model. Our survey respondents rated the importance of backward interpretability as 4.3 out of 5 (scale 1-5). Backward interpretability of QRhythm was less convincing; 1 (17%) user reported not understanding the reasoning underlying the decisions made by QRhythm well, 3 (50%) were neutral on the

subject, and 2 (33%) reported understanding the reasoning somewhat well.

Maybe the largest obstacle preventing clinical acceptance of AI in health care is trust. ML models require complex mathematics to be functional. As a result, the methodology underlying their decision-making is inherently murky for nonexperts in the field, leading to mistrust by those who do not understand their mechanisms. A study concerning patient apprehension toward AI in health care highlighted that one factor integral to trust in AI was safety of the recommendations made by the model [43]. These concerns were shared by our respondents who rated patient safety as the most important characteristic of the app with an importance rating of 4.7 out of 5. Asan et al [44] highlighted the importance of the transparency of a model when gaining trust. Given the black box nature of these models, achieving transparency is a difficult task. To do so, steps such as furthering education concerning ML in the health care field and providing accessible and understandable explanations of models should be taken.

Limitations

QRhythm is in the beta testing phase of operation and currently relies heavily on the SL model for recommendations owing to the need for interactive training of RL. Time and increased

deployment are needed to improve the accuracy of the recommendations of the model, and additional research is needed to identify a training environment that is safe but also provides meaningful opportunities to apply a computer algorithm in clinical care decisions. Importantly, our work has uncovered the challenges with integration of software development lifecycles, which generally proceed best in a bottom-up, just-in-time development life cycle as employed in the Agile development process, with the necessary top-down guidance from clinical studies and expert opinion. Development of a CDSS that not only provides usability but also meaningful predictions toward an improvement in clinical outcomes is the ultimate goal, and this work represents an important first step.

Conclusions

In summary, we introduced a novel ML-based model first utilizing SL and then RL to aid in the decision-making process for rhythm strategy for patients with AF. We asked providers to respond to a survey to assess apprehensions regarding the acceptance of such a model for widespread use in clinical practice. Our results show that interpretability and trust of a model are key to acceptance, and providing transparent explanations underlying model reasoning and ensuring the safety of model recommendations are key aspects to improving interpretability and trust.

Abstract

Background: The high prevalence and adverse consequences of excessive drinking among lower-educated adolescents and young adults are public concerns in the Netherlands. Evidence-based alcohol prevention programs targeting adolescents and young adults with a low educational background are sparse.

Objective: This study aimed to describe the planned process for the theory- and evidence-based development, implementation, and evaluation of a dynamically tailored mobile alcohol intervention, entitled *What Do You Drink* (WDYD), aimed at lower-educated students from secondary vocational education and training (*Middelbaar Beroepsonderwijs* in Dutch).

Methods: We used intervention mapping as the framework for the systematic development of WDYD. It consists of the following six steps: assessing needs (step 1), formulating intervention objectives (step 2), translating theoretical methods into practical applications (step 3), integrating these into a coherent program (step 4), anticipating future implementation and adoption (step 5), and developing an evaluation plan (step 6).

Results: Reducing excessive drinking among Dutch lower-educated students aged 16 to 24 years was defined as the desired behavioral outcome and subdivided into the following five program objectives: make the decision to reduce drinking, set realistic drinking goals, use effective strategies to achieve drinking goals, monitor own drinking behavior, and evaluate own drinking behavior and adjust goals. Risk awareness, motivation, social norms, and self-efficacy were identified as the most important and changeable individual determinants related to excessive drinking and, therefore, were incorporated into WDYD. Dynamic tailoring was selected as the basic intervention method for changing these determinants. A user-centered design strategy was used to enhance the fit of the intervention to the needs of students. The intervention was developed in 4 iterations, and the prototypes were subsequently tested with the students and refined. This resulted in a completely automated, standalone native app in which students received dynamically tailored feedback regarding their alcohol use and goal achievement via multiple sessions within 17 weeks based on diary data assessing their alcohol consumption, motivation, confidence, and mood. A randomized controlled trial with ecological momentary assessments will be used to examine the effects, use, and acceptability of the intervention.

Conclusions: The use of intervention mapping led to the development of an innovative, evidence-based intervention to reduce excessive alcohol consumption among lower-educated Dutch adolescents and young adults. Developing an intervention based on theory and empirical evidence enables researchers and program planners to identify and retain effective intervention elements and to translate the intervention to new populations and settings. This is important, as *black boxes*, or poorly described interventions, have long been a criticism of the eHealth field, and effective intervention elements across mobile health alcohol interventions are still largely unknown.

Introduction

Health and Behavioral Problem

Alcohol is one of the most commonly used substances among adolescents and young adults in the European Union. Nearly half (43.8%) of adolescents aged 15 to 19 years are current drinkers, and this prevalence increases (58%) among young adults aged 20 to 24 years. Among these groups, 51.1% (adolescents) and 54.5% (adults), drink alcohol excessively on at least one occasion per month [1]. Excessive drinking is defined as heavy drinking (ie, drinking more than the recommended weekly consumption) and binge drinking (ie, drinking more than the recommended amount on 1 occasion [2]). It is well established that excessive drinking has various negative consequences regarding health, social relationships, academic performance, and finishing school [1]. It increases the risk of (physical) violence, drunk driving, injuries, risky sexual behavior, episodic memory deficits, the development of alcohol use disorders [1,3], tissue damage in the body [4], and various forms of cancer [5].

Excessive Drinking

In the Netherlands, various studies have shown that adolescents and young adults engage in excessive drinking [6-8]. For instance, 66% to 70% of adolescents and young adults engage in heavy drinking [8]. In the Netherlands, heavy drinking is defined as drinking more than what is proposed in the low-risk guidelines [9], in which adolescents (aged 15-17 years) are recommended to drink no alcohol and adults are recommended to drink no alcohol or, in any case, ≤ 1 standard drink per day. In addition, 14% to 19% of young adolescents and adults engage in binge drinking [8]. This is defined as drinking more than 4 (for women) or 6 (for men) standard alcohol units on 1 occasion at least once per week [10].

Need for Alcohol Interventions Among Lower-Educated Students

From a public health perspective, there is an urgent need to develop and evaluate alcohol interventions that target lower-educated adolescents and young adults. When completing secondary education, students in the Netherlands can follow 3 levels of education: the lowest level is secondary vocational education and training (*Middelbaar Beroepsonderwijs* [MBO] in Dutch), the intermediate level is higher professional education (*Hoger Beroepsonderwijs* in Dutch), and the highest level is higher education (*Wetenschappelijk Onderwijs* in Dutch). In this study, we refer to students who follow a lower educational level as MBO students. MBO schools prepare students for the labor market or continuing education. In the academic year 2021-2022, there were 61 MBO schools in the Netherlands, with 504,300 students [11]. Regarding adolescents (students

aged 16-18 years), 21% of the students who followed a lower educational level drank >10 glasses of alcohol on a weekend day [6]. Regarding young adults, the majority of young adults who followed a lower educational level drank alcohol in the past 12 months (63.1%), 42.7% engaged in heavy drinking, and 6.5% engaged in binge drinking [8]. Most interventions are targeted at higher-educated students [12-14]; these are mostly brief interventions, these interventions have shown modest effect sizes, and use effective techniques such as motivational interviewing, personalized feedback, identification of risk situations, and goal setting. However, interventions that effectively reduce excessive drinking among lower-educated students are still lacking, and thus, effective mechanisms that can be applied in these interventions are still largely unknown [15].

This Study

This study aimed to describe the planned process for the theory- and evidence-based development, implementation, and evaluation of a dynamically tailored mobile intervention, entitled *What Do You Drink* (WDYD), targeting Dutch lower-educated adolescents and young adults who engage in excessive alcohol drinking. WDYD is based on the self-determination theory (SDT) [16] and self-regulation principles [17]. SDT states that autonomous motivation (ie, feeling that one's behavior can be chosen), competence (ie, feeling confident and competent), and relatedness (ie, feeling related to and understood by others) are key targets for behavior change [18]. Regarding self-regulation, people go through the following three phases: (1) forethought, in which they prepare for behavior change via self-motivational beliefs and goal setting; (2) performance, in which they use strategies to reach goals and monitor their behavior; and (3) self-reflection, where they evaluate used strategies and learn from success or failure [17]. The developmental process is elaborated by following the six steps of the intervention mapping (IM) protocol [19], which include assessing needs (step 1), defining performance and change objectives (step 2), defining theory- and evidence-based methods and practical applications (step 3), producing the program (step 4), defining a program implementation plan (step 5), and defining a plan for process and effect evaluation (step 6). These steps are described in detail later.

Methods

We first describe the final intervention, followed by a description of the step-by-step systematic development of the intervention.

WDYD Intervention

WDYD is a dynamically tailored mobile intervention to reduce excessive drinking among Dutch lower-educated adolescents

and young adults. WDYD is an 18-week intervention consisting of 10 sessions. It starts with a weekly session (weeks 0-5), followed by sessions every 2 weeks (weeks 7 and 9) and finally every month (weeks 13 and 17). In each session, the participants can choose from a couple of exercises that have been preselected to meet their needs, based on their activities and recordings in the app. The app consists of 39 different exercises in the form of mini-interventions and 22 brief videos in the form of role model stories. Screenshots of the intervention are provided in Figures S1-S16 in [Multimedia Appendix 1](#).

In the first session of WDYD, the program was introduced, and users gave an estimation of their weekly alcohol consumption, received normative feedback on alcohol consumption (ie, own consumption compared with the Dutch guidelines [20]), and answered a question on whether they will take the challenge of reducing their alcohol consumption (*yes or no, I am not in the mood or no, I do not want that or no, or I am not sure I can*). Those who answer *no* receive a movie and can choose 1 of 2 mini-interventions targeting mood, motivation, or self-confidence (depending on their answer) and are asked again, after the mini-intervention, whether they want to reduce their alcohol consumption; those who answer *yes* to the first or second question are asked to plan how much they would like to drink for each day of the next week, can view a movie, and can choose 1 of 2 mini-interventions targeting planning. The session ends with a date and proposed time for the next session. Users who have set a goal to reduce their drinking are informed that they will be asked to fill out a diary daily for the next week. When users chose not to reduce their alcohol consumption, a similar intervention was repeated in the following sessions. Users who did not set a goal after 3 sessions were offered the option to continue with WDYD, take a break for 3 weeks, or stop receiving invitations for sessions.

When users chose to set an alcohol reduction goal in one of the sessions, they received daily reminders to fill out a diary to monitor their alcohol consumption (which was based on alcohol consumption of the previous day), current mood, the importance of reaching their self-set goal (to assess motivation), and perceived confidence in reaching that goal (to assess self-confidence). In addition, the follow-up sessions consisted of an overview and feedback of goal progress of the past week based on the 7 preceding diaries, the option to view a movie and to choose 1 out of 2 mini-interventions tailored to their personal situation based on their diary input (ie, when participants did not meet the goal for at least two days and mood, importance, or self-confidence had a low score), and the option to adjust their goal and consequently viewing a movie and choosing 1 of 2 mini-interventions targeting planning. In addition to the sessions, users received a notification and could select 1 of the 2 mini-interventions targeting relapse prevention (when they had not reached their goal for 3 consecutive days after having reached at least five goals). When users had not reached their goal for the last 3 consecutive days and their mood was low, they received a notification and could select 1 of 2 mini-interventions targeting mood. When users reached their goal for several days, they received positive reinforcement messages, and when they did not fill out diaries for a couple of days, they received compliance-enhancement messages. These,

as well as reminders for the sessions, were offered via push notifications. In the home menu, 4 exercises were always readily available as well as 2 movies based on role modeling. For each session, participants received an invitation (at 7:30 PM or at a time chosen by participants) and 3 reminders via push notifications in case a session was not started or ended (ie, days 1, 4, and 7). The invitation for the diaries was sent via push notification at 11 AM, and a reminder was sent at 5 PM on the same day; the diary was available for 1 day, so participants were not able to fill out earlier diaries (approximately 1-minute completion time per diary).

The WDYD app consisted of 5 menus. The first menu showed participants when the next session was scheduled, the exercises they could perform, and movies they could view between sessions. The second menu showed the participants which exercises were their favorites. The third menu was the diary. The fourth menu provided an overview of alcohol intake in the week based on the diary input. Finally, the fifth menu was a profile page, in which participants could view their registration details, read a brief explanation regarding WDYD, and decide whom to contact via email in case of questions regarding the app. Screenshots of WDYD are provided in Figures S1-S16 in [Multimedia Appendix 1](#).

Systematic Development of WDYD

WDYD was systematically developed using IM [19], and a user-centered design [21] was applied, closely involving the target group in the intervention development. IM is used to provide a systematic and detailed description of the development of WDYD. The IM protocol provides a framework for the development of health promotion programs. It describes a step-by-step procedure that supports effective decision-making and the proper use of theory and empirical evidence. Each step has a different focus and approach for the use of evidence and theory [19].

IM Steps

Step 1 of IM consists of a needs assessment. In this step, the health problem, behavioral and environmental causes of this problem, and related determinants are identified. In addition, the overall intervention goals, which are the desired outcomes, are defined. These health problems and causes have already been described in the *Introduction* section, and the related determinants are described in the *Results* section (IM step 2).

In step 2, the program objective and desired behavioral outcome were defined. As part of this step, the performance objectives of the behavior were formulated, functioning as the subbehaviors that underlie the program objective and behavioral outcome. Next, the changeable determinants associated with the behavioral outcome were identified. Combining the performance objectives with the determinants resulted in change objectives. Change objectives are defined as statements of what the target population should learn to change to achieve the desired behavioral outcome.

In step 3, theory- and evidence-based methods were linked to the change objectives for the behavioral outcome. Subsequently, practical applications were selected and designed to deliver theory- and evidence-based methods. Practical applications are

specific techniques for the practical use of theory- and evidence-based methods in ways that fit the target group and the context in which the intervention will be delivered. The parameters for use under which the method would be effective were considered in the selection of practical applications.

In step 4, the practical applications of the intervention methods were translated into program production. The intervention materials were developed and produced in four iterations according to user-centered design to ensure it fits the needs of users [21]: (1) analyze user needs via design and concept testing, (2) test a web-based static prototype, (3) test a web-based working prototype, and (4) test the concept intervention. In each iteration, the MBO students were asked to provide input and feedback for the next iteration.

In step 5, a plan for adoption and implementation was defined, including a program that would influence the behavior of individuals who would make decisions regarding adopting and using the program. Finally, in step 6, the plan for the effect and process evaluation of the intervention is discussed [19].

Ethics Approval

This study was approved by the Ethical Committee of the Faculty of Social Sciences of Radboud University Nijmegen (number ECSW2016-1403-390).

Results

Behavioral Outcome, Performance Objectives, Determinants, and Change Objectives (IM Step 1)

Behavioral Outcome

The objective of the program is *to reduce excessive drinking among Dutch lower-educated students aged 16 to 24 years*. The desired behavioral outcome of the WDYD intervention was formulated as follows: *Dutch lower-educated students aged 16 to 24 years drink within the normative limits of the Dutch National Health Council for low-risk drinking* [20]. This implies zero alcohol consumption for adolescents (aged 16-17 years), and for adults (aged 18-24 years), it implies a mean alcohol consumption that will not exceed 7 (for women) or 14 (for men) glasses of standard alcohol units per week and, in case of binge drinking, ≥ 4 (for women) or ≥ 6 (for men) standard alcohol units on 1 occasion after having received the intervention [10].

Performance Objectives

As part of the systematic development approach (IM step 2 [19]), we defined the performance objectives of the behavior (subbehaviors that underlie the program objective and behavioral outcome). The intervention targets are based on self-regulation principles [17], which break down behavioral outcomes into subgoals. Performance objectives were formulated in the order of the behavior change process, including deciding to reduce alcohol consumption, setting goals, using strategies to achieve drinking goals, and monitoring and evaluating one's own alcohol drinking behavior. The performance objectives are presented in [Table 1](#).

Table 1. Matrix of the change objectives of the dynamically tailored mobile *What Do You Drink* intervention to reduce excessive alcohol drinking among lower-educated students (aged 16-24 years) in the Netherlands.

Performance objective	Determinant			
	Risk awareness	Motivation	Self-efficacy	Social norms
1. Make the decision to reduce alcohol drinking	Acknowledge the long-term and short-term risks of alcohol drinking; be aware of responsible drinking norms	Understand misconceptions regarding positive expectancies of alcohol consumption; acknowledge the advantages of drinking less at short and long term; express the importance of drinking less or responsibly	Express confidence to reduce alcohol drinking	Experience positive norms from peers to reduce alcohol drinking
2. Set realistic drinking goals	Acknowledge the urge to set realistic drinking goals; be aware of drinking norms	Feel committed to self-set goals	Express confidence in setting realistic drinking goals	Communicate regarding realistic drinking goals with peers or buddy; ask for help from peers or buddy in setting realistic drinking goals
3. Use effective strategies to achieve drinking goals	Be aware of challenging situations	Feel motivated to achieve drinking goals	Express confidence in achieving drinking goals	Communicate regarding drinking goals with friends or peers or family or buddy; resist social pressure to drink more than the self-set goals; learn from others how they effectively reduce drinking
4. Monitor own drinking behavior	Be aware of own drinking behavior	— ^a	—	—
5. Evaluate own drinking behavior and set goals				
5.1. If successful, maintain reduced alcohol drinking or adapt goal (for further reduction)	Recognize congruence and discrepancy between own drinking behavior and set goals; acknowledge the urge to maintain reduced alcohol drinking or adapt goal	Feel that reducing their goal is (socially) rewarding	Express confidence in maintaining reduced alcohol drinking or adapt goal	—
5.2. If unsuccessful (lapse), revise used strategies in reducing alcohol drinking or adapt drinking goal	Recognize congruence and discrepancy between own drinking behavior and set goals	Feel motivated to revise used strategies to reduce alcohol drinking; feel motivated to adapt drinking goal after lapse	Express confidence to deal with tempting or challenging situations; express confidence to manage negative feelings	Learn from others how they cope with lapses and revise used strategies to reduce alcohol drinking and adapt drinking goals

^aNot available (missing data; there were no change objectives made for the combination of this performance objective and determinant).

Determinants

A systematic literature search resulted in 4 changeable determinants of excessive drinking among adolescents and young adults: risk awareness, motivation, self-efficacy, and social norms. These are related to the key targets of SDT for behavior change (ie, autonomous motivation, competence, and relatedness) [16,18]. First, those who drink excessively usually underestimate their amount of drinking as well as the short- and long-term effects of excessive drinking [22-24]. According to the precaution adoption process model [25], awareness of the risk involved in performing a particular behavior is crucial in taking the first step toward behavioral change. Therefore, increasing risk awareness may be an effective mechanism for reducing alcohol consumption.

Second, intrinsic motivation is a risk factor for excessive drinking among young adults [26]. A Dutch study targeting alcohol reduction among adolescents and young adults was not

effective for lower-educated students because they were particularly unmotivated to change their behavior [27]. This was probably due to the focus on higher-educated students and those ready to reduce excessive drinking in the intervention. Increased motivation to drink alcohol also influences drinking behavior. For instance, a study showed that motivations to drink alcohol that included positive outcomes of drinking (eg, socializing and having fun) was related to more drinking [28]. Increasing intrinsic motivation to reduce drinking through an intervention that suits the needs of the target group and decreasing motivation to drink alcohol by focusing on socially evoked alcohol drinking might be effective mechanisms for behavioral change. On the basis of the SDT [16], intrinsic motivation is a key factor in the adaptive self-regulation of behavioral change. In addition, increasing intrinsic motivation to reduce drinking among adolescents and young adults who drink excessively is shown to decrease alcohol consumption

[29,30]. Therefore, increasing intrinsic motivation may be an effective mechanism for reducing alcohol consumption.

Third, self-efficacy is related to alcohol drinking [26]. Young adults with low self-efficacy to refuse alcohol drinking are more likely to engage in heavy drinking [31]. Drinking refusal self-efficacy is shown to be affected by mood [32]. A negative mood seems to contribute to a lowered drinking refusal self-efficacy, resulting in more maladaptive drinking behaviors, such as uncontrolled excessive drinking [33]. High perceived self-efficacy in refusing alcohol drinking is shown to result in less high-risk drinking behaviors [34]. In addition, drinking refusal self-efficacy is affected by self-efficacy expectations regarding dealing with social pressure. Thus, enhancing self-efficacy may be an effective mechanism for reducing alcohol consumption.

Feeling confident in dealing with social pressure leads to a decrease in alcohol consumption and binge drinking [27]. Social norms, the fourth determinant, also comes into play. Social pressure plays a role in excessive drinking among young adults [35,36], with social norms perceived by peers in particular [24,37]. Thus, not only feeling more confident in coping with social pressure but also addressing the social norms that correspond with this pressure could function as changeable factors in decreasing excessive alcohol consumption. Thus, enhancing self-efficacy may be an effective mechanism for reducing alcohol consumption.

Change Objectives

To define the change objectives, the performance objectives were combined with the determinants, resulting in specific goals that would enhance the behavior change process during the intervention (eg, *express confidence to reduce alcohol drinking*). Table 1 depicts the matrix of the performance objectives, with the change objectives specified per determinant in the WDYD intervention. Regarding risk awareness (determinant), when making the decision to drink less alcohol (performance objective 1), an example of a change objective is that one should be aware of the short- and long-term risks of alcohol drinking and of responsible drinking norms. Regarding intrinsic motivation (determinant), to set realistic drinking goals (performance objective 2), an example of a change objective is that one should feel committed to their self-set goals. Regarding self-efficacy (determinant), when using effective strategies to achieve drinking goals (performance objective 3), an example of a change objective is that one should express confidence in achieving drinking goals. Regarding social norms, when using effective strategies to achieve drinking goals (performance objective 3), an example of a change objective is that one should communicate their goals with others or learn from others how they effectively reduce drinking.

Selection of Methods and Practical Applications (IM Step 3)

Theory- and Evidence-Based Methods

Next, we selected theory- and evidence-based methods and their corresponding practical applications for the intervention (IM step 3) [19]. Multimedia Appendix 2 provides an overview of the theory- and evidence-based methods that we selected based

on the change objectives presented in Table 1. Dynamic tailoring, or just-in-time adaptive intervention (JITAI), was selected as the overarching method. It ensures not only personalization of feedback to the individual but also adaptation based on variations in time. In other words, methods can be tailored to the situation of a person based on psychological and behavioral changes over time [38,39]. Dynamic tailoring is based on the principle of timing of the right type and amount of support. This requires monitoring of the individual. Dynamic tailoring or JITAI has been more effective than nondynamic tailoring or non-JITAI [39,40]. The parameters for use under which tailoring is effective are that the intervention is tailored to determinants related to behavior change or relevance (eg, age, sex, and alcohol consumption). These were applied; the determinants are described in IM step 2, and the messages are tailored to users' age, sex, and current alcohol consumption based on input from the diaries.

We used theory- and evidence-based methods derived from self-regulation [17] theories as the broad umbrella, as these target performance objectives directly, including self-monitoring [41], behavioral feedback, and goal setting [42]. These methods have been found to be effective in reducing alcohol consumption [12,43]. Furthermore, these self-regulatory methods can cause participants to see the discrepancy between their alcohol drinking goal and behavior, leading to increased risk awareness. Other methods applied to increase awareness include normative feedback and personalized risk information [44].

To increase motivation, we used methods based on motivational interviewing and self-reward. Motivational interviewing [45] is an effective method for alcohol reduction interventions targeting adolescents and young adults [14,46]. Self-reward has not yet been properly examined as an effective method for changing behavior [47], but it has shown promising effects on promoting behavior change and maintenance of physical activity [48] and fruit consumption [49].

To improve self-efficacy in coping with difficult alcohol-related situations, we included methods such as coping planning and relapse prevention. Problem solving is associated with a reduction in excessive alcohol consumption [50], which includes coping planning and relapse prevention [51]. Self-efficacy was also increased through self-persuasion [52] and stress management [53]. Self-persuasion can reduce alcohol consumption compared with direct persuasion (ie, providing arguments) [54]. Research has shown that stress management can reduce negative emotions and alcohol consumption among students [55].

To address social norms, modeling and social support were incorporated into the intervention. Modeling [56,57] has been shown to be effective when normative information on the alcohol consumption of peers (eg, negative attitude toward excessive drinking) is given [58]. Social support [59] has not yet been properly examined as an effective method for reducing alcohol consumption. In the context of alcoholics anonymous, it has been suggested as an effective mechanism in promoting a sober lifestyle [60] and has also been shown to be an effective method in various health behavior change interventions [61].

Practical Applications

The practical application of the chosen methods as part of WDYD is presented in [Multimedia Appendix 2](#). Here, we provide examples of the practical applications and the parameters for use under which the methods are effective. First, we provide 2 examples regarding performance objective 1 (*making the decision to reduce drinking*). To increase users' awareness of possible drinking norms (change objective), targeting the determinant *risk awareness*, the method *normative feedback* will be applied keeping the parameter for use in mind, that is, the feedback needs to be individual, follow the behavior in time, and be specific [62]. In the practical application, users will receive information regarding their own alcohol consumption compared with alcohol drinking guidelines [20] (Figure S1 in [Multimedia Appendix 1](#)). To target the determinants *motivation and self-efficacy*, the method *motivational interviewing* was used by means of several practical applications in the app while maintaining the parameters for use, such as a supportive relationship with the client combined with the evocation of change talk in a manner that is collaborative, evocative, autonomy supporting, and exploring rather than confronting, educating, authoritative, and explanative [62]. The practical applications of this are a value clarification, importance and confidence rulers, identifying personal strengths, and looking forward and back. For example, to allow users to express the importance of drinking less (change objective for determinant *motivation*), the practical application *values clarification* was used to explore among users important values and to evoke change talk by examining among users how these fit with reducing their alcohol consumption. In addition, upon the interest of the user, examples of values among peers and how these values relate to reduced drinking were provided (Figures S2-S5 in [Multimedia Appendix 1](#)).

Second, 2 examples of practical applications for performance objective 2 (*set realistic drinking goals*) are described. App users chose their alcohol drinking goals based on their preferences and abilities to achieve their goals. Users were encouraged to set smart goals that were specific, measurable, achievable, relevant, and time bound. The app provided different exercises to achieve these drinking goals. To enhance expressing confidence in setting realistic drinking goals (change objective), targeting the determinant *self-efficacy*, the method *goal setting* was practically applied by asking users to set drinking goals based on their consumption during the previous week and checking whether the set goals are realistic (Figure S6 in [Multimedia Appendix 1](#)). The reference period (ie, alcohol consumption in the past week) and checking whether the set goals were realistic were included to adhere to the parameters for use of goal setting (ie, users feel committed to their goal, and goals are difficult but available within the individual skill level [62]). To stimulate communication regarding realistic drinking goals with peers or a buddy and to ask for help in setting realistic drinking goals by peers or a buddy (change objectives), targeting the determinant *social norms*, the method *mobilize social support* was chosen. The parameter for the use of mobilizing social support is, that support for behavior change is positive and includes caring, trust, openness, and acceptance, [62]. This was practically applied by stimulating users to choose

a buddy among their friends who could help them reduce alcohol consumption and to specify how they can help (Figures S7-S10 in [Multimedia Appendix 1](#)).

A total of 3 examples of practical applications with regard to performance objective 3 (*use effective strategies to achieve drinking goals*) are described. To promote resistance to social pressure to drink more than the self-set goals and learning from others how they effectively reduce drinking (change objectives), targeting *self-efficacy*, the method *modeling* was practically applied by showing videos and role model stories with tips and tricks from peers on how they reduce alcohol drinking and how they say no to alcohol, keeping in mind the parameters for use of modeling (ie, the user can identify with the model, and the model needs to be a coping model who provides their own solutions [62] (Figures S11 and S12 in [Multimedia Appendix 1](#)). To promote feeling motivated to achieve drinking goals, targeting the determinant *motivation*, the method *self-reward* was practically applied by an exercise focusing on how and when to reward yourself. The parameter for use is that self-praise or self-reward is prompted if there has been effort or progress in performing the behavior [63]. This was applied by asking users to select a behavioral achievement (eg, reaching their goal for alcohol consumption for 1 day, 3 days, or a week) and to link a reward to this achievement.

Regarding performance objective 4 (*monitor own drinking behavior*), an example of a practical application of the method *self-monitoring* to enhance awareness of one's own drinking behavior (change objective), targeting the determinants *risk awareness and motivation*, was an alcohol drinking diary, along with a mood diary. The parameters for the use of self-monitoring are that the monitoring must be of a specific behavior, that the data must be interpreted and used, and that the reward must be reinforced to users [62]. This was applied by prompting users to fill in their diary on a daily basis, specifying how many glasses of alcohol they drank yesterday and how they are feeling today. They could also indicate how important they think it is to reach their alcohol goal for that day and how much confidence they have in reaching that goal. Users received a notification for the diary at 11 AM and a reminder at 5 PM when they did not fill in their diary to promote the use of the diary. The app contained a separate page where users were able to see their diary and progress regarding their alcohol drinking goals. If users reached their drinking goals for a couple of days in a row, a positive reinforcement of progress toward goals was prompted (Figures S13 and S14 in [Multimedia Appendix 1](#)).

With regard to performance objective 5 (*evaluate own drinking behavior and set goals*), 2 examples of practical applications are provided. To promote recognition of congruence and discrepancy between own drinking behavior and set goals (change objective), targeting the determinant *risk awareness*, the method *behavioral feedback* was applied. The parameter for use is that feedback needs to be individual, follow the behavior in time, and be specific [62]. This was applied by showing the user the discrepancy between the set goals and drinking behavior in glasses per day of the past week in a graph (Figure S15 in [Multimedia Appendix 1](#)). To stimulate users expressing confidence in maintaining reduced alcohol consumption or adapting goals (change objective), targeting the

determinant *self-efficacy*, the methods *relapse prevention* and *planning coping responses* were applied. The parameter for use is that high-risk situations are identified and coping responses are practiced. This was applied with exercises focusing on learning from lapses (eg, drinking too much on 1 occasion) and how to get back on track. For example, in an exercise, users are stimulated to identify high-risk situations (ie, where, with whom, their thoughts, feelings, and consequences) and to learn coping responses (ie, helping thoughts and responses). They can also see an example of a peer who describes a high-risk situation and plans a coping response.

Program Production of WDYD (IM Step 4)

WDYD was systematically and iteratively developed in 4 phases with the active involvement of lower-educated students to examine what fits their needs (IM step 4) [19], following user-centered design principles [21]. WDYD was developed by the Research Institute for Applied Sciences (Nederlandse organisatie voor Toegepast-Natuurwetenschappelijk Onderzoek), Trimbos Institute, and Radboud University Nijmegen, and the software for WDYD was developed by Newstory. Students from 2 MBO schools participated in the iterative development of WDYD. They were recruited via a contact person at each school (ie, a teacher). The students involved in the development were diverse in terms of sex, age, and alcohol consumption. Their inputs were included in the following version and were consecutively pretested. Participants received a gift voucher as a reward for their participation in the pretests. An advisory board of relevant stakeholders (Trimbos Institute, Dutch MBO Council, MBO's Nova College and Deltion College, Dutch Foundation Testjeleefstijl, Open University Heerlen, Maastricht University, and Radboud University Nijmegen) offered recommendations for the program design, implementation, and evaluation. WDYD was developed in 4 phases and pretests. The aim of the pretests was to evaluate the preferences of the students, that is, their needs and requirements for the program and their preferred strategies with regard to layout and future use (eg, channel, frequency, and duration). After each pretest, feedback was processed in the prototype, and the prototype was further developed based on recommendations.

The first pretest of WDYD was a concept test consisting of a scenario of the program and mock-ups of possible strategies used for improving motivation, self-efficacy, mood, and planning and for preventing relapse. This concept was tested through 4 focus group interviews with students who engaged in excessive drinking (N=23 students). The mean age of the participants was 17 (range 15-21) years, 52% (12/23) were male, and they varied according to study type (social care: 6/23, 26%; car engineering: 5/23, 22%; audiovisual: 3/23, 13%; aviation and service: 3/23, 13%; legal service: 2/23, 9%; photography: 2/23, 9%; executive secretary: 1/23, 4%; and enforcement: 1/23, 4%). The concept was positively evaluated with a mean grade of 7.1 on a 10-point scale (1=very bad to 10=excellent; range 6.5-8.5). Students were positive regarding the variety of methods used and the tone of voice in that they experience an autonomous choice to reduce their drinking. They perceived the Dutch guidelines [9] (no alcohol for adolescents and maximum 1 standard drink per day for adults) as somewhat unrealistic, and most students indicated that they did not want to reduce alcohol

consumption. They experienced feelings of shame in using a program to reduce their alcohol consumption and did not feel the need to ask for help to reduce their consumption; they indicated that it is important that WDYD can be used individually and privately, and they suggested that an app may be a good solution for that. Participants indicated that privacy in the use of the program is crucial, as it accounts for the experience of freedom or autonomy of choice (with regard to the decision to reduce alcohol drinking as well as which program parts they want to use and when). Suggestions for further development were to enhance personal relevance (eg, information regarding the purpose and target group of the program, key focus on coping with challenging situations and empowerment instead of therapeutic focus, and information regarding the consequences of alcohol drinking), language (ie, avoiding therapeutic language and explaining difficult terms, such as binge drinking), guarantee privacy of use (ie, preference for the program to be used via an app and not wanting to share program content with others), and duration and frequency (ie, they wanted to spend a maximum of 15 minutes per week on the program; this may be a couple of times per week to, for example, monitor drinking; they wanted to use it until they drank less or reached their goal). This concept test resulted in a production document in which the features, functionalities, and requirements of WDYD were stated based on the students' recommendations on the first prototype.

The second pretest consisted of the evaluation of a web-based, static prototype in 5 focus group interviews, in which the prototype was evaluated individually (students could scroll through the pages via a link on their phone and write down their notes), both individually and classically (the prototype was presented via a beamer), or vice versa. These mock-ups were presented as several pages, illustrating the process of navigating through the app. The questions focused on the practical applications of the behavior change methods in the app (eg, exercises, diaries, and notifications) and the design. The sample consisted of 57% (33/58) male students, the participants' mean age was 18.4 (range 16-22) years, and they drank on average 10 glasses of alcohol per week (range 0-56 glasses). More than half of the sample (30/58, 52%) engaged in binge drinking at least once a week and drank >7 glasses of alcohol weekly (30/58, 52%). The app was evaluated with a mean grade of 7.0 on a 10-point scale (1=very bad to 10=excellent; range 4-8.5). Students were positive regarding the design, user-friendliness, and monitoring of their drinking behavior. The app was evaluated as very user intuitive: it was clear what they needed to do and how they could do it. Some of the exercises were unclear, especially the titles, pictures, or icons, and the texts were evaluated as too long. Although we explained difficult words (ie, binge drinking), students struggled to read them, so they were better avoided. In addition, participants preferred use of pictures, icons, and shortened texts. They also suggested using videos for more variety and providing them with notifications for completing the diary. They recommended reducing the amount of text, explaining some exercises more clearly, using more and better suitable pictures, and using swiping to navigate through the different pages of the exercises (instead of the next or previous page buttons). These

recommendations were processed into a third prototype of the app.

The third pretest consisted of an evaluation of a web-based working prototype of the app via an individual interview (N=3 students). Participants were asked to download the app on their phone and use it daily for a couple of days (including the weekend). After this, they were called for an evaluation. The questions were focused on unclarity, navigation, content, usability, and overall impression. A total of 67% (2/3) of the students were male, the mean age was 17.3 (range 16-18) years, they drank an average of 9 glasses of alcohol per week (range 5-12 glasses), 67% (2/3) of the students drank >7 glasses per week, and no participants engaged in binge drinking (ie, 2 of the male students drank 5 glasses per day on 2 consecutive days of the weekend). The prototype was positively evaluated with a mean grade of 7.3 on a 10-point scale (1=very bad to 10=excellent; range 6-8). The students were positive regarding the design, navigation, language, and interactive nature of the app. They were also positive regarding the ease of use and time for participation. They suggested further reducing the amount of (informative) texts and improving the visibility of the role model videos. These recommendations were processed in the fourth prototype of WDYD.

The fourth pretest consisted of an evaluation of the full product (ie, the working WDYD app) in individual interviews (N=4 students). Students used the prototype in the form of a mobile app for at least eight days so that they could have received the baseline questionnaire, 2 sessions, and notifications to fill out their diary daily. After this period, they were called for an evaluation. The interviews focused on the usability and content of the app. The mean age of the sample was 18.3 (range 17-19) years, and 50% (2/4) of the students were male. They drank on average 5.3 glasses of alcohol weekly (range 3-8), 25% (1/4) drank >7 glasses per week, and 25% (1/4) engaged in binge drinking at least once a week. The app was evaluated very positively with a mean grade of 8.2 (1=very bad to 10=excellent; range 7.8-8.5). At the start, students had somewhat low expectations of the app, but they were positively surprised: they were positive regarding informativity, design, user-friendliness (ie, ease of use and time needed to participate), language (ie, understandable), notifications (amount and type), and freedom of choice they experience within the app (eg, the option to view a video and the option to choose 1 out of 2 exercises). The number of notifications was evaluated as good, but there was room for improvement: 1 participant received the notification although they had already filled in the diary, and 2 participants received a reminder although they had already filled in the diary; this needs to be improved in the next version. The preference for the use of the weekly overview (ie, a graphical overview of their alcohol consumption of the week based on the diary input) varied; some participants evaluated it as informative, whereas others preferred the use of the diary as informative in itself and indicated that a weekly overview was not needed. The weekly overview was maintained in the diary, and users could decide for themselves whether to use this overview. The feedback was perceived as somewhat brief, but this was not changed because they only experienced 2 out of the 10 sessions, and during the

preceding pretests, the amount of feedback was perceived as too much.

Suggestions for improvements were processed into the final version of WDYD, which was used for the randomized controlled trial.

Implementation Plan of WDYD (IM Step 5)

To ensure successful implementation (IM step 5) [19] of WDYD, the target group was intensively and iteratively involved in the developmental process of the intervention, following user-based design principles [21]. Students from 2 MBO schools participated in 4 different pretests (refer to the Program Production of WDYD subsection). In addition, 2 classes of MBO students in media design developed short videos in which role models (ie, students) provided tips and tricks to reduce their alcohol consumption and to deal with challenges. These videos were developed in sprint sessions (writing a plan, developing scripts, and refining the videos), in which students received feedback from their teacher and 2 developers of WDYD and made refinements to the plan, scripts, and videos. This resulted in 22 videos that were incorporated into WDYD as part of several exercises.

The intervention was developed and implemented in collaboration with the Trimbos Institute. The Trimbos Institute was the owner of WDYD from the start, as they manage the knowledge network for e- and m-mental health in the Netherlands. This enhanced the opportunity for a broad implementation of WDYD and integration in interventions already used by the Trimbos Institute nationally.

Several strategies have been implemented to specifically stimulate the sustained use of WDYD. Notifications were used to invite and remind participants to fill in their diary, participate in a session, and keep up with their alcohol drinking goals (positive reinforcement messages). This way of prompting a review of progress toward goals is associated with a reduction in alcohol consumption frequency [58]. In light of behavioral maintenance, motivational interviewing was applied to establish a working alliance and to increase intervention engagement, intrinsic motivation, and confidence for change [45]. WDYD not only consisted of several motivational interviewing exercises (such as values clarification, importance and confidence ruler, identifying personal strengths, looking forward, and looking back) but also applied principles of motivational interviewing. These principles were autonomy support (ie, by providing participants as much choice as possible, eg, to provide them with the chance to plan the time to the next session, to provide the choice to view a video, and to choose 1 out of 2 exercises), partnership (ie, the input of participants in the diaries and sessions was the point for departure of the sessions, and participants were stimulated to provide their opinion or solution in the exercises), acceptance and compassion (ie, feedback via push notifications or sessions were written empathetically and personal, without coercion or blame), and evocation (ie, the point of departure for feedback within WDYD was the input of the participant in the diary and sessions; the exercises included in WDYD were interactive, and participants were encouraged to elaborate on their own motivation, confidence, planning strategies, mood, and relapse prevention strategies). In addition,

dynamic tailoring was implemented to elicit behavior change, but it was also used to prevent intervention fatigue and, therefore, induce sustained use [15,38] by withholding from intervening when a user is not receptive to the intervention (eg, when a user does not fill in the diary repeatedly, no exercise will be offered).

Evaluation Plan of WDYD (IM Step 6)

To evaluate the effectiveness of WDYD (IM step 6) [19], a study protocol was written, and a 2-arm randomized controlled trial was planned (trial registration: Netherland Trial Registry NTR6619 [64]). The goal was to randomly assign participants to the intervention group (ie, WDYD intervention) or the control group (ie, no intervention). The participants were recruited via a web-based lifestyle monitor for MBO students [65]. Students who drank alcohol excessively according to the monitor were invited to participate in the study. The eligibility criteria for participation in the study were (1) drinking excessively, that is, drinking more than the low-risk drinking guidelines recommended for adolescents (aged 16-17 years) to drink no alcohol and for adults to drink a maximum of 1 (women) or 2 (men) glasses of standard alcohol units daily, or (2) binge drinking, that is, drinking ≥ 4 (for women) or ≥ 6 (for men) standard alcohol units on 1 occasion [20]. In addition, participants had to be aged ≥ 16 years at the time they signed up, have to be computer or internet literate, and have to provide their informed consent before participation in the study.

The primary outcome measures were excessive drinking (yes or no), binge drinking (yes or no), and the mean weekly alcohol consumption. The secondary outcome measures were intrinsic motivation and self-confidence toward reducing alcohol consumption and the mood of the participant. Outcomes were assessed at baseline, week 9, and week 33 by using web-based surveys and ecological momentary assessments [66]. The ecologic momentary assessments will consist of brief daily diary measurements, assessed every 6 weeks for 7 consecutive days, ending after 33 weeks (ie, weeks 1, 7, 13, 19, 25, 31, and 33 after baseline). Participants in the intervention group will evaluate WDYD in a web-based survey at week 9 after baseline, and they will receive questions on overall acceptability (mean grade), usability of the app, information supplied, and design principles behind the app.

Discussion

Principal Findings

This study provides a comprehensive and detailed description of the rationale and plan for the development, implementation, and evaluation of WDYD, a dynamically tailored mobile health intervention. WDYD was developed to reduce excessive drinking among lower-educated adolescents and young adults in the Netherlands. The IM protocol was followed for the development of WDYD [19]. Furthermore, a user-centered approach was applied in designing the intervention [21].

Contribution of IM

Poorly described interventions, or *black boxes*, have long been criticized in the eHealth field [67,68]. Treatment rationales within empirical papers are often briefly described in the

methods section, where the theoretical framework, delivery, behavior change techniques, and content of the intervention are addressed to a limited extent [19]. The IM approach resulted in a systematically developed intervention by using theory-driven and evidence-based methods. The proper description of behavior change techniques and their practical applications in WDYD contributed to the replicability of the intervention. Furthermore, it can inspire researchers to design new interventions [69].

WDYD was developed in response to an earlier web-based, brief, single-session version of WDYD. This older version showed nonsignificant results for lower-educated adolescents and young adults (aged 16-24 years) and pointed out specific recommendations for improvement [27]. For instance, the new version of WDYD included exercises for students not ready to reduce excessive drinking and implement known conditions for the effectiveness of motivational interviewing (eg, autonomy support, evoking change talk, and partnership) and a nonjudgmental tone of voice [45]. The new version of WDYD was a longer and more intensive intervention, which included multiple sessions to facilitate improvement in intrinsic motivation for change as well as goal striving and persistence [17]. It was based on effective interventions using these strategies [70,71]. The IM protocol is useful for revising and updating existing interventions and provides an opportunity to account for earlier study flaws and limitations.

User-Centered Design

A user-centered design is crucial to maximize the fit of the intervention with the target group [72]. The user-centered design approach resulted in the intensive involvement of the target group in the developmental process of WDYD. The 4 pretests demonstrated how involving the target group led to an increasingly suited intervention, resulting in more positive evaluations of the app. After every pretest, the app was adjusted according to the feedback and recommendations of the target group. This led to changes in the design that would have been easily missed if the target group was not involved in the developmental process. For instance, the pretests indicated that students struggled with difficult wordings (eg, binge drinking), so they were avoided as much as possible. Another example was that students preferred the use of brief textual feedback in the app, alternate textual feedback with pictures and icons, and enhanced variability by including videos. Therefore, we decided to let students develop videos themselves, which included the role model stories of students who provided tips to reduce their alcohol intake and deal with challenges. In addition, textual feedback was rewritten in a terse style, and pictures and icons were added.

Limitations

There are some limitations regarding the developmental process of WDYD. First, the sample sizes of the 2 final pretests were small. Moreover, not all pretests included excessive drinkers only, as the focus of these tests was on evaluating usability and intuitive use. This may explain why participants in the final 2 pretests evaluated the app as more positive (mean grades of pretests 3 and 4 were 7.3 and 8.2, respectively, compared with pretests 1 and 2, which were 7.1 and 7.0, respectively). Therefore, the results of the final 2 pretests should be interpreted

cautiously. However, having only a handful of students in the qualitative evaluation allowed for in-depth interviews, addressing all facets of the app. Second, the final pretest indicated some flaws with regard to the notifications (eg, notifications for the diary were sent although participants had already filled in the diary). This was resolved and thoroughly tested before implementation in the trial. Third, lower-educated students appeared to be a very challenging target group; on the one hand, students indicated in the pretests that they preferred a brief intervention, to spend a maximum of 15 minutes of their time for the intervention per week, that the textual feedback was as brief as possible, and that the intervention included as much freedom of choice as possible. Therefore, we provided students with several options (eg, viewing a video and choosing 1 out of 2 tailored exercises). On the other hand, as an

intervention developer, intervention time is essential for inducing behavior change, and providing users with freedom of choice increases the risk of lower exposure. In addition, personal relevance of the app remained a problem throughout the pretests; even in the fourth pretest, the expectations of students of the app were low, but when participating, they were surprised by the app and perceived it as informative and supportive.

Conclusions

It can be concluded that IM and user-centered design are useful means to develop an evidence-based and theory-driven intervention to reduce excessive drinking among lower-educated students. The target group of lower-educated students who drink alcohol excessively needs more attention in future research to design well-suited and effective interventions.

Acknowledgments

This study was funded by the Netherlands Organization for Health Research and Development (ZorgOnderzoek Nederland en Medische Wetenschappen 531001105). The authors would like to thank all the participants, Nova College, Deltion College, the Dutch Middelbaar Beroepsonderwijs council, Dutch Foundation Testjeleefstijl, and Open University Heerlen for their participation in the development of *What Do You Drink*.

Authors' Contributions

HvK, PvE, CV, JK, and MK developed the *What Do You Drink* intervention. HvK, RA, PvE, and CV wrote the paper. MK and JK provided feedback on drafts of the paper. All authors read and approved the manuscript for publication.

Conflicts of Interest

None declared.

Abstract

Background: Burnout is a hidden productivity killer in organizations. Finding a solution to efficiently measure and proactively prevent or rehabilitate employees with burnout is a challenge. To meet this unabated demand, companies and caregivers can focus on proactive measures to prevent “Burnout as an Occupational Phenomenon.”

Objective: We aimed to address effectiveness, reliability, and validity of the empowerment for participation (EFP) batch of assessments to measure burnout risk in relation to the efficacy of web-based interventions using cognitive behavioral therapy (CBT) and floating to improve mental health and well-being. We introduced three risk assessments: risk for burnout, risk of anxiety, and risk for depression.

Methods: We used an interventional, empirical, and parallel design using raw EFP psychometric data to measure the effectiveness of web-based therapy to reduce the risk of burnout between a control group and web-based therapy group. A total of 50 participants were selected. The rehabilitation and control groups consisted of 25 normally distributed employees each. The rehabilitation group received therapy, whereas the control group had not yet received any form of therapy. IBM SPSS was used to analyze the data collected, and a repeated measures ANOVA, an analysis of covariance, a discriminant analysis, and a construct validity analysis were used to test for reliability and validity. The group was selected from a list of employees within the My-E-Health ecosystem who showed a moderate or high risk for burnout. All assessments and mixed-method CBT were web-based, and floating was conducted at designated locations. The complete EFP assessment was integrated into a digital ecosystem designed for this purpose and therapy, offering a secure and encrypted ecosystem.

Results: There was a statistically significant difference between pre- and postassessment scores for burnout. The reliability of the burnout measure was good (Cronbach $\alpha=.858$; mean 1.826, SD 3.008; Cohen $d=0.607$; $P<.001$) with a high validity of 0.9420. A paired samples 2-tailed test showed a good t score of 4.292 and $P<.001$, with a good effect size, Cohen $d=0.607$. Web-based therapy reduced the risk for burnout in participants compared with the control group. Tests of between-subject effects show $F=16.964$, a significant difference between the control group and the web-based therapy group: $P<.001$, with movement between the group variables of 0.261 or 26.1% for the dependent variable.

Conclusions: This study suggests good reliability and validity of using web-based interventional mixed methods CBT to reduce the risk of burnout. The EFP batch of web-based assessments could reliably identify morbidity risk levels and successfully measure clinical interventions and rehabilitation with consistently reliable results to serve as both a diagnostic and therapeutic tool worthy of major research in the future.

Introduction

Measuring Burnout

Burnout within the workplace is a major problem in recent times; therefore, this paper aimed to show that early web-based identification and intervention are effective in addressing this demand. Bucci and Berry [1] argued that the digital revolution is evolving at an unstoppable pace. They also accept that the explosion of digital technology and mental health care is under greater pressure to path digitally mediated interventions and services. Nonetheless, Hollis et al [2] believe that “digital technology has the potential to transform mental health care by connecting patients, services and health data in new ways. Digital web-based applications can offer patients greater access to information and services and enhance clinical management and early intervention through access to real-time patient data.” However, both Hollis et al [2] and Bucci and Berry [1] agree that there are substantial gaps in the evidence base underlying these technologies.

A meta-analysis carried out by Duijts et al [3] showed that predictors of sickness can be used in a homogeneous manner to identify presenteeism. Presenteeism relates to those who choose to remain at work, even though they are not physically or psychologically well, thereby impacting productivity, team dynamics, workflow, and the bottom line [4,5]. A literature review also revealed that key work factors associated with psychological ill-health and absence in staff were associated with long work hours, work overload and pressure, lack of control, lack of participation in decision-making, poor social support, and unclear management and work roles [4,5].

Michie and Williams [6] showed that sickness absence was associated with a poor management style. In the same report, they also showed that successful interventions used training and organizational approaches to increase participation in decision-making, problem solving, and communication techniques, as well as additional support and feedback for individuals. They concluded that many of the work-related variables associated with high levels of psychological ill-health were potentially amenable to change.

Smith and Beaton [7] raised the need for an accurate assessment of psychosocial changes in working conditions [7]. They also stressed the need for these measurements to focus on the collection of data at baseline, and if possible, a follow-up time point.

Over the years, many complex attempts have been made to measure burnout. These include, but are not limited to, assessments for job satisfaction and performance in 1991 [8], development of a measure of workplace deviance in 2000 [9], the World Health Organization’s Health and Work Performance Questionnaire in 2003 [10], the Stanford Presenteeism Scale in 2005 [11], the Utrecht Work Engagement Scale in 2002 [12], and others. What is evident and common in all the above measures is that they are static and retroactive in nature; they

lack continuity in understanding an individual over time and within their changing environments. According to Michelsen [13,14], a reliable and valid methodology to support individual psychological safety and engagement needs continuity in its construct. He suggests that individual measures need to have the ability to monitor individuals within their environment, over time, and dynamically show deviations, mean scores, and trends covering a broad spectrum of issues that affect psychological well-being, engagement, and participation in a myriad of situations within the workplace.

Originally designed in early 2001, as a psychosocial monitoring tool used to assess employees undergoing transformational change initiatives within their companies [13], the empowerment for participation (EFP) battery used today has seen numerous upgrades, from its original paper format to a digital (HTML) version in 2007, to the fully interactive web-based ecosystem used currently. The assessments were accessed via a secure and encrypted web-based ecosystem.

The *EFP assessment battery* consists of 4 assessments and a 360° mirror feedback assessment when objective feedback is required (not addressed herein). All assessments are scored using the visual analog scale (VAS), which consists of a straight line with a beginning and end point; for example, very good to very poor. As the slider moves from left to right, the text positioned at either end of the line increases as the opposite end decreases. The position at which the slider stops is represented by a number from 0 to 20. The slider can be moved in either direction or in accordance with the assessed feels regarding that specific question. To minimize the clustering of points around a preferred numeric value or description as used by Likert-type assessment scales, no visible numeric values or intermediate points are visible or seen by the assessed. The *Journal of Behavior Therapy and Experimental Psychiatry* showed that the VAS scales used enable simple and rapid assessment of the state of anxiety and exhibit superior psychometric properties [15].

The *EFP Motivation Assessment* consists of 20 VAS questions (Cronbach $\alpha=.939$) and aims to show the level at which the individual’s motivation lies. It measures an individual’s motivation in areas such as transparency (openness), meaning, identification, balance, teamwork, stimulation, self-esteem, participation, and engagement among others. Validation analysis showed that 95.9% of the original grouped cases were correctly classified, 93.2% of cross-validated grouped cases were correctly classified (effect size=0.881; Wilks lambda=0.106; $P<.001$), and good group centroid separations from low motivation to high motivation were noted, indicating an excellent measure [14].

The *EFP Stress Assessment* consists of 20 VAS questions (Cronbach $\alpha=.887$) and aims to show the level of an individual’s stress level by measuring several stressors and symptoms in areas such as communication, knowledge, conflict, justice, values, safety, and health in the workplace. Earlier analysis showed good validity, where 91.8% of the original grouped

cases were correctly classified, 89% of cross-validated grouped cases were correctly classified (effect size=0.913; Wilks lambda=0.072; $P<.001$), and good group centroid separations from low stress to highly stressed were noted, indicating an excellent measure [14].

The EFP *Defense Routines Assessment* consists of 20 VAS questions (Cronbach $\alpha=.870$). The purpose here is to map and understand an individual's defense routines and the ability to engage in work and life effectively and openly. The concept of defense mechanism was driven by Freud [16] in 1923, where more difficult-to-handle associations are considered to exist in the so-called primary process (subconscious process), usually considered as an antagonistic relation to the secondary process (conscious processes). Rather, the *Defense Routines Assessment* uses redefinition by Neisser [17] of these processes, where they are not perceived as antagonistic but instead as essential to each other. This suggests that the secondary process provides opportunities to process primary material through an appreciation of the routines that the individual creates as a defense. According to Senge [18] and Michelsen [13], defense routines are habits created to protect us from threats to our self-image and identity. Therefore, these routines provide protection against our deepest assumptions. The *Defense Routines Assessment* aims to measure these routines in areas such as guilt, flexibility, forgiveness, communication, conflict, control, and rationality. Michelsen [13] showed that 97.3% of the original grouped cases were correctly classified, 94.5% of cross-validated grouped cases were correctly classified (effect size=0.891; Wilks lambda=0.103; $P<.001$), and good group centroid separations from low defense routes to moderate defense routes were noted, indicating a very good measure [14].

The EFP *Perpetual Motivation Positioning* assessment consists of 50 VAS questions (Cronbach $\alpha=.944$), divided into seven subscales: (1) knowledge, (2) external demands, (3) social environment, (4) health and safety, (5) self-expectations, (6) openness, and (7) self-esteem. The assessment is presented in a visual spider-gram for easy visual identification of areas in conflict. For example, deviations or anomalies with external demands, self-expectations, and social environments are usually associated with those persons exhibiting psychological challenges or some degree of burnout. The purpose of the assessment is to gain insight into a person's boundaries, participation and adaptability, trust, creativity, openness, and more. In an earlier analysis of the EFP assessment, statistical validation showed that 100% of the original grouped cases were correctly classified, 97.3% of cross-validated grouped cases were correctly classified with an effect size of 0.908 (Wilks lambda=0.084; $P<.001$), and good group centroid separations from low adaptability to high adaptability were noted, indicating an excellent measure [14].

The *Risk for Burnout* report has 30 questions that make up the risk assessment (Cronbach $\alpha=.928$; $P<.001$ partial eta squared=0.900; Cohen $d=0.900$). They were compiled from the EFP batch of questions as follows: (5) motivation; (5) stress; (5) defense routines; (0) knowledge; (6) *Perpetual Motivation Positioning* external demands; (0) social environment; (2) health and safety; (3) self-expectancy; (0) openness; and (2) self-esteem. There are four subdimension measures: (1) external

demands, (2) self-expectancy, (3) depersonalization, and (4) symptoms. All questions are VAS formatted with values ranging from 0 to 20 and a total accumulated score ranging from 0 to 600. The purpose of the risk assessment scale is directly associated with preventive care and proactive cognitive behavior therapy (CBT), used to address any identified trends or associated risks. Because My-E-Health is a registered company health care provider, this EFP Risk for Burnout (EFPRB) measure has served and proven its reliability and validity in preventing workplace-related psychological ill-health, indicating an excellent measure [14].

To avoid psychological and central tendencies and to increase the reliability and validity of the burnout measure, several measures were taken during the year. First, individuals taking the assessments are not limited to symptomatically related questions for specific diagnoses; rather, they take holistic and situation-based questions regarding their general environmental well-being and how they feel within that context. Second, all questions are VASs, and lastly, there are embedded control questions to check for similar question variance anomalies.

There are five risk levels of burnout in the EFPRB assessment—risk levels are provided in relation to the total score or the mean score following a linear guide: 0 to 99 points (mean 0-3.300)=no evidence of burnout, 100 to 199 points (mean 3.333-6.6333)=low risk for burnout, 200 to 299 points (mean 6.6667-9.9667)=moderate risk for burnout, 300 to 399 points (mean 10.00-13.300)=high risk for burnout, and 400 to 600 points (mean 13.3333-20)=burnout. These have proven to be statistically significant in previous studies ($N=73$)—risk for burnout: Cronbach $\alpha=.928$; $P<.001$; partial eta squared=0.900, Cohen $d=0.900$ (Michelsen, 2021 [4]). It has excellent content validity: internal validity of $P>.93$ and external validity of $P>.91$ [4].

Prevention or Rehabilitation Interventions

Measuring and identifying burnout risks and implementing preventive measures early are simpler than retroactive approaches. Retroactive or burned-out cases are those with a high degree of causal and symptomatic reactions already embedded into one's behavior and specifically related to their individual burnout. This requires immediate support for staff-off or sick leave. In some cases, up to 2 years. Understanding these nuances is just part of the complex equation used to evaluate the causes leading to mental health exhaustion and their symptomatic effects on the individual [4].

Internet-based therapy using CBT is now considered an effective way to treat a range of psychological disorders [19,20]. Michelsen [4] suggested that a solution can be found by merging a measurement, causal and symptomatic identification instrument, and an interactive web-based solution to improve access and efficacy in treatment.

Naturally, efficacy in treatment requires many approaches to be discussed herein, namely accessibility, psychological safety (both psychological and data-driven), chemistry (patient and caregiver), an interactive web-based environment to enhance cognitive awareness of self, and a measurement system to

demonstrate patient and counselor treatment progress and empowerment.

Web-based (24/7) access provides the employee with a patient-centric ecosystem with access to a multimodal caregiver team (various specialties from a health coach, psychotherapist, psychologist, medical doctor, counselor, dietician, and others), where the individual can and even choose their care team from available caregivers. The My-E-Health ecosystem provides this type of multimodal access, and it opens the caregiver team's booking calendar to the patient so that the patient can easily book appointments as needed.

Psychological safety should be provided for both the individual and the health care teams. According to a study by Grailey et al, in 2021 [21], a health care team requires a shared belief of psychological safety to allow for interpersonal risk taking, improve innovation, and reduce errors through team InterVision. The My-E-Health model conducts weekly InterVision. Therefore, a multimodal web-based health care team can provide psychological safety via team connectedness designed around a consensus-driven patient-centric system used by My-E-Health. In 2021, Hunt et al [22] showed that psychological safety is an important component of safe and effective patient care in mental health services. Patient psychological safety is as important as the outcome of the health care team. According to Fathers and Stevens [23], it is important to make a patient's experience positive. They also believe that good communication (combining visual, verbal, and written communication to best convey the treatment message) is of greatest importance as well as accessible and correct information and that caregivers should speak clearly not rushing the patient but adapting to the patient's pace. Maintaining a patient's dignity, integrity, and privacy is a vital component of psychological safety [23]. Psychological safety includes the use of a secure and encrypted web-based framework in which secure conversation tunnels can be built between the patient and caregivers. Understanding that one's personal data are always kept private and not shared with persons outside of the care team also supports this. Aggregate data, quality assurance, and oversight are fundamentally important for all stakeholders. This is also supported by InterVision and consensus among the multimodal teams in an internal weekly session.

According to Laughton-Brown [24], chemistry between counselors (any member of the health care team) and employees (patients) is of primary concern, as a trusting relationship is fundamental to good therapy. Facilitating this chemistry can be enhanced by the psychological safety offered by the multimodal care team. This can be improved during the initial web-based therapy (providing feedback on the results of the assessments) through cognition by connecting the visual cortex (visually recognizing and concurring with one's status) and accepting it by validating how the patient feels. This content validation uses the cognitive dissonance theory to connect the subjective situational environment (experience by the patient) to their status and well-being.

Therapy and sick leave are recommended for individuals assessed to be "burned-out," and they are immediately placed into the company rehabilitation program. Employees fluctuating

between the lower two categories on the EFPRB scale (no evidence and low risk) require no additional care and continue their normal quarterly feedback sessions with their health coaches. However, individuals that show a "Moderate Risk for Burnout" level enter a modified web-based rehabilitation program to address identified concerns and receive the necessary guidance to build the needed coping skills to address said issues. Employees falling into the "High Risk for Burnout" category enter an individually designed intervention or proactive rehabilitation program, usually all 3 of the components described herein.

Interactive and Integrated Web-Based Environment

The advantage of the web-based environment over that of traditional clinical settings is that it can be interactive and integrate a myriad of digital and visual tools and various media. Marikyan et al [25] also believe that connecting the dots using cognitive dissonance in technology adoption is rapidly becoming the norm. For web-based therapy systems to be as effective as possible, an interactive ecosystem that provides users with the ability to adapt treatment models to the needs of the patient, and not the reverse. Furthermore, patient-validated assessments can monitor progress if assessed monthly during treatment. Michelsen [4] believes that visual and cognitive recognition and interactivity among the patient, caregiver, and interactive environment help empower the individual [4].

Web-based tools can be used to enhance clinical therapy sessions by providing interactive solutions, as used in Gestalt therapy, to demonstrate possible patient cognitive distortions, dissonance, and self-awareness and visually illuminate areas that may inhibit self-empowerment. These tools can be used in one or a combination of various psychological disciplines (CBT, acceptance commitment theory, and dialectical behavioral therapy and psychodynamic, interpersonal, and transpersonal) and can transform how future web-based mental health ecosystems can work. Finding a workable and sustainable solution that can proactively monitor and positively impact mental health and the effects of burnout will ultimately support systemic evidence-based interventions to identify and manage presenteeism [14].

Methods

Recruitment of Participants

The participants were employees of contracted companies within the My-E-Health company health care and well-being platform. Both the control and therapy groups were gainfully employed and belonged to the My-E-Health company health care program. Their ages ranged from 22 to 68 (mean 43.28, SD 11.317 years) with homogeneity. The study consisted of 28 (56%) males and 22 (44%) females with a mean of 1.44 and SD of 0.501, suggesting good homogeneity. At the time of their assessment, employees had been working at specific positions for 12 months to 16 years.

The control group (n=25, age: mean 42.92, median 41.00, SD 10.71 years) consisted of 11 men (44%) and 14 women (56%). The treatment group (n=25, age: mean 43.64, median 41.00, SD 12.10 years) consisted of 17 (68%) men and 8 (32%) women.

This Study

The aim of this study was to evaluate the effectiveness of web-based therapy in addressing and lowering the risk of employee burnout among randomly selected employees in 4 private companies located in Sweden and the United Kingdom. The hypothesis is that, compared with the control group, the intervention group will demonstrate decreased levels of burnout and that these improvements will remain after 6 months. The research questions of this study were as follows:

1. Is web-based therapy effective in reducing existing burnout?
2. Is web-based therapy effective in reducing the risk for burnout for participants compared with the control group?

Clinical Trial Design and Criteria

This study was approved by the Regional Ethics Committee in Lund, Sweden, in 2017 and began before clinical trial registration. This interventional and empirical study examined the effectiveness of web-based CBT in reducing burnout. A parallel study of a control group was conducted. Both the intervention therapy group and the control groups were selected from a list of employees within the My-E-Health company health care ecosystem that had been assessed on the EFP Burnout Scale to have “Moderate Risk of Burnout,” “High Risk of Burnout” or with “Burnout.” Inclusion criteria include the following: (1) a moderate or high risk for burnout; (2) employees with a current burnout diagnosis from a hospital or outpatient or psychiatric clinic; (3) a fully employed person with a member organization; and (4) no other inclusion criteria. The exclusion criteria were (1) no evidence of burnout on the EFP scale, (2) low risk of burnout on the EFP scale, (3) unemployed persons, and (4) no other exclusion criteria. The inclusion group (n=50) consisted of a control group (n=25) and interventional therapy group (n=25).

The postassessment value was used as the dependent variable. The control group consisted of 25 normally distributed employees (n=25) who had not yet received any form of therapy but only received feedback related to their EFP assessment scores and a therapy group (n=25) consisted of those who received interventional CBT. Both groups were required to validate the pretest and posttest EFP assessment results. Repeated measures ANOVA and analysis of covariance (ANCOVA) analyses were performed using the SPSS (IBM) program.

Intervention Package Used to Reduce Moderate and High Risk for Burnout

The therapeutic package developed by My-E-Health for the treatment of employees, health care professionals, and patients with moderate-to-high risk for burnout consists of three components:

1. The web-based test battery, known as the EFP assessment and the Risk Assessment for Mental Exhaustion (identify the risk level for burnout) and many of the causal aspects related to that risk level.
2. Web-based therapy that is either proactive or preventive in nature or retroactive and encompasses mixed-methods therapy using a mix of CBT, acceptance commitment

theory, dialectical behavioral therapy, transpersonal and psychodynamic therapy, as well as mindfulness techniques such as mindfulness walks (isolating the sensors independently during a walk) and other parasympathetic bottom-up or top-down strategies. These help to bring the patient into the present while addressing both the sympathetic response (fight or flight response) and parasympathetic response (rest or relax and digest response) approaches, also complemented with daily routines to stimulate natural hormone release.

3. Flotation REST (Restricted Environmental Stimulation Technique) completed at any of many floating centers internationally, a minimum of 10 floating sessions 2 to 3 times weekly (depending on the level of exhaustion) for 4 to 5 weeks. Each floating session was followed by a web-based therapy session.

One purpose of the *first component* (EFP) is to detect the severity, early symptoms, and associated causes that lead to a risk for burnout. This facilitates preventive and proactive treatment while at work and not waiting until someone is on sick leave. Another aim was to provide an adequate description of problems (symptomatic and causal in nature), irrespective of severity, for appropriate treatment methods to be introduced and for proper monitoring and evaluation. The psychometric assessments included in the EFP represent a compilation of a range of well-tested test techniques, which are also found in other psychological tests. The EFP batch assessment uses a new approach in that it uses well-tested techniques that have been combined into a whole, where the different parts are allowed to mirror and deepen the understanding and correlation with each other to provide a better overall assessment of an individual's psychological challenges, causes, hurdles, or conditions. Here, individuals can connect with their coach, caregiver, or multimodal team, complete their psychometrics (as needed in therapy or at least on a quarterly basis) and receive live, interactive, face-to-face feedback about their results.

The *second component*, the web-based therapy or mental health coaching program, focuses on improving the individual's situational awareness and understanding of the present, to addressing any cognitive distortions or cognitive dissonance and empowering a path forward. This is accomplished by using an interactive web-based ecosystem as well as learning to identify and listen to their signals and using “mixed methods CBT” and mindfulness to activate their visual cortexes to empower themselves to change. The phase can also include activities designed to help individual patients listen to their bodies and nervous systems (sympathetic and parasympathetic) and to naturally manage hormonal stimulation via daily routines [26-33]. International studies show that web-based counseling combined with CBT (in all its forms) and associated decluttering activities such as mindful-walks, yogic breathing, meditation, yoga, yin yoga, yoga nidra, visualization, aroma therapy, hot shows, cold therapy, and much more, can be used effectively for a variety of clinical problems [34-37]. There are many different relaxation techniques, such as meditation, Tai-Chi, yoga, and qigong [38]; nonetheless, these methods often require long and regular practice before the benefits become apparent. Therefore, a combination of relaxation exercises to activate the

parasympathetic nervous system and an effective and well-known method to reduce physiological and psychological responses to stress and anxiety [39] is needed. Reducing stress with stress-reduction therapy and relaxation training to increase a sense of “mindfulness” usually involves many hours of practice. It is also understood that people with the greatest need for relaxation training are also those having the toughest time in implementing and completing such training [40].

Posttherapy treatment includes continuity with web-based quarterly feedback, which has proven to be an effective way to solidify treatment and prevent relapse. Nonetheless, the evidence for web-based CBT and other methods is well investigated (Carlbring et al, 2018 [40]) and need not be further discussed here. For patients with a moderate-to-high risk of burnout, this phase starts and coincides with the third component.

In contrast, *the third component*, the flotation REST, may not be as well known; therefore, it will be described in more detail below. In step 2, we focus on the treatment of clinical and symptomatic parameters affecting the patient. These include interactive situational analysis of the patient in relation to their holistic self: causes and empowering solutions to empowerment and symptomatic therapy. This can include decluttering exercises to help reduce the constant onslaught of stimuli that activates the autonomic nervous system (sympathetic and parasympathetic nervous systems) and many others. It is well known that a heightened state of stimuli leads to an overactive amygdala signaling the hypothalamus and autonomic nervous system to be on guard or in “Fight or Flight” mode [41]. This state increases involuntary body functions such as blood pressure, pulse, dilation of the blood vessels, and breathing caused as the adrenal glands stimulate a hormone called epinephrine (adrenaline) and secrete it into the blood [41]. Consequently, the hypothalamus and pituitary gland (HPA axis) triggers the release of blood sugar (glucose and fats) as well as the activation of various corticosteroids. This, in turn, affects an individual’s circadian rhythms, sleep, fatigue, and behavior. Patients exhibiting various degrees of stress, anxiety, depression, or burnout usually find themselves in a heightened state, an exhaustive state, or somewhere in between [42]. Step 3 flotation REST or float therapy acts as a break to the sympathetic nervous system by activating the parasympathetic nervous system (producing the rest, relax, and digestive state) by eliminating extra stimuli, muscle tension, stress, and more coming from within or from the situational environment facing the patient [43].

Flotation REST was first introduced by Dr John Lilly in 1954 as an isolation tank to help isolate persons from gravity, the onslaught of external stimuli. Experiences of Dr Lilly with weightlessness and high-altitude flight and isolation also seem to coincide with the meditative experiences of Robert A Monroe, the founder of The Monroe Institute, and his meditative experiences related to monotonous low-frequency stimuli in the exploration of human consciousness leading to a state of rest or relaxation. Both the aforementioned practiced isolation and a form of deep meditation.

Benson [44] argued that the positive effects derived from these various relaxation techniques may be due to deep relaxation,

which simultaneously triggers the so-called a relaxation response (RR). Yogic breathing techniques can also improve the transition effectiveness after entering the tank to achieve a state of relaxation [45]. It is also well known that individuals in a state of acute crisis are not, as a rule, susceptible to rehabilitation efforts, so catching challenges early and combining the 3 proactive components within the intervention program where individuals can benefit from more professionally oriented interventions, creating distance and learning the necessary coping skills to manage daily challenges [45].

Relax Response

Relax response (RR) is identified as the physiological opposite of the “fight-flight response” or stress response [46]. RR is associated with instantly occurring physiological changes, including reduced sympathetic nervous system activity; reduced metabolism; and lowered heart rate, blood pressure, and respiratory rate [45,47]. Activation of the parasympathetic nervous system deactivates corticosteroid effects and improves recovery, improves sleep quality [42], and further creates less dependency on alcohol and psychoactive medications, while increasing the sense of control and efficacy in stressful situations [48].

Currently, techniques are used to induce relaxation and trigger RR. Many symptomatic pharmacological treatments rarely succeed in successfully treating stress-related disorders [49].

Ben-Menachem [50] believed that two main factors were necessary to trigger RR: (1) reduced sensory stimulation and (2) decreased body movement. Flotation REST triggers RR (parasympathetic nervous system) by removing many of the negative stimuli by introducing effortless deep relaxation in a weightless, dark isolated floating pod [50]. It has been shown that the effect of a rehabilitation program diminishes if delayed too long. Introducing rehabilitation efforts at an earlier stage using proactive relaxation therapy, in conjunction with mixed methods CBT, for those displaying a moderate-to-high risk of stress, anxiety, or burnout [14], ensures faster recovery.

The floating pod or floating chamber was filled to a height of approximately 20 cm with lukewarm water (approximately 35 °C-36 °C or 95 °F-96.8 °F) mixed with a magnesium sulfate to water specific gravity ratio of 1.25:1. The chamber can be either a large room designed for patients with claustrophobia or a pod that resembles an egg shape. The patient literally floats like a cork in a weightless environment during their floating sessions. Some patients have likened it to the safety of a womb before birth. Some spas that use floating tanks may use soft music during a floating session; nonetheless, no music is played if one is in therapy. Tanks are equipped with soft lights; however, the patients turn them off when comfortable. Sensory isolation is achieved when decluttering emerges, and an individual finds mindfulness by intuitively and visually moving into the primary process [43]. In psychology, this is referred to as the primary process. As decluttering, breathing, and meditating take hold and the patient achieves the here-and-now or present, the secondary process emerges for a more mature style of thought. In some cases, patients may fall asleep during this phase. Professor Kjellgren has shown in her research that it is restful and psychologically beneficial to experience recurring episodes

of just “being in the present weightlessness state” induced by a flotation tank [51].

The flotation tank is constructed such that the participant has full control and can stop when they wish to. The lid is easily opened from the inside as well as from the outside. By pressing the buttons inside the tank, the participant could turn on a light in the tank or call for the staff. The water salinity is remarkably high, which provides a good carrying capacity. The high buoyancy in combination with the low water level (approximately 30 cm or 12 inches in depth) provides additional psychological safety (needed for the parasympathetic nervous system to activate) and security. The water is automatically circulated and filtered through a 5- μ m filter and processed via a UV light system before and between the floats. Each participant floats in a safe and clean environment. At the same time, it must be emphasized that flotation REST is a “mild” form of REST, and there are no reports in the literature on hazards or problems to patients.

Jonsson [52] showed that these techniques can trigger RRs even in patients with severe anxiety (generalized anxiety disorder), depression, posttraumatic stress disorder [52], and burnout.

Ethics Approval

The study protocol was approved by the Regional Ethical Board in Lund, Sweden (Dnr 2017/761). All personal data were anonymized, all cases were provided with identification tags, and all individual identifying information was excluded before any research and when the data were transferred into the matrix used for statistical analyses.

Procedures for Assessment, Collection, and Data Analyses

Data were extrapolated from the organizations in the My-E-Health program. All employees agreed to the co-ownership of the data and participated in the research. All individuals have approved our General Data Protection Regulation (GDPR) regulations and responsibilities and are currently or were members of our company health care program. A total of 73 ($n=50$) employees took 100 batches of EFP assessments. However, for the purpose of this study, only the first and last assessments will be used. Employees were informed about the ongoing research and the objectives of the studies, anonymity, and confidentiality of the survey.

Because all assessed individuals entering the My-E-Health EFP platform were unknown upon entry (as little information was known about them before their assessments, no prequalification or demographics were applied, and no individual categorization or adjustments were made), they should be considered one large cohort. There was only one contingency, and all assessed individuals within this study were full-time employees. Their

assessments were subjective and purely based on how individuals interpreted their own situational environment, health, and well-being. Personal data were strictly kept private between the individuals and their counselors or caregivers. No information was made available to employer organizations other than the aggregate data pertaining to their company.

Procedure, Access, Measures, and Web-Based Treatment

For web-based therapy to reach its full potential, individual integrity, privacy, solid measures with reliability and validity, and an interactive framework are necessary. Naturally, the web-based ecosystem needs to provide psychological safety where individuals can feel safe, access an encrypted “Private Space,” and receive live video feedback within an interactive environment. The EFP batch is accessed via a web-based ecosystem designed to proactively support individuals in their eHealth needs. Here, individuals can connect with their coach, caregiver, physician, or psychologist; complete their psychometrics (as needed or at least on a quarterly basis); and receive live counseling about their results. All communications were encrypted and performed within a secure (Health Insurance Portability and Accountability Act– and General Data Protection Regulation–compliant) framework to protect individual integrity. Any identified deviations can be addressed early together with the caregiver or certified counselor, using the inbuilt CBT framework.

The EFP assessment battery consists of the 4 assessments discussed earlier. All assessments are scored using the VASs, consisting of a straight line with a beginning and end point; for example, very good to poor (Figure 1). As the slider moves from left to right, the text positioned at either end of the line increases as the opposite end decreases. The position at which the slider stops is represented by a number from 0 to 20. The slider can be moved in either direction or in accordance with the assessed feels regarding that specific question. To minimize the clustering of points around a preferred numeric value or description as used by Likert-type assessment scales, no visible numeric values or intermediate points are visible or seen by the assessed. The *Journal of Behavior Therapy and Experimental Psychiatry* showed that the VAS-A scales used below enable a simple and rapid assessment of the state of anxiety and exhibit superior psychometric properties (Abend et al, 2014 [15]).

Figure 1 shows an EFP assessment question scored using the VAS, consisting of a straight line with a beginning and end point: very good to poor in this example. The VAS line has hidden values to minimize central tendencies. The button can be moved in either direction, either left or right based-upon how an individual may feel, and the scale variables increase or decrease proportionally.

Figure 1. Visual analog scale used in assessments.

Statistical Analysis Requirements

Several assumptions that needed to be met before running the analysis of the pre- and posttest data were made. The ANCOVA will control for the pretest values to analyze the posttest values and examine whether there is a significant difference between the control group and the therapy group while controlling for the pretest values. ANOVA requires an assumption of normality where both the pretest and posttest are normally distributed.

ANCOVA Assumptions

To run an ANCOVA, 2 assumptions must be met to ensure that the covariate meets the requirements to run the ANCOVA. The first assumption is that the pretest cannot be statistically significantly different across the levels of the independent variables of the group. ($n=50$; control group, $n=25$, and web-based therapy group, $n=25$). This means that there was no difference between the control group and the treatment group for the pretest or initial assessment test.

The procedure used a general linear model univariate analysis to check whether the covariates met the requirements to run the ANCOVA. Assumption test 1, testing between-subject effects using the pretest for burnout as the dependent variable, showed no significant difference between the groups for burnout ($P>.07$), thereby passing the first assumption.

The second assumption is the homogeneity of the regression test between the subjects' effects. The dependent variable is the posttest assessment for burnout, and the covariate is the pretest assessment for burnout, where the group was the fixed factor. To pass this assumption, the group times the pretest for burnout cannot be significant. The results showed a nonsignificant result of $P>.13$, thereby meeting the homogeneity of the regression condition and passing the requirements needed to move forward with an ANCOVA.

ANOVA Assumptions

There are 4 assumptions that need to be met to complete a repeated measures ANOVA with normality being the most important, where both the pretest and posttest are normally distributed:

The dependent variable should be interval or ratio data.

1. The participants are randomly sampled from the population.
2. The dependent variable is normally distributed in the population at each level of the independent variables.
3. The variability in the difference between any pair of groups should be the same as that between any other pair of groups.

The test for normality showed no missing values and that the data did not exhibit statistically different normality values for both the pretest and posttest (Kolmogorov-Smirnov test=0.200), confirming the null hypothesis. Shapiro-Wilk analysis for normality for the burnout pretest ($P=.69$) and for the burnout posttest ($P=.17$) confirmed that we could. This result confirms that the null hypothesis can be accepted (or cannot be rejected).

A descriptive analysis showed acceptable burnout pretest (skewness=-0.179 and kurtosis=-0.565) and burnout posttest (skewness=0.027 and kurtosis=-1.057) values for skewness and kurtosis. The EFP pretest assessment for burnout showed a normal distribution ($n=50$; mean 7.62, SD 2.90). The EFP posttest assessment for burnout showed ($n=50$; mean 5.80, SD 2.612). There were no outliers, and both pre- and posttest EFP assessments showed a normal distribution.

Paired samples statistics showed group mean scores for the pretest for burnout at mean 7.624 with an SE of 0.41008 and posttest mean 5.7980 with an SE of 0.36946, meeting the assumption to run the ANOVA. Paired samples correlations showed no correlation, 0.408 and $P<.003$ to meet the assumption needed to run ANOVA. Therefore, all 4 assumptions for running the ANOVA were met.

Normality was not violated, and the assumptions for both the ANCOVA and ANOVA were met.

Results

Overview

The results are organized into four sections: an ANCOVA, a repeated measures ANOVA, reliability for internal validity using discriminant statistics, and external content validity analysis.

A descriptive output of the ANCOVA showed a clear difference in the mean scores for the control group, mean 6.572, SD 2.54 and the web-based intervention CBT group, mean 5.024, SD 2.49 where a lower score represents a lower risk for burnout. In controlling the pretest assessment for burnout scores, the between-subject effects group analysis showed statistically significant differences between the groups on the posttest assessment for burnout: $F=12.624$, $P<.001$, and a partial eta squared (0.212) or membership difference between the groups of 21.2% (Figure 2).

Figure 2 presents the estimated marginal means for the posttest assessment for burnout between the groups, which shows a significant drop in the risk for burnout for the intervention CBT web-based therapy group as opposed to the control group.

Figure 2. Pretest and posttest results.

Covariates appearing in the model are evaluated at the following values: Burnout.Mean.Intl=7.6240

Repeated Measures ANOVA

When running a repeated measures ANOVA, the paired samples test showed good results (t score of 4.292; $P < .001$ with a good effect size Cohen $d = 0.607$) obtained from the mean average 1.826 divided by the SD 3.008. The paired samples effect sizes for the pretest (Cohen $d = 0.607$, 95% CI 0.302-0.906) and posttest (Cohen $d = 0.602$, 95% CI 0.300-0.899) also showed good effect sizes.

Using the general linear model ANOVA between subjects to analyze the difference between the pre- and posttest scores as a dependent variable and the $n = 50$ group (the control and intervention CBT group) as the fixed factors, with the posttest assessment for burnout as the covariate, the descriptive statistics for the univariate analysis of variance showed a significant difference in the mean scores for the control group (mean 0.304, SD 2.085) versus the intervention CBT web-based group (mean 3.348).

The Levene test of equality of error variances tests the null hypothesis that the error variance of the dependent variable is equal across the groups. Burnout difference based on mean (Levene_{1,48} = 3.629; $P = .06$). Burnout difference based on median

(Levene_{1,48} = 2.354; $P = .13$). This fails the assumption; therefore, the null hypothesis can be accepted.

Tests of between-subject effects (Table 1) show that $F = 16.964$ and a significant difference between the control group and the web-based therapy group: $P < .001$ with an effect size or movement between the group variables or change of 0.261 or 26.1% for the dependent variable.

An independent-samples t test, with the difference in burnout scores between the groups, where the difference in score becomes the dependent variable and the group the fixed factor is presented in Table 2. Group statistics for the independent-samples t test using the difference in burnout scores as the dependent variable showed a large mean difference for the control group (mean 0.3040) and the web-based therapy group (mean 3.3480). This is confirmed when the equal variances assumed are calculated using the Levene test for equality of variances ($F = 3.629$; significance = .063; t_{48} test = -0.4.119; $P < .001$; CI -4.5299 to -1.5580).

Table 2 shows a clear burnout difference between the control group and the intervention group.

Table 1. Tests of between-subject effects shows a 26.1% difference between the groups (dependent variable: burnout difference).

Table 2. Burnout difference between the control group and the intervention group (N=50).

Burnout difference	Participants, n (%)	Values, mean (SD)	Values, SE
Control	25 (50)	0.3040 (2.08536)	0.41707
Web-based therapy	25 (50)	3.3480 (3.05070)	0.61014

Reliability

Cronbach α was used to measure the internal reliability, where a Cronbach α of $\geq .70$ is considered acceptable, Cronbach α of $\geq .80$ is considered good, and an Cronbach α of $\geq .90$ is considered excellent. The coefficient α for international reliability showed good results (N=50; Cronbach α = .858; mean 1.826, SD 3.008; Cohen *d* = 0.607; *P* < .001).

Internal Validity Using Discriminant Statistics

The discriminant validity showed significant reliability and validity. Predicted group membership between the control group and the therapy group classifications was conducted on the pretest and posttest assessments for burnout and three EFP assessments—stress, motivation, and anxiety, as follows:

1. Pretest (78% of original grouped cases were correctly classified; effect size=0.733; Wilks lambda=0.711; *P* < .003). Subject matrix function pooled within-groups correlations between discriminating variable and standardized canonical discriminant functions the variable ordered by absolute size of correlation within function shows the following: stress pretest assessment <0.023, motivation pretest assessment >−0.281, anxiety posttest assessment >0.520, and burnout >0.423. Functions at group centroids functions shows the control group

at −0.625 and the web-based therapy group at 0.625. There were no mission or out-of-range variables.

2. Posttest (70% of original grouped cases were correctly classified; effect size=0.682; Wilks lambda=0.784; *P* < .02). Subject Matrix function pooled within-groups correlations between discriminating variable and standardized canonical discriminant functions the variable ordered by absolute size of correlation within function shows the following: stress posttest assessment <0.814, motivation posttest assessment >−0.668, anxiety posttest assessment >0.495, and burnout >0.598. Functions at group centroids functions shows the control group at 0.514 and the web-based therapy group at −0.514. There were no mission or out-of-range variables.

External Validity

An external construct validity question was asked after the pretest EFP and posttest EFP assessments. This study aimed to establish whether the measured results corresponded to how they felt at that point. All participants (the web-based therapy group and the control group) were asked to accurately validate (0-100) how they really felt in relation to the assessment results. All participants answered both validation questions, resulting in a (median=0.95 or >0.9414) construct validity for the pretest and a >0.9420 for the posttest (Table 3).

Table 3. Frequency table showing content validity results where each employee validates and confirms the accuracy of their assessed results to how they feel. A visual analog scale (VAS) is presented to the assessed employees, and they are prompted online to validate their scores. This is done during the web-based session with their counselor. The accuracy (validity) and correctness of the assessment measures for both preassessment for burnout (0.9414) and postassessment for burnout (0.9420) showed excellent content validity.

Discussion

Principal Findings

The proverb “prevention is better than a cure” cannot be truer in the case of employee burnout. All individuals within this construct were affected by it. It is well proven that burnout can destroy a person’s ability to engage in work and life [4,14]. Burnout affects productivity within the workplace and directly affects company presenteeism rates [5]. Low productivity rates can also be correlated with employee defense routines [13,51].

Companies spend billions of US Dollars on preventive maintenance each year in efforts to maintain their physical machinery and equipment but very little on preventing unseen personnel burnout. Similar to machines that break when a part is not changed in time, productive employees experience burnout when their need to recharge is ignored [14,17,53]. In a *Harvard Business Review* article “1 in 5 Employees Is Highly Engaged and at the Risk of Burnout,” Seppälä and Moeller (2018 [54]) described how a company’s most important resource, their highly motivated employees, are at risk for burnout. These motivated employees are the ones that you repeatedly turn to, because they are dependable and efficient, and they always do the work. This affects work, colleagues, teamwork, innovation, creativity, and company continuity. Stress, anxiety, and psychosocial risks are widely recognized as major challenges to occupational health and safety, and these include stress, anxiety, depression, and burnout, which are all engagement killers that cost companies more than US \$1 trillion annually [4,5,13,14,55].

As time and space continue to implode, companies increasingly depend on highly engaged employees. A company’s drive to increase output not only drives them to turn a blind eye to the needed or required employee maintenance but they also tend to ignore, all so frequent, signals by reframing those signals into

resilience training to further increase the output of their highly engaged workers. Companies literally play Russian roulette with the mental health of their most valued employees.

Addressing this problem requires the same discipline as your car service or any other scheduled maintenance. When an engine signal light comes on in your car, you take your car in for service. If you show signs of any risk for burnout, you should also take yourself in for tune-up or service. Preventive maintenance requires good tools to measure tolerances, deviations, and acceptable levels to operate sustainably. Unfortunately, today, there are many fancy-looking well-being or mental health apps on the market with 0 validity and reliability. Their flashy content looks good and they cost almost nothing in return, and as the old saying goes, “you get what you pay for” cannot be more from the truth. It is easy to provide a simple PDF one-page problem analysis without providing a solution or services to support companies in their preventive efforts is another whole story.

It has been shown that preventive and proactive treatment can reduce a person’s risk of burnout, and the chances that the differences occur through random error alone cannot be considered. This study found a statistically significant difference, showing that web-based therapy reduces the risk for burnout.

If used correctly, coaches, therapists, psychologists, and medical personnel can effectively reduce costs by proactively engaging with clients. The benefits of using the My-E-Health approach with the EFP batch mean that intervention can begin at an early phase when psychosocial challenges are in their infancy. This alone will reduce both the cost and effort needed to prevent the “slippery slope effect” into work-related burnout, as well as an individual’s personal pain.

Nevertheless, this full-service method can be used to proactively measure, identify, and treat other mental health challenges, such

as anxiety, depression, and posttraumatic stress disorder. Therefore, broader use of the EFP batch as a measure of psychosocial situational well-being is highly plausible.

Limitations

The study was registered in ClinicalTrials.gov on April 25, 2022, and not preregistered, as it was already approved by the Swedish Regional Ethics Committee in 2017; therefore, the authors do not see this as a limitation, but some might. Although there was an acceptable sample size of $N=50$ with an effect size of Cohen $d=0.607$, larger sample sizes are always desirable in clinical studies. In addition, published materials related to the prevention and rehabilitation of burnout are a limiting factor; however, this can be seen as an opportunity for clinicians and researchers to assess the clinical effectiveness of early identification and rehabilitation in future studies.

Conclusions

Although there are many internet-based intervention studies on stress-related issues, few have addressed burnout. This original study suggests the effectiveness of web-based intervention therapy in reducing the impact of burnout in the workplace. It

also provides good evidence for the use of web-based tools in prevention and early identification to measure company exposure and the risk of employee burnout. The EFP batch of web-based assessments can reliably assess company morbidity risk levels and successfully measure clinical interventions and rehabilitation, thereby reliably serving as both a diagnostic and therapeutic tool worthy of major research in the future.

Web-based therapy is effective in reducing burnout. Reliability of the burnout measure was good (Cronbach $\alpha=0.858$; mean 1.826, SD 3.008; Cohen $d=0.607$; $P<.001$) as well as the instrument validity (0.9420). A paired samples test showed a good t score of 4.292 and $P<.001$, with a good effect size Cohen $d=0.607$.

Web-based therapy was effective in reducing the risk for burnout in participants compared with the control group. Tests of between-subject effects showed $F=16.964$ and a significant difference between the control group and the web-based therapy group: $P<.001$, with movement between the group variables or change of 0.261 or 26.1% for the dependent variable. Therefore, after controlling for pretest, is there a statistically significant difference between the levels of the independent variables?

Acknowledgments

Financial support for this study was provided by JAC International and Science College.

The authors would like to thank the University of Karlstad, Science College and My-E-Health for their participation and access to the materials used in this study.

Abstract

Background: Children with medical complexity (CMC) are a group of young people who have severe complex chronic conditions, substantial family-identified service needs, functional limitations, and high health care resource use. Technology-enabled hospital-to-home interventions designed to deliver comprehensive care in the home setting are needed to ease CMC family stress, provide proactive and comprehensive care to this fragile population, and avoid hospital admissions, where possible.

Objective: In this usability testing study, we aimed to assess areas of strength and opportunity within the DigiComp Kids system, a hospital-to-home intervention for CMC and their families and care providers.

Methods: Hospital-based clinicians, family members of medically complex children, and home-based clinicians participated in DigiComp Kids usability testing. Participants were recorded and tasked to think aloud while completing usability testing tasks. Participants were scored on the metrics of effectiveness, efficiency, and satisfaction, and the total usability score was calculated using the Single Usability Metric. Participants also provided insights into user experiences during the postusability testing interviews.

Results: A total of 15 participants (5 hospital-based clinicians, 6 family members, and 4 home-based clinicians) participated in DigiComp Kids usability testing. The participants were able to complete all assigned tasks independently. Error-free rates for tasks ranged from 58% to 100%; the average satisfaction rating across groups was $\geq 80\%$, as measured by the Single Ease Question. Task times of participants were variable compared with the task times of an expert DigiComp Kids user. Single Usability Metric scores ranged from 80.5% to 89.5%. In qualitative interviews, participants stressed the need to find the right fit between user needs and the effort required to use the system. Interviews also revealed that the value of the DigiComp Kids system was in its ability to create a digital bridge between hospital and home, enabling participants to foster and maintain connections across boundaries.

Conclusions: Usability testing revealed strong scores across the groups. Insights gained include the importance of tailoring the implementation of the system to match individual user needs, streamlining key system features, and consideration of the meaning attached to system use by participants to allow for insight into system adoption and sustainment.

Introduction

Background

Children with medical complexities (CMCs) have a significant disease burden, including neurological impairment and organ dysfunction [1]. Medical advances have led to many CMC living longer than would previously have been possible with the added support of technologies such as ventilators and feeding tubes [2]. International epidemiological data indicate that CMC commonly constitute <1% of all children in a given population [1,3,4]; however, Canadian data show that this fraction of the population accounts for up to one-third of pediatric health-related expenditures [1]. Within the current care model, CMC have, on average, 5 or more inpatient hospital stays per year, with a median of 38 days [5]. In addition to the expertise of their acute care hospital teams and specialists, families of technology-dependent CMC often require specialized home care nursing [6]; however, health professional support for this population is fragmented in terms of home and specialist care, with considerable variation in the provision of these services by region. Many regions lack adequate numbers of specialized pediatric home care nurses trained to care for CMC, and specialist care is often episodic, separated geographically from hospital and home care, and lacks integration in terms of communication and documentation with other care systems [6,7].

To reduce poor outcomes such as unmet health care needs as well as emergent and repeated hospitalizations of CMC, care models are needed that emphasize care coordination (organized care with a clear division of responsibility [5]), timely access to urgent care, and a focus on proactive, comprehensive care, as opposed to care that is reactive and episodic [8]. In other complex populations such as frail older people and adults coping with cancer, hospital-to-home models of care using technology-enabled digital health care systems have successfully been used to decrease unmet health needs and unplanned hospitalizations [9,10].

Although technology-enabled digital health care systems can theoretically help bridge the gap between hospital and home and improve outcomes in CMC, this area remains largely underexplored for this population. Despite the relatively low number of studies in this area, research has shown promise in easing the burden of care on CMC families and reducing poor outcomes such as reducing urgent and in-person health care delivery. For example, preliminary data from a virtual hospital-to-home intervention for CMC consisting of vital sign monitoring and virtual communication with a hospital-based clinical team showed a 42% reduction in emergency department visits per patient per month and a 26% reduction in inpatient admissions, with a 95% patient satisfaction rating [11]. Another virtual intervention program involving unrestricted access to a specialist health care team for parents of CMC via telephone, email, telemedicine, and in-person consultations demonstrated an increase in total health system encounters but a decrease in in-person home and clinic care [12]. These early studies demonstrate that virtual care models can indeed improve outcomes for CMC; however, the lack of scalable, standardized

virtual care models, despite these promising results, suggests that a deeper exploration of factors influencing adoption, scalability, and spread is warranted.

Usability Testing

Usability testing studies assist in understanding the interactions between people and technology to investigate the ease of use, learnability, and perceived benefits and challenges of novel systems according to diverse end user groups (those for whom a technology or product is ultimately designed) [13]. The granularity of these studies provides detailed usability information that informs larger concepts such as intervention adoption, scale, and spread. The metrics of effectiveness, efficiency, and satisfaction are widely accepted as important components in the composite concept of usability and should be incorporated into usability measurement and reporting [14]. In addition, qualitative user experience data provide valuable insight into user behaviors, perspectives, needs, and desired outcomes from technology systems, helping to inform the relevance and acceptance of the technology by end users [15]. In this study, we aimed to investigate the usability of a virtual hospital-to-home health system for CMC and their families, called DigiComp Kids (Cloud DX technology).

DigiComp Kids Intervention

The DigiComp Kids intervention uses the Cloud DX Connected Health System and consists of a hospital clinician portal and a home-based kit designed to communicate with one another. The hospital clinician portal is intended to enable hospital-based clinical teams to review biometric data and health information submitted by families and home-based clinicians as well as to send health information to home-based kits to facilitate home-based care management decision-making. Hospital-based clinicians can review submitted patient vital sign measurements, photos, and survey responses; configure individual vital sign parameters and alerts for each patient; send and receive secure messages with family members and home-based clinicians; send health-related documents to families and home-based clinicians such as care plans or medication schedules; schedule and initiate video calls with families and home-based clinicians; and document patient care information directly within the hospital clinician portal. The home-based kit is intended for use by CMC family members and their home-based clinicians to transmit biometric data and health information to hospital-based clinical teams as well as to receive health information sent by hospital-based clinical teams. Components of the home-based kit include a Samsung tablet, a Bluetooth-enabled pulse oximeter with heart rate monitoring capabilities, and a dual tympanic-temporal infrared thermometer. Kit components facilitate remote monitoring of biophysical parameters such as body temperature, heart rate, oxygen saturation, and respiratory rate (manual measurement); submission of responses to health-related monitoring questions; direct upload of photos to the cloud-based patient chart; real-time connection with hospital-based providers via video link and secure text messaging; and virtual appointment scheduling.

The DigiComp Kids system was designed with hospital-based clinicians, CMC families, and home-based clinicians to allow for comprehensive team-based care for CMC in the home

setting. Details of the design methodology are available in detail in a previously published manuscript [16]. The aim of the DigiComp Kids system is to connect hospital-based clinical teams with CMC families and their home clinicians to proactively monitor CMC health needs and respond to them in a timely manner. By better connecting families with home- and hospital-based clinicians, the DigiComp Kids system has been designed to facilitate safe care at home for CMC.

Objectives

The objective of this usability testing study was to assess areas of strength and opportunity within the DigiComp Kids system according to hospital-based clinicians, medically complex children and their family members, and home-based clinicians. During this early formative stage, the results from this usability testing study will assist in making further improvements to the DigiComp Kids system during the preclinical implementation phase.

Methods

Ethics Approval

The Hamilton Integrated Research Ethics Board (HiREB Project #8324) approved this study. All participants provided informed consent before engaging in usability testing.

Setting, Recruitment, and Participant Groups

Usability testing took place entirely virtually because of the need for physical distancing and research regulations in place during the COVID-19 pandemic. In usability testing studies, the engagement of 4 or more participants per group is typically sufficient to detect >80% usability problems [17]; thus, we recruited 6 family members, 4 home-based clinicians, and 5 hospital-based clinicians, for a total of 15 usability testing participants. All participants resided in Southern Ontario, and usability testing was conducted between November and December 2020.

Hospital-based and home-based clinicians were recruited via the networks of various members of the study team (MB, NC, AL, MHM, and SR). Emails were sent to distribution lists and individual contacts known to be working with CMC in either hospital or home settings. The included clinicians spoke and read English, had at least 3 months of experience caring for CMC in hospital or home settings, and provided informed consent to participate. Hospital-based clinicians included a system navigator, complex care nurse practitioner, and 3 registered nurses working with CMC populations. Home-based clinicians included registered nurses and a registered practical nurse working directly with CMC in home settings as well as a clinical nurse specialist whose role is to support the provision of home care by offering remote clinical support.

Family participants were recruited by a clinical member of the study team (AL) and a CMC family partner on the study team (SR). The included family participants lived in the Southern Ontario area, had a child that met the definition of medical complexity [18], spoke and read English, and provided informed consent for both themselves and their child to participate. In

this study, all recruited family members were mothers of medically complex children.

Procedures

Our usability testing procedure incorporated both quantitative and qualitative measures via standardized usability testing and individual participant interviews to capture user effectiveness, efficiency, satisfaction, and user experience.

Training

Overview

All participants received DigiComp Kids intervention training using the Connected Health System through a dedicated virtual session. Before training, participants received either an at-home Connected Health System kit (family members and home-based clinicians) or access to the hospital Connected Health System clinician portal (hospital-based clinicians) as appropriate. All participants also received an electronic standardized training manual developed by the lead author of this study (MB) to guide the training session. The purpose of the training sessions was to orient participants to the DigiComp Kids program using the Connected Health System and its features and to allow participants to navigate the system and ask questions. Participants were given a general background on the project and the way that the home- and hospital-based systems interact, before being specifically trained on the relevant components for their group, as detailed in subsequent sections.

Hospital-Based Clinicians

Hospital-based clinicians were trained in the use of the hospital clinician portal. Training was guided by a standardized training manual that clinicians could refer to as needed throughout the training and testing sessions. Training topics included patient vital sign alert management and configuration; communication with families and home-based clinicians via secure chat messages and video calls; patient home-based care scheduling, including changes to care plans, medications, and required data entry from families or home-based clinicians; and direct documentation within the cloud-based platform. All tasks were demonstrated by the trainer (MB) via remote screen sharing, and participants were subsequently given the opportunity to practice tasks to solidify their information retention and application.

Families and Home-Based Clinicians

CMC family members and home-based clinicians were trained in the use of the at-home DigiComp Kids kit. Practice kits were delivered to family and home-based clinician participants before training. Similar to the hospital-based clinician training, home-based training was guided by a standardized training manual provided to participants for their use throughout the training and testing sessions. Topics for participant training included tablet log-in and setup; sending and receiving secure chat messages; viewing and undertaking scheduled vital signs assessments, photos, and surveys; and locating shared documentation such as care plans and medication orders. Participants were guided through tasks by the trainers (MB and NK) over video and were encouraged to follow along and participate with their kits before the testing session took place.

Testing

Testing for all participants was scheduled either immediately following or as soon as possible after the training sessions within a few days. All testing sessions were audio-visual recorded using videoconferencing software to facilitate the review and scoring of usability testing sessions at a later time.

Hospital-Based Clinicians

Following the training session, hospital-based clinicians participated in an individual virtual testing session facilitated by a moderator (MB). Testing sessions began by reminding the participants that usability testing was intended to test the DigiComp Kids system and approach usability training and not their performance or abilities as clinicians. Participants were given an opportunity to ask questions and were reminded that there would be a scheduled break during testing, but that they could request additional breaks at any time.

Next, participants were asked to think aloud during usability testing. Thinking aloud involves participants concurrently performing a task while verbalizing what comes to mind during the performance of that task [19]. The purpose of thinking aloud is for the moderator to gather relevant data on specific issues of usability, such as system navigation issues, areas of frustration or obscurity, or confusion around the workflow when using the system.

Hospital-based clinicians were asked to complete a series of usability testing tasks guided by a standardized testing protocol. Tasks within the protocol represented the core competencies for the hospital clinician portal, including locating patient information; responding to changes in patient vital signs; and communication, documentation, and scheduling of patient tasks such as surveys and video calls. Usability testing tasks for hospital-based clinicians are listed briefly in [Textbox 1](#) and in further detail in [Multimedia Appendix 1](#).

Textbox 1. User testing tasks for hospital-based clinicians.

Tasks

- Task 1: Verbalize vital signs readings and any generated alerts for last assessment
- Task 2: Change Emma's heart rate parameters from 0 (low) to 80 (high) bpm to 90 (low) to 130 (high) bpm
- Task 3: Request a video call with Emma's family
- Task 4: Add a note to the oxygen saturation reading from this morning
- Task 5: Add assessment to chart with actions taken
- Task 6: Schedule a video call with Emma's family in 4 hours
- Task 7: Change Emma's risk stratification to "medium"
- Task 8: Change the "Wellness Survey" from being sent once weekly to being sent every day for 5 days
- Task 9: Send a chat message to Emma's family

To add realism to the usability test, the participant tasks were conducted in the context of a simulated patient case. The fictional patient used for this case was a 2.5-year-old girl diagnosed with spinal muscular atrophy type 1, named Emma. Participants were introduced to Emma as their patient and provided clinical information on her condition, such as her main clinical issues (generalized low muscular tone and respiratory impairment) and the technical support used (portable oxygen and suction machine) to maintain her well-being at home. At prespecified time points, hospital-based clinicians were given new information about their patient case to indicate the progression of the patient scenario over time. Participants were asked to respond to information and updates on their patients given by the moderator throughout the testing process by following the clinical protocols that were taught during their training session. Further details of the patient are available in [Multimedia Appendix 2](#).

Families and Home-Based Clinicians

CMC family members and home-based clinicians each participated in an individual usability testing protocol facilitated by a moderator (MB or NK). Think-aloud procedures were explained to the participants, as described earlier, and all

participants were given the opportunity to ask questions before beginning their testing sessions. In contrast to the hospital-based clinician participants, usability testing sessions for family members and home-based clinicians did not take place within the context of a patient case but rather focused on undertaking day-to-day tasks related to caring for CMC using the DigiComp Kids home-based technology kit. During these sessions, family members and home-based clinicians were invited to imagine the use of a home-based technology kit with a medically complex child to which they provided care. For realism, family members were also given the option of applying peripheral vital sign devices (eg, pulse oximeter and thermometer) to their children, depending on their comfort level. The content of home-based clinician and family member usability testing sessions focused on device setup and log-in, peripheral vital sign device application and use, submission of clinical information such as responses to survey questions and photos to a simulated hospital-based clinical team, location of information sent by a simulated hospital-based team, and determination of required daily tasks using the scheduling function. Usability testing tasks for home-based clinicians and family members are listed briefly in [Textbox 2](#) and in further detail in [Multimedia Appendix 3](#).

Textbox 2. User testing tasks for family members and home-based clinicians.

Tasks

- Task 1: Set up and turn on the tablet
- Task 2: Log-in to the tablet
- Task 3: View and interpret pending measurements and surveys using red asterisk
- Task 4: Complete or describe temperature measurement
- Task 5: Complete or describe oxygen saturation measurement
- Task 6: Complete and submit Wellness Survey
- Task 7: Find and read out the up-to-date list of child’s medications
- Task 8: Take and submit a photo using the tablet

Interviews

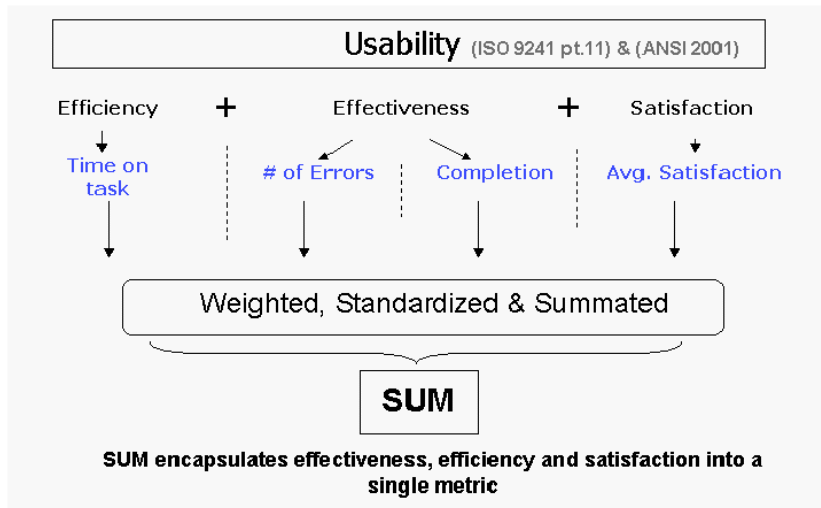

Immediately following the individual testing sessions, each participant was interviewed about their experience of participating in DigiComp Kids usability testing. The purpose of the qualitative data collection in this study was to improve our understanding of the usability of *DigiComp Kids* by triangulating quantitative usability metrics with user experience data from interviews [20,21]. A semistructured interview guide was developed using constructs from a holistic framework to improve the uptake and impact of eHealth technologies [21]. Specifically, the constructs used to guide the interview questions were those of “technology”—the hardware and software comprising the DigiComp Kids system; “people”—the participants themselves and other individuals specified by the participants; and context—the social, cultural, and physical

environment in which the system is situated [21]. Across these categories, questions were designed to solicit areas of ease, frustration, and future improvement. Probing questions were used to encourage elaboration and clarification of participants’ responses where needed. Interview sessions were audio recorded using videoconferencing software. The interview guide can be found in [Multimedia Appendix 4](#).

Measures

Usability is a composite measure comprising task completion, error rate, task time, and satisfaction score metrics [22]. Each of these measures was collected for each task that a user attempted during DigiComp Kids usability testing, with the goal of combining these measures into a Single Usability Metric (SUM) or SUM score [22] (Figure 1).

Figure 1. SUM model (reproduced from Sauro and Kinlund [22]). SUM: Single Usability Metric.

Task completion, error rates, task times, and satisfaction were calculated and standardized following the methods detailed by Sauro and Kinlund [22]. Task completion scores represented the ratio of successful task completion by participants to task attempts. Error rates were computed by dividing errors committed by the task error potential (number of participants multiplied by the number of subtasks per task) to account for multiple possible errors committed by the same participant on the same task. This value is subtracted from one to calculate the error-free rate, enabling it to be combined with other

usability metrics into a summative score [22]. Task times and satisfaction scores were standardized by computing Z scores. To achieve this, a specification limit was set to represent an acceptable score. The specification limit for task time was the time it took an expert user to complete the task, multiplied by 1.5 [23], and for satisfaction, a value of 5.6 was used on the 7-point Single Ease Question satisfaction scale [24,25]. Detailed formulas for the usability measures can be found in [Multimedia Appendix 5](#) [22-25].

Data Management and Analyses

Quantitative Analysis

Microsoft Excel [26] v 16.3 was used for all quantitative statistical analyses. Descriptive statistics were used to summarize participants' demographic data, child diagnostic information (family members), and professional work experience (clinicians).

In addition to reporting usability metrics by user group and task, Sauro and Kinlund [22] demonstrated that the constructs of efficiency, effectiveness, and satisfaction can be represented using a single SUM. Using SUM, usability as a construct is represented as a single score, making it intuitive to interpret without sacrificing the precision of using all 4 variables [22]. To construct the SUM, standardized metrics (task completion, error rates, task satisfaction, and task times) were averaged to create a single, summated score. This single score represents the overall usability of the DigiComp Kids system, equally weighted for the metrics of task completion, error rates, satisfaction, and task times.

Qualitative Analysis

Audiotaped interviews were transcribed verbatim, and the lead author (MB) proofread the transcripts to ensure accuracy. A qualitative descriptive approach was used to analyze the data. Initially, the 3 transcripts were read several times by 3 authors with qualitative training (MB, NK, and NC) before meeting to develop a coding scheme. The coding scheme was developed deductively using theoretical concepts from a holistic framework, including technology, people, and context [21]. This initial coding scheme was used to independently double-code 4 transcripts (MB and NK or MB and NC) using the Dedoose data management software and thematic analysis techniques [27,28]. Team members met to discuss preliminary findings and refine the coding structure. The remainder of the

transcripts was coded by one author (MB or NK), and the authors met to discuss emerging themes.

Multiple measures were used to maintain rigor during the qualitative analysis. First, 1 author (NC) with qualitative expertise guided the qualitative data collection and analysis processes, approving methodological decisions before they were carried out. Second, all authors involved in the qualitative portion of the project (MB, NK, and NC) met weekly during the qualitative analysis process and were contacted via email between meetings to review the progress and discuss methodological issues. Process meetings were particularly helpful when major methodological milestones were encountered, for example, when defining and refining the code tree or when developing emerging themes. The process of peer review and triangulation of ideas helps establish confirmability in decisions [29]. Finally, a detailed audit trail was kept throughout the analysis process, documenting reflexive memos, meeting notes, coding and thematic decisions, and methodological processes.

Results

Demographics

Hospital-Based Clinicians

A total of 5 hospital-based clinicians participated in usability testing using the clinician portal (Figure 2). All participants were female, and the majority were employed full time and educated at a bachelor's or graduate degree level. One participant was identified as a system navigator, and the rest were registered nurses or nurse practitioners. The average length of clinical practice among participants was 12 years, with 5 years practicing in CMC populations. The hospital-based clinician's demographic variables are presented in Table 1.

Figure 2. Clinician portal.

Complex care	3 (60)
Length of clinical practice (years), mean (SD)	12 (10.6)
Length of clinical practice with complex populations (years), mean (SD)	5 (2.3)

Family Members and Children

A total of 6 family members participated in usability testing using the Connected Health Kit (Figure 3). Overall, 4 CMC participated in usability testing with their family members, and 2 family members simulated usability testing tasks because their children were unavailable during the testing time. All participating family members were female, and most were White and married. Most family members were educated at university

level and working full time or on leave. The experience level of family members using tablet technology was evenly distributed from “somewhat experienced” to “expert.” The medically complex children of family members in this study were mostly male and White and aged between 2 and 7 years. CMC had 4 to 6 diagnosed chronic conditions and relied on a wide range of assistive technologies for support, as presented in Table 2.

Home-Based Clinicians

A total of 4 home-based clinicians participated in the usability testing. All home-based clinicians were White women who were employed in contract or part-time positions by community

agencies or CMC families. The average length of clinical practice among participants was 14 years, with 12 years spent practicing CMC populations. The demographic characteristics of home-based clinicians are presented in [Table 3](#).

Table 3. Home-based clinician characteristics.

Home-based clinicians (n=4)	Values
Gender (female), n (%)	4 (100)
Ethnicity (White), n (%)	4 (100)
Role, n (%)	
Registered nurse	2 (50)

Task 8	1.00	0.58	0.6554	0.2420	0.6202
Score, mean (SD)	1.00 (0)	0.8987 (0.172)	0.8058 (0.160)	0.5122 (0.298)	0.8057 (0.136)

DigiComp Kids usability testing revealed strong usability across end user groups with respect to task completion, errors, end user satisfaction, and task time. The average total SUM for hospital-based clinicians was 89.53%; family participants scored 86.81% across tasks, whereas home-based clinicians scored 80.57%. In terms of the individual score components, participants in all groups achieved task completion scores of 100%. Error rates varied (range 58%-100% error free), with participants achieving perfect scores across some tasks, whereas other tasks proved more complex and drew many errors. In general, participants committed more errors on tasks in which more steps were required to complete them (eg, task 8 for hospital-based clinicians). Participant satisfaction, as measured by the Single Ease Question, was generally high, with all groups, on average, reporting satisfaction scores of 80% or higher. A direct positive correlation was observed between the error-free rates and satisfaction scores. In general, simpler tasks (ie, those with fewer error opportunities) were more likely to be completed error free than more complicated tasks, and those tasks that were completed without errors by participants had higher satisfaction scores than those in which participants committed many errors. Task times varied across groups and were consistently the lowest scores of the 4 usability measures.

Qualitative Findings

Thematic analysis of qualitative interview data generated 5 themes: fostering and maintaining team connections across

boundaries; finding the right fit between user needs and required effort; improving system efficiencies and eliminating redundancies; making the system work in daily life; and reflecting on current and future technology needs.

Fostering and Maintaining Connections Across Boundaries

An important value highlighted in the co-design process for DigiComp Kids was that the system should aim to foster a sense of cohesion and connection between hospital-based clinicians, families, and home-based clinicians. During qualitative interviews, this aspect of the DigiComp Kids system was touched on by 12 of 15 participants, highlighting its importance. For example, 1 parent participant relayed:

Like, we were going to have an NG tube and we were going to come home with it and like having someone to walk us through, like doing those kinds of things that freak me out right now. I don't want to do that... I don't have the confidence of me to be listening to see if it went in. But if that [video call] was a possibility that would like totally ease my stress, like if she pulled out an NG tube that it would, um that somebody would be there to walk me through it.
[Parent 002]

For this participant, the possibility of remotely connecting with a clinician meant easing her stress while performing the procedure for her child at home. Similarly, hospital-based

clinicians agreed that connecting with families at home would enable them to play a more supportive role for the child and the family:

I think that this also provides reassurance to families when they're calling clinicians or emailing clinicians and they're unsure of when they're going to get a response. It might make families feel better. Even when it's an initial discharge say from the NICU and a technology dependent kid and there's a lot of anxiety on whether they'll be able to reach clinicians or whether they live really far away geographically. They'll have this one-on-one support depending on the hours. [Hospital 012]

For families and care teams situated in different geographic areas, having access to a communication channel via a remote system can help break down boundaries and facilitate team cohesion and support.

Finding the Right Fit Between User Needs and Required Effort

Family members and hospital-based clinicians spoke of the need for the DigiComp Kids system to be implemented using flexible protocols that allow users to titrate their use of the system up or down as needed. Family members commented that CMC has labile medical conditions, resulting in a continuum of disease severity and subsequent health needs, depending on the manifestation of their conditions. The participants commented that the right fit between the user and the system would need to be struck to balance daily user requirements with self-identified user needs. One family member shared the importance of making the tool worthwhile to use:

Adding in another thing as another day-to-day task, that kind of seems like a bit much. If it was a point of time where we were trying to track something or a point where we were trying to wean him off the vent and we really wanted to zoom in on something, some numbers, I could see it being a daily thing... I'm trying to think of how it would be used as more tool rather than another chore, task to do with a complex kid. [Parent 001]

Similarly, another family member spoke of the need for system use to add value to their lives as a motivation to adopt the system:

But having the unit open and on every day, unless it's for a specific reason, it sounds really selfish but I feel like we would just open and use it if we needed something dealt with, not just so the team could find information of how normal our day is going. If that makes sense? [Parent 002]

The fit or balance of required effort versus user needs was touched on by most participants as an important factor in whether they could envision adopting the DigiComp Kids system as part of their daily care routine.

Improving System Efficiencies and Eliminating Redundancies

In terms of improving system efficiency and eliminating redundancies, 5 participants spoke to the potential for the DigiComp Kids system to streamline and accelerate the timing of communication between clinicians. Using DigiComp Kids to enable multiple clinicians to view real-time patient data and communicate necessary changes in a timely fashion was seen as an important care improvement. For example, 1 home care clinician said:

Because [the hospital-based clinicians] are able to end up getting changes right away... rather than, for families what they would do is they would call the hospital, that they would page someone and then depending on how busy the person, [or] the team is, sometimes it takes a bit longer to answer that call or get back. [Home care 007]

The DigiComp Kids system was seen as a strategy to accelerate necessary changes to care plans by allowing families, home-based clinicians, and hospital-based clinicians to view data in real time as patient changes are taking place. Other important factors for streamlining communication that arose in the interviews were ease of access to information and system interoperability, as detailed by the following participant:

I think this is so great. Honestly if everyone could just use this and have access to this, everyone's life would be so much easier. Nurses, specialists, complex care teams, homecare, like I do not understand why we we're are on so many different platforms for one patient. [Home care 009]

Finally, participants also pointed out areas for improvement in the DigiComp Kids system that would further improve its usefulness with regard to streamlining team communication and work processes. For example:

When you have interdisciplinary groups, you're like well I need this person to be able to address this issue and they might not be present at the time. I think that's always the challenge in team communication, trying to get messages to people and you know in hospital, it's like flagging charts and paging. So, if there was some way to flag people, that we need their attention, that would be really useful. [Hospital 011]

Participants contributed important insights with respect to the context in which the DigiComp Kids system would be implemented and made suggestions on how the system could be further optimized to enable efficiency and eliminate redundancies.

Making the System Work in Daily Life

The fourth theme generated from the participant interviews was "Making the system work in daily life." Facets of this theme include envisioning how the DigiComp Kids system would fit into daily workflows for families and clinicians as well as the practicality of using the system in real life. For example, parents spoke of the advantage of using the DigiComp Kids system to

provide a thorough report and history of the child to different care providers:

And the more I kind of say it, the more excited I get about the idea of having it on my phone. Because even just pulling up, you know going to an appointment or having to go to the hospital or even just in a complex care appointment, being like, this is what he's currently doing. This is our history, our results history. Or I've taken subsequent pictures, check out this camera roll of all of the things I've documented for you. [Parent 003]

This parent envisioned using the system as a “one-stop” documentation hub that would be accessible from their phone to share with different health care providers. Similarly, hospital-based clinicians spoke of envisioned positive changes in their workflows while using the system.

I think the live feature of chats, of getting notified when things are happening in the home is fantastic in comparison to our regular phone call where a message is left or an email where a message is left. And you only get to it at the end of the day. Whether clinicians get notified during these events that are occurring. I think it's great. [Hospital 012]

Streamlining workflows to enable families and clinicians to easily access information and engage in real time with each other was viewed as a potential advantage of the DigiComp Kids system. These real-time connections were discussed as having the potential to facilitate proactive patient care and earlier intervention in case of patient deterioration. Finally, participants again assisted in contextualizing the proposed workflows for the intervention and identifying the necessary backups and safeguards in case of unforeseen issues:

The other thing would be a power failure, if you like potentially were working in an environment like, you'd have to have a back-up. Like if it did work for your routine documentation, you'd have to have a protocol for all your back-up um, documentation. But I guess just if you don't have working power or working internet or data, I guess through the iPad then it may not function properly. [Home care 008]

Reflecting on Current and Future Technology Needs

The fifth and final theme generated from the interview data was participant reflections on how DigiComp Kids might fit with their current and future technology needs. One home care nurse highlighted how the DigiComp Kids system might enable families and clinicians to have a clear understanding of disease progression to enable proactive care planning:

I think the result dashboard probably would be helpful so that we can see changes over time. I'm thinking like specifically if they have some sort of progressive disease or something that affects let's say their breathing and their respiratory system. I think it would be helpful to those numbers over time and allow people to make decisions based on those numbers. [Home care 010]

The DigiComp Kids system tracks and trends patient disease progress over time, enabling families and care providers to accurately understand current needs and forecast anticipated future needs. Importantly, the system can do this without adding additional charting for families who are already busy taking care of medically complex children. One parent commented:

I do a really bad job of tracking things. And so, having something that kind of does it for me and keeps it all together in one spot. We're one of the few families that choose not to have nursing, so I don't even have nursing charts. So, if somebody were to ask me... I can tell you what his normal oxygen levels are, and his normal heart rate is because I see it every night. But I have no idea what his blood pressure is or anything, not a clue. Because we don't have nursing and I just don't keep track. [Parent 005]

Ongoing tracking of disease progression was deemed an important part of providing anticipatory and proactive care, ultimately benefiting medically complex children, their families, and health care providers alike.

Discussion

Principal Findings

This study was conducted to assess the usability of the DigiComp Kids intervention using the Cloud DX Connected Health System. By conducting usability testing, areas of strength and opportunity can be identified in virtual health innovations before large-scale clinical implementation.

The DigiComp Kids intervention using the Connected Health System attained high usability scores across groups, with SUM scores achieved by hospital-based clinicians, family participants, and home-based clinicians placing them in the 97th, 93rd, and 80th percentiles, respectively, in relation to SUM scores across all technology industries [30]. In addition, consistent with the definition of usability by Sauro and Kinlund [22], we noted a direct positive correlation between task error-free rates and task satisfaction.

Qualitative participant feedback highlighted favorable aspects of the DigiComp Kids system, such as its ability to connect home-based and hospital-based clinicians across geographic boundaries, to eliminate inefficiencies in care processes, and to encourage more proactive tracking of disease progress and planning for future needs. In addition, the participants assisted in contextualizing the intervention with regard to their daily lives and workflows, highlighting areas where the system could be further refined to improve the fit between user needs and system requirements.

Interpretation

The DigiComp Kids intervention outranked most reported intervention SUM scores across the technology industries. We hypothesized that part of our high usability scores stems from the DigiComp Kids intervention, which has been co-designed alongside hospital-based clinicians, family members of CMC, and home-based clinicians. By intentionally building the system with the needs of our end users in mind, the co-design process

may have contributed to the intervention achieving high SUM scores across the end user groups. Of particular interest is one component of the total SUM score, the task completion score, which was 100% across all usability participants. This score is well above the average task completion rate for technologies from usability literature, which is 78% [31]. It is possible that our task completion rates were falsely inflated due to user belief bias, whereby participants believed that the task they were being asked to complete in the simulated testing environment was indeed achievable and therefore tried harder to complete the assigned task than they might have in a real-life scenario [32]. Although we cannot determine whether user belief bias influenced our task completion scores, they should be interpreted with caution.

Qualitative interview data yielded insights beyond reflections on immediate usability testing procedures. As participants were questioned about the value of using the DigiComp Kids intervention in their daily lives, many responded by transcending their immediate circumstances, reflecting on what meaning the intervention would hold for them in the short term and long term. For example, some family participants were able to envision DigiComp Kids as part of their future daily lives, with their children in worse health than they were presently. The meaning of the system for these parents seemed to lie in its ability to create a digital bridge between hospital and home for families in need of support, either now or in the future. Evaluating the utility of a system by envisioning the role of technology in one's future circumstances is a view supported by the literature on digital technology adoption, in that users may change their perceptions of technology value and meaning over time as their circumstances change [33]. These findings highlight the need for those responsible for implementing technological innovations such as the DigiComp Kids system to interpret user feedback in context, paying particular attention to the meaning that participants place on technology in their present and future lives. Consideration of these user perspectives allows for insight into the factors that affect technology adoption, abandonment, or sustainment [34].

Comparisons With Prior Work

The results from DigiComp Kids usability testing using the Connected Health System built on previous usability studies by highlighting the critical roles of multimethod data collection in usability testing, consideration of the critical role of human factors, and the role of virtual health systems in connecting patients, families, and clinicians across traditional geographic barriers, as detailed below.

DigiComp Kids usability testing resulted in relatively high SUM scores across the end user groups. Despite this, the interview findings gathered from end users in our study assisted in identifying areas for improvement in the DigiComp Kids intervention. As emphasized by the DigiComp Kids study participants, the process of implementing virtual health interventions requires attention to be paid to the subjective needs of end users, together with the goals of the intervention and system requirements. These subjective needs are often best gathered using qualitative techniques, which help distill user experience data essential to assessing end user acceptance. This

finding aligns with the literature, in which subjective user needs gathered via qualitative techniques illuminate distinct and important insights into end user acceptance. For example, in a study on the comparative effectiveness of 3 virtual health media for communicating health information to parents, the authors found no significant differences in the knowledge retention or efficiency of parents using each of the 3 tools; however, subjective feedback revealed a strong preference for one tool over the other 2. Similar to the qualitative results generated by family members in DigiComp Kids, parents in this study desired a tool that was simple, trustworthy, efficient, and provided practical information on condition management [35]. These qualities were important to parents in this study and were found to influence parents' perceptions of the usability of different media, separate from quantitative metrics of usability that were collected [35]. This study highlights the importance of gathering both quantitative and qualitative information from end users, as each may offer different insights into end user preferences and overall usability. In our study, gathering qualitative experience data helped contextualize the intervention and raised issues for system improvement that otherwise may not have been uncovered until full-scale implementation.

A second important finding of the DigiComp Kids usability testing was the critical role of human factors in virtual health system usability. Human factors, or the ways in which people interact with technology, have a critical impact on the success of virtual innovations [36]. In our study, participants engaged in 2 tasks wherein icons or functions that they were required to access were hidden, either within another icon on the tablet or in a different section of the clinician's portal. For instance, in task 7 for family and home-based clinicians (find and up-to-date medication lists), the folder that participants were required to locate was hidden within another folder. Conversely, all other icons that the participants were asked to find were accessible through paths from the main screen. Similarly, when hospital-based clinicians undertook task 8 (changing the schedule of the Wellness Surveys to be sent to participants), they needed to navigate from the individual patient profile to the main hospital clinician portal before being able to access the survey scheduling function, whereas all other clinician tasks were accessible through the individual patient profile. These 2 tasks resulted in high error rates, and low satisfaction ratings were corroborated by frustration voiced by participants in the qualitative interviews. Similar results have been reported in other usability studies. For example, in a study in which the authors tested the usability of patient portals for parents of children with chronic diseases (ie, cystic fibrosis, diabetes, and arthritis) using scenario-based usability testing and think-aloud protocols, high error rates and low completion scores resulted when information was located in a different place than participants expected [37]. Similarly, a systematic review examining the usability of eHealth interventions for adolescents with juvenile idiopathic arthritis found that adolescents using an iPod touch to input pain data made more errors, required more time per task, and reported that the device had a lower satisfaction rating than either computer-assisted or paper-based data entry [38]. This direct relationship between system ease of use and task performance emphasizes the importance of

understanding human factors within formative usability testing procedures when innovating in the virtual health sphere [34].

Finally, of particular importance to DigiComp Kids participants was their ability to connect with remote clinicians in different geographic locations. In a similar usability study, McGillion et al [39] examined the usability of a postoperative hospital-to-home remote automated monitoring intervention and found that being able to connect remotely with care team members was invaluable, particularly for patients experiencing acute recovery. As was the case in our study, patient participants expressed a sense of security in knowing that a clinician would be able to monitor their postoperative progress and be reachable, should it be required [39]. Similarly, in a study evaluating an online symptom monitoring intervention for families of children with life-limiting illnesses, the authors reported increased parental empowerment over time in the study, demonstrating the value of digital technologies in supporting parents caring for their children at home [40]. This theme reinforces the important role that virtual health technologies can play in transcending traditional barriers to providing and receiving health care, such as physical location, while offering patients and families additional support in their home environments. This point may be particularly important for patients and families with frequent or intensive health care requirements, such as those with complex chronic conditions.

Limitations

One potential limitation of this study was the lack of diversity in the participant samples. All participants in this study were English-speaking females, and the majority were White. Although the prevalent groups included in this study (ie, primary caregivers for children and nurses) have historically been predominantly female, the inclusion of male participants may have yielded different results. The inclusion of non-English-speaking participants was not possible at the time of this study because of the limitations of the study team. In addition, family participants were well educated and at least “somewhat experienced” using tablet technology; thus, our results may not be reflective of family members with lower education or less experience with tablet computing. Although the objective of a usability testing study is not to generalize results to a broad population but to uncover areas of usability

strength and opportunities to make refinements, it is possible that the inclusion of a more diverse group of participants would have yielded different results and perspectives.

Another potential limitation of this study is that the collection of data related to the SUM metric and its components may have missed information that other scales capture. Our choice to collect data on effectiveness, efficiency, and satisfaction was guided by the accepted usability standards [14], which are well captured in the SUM. However, other scales, such as the Net Promoter score [41] and the Standardized User Experience Percentile Rank Questionnaire [42], capture data that we did not, such as participant ratings of trust and credibility of the intervention. We are confident that some of these data were captured in qualitative interviews; however, we did not collect quantitative data related to them.

Finally, the task completion rates across all groups were 100%, as presented in Tables 4-6. This may represent a user belief bias in our results, such that participants may be more likely to believe that the task they are being asked to complete is indeed achievable in a simulated testing scenario. Alternatively, because participants were trained in the DigiComp Kids system use immediately before usability testing, perfect task completion scores may simply represent increased training material retention by participants because of the short interval between training and testing times.

Conclusions

The implementation of virtual health system solutions for CMCs and their families is an important initiative in providing comprehensive care in the home setting. This usability testing study offered valuable insights into the preclinical implementation phase of the DigiComp Kids intervention using the Connected Health System. Examples of such insights include the importance of tailoring the implementation of the system to match individual user needs, streamlining system features in key areas to allow for intuitive system use with the fewest steps required to complete tasks, and investigating and considering the meaning attached to system use by participants to allow for insight into system adoption and sustainment. Taken together, these findings emphasize the importance of formative virtual health system testing to uncover challenges early and refine interventions to suit the needs of end users.

Conflicts of Interest

MHM is involved in several studies that Cloud DX provides in-kind support to, including the PVC-RAM trials, VERDICT, VERDICT-2 and VISION-2. The authors have no further conflicts to declare.

Abstract

Background: Artificial intelligence has provided new opportunities for human interactions with technology for the practice of medicine. Among the recent artificial intelligence innovations, personal voice assistants have been broadly adopted. This highlights their potential for health care-related applications such as behavioral counseling to promote healthy lifestyle habits and emotional well-being. However, the use of voice-based applications for behavioral therapy has not been previously evaluated.

Objective: This study aimed to conduct a formative user evaluation of Lumen, a virtual voice-based coach developed as an Alexa skill that delivers evidence-based, problem-solving treatment for patients with mild to moderate depression and/or anxiety.

Methods: A total of 26 participants completed 2 therapy sessions—an introductory (session 1) and a problem-solving (session 2)—with Lumen. Following each session with Lumen, participants completed user experience, task-related workload, and work alliance surveys. They also participated in semistructured interviews addressing the benefits, challenges and barriers to Lumen use, and design recommendations. We evaluated the differences in user experience, task load, and work alliance between sessions using 2-tailed paired *t* tests. Interview transcripts were coded using an inductive thematic analysis to characterize the participants' perspectives regarding Lumen use.

Results: Participants found Lumen to provide high pragmatic usability and favorable user experience, with marginal task load during interactions for both Lumen sessions. However, participants experienced a higher temporal workload during the problem-solving session, suggesting a feeling of being rushed during their communicative interactions. On the basis of the qualitative analysis, the following themes were identified: Lumen's on-demand accessibility and the delivery of a complex problem-solving treatment task with a simplistic structure for achieving therapy goals; themes related to Lumen improvements included streamlining and improved personalization of conversations, slower pacing of conversations, and providing additional context during therapy sessions.

Conclusions: On the basis of an in-depth formative evaluation, we found that Lumen supported the ability to conduct cognitively plausible interactions for the delivery of behavioral therapy. Several design suggestions identified from the study including reducing temporal and cognitive load during conversational interactions, developing more natural conversations, and expanding privacy and security features were incorporated in the revised version of Lumen. Although further research is needed, the promising findings from this study highlight the potential for using Lumen to deliver personalized and accessible mental health care, filling a gap in traditional mental health services.

KEYWORDS

voice assistants; behavioral therapy; problem-solving therapy; mental health; artificial intelligence; user evaluation

Introduction

Artificial intelligence (AI) has provided new opportunities for human interactions with technology for care delivery [1]. These include remote monitoring, mobile health apps (eg, chatbots), and the use of a wide variety of sensors for remote monitoring and surveillance. Of the recent innovations, personal voice assistants that rely on AI-based platforms such as Amazon's Alexa, Google Home, Cortana, and Siri have transformed how humans search for information, with recent reports suggesting that nearly 30% of search queries rely on voice-based input [2]. Broad adoption of such platforms lends support for their potential utility in health care-related applications such as behavioral counseling to promote healthy lifestyle habits and emotional well-being [3,4]. However, current health care-related applications of voice assistants are generally rudimentary, and few of them have been developed for delivering evidence-based therapies or have been subjected to careful evaluation (eg, to inform development or for their effect on clinical or behavioral outcomes) [5]. To this end, we developed and evaluated Lumen, an end-to-end voice-based virtual coach that was developed as a stand-alone Alexa application. Lumen delivers evidence-based problem-solving treatment (PST) for patients with mild to moderate symptoms of depression and anxiety.

Lumen, by design, is different from the current spectrum of voice-based health applications that primarily support web-based information-seeking activities [4]. Studies on such information-seeking activities performed on voice assistants have focused on the quality and content of voice assistant responses for several topics including health behavior and lifestyle [6,7], mental health, interpersonal violence, addiction help [8,9], patient and consumer safety risks [10], vaccines [11], postpartum depression [12], medication names [13], and sexual health [14]. The findings across these studies consistently highlight the shortcomings associated with the quality of the information retrieved during these voice-based searches. For example, Bickmore et al [10] found that Siri, Alexa, and Google Assistant platforms and their underlying algorithms were effective in completing only 43% of requests regarding situations that required medical expertise, and 29% of the responses could have resulted in some degree of patient harm [10]. Other applications, mostly preliminary prototypes, have been developed for assessment and support. These applications have been used for delivering visual acuity tests [15], support for coping with chronic disease [16], and for nutritional planning [17]. However, it is important to note that these applications have largely lacked outcome assessment or incorporation of behavioral therapy [4]. Although text-based behavioral therapy applications (eg, chatbots) have shown promise in mitigating psychiatric disorders [18,19], several challenges exist including long-term adherence and engagement limited to younger age groups [20]. Therefore, it is plausible that voice-based therapy delivery may mitigate some of these issues.

In this paper, we describe the design and formative evaluation of Lumen, with the following research objectives: (1) to characterize the user experience, task-related workload associated with interactive communication, and participant alliance with delivered treatment and (2) to identify and describe user perspectives including the benefits, challenges, and barriers to Lumen use and recommendations for design improvements.

Methods

In the following sections, we describe the design components of Lumen, its features, and the mixed methods study that was conducted.

Lumen

Lumen is a virtual voice-based coach that delivers an evidence-based, 8-session PST program for patients with mild to moderate depression and anxiety. The first 4 PST sessions were conducted weekly, followed by 4 biweekly sessions. Each PST session lasted approximately 45 minutes to 1 hour. Lumen was designed to align with the evidence-based PST program.

Lumen's design was based on two overarching principles: (1) providing cognitively plausible conversations, that is, aligning Lumen's conversations with the cognitive processes of human communicative interactions [5] and (2) alignment with the principles of evidence-based PST. This PST program was previously tested and delivered with a human coach [21]; Lumen incorporates essential components of the treatment protocol for coaching and monitors progress using surveys and ecological momentary assessments. All Lumen design components are delivered in an integrated environment, coordinated through the voice-only platform and associated mobile tools (Figure 1 provides an overview of the components of Lumen and their interactions).

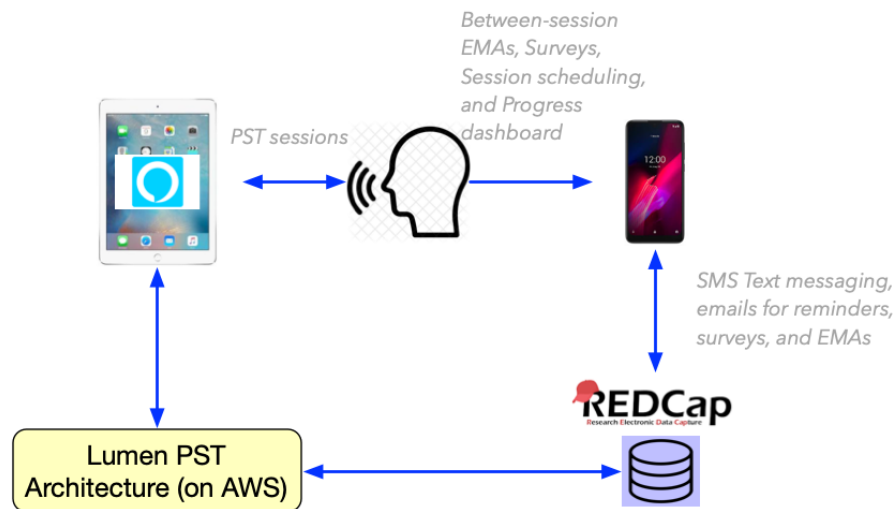

Developed on Amazon's Alexa platform, Lumen's architecture incorporates an intelligent conversation manager that manages the content, structure, and flow of interactive conversations between a patient and Lumen and a context manager that incorporates context awareness into the conversations. Using underlying AI capabilities of the Alexa platform, the conversation manager uses user verbal input to provide appropriate, synchronous responses, aligned with PST's treatment guidelines. PST content and conversational structure were designed in consultation with master PST trainers and PST experts.

The context manager provides contextual awareness to the interactions by incorporating user input from surveys and ecological momentary assessments (delivered asynchronously through mobile apps) and treatment progression and continuity (eg, review of patient problems and action plans from a previous session; Sections A and B in [Multimedia Appendix 1](#) provide additional details of the Lumen architecture and features).

We followed an iterative user-centered design process, comprising brainstorming sessions with software engineers, interaction designers, psychiatrists, and researchers; prototype

development on the Alexa platform; and several iterations of internal testing.

Figure 1. User interaction with Lumen for problem-solving treatment (PST) sessions highlighting the various components. AWS: Amazon Web Services; EMA: ecological momentary assessment.

Participants and Study Design

Participants for this formative evaluation were recruited from the recently completed Engaging Self-Regulation Targets to Understand the Mechanisms of Behavior Change and Improve Mood and Weight Outcomes (ENGAGE-2) trial (ClinicalTrials.gov, National Clinical Trial#03841682), in which a PST-certified health coach delivered integrated collaborative care for depression and obesity to intervention participants, whereas those in the control group received usual care. A convenience sample (91/106, 85.8%) of ENGAGE-2 participants was contacted for assessing their interest in participating in a study with a virtual PST coach. Of these 91 participants, 26 (28%) expressed interest and consented to participate. Of the 26 participants, 17 (65%) had prior PST experience (ie, part of the ENGAGE-2 intervention group) and 9 (35%) did not have prior PST experience (ie, part of the ENGAGE-2 control group).

This was an observational study, with each participant completing 2 Lumen sessions: an *introductory* first session (termed S1; n=26) and a *problem-solving* second session (termed S2; n=24, missing 2 of the 9 ENGAGE-2 control participants). The 2 sessions represented the overarching structure of the 8-session, evidence-based PST evaluated in a previous trial [21]; S1 represented an initial overview session, and S2 represented a problem-solving session that was repeated in sessions 2 to 8 during the evidence-based PST.

In S1, Lumen provides a program overview, provides a detailed introduction to the PST process and behavioral activation, and guides the participant to create a list of problems to address in subsequent sessions. In S2, Lumen guides the participant through the steps of problem-solving: identifying a problem to address, setting a goal, brainstorming possible solutions, evaluating the pros and cons of each solution, selecting a solution to implement, and developing an action plan to carry out before the next session. S2 concludes with behavioral activation coaching, where Lumen assists participants with

selecting a social, physical, and pleasant activity to partake before the next session.

The full Lumen PST program included 6 more problem-solving sessions that followed the same structure as S2; this was the rationale for testing only 1 problem-solving session during this formative evaluation. As such, the purpose of the 2-session approach was to conduct a representative evaluation of all Lumen sessions and to evaluate whether there were differences in participant experience and interactions between the sessions.

Ethics Approval

The study was approved by the institutional review board of the University of Illinois (IRB#2020-0918). All participants provided written consent.

Procedure

Consented participants were provided access to the Lumen S1 and S2 skills via the Alexa application and were given instructions on how to enable the skills on the Alexa app on their personal phones or mobile devices. All user interviews were conducted remotely by a trained research coordinator using the Zoom (Zoom Video Communications) videoconferencing platform. Participants were first provided with a brief overview of the study purpose, and their access to the Lumen skill (designed as a private skill, which was available by invitation only) was verified. During the session, a research coordinator went through a list of tips to effectively communicate with Lumen and answer any questions. After this, participants were instructed to turn off their video, and audio recording via Zoom was enabled from this point. Participants then opened the Alexa app and said “Open Lumen Coach” to begin their Lumen session. During their Lumen sessions, the trained note taker took notes of any deviations from the session script or any technical problems.

After each Lumen session, the coordinator followed a semistructured interview script that included the following

components. First, participants were asked to walk through their interaction experience with Lumen during their completed session, reflecting on what worked, what did not, and challenges they faced. Although the same procedure was followed for both Lumen sessions, interview questions varied slightly from S1 to S2 to inquire about session-specific content. Interview questions after S1 focused on participants' impressions of Lumen, suggestions for improving Lumen, evaluating the usefulness of tips on how to communicate with Lumen, and impressions of the PST overview. Interview questions after S2 included questions about participants' impressions of Lumen that were different from S1, delivery of PST by Lumen, and factors affecting their likelihood of Lumen use in the future. S1 and S2 were conducted several days apart, and participants had access to the specific sessions only a day or so before the session.

After the interviews were completed, participants were emailed a link to 3 brief postinterview surveys related to user experience, workload, and the collaborative relationship between the participant and Lumen (User Experience Questionnaire Short Version [UEQ-S] [22], NASA Task Load Index [TLX] [23], and Working Alliance Inventory–Technology Version [WAI-Tech] [24]).

Audio recordings of the interviews (26 for S1 and 24 for S2) were transcribed using the Trint audio transcription software for subsequent analysis. All (26/26, 100%) postinterview surveys were completed after S1, and 95% (23/24) postinterview surveys were completed after S2.

Data Analysis

Data analysis included coding of interview transcripts using thematic analyses and descriptive summaries of user experience, task load, and WAI-Tech surveys.

Coding of Transcripts

All interview transcripts were coded using an inductive thematic analysis to characterize the participants' perspectives regarding their interaction with Lumen [25] (Section E in [Multimedia Appendix 1](#) provides the interview guide). This approach involved the following stages: first, 2 coauthors (CRR and EAK) read the interview transcripts to familiarize themselves with the content. Next, a set of "open codes" was created to characterize the content and context discussed in the interviews (ie, inductive coding) [26]. These initial codes were compared across the transcripts to identify repeated and interrelated subthemes. Similar subthemes were grouped over multiple review sessions to develop a set of 6 overarching themes. All responses were coded; some responses were assigned multiple codes, in an order of relevance; however, only the primary assigned code was used for all analyses. Two coauthors (EAK and CRR) independently coded a set of 5 transcripts with a high degree of interrater agreement (Cohen κ ranged from 0.83 to 1 with mean 0.93, SD 0.07). Discrepancies were resolved through discussions with the first author (TK). Subsequently, all remaining transcripts were coded.

Surveys

From the UEQ-S survey, pragmatic quality and hedonic quality scale values were calculated by rescaling the survey responses to the range -3 to 3 and calculating item means within each scale using the UEQ-S Data Analysis Tool [27]. Pragmatic quality refers to the task- or goal-related interaction qualities (eg, efficiency, perspicuity, and dependability) that a user aims to reach when using the product. Hedonic quality refers to the aspects related to pleasure or fun (eg, stimulation and novelty) while using the product. Values <-0.8 represent a negative evaluation, between -0.8 and 0.8 represent a neutral evaluation, and >0.8 represent a positive evaluation on each scale.

The NASA TLX rating sheet was administered assuming similar weights for each of the 5 task load items (except for physical demand, which was not considered, as it was irrelevant to Lumen): mental demand, temporal demand (eg, being rushed), effort, frustration, and performance. Each item was then rescaled to the range 5 to 100 by multiplying the raw score by 5.

From the WAI-Tech survey, three 12-item subscale (task, goal, and bond) scores and an overall score were calculated as item means within each subscale. The task subscale reflected how responsive Lumen was to the participant's focus or need; the goal subscale reflected the extent to which goals were important, mutual, and capable of being accomplished; and the bond subscale reflected the degree of mutual liking and attachment [24]. A higher overall score reflected a more positive rating of the working alliance.

Given that the 2 sessions focused on 2 primary structural components of PST sessions—a session overview and a problem-solving session—we compared whether there were differences in the user experience, task load, or work alliance between these sessions. To this end, scores on each of the scales between S1 and S2 were compared using paired t tests. Analyses were conducted using SAS (version 9.4; SAS Institute Inc); statistical significance was defined by 2-sided $P < .05$. Additional analyses comparing PST-experienced and PST-naive participants can be found in Section F in [Multimedia Appendix 1](#).

Results

General Characteristics

Among the 26 participants, 20 (77%) were female, 19 (73%) were racial or ethnic minorities ($n=13$, 50% Black; $n=6$, 23% Hispanic) with an average age of 43.9 (SD 11.9) years, 10 (38%) had a high school or some college education, and 14 (54%) had an annual family income of $<US \$55,000$ ([Table 1](#)). Participants with previous PST experience (17/26, 65%) and those without previous PST experience (9/26, 35%) did not differ in age, race, income, or educational status, although 65% (11/17) of the participants with previous PST experience and 100% (9/9) of the participants without PST experience were female ($P=.04$).

Table 1. Baseline characteristics by prior problem-solving treatment (PST) experience.

Characteristic	All Lumen formative evaluation participants (N=26)	Participants with prior PST experience (n=17)	Participants without prior PST experience (n=9)	P value
Age (years), mean (SD)	43.9 (11.9)	42.6 (13.2)	46.3 (9.2)	.46
Female, n (%)	20 (77)	11 (65)	9 (100)	.04
Race or ethnicity, n (%)				
Non-Hispanic White	4 (15)	3 (18)	1 (11)	.34
African American	13 (50)	9 (53)	4 (44)	.34
Asian or Pacific Islander	1 (4)	1 (6)	0 (0)	.34
Hispanic	6 (23)	2 (12)	4 (44)	.34
Other (eg, decline to state or multirace)	2 (8)	2 (12)	0 (0)	.34
Education, n (%)				
High school or general education or less	2 (8)	1 (6)	1 (11)	.95
College—1 year to 3 years	8 (31)	5 (29)	3 (33)	.95
College—≥4 years	10 (38)	7 (41)	3 (33)	.95
Post college	6 (23)	4 (23)	2 (22)	.95
Income (US \$), n (%)				
<35,000	7 (27)	4 (23)	3 (33)	.32
35,000 to <55,000	7 (27)	3 (18)	4 (44)	.32
55,000 to <75,000	5 (19)	4 (23)	1 (11)	.32
≥75,000	7 (27)	6 (35)	1 (11)	.32

User Experience, Task Load, and Working Alliance

Participants had a positive evaluation (values >0.8) for pragmatic (S1: mean 1.3, SD 1.2 and S2: mean 1.4, SD 0.9), hedonic (S1: mean 1.0, SD 1.1; S2: mean 1.2, SD 1.0), and overall (S1: mean 1.2, SD 1.0; S2: mean 1.3, SD 0.8) qualities related to their user experience with Lumen for both sessions. There were no statistically significant differences between the 2 sessions ($t_{22}=0.37, 0.00, \text{ and } 0.25$ and $P=.71, .99, \text{ and } .80$ for pragmatic, hedonic, and overall scores, respectively).

Across both sessions, participants encountered medium (approximately 50) across the mental (cognitive), effort, frustration, and performance dimensions of the NASA TLX scale. There were no statistically significant differences between

S1 and S2 (Table 2). However, participants rated as having experienced more temporal workload in S2 (mean 52.0, SD 29.1) than S1 (mean 36.5, SD 23.2; $P=.03$), suggesting feeling rushed during their interaction with Lumen in S2.

The scores on the 7-point WAI-Tech survey for task (S1: mean 5.2, SD 0.9; S2: mean 5.3, SD 0.9), bond (S1: mean 4.9, SD 1.0; S2: mean 4.7, SD 1.0), and goal (S1: mean 5.0, SD 0.9; S2: mean 5.1, SD 0.9) subscales were moderately high, indicating that Lumen-based PST sessions were perceived to be aligned with the participants' needs, addressing their potential goals and the degree of mutual liking. There were no statistically significant differences between both sessions on the task, goal, and bond scales or the overall scores (Table 3).

Table 2. Paired *t* test results comparing NASA Task Load Index scores between sessions 1 and 2.

Question	Session 1 (n=26), mean (SD)	Session 2, (n=23), mean (SD)	<i>t</i> test (<i>df</i>)	<i>P</i> value
How mentally demanding was the task? (<i>mental demand</i> ^a)	42.7 (25.0)	53.9 (26.1)	-1.80 (22)	.09
How hurried or rushed were you in the pace of the task? (<i>temporal demand</i>)	36.5 (23.2)	52.0 (29.1)	-2.37 (22)	.03
How hard did you have to work to accomplish your level of performance? (<i>effort</i>)	36.0 (23.4)	42.8 (18.9)	-1.44 (22)	.16
How insecure, discouraged, irritated, stressed, and annoyed were you? (<i>frustration</i>)	31.9 (22.0)	38.5 (24.6)	-0.95 (22)	.35
How successful were you in accomplishing what you were asked to do? (<i>performance</i>)	34.6 (23.1)	37.2 (23.3)	-0.37 (22)	.71

^aItalicized text shows the various categories of the NASA Task Load Index scales.

Table 3. Paired *t* test results comparing task, goal, and bond subscales of the Working Alliance Inventory–Technology Version between sessions 1 and 2.

Scale	Session 1, mean (SD)	Session 2, mean (SD)	<i>t</i> test (<i>df</i>)	<i>P</i> value
Task subscale	5.2 (0.9)	5.3 (0.9)	0.11 (22)	.92
Bond subscale	4.9 (1.0)	4.7 (1.0)	1.49 (22)	.15
Goal subscale	5.0 (0.9)	5.1 (0.9)	-0.32 (22)	.75
Overall scale	5.0 (0.9)	5.0 (0.9)	0.56 (22)	.58

User Perspectives of Lumen

On the basis of the thematic analysis, we identified 6 categories that highlighted key user perspectives regarding Lumen. This included (total, N=536 coded themes across all categories; % of each category across all transcripts): (1) comparing Lumen with a human coach (ie, a human-AI comparison; 200/536, 37.3%), (2) task load experienced during Lumen interactions (102/536, 19%), (3) perception of PST delivered by Lumen (82/536, 15.2%), (4) user suggestions for improving Lumen (81/536, 15.1%), (5) natural language understanding of Lumen (44/536, 8.2%), and (6) technical issues (27/536, 5%) that were encountered during the 2 Lumen sessions (detailed descriptions of each of these categories along with exemplary quotations are provided in Table 4).

Comparisons of Lumen with a human coach included several aspects: potential flexibility, ease of accessibility of Lumen for those who cannot attend face-to-face appointments, and cost-related advantages. Participants also highlighted the nonhuman nature of the interaction, describing the lack of changes in tone, emotion, instant feedback, and desiring a “more personalized human touch.” Nevertheless, nearly all participants described the potential advantages related to Lumen’s accessibility, allowing those in need for therapy easily access a coach at any time:

...the fact that the flexibility of it, the fact that I could be at home, where I could be in my car, or that, you know, I could take a moment and stop at work and go in a quiet room instead of having to, you know, actually go out and, you know, go to a building, find parking, all of the inconveniences that come with [face-to-face] appointments...

In addition, and importantly, participants with previous PST experience expressed that the Lumen sessions were similar to the human coach sessions that they had previously engaged in.

Participants also highlighted the workload associated with Lumen sessions, sometimes describing the difficulty in pausing sessions to collect thoughts as they worked through the steps of PST. This was especially the case in S2, where participants were required to brainstorm multiple solutions to a problem and then list the pros and cons of each solution. The workload challenges identified were related to pacing of the sessions (temporal load) and the amount of information that was directed at the participants (cognitive load). One of the participants explained that the short time to respond made them “feel pressured to come up with something ...[...]. But she [Lumen] did ask if I needed more time, but when I was responding my answers, I [still] felt like it was a short time and I almost felt cut off.”

Participants described their perceptions of the PST program or structure as well as Lumen’s role in delivering PST. Their comments highlighted the importance of the PST stepwise structured approach and Lumen’s PST coaching that enabled them to create goals that could have been overwhelming:

If my goal is truly trying and I have a problem, I just feel overwhelmed. I don’t know how to attack it. Well, Lumen supplies that. It breaks it down. It pulls all of the jumbled information out of my head, leaves the emotion behind and helps me lay out a plan for essentially attacking the problem without the emotional stress of it.

Participants provided several suggestions for improvement. This included further personalizing the PST sessions, creating

embodied avatars for Lumen, incorporating a friendlier voice, and investigating ways for reducing the task load associated with the interactions. One of the most insightful aspects was several participants highlighting the importance of cognitive “offloading” [28]. This was especially aligned with the need to reduce the cognitive load associated with conversational interactions, especially during the problem-solving session (S2), where participants had to identify and work through a problem, set a goal, identify and evaluate possible solutions, and then devise a structured action plan to address the problem. Participants also suggested the need for visualizing their tasks, either digital or paper-based, that would help in organizing their thought processes and saving the notes for future interactions,

as highlighted in the following quote: *“If it would have a way in app, I mean, [...] but like a way to help me, a way to help track for me what my progress is.”*

Although there were a few instances of technical issues where the participants’ verbal responses were not comprehended by Lumen because of issues related to accent or ambient noise, these issues were minimal and most users noted the ease of interaction, as described in the following quote: *“I was pretty much impressed with how easy was to use and, you know, it wasn’t intimidating at all.”* Additional examples of Lumen interactions including problem-solving conversations are provided in Section D in [Multimedia Appendix 1](#).

Table 4. Coding categories, their description, and examples from the interviews.

Coding category (spread ^a , %)	Description	Example from data
Interactive task load (78%)	Participant description of the demands of interacting with Lumen. Includes: <ul style="list-style-type: none"> • Temporal load (pace of interactions, whether there was ample time to provide a response) • Cognitive load (density of content and length of sessions) 	<ul style="list-style-type: none"> • “I felt kind of rushed when it was like time to, like, think through and write things” (3502) [Temporal load] • “Sometimes it’s telling you a lot of things. So, for a user, it’s hard...You’re not looking at somebody. So, you’re really, really having to concentrate and pay attention, so if by any chance you miss something, then you kind of get lost” (1213) [Cognitive load]
Natural language understanding (46%)	Participant description of challenges that Lumen faced with understanding participants’ verbal responses. Includes: <ul style="list-style-type: none"> • Spoken comprehension (breakdowns due to Lumen’s comprehension) • Accent or enunciation issues (eg, understanding names) 	<ul style="list-style-type: none"> • “I think it was difficult to provide the prompts that were requested, and I suspect that depending on the person’s accent or if they’re from—if maybe their English isn’t exactly clear, there may be some language issues” (5457) [Spoken comprehension and accent or enunciation issues]
Comparison with human coach (100%)	Comparison of Lumen to a human coach. Includes: <ul style="list-style-type: none"> • Naturalness of voice or tone (presence or absence of emotion) • Interactive engagement in conversation (whether Lumen was conversational) • Lumen’s tone or inflection (identifying when Lumen was asking a question vs making a statement) • Lumen vs human PST^b content (comparing depth of help Lumen provided relative to human in delivery of PST) • Perceived Lumen benefits or drawbacks (pros and cons of receiving PST from Lumen relative to human, eg, accessibility, availability, and comfort with disclosure) 	<ul style="list-style-type: none"> • “...just robotic. Like, I’m talking to like a machine robot. That’s my initial thought. But at the same time, not in the way that it’s like dumb, but in that it’s like very scientific and not very like human.” (6132) (Naturalness of voice or tone) • “I think initially for me, what may be missing that I picked up on right away is the human interaction component. [...] a human as opposed to talking to like a device or a computer [...] So, I don’t know how differently it’ll be the more I become engaged with it.” (3498) [Interactive engagement in conversation] • “When I spoke with [the human coach], I found myself venting, if I may, and going in every which direction, whereas Lumen forces me to stay very rigid, and sometimes when going through problem solving, the emotional release of going in every which direction, direction, rather than going straight and narrow feels a lot more comfortable.” (3831) [Lumen vs human PST] • “it allows accessibility to people who can’t travel or maybe they feel anxious around talking to another person. So, it eliminates like class, it eliminates race, it eliminates sex. It eliminates sort of those prejudice that could happen in like a person-to-person to person setting.” (6132) [Perceived Lumen benefits]
PST features in Lumen (78%)	Description of the PST features as delivered by Lumen. Includes: <ul style="list-style-type: none"> • Program structure or format (feedback around the stepwise PST process) • Virtual PST coaching (describing Lumen’s role in the PST process) 	<ul style="list-style-type: none"> • “You know, I think if I’m if I am if my goal is truly trying and I have a problem, I just feel overwhelmed. I don’t know how to attack it. Well Lumen supplies that. It breaks it down. It pulls all of the jumbled information out of my head, leaves the emotion behind and helps me lay out a plan for essentially attacking the problem without the emotional stress of it.” (3831) [Program structure or format and virtual PST coaching]

Coding category (spread ^a , %)	Description	Example from data
User recommendations (62%)	Participants' recommendations for: <ul style="list-style-type: none"> Lumen improvements (ideas for functions or features in the user interface) Interacting with Lumen (tips for others to have an effective session with Lumen) 	<ul style="list-style-type: none"> "I would tell them that like, so like you're talking to a computerized app, so make sure you're speaking clearly and slowly and like follow directions in order to get what you're what you need from it." (6132) [Interacting with Lumen] "I would say as a part of the app, have basically have the binder already inside the app and then maybe have a link to a principal PDF for those who want to do that." (6023) [Lumen improvements] "I think it would be kind of cool, especially with it being linked with Alexa is if it had the ability to pick up key-words. So, like if I, you know, saying like I need to work on my diet or trainer or whatever, that somehow it was able to tap into some of those keywords. And while it's talking back to me saying, you know. You know, we've looked into like some trainings in your area. We are going to send you emails of, you know, something like that that would be like really great or hear from information regarding blah, blah, blah, blah, blah." (3498) [Lumen improvements] "She could be better if she if I could see it, even though is a mechanical thing or robot, I want to see Lumen, so I know how Lumen it looks...I'd rather see the person I'm talking to, even though [it] is a machine or whatever it is I would rather see, you know." (7323) [Lumen improvements]
Technical issues (36%)	Technical issues that were experienced by participants during the sessions. Includes: <ul style="list-style-type: none"> Breakdowns in conversation 	<ul style="list-style-type: none"> "Well, I was a little confused when it just stopped. It was still on the app. [...] And then it just completely shut the app." (3470) [Breakdowns in conversation]

^aSpread refers to the percentage of transcripts (total=50) that the coding category was present.

^bPST: problem-solving treatment.

Discussion

Principal Findings

We designed and developed a virtual voice-based coach, Lumen, which delivers an evidence-based PST program for depression and anxiety. To the best of our knowledge, Lumen is one of the first voice-based virtual coach application for delivering behavioral therapy. In contrast to prior research that has primarily used voice assistants in web-based information-seeking tasks, Lumen delivers therapy aligned with the goals and principles of an empirically validated PST program. In this developmental evaluation, participants found the Lumen virtual coach to have high pragmatic usability and user experience, with limited task load during interactions. Participants also highlighted the considerable advantages of Lumen including the on-demand accessibility to a virtual therapist and the delivery of a complex PST task with a simplistic structure and organization for achieving therapy goals. Moreover, although the second session required increased user input, there were no marked differences in effort or interaction quality, except for temporal load (associated with the pace of the conversations), which was highlighted by the participants in their interviews. In addition, the participants highlighted the lack of personalization and deep engagement in the conversation and the relative lack of emotional engagement in the conversations.

Comparison With Prior Work

PST, traditionally delivered by human coaches in face-to-face or phone-based settings, has been developed on mobile platforms [29]. However, similar to other text-based mobile apps, participant engagement with mobile PST platforms has been challenging [30]. To this end, Lumen offers a novel, voice-based mechanism for seemingly naturalistic voice interactions, potentially replicating interactions with a therapist. As previously described, much of the prior work has relied on evaluating the quality health information-seeking tasks using voice-based personal assistants (eg, [8,9]). Moreover, many of the previously developed applications have been preliminary prototypes (eg, [15]) that lacked extensive evaluation or outcome assessment. To the best of our knowledge, this is one of the first fully functional voice-based applications that provides end-to-end support for behavioral therapy (in this case, PST).

Design Changes

Several design changes were incorporated in response to participants' suggestions. To reduce the temporal and cognitive load (ie, reducing the pace of conversations), we incorporated multiple functionalities within Lumen. First, we split longer conversations (especially in S1, where Lumen provided an overview of the PST) into multiple shorter conversations to reduce the mean length of conversations between Lumen and the participant. Such shorter conversations allow for more interactive turns and have been shown to improve the common

ground and engagement between conversational partners [5,31-34]. Second, we developed functionality that allowed participants to repeat, pause, and resume conversations. This allowed participants to ask Lumen to repeat instructions if they could not keep up with the content or to pause conversations in situations where they needed to take a break. Finally, we slowed the pace of the conversations to reduce temporal demand.

In addition, based on suggestions, we also developed a workbook to accompany Lumen in both physical and digital forms. The workbook includes content corresponding to the PST and simple worksheets for taking notes and facilitating brainstorming problem-solving goals, developing and evaluating potential solutions, and creating action plans. Such a cognitive aid helps in externalizing the thought processes [28,35,36] and creating a record for follow-up after the session. Recording and brainstorming with tools also affords cognitive benefits, especially with older adults, such as prospective memory regarding the goals and action plans that were created [37]. We also developed several features linked to Lumen to further integrate contextual aspects regarding the user including their current status and progress. For example, participants can track their progress by viewing their completed sessions and responses to the Patient Health Questionnaire-9 and General Anxiety Disorder-7 surveys on a user dashboard. Similarly, responses on the Patient Health Questionnaire-9 and General Anxiety Disorder-7 surveys were integrated into the Lumen session and reviewed during the session to help participants monitor the level of their depressive and anxiety symptoms.

Finally, we heeded several privacy and security considerations for pragmatic implementation and testing in a real-world setting within the context of a planned pilot randomized clinical trial. To this end, we will afford trial participants access to the Lumen skill within the Amazon Alexa app on a fully encrypted and locked down iPad, with timed exits for nonuse. This allows for preventing accidental recording issues that have been reported regarding the use of voice-based smart devices (Section B, [Multimedia Appendix 1](#)). The iPad-based delivery is aligned with the concept of using a stand-alone “device as a therapist” for the planned trial. However, additional considerations regarding voice-based profile verifications and security considerations are necessary for a wider, pragmatic use of Lumen as a daily therapy tool.

Despite these changes, several aspects of Lumen’s design and interaction are limited by current AI-based voice technology. In particular, the natural language understanding challenges of voice-based technology are well documented [10]. These include difficulties in parsing tone, accent, and pronunciation in spoken language, creating breakdowns in conversation and making it functionally impossible to have a free-form, open-ended conversation with these devices. In addition, current technology is also not able to discern differences in emotion or other verbal cues that are easily interpreted in face-to-face human conversations [5]. With ongoing improvements in technology, these challenges are likely to be mitigated over time, allowing for continued improvement of Lumen for optimized user experience.

Limitations

This mixed methods formative research study had several limitations. The study was based on a small sample of users (N=26) who used Lumen in a relatively controlled environment. However, participants were engaged in 2 sessions and performed the Lumen interactions without external support. Only 2 sessions were evaluated with participants, and as such, we could not characterize participants’ experience with the entire 8-session PST program. However, structurally, sessions 2 to 8 mirror the S2 evaluated in this study. It is likely that participants will become more or less comfortable with the Lumen interactions in the later sessions. Given the formative and controlled nature of this study, we could not assess the impact of the various measures (ie, task load and work alliance) over time. We will be able to determine such longitudinal effects in our ongoing pilot clinical trial. Sessions were attended by a research coordinator and a trained note taker. It is not known whether their presence influenced the participants’ use of Lumen or their responses to the interview questions.

Notwithstanding those technological and research limitations, the findings from the formative evaluation and the subsequent improvements in design and functionalities position Lumen to be a “minimum viable product” that is highly acceptable to participants, appears to veridically reflect PST content, and is ready for potential real-world pilot testing. Recruitment has been completed for the pilot clinical trial (ClinicalTrials.gov, NCT# 04524104) in which 63 adults with mild to moderate depressive and anxiety symptoms have been randomized in a 2:1 ratio to the Lumen intervention or the wait-list control group and followed for 4 months. The objectives of the pilot trial are 3-fold: (1) to determine the feasibility and acceptability of the Lumen virtual coach for delivering the 8-session PST program; (2) to assess neural target engagement by comparing changes in the amygdala and dorsal lateral prefrontal cortex in functional neuroimaging between the Lumen intervention and wait-list control groups; and (3) to examine the relationship between neural target engagement and changes in self-reported measures of mood, coping, and psychosocial functioning. The pilot trial will provide the preliminary data needed to accelerate the clinical and translational research on this novel digital psychotherapy and to catalyze future development and definitive efficacy clinical trials.

Conclusions

With a goal of overcoming the lack of empirical evidence for AI-based voice applications in behavioral therapy, we developed a voice-only virtual coach, Lumen, for delivering PST. The findings from the formative evaluation highlight feasibility, accessibility, and favorable user experience. Suggestions for more natural conversations and better contextual support have resulted in an improved, minimally viable product. Lumen is being tested in a clinical trial to evaluate its neural mechanism of action and therapeutic potential in depression and anxiety. If successful, Lumen can be a viable voice-based therapist offering a realistic and cognitively plausible verbal interaction for personalized and accessible mental health care, filling a gap in traditional mental health services.

Acknowledgments

This study was funded by a grant from the National Institute of Mental Health (grant number R61MH119237).

Data Availability

Deidentified data from this study are not available in a public archive. Deidentified data from this study will be made available (as permissible according to institutional review board standards) by emailing the corresponding author.

Authors' Contributions

TK, CRR, NEW, JMS, and JM conceived the study; TK, CRR, EAK, and NL collected the data; TK, CRR, EAK, NL, and NEW were involved in the preliminary analysis; and all authors participated in the interpretation of the results, writing of the manuscript, and critical review. All authors approved the final manuscript for submission.

Conflicts of Interest

TK is a paid consultant for Pfizer, Inc outside of this work. JM is a paid scientific consultant for Health Mentor Inc (San Jose, California, United States). OAA is the cofounder of KeyWise AI and serves on the advisory boards of Blueprint Health and Embodied Labs. The other authors report no conflicts of interest.

Multimedia Appendix 1

Details of the Lumen architecture and user interaction patterns with Lumen.

Abstract

Background: The Philippines HIV epidemic is one of the fastest growing epidemics globally, and infections among men who have sex with men are increasing at an alarming rate. Connect for Life Philippines is a mobile health (mHealth) intervention that supports antiretroviral therapy (ART) adherence in this key population through individualized voice calls and SMS text messages.

Objective: The objective of this process evaluation is to assess the intervention reach, dose delivered and received, fidelity, and acceptability and to describe contextual factors affecting the implementation of an mHealth adherence support intervention for patients on ART in a clinic in Metro Manila, Philippines.

Methods: A mixed methods process evaluation approach was used in an observational cohort study. Quantitative data sources for the process evaluation were call and SMS text message logs obtained from the mHealth platform and questionnaires collected at 12-, 24-, and 48-week study visits. Qualitative data were collected from process reports and through a series of focus group discussions conducted with a subset of participants during the intervention development phase, after an initial 8-week pilot phase, and at the end of the study.

Results: The 462 study participants received 31,095 interactive voice calls and 8234 SMS text messages during the study. Owing to technical issues, intervention fidelity was low, with only 22.1% (102/462) of the participants receiving reminders via voice calls and others (360/462, 77.9%) receiving only SMS text messages during the intervention. After 48 weeks in the study, 63.5% (293/462) of the participants reported that they would be quite likely or very likely to recommend the program to a friend, and 53.8% (249/462) of the participants reported that they benefited quite a bit or very much from the intervention. Participants who were on ART for <6 months at the beginning of the study and those who received the daily or weekly pill reminders were more likely to report that they benefited from the intervention ($P=.02$ and $P=.01$, respectively).

Conclusions: The Connect for Life intervention had high participant satisfaction and acceptability, especially among those who received high dose of the intervention. However, poor reliability of local telecommunication networks had a large impact on the intervention's usability, fidelity, and dose received.

Introduction

Background

The HIV epidemic in the Philippines is one of the fastest growing epidemics globally, with 207% increase in new HIV infections and 388% increase in AIDS deaths from 2010 to 2020. In 2020, an estimated 73% of people living with HIV in the Philippines knew their status and 44% of people living with HIV were on antiretroviral therapy (ART) [1-4]. In 2 studies of cohorts of patients with HIV in Manila, 84% to 90% of patients who started ART had achieved viral suppression [4,5]. Most new and existing HIV infections occur among men who have sex with men (MSM) [3]. Improving treatment coverage, retention, adherence, and viral suppression are key to slowing the spread of HIV in the Philippines. Unfortunately, widespread stigma, lack of knowledge, and barriers to accessing care pose a challenge to engaging patients in testing and ensuring high levels of adherence to ART and retention in care [6-8]. High rates of first-line treatment failure, loss to follow-up, and suboptimal treatment adherence lead to poor outcomes in many patients with HIV in the Philippines [9,10].

This paper describes the process evaluation of a mobile phone technology for health (mobile health [mHealth]) intervention for people living with HIV in Metro Manila, Philippines. To support ART adherence, the intervention, Connect for Life, provided patients with HIV with individualized voice calls and SMS text messages, pill reminders, appointment reminders, symptom reporting, health tips, and adherence feedback.

The Connect for Life platform was developed by Janssen Global Public Health, and before adaptation for the Philippines, its versions were piloted in India and Uganda. The mMitra (mobile friend) project in India aimed to improve maternal health outcomes through health messages to pregnant women [11,12]. The Treatment Advice using Mobile Alerts project in India [13,14] and Call for Life Uganda [15,16] supported ART adherence among people living with HIV.

Process Evaluation of mHealth Interventions

As mHealth technologies have become widespread in low-income and middle-income countries, mobile phone interventions have become increasingly popular in the global health and development sectors as an inexpensive and efficient way to communicate and deliver services. Several trials have shown that mHealth approaches show potential for improving self-management of chronic diseases, including adherence to HIV medications [17-21], whereas systematic reviews show mixed outcomes of mHealth interventions and highlight the need for more rigorous evaluation methods and longer follow-up periods in mHealth studies [22-31].

Trials assessing mHealth adherence interventions for HIV often do not include process evaluations to examine the fidelity and

quality of the intervention delivery, causal mechanisms for the health outcomes, contextual factors affecting the delivery, and costs to implement [29,32,33]. For mHealth interventions, current guidance suggests that practitioners should also include a minimum set of information about the content, context, and technical features of the intervention, including aspects such as ease of use, content quality, privacy and security, service quality, personalization, and perceived enjoyment [34-37].

Process evaluations of SMS text messages and interactive voice response systems (IVRSs) have examined fidelity, reach, dose delivered, and user satisfaction for projects ranging from water and sanitation to prevent diarrheal disease [38]; airline pilot fatigue [39]; and prevention of weight gain, smoking, or HIV among young people [40-42]. A systematic review of mHealth projects in Africa found that in projects where acceptability and usability of mHealth technology among participants was measured, it was generally high. However, infrastructure issues (unreliable network and internet and electricity access) were frequently cited as key challenges in delivery [24].

The success of mHealth projects in achieving the intended health outcomes is almost entirely dependent on the adaptation and delivery of the intervention in local contexts. Having a complete understanding of the implementation process of an mHealth intervention can enable practitioners to interpret the outcomes and replicate the intervention in other contexts. Therefore, we performed a process evaluation alongside the Connect for Life Philippines prospective cohort study. The process evaluation examined the fidelity, dose delivered and received, reach, usability, acceptability, and cost of the Connect for Life Philippines intervention.

Methods

Recruitment

The study was conducted at the Sustained Health Initiatives of the Philippines (SHIP) Clinic, a low-cost, private facility in Metro Manila, a city with approximately 13 million people in the predominantly Catholic country of the Philippines.

SHIP Clinic provides HIV primary care and wraparound services to approximately 900 people living with HIV. Approximately 98% of SHIP's clients are MSM, with an average age of 30 years at initial consultation. Most are full-time or part-time employees. The clients come from all regions of Metro Manila, and some live in other provinces.

Recruitment into the Connect for Life study occurred in person at the study site between October 2016 and December 2017. As patients checked in for their routine clinic visits, the study coordinator approached all patients seated in the clinic waiting room, briefly introduced the study following a recruitment script, elicited their interest in participating, screened them for

eligibility, completed the informed consent process, and provided a brief orientation to the intervention.

Connect for Life Mobile Phone ART Adherence Support Intervention

The study team worked with IT specialists and public health professionals from Janssen Global Public Health, University of the Philippines, and local IT companies to develop the content and functionality of the Connect for Life mHealth platform (Figure 1). Connect for Life is a technology built on the Mobile Technology for Community Health (MOTEC; Grameen Foundation) open-source software platform [43]. It enables health facilities to connect to patients via their mobile phones through IVRS call flows or SMS text messages. As Connect for Life works through phone calls and SMS text messages, it does not require the user to have a smartphone, install an app, or have mobile internet connection. This makes it accessible to a wide range of users in the Philippines, where, in 2015, mobile phone penetration was high, but smart phone coverage and internet access were low (with 113 mobile subscriptions per 100 people, 99% of the population reached by network coverage, and 22% of the population owning a smart phone) [44-46].

The study team tailored the Connect for Life platform for the Philippine context. Some existing features were retained, such as reminders sent on the recipient's preferred days and times, health tips, and symptom screening. New features were developed, such as medical record functionality and adherence feedback scores. Clinicians at the study site developed new

content for the voice and SMS text messages, which were recorded by a local voice talent agency. During the formative study and intervention development stage, a series of focus groups were conducted to engage with patients at the clinic about their adherence behaviors and preferences for configuration and content, and their feedback was incorporated to ensure that the intervention was tailored to the target population [47-49].

The Connect for Life system was installed in a secure cloud server environment and linked to a local telecom provider through application programming interface integration to execute calls and SMS text messages. A local IT service provider was contracted to monitor server functionality, install software updates, and troubleshoot technical issues. The Connect for Life software developers provided in-depth technical training and software documentation to the local IT provider and training for the clinical staff on how to use the Connect for Life web-based platform.

The intervention development process was guided by the Behavior Change Wheel and the Capability Opportunity Motivation–Behavior model developed by Michie, Atkins, and West [50-52]. Behavior change techniques related specifically to ART adherence were informed by the information-motivation-behavioral skills model of ART adherence [53]. Each service in the intervention package was designed to address ≥ 1 of the 3 main components that drive behavior in the Capability Opportunity Motivation–Behavior model, as outlined in Figure 2 [47,48].

Figure 1. Connect for Life Philippines mobile health intervention functions. ART: antiretroviral therapy; IVRS: interactive voice response system; PIN: personal identification number.

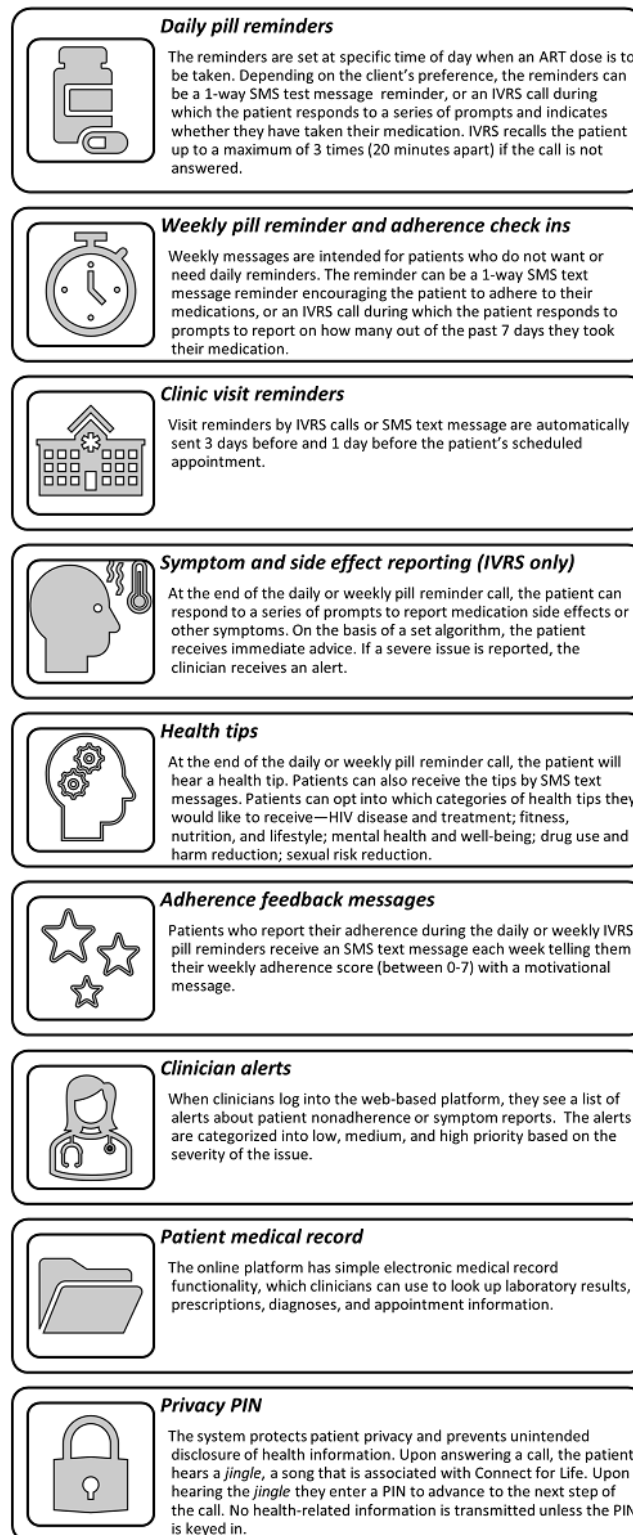

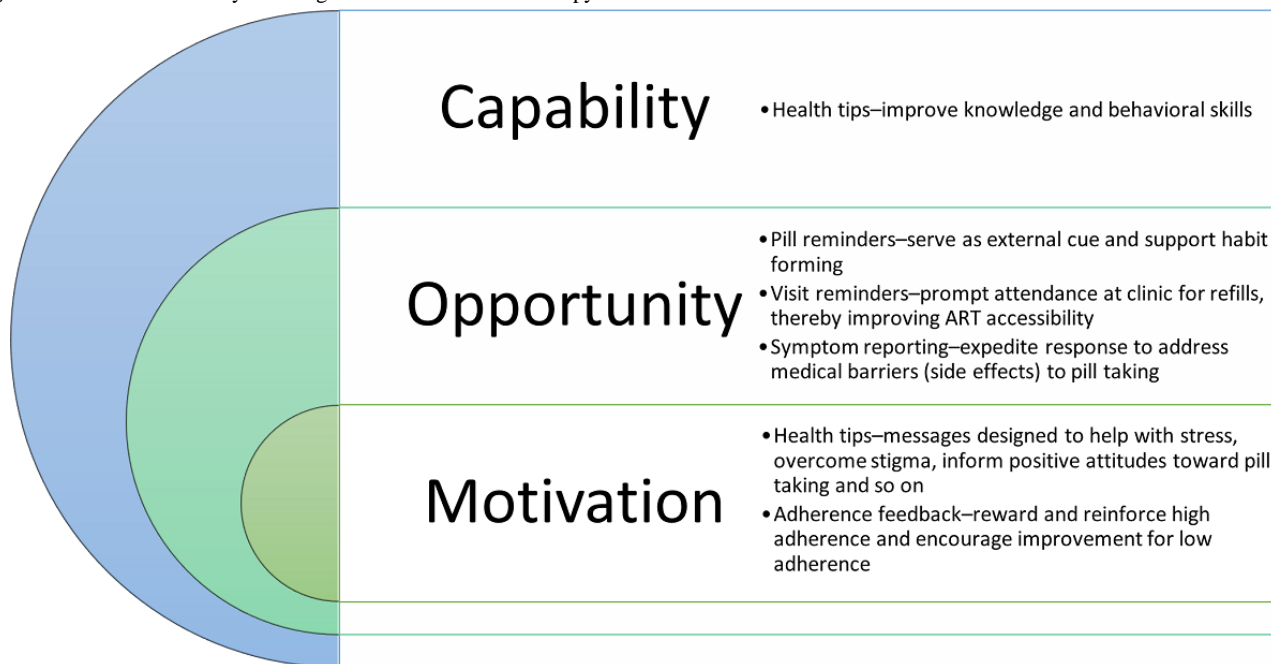

Figure 2. Intervention theory of change. ART: antiretroviral therapy.

Data Collection and Analysis

A mixed methods approach was used with qualitative data embedded in the experimental design of the 48-week prospective cohort study [54]. The design allowed us to assess participants' use of and experience with the system and use quantitative and qualitative analyses to generate complementary data about acceptability, usability, and the impact of contextual factors on the intervention.

The process evaluation measures were based on the framework proposed by Linnan and Steckler [55], which defines the approach to adequately describe the context, reach, dose (delivered and received), acceptability, and fidelity of the intervention. Additional aspects related to reporting on mHealth technology were included based on guidance from the mHealth Evidence Reporting and Assessment checklist [36].

The process evaluation questions, tools, methods, and data sources are described in [Multimedia Appendix 1](#).

To measure the fidelity and dose of intervention delivery, records from the mHealth platform detailing the services received by each participant were exported. To understand the usability and acceptability of the intervention, participants completed self-administered paper-based questionnaires at 3 time points during the study. Where questionnaires had blank or missing fields, all available data points were included in the analysis. Data distributions were explored to categorize the responses to the questionnaires. Associations between acceptability of the intervention and independent variables (time point, treatment experience, and reminder frequency) were calculated using chi-square tests. Data analysis was conducted using Stata 15.

Qualitative feedback was collected in several ways: routine monthly process reports from clinicians to document implementation successes and challenges, comments recorded on the acceptability questionnaires, and a series of focus group

discussions (FGDs). The study team conducted 2 FGDs with a total of 12 participants during the intervention development phase in 2016. In early 2017, a total of 2 additional FGDs were conducted with 5 participants after an 8-week pilot phase. Finally, in 2018, during the final 2 months of the study, 3 FGDs were conducted with 15 participants. The FGDs were transcribed, transcripts were manually coded using a deductive coding methodology to group responses by topic areas in the FGD guide, subtopics were assigned through line-by-line coding, and data were consolidated in a structured template that enabled identification of salient themes. Results from the FGDs in the formative and pilot phases informed the content and structure of the intervention and helped to identify implementation issues early in the project [47].

Ethics Approval

Ethics approval for the study was obtained from the University of the Philippines Manila research ethics board (protocol number 2016-265-01) and the London School of Hygiene and Tropical Medicine (reference number 11631). All participants provided written consent before inclusion in the study.

Results

Study Population and Intervention Delivery

Process Evaluation Questions 1 and 2: Reach and Recruitment

Of approximately 675 patients receiving ART services at the study site during the recruitment period, 485 (71.9%) were approached by the study coordinator while attending a routine visit at the clinic, 464 (68.7%) were interested in learning about the study, and 462 (68.4%) met the eligibility criteria and consented to participate.

Reasons for refusal (21/485, 4.3%) included no need or desire for adherence support, not wanting to receive messages or calls on their mobile phone, privacy concerns, and frequent travel

out of the country. Of the 0.4% (2/464) of the patients who were excluded, one was ineligible because he did not speak English and the other did not have a mobile phone.

All but 1 of the participants in the study (461/462, 99.8%) identified as male, and 98.5% (455/462) were MSM. The mean age at enrollment was 32.4 (SD 5.7) years. University or postgraduate studies had been completed by 85.9% (397/462) of the participants, and 91.3% (422/462) were employed or enrolled in university, which reflects the higher-than-average socioeconomic status of patients at the study site, a private fee-for-service clinic.

At the time of enrollment, 92.2% (426/462) of the participants were already taking ART and 7.8% (36/462) had not yet started. Of those already taking ART, perfect adherence of 100% of doses taken in the last 30 days was reported by 52.1% (222/426) of the participants, 95% to 99% adherence was reported by 26.6% (113/426), 90% to 94% adherence was reported by 12.7% (54/426), and adherence of <90% was reported by 8.7% (37/426).

Participants were followed for 48 weeks, during which time 91.1% (421/462) of the participants were retained for the study duration and active on ART at the study site, 0.6% (3/462) had withdrawn from the study but were still in care, 0.6% (3/462) had died, 3.9% (18/462) had defaulted from treatment, and 3.7% (17/462) had transferred to another clinic.

Process Evaluation Question 3: Fidelity

The process evaluation found that the fidelity of the intervention was low. The planned intervention consisted of daily IVRS pill

reminder calls for all participants in the first 6 months of ART and weekly IVRS calls for those on ART for >6 months. During the study, only 22.1% (102/462) of the participants received the IVRS intervention, whereas 72.7% (336/462) received a scaled-down SMS text message version of the intervention. The reasons for the small proportion of participants receiving the voice calls were technology-related challenges described in the *Usability and Context* section.

Process Evaluation Questions 4 and 5: Dose Delivered

Of the 462 participants, 95 (20.6%) participants received a combination of voice calls and SMS text messages, 336 (72.7%) received SMS text messages only, 7 (1.5%) received voice calls only, and 24 (5.2%) received neither.

The 22.1% (102/462) of the participants who opted for IVRS services received a total of 30,940 calls during their study enrollment period (Table 1). During the calls, participants listened to 3980 health tips. Only 2 symptom or side effect reports were made. An average of 303 calls were made per participant, which included repeat reminder calls (up to 3 calls per day) if the initial call was unanswered. Of all the scheduled outgoing IVRS calls by the Connect for Life system, only 0.14% (44/31,095) of the calls failed to initiate owing to a software or platform issue.

The 93.3% (431/462) of the participants who opted for SMS text messages received 8234 messages in total: 2468 (29.97%) adherence feedback, 417 (5.06%) health tips, 2272 (27.59%) pill reminders, and 3077 (37.37%) visit reminders.

Table 1. IVRS^a and SMS text message services provided.

Services	Participants who received the service (N=462), n (%)	Total number of calls and messages delivered after enrollment (N=30,940 calls; N=8234 SMS text messages), n (%)	Number of calls and SMS text messages per participant, mean (SD)
IVRS calls (n=102)			
Any	102 (22.1)	30,940 (100)	303 (324.3)
Listened to health tip	69 (14.9)	3980 (12.86)	58 (80.1)
Reported symptoms or side effects	2 (0.4)	2 (0.01)	1 (0)
SMS text messages (n=431)			
Any	431 (93.3)	8234 (100)	19 (49)
Adherence feedback	70 (15.2)	2468 (30)	35 (17.3)
Health tip	11 (2.4)	417 (5.1)	38 (45.7)
Pill reminder	10 (2.2)	2272 (27.6)	227 (187.3)
Visit reminder	428 (92.6)	3077 (37.4)	7 (4)

^aIVRS: interactive voice response system.

Process Evaluation Question 6: Dose Received

Including setup calls during the visits, of the 31,095 outgoing calls made by the Connect for Life system, 8119 (26.11%) were answered by the participants. To listen to the message, the

participant had to enter their personal identification number (PIN). A PIN attempt was recorded for 66.87% (5429/8119) of the calls that were answered, and the PIN was entered successfully in 84.56% (4591/5429) of the PIN attempts (Figure 3).

Figure 3. Interactive voice response system calls made and outcomes. PIN: personal identification number.

Of the 2690 calls that were answered and no PIN was entered, an estimated 1846 (68.62%) went to voicemail. This estimate was based on the number of seconds the call was connected before it was automatically terminated by the software (approximately 140 seconds).

Experiences of Participants and Providers

Process Evaluation Questions 7 and 8: Usability and Context

The biggest technology challenge that the project faced was frequent dial tone multifrequency (DTMF) malfunction during IVRS calls. This was reported by study participants and observed by the study staff during the process of activation of the IVRS service. During the DTMF malfunction, the system was unable to recognize the tones as users pressed number keys

on their phones, resulting in invalid PINs or inability to navigate the IVRS menus. DTMF failure was suspected during an estimated 32.08% (2605/8119) of calls that were answered by participants (1767/2605, 67.83% of the answered calls where no PIN was entered and 838/2605, 32.17% calls where an invalid PIN was entered). Enrollment was temporarily suspended, and an investigation of the issue found that the DTMF malfunctions were related to the telecommunication infrastructure rather than the Connect for Life platform; therefore, it was not possible for the study team to correct the issues.

Only 46.1% (159/345) of the participants reported that they found the Connect for Life system quite easy or very easy to use (Figure 4), indicating that ease of use can be improved.

Figure 4. Intervention acceptability after 48 weeks (n=392 respondents).

The provider’s experience with the system was largely positive. In monthly process reports, clinicians reported that the medical record functionality facilitated easy access to laboratory results, medication history, diagnosis, and other information, which had previously been recorded in Microsoft Word documents and

paper charts. Clinicians also reported that the alert function, which flagged patients with poor adherence or side effects for the clinician to follow up, was overwhelming to use. The symptom reporting alerts were useful, but these alerts were “buried” in a long list of alerts about missed doses and missed

clinic visits. This occurred when participants failed to answer calls and responded to the IVRS prompts, which triggered alerts for nonadherence, resulting in high numbers of inaccurate alerts for missed doses. Clinicians recommended reviewing and updating the criteria for generating alerts.

Clinic staff also observed that across the clinic, participant compliance with attending appointments on the scheduled date and time improved from 17% before the study to >30% after the implementation of Connect for Life. They attributed this improvement to the visit reminders sent through SMS text messages. The improved on-time visit attendance saved staff time and effort by reducing the need to call patients and reschedule appointments.

Process Evaluation Question 9: Acceptability and Satisfaction

Acceptability

Acceptability questionnaires were collected at 3 time points (426/462, 92.2% completed at the 12-week visit; 335/462, 72.5% at the 24-week visit; and 392/462, 84.8% at the 48-week visit). Acceptability levels are summarized in [Figure 4](#).

After 48 weeks in the study, 63.5% (221/348) of the participants reported that they would be quite likely or very likely to recommend the program to a friend, and 53.9% (187/347) of the participants reported that they benefited quite a bit or very much from the intervention.

Some participants reported concern over privacy and inconvenience, with 12.4% (43/347) of the participants reporting that the messages and calls disturbed them quite a bit or very much during their work or other important activities and 11.3% (39/345) of the participants stating it was quite likely or very likely that the intervention could cause unwanted disclosure of HIV status. Social harm monitoring was conducted at each study visit and no instances of disclosure were reported.

Associations between acceptability and several independent variables were explored.

Time on Study

There was no strong evidence of difference in the acceptability indicators at different time points after enrollment. The proportion of participants who reported that the intervention benefited them quite a bit or very much was 45.2% (128/283) at the 12-week study visit, 54.3% (188/346) at the 24-week visit, and 53.9% (187/347) at the 48-week visit ($P=.51$).

Time on Treatment

Among participants who had started ART <6 months before enrollment in the intervention, after 48 weeks, 65% (39/60)

reported that the intervention benefited them quite a bit or very much, compared with only 51.6% (148/287) of the more experienced participants who had been on ART for >6 months at the time of enrollment ($P=.02$).

Frequency of Service

People who received daily or weekly pill reminders were much more likely to report that the intervention benefited them compared with those who did not receive pill reminders. This trend was consistent across all time points. At the 48-week visit, 70% (21/30) of the participants who received weekly pill reminder and 64% (9/14) of those who received daily pill reminder reported that they benefited quite a bit or very much from the intervention compared with only 51.5% (157/305) of those who received no reminders ($P=.01$).

There was no evidence of difference between those receiving daily and those receiving weekly pill reminders in terms of acceptability of the frequency of pill reminders or participants' likelihood to recommend Connect for Life to a friend. Of those who received daily pill reminder, 14% (11/78 observations) said that there were "too many" reminders, whereas 7% (4/58 observations) of those who received weekly pill reminder said that there were "too many" reminders ($P=.29$). At week 48, a total of 80% (24/30) of the participants who received weekly pill reminders were quite likely or very likely to recommend to a friend, compared with 64% (9/14) of those who received daily pill reminders and 61.4% (188/306) of those who received no reminders ($P=.30$).

Other Factors

No association was observed between viral load suppression or HIV knowledge score and intervention acceptability.

Qualitative Feedback From FGDs and Adherence Questionnaires

Qualitative data were collected to facilitate better understanding of participants' experiences with the system and the contextual and motivating factors influencing the use, acceptability, and usability of the intervention.

The key findings from the acceptability questionnaires and the FGDs at the end of the study were that the intervention was received positively, and participants believed that the intervention should continue after the study ended. Several main themes emerged—the importance of personalized reminders, technical challenges and usability issues, desire for health tips, and importance of social support as part of HIV care ([Textbox 1](#)).

Textbox 1. Main themes from focus group discussions (FGDs).**Personalized reminders**

- Participants liked that the intervention was highly personalizable, enabling them to select the frequency and time of calls or SMS text messages and the topics of health tips. Preferences for voice calls and SMS text messages varied. Participants also reported that they found the visit reminders and pill reminders to be helpful for their adherence; however, most patients were using their own alarms or pill boxes as adherence tools. Several participants who only received the visit reminder service expressed interest in trying the pill reminders and health tips after hearing the feedback from participants who received those components of the service:

It is an advantage being reminded at work especially when you get busy so you would not miss to take your medicine on time.

Receiving pill reminder call on a weekly basis made me more aware of the time and I think it is more beneficial to those who has tight schedule. But in my end, I never forget a dose with the aid of alarm clock.

For me, the two times [visit] reminder is fine. Actually, it is very helpful on reminding me on my next visit. There are times that I got surprised receiving the text because I already forgot that I have a follow-up visit.

Technical challenges

- Participants who received the calls described challenges with entering their personal identification number and with navigating the interactive voice response system (these challenges were owing to failure of the dial tone multifrequency technology) and more broadly about the hassle of responding to the prompts in the calls. Even when the call went unanswered, it still served as a prompt to take medication:

In the evening, I don't know how to use the PIN so whenever I received the call (usually an international number) and hear the music, I already know that it is the pill reminder call. I actually can't go through the IVR because I don't know exactly when I need to enter the PIN... On the other hand, the call itself serves as an alarm to take my meds though I was not able to answer or enter my PIN.

Health tips

- Participants expressed that although they use the internet to find health information, they trusted health tips from Connect for Life more, because the information was vetted by their health care provider. They liked that the health tips included information on a range of related health topics, such as nutrition and mental health, in addition to the HIV basics. However, some participants were unwilling to receive tips via SMS text message because of concerns about privacy, and some stated that they knew someone who they could ask for health information:

In general, I think it is better that the health tips are coming from Sustained Health Initiatives of the Philippines and recommended by health care professionals. It would be more reliable as compared to information in the Google.

It's like trivia for today, even you are on meds for a long time already.

Social support

- Almost all FGD participants mentioned the importance of human connection. Several participants mentioned that they would prefer to connect to a live person in addition to electronic information, especially regarding symptom management. Participants stressed the role of support from their health care providers or other patients in helping them to understand more about living with HIV:

I would like to suggest having someone to reach to answer a not so relevant question like if I have stomach-ache and I want to know if it is connected to my meds or a side effect versus to searching in Google which is sometimes inaccurate.

Exchange of experiences [is important] especially to the new patient so they would know what to do. They would feel that they are not alone, because you won't know how to avoid feeling self-pity. At least with a support group they have someone to communicate with.

Process Evaluation Question 10: Cost

A description of the types of expenses involved in the implementation and the approximate costs from the Philippines setting are shown in [Table 2](#).

Table 2. Costs involved in the intervention.

Aspect	Description	Cost
Cloud hosting of solution	The database and software require hosting on RDS ^a and EC2 ^b server instance. The cost of a monthly or yearly subscription depends on the amount of storage needed and payment schedule. Our database includes data for approximately 700 patients.	US \$50 per month
VOIP ^c provider	This may be the local telecommunications company (eg, Vodacom and Globe) or a specialist service provider.	PHP 0.50 (US \$0.01) per SMS text message or PHP 5 (US \$0.10) per minute for voice calls
Local service provider IT support	IT support monitors the server, VOIP functionality, and software updates and manages users' log-ins. Our local IT support provides up to 20 hours of support monthly and charges an hourly rate for additional support.	PHP 10,000 (US \$200) per month
Staff	An administrative clerk, counselor, or other cadre of staff will allocate time and effort to enroll patients on the system, activate their services, monitor alerts, and update details.	Cost varies (0.1-0.5 FTE ^d of administrator)

^aRDS: relational database service.

^bEC2: Elastic Compute Cloud.

^cVOIP: voice over IP.

^dFTE: full time equivalent.

Discussion

Principal Findings

During the study, >31,000 IVRS calls and 8000 SMS text messages were sent to 462 study participants. The Connect for Life system was acceptable to both participants and providers. Participants liked that the intervention was highly personalizable, enabling them to select the frequency and time of calls or SMS text messages and the topics of health tips. Feedback on the pill reminders, visit reminders, and health tips was very positive. Participants appreciated that health tips covered a variety of topics beyond HIV basics. The FGDs revealed that acceptability of the weekly adherence scores and symptom reporting functionalities of the intervention was low, as these 2 functions required lengthy navigation of the IVRS menu.

Owing to technical issues, the intervention was not implemented as originally intended, with only 22.1% (102/462) of the participants receiving the IVRS pill reminder intervention and others receiving a scaled-back SMS text message intervention. When the technical issues were first identified, enrollment in the study was paused for 3 months, while the study team assessed the cause of the issue. Ultimately, the issue of DTMF malfunction was attributed to issues in the telecommunications system that neither the telecommunications provider nor the Connect for Life developers could resolve. When enrollment was resumed, participants were provided SMS text messages rather than IVRS services. Despite the technical challenges, acceptability remained high, and only 0.6% (3/462) of the participants withdrew from the study. Following the study, the frequency of technical issues has decreased significantly, and the study site has continued to provide the service. Currently, pill reminder calls are a routine service for all new patients undergoing ART.

Notably, the technical challenges experienced in delivering the intervention were related to navigating the IVRS menu and made it difficult to distinguish whether the issues raised with

ease of use or overall satisfaction were related to the technical challenges (ie, the dial tones were not recognized when keyed in) or to the product design (ie, IVRS menus were very complicated). The accuracy of the adherence scores in the weekly feedback SMS text messages was dependent on successful navigation of the IVRS process. This type of feedback may have been better delivered via a smart phone app rather than an IVRS setup. The interactive component of the IVRS system was an important aspect of the study design, which was not effectively evaluated in this study owing to the low number of participants who received this part of the service, warranting ongoing monitoring and future studies.

The scaled-back intervention provided everyone with visit reminders, which addressed part of the theory of change by improving medication accessibility through timely refills, but did little to prompt pill-taking, habit forming, and improvements in health knowledge. Individuals who received a high dose of the intervention (daily or weekly pill reminders) were more likely to recommend the intervention to others, suggesting that the planned intervention was more acceptable than the scaled-back version.

Our analysis of dose received shows that the call answer rate was low, with only 26.24% (8119/30,940) of outgoing calls answered, which is reflective of a preference for SMS text messages and chat services among the target population. The requirement of a PIN reduced exposure to the intervention, which was mostly owing to technological challenges. After experiencing technical difficulties several times, many participants stopped answering the calls. However, some mentioned that the phone ringing at the set time each day served as an effective adherence reminder.

Privacy considerations were paramount, with 11% (51/462) of the participants reporting that they had concerns about the potential for disclosure of their HIV status. Therefore, in situations where entering a PIN is a barrier to intervention exposure, practitioners can consider adapting the content to

eliminate potentially sensitive health information and delivering the service with no PIN requirement.

Ultimately, the study showed the importance of choosing technologies that can function in local contexts. In low-resource settings, it may take time to scale-up technologies that will be quick to roll out in high-resource settings. Practitioners must identify service providers with appropriate capacity and ensure that patients have the skills and motivation to use the intervention. Conducting an iterative process with several pilot stages is advantageous, as it enables practitioners to identify the problems with functionality and adapt the intervention before scaling up.

An important aspect of the intervention was that, through this regular contact from the clinic, participants felt cared for and felt that their health care provider was concerned about their well-being. This social support was a key motivator for adherence. Participants requested to be able to speak to someone about side effects or for social support, suggesting that an intervention that links calls to counselors more effectively may be an area for future evaluation.

Comparison With Previous Studies

The Connect for Life Philippines intervention was adapted from the same platform used for Call for Life Uganda and mMitra and Treatment Advice using Mobile Alerts in India. Acceptability was high in all 3 settings [11,16]. However, there were differences in the preferences and use patterns of the participants in the Philippines setting compared with those in Uganda and India. The Philippines had a high preference for SMS text messages over voice calls and a low call answer rate. The Connect for Life Philippines and Call for Life Uganda projects experienced similar challenges with network instability issues in the early stages [16].

Similar to Connect for Life and Call for Life, other mHealth interventions for people living with HIV have shown improvements in ART adherence, even where participant response rates (ie, dose received) are low [29,31,56]. For example, the PositiveLinks app used by people living with HIV in Virginia, United States, had response rates of <40% to most app prompts, but participant retention in care, CD4 results, and viral suppression improved significantly [57]. There is an important distinction between adherence to the intervention (ie, calls, app prompts, and device use) and adherence to medication.

Strengths and Limitations

A strength of the Connect for Life platform is its scalability; the project can easily be expanded to cover a large number of sites and patients with great cost efficiency, if those facilities have access to computers and internet connectivity. To deliver the project at scale, creation of content in regional languages will be an important consideration. The platform is adaptable, as the local IT provider can add and remove new data fields and update the SMS text message content, voice files, and call flows. However, changes to the functionality of the software or interoperability with other systems will require support from the software developers at Johnson and Johnson Global Public Health. The Philippines Department of Health has plans to implement electronic reporting systems for HIV services at an

aggregated level. If the department is ever to implement a patient-level electronic medical record, interoperability with Connect for Life will be an important consideration to ensure delivery at scale.

A strength of this process evaluation study is the mixed methods and participatory approach. The study used prospectively collected quantitative data on participants' responses to the intervention and qualitative feedback from questionnaires, monthly process reports, and FGDs. The evaluation included the users of the intervention, clinical service providers, and developers of the technology platform.

The methodology addressed all key components in process evaluation for public health interventions and studies (context, reach, dose delivered, dose received, fidelity, implementation, and recruitment) [55]. Furthermore, the study included information on the technology platform, infrastructure, security, and cost, as guided by the mHealth Evidence Reporting and Assessment checklist developed by the World Health Organization mHealth Technical Evidence Review Group [35].

A limitation of our approach was that the evaluation was conducted by the same study team responsible for planning and implementing the intervention, rather than by independent evaluators. Other limitations included the convenience sampling strategy for participants in the FGDs and the low participation in the focus groups. Although the study team approached many individuals to participate, it was a challenge to identify those who were willing owing to reluctance to disclose their HIV status in a group. Furthermore, owing to transportation challenges, there was low attendance among those who confirmed their intention to participate in the groups.

Incomplete data may have affected the interpretation of the results. Of the 462 participants in the study, 440 (95.2%) attended the final study visit at week 48, and 89.1% (392/440) of them completed the questionnaire during the final visit. There may be differences in the experiences of participants who transferred out, died, withdrew from the study or were lost to follow-up, attended but did not complete the questionnaire, and completed the questionnaire.

This study focused on MSM in Metro Manila, and the study population was urban and highly educated. Participants may have had alternative adherence reminders, including self-set phone alarms and email alerts. Therefore, the results are not broadly generalizable to other contexts.

Conclusions

mHealth interventions are useful to support adherence, as they have low replication costs and are highly adaptable to specific cultural contexts. On the basis of the findings of this process evaluation, we can guide practitioners implementing mHealth interventions to support medication adherence to consider the following recommendations:

1. The intervention should allow the participant to personalize the service based on their preferences for delivery by SMS text message or voice calls, timing of messages and calls, and selection of content.

- Limit the complexity of the IVRS menus to reduce the “hassle” factor and likelihood of technical failures. If the navigation of menus is a key aspect of the intervention, consider using an app or a chatbot instead of, or in addition to, an IVRS system.
 - Consider how to use the mHealth intervention to facilitate human interaction. For example, certain responses to the intervention may prompt counselor-, clinician-, or peer support.
 - Ensure that the roll out of an existing mHealth technology in a new setting is an iterative process that includes robust process evaluation methods. Rigorous pilot-testing is needed to ensure technical function. Work plans should include ample time and budget for adaptation of the technology.
- The Connect for Life mHealth intervention to support adherence to ART had high participant satisfaction and acceptability. However, the feasibility of the intervention was dependent on the reliability of local telecommunications networks, and poor reliability of the local mobile networks had a large impact on the intervention’s usability, fidelity, and dose received.
- The process evaluation allowed us to better understand the preferences and use patterns of mHealth services by MSM in the Philippines. This will enable the effective scale-up of mHealth services for this key population, which is essential in the context of the dual HIV and COVID-19 pandemics, where more services must be delivered virtually.

Acknowledgments

This study received sponsorship from Johnson and Johnson Global Public Health. The authors are thankful to their collaborators in the Johnson and Johnson team for developing the Connect for Life platform and for their extensive work in tailoring the technology to the Philippine setting: RG, Paula McKenna, Piet Knaepen, Avinash Agrawal, and Jurgen de Beckker. Furthermore, this study would not have been possible without the efforts of the implementing partner, the Sexually Transmitted Infection and AIDS Guidance Intervention and Prevention Unit at the Philippine General Hospital. The authors thank Cari Free, Ford Hickson, and James Hargreaves at the London School of Hygiene and Tropical Medicine for their guidance during protocol development, especially regarding intervention development, behavior change theory, and process evaluation methodology. The study was funded through a sponsorship agreement with Johnson and Johnson Global Public Health, the developer of the Connect for Life platform. According to the licensing agreement, all platform content and data are owned solely by the licensee (Sustained Health Initiatives of the Philippines). Although Johnson and Johnson Global Public Health had a collaborative role in the intervention development phase, all data collection and analysis were conducted by the study team at the Sustained Health Initiatives of the Philippines.

Conflicts of Interest

None declared.

Multimedia Appendix 1

Process evaluation methodology.

Abstract

Background: Alcohol use disorder (AUD) is associated with severe chronic medical conditions and premature mortality. Expanding the reach or access to effective evidence-based treatments to help persons with AUD is a public health objective. Mobile phone or smartphone technology has the potential to increase the dissemination of clinical and behavioral interventions (mobile health interventions) that increase the initiation and maintenance of sobriety among individuals with AUD. Studies about how this group uses their mobile phone and their attitudes toward technology may have meaningful implications for participant engagement with these interventions.

Objective: This exploratory study examined the potential relationships among demographic characteristics (race, gender, age, marital status, and income), substance use characteristics (frequency of alcohol and cannabis use), and clinical variables (anxiety and depression symptoms) with indicators of mobile phone use behaviors and attitudes toward technology.

Methods: A sample of 71 adults with AUD (mean age 42.9, SD 10.9 years) engaged in an alcohol partial hospitalization program completed 4 subscales from the Media Technology Usage and Attitudes assessment: *Smartphone Usage* measures various mobile phone behaviors and activities, *Positive Attitudes* and *Negative Attitudes* measure attitudes toward technology, and the *Technological Anxiety/Dependence* measure assesses level of anxiety when individuals are separated from their phone and dependence on this device. Participants also provided demographic information and completed the Epidemiologic Studies Depression Scale (CES-D) and the Generalized Anxiety Disorder (GAD-7) scale. Lastly, participants reported their frequency of alcohol use over the past 3 months using the Drug Use Frequency Scale.

Results: Results for the demographic factors showed a significant main effect for age, *Smartphone Usage* ($P=.003$; $\eta_p^2=0.14$), and *Positive Attitudes* ($P=.01$; $\eta_p^2=0.07$). Marital status ($P=.03$; $\eta_p^2=0.13$) and income ($P=.03$; $\eta_p^2=0.14$) were associated only with the Technological Anxiety and Dependence subscale. Moreover, a significant trend was found for alcohol use and the *Technological Anxiety/Dependence* subscale ($P=.06$; $R^2=0.02$). Lastly, CES-D scores ($P=.03$; $R^2=0.08$) and GAD symptoms ($P=.004$; $R^2=0.13$) were significant predictors only of the *Technological Anxiety/Dependence* subscale.

Conclusions: Findings indicate differences in mobile phone use patterns and attitudes toward technology across demographic, substance use, and clinical measures among patients with AUD. These results may help inform the development of future mHealth interventions among this population.

Introduction

Background

Many chronic health problems are associated with alcohol use disorder (AUD), including stroke, high blood pressure, heart disease, cancer of the esophagus, liver, and colon [1-3]. AUD is also related to a plethora of psychological and behavioral problems [3]. According to the 2019 National Survey on Drug Use and Health, prevalence rates of AUD among US adults show that 14.1 million have this disorder [4]. Approximately 88,000 people die annually from alcohol-related diseases [4,5], making it a significant public health concern. Accordingly, an objective of alcohol treatments is to help patients abstain from alcohol use.

Long-term abstinence has been shown to improve various complications of alcohol-related diseases [6]. Abstinence maintenance is intricately linked with the successful completion of the initial days following alcohol cessation, when individuals tend to experience elevated anxiety, depression, and cravings for alcohol and are thus at high risk for a relapse occurrence [7,8]. Patients at this stage tend to report low self-efficacy to effectively manage daily triggers for alcohol consumption [9,10]. Consequently, fundamental strategies to facilitate the acquisition of sobriety and long-term maintenance requires real-time interventions that provide individuals with ongoing support and the necessary skills to manage relapse risk factors [9,10]. Mobile phone technologies are among the recommended platforms to augment public health impact [11,12] and can be harnessed to increase reach and dissemination of multifaceted approaches designed to effectively address both cognitions and behaviors associated with AUD.

The wide availability of mobile phone or smartphone ownership (97%) and frequent app usage (80% in the past 30 days) among US adults [13,14] provides an opportunity for researchers to reach this population at scale. Traditional face-to-face substance use intervention programs are inherently limited in their ability to assess and treat real-time risks that can occur in the individual's day-to-day environment [11]. Moreover, low engagement and high attrition are common among traditional substance use treatment interventions with this population, particularly among patients in early recovery [11,15,16]. Smartphone-delivered interventions have shown promising results in increasing engagement and improving outcomes with mental health and behavioral health treatments, although most mHealth studies lack any theoretical framework [11,17,18]. For example, a recent review shows efficacy of mHealth alcohol use interventions, but results remain mixed overall [11].

According to Golbert et al [11], strengthening the rigor of this emerging research requires applying theoretically informed approaches and the use of randomized controlled trials (RCTs) to adequately assess the effect of these new interventions [11]. To our knowledge, there are 2 theory-informed, smartphone app delivered interventions for adults with AUD being conducted [19,20]. While these studies could help determine the efficacy of these technology-based approaches for improving alcohol use outcomes, essential to their success is an understanding of how individuals with AUD use their mobile phone in their daily lives and their attitudes toward technology, which may have an effect on participants' engagement with these interventions.

Studies conducted with general populations have demonstrated variability in mobile use patterns across demographic subgroups (eg, men vs women, White vs non-White, and married vs single) [21,22]. Correspondingly, these findings have been used to inform the development of mHealth approaches addressing barriers and facilitators for behaviors that are more likely to appeal to particular groups [21,22]. Similar assessment studies with individuals with AUD may provide guidance for the development of mHealth intervention approaches in different subgroups of this population, such as those with higher levels of comorbid affective symptoms (eg, anxiety and depression). Because mHealth interventions with individuals with AUD is a developing research area, examining predictors of smartphone use and attitudes toward technology is an important step toward advancing this work.

Objectives

This study explores mobile use behaviors and attitudes toward technology among adults with AUD receiving outpatient treatment. In addition to demographic characteristics (eg, age, gender, and marital status), mental health factors (eg, anxiety and depression symptoms), which are highly relevant to this population [23,24], were also examined as potential correlates of mobile phone behaviors and attitudes toward technology. Moreover, a potential effect of the level of alcohol use on mobile phone behaviors and attitudes toward technology was explored.

Methods

Participant Recruitment and Study Design

Participants were recruited from an alcohol and drug partial hospitalization program at a private hospital in the Northeastern United States. This program provides an abstinence-based and cognitive-behavioral treatment. Patients attend 3-4 groups per day (eg, relapse prevention, drink, drug refusal skills, goal-setting, etc), daily individual counseling with a mental

health worker, and medication management with an attending psychiatrist. Adult patients were approached by research staff to determine their interest in participating in a study designed to develop or test a 12-week smartphone app for increasing physical activity engagement among adults in early recovery from alcohol. Recruitment occurred in 2 phases: as part of an open pilot and then subsequently as part of a RCT. Data collected as part of the baseline assessment from each of these phases were examined in this paper.

Ethics Approval

The study was approved by the Institutional Review Board at Butler Hospital (IRB# 1604-003).

Measures

Demographic information was collected for race, age, ethnicity, gender, marital status, income, and education.

Media and Technology Usage and Attitudes (MTUA) Scale

The MTUA is a 50-item scale with 15 subscales. In this study, we administered 4 subscales: *Smartphone Usage*, *Positive Attitudes Toward Technology*, *Negative Attitudes Toward Technology*, and *Technological Anxiety/Dependence*. Each subscale has been shown to have strong validity and reliability [25]. The *Smartphone Usage* subscale consists of 7 items assessing the frequency, on a 10-point frequency, ranging from 1=never to 10=all of the time, of engaging in various smartphone activities (eg, texting, emailing, taking pictures). The other 3 subscales are measured based on a Likert-type scale, ranging from 1=strongly agree to 5=strongly disagree [25] and assess different attitudes toward technology: (1) *Positive Attitudes* subscale (an item is “I feel I get more accomplished because of technology”), (2) *Negative Attitudes* subscale (an item is “new technology makes life more complicated”), and (3) *Technological Anxiety/Dependence* subscale measures anxiety that resulted from individuals being away from their phone (an item is “I get anxious when I don’t have my phone with me”).

The Drug Use Frequency Scale

The Drug Use Frequency Scale is a self-report instrument consisting of 10 items that measure the frequency of use for different substances over the past 3 months [26]. Participants reported their frequency of alcohol use (and use of other substances) using a 7-point Likert-type scale ranging from 0=not all to 7=every day. A score of ≥ 5 indicates a high frequency of substance use [26].

Generalized Anxiety Disorder 7-item (GAD-7)

The GAD-7 scale consists of items that reflect the diagnostic symptom criteria for this disorder (eg, “feeling anxious, nervous, and on edge”) based on the Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition [27]. Participants are asked to indicate how often in the last 2 weeks they were bothered by the different symptoms. Response options are 0=not at all to 3=nearly every day. Items 1-7 are summed to provide a total score [27].

The Center for Epidemiologic Studies Depression (CES-D) Scale

CES-D is a 20-item self-report measure that assesses the presence of depression symptoms experienced over the past week [28]. Each item is measured on a 4-point Likert-type scale that indicates the frequency of depression symptoms ranging from 0=rarely or none of the time to 3=most or all of the times. A sum of scores is calculated for this measure [28].

Statistical Methods

Overview

Frequencies for the following demographic characteristics were examined in the combined data set from the 2 trials (open pilot and RCT): race, marital status, age, gender, ethnicity, education, employment, and income. There were missing data for variables (eg, employment, education, and income) not collected in the open pilot study.

Sample Characteristics and Development of Subgroups

Sample size constraints for the variables race and marital status allowed for comparison between being White and non-White and married/living with a partner vs single/divorced/widowed. For age, a median split approach was used to create 2 age groups: ≥ 43 years and ≤ 44 years. Less than 1% of the sample reported an ethnic identity, and hence group comparisons were not feasible. Employment status was coded into 2 groups: employed vs unemployed/retired/disabled. For education, the groups were high school/some college versus college degree/advanced degrees. Annual income was reported by 39 participants and was coded into 2 categories: \leq US \$75,000 and \geq US \$75,000.

Preliminary Analyses

Chi-square tests were used to explore potential proportion difference among race, gender, age (independent variables), and marital status, education, employment, and annual income (dependent variables). A series of ANOVA models evaluated mean differences for the abovementioned 7 demographics and the 3 dependent variables, GAD-7, CES-D, and alcohol use.

Primary Analyses

ANOVA evaluated demographic differences for each of the 4 MTUA subscales. Separate linear regression analyses were used to explore a potential association between anxiety (GAD-7) and depression (CES-D), alcohol use (independent variables), and each of the MTUA subscales (dependent variables). In addition to statistical significance, partial eta-squared (η_p^2), R , or $R^2\beta$ values were used, as appropriate, to demonstrate the level of association between the independent variables and dependent measures [29,30].

Results

Sample Description

The majority of participants identified as White (56/70, 80%), others identified as non-White (14/70, 20%), and over half of the participants were men (36/62, 58%). Nearly half of the sample was aged ≤ 43 years (30/61, 49%), while 51% (31/61)

of participants were aged ≥ 44 years. Participant age range was 20-64 (mean 42.89, SD 10.9) years. Fifteen participants were married/living with a partner (15/40, 38%), and 25 (63%) were single/divorced/widowed. For education, 43% (17/40) of participants were in the high school/some college category, and 57% (23/40) were in the college degree/advanced degrees group. Moreover, 56% (27/48) of the sample was employed, and 12% (25/48) were unemployed/retired/disabled. Furthermore, 67% (24/39) of participants reported an annual income of \leq US \$75,000, while 39% reported an annual income of \geq US \$75,000. The distribution of alcohol use variables showed that 37%

(26/71) of the sample reported consuming alcohol for “5-6 days a week” over the past 3 months. A higher number of participants (33/71, 47%) reported consuming alcohol “every day” over the past 3 months.

There were no statistically significant differences for race, gender, age and marital status, education, employment, and annual income (Table 1).

Moreover, there were no statistically significant relationships between the demographics and the GAD-7, CES-D, and alcohol use variables (see Table 2).

MTUA Subscales and Demographic Characteristics

Smartphone Usage Subscale

Smartphone usage scores were significantly different between the 2 age groups ($F_{1,69}=10.87$; $P=.002$; $\eta_p^2=0.14$). Participants

aged ≤ 43 years had a higher mean score on this measure (mean 29.46, SD 5.07) than those aged ≥ 44 years (mean 24.35, SD 7.67). There were no significant relationships for the subscale and the other demographic variables. Detailed information can be found in Table 3.

Table 3. Inferential statistics for the demographics, Media Technology Usage and Attitudes subscales, and clinical characteristics.

Demographics								
Race	0.911 (1,68)	.34	0.071 (1,68)	.79	0.190 (1,68)	.66	0.548 (1,67)	.46
Gender	2.353 (1,60)	.13	0.847 (1,60)	.36	0.058 (1,60)	.81	0.106 (1,60)	.75
Age	10.87 (1,69)	.002	4.819 (1,69)	.03	0.493 (1,68)	.49	0.788 (1,69)	.79
Marital status	0.374 (1,38)	.55	2.629 (1,38)	.11	0.352 (1,37)	.56	5.468 (1,38)	.03
Education	0.065 (1,38)	.80	3.368 (1,38)	.07	2.586 (1,37)	.12	1.084 (1,38)	.30
Employment	0.153 (1,46)	.70	6.196 (1,46)	.02	0.164 (1,45)	.69	1.257 (1,46)	.27
Annual income	0.403 (1,37)	.53	0.585 (1,37)	.45	0.583 (1,36)	.45	6.196 (1,37)	.02
Clinical characteristics								
Generalized Anxiety Disorder	2.194 (1,65)	.14	0.868 (1,65)	.36	0.331 (1,64)	.57	5.135 (1,65)	.03
Epidemiologic Studies Depression Scale	3.554 (1,62)	.06	2.194 (1,65)	.14	0.113 (1,62)	.74	9.024 (1,62)	.004
Alcohol use	0.525 (1,69)	.47	0.374 (1,69)	.54	0.046 (1,68)	.83	3.640 (1,69)	.06

Positive Attitudes Subscale

Positive attitudes toward technology were significantly different between the 2 age groups, ($F_{1,69}=4.819$; $P=.03$; $\eta_p^2=0.07$). Specifically, younger participants, aged ≤ 43 years, had a greater positive attitude toward technology (mean 22.75, SD 3.90) than those in the older age group, aged ≥ 44 years (mean 20.94, SD 2.63). As shown in Table 3, there were no significant relationships for this subscale and the other demographic variables.

Technological Anxiety/Dependence Subscale

Marital status was associated with *Technological Anxiety/Dependence* ($F_{1,38}=5.468$; $P=.03$; $\eta_p^2=0.13$). Participants who were married reported less anxiety when separated from their phone and less dependence on their device (mean 8.26, SD 3.43) compared to the single, divorced, widow group (mean 10.48, SD 2.54). In addition, differences in scores on the *Technological Anxiety/Dependence* subscale were also observed between the income groups ($F_{1,37}=6.196$; $P=.02$; $\eta_p^2=0.14$). Individuals with an annual income of \leq US \$75,000 had greater technological anxiety or dependence on their phone (mean 10.63, SD 2.28) versus those with an annual income of \geq US \$75,000 (mean 8.27, SD 3.65). There were no significant relationships between the 2 subscales and the other demographic variables (see Table 3).

MTUA Subscales and Anxiety and Depression Symptoms

Anxiety was a significant predictor of *Technological Anxiety/Dependence* scores ($F_{1,65}=5.135$; $P=.03$). The correlation coefficient ($R=0.27$) shows a positive linear relationship between the 2 variables. Anxiety symptoms accounted for 8% ($R^2=0.08$) of variance in *Technological Anxiety/Dependence* scores. A

significant β coefficient of .22 ($t=2.266$; $P=.03$), suggesting a one-unit increase of 0.22 in reported anxiety and dependency on technology for every 1-point increase in anxiety, as measured by the GAD-7 scale. Significant findings were not found between anxiety and *Smartphone Usage* ($F_{1,65}=2.194$; $P=.14$), *Positive Attitude* ($F_{1,65}=0.868$; $P=.36$), and *Negative Attitude* ($F_{1,64}=0.331$; $P=.57$).

Depressive symptoms were also a significant predictor of *Technological Anxiety/Dependence* subscale scores ($F_{1,62}=9.024$; $P=.004$). The correlation coefficient ($R=0.36$) shows a positive and linear relationship between the 2 variables. Depression symptoms account for 13% ($R^2=0.13$) of variance in the *Technological Anxiety/Dependence* measure. A significant β coefficient of .36 ($t=3.004$; $P=.004$) was noted, indicating for one-unit increase in depression, there is a .36 increase in technological anxiety/dependence. A near significant trend was noted between depression symptoms and *Positive Attitude* ($F_{1,62}=3.554$; $P=.06$). Results for the other subscales were as follows: *Smartphone Usage* ($F_{1,62}=1.316$; $P=.26$) and *Negative Attitude* ($F_{1,61}=0.113$; $P=.74$).

MTUA Subscales and Alcohol Use

Frequency of alcohol use in the past 3 months and reported anxiety when being away from one's mobile phone or being dependent on this device showed a near significant trend ($F_{1,69}=3.640$; $P=.06$; $R^2=0.02$). Results for the other subscales were as follows: *Smartphone Usage* ($F_{1,69}=0.525$, $P=.47$), *Positive Attitudes* ($F_{1,69}=0.612$, $P=.54$), and *Negative Attitudes* ($F_{1,68}=0.046$, $P=.83$).

Discussion

Principal Findings

This study provides an examination of mobile phone use behavioral patterns and attitudes toward technology among a sample of adults with alcohol use disorder (AUD) in early recovery. Demographics, anxiety and depressive symptoms, and alcohol use were associated with smartphone usage and attitudes toward technology. These results may provide insights into the development of mobile phone delivered intervention (mHealth) approaches for individuals with AUD.

Relative to older patients with AUD, those aged ≤ 43 years reported higher rates of smartphone usage and were more likely to have positive attitudes about media use. Specifically, younger patients had greater reliance on their mobile phone to complete various tasks, such as using apps, searching for directions, and browsing the web and reported a more positive view of these activities. These results are consistent with previous studies demonstrating a strong association between being a younger age and greater reliance on this device to complete many daily tasks—aided by easy access to the internet—compared to older adults [21,22]. High usage of mobile apps has been shown to be associated with perceived importance in facilitating the accomplishment of targeted goals using these platforms [21,22].

Therefore, this younger subgroup of patients may be very receptive to using a smartphone app to help during early recovery, and mHealth strategies consistent with how this group uses their phone are likely to be more acceptable and engaging. For example, a mobile phone app with a “resource” feature on AUD may provide a menu of information on the psychophysiological impact of this disorder, effective treatments, including strategies for managing risks for relapse, such as environmental triggers, depression, anxiety, and cravings [1,2,4]. Given existing barriers to treatment and the impact of chronic alcohol use on long-term memory and cognitive functioning [6], ready access to this information in moments of greatest need (eg, high-risk situations) may be critical toward improving alcohol treatment outcomes.

Our findings also demonstrated that single/divorced/widowed participants indicated greater anxiety without their phone or feeling more dependent on this device than those who were married/living with a partner. A previous study assessing mobile phone use behaviors among a nonclinical population has shown overall similar results [21]. It is possible that individuals with AUD who do not live with a partner are more likely to rely on their phone to remain connected with family members or friends. Therefore, when developing technology-supported approaches for individuals with AUD not living with partners, app features that allow participants to easily connect with others may be desirable. For example, apps that contain message boards that allow communication between users or being able to use certain *keywords* (eg, “struggling”) to immediately connect with a clinician to receive additional support to address emerging barriers or experiences could be an attractive app feature in this subgroup individuals.

Moreover, participants with an annual income of \leq US \$75,000 also showed higher anxiety without their phone or were more dependent on their device. A Pew Research Center report on mobile phone usage and annual income conducted between 2013 and 2021 showed individuals of this income bracket as being more smartphone-dependent than their higher-income counterparts [13]. While it is not clear what contributes to the difference in dependency on smartphones between income groups, this report found individuals of this income level are more likely to be “smartphone only internet users” and less likely to own other devices (eg, a computer or iPad) [13]. It is possible that lower financial resources indicate greater increased reliance to on this device to complete many and different tasks. Moreover, AUD is more prevalent among socioeconomically disadvantaged groups than those of a higher income level [31,32]. This intersection has been associated with a higher prevalence of many chronic conditions, such as liver disease, type 2 diabetes, hypertension, and some cancers, compared to the general population [2,33,34]. The current evidence shows that low-income adults with AUD are significantly dependent on their mobile phone and thus suggests the potential acceptability of mHealth programs among this subgroup. Accordingly, researchers have the opportunity to deliver both clinical and behavioral health intervention approaches that address cognitions and behaviors salient in increasing sobriety and thereby decreasing associated health risks among this group. For example, engagement in physical activity or yoga has shown to be beneficial as an adjunctive tool in treatments for AUD [35-37]; however, these interventions are small and are typically delivered in person and over many months. Accordingly, mHealth approaches have the potential to reach a large section of this group and promote sobriety on a large scale.

Lastly, the study findings showed that anxiety and depression symptoms were significant predictors of *Technological Anxiety/Dependence* scores, although they accounted for minimal variance ($R^2=0.08$ and 0.13 , respectively). Nevertheless, anxiety and depression symptoms are highly prevalent among individuals with AUD, and mobile phone app programs that would allow participants to track their symptoms may provide insights into trends associated, such as the relationship between anxiety or depression symptoms and alcohol cravings. Additionally, an app feature that could enable participants to share this type of information with their provider could help inform treatment decisions. However, more research is necessary to determine whether media anxiety and phone dependency may, in fact, be contributing toward an increase in anxiety and depression symptoms in this population.

Limitations and Future Work

An important limitation of this study is the lack of heterogeneity with respect to participant ethnicity, preventing an assessment of a potential relationship between a particular ethnic group and mobile phone or media constructs. For example, Latinx populations have increased incidence rates of AUD that may be linked to minority stress and socioeconomic status [31, 32]. Assessment of mobile use behaviors among Latinx adults with AUD is an important research area to determine the potential receptiveness of mHealth substance abuse treatment approaches

in this group. Accordingly, more research is needed to extend the current understanding of the nature or frequency of mobile phone usage and views of this technology across different demographic subgroups with AUD. In addition, participants enrolled in this study were interested in using a smartphone app to help them increase their physical activity in early recovery. It is possible that the results of this study may not generalize to the broader AUD patient population. Moreover, future studies with a larger sample size with AUD is needed to assess these relationships. Despite these limitations, the findings may help inform future mHealth approaches that can be used to augment addiction treatment in individuals with AUD. Aligned with the goals of precision medicine, mHealth approaches that are

tailored to specific individuals needs and characteristics may be more effective in improving overall treatment outcomes.

Conclusions

Notwithstanding these limitations, the study findings provide insight into the relationship between age, marital status, income, depression, and anxiety on empirical constructs for mobile phone use behaviors in adults with AUD. Moreover, the study results provide knowledge into mHealth approaches that are likely to appeal to the needs of different demographic adult subgroups with AUD. Our findings accentuate the need to fully understand individuals' mobile phone use and attitudes toward technology to evaluate their potential influence on the level of engagement with mHealth interventions in different adult groups with AUD.

Abstract

Background: Machine learning uses algorithms that improve automatically through experience. This statistical learning approach is a natural extension of traditional statistical methods and can offer potential advantages for certain problems. The feasibility of using machine learning techniques in health care is predicated on access to a sufficient volume of data in a problem space.

Objective: This study aimed to assess the feasibility of data collection from an adolescent population before and after a posterior spine fusion operation.

Methods: Both physical and psychosocial data were collected. Adolescents scheduled for a posterior spine fusion operation were approached when they were scheduled for the surgery. The study collected repeated measures of patient data, including at least 2 weeks prior to the operation and 6 months after the patients were discharged from the hospital. Patients were provided with a Fitbit Charge 4 (consumer-grade health tracker) and instructed to wear it as often as possible. A third-party web-based portal was used to collect and store the Fitbit data, and patients were trained on how to download and sync their personal device data on step counts, sleep time, and heart rate onto the web-based portal. Demographic and physiologic data recorded in the electronic medical record were retrieved from the hospital data warehouse. We evaluated changes in the patients' psychological profile over time using several validated questionnaires (ie, Pain Catastrophizing Scale, Patient Health Questionnaire, Generalized Anxiety Disorder Scale, and Pediatric Quality of Life Inventory). Questionnaires were administered to patients using Qualtrics software. Patients received the questionnaire prior to and during the hospitalization and again at 3 and 6 months postsurgery. We administered paper-based questionnaires for the self-report of daily pain scores and the use of analgesic medications.

Results: There were several challenges to data collection from the study population. Only 38% (32/84) of the patients we approached met eligibility criteria, and 50% (16/32) of the enrolled patients dropped out during the follow-up period—on average 17.6 weeks into the study. Of those who completed the study, 69% (9/13) reliably wore the Fitbit and downloaded data into the web-based portal. These patients also had a high response rate to the psychosocial surveys. However, none of the patients who finished the study completed the paper-based pain diary. There were no difficulties accessing the demographic and clinical data stored in the hospital data warehouse.

Conclusions: This study identifies several challenges to long-term medical follow-up in adolescents, including willingness to participate in these types of studies and compliance with the various data collection approaches. Several of these challenges—insufficient incentives and personal contact between researchers and patients—should be addressed in future studies.

Introduction

Physicians and public health workers are often asked to make predictions on patient health outcomes after specific medical and surgical treatments. Over the years, many medical specialties have created prediction models to identify treatments that optimize patient health outcomes [1,2]. In general, these systems are based on traditional logistic regression models that use a limited set of clinical and physiological variables.

Machine learning (ML) uses statistical learning to uncover complex nonlinear relationships among data. ML identifies patterns from big data sets and, subsequently, enables researchers to predict outcomes [3]. Discovering nonlinearities in the data is how ML techniques such as neural networks can complement traditional statistical methods for analyzing complex medical problems, such as presurgical, intrasurgical, and postsurgical outcomes [4].

Recent advances in wearable technology, as well as improvements in data mining capability, have allowed physicians to gain access to a wide variety of patients' physiologic, behavioral, and psychological data that can be used to build ML models [5,6]. Wearable technology enables the repeated or continuous digital measurement of different types of parameters. Typically, the real-time measurement of the 4 basic vital signs (ie, temperature, heart rate, respiration rate, and blood pressure) is limited to a single event over several months, most often during a visit to a primary care physician. Wearables enable the longitudinal measurement of these and other parameters with high precision [7]. Similarly, wearables can provide approximate information about sleep patterns, differentiating wake from sleep [8], as well as accurately measuring step count and activity duration [9].

There are few studies evaluating the feasibility of the various data collection methods in this context. There are still substantial barriers to the widespread use of wearable technology and web-based surveys in clinical research among adolescents. Although most of the technological barriers have been addressed in the last decade, patients' compliance with wearing the tracking devices as well as patients' fatigue from repeated communications with the care team are still major challenges. Reports from commercial studies indicate that 50% of new users of wearables and 74% of new users of health apps stop using them within 2 weeks [10]. Patient participation is often related to the extent of how they feel the clinical study they initially agree to participate in can actually meet their needs, fulfill their expectations, and align with their goals [11,12]. In general, patient attitude is often tied to perceived usefulness in long-term studies [13].

Given these considerations, this study evaluated the feasibility of monitoring health parameters in adolescents prior, during, and 6 months after a posterior spine fusion (PSF) operation. We assessed patients' adherence with wearing a health tracking device, answering web-based surveys, and filling out paper surveys. We also evaluated the feasibility of data extraction from the hospital data warehouse and the aggregating of the extracted data with data from the original electronic medical record (EMR).

Methods

Recruitment and Study Population

Patients were approached at the time of their evaluation in the orthopedic surgeons' office once they had been scheduled for a PSF operation and evaluated to determine whether they met the inclusion criteria, which included the following.

- Patients with idiopathic scoliosis scheduled for PSF surgery at Johns Hopkins All Children's Hospital
- Patients of both sexes, aged 12 to 19 years
- Participants, parents, or legal guardians with reliable Wi-Fi or a cellular internet access data plan
- Participants, parents, or legal guardians with a compatible Bluetooth smartphone or home computer
- Completion of written informed consent by participants, their parents, or legal guardians
- Participants and parents were able to understand the instructions to upload data

Once the consent to participate in the study was obtained, we distributed a Fitbit device with the corresponding instructions on its use and downloaded the information onto a secure website for subsequent data analysis.

Data Sources and Study Variables

Data were collected from the following sources: (1) wearable devices (Fitbit Charge 4), (2) hospital data warehouse, (3) electronic surveys, and (4) paper pain diaries.

Adherence

We defined adherence to the protocol as patients who answered at least 75% of the Qualtrics surveys and wore the tracking device at least 75% of the time.

Fitbit Data

Patients received a Fitbit Charge 4 (Fitbit) at the time of enrollment. The Fitbit Charge 4 is a lightweight, noninvasive wearable tracking device that reports daily step count, vigorous activity minutes, heart rate, and sleep patterns to the user's smartphone or computer. The study team asked the patients to sync the device on a daily basis. We created personal Fitbit accounts linked to Fitabase (Small Steps Labs), a Health Insurance Portability and Accountability Act-compliant, encrypted, and password-protected portal that aggregates data from the Fitbit server for easier extraction. We collected the following data from Fitabase: daily steps, time spent asleep (minutes/day), and heart rate (beats/minute). Data captured by the Fitbit were synced to the patient's personal device using the Fitbit app and subsequently stored on the central cloud-based Fitbit cloud services. The Fitabase portal extracted the patient-level data from the Fitbit cloud services.

GPS function was disabled by default by the study coordinators, and study participants were advised not to alter this functionality on their device or smartphone app.

EMR Data

A variety of demographic and physiologic data are stored in the EMR. Johns Hopkins All Children's Hospital has built a

physiologic data warehouse that stores inpatient physiologic data in a long-term storage solution. The system comprises data captured from operating rooms and specific patient care areas throughout the hospital. For the purpose of this study, we retrieved age, sex, medications, and pain scores. Once data were extracted from the hospital data warehouse, they were stored in a REDCap research database (REDCap Consortium). Data were collected before, during, and for 6 months after the PSF operation.

Psychosocial Data

To identify psychosocial difficulties or barriers to recovery from surgery, psychosocial surveys were administered to patients via the QualtricsXM web-based software platform (SAP America Inc) before, during, and 3 and 6 months post-PSF surgery. We used the following validated surveys: Pain Catastrophizing Scale [12], Patient Health Questionnaire [13], Generalized Anxiety Disorder Scale [14], and Pediatric Quality of Life Inventory [15]. The survey data were collected and stored using REDCap.

Pain Diary Data

Patients completed a daily paper diary documenting pain levels and analgesic medications. These data were manually inputted and stored in REDCap.

Statistical Analysis

Continuous variables were summarized with means, SDs, and ranges (minimum to maximum), and categorical variables were summarized with counts and percentages. Statistical comparisons between compliant and noncompliant groups were evaluated with 2-tailed *t* tests for independent samples, and 2-sided *P* values <.05 were considered statistically significant. Statistical analyses were performed using the *Pandas* and *NumPy* Python packages (Python Software Foundation).

Ethics Approval

This study was reviewed and approved by the Johns Hopkins All Children's Hospital Institutional Review Board (IRB00211758). Written consent was obtained from the parents and study participants.

Results

In total, 2 orthopedic surgeons evaluated 108 patients with a diagnosis of idiopathic scoliosis between October 2020 and September 2021. Of the 108 patients scheduled for a PSF surgery, 84 (77.7%) were approached. Of the 84 patients approached, 32 (38%) were enrolled in the study. The reasons why we were not able to enroll the other patients approached are listed in [Table 1](#).

[Table 1](#) lists the reasons why 62% (52/84) of the patients who were approached were not enrolled in the study. Of the 52

patients not enrolled, 25% (n=13) did not meet the inclusion criteria. In 46% (n=24) of the patients, we were not able to reach out on time to enroll them or there was not sufficient time to establish at least 2 weeks of baseline values prior to the scheduled surgery because of staffing limitations.

At the time of writing, of the 32 enrolled patients, 13 (41%) have completed the 6-month follow-up period, and 3 (9%) are still in the process of completing the follow-up. The remaining 16 (50%) patients dropped out during the follow-up period and did not complete the study. [Table 2](#) lists the reasons why patients did not complete the 6-month study period. Patients dropped out of the study on average 17.6 (SD 7.2; range 6-31) weeks from the day of surgery ([Table 3](#)). Of the 16 patients who dropped out of the study, the average age was 14 (SD 1.3; range 12-17) years, and there were 10 (62%) girls and 6 (38%) boys. Of the 16 patients who completed the study, there were 11 (69%) girls and 5 (31%) boys, and the average age was 14.8 (SD 1.9; range 13-18) years. There was no statistical difference between the 2 groups (*P*=.80) with respect to age and sex distribution. We defined noncompliant patients as those who did not complete the Qualtrics survey at least 75% of the time.

Of the 32 enrolled patients, 12 (38%) were considered noncompliant because they failed to complete the Qualtrics survey at least 75% of the time. However, 1 of them completed the Fitbit portion of the study. The remaining 11 patients stopped synchronizing the device within 1 to 5 months after the surgery.

Of the 13 patients who completed the follow-up, 12 (92%) patients were consistent in wearing the Fitbit at least 75% of the time during the day ([Table 4](#)). Their adherence was constant over the 6-month study. Additionally, 11 (85%) patients were also compliant in wearing the Fitbit at least 75% of the time at night for the duration of the study ([Table 4](#)).

Of the 13 patients who completed the follow-up, 9 (69%) completed the Qualtrics questionnaires throughout the entire study, and only 4 (31%) completed the Qualtrics questionnaires at least 75% of the time over the study period ([Table 5](#)).

The follow-up involved paper-based surveys to assess pain scores and the use of analgesic medications. None of the 13 patients who have completed the study were compliant with completing the pain paper diary during the study period.

We were able to retrieve the pain scores from the hospital data warehouse. These data were manually matched with those recorded in the patients' EMR, and no discrepancies were found between the 2 databases. We collected additional demographic and clinical data, including the daily morphine equivalent doses of opioids administered and amount of blood transfusions (data not shown).

Table 1. Reasons why patients were not enrolled in the study.

Reason	Patient (N=84), n (%)	Detail
Not meeting inclusion criteria	13 (15)	Either above or below study age limits
Unable to operate Fitbit	5 (6)	Mental delay or Spanish-speaking only
Eligible for the study but denied participation	10 (12)	N/A ^a
Researchers missed enrollment encounter	19 (23)	Limited staffing
Not sufficient time to obtain baseline values	5 (6)	Changes in surgery scheduling

^aN/A: not applicable.

Table 2. Reasons why patients dropped out of the study once they were enrolled.

Reason	Patient (N=32), n (%)
Completed study	13 (41)
Still enrolled	3 (9)
Parents asked to stop	2 (6)
Lost Fitbit	2 (6)
Noncompliant	12 (38)

Table 3. Duration of patients' participation in the study before dropping out prior to the 6-month (26 weeks) follow-up. There was 1 patient who never started the study even though she signed the written consent form.

Patient number	Study participation (week), n
1	9
2	21
3	26
4	31
5	11
6	10
7	14
8	6
9	24
10	23
11	26

13	16
14	15
15	12
16	18

Table 4. Patients' adherence with wearing Fitbit devices during the day and night. Data reflect the percent of time patients wore the Fitbit during the first and second study periods (1-3 and 4-6 months, respectively).

Study period, percentage of time wearing the Fitbit	During the day (N=13), n (%)	During the night (N=13), n (%)
1-3 months		
100%	11 (85)	5 (38)
75%	1 (8)	6 (46)
50%	1 (8)	2 (15)
25%	0 (0)	0 (0)
4-6 months		
100%	7 (54)	6 (46)
75%	5 (38)	5 (38)
50%	1 (8)	1 (8)
25%	0 (0)	1 (8)

Table 5. Number of patients who responded to the Qualtrics surveys over the study period.

Percentage response to Qualtrics surveys	Patient (N=13), n (%)
100%	9 (69)
75%	4 (31)
50%	0 (0)
25%	0 (0)

Discussion

Principal Findings

The goal of this study was to assess whether it is possible to collect meaningful and reliable clinical data over extended periods of time from adolescents who needed a surgical procedure using different techniques. This was the preliminary phase of a project that will use ML to predict outcomes after complex surgical procedures in children and adolescents.

This study showed that it is possible to conduct long-term health outcome assessment in adolescents using tracking devices and web-based apps that allow repeated surveys of populations. The study confirmed that there are multiple obstacles to conducting and completing this type of study. The willingness of adolescents and parents to participate and complete the surveys are major limiting factors. It was not surprising to find that adolescents were more compliant with completing electronic surveys than paper surveys.

Comparisons With Prior Work

There are few data on children and adolescents' willingness to participate in clinical trials as well as their use of tracking devices and electronic surveys.

We faced several challenges when conducting this study. We encountered problems enrolling patients in the study. Once patients were enrolled, there was a relative high number of dropouts. Only 38% of the patients we contacted agreed to be enrolled in the study, and once enrolled, only 50% of them completed the study.

Adult studies have shown that provider and patient factors are common barriers to patients' enrollment in clinical studies. A lack of time and resources often prevent physicians from being involved in patients' enrollment [14,15]. The presence of a strong, trusting relationship between physicians and patients is often a determining factor in patients and parents' willingness to participate in a study [16]. The fear of experimentation and medical mistrust are common barriers to participation in clinical studies [17,18]. Privacy concerns may have also played a role in parents' decision not to participate in the study. Our low number of enrolled patients might be attributed to the lack of direct contact between the principal investigator and patients, as patients were contacted by research personnel who were not directly involved in the patients' care. Similarly, the lack of personal contact between the researchers and patients may have influenced the large number of dropouts.

The feasibility of using ML techniques is predicated on the access to patients' data and building reliable data sets. We collected data prior, during, and after the hospital stay of adolescents who underwent a PSF operation. We used paper-based surveys, electronic surveys, wireless-enabled wearable technology, and hospital-based data warehouse to collect patients' data. The goal was to acquire a broad set of data, including numerical, categorical, time-series, and text data.

Peer-reviewed research on the use of Fitbit devices found that the device is reliable for tracking daily activity in healthy young adults [19]. Barriers to wearing tracking devices have been reported in the literature. Many of the issues reported in early studies have been addressed by the manufacturer as new devices are now waterproof and new batteries provide long intervals between recharges. With respect to monitoring sleep, devices

such as Fitbits are not a substitute of polysomnography. However, there is consensus among researchers that devices such as Fitbit can provide gross estimates of time spent sleeping [8]. It is still controversial whether they can offer an accurate reading of the sleep stages [20]. The new generation Fitbits can provide a much wider set of information.

We were able to retrieve the number of steps and the number of minutes the patients spent sleeping from the Fitabase.

It was interesting to notice that the patients who remained in the study for 6 months were also very compliant with wearing the Fitbit. The patients who were not compliant with answering the Qualtrics surveys were also not compliant with wearing the Fitbit, with the exception of 1 patient. This seems to indicate that they dropped out because of a general lack of interest in continuing with the study and not because of the specific burden of complying with either the Qualtrics survey or wearing the Fitbit.

A potential draw back on the long-term use of these tracking devices is the novelty factor, with waning interest in wearing these devices after a couple of weeks [21,22]. Our overall patients' adherence with constantly wearing the Fitbit was similar to their adherence with answering the Qualtrics surveys. Further analysis and possibly creating focus groups will help the understanding of these differences in adolescents' behaviors.

The widespread introduction of EMRs has allowed clinician, administrators, and researchers to have rapid access to a wealth of patients' demographic and clinical data. EMR data can be transferred into clinical and research registers independently from registry purposes. We were able to collect data we consider to be relevant in this pilot feasibility study. There are challenges to this methodology, with the main concern being the accuracy of the data inputted into the EMR and registries. Authors have suggested creating some form of data curation to review and assess data quality. For the purpose of this study, we collected demographic and numerical data while the patients were hospitalized, with the majority of the data automatically recorded by hospital monitor devices. The only self-reported data were the pain scores, where nurses used a numeric scale to document

the patients' pain levels during the hospital stay [23]. We confirmed the accuracy of the process by manually verifying the EMR with the data extrapolated from the hospital warehouse.

It was not surprising to observe a low adherence to filling out the follow-up paper diary documenting the patients' pain level and use of analgesic medications. Recent surveys have shown that approximately 75% of adolescents own a smartphone [24]. The same survey highlighted how teenagers prefer texting to talking to their peers. In addition, there is also some evidence that adolescents prefer electronic books to paper books [25]. These findings may explain why our patients were compliant with answering electronic surveys but did not complete the paper surveys. Additionally, a very demanding schedule where patients were asked to report daily pain scores and medications used for 6 months may have caused survey fatigue.

Limitations

There are a few limitations to this study. The relatively low percentage of patients willing to participate and then comply with the study requirements may have introduced a selection bias. The lack of data on pain levels throughout the study has resulted in the inability to make correlations between pain levels and behaviors.

Conclusions

This preliminary study showed that it is possible to conduct long-term studies and evaluate the different aspects of adolescents' behaviors and outcomes of health interventions using wearable devices and web-based surveys. These technologies may substantially lower the cost of conducting this type of research.

This study confirmed that there are barriers to engaging relatively healthy adolescents and keeping them interested in participating in this type of long-term study.

Further studies are needed to identify better ways of informing patients and their families of the relevance of these long-term studies. Researchers should also design strict reminder schedules including periodic texts, phone calls, and emails and consider rewards to keep patients engaged in these long-term surveys.

Conflicts of Interest

None declared.

Abstract

Background: Type 2 diabetes (T2D) is a lifestyle-related disease whose prevalence increases with age. Diabetes self-management through mobile health (mHealth) apps enables patients with T2D to improve their health. According to the Technology Acceptance Model (TAM), technology acceptance (ie, intended use) is necessary to ensure mHealth can be implemented successfully. Therefore, the specific acceptance requirements of patients with T2D should be considered.

Objective: This cross-sectional study aims to examine the extent to which different TAM predictors are associated with the acceptance of a diabetes app including an electronic coach (eCoach; Iris app) among patients with T2D.

Methods: Using a web-based survey, data on 92 patients with T2D (mean age 62.76 years, SD 8.29 years) were collected. Acceptance of the Iris app with the TAM predictors (ie, perceived usefulness, perceived ease of use, social influence, perceived self-efficacy, perceived security, prior usage experience, perceived health, and propensity of data/information sharing) was assessed. Further, control variables (ie, gender, age, education, ethnicity, household, BMI, amount of years with diabetes, diabetes-related complaints, and medication use) were assessed.

Results: Multiple linear regression analyses showed that acceptance of the Iris app was positively associated with perceived usefulness ($\beta=.57, P<.001$), social influence (subjective norm; $\beta=.20, P=.004$), and willingness to share data ($\beta=.25, P<.001$). In addition, acceptance regarding the Iris app was higher among patients with T2D with overweight ($\beta=.23, P=.01$) or obese BMI ($\beta=.21, P=.01$). The model explained 75.8% of the variance in the acceptance of the Iris app by patients with T2D. In addition, perceived usefulness of the Iris app was positively related to perceived ease of use ($\beta=.32, P<.001$), subjective norm ($\beta=.26, P=.004$), perceived control ($\beta=.19, P=.03$), willingness to share data ($\beta=.20, P=.01$) regarding the Iris app, and perceived security regarding general use of apps/smartphone/internet ($\beta=.15, P=.04$). The model explained 58.2% of the variance in patients' perceived usefulness about the Iris app.

Conclusions: Among patients with T2D, the belief that the use of the Iris app is helpful/beneficial, the willingness to share their Iris app data, and others' approval of using this app can stimulate the acceptance of this app. In addition, the belief that the use of (health) apps is reliable and secure, the belief that the use of the Iris app is easy to use, a higher perceived capability and personal control with using this app, the willingness to share their Iris app data, and others' approval of using this app can stimulate the perceived usefulness of such an app. These TAM predictors explained a high variance in acceptance and perceived usefulness of the Iris app. Implications for practice are addressed.

KEYWORDS

mobile health; type 2 diabetes; self-management; eCoach; Technology Acceptance Model

Introduction

Background

Type 2 diabetes (T2D) is a global public health problem leading to increased mortality and morbidity risk. Furthermore, T2D can affect patients socially and economically [1]. The prevalence of this chronic disease is high and still increasing [2,3]; in particular, people older than 50 years are at an increased risk [4-6]. In addition, T2D prevalence is higher among people with low socioeconomic status (SES) [7]. Empirical evidence indicates that a healthier lifestyle (eg, eating healthy and more physical activity) and monitoring blood glucose levels may improve the health status of patients with T2D and reduce health complications of diabetes [5,8]. For societal, economic, and ethical reasons, increasing demands are made on individuals to self-manage their own health and to maintain a healthy lifestyle. Patients with T2D are supposed to take control over their life and health, and diabetes self-management is therefore crucial [9].

For patients with T2D, mobile health (mHealth) apps can be a valuable tool to support self-management [9,10]. In general, the advantages of mHealth apps include a wide reach of people, and tailored and timely health information, education, and support [11]. Regarding T2D, many apps have been developed over the past years, which focus on supporting self-management and education of patients with T2D to promote a healthy lifestyle and health [4,11,12]. However, the elements of these apps vary, and may include insulin management applications, wearable blood glucose meters, automated SMS text messages, health diaries, and virtual health coaching [11]. The meta-analysis of Greenwood et al [9] showed that apps including components of 2-way communication, personalized data, and tailored education and feedback contributed most to an improved HbA1c (also referred to as glycohemoglobin or hemoglobin A1c, an indicator of adequate diabetes management). Previous empirical studies showed that the usability and efficacy of these T2D apps vary to a great extent [13]. Technology acceptance is crucial to ensure mHealth, such as these T2D apps, can be implemented as planned, and thus understanding the requirements for this acceptance is very important. The few empirical studies that examined the predictors of patients' acceptance of diabetes management showed that predictors based on extended versions of the Technology Acceptance Model (TAM; [14]) explained a high variance (around 60%) in patient's intention to use diabetes management apps, which is a proxy for acceptance [15]. To anticipate the development of the Iris (T2D) app, which is intended as an electronic coach (eCoach) to support self-management of patients with T2D, the aim of this study is to determine which predictors are associated with acceptance of this specific app (for a description of the Iris app, see the "Methods" section).

Prior Research

The TAM [14] is one of the most prevailing, dominant theoretical models that has been frequently applied to predict

consumer acceptance of health technology such as mHealth [16]. The TAM is based on social-cognitive models such as the Theory of Planned Behavior [17,18], Diffusion of Innovations Theory [19], and Social Cognitive Theory [20]. According to the original TAM, behavior (in this case, using the Iris app) is determined by behavioral intention, which is a proxy for acceptance. Furthermore, the following 2 major cognitive predictors, perceived usefulness and perceived ease of use, directly predict acceptance of health technology such as the Iris app. Perceived usefulness refers to an individual's belief that the use of this technology is helpful/beneficial, whereas perceived ease of use refers to an individual's belief that this technology is easy to use [14,16].

In the course of the years, the original TAM has been modified by extending it with additional predictors. Several extended TAM models have been proposed. For example, the Unified Theory of Acceptance and Use of Technology (UTAUT; [21,22]) included social influence (ie, subjective norms) as another important cognitive factor that predicts acceptance of health technology. Subjective norms refer to an individual's belief of how other people, especially the people whom they trust and resort to, will evaluate them when using the technology [21]. In addition, Cialdini [23] has emphasized the importance of social norms and made a distinction between injunctive norms (ie, an individual's belief of what most other people approve of) and descriptive norms (ie, an individual's belief of what most other people typically do). Thus, social influence in the TAM can refer to injunctive and descriptive social norms, where subjective norms are a person's perception of injunctive norms of relevant other persons [24]. The UTAUT [21], Senior Technology Acceptance Model (STAM; [25]), and an extension of the TAM by Fathema et al [26] included perceived self-efficacy/behavioral control as a cognitive factor predicting perceived usefulness, perceived ease of use, and acceptance. Perceived self-efficacy/control refers to an individual's belief to successfully handle technology and personal control over technology [26]. Other examples of extended versions of the TAM included perceived security and trust (ie, the extent to which a user believes that a particular service is secure), prior usage experience with mobile phones and eHealth, perceived health (ie, self-management of diabetes), and willingness to share data (ie, willingness to share personal information/data; eg, [16,21,25,27-40]). Although several predictors have been proposed according to (extended) TAM models, only a few empirical studies examined TAM predictors of diabetes management apps and showed support for these predictors [15]. Nevertheless, empirical studies that tested the TAM predictors regarding acceptance of T2D eCoaching apps, specifically, are lacking. Previous studies focused predominantly on the usability and efficacy of T2D apps [13] or used a qualitative approach to examine the acceptance of diabetes apps (eg, [41]).

Study Objective

The aim of this study was to examine the predictors associated with the acceptance of the Iris app for patients with T2D. According to (extended) TAM models, we hypothesize that the

following predictors are positively associated with acceptance of the Iris app: perceived usefulness, perceived ease of use, social influence (ie, descriptive and subjective social norms), perceived self-efficacy/behavioral control, perceived security, prior usage experience, perceived health, and willingness to share data. In line with others (eg, [21,24]), we included the following control variables: sociodemographic factors (ie, gender, age, education, ethnicity, household) and health-related factors (ie, BMI, amount of years with diabetes, diabetes-related complaints, and medication use).

Methods

Participants

Participants provided informed consent prior to completing the 20-minute survey. Inclusion criterion was men and women with T2D who had a smartphone that they used regularly. We used convenience sampling. Recruitment took place from July to November 2018 through an advertisement on the website of the Dutch Diabetes Association [42], through flyers handed out at the National Diabetes Challenge festival in Amsterdam (September 2018), and through a Facebook advertisement in November 2018. The online survey was an “open survey” that was voluntary and accessible for individuals who received, through these advertisements and flyers, the link to the study information and survey online. In total, 97 participants filled out the online survey. The individuals who provided digital informed consent filled in all items on the questionnaire. Thus, the participation rate equaled the completion rate. As a reward, participants received an online web shop voucher of €10 (US \$10.43).

Procedure

The recruitment materials included a link that referred interested individuals to the study information online (including information about the duration of the survey, incentive, data storage, the research team, and the purpose of the study) and a subsequent consent page. Following digital consent, participants could continue to fill in the survey. The 20-minute survey consisted of questions regarding their experience with (diabetes) apps and their willingness to share health information with others. Privacy and anonymity of the participants were guaranteed.

The Anticipated App Iris

The Iris app is a dynamically tailored intervention that provides personalized diet and physical activity advice, as well as behavioral support. Users start with intake: First, users fill out health data (eg, BMI, medication usage, HbA1c). Second, users can decide whether they are willing to work on a physical activity or diet goal. To provide personalized dietary advice, users are asked to rate from different food products (eg, fruits, vegetables, sugar-sweetened beverages) their average intake per week (quantity per day and number of days per week). Similarly, when users select a physical activity goal, they are

asked to rate their activities on a general week (physical activity toward work, at work, around the house, leisure time, and sports). Based on the health data, users are provided with a recommended diet (Mediterranean, low carbohydrate, or low caloric diet). Based on the dietary intake or physical activity data, users are provided with feedback on what food categories or physical activities are compliant with the recommended intake, and which categories could be improved. Next, users can self-set a specific daily or weekly goal (eg, eating 2 pieces of fruit for 3 days).

When a goal is set, a user will be asked to daily assess whether they have reached their goal, and assess their goal motivation, goal competence, and mood (each on a 3-point scale: negative, neutral, or positive). The app includes a monitoring page, where people can monitor the number of times they reached their goal for 7 days. In addition, based on whether a goal was (partly) reached or not, each week a user is provided with (positive) feedback on their performance. Furthermore, based on the daily diary data, the most important barriers for not reaching a goal are assessed (motivation, competence, planning, or mood), and a tailored intervention is recommended to overcome the barrier, based on an effective behavior change technique.

Measurements

The majority of the measurements were self-constructed and based on theoretical reasoning (original and modified versions of the TAM), empirical studies (eg, [16]), and the results of the 3 focus group interviews we conducted regarding the barriers and facilitators to use the Iris app (n=23 patients with diabetes). The outcome variable was technology acceptance. Predictors of technology acceptance included perceived usefulness, perceived ease of use, social influence, perceived self-efficacy, perceived security, prior usage experience, propensity of data/information sharing, and perceived health. According to the TAM, these predictors can align with the use of mHealth technology in general (eg, apps, smartphone, and internet) as well as to a specific mHealth technology (eg, a specific app such as the Iris app). In our study, we distinguished these TAM predictors. To examine the specific predictors of the Iris app, we provided participants with mock-ups of this app, explaining different elements of the potential coach, to provide participants with an idea about what the Iris app (ie, digital coach) would offer. A display with different screens of the Iris app was shown to the participants (Figure 1). We will first describe in detail below the assessment of the outcome variable; followed by the TAM predictors regarding the general use of apps, smartphone, and internet and the TAM predictors regarding the use of the Iris app; and finally the control variables. Unless otherwise specified, all questionnaire items were answered on a 5-point Likert scale ranging from 1 (strongly disagree) to 5 (strongly agree). The description of the items of the outcome variable and predictors (including Cronbach α) is depicted in Table 1. If the variable was measured with 2 or more items, the mean was used to compute the variable.

Figure 1. Screenshots of the Iris T2D app. (A) Introduction of the coach Iris. (B) Nutritional advice. (C) Setting daily dietary goals. (D) Daily reminder. (E) Feedback and compliments. (F) Tips and exercises.

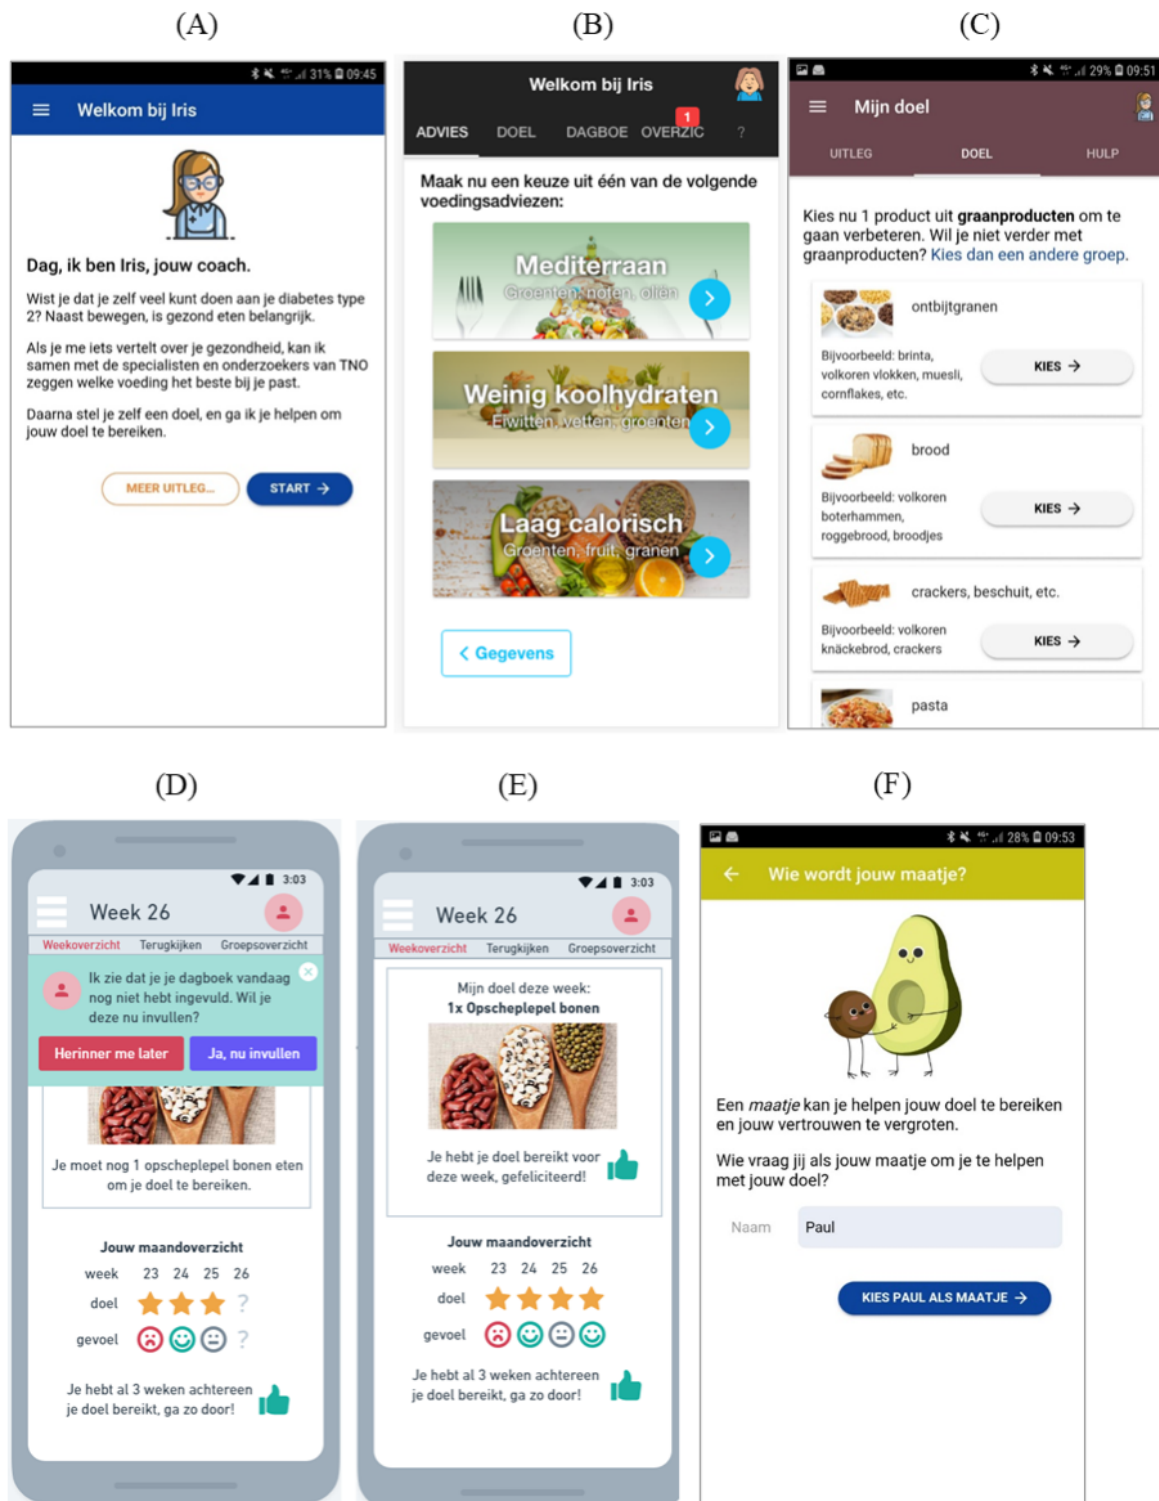

Table 1. Descriptive statistics of the outcome variable and TAM predictors.

Construct	Item	Cronbach α	Mean (SD)	n
Outcome variable				
Acceptance of the Iris app	<ul style="list-style-type: none"> I would like to use the Iris app, if this was presented to me. I intend to use the Iris app to improve my health. I would use the Iris app for managing type 2 diabetes. 	.936	3.67 (0.91)	N/A ^a
Predictors regarding the general use of apps/smartphone/internet				
Perceived usefulness/outcome expectancies	<ul style="list-style-type: none"> Health apps can help me improve my health. Health apps make it easier for me to cope with my diabetes. Health apps ensure that I am less dependent on others. By daily keeping track of my diet, I am better at coping with my diabetes. I appreciate it when I receive direct advice from an app to improve my lifestyle. An app needs to be fun, if I want to use it. I like to use my mobile phone. I find it annoying to receive daily reminders of an app {R}^b. I question whether an health app can support me quite effectively {R}. 	.787	3.64 (0.69)	91
Perceived ease of use	<ul style="list-style-type: none"> I find it easy to use health apps. I quickly learn how to operate new apps. 	$r=0.702$, $P<.001^c$	3.65 (1.06)	89
Social influence

Prior usage experience				
Behavior regarding internet use	<ul style="list-style-type: none"> I use the internet to search for information about my diabetes (problems). 	N/A	3.86 (1.27)	87
Frequency of smartphone use ^e	<ul style="list-style-type: none"> How often do you use your smartphone? 	N/A	N/A	92
Use of app for their diabetes ^e	<ul style="list-style-type: none"> Do you use apps for your diabetes and which one(s)? 	N/A	N/A	92
Perceived health				
Attitude regarding diabetes self-management	<ul style="list-style-type: none"> I am worried about my diabetes. I have my diabetes well in hand. I think that my treatment (medication/insulin) helps my diabetes. With eating healthy food, I can decrease the risk of diabetes problems. Exercising helps to reduce diabetes problems. My weight is of influence on my diabetes. My health is important for me. I would like to improve my overall health. 	.730	3.65 (0.67)	92

Construct	Item	Cronbach α	Mean (SD)	n
Self-efficacy regarding diabetes self-management	• I succeed in controlling my diabetes.	.822	4.19 (0.57)	92
	• I succeed in eating healthy daily.			
	• I succeed to sufficiently exercising weekly.			
	• I succeed to watch out for the number of meals and snacks.			
	• I succeed in checking my blood glucose regularly.			
Self-care regarding diabetes self-management	• I take my diet into account for a good blood glucose level.	.730	3.54 (0.71)	92
	• I take my diabetes medication as required.			
	• I have tried to lose weight because of my diabetes.			
	• Once in a while I eat too much sweetness and other food rich in carbohydrates {R}.			
	• I prefer not to go to doctor appointments for my diabetes {R}.			
	• Sometimes I eat more than I intended to {R}.			
	• I tend to skip exercise/sport {R}.			
	• I am bad taking care of myself with respect to diabetes {R}.			
Predictors regarding the use of the Iris app				
Perceived usefulness	• I like a digital coach that motivates me to eat healthier.	$r=0.863$, $P<.001^c$	3.53 (0.88)	92
	• I find it useful if a digital coach motivates me to eat healthier.			
Perceived ease of use	• I question whether a digital coach can support me quite effectively {R}.	.698	3.03 (0.71)	92
	• I find it unpleasant if I would receive daily messages of a digital coach {R}.			
	• I prefer to be supported by a real person {R}.			
	• It is easier for me to cope with my diabetes with a digital coach.			
Perceived social influence				
Subjective norm	• My health practitioner would find it important that I use the digital coach.	$r=0.568$, $P<.001^c$	3.14 (0.73)	92
	• People close to me (family, friends) would find it important that I use the digital coach.			
Perceived control	• I succeed in using a digital coach daily.	N/A	3.25 (1.04)	92
Willingness to share data	• My general practitioner would be allowed to view the data that I maintain in the app.	.835	3.86 (0.80)	92
	• My data that I gather in the app can be used for research.			
	• I would share my data if these help other patients with diabetes.			

^aN/A: not applicable.

^b{R} means reverse coded.

^cCronbach α could not be calculated for variables with 2 items, and therefore Pearson correlation (r) and P value were reported.

^dThese 2 predictors had a great number of missing information because participants responded that “they did not know” (30/92, 33% and 29/92, 32%, respectively).

^eThese 2 predictors were dichotomous; for more information about the percentage of these predictors, see [Table 2](#).

Overview

3 items. An additional response option to the 5-point Likert scale included “not applicable,” which was recoded as missing.

Outcome

The outcome variable was acceptance of the Iris app. Acceptance refers to the intended use of the Iris app. It was measured with

TAM Predictors Regarding the General Use of Apps, Smartphone, and Internet

Perceived usefulness was assessed by outcome expectancies that indicate the positive consequences of using health apps. It was measured with 9 items.

Perceived ease of use was assessed with 2 items.

Perceived social influence was assessed by the following 2 variables: subjective norm (also referred to as injunctive norm) regarding app use, and descriptive norm regarding app use. Subjective norm regarding app use was measured with 1 item on a 5-point Likert scale ranging from 1 (strongly agree) to 5 (strongly disagree). Answers were reverse coded. Descriptive norm regarding app use was measured with 1 item on a 5-point Likert scale ranging from 1 (strongly agree) to 5 (strongly disagree). Answers were reverse recorded.

Perceived security was assessed with 4 items.

Prior usage experience was assessed by the following 3 variables. Behavior regarding internet use was measured with 1 item. Frequency of smartphone use was measured with 1 item and response categories were recoded into 2 categories: “more than 1 time a day” and “daily to weekly.” Use of apps for their diabetes was measured with different responses (eg, Koolhydraatkenner; Mijn Eetmeter; MyFitnessPal), and computed into 2 response categories: “do not use any apps for diabetes management” and “yes, do use, 1 or more apps for diabetes management.”

Perceived health was assessed by the following 3 variables, obtained from the Diabetes Management Self-Efficacy Scale (DMSES; [43]) and the Diabetes Self-Management Questionnaire (DSMQ; [44]). *Self-efficacy regarding diabetes self-management* was measured with 5 items. *Attitudes regarding diabetes self-management* were measured with 8 items. For each item, participants could also answer “not applicable,” which was recoded as missing. *Self-care regarding diabetes self-management* was measured with 8 items. A high score represents positive self-care.

TAM Predictors Regarding the Use of the Iris App

Perceived usefulness was assessed with 2 items.

Perceived ease of use was assessed with 4 items.

Perceived social influence was assessed by the subjective norm regarding digital coach use with 2 items. Descriptive norm was not measured because the digital coach was not yet publicly available or in use.

Perceived control was measured with 1 item.

Willingness to share data was measured with 3 items.

Control Variables

Sociodemographic Factors

Gender was coded as “male” and “female.” Age was categorized into 2 based on the sample median: “<63 (=25-62) years” and “≥63 (63-84) years.” Education was assessed using 10 categories (ranging from primary education to university degree), and recoded into 3 categories, of which low-level education was

computed as the reference category and intermediate- and high-level education as the 2 dummies. Ethnicity was based on country of birth. This variable was recoded into 2 categories: “Dutch” and “other.” Household was recoded into 2 categories: “living alone” and “living together with partner and/or children.”

Health-Related Factors

BMI was measured by length (in centimeters but recoded into meters) and weight (kg). We calculated BMI (kg/m^2), and classified it into 3 categories: “normal” (≥ 20 and $< 25 \text{ kg}/\text{m}^2$), “overweight” (≥ 25 and $< 30 \text{ kg}/\text{m}^2$), and “obese” ($\geq 30 \text{ kg}/\text{m}^2$) [45]. We computed 2 dummies with “normal” BMI as the reference category.

Amount of years with diabetes was measured by asking how long (number of years) people were diagnosed with T2D. Diabetes-related complaints that participants could indicate included, for example, eye problems, nerve damage (neuropathy), kidney problems. Ticking more than 1 box was possible. This was computed into the following 2 categories: “no, having no complaints” and “yes, having 1 or more complaints.” Medication use was measured by asking which medicines do you use for your T2D, and was computed into the following 2 categories: “not using medication” and “using medication.”

Data Analyses

We first checked for multicollinearity ($r \geq 0.80$) between the predictors, but this was not the case. The full correlation table, including correlations between the predictors, can be requested from the first author. To examine the research question, we performed the analyses in 3 steps. First, we performed bivariate linear regression analyses with the (control) variables and the outcome (step 1). Second, we conducted a multiple linear regression analysis (step 2), including the significant (control) variables of step 1. We first analyzed, in step 2a, a multiple linear regression model including the significant TAM predictors regarding the general use of apps, smartphone, and internet as well as the use of the Iris app (eg, perceived usefulness, perceived ease of use, descriptive and subjective norms, perceived self-efficacy/behavioral control, perceived security, prior usage experience, perceived health, and willingness to share data). Subsequently, in step 2b, we added the significant control variables (eg, gender, age, education, ethnicity, household, BMI, amount of years with diabetes, diabetes-related complaints, and medication use) to the multiple linear regression model. Finally, we repeated the multiple linear regression analysis with only the significant (control) variables of step 2 (step 3). We used pairwise missing data and a P value $< .05$ was considered significant. Moreover, we computed the R^2 for steps 2 and 3. To provide more additional information about the model quality, we plotted the dependent variable against the predicted values, and performed bootstrapping. Overall, the scatterplot shows that the model gives a pretty good prediction for the outcome (see [Multimedia Appendix 1](#)). In addition, the bootstrapping analyses indicated that overall our model is quite robust.

Ethics Approval

The Institutional Review Board (IRB) of the Netherlands Organization for Applied Scientific Research (ie, TNO) approved the study (IRB registration number: 2018-029).

Results

Demographics and Descriptive Analysis

Of the 97 participants that filled out the survey, 2 participants never used a smartphone and 1 participant had missing values on the majority of the questions, and thus, were removed from the data set and analyses. In addition, 2 other participants were excluded from the analyses, as they indicated that they did not experience any diabetes-related complaints, did not use

medication, and had 0 years of diabetes, ergo they may not have had T2D. Thus, in total, 92 participants were included in the data analyses. The sample characteristics of the 92 participants are presented in [Table 2](#). The majority of the participants (57/92, 62%) did not use an app for diabetes management. The participants that did use health or lifestyle apps predominantly used the app “MyFitnessPal” (9/92, 10%), and 2 Dutch food-related apps, namely, “Koolhydraatkenner” (10/92, 11%) and “Mijn Eetmeter” (14/92, 15%).

Descriptive analyses (mean and SD) of the predictors and outcome are depicted in [Table 1](#). Except for descriptive norms regarding app use (mean 2.81, SD 1.20), average ratings were higher than 3 on all variables, implying a positive stand on these variables.

Table 2. Demographics of the study participants (n=92).

Variable	Values
Female gender, n (%)	48 (52)
Age (years)	
Range	25-80
Mean (SD)	62.76 (8.29)
≥63 ^a , n (%)	49 (53)
Missing, n (%)	1 (1)
BMI (kg/m²), n (%)	
<25 (normal)	15 (16)
25-<30 (overweight)	39 (42)
≥30 (obese)	35 (38)
Missing	3 (3)
Highest completed level of education, n (%)	
Low	40 (44)
Intermediate	28 (30)
High	24 (26)
Country of birth (the Netherlands), n (%)	86 (93)
Household (together with partner or children), n (%)	76 (83)
Frequency of phone use (>1 time/day), n (%)	74 (80)
Number of years with diabetes	
Range	0-34 ^b
Mean (SD)	11.41 (8.32)
Missing, n (%)	2 (2)
Diabetes-related complaints (yes), n (%)	80 (87)
Medication use (yes), n (%)	82 (89)
Practitioner, n (%)	
General practitioner/nurse practitioner	68 (74)
Hospital doctor	21 (23)
Other	3 (3)
Use of apps for diabetes management (yes), n (%)	35 (38)

^aThe median was used to divide age into 2 categories.

^bThere was 1 person indicating 0 years with diabetes, but also indicated medication use and complaints regarding diabetes and was included in the sample.

Predictors Associated With the Acceptance of the Iris App

We first identified with bivariate linear regression analyses the factors that were significantly (ie, $P < .05$) associated with the acceptance of the Iris app (Table 3, step 1). The findings indicated that beliefs of patients with T2D that general and specific use of technology is helpful/beneficial ($\beta = .42$, $P < .001$ and $\beta = .81$, $P < .001$, respectively) and easy to use ($\beta = .32$, $P = .003$ and $\beta = .55$, $P < .001$, respectively) increased the acceptance of the app. Besides, their belief that using (health) apps is reliable and secure was related to an increase in the acceptance of the app ($\beta = .29$, $P = .005$). Patients with T2D who used the internet

to search for information about their diabetes ($\beta = .29$, $P = .007$) or had a positive attitude toward diabetes self-management ($\beta = .34$, $P = .001$) showed a higher acceptance of the app. Except for behavior regarding internet use, prior usage (frequency of smartphone use, $\beta = .09$, $P = .40$; use of apps for their diabetes, $\beta = .02$, $P = .84$) was not significantly associated with acceptance of the app. Furthermore, perceived health (self-efficacy regarding diabetes self-management, $\beta = -.05$, $P = .62$; and self-care regarding diabetes self-management, $\beta = -.15$, $P = .15$), except for attitude regarding diabetes self-management, was not significantly associated with acceptance of the app. Beliefs of patients with T2D that others (health practitioner, family, friends) approved of using the app ($\beta = .61$, $P < .001$) and

perceiving a higher capability and personal control over using the app ($\beta=.58, P<.001$) increased the acceptance of the Iris app. Descriptive norms regarding the general use of apps, smartphone, and internet were not significantly associated with acceptance of the app ($\beta=.13, P=.32$). Patients with T2D who were willing to share their app data showed an increase in the acceptance of the app ($\beta=.52, P<.001$). Furthermore, being overweight ($\beta=.40, P=.008$) or experiencing more diabetes-related complaints ($\beta=.32, P=.002$) was significantly associated with a higher acceptance of the app. The sociodemographic factors (gender, age, education level, ethnicity, household) were not associated with a higher acceptance of the app.

Only the (control) variables that showed to be significant ($P<.05$) in the bivariate analyses were entered in the multiple linear regression analysis (Table 3, step 2b). The findings indicated that beliefs of patients with T2D that the use of app is helpful/beneficial ($\beta=.52, P<.001$), that others approved of using this app ($\beta=.18, P=.02$), and whether they were willing to share their app data ($\beta=.22, P=.002$) increased the acceptance of the Iris app. Furthermore, being overweight ($\beta=.22, P=.01$) or obese ($\beta=.20, P=.02$) was associated with an increase in the acceptance of the Iris app compared with having a “normal” weight. Moreover, the multiple regression analysis that we repeated with only the significant (control) variables (ie, for those where $P<.05$) of step 2 (Table 4, step 3) showed a similar pattern of results.

As perceived usefulness of the app showed to have a strong effect, we performed additional analyses to examine the predictors related to perceived usefulness of the app. We used the same statistical procedure as we did for acceptance of the app. The findings of the bivariate analyses for perceived usefulness of the app (Table 5, step 1) showed to be similar as the findings of the bivariate analyses for acceptance of the app, except for BMI, which was not significantly related to perceived usefulness of the app ($\beta=.24, P=.11$). The significant (control) variables (ie, $P<.05$) were entered in the multiple regression analysis (Table 5, Step 2b). The findings were partly in line with the findings of the acceptance of the app. Similar to the findings of the acceptance of the app, beliefs of patients with T2D that others (ie, health practitioner, family, friends) approved of using the app ($\beta=.26, P=.006$) and their willingness to share their app data ($\beta=.22, P=.01$) were related to an increase in perceived usefulness of the app. In contrast to the findings of the acceptance of the app, the findings also showed that beliefs of patients with T2D that the use of (health) apps is reliable and secure ($\beta=.24, P=.04$), that the use of the digital coach is easy to use ($\beta=.32, P=.003$), and that higher perceived capability and personal control with using the app ($\beta=.21, P=.03$) were related to an increase in the perceived usefulness of the app. Moreover, the multiple regression analysis, which we repeated with only the significant (control) variables (ie, $P<.05$) of step 2 (Table 6, Step 3), showed a similar pattern of results.

Discussion

Principal Findings

In this study we examined which factors could explain acceptance of a diabetes self-management eCoach (the Iris app). Acceptance of the app was mainly predicted by perceived usefulness, positive subjective norms, and willingness to share data. In addition, perceived usefulness was predicted by perceived security, positive subjective norms, willingness to share data, perceived ease of use, and perceived control. These predictors explained a high variance in acceptance and perceived usefulness of the Iris app (75.8% and 58.2%, respectively). Moreover, the TAM predictors regarding the use of the Iris app were more strongly associated with acceptance of this app than the predictors regarding the general usage of apps, smartphone, and internet. This can be explained by the compatibility principle, which indicates that the outcome variable will be better predicted if the specificity of the predictor matches the specificity of the outcome [46]. Furthermore, our study included elderly people (mean age of our sample was 63 years) and those with low educational level (40/92, 44%). Previous studies implied that elderly people and people with low SES may be more reluctant to use mHealth as they encounter more barriers while using innovative mHealth technologies [4,47]. Our findings showed that this was not the case regarding the Iris app, as there was no association between the sociodemographic factors (gender, age, education level, ethnicity, household) and the acceptance or perceived usefulness of the app.

Regarding the 2 core TAM predictors, perceived usefulness was strong and positively associated with acceptance of the Iris app, whereas perceived ease of use was not associated with acceptance of the app. However, perceived ease of use was moderately related to perceived usefulness of the app, which is in line with the TAM and a recent meta-analysis [48]. Moreover, perceived usefulness regarding the use of the (Iris) app showed to be a predictor but not perceived usefulness regarding the general use of apps, smartphone, and internet. Our findings imply that perceived usefulness is the most important predictor of acceptance of health technology, which is in line with previous studies (eg, [15,16,31,49]). Although our finding regarding perceived ease of use is in contrast to previous studies (eg, [31,49-51]), it was in line with the findings of Dou et al [16] and Zhang et al [15]. Their results did not show a significant association between perceived ease of use and patient's intention to use smartphone health technology [16] or diabetes management apps [15], but rather implied an indirect association through perceived usefulness. Thus, if people feel the technology is easy to use, they would be more likely to develop positive attitudes toward the use of the health technology and perceive it as beneficial and helpful.

Besides the 2 core elements, the TAM has been extended with a range of other predictors. Our findings showed support for social influence as a predictor, but only for subjective norms specifically regarding the Iris app but not for subjective norms regarding the general use of mHealth technology (ie, apps, smartphone, and internet) nor descriptive norms. Thus, patients with T2D tend to do what is socially approved by other people

regarding the use of the Iris app but not necessarily what is popular to do. A possible explanation as to why we did not find support for descriptive norms is that we did not measure this specifically regarding the app. Another possible explanation may be that, to assess descriptive norms, patients with T2D were only asked about the people they know. These people, however, are not necessarily the role models who patients with T2D acknowledge as important in their lives (eg, family, friends, health practitioner) or who they can identify with (eg, others who also have T2D). By contrast, to assess subjective norms, patients with T2D were explicitly asked about the people who are important in their lives (ie, family, friends, health practitioner).

Our findings showed that perceived behavioral control was not associated with acceptance of the Iris app by patients with T2D but was associated with perceived usefulness of the app. Individuals believing that they are capable of using the app are also more likely to perceive the app as beneficial and helpful. This finding is in line with extended models of the TAM [21,26] and with the findings of Dou et al [16]. They implied that perceived behavioral control was associated with perceived ease of use. In our study we did not examine this association, although we additionally calculated the correlation, which showed, in line with Dou et al [16], a significant, positive association ($r=0.484$, $P<.001$, $n=92$).

Our findings showed that willingness to share data predicted acceptance and perceived usefulness of the Iris app among patients with T2D. These findings imply that patients with T2D need to be convinced to share their app data. To do so, 2 issues might be important and need to be considered to increase the willingness of individuals to share their app data. First, some individuals (eg, older people, females, lower educated people, and people with a low propensity to trust others) are less willing to share information because they worry more about their privacy than others [37]. Our findings did not show a significant correlation between perceived security (including privacy) of health apps in general and sharing data of the Iris app ($r=0.174$, $P=.10$, $n=92$). Nevertheless, perceived security predicted perceived usefulness of the Iris app. However, more research is needed to examine which individuals are less likely to perceive security or share data on health technology use, and how these individuals can be convinced to share their data. Second, the data processing of the organization providing the mHealth tool can play an important role in convincing individuals to share information/data [37]. For example, the organization can consider the following aspects: (1) being transparent about the collection and storage of the data/information; (2) providing control to the individuals over whether or not their information/data are being collected, stored, and used; and (3) guaranteeing good security of the storage of the data/information [37].

Limitations

Some limitations of this study also need to be addressed. First, this study used cross-sectional data. Therefore, we are not able to determine or provide interpretations of causality or possible predictors. Thus, although we talk about predictors, this needs to be interpreted with caution. Second, calculations in sample

size software (Pass version 15) showed that our sample size achieves 80% power to detect a medium to large effect in the multiple regression analyses in step 2, with a significance level of .05. Furthermore, due to the sample size, we did not have sufficient power to test moderation effects of, for example, the sociodemographic factors (gender, age, education, ethnicity, household) or prior usage experience. Third, the majority of the measurements were self-constructed and based on the TAM, or empirical studies based on the TAM (eg, [16]), and the results of the 3 focus group interviews we conducted regarding the barriers and facilitators to use the Iris app among patients with diabetes. The reliability of the scales were good (Cronbach α ranged from .70 to .94). In addition, experts did check the face and content validity of the survey, but further validation of the survey is recommended. Fourth, although the explained variance was high in acceptance and perceived usefulness of the eCoach (75.8% and 58.2%, respectively), other important factors (eg, relationship to the doctor, resistance to change, enjoyment factor, technology anxiety, perceived value) might have contributed to an additional increase in the explained variance [16,52]. Moreover, for the final model (step 3), the scatterplots (see [Multimedia Appendices 1 and 2](#)) show that the model gives a pretty good prediction but that at the extremes there is a bit more dispersion in prediction. These other important factors might improve the model quality in future research. Finally, the participants that we recruited via online advertisement might also be the ones that often use mHealth technology, and thus, who perceive ease of use as less important. However, the descriptive statistics show this is probably not the case, as less than 40% (35/92, 38%) of the participants used an app for diabetes management.

Implications for Practice and Future Research

Our findings regarding subjective norms imply that (general) health practitioners, family, and friends might play an important role in facilitating the acceptance and perceived usefulness of the Iris app. To successfully develop and introduce this app for diabetes management among patients with T2D (including

elderly and lower educated people), it might be important to focus our efforts on blending the app with contact and communication with (general) health practitioners. For example, the health practitioner could play a role in discussing and encouraging the patient with T2D to share their app data, in explaining why the app could be beneficial/useful for managing their diabetes, and in communicating and guaranteeing the privacy when using the app. Moreover, family and friends increased the patients' acceptance and perceived usefulness of the app through their approval of using the app, and therefore they perhaps could also play a role in discussing and encouraging the patient with T2D to use the app.

Although our findings indicated that the explained variance was high in acceptance and perceived usefulness of the Iris app (75.8% and 58.2%, respectively), future research might also examine other additional predictors that might be essential for the acceptance of a diabetes self-management eCoach (eg, relationship to the doctor, social relationship, resistance to change, personal innovativeness, enjoyment factor, technology anxiety, perceived value) [16,52,53]. Furthermore, to develop and introduce an app for diabetes self-management, future research should need to identify which features of the app are effective for which type of individuals [11].

Conclusions

To stimulate the acceptance of a self-management eCoach for patients with T2D (including elderly people and lower educated people), we need to achieve that patients with T2D perceive the app as beneficial and helpful to use, and are willing to share their app data. In addition, we need to achieve that the people who are important in the life of patients with T2D (eg, family, friends, health practitioner) socially approve the use of this app. Furthermore, elderly and lower educated people were represented within our sample, but did not seem to score lower on acceptance of perceived usefulness of the app compared with younger people (<63 years old) or higher educated people (completing an intermediate or high level of education).

Acknowledgments

We thank the participants for completing the web-based survey. Furthermore, we thank our colleagues Sophie Wins and Arjan Huizing for their contribution. Sophie Wins helped with the data collection, and Arjan Huizing provided statistical advice.

Abstract

Background: Chronic pain is a complex disease with high prevalence rates, and many individuals who are affected do not receive adequate treatment. As a complement to conventional therapies, eHealth interventions could provide many benefits to a multimodal treatment approach for patients with chronic pain, whereby future use is associated with the acceptance of these interventions.

Objective: This study aims to assess the acceptance of eHealth pain management interventions among patients with chronic pain and identify the influencing factors on acceptance. A further objective of the study is to evaluate the viability of the Unified Theory of Acceptance and Use of Technology (UTAUT) model and compare it with its extended version in terms of explained variance of acceptance.

Methods: We performed a cross-sectional web-based study. In total, 307 participants with chronic pain, as defined according to the International Association for the Study of Pain criteria, were recruited through flyers, posters, and web-based inquiries between December 2020 and July 2021. In addition to sociodemographic and medical data, the assessment included validated psychometric instruments and an extended version of the well-established UTAUT model. For statistical analyses, group comparisons and multiple hierarchical regression analyses were performed.

Results: The acceptance of eHealth pain management interventions among patients with chronic pain was overall moderate to high (mean 3.67, SD 0.89). There was significant difference in acceptance among age groups ($W=9674.0$; $r=0.156$; $P=.04$). *Effort expectancy* ($\beta=.37$; $P<.001$), *performance expectancy* ($\beta=.33$; $P<.001$), and *social influence* ($\beta=.34$; $P<.001$) proved to be the most important predictors of acceptance. The extended UTAUT (including the original UTAUT factors as well as sociodemographic, medical, and eHealth-related factors) model explained 66.4% of the variance in acceptance, thus supporting the viability of the model. Compared with the original UTAUT model (*performance expectancy*, *effort expectancy*, and *social influence*), the extended model explained significantly more variance ($F_{25,278}=1.74$; $P=.02$).

Conclusions: Given the association between acceptance and future use, the knowledge of the influencing factors on acceptance should be used in the development and promotion of eHealth pain management interventions. Overall, the acceptance of eHealth pain management interventions was moderate to high. In total, 8 predictors proved to be significant predictors of acceptance. The UTAUT model is a valuable instrument for determining acceptance as well as the factors that influence acceptance of eHealth

pain management interventions among patients with chronic pain. The extended UTAUT model provided the greatest predictive value for acceptance.

Introduction

Background

According to the International Association for the Study of Pain, pain is defined as “an unpleasant sensory and emotional experience associated with, or resembling that associated with, actual or potential tissue damage” [1]. Pain is considered chronic when it persists or recurs for >3 months [2], whereby different time periods can be found in the literature. Keeping the definition in mind, chronic pain is not only a diagnosis in its own right but also occurs as a symptom in connection with numerous somatic and mental diseases. This in turn explains the high prevalence of chronic pain worldwide [3,4], with the number of diseases with chronic pain continuing to increase because of changing demographics [5,6].

Chronic pain negatively affects quality of life, is associated with sleep disorders and mental illness, and leads to increased mortality [4,7,8]. Chronic pain produces extraordinary costs stemming from absence from work, loss of productivity, hospital stays, physician consultations, diagnostics, and treatment [9,10]. Although chronic pain affects a large part of the population worldwide, the care provided for patients seems to be insufficient. The period between the appearance of the first symptoms of a chronic pain condition and the start of pain therapy averages 4 years in Germany [11]. Patients who have to wait for >6 months for treatment show a worsening of their quality of life and a higher risk of being diagnosed with comorbid depression [12]. It is important to come up with new solutions for adequate health care for patients with chronic pain to improve the imbalance between the increasing numbers of such patients and the need for treatment, which remains unmet because of the comparatively small number of licensed pain therapists [11].

In clinical medicine, eHealth approaches can offer a variety of different treatment options. eHealth is a broad term that includes the use of electronic options such as mobile phones and computers to expand medical care [13]. Although eHealth interventions offer many benefits in the management of patients with chronic pain, they also present difficulties. First, not all patients have the same technical requirements. Thus, the use of eHealth is dependent on the socioeconomic status of patients [14]. In addition, difficulties could arise because of the possible physical distance between physician and patient or a lack of trust in the technology and concerns about data security [15-18]. eHealth interventions can provide a cost-effective extension of chronic pain health care that is flexible in terms of time and location [19]. Another benefit is the reduced requirement for caregiver resources in comparison with conventional face-to-face treatment. The anonymity provided by eHealth

might be able to lower the threshold for seeking therapy and reduce stigmatization [20]. Especially during the COVID-19 pandemic, care for patients with chronic pain became severely limited with a significant decrease in face-to-face treatment options because of pandemic restrictions [21].

Across different patient groups, research has shown that eHealth interventions have outcomes that are comparable to those of face-to-face therapy [22-24], in particular in the treatment of chronic pain [24]. Especially eHealth interventions that focus on internet-delivered cognitive behavioral therapy [25] and internet-based psychoeducational and therapeutic programs have provided satisfactory improvements in various patient-relevant outcomes such as pain magnitude, disability, and comorbid depression [26].

The initial results of such interventions have been promising [27,28], and it is certain that the efficacy of, as well as adherence to, new eHealth interventions strongly depend on patients' intention and perseverance to use them [29].

Numerous offerings, including pain apps, are already available, and a review comparing pain apps between 2011 and 2016 shows an increase in the number of apps [30,31]; yet, among the large number of apps, just 8% were developed with the assistance of health care professionals, and almost none of the reviewed apps have been thoroughly tested for effectiveness with regard to pain-related health outcomes. None of the apps offered self-management options [32]. The quality of the offerings is therefore questionable, and need-oriented care cannot be guaranteed in the absence of evidence.

Considering that three-fourths of users discontinue using an app within 48 hours of downloading it [33], it is important for clinical practice to identify the factors that drive patients to use, and stay adherent to, web-based interventions such as mobile apps. For the successful use of eHealth interventions, it is important to measure the acceptance of potential users because acceptance represents the key predictor of actual use. Acceptance in this case can be understood as intention to use and can therefore be operationalized as behavioral intention (BI) [34]. One way to increase acceptance is to involve the target group in the development process of eHealth interventions [35].

Until now, knowledge on the acceptance of eHealth interventions has been inconsistent. Before the development of the Unified Theory of Acceptance and Use of Technology (UTAUT), there was no validated instrument to determine the influencing factors of acceptance [16,36]. The UTAUT now provides a validated and well-established instrument that can be used to identify predictors that influence the acceptance of eHealth interventions. Barriers to acceptance are also identified;

therefore, they can be avoided or adequately addressed in the development of eHealth interventions [34,36,37].

The UTAUT was developed as a combination of different models to estimate the intention to use technology as well as predict actual use behavior. It is suitable for assessing the likelihood of eHealth use in different groups [16,37,38]. The instrument consists of four core predictors as direct determinants of user acceptance and use behavior: performance expectancy (PE), effort expectancy (EE), social influence (SI), and facilitating conditions (FCs), where FCs influence actual use but not the intention to use, also called BI (acceptance); PE covers the extent to which a patient believes that they will benefit from using eHealth offerings; and EE represents the expected effort associated with the use of eHealth offerings. The factor SI describes the degree to which patients believe that persons of trust think they should use eHealth offerings. FCs define the patients' perception that an organizational and technical infrastructure exists to enable the use of eHealth offerings. The first three predictors PE, EE, and SI are direct determinants of acceptance; that is, the intention to use pain management apps. FCs are direct determinants of actual use behavior. To the best of our knowledge, the UTAUT has never been used among patients with chronic pain.

Objectives

To further develop urgently needed eHealth approaches in pain care, the lack of knowledge about the acceptance of eHealth pain management interventions must be remedied. Therefore, this study aimed to assess the acceptance of eHealth pain management interventions among patients with chronic pain and identify the factors that influence their acceptance of such interventions. The acceptance is influenced by sociodemographic factors such as age [16,38,39], education [16,39], and employment [38], as well as prior eHealth use [39] and depressive symptoms [16,38,39]. An additional objective of the study was to examine the viability of the UTAUT model with its three predictors of acceptance (PE, EE, and SI) and compare it with the extended UTAUT model used in this study. The hypotheses of the study are as follows:

1. Previous studies have indicated overall low [16,40] to moderate [38,41,42] acceptance of eHealth interventions in different target groups. We expected similar results regarding acceptance of eHealth pain management interventions in patients affected by chronic pain.
2. We hypothesized a positive relationship between the UTAUT model's three core predictors of acceptance (PE, EE, and SI) and acceptance, as demonstrated in previous research [34,38,42]. Therefore, we expected the results to confirm the viability of the UTAUT model.
3. Age [16,38,39], gender [39], education [16,39], occupational status [38], prior eHealth use [39], internet anxiety [41], and mental health variables [16,38,39] are considered to be influencing factors on acceptance. We expected divergent levels of acceptance in the different subgroups in accordance with sociodemographic and health-related factors.

4. Furthermore, we anticipated a significantly higher level of explained variance using the extended UTAUT model compared with the original UTAUT [42].

Methods

Study Design and Participants

A cross-sectional study was conducted to determine the predictors that influence the acceptance of pain management apps. Between December 2020 and July 2021, participants were recruited with flyers and posters distributed at hospitals and practices of physicians and physiotherapists, as well as through web-based inquiries in pain-related social media support groups. Patients who endorsed pain were regarded as eligible for the survey. To be included in the data analysis, fulfilling the diagnosis criteria of chronic pain (International Association for the Study of Pain and International Classification of Diseases, Eleventh Revision, criteria) [2,43] was mandatory. Additional criteria for patients wishing to take part in the study were age ≥ 18 years, sufficient German-language knowledge, internet access, and providing electronic informed consent. The study was anonymous and voluntary. The survey was designed to be completed in 15 to 20 minutes, and the average time to completion was approximately 20 (SD 7.07) minutes. Of the 525 participants who started the survey and provided informed consent, 342 (65.1%) completed the survey, resulting in a completion rate of 65.1%. Of these 342 participants, 2 (0.6%) reported a *pain duration of < 3 months* and were excluded for not meeting the aforementioned definition of chronic pain. We also excluded the fastest 5% (16/342) and slowest 5% (17/342) of the participants from the study to ensure data quality because slow or fast completion can be an indication of lack of attention and care [44,45]. By excluding extremely fast and slow responders, it was possible to ensure that the data analysis was based on an average sample. This minimized possible biases in response behavior. Thus, of the 525 participants who started the survey and provided informed consent, 307 (58.5%) were included in the data analysis.

Ethics Approval

The study was conducted in accordance with the Declaration of Helsinki and approved by the ethics committee of the medical faculty of the University of Duisburg-Essen (19-89-47-BO).

Assessment Instruments

Patient-related data were collected using self-generated items on sociodemographic characteristics, including gender, age, marital status, educational qualifications, employment, and place of residence. Medical data included chronic pain diagnosis criteria, prior treatment, and more detailed description of the symptoms.

Depressive symptoms were screened with the Patient Health Questionnaire depression scale (PHQ-8) [46], in which 8 items assess depressive symptoms on a 4-point Likert scale (from 0=not at all to 3=nearly every day). Scores above the cutoff of 10 indicate major depressive symptoms. The Cronbach α value for this instrument was .84 in this study, indicating high internal consistency. The level of eHealth literacy was assessed with the German version of the eHealth Literacy Scale (eHEALS)

[47]. The scale assumes that reading skills are required to use technical offerings, the so-called literacy level. The eHEALS consists of 8 items to measure the skills in this regard. The items are intended to determine knowledge, comfort, and skills in finding, evaluating, and using eHealth information [47]. Sum scores for the eHEALS range from 8 to 40, with higher scores indicating a higher level of eHealth literacy. The Cronbach α value for this instrument was .90 in this study, indicating excellent internal consistency. Using self-generated items, further information concerning the general use of the internet and eHealth was collected. Participants were asked about their private use of media, such as duration and frequency of private internet use and confidence in dealing with eHealth. Internet anxiety was assessed by 3 items regarding concerns about internet use, with answers ranging from 1=strongly disagree to 5=strongly agree. Values above 5 indicate very high internet anxiety. The Cronbach α value for this instrument was .80 in this study, indicating sufficient internal consistency. Data regarding prior eHealth use were also collected.

The UTAUT was used to determine the factors that influence the acceptance of eHealth pain management interventions in patients with chronic pain. The instrument consists of 12 items. Responses are provided using a 5-point Likert scale ranging from 1=totally disagree to 5=totally agree. The added items, including sociodemographic, psychometric, medical, and eHealth-related variables, operate as direct predictors of acceptance. The individual items can be assigned to the predictors PE, EE, and SI. BI, which was operationalized as acceptance, was measured with 3 additional items. In this study, the values for Cronbach α were .90 for PE, .77 for EE, .82 for SI, and .87 for BI (=acceptance), indicating adequate to high internal consistency. More factors were added, including other sociodemographic, medical, and eHealth-related data, as direct predictors of acceptance to the original UTAUT model. The questionnaire with the exact wording of the items is presented in [Multimedia Appendix 1 \[16,34,38,40,42,48\]](#).

Statistical Analyses

Data analysis was performed using SPSS software (version 26.0; IBM Corp) and R (version 4.0.3; The R Foundation for Statistical Computing). Sum scores for PHQ-8 and eHEALS and mean scores for self-generated items for internet anxiety and eHealth-related knowledge were computed. Furthermore, the UTAUT model with its four scales (PE, EE, SI, and BI) was calculated, and the acceptance (=BI) scores were divided into categories based on previous research [16,38,42]: low acceptance was indicated by scores between 1 and 2.34, moderate acceptance between 2.35 and 3.67, and high acceptance between 3.68 and 5. As Shapiro-Wilk tests revealed that the data were not normally distributed, Wilcoxon rank-sum tests and an ANOVA were used to compare acceptance among the groups (age, number of treatments, treatment effectiveness,

cutoff score for PHQ-8, and experience with eHealth). Bonferroni-adjusted α levels were applied. A median split was used to dichotomize age. Multiple hierarchical regression analysis was applied to examine possible predictors of acceptance. Predictors were included blockwise: (1) sociodemographic data, (2) psychometric and medical data, (3) eHealth-related variables, and (4) UTAUT predictors. The extended model was additionally tested against the restricted UTAUT model that only included the UTAUT predictors (PE, EE, and SI). Homoscedasticity was tested through Breusch-Pagan tests. The level of significance was set at $\alpha < .05$. Effect sizes are presented according to Cohen [49], with values around 0.2, 0.5, and 0.8 being considered small, medium, and large effects, respectively.

Results

Sociodemographic, Medical, and Psychometric Data

The vast majority, that is, 92.5% (284/307), of the participants were women, 7.2% (22/307) were men, and 1 (0.3%) self-identified as nonbinary. The mean age of the participants was 45.96 (SD 10.66) years. The participants ranged in age from 18 to 69 years.

Most (280/307, 91.2%) of the patients had endorsed pain for at least 12 months; for 83.1% (255/307), the pain lasted for >2 years. Pain frequency was most frequently reported as permanent (143/307, 46.6%) and daily (102/307, 33.2%). In total, 17.3% (53/307) of the participants had tried >6 different pain treatments. More than half (183/307, 59.6%) of the participants had already received 3 to 6 different pain treatments, and 23.1% (71/307) had tried <3 different pain treatments. More than half (184/307, 59.9%) considered prior treatment efficient. The reported treatments included surgery, medication, psychotherapy, and alternative healing methods. In the PHQ-8 questionnaire, 73.3% (225/307) of the participants achieved a score above the cutoff of 10, indicating depressive symptoms. For further details, refer to [Table 1](#).

Of the 307 participants, 208 (67.8%) had no experience with eHealth pain management interventions. However, regarding digital media use, only 7.8% (24/307) of the participants reported feeling very insecure or a little uncertain. This represents a high level of confidence in the use of digital media in the sample, with 81.4% (250/307) of the participants feeling secure about using digital media (mean 4.17, SD 1.01). The mean level of internet anxiety in this sample was 1.78 (SD 0.83), whereas values above 5 indicate a very high level of internet anxiety. Thus, internet anxiety was low in the sample. On average, the participants showed a high level of eHealth literacy (mean 30.40, SD 5.34) according to eHEALS [47]. For further details, refer to [Table 2](#).

^cUTAUT: Unified Theory of Acceptance and Use of Technology.

Acceptance of eHealth Pain Management Interventions

General acceptance was moderate to high, with a mean of 3.67 (SD 0.89). In total, 9.1% (28/307) of the participants showed low level of acceptance, 47.2% (145/307) showed moderate level of acceptance, and 43.6% (134/307) showed high level of acceptance.

Of the 307 participants, 154 (50.2%) were below the median age of 47 years, and the mean acceptance score in this group was 3.80 (SD 0.87), whereas 153 (49.8%) had a median age of ≥ 47 years and had a mean acceptance score of 3.55 (SD 0.89). The Wilcoxon rank-sum test revealed a significantly higher acceptance in the younger age group ($W=9674.0$; $r=0.156$; $P=.04$). Acceptance did not differ significantly among the groups divided by occupational ($F_{3,303}=0.44$; $P=.99$) or educational status ($W=10,515.0$; $P=.76$). There were no significant differences in acceptance regarding number of treatments ($F_{2,304}=2.27$; $P=.74$), treatment effectiveness ($W=9037.5$; $P=.67$),

cutoff for PHQ-8 ($W=8487.0$; $P=.99$), and experience with eHealth ($W=10,288.0$; $P=.99$).

Predictors of Acceptance of eHealth Pain Management Interventions

Multiple hierarchical regression analysis revealed that the sociodemographic predictors included in the first step explained 4.1% of the variance of acceptance ($R^2=0.041$; $F_{7,299}=1.83$; $P=.08$). In the first step, *age* significantly predicted acceptance ($\beta=-.01$; $P=.004$). With the second step, which included the psychometric and medical predictors ($R^2=0.069$; $F_{13,293}=1.66$; $P=.07$), the explained variance increased significantly to 6.9% ($\Delta R^2=0.028$; $F_{6,293}=2.97$; $P=.001$), although none of the included variables were significant predictors on their own. The eHealth-related predictors included in the third step ($R^2=0.130$; $F_{25,281}=1.68$; $P=.03$) further increased the explained variance significantly to 13% ($\Delta R^2=0.061$; $F_{12,281}=4.22$; $P<.001$). In the third step, *place of residence: medium-sized city* ($\beta=-.27$;

$P=.048$), *confidence in dealing with eHealth: neutral* ($\beta=.69$; $P=.04$), *confidence in dealing with eHealth: rather confident* ($\beta=.66$; $P=.03$), and *confidence in dealing with eHealth: very confident* ($\beta=.71$; $P=.02$) were additional significant predictors.

The last step included the UTAUT predictors ($R^2=0.664$; $F_{28,278}=19.63$; $P<.001$) and explained 66.4% of the variance in acceptance. The additional predictors increased the explained variance significantly by 53.4% ($\Delta R^2=0.534$; $F_{3,278}=147.46$;

$P<.001$). As expected, *EE* ($\beta=.37$), *PE* ($\beta=.33$), and *SI* ($\beta=.34$) significantly predicted acceptance (all $P<.001$). In addition to the UTAUT predictors, the following variables were found to be significant predictors of acceptance in the overall model (step 4): *place of residence: small town* ($\beta=-.28$; $P=.004$), *private daily internet use: 2 to 3 hours* ($\beta=-.25$; $P=.02$), and *private daily internet use: >4 hours* ($\beta=-.29$; $P=.02$). Table 3 presents an overview of the parameters included in each step in the hierarchical regression model.

Table 3. Hierarchical regression model of acceptance (the extended Unified Theory of Acceptance and Use of Technology model; N=307).

Restricted UTAUT Versus Extended UTAUT Model

In our study, the explained variance for the restricted UTAUT with the three core predictors PE, EE, and SI was 61.2% ($R^2=0.612$, $R^2_{adj}=0.608$). The explained variance for our extended UTAUT model with added sociodemographic, medical, and eHealth-related factors reached 66.4% ($R^2=0.664$, $R^2_{adj}=0.630$) of explained variance. The comparison of the 2 models revealed a significant difference in explained variance ($F_{25,278}=1.74$; $P=.02$). Thus, the extended UTAUT model explains more variance in the acceptance of eHealth pain management interventions among patients with chronic pain.

Discussion

Principal Findings

The main objective of the study was to determine the acceptance of eHealth pain management interventions among patients with chronic pain, as well as identify the factors that influence acceptance. Overall, the acceptance among patients with chronic pain in this study was moderate to high. In total, 43.6% (134/307) of the participants showed a high level of acceptance, 47.2% (145/307) showed a moderate level of acceptance, and only 9.1% (28/307) showed a low level of acceptance.

We were able to confirm the positive relationship between the three core predictors (PE, EE, and SI) of the UTAUT model and acceptance, as demonstrated previously; for example, in patients with diabetes or obesity [34,38,42]. The 3 core predictors of the restricted UTAUT explained 61.2% of the variance in this study. This result is comparable to that in the original study in which the UTAUT was evaluated [50]. This underlines the viability of the UTAUT to be used for eHealth pain management interventions among patients with chronic pain. A comparison of the restricted UTAUT model and the extended UTAUT model revealed a higher explained variance for the extended UTAUT that included the added predictors. The additional factors were included in the extended UTAUT model because additional factors beyond the core predictors can be assumed to influence acceptance.

Age was a significant predictor of acceptance in this study. Young age, defined here as age <47 years, the median age in our sample, was associated with greater acceptance. This is consistent with the results from previous studies [16,39,42]. To increase acceptance among older patients too, they can be especially reached out to when addressing the target group for an intervention. With regard to the influence of SI on acceptance, this could be achieved, for example, through a recommendation by the family physician. We did not include gender in the analysis because our sample was not representative in terms of gender distribution. The place of residence was found

to have an influence on acceptance. Patients living in a medium-sized city or small town showed an increased level of acceptance. It is possible that there are fewer face-to-face treatments available in small towns than in large cities. However, when it comes to rural municipalities, we did not observe an increased level of acceptance. This might be comparable to the finding that in rural areas internet-based media platforms are used less often than in cities [51], which might indicate a more reserved attitude and makes individuals from rural areas a relevant target group for interventions that aim to increase acceptance. Education was not significantly associated with acceptance in our study, in contrast to previous studies [16,39]. However, it should be mentioned that an above-average number of participants in the survey have a university degree, and this could at least have had an influence on the high eHealth literacy level in the survey. The lack of effect of education could simply be because people with low education and who might have rated their acceptance level as low are not adequately represented in the study. Of note, this overrepresentation is a common bias in psychological research: 96% of psychological studies are conducted on Western, educated, industrialized, rich, and democratic samples [52,53]. Occupational status was also not significantly associated with acceptance. We did not observe an increased level of acceptance in patients with a higher number of treatment attempts and lower treatment effectiveness. On the one hand, it can be assumed that patients who have already tried various treatments and have still not found an effective treatment may be more willing to try other options, such as web-based interventions. On the other hand, it is possible that patients for whom no treatment has been successful even after many attempts may be suspicious of new forms of treatment because the absence of treatment success has lowered their trust level and perceived self-efficacy. It is possible that these effects may cancel each other out. Internet anxiety was low in the sample, which is in line with overall frequent private internet use and the fact that a proportion of the participants were recruited through the internet. The high level of confidence in the use of digital media underlines the patients' confidence in using eHealth technologies. Internet anxiety did not have a significant influence on acceptance. However, confidence in dealing with eHealth had an influence on acceptance. Acceptance in participants who felt confident was significantly higher than in those who described their confidence level as neutral. This might provide an opportunity to increase acceptance in the future; for example, the confidence could be increased in advance through training or tutorials by providing comprehensive information and personal assistance during the use of eHealth pain management interventions. Furthermore, it is noteworthy that despite frequent private internet use, only 32.2% (99/307) of the participants had already had experience with eHealth. It is unclear whether this is due to a shortage of eHealth offerings in everyday clinical practice or previous skepticism about

eHealth. Nevertheless, prior experience with eHealth had no influence on acceptance in this study.

In contrast to previous studies [42], we observed no association between depressive symptoms and acceptance of eHealth pain management interventions. The reasons for the high proportion (225/307, 73.3%) of participants with depressive symptoms may be multifactorial. First, the proportion of patients with depressive symptoms is higher among patients with chronic pain than in the general population [54-58]. Second, the data collection took place during the COVID-19 pandemic when the prevalence of depression was elevated [59]. However, the fact that an excessively high proportion (225/307, 73.3%) of participants in our sample showed depressive symptoms underlines the comorbidity of chronic pain and mental health burden [54,55]. Interestingly, acceptance decreased with increasing duration of private daily internet use. An explanation for this finding could be that participants who already use the internet a lot in their daily lives do not want to further extend the hours of internet use and therefore do not want to seek therapy through the internet. To assess this more accurately, it would be useful to conduct future studies to determine how patients with chronic pain use the internet and whether internet use itself is associated with acceptance. It would be interesting to know whether they associate internet use with work or see it more as entertainment, which they would like to keep separate from serious topics such as the treatment of their illnesses. In this case, future studies could also include questions on the circumstances in which participants judge offerings as serious.

Although we did not find an influence on the acceptance of eHealth pain management interventions for several of the aforementioned factors, overall acceptance was higher than in previous studies [37,38,40-42]. Several explanations for this can be considered. First, patients were also recruited through social media, and social media users might generally be more accepting of web-based programs. The fact that mainly women participated in the survey should also be noted. In a previous study with patients with diabetes, acceptance of eHealth interventions was significantly higher among women than among men [38]. Understanding the reasons behind possible gender differences in eHealth acceptance would thus be necessary to improve eHealth acceptance among men. An alternative explanation could be that patients with chronic pain generally show higher acceptance than other groups. To further investigate this, patients with chronic pain would need to be compared with other patient populations. Another reason for the higher acceptance could be the timing of data collection. It is likely that acceptance of eHealth interventions changes with their increasing implementation in health care [60]. In addition, younger people are already showing increased acceptance, and as they will make up a large part of the population in the future because of demographic change, increased acceptance can also be expected as a result.

Even with the extended UTAUT, only selected factors were tested for their influence on the acceptance of eHealth pain management interventions. It is likely that there are additional factors that need to be investigated to further understand acceptance and implementation of eHealth pain management interventions. Further research should target these influences.

Limitations

The results of the study should be interpreted in the context of the limitations discussed herein. A proportion of participants were reached through inquiries in web-based support groups. Part of the reason for this may be the timing of data collection. Because of the COVID-19 pandemic, for example, time spent by patients waiting inside physicians' offices was reduced, and hand-distributed flyers were accepted reluctantly, which made offline recruitment more difficult. It is quite possible that by recruiting through the internet, mainly those who are already more willing to use the internet were reached. Thus, a selection bias cannot be ruled out. In future surveys, more emphasis should be placed on recruiting through in-person channels. Because of the predominance of female participants, the influence of gender could not be investigated. The excessive proportion (284/307, 92.5%) of women in the sample is not representative of the gender composition in the overall population of patients with chronic pain, which limits the generalizability of the results because of sampling bias. A reason for this could be that recruitment widely took place in social media groups, which largely consist of female members, including groups for people with endometriosis and fibromyalgia, where the majority of those affected are women [61,62]. Furthermore, the study provides only a theoretical account of whether patients with chronic pain would be willing to use eHealth pain management interventions. If one regards acceptance as BI to use such offerings, the extent of their actual use remains to be determined. However, considering the intention-behavior gap [63], that is, the phenomenon that the intention to do something does not lead to real behavior to the same extent, it remains unclear whether the observed intention will also lead to actual use. Future studies should thus compare survey results of acceptance with subsequent use of such interventions. Nevertheless, knowledge of the factors influencing acceptance should be used and specifically addressed in the development of eHealth pain management interventions.

Conclusions

This study was able to demonstrate overall moderate to high acceptance of eHealth pain management interventions among patients with chronic pain. This high rate of acceptance suggests that eHealth interventions can offer a viable alternative for situations in which face-to-face treatment is not possible. The factors PE, EE, and SI were core predictors of acceptance. The extended UTAUT proved to be a useful tool for determining acceptance as well as the factors that influence the acceptance of eHealth pain management interventions among patients with chronic pain. Understanding the factors that influence acceptance is important to provide tailored eHealth pain management interventions and promote their actual use. When access to face-to-face treatment is limited, eHealth interventions offer a good alternative. With all that, we emphasize that the aim is not to replace face-to-face treatment but to complement it; for example, eHealth interventions can help bridge the gap until face-to-face therapy is received or complement existing therapies. Finally, this study highlights the importance of taking patients' expectations, needs, and capabilities into account when developing new treatment approaches.

Acknowledgments

This work was funded by the Deutsche Forschungsgemeinschaft (German Research Foundation; 422744262–TRR 289).

Authors' Contributions

AB, MT, and E-MS initiated and conceptualized the study. LJ and PS performed the statistical analyses and interpretation of the data, and PS wrote the first draft of the manuscript. Data acquisition was performed by LJ and PS. AB, CR, MT, and E-MS contributed to the design of the study. UK and DM gave important input regarding the specifics of the target cohort. All authors contributed to the further writing of the manuscript and approved its final version.

Conflicts of Interest

None declared.

Abstract

Background: Social messaging strategies such as SMS text messaging and radio are promising avenues for health promotion and behavior change in low- to middle-income settings. However, evidence of their acceptability, feasibility, and impact in the context of young women's health and micronutrient deficiencies is lacking.

Objective: This study aimed to evaluate the feasibility of an automated 2-way text messaging intervention nested in an ongoing preconception health trial, the Healthy Life Trajectories Initiative (HeLTI; HeLTI *Bukhali*) in Soweto, South Africa. Second, we aimed to evaluate the acceptability of a health promotion radio serial, which aired concurrently in the region.

Methods: In this feasibility study, 120 participants enrolled in HeLTI *Bukhali* between November 2020 and February 2021 received the 6-month 2-way text messaging intervention. Quantitative and qualitative data on intervention acceptability, usability, interaction, perceived benefit, and fidelity were collected during 5 focus group discussions (FGDs) and from study data logs. During the FGDs, data were collected on the acceptability of the radio serial. Following the text messaging intervention, capillary hemoglobin levels were assessed, and a participant questionnaire provided information on adherence and attitudes toward supplements. The text messaging control group comprised the first 120 women recruited from November 2019 to February 2020, who received the *Bukhali* intervention but not the text messages. Statistical significance testing and a linear mixed model were used for indicative effect comparisons between the text message-receiving and control groups.

Results: The text messaging intervention was found to be acceptable and to have perceived benefits, including being reminded to take supplements, gaining knowledge, and feeling supported by the study team. The use of the 2-way text messaging reply function was limited, with only a 10.8% (13/120) response rate by week 24. Barriers to replying included a lack of interest or phone credit and technical issues. Regarding the indicative effect, participants receiving the text messages had higher self-reported adherence at follow-up than the text messaging control group (42/63, 67% vs 33/85, 39% taking supplements every time; $P=.02$), and altitude-adjusted hemoglobin increased more between baseline and follow-up in the SMS text message-receiving group than

in the text messaging control group (1.03, 95% CI 0.49-1.57; $P < .001$). The radio serial content was acceptable, although few participants reported exposure before the FGD.

Conclusions: Women reported that the text messaging intervention was useful and described the benefits of receiving the messages. Examination of hemoglobin status indicated a promising beneficial effect of text messaging support on adherence to micronutrient supplementation, requiring further exploration through randomized controlled studies. Health promotion through radio and text messages were both found to be acceptable, although more research into the radio serial reach among young women is needed.

Introduction

Background

Women's health and nutritional status before and during pregnancy are increasingly being identified as important determinants of their future health, pregnancy success, and the health of the next generation [1]. However, across high-, middle-, and low-income countries, both over- and undernutrition remain prevalent before and during pregnancy, and nonadherence to nutritional recommendations is a global issue [1-7]. Micronutrient deficiencies persist in South Africa, with anemia affecting 23% to 31% of women of reproductive age in urban settings [8,9]. In this context, preconception health and its consequences have also been identified as important knowledge gaps among young women [10].

Using digital spaces for health promotion and health behavior change is an increasing global phenomenon. In South Africa, radio is the most consumed form of media, with an estimated 37.8 million weekly listeners, of whom approximately 30% listen via mobile phones [11]. Although radio messaging has shown promise for improving health knowledge [12], health behavior changes may be more effectively achieved when messaging is targeted to specific population subgroups and tailored to the needs of the individual [13].

SMS text messaging interventions are a potential avenue for providing targeted and tailored behavior change support, reinforced by the high level of mobile phone penetration in many low- to middle-income settings. For example, approximately 96% of households in South Africa in 2018 had a mobile phone, and of the country's population, 82% were estimated to have a smartphone subscription (smartphone penetration) [14]. Increasing data support the use of various SMS text messaging interventions to improve appointment attendance, medication adherence, and risk-related behavior change, mostly in the context of chronic diseases [15-19]. However, systematic reviews from low- to middle-income countries have found mixed or inconclusive evidence of the impact of SMS text messaging interventions, which are often not explicitly designed using behavior change theory [20-22]. In South Africa, SMS text messaging interventions have shown highly promising results for HIV care adherence, support, and education [23-25], as well as for pregnant and postpartum

women, through the National MomConnect SMS text message health messaging program [26,27]. Data from high-income settings suggest that a 2-way SMS text messaging intervention can support nutritional behavior change, resulting in weight loss and maintenance in the postpartum period [28], and that a mobile app can effectively improve preconception nutrition [29]. However, to the best of our knowledge, the use of SMS text messaging to improve nutritional status during the preconception period has not been previously explored.

Objectives

The main aim of this study was to evaluate the feasibility of a tailored 6-month SMS text messaging intervention to support adherence to preconception micronutrient supplementation in women enrolled in the Healthy Life Trajectories Initiative (HeLTI) *Bukhali* trial, a complex preconception health trial in Soweto, South Africa. This included an evaluation of the acceptability, usability, perceived benefit, fidelity, cost, and indicative effects of the SMS text messaging intervention for promoting supplement adherence. The second objective was to evaluate the acceptability of a radio serial and accompanying Facebook page aimed at supporting health promotion in the trial setting, which was aired toward the end of the SMS text messaging intervention.

Methods

Setting and Population

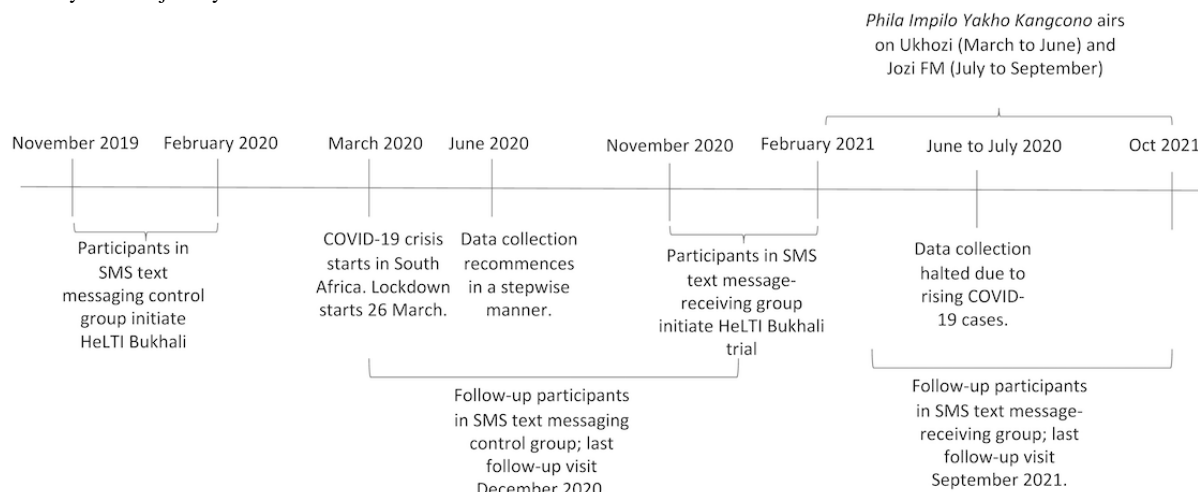

This study was nested in the intervention group of the South African site of the HeLTI *Bukhali* study, a randomized controlled trial that aimed to evaluate a multifaceted intervention for promoting the health of women of reproductive age (18-28 years) [30,31]. Similar trials are ongoing in Canada, India, and China in collaboration with the World Health Organization. HeLTI *Bukhali* is based in Soweto, a historically disadvantaged township bordering Johannesburg, with approximately 1.3 million residents, and recruitment started in 2018. The intervention was delivered by research staff trained in healthy conversation skills [32], who distributed educational resource material and provide health feedback in terms of BMI, hemoglobin, blood pressure, hemoglobin A_{1c} to assess hyperglycemia, HIV testing, and mental health and facilitated sessions to support improved health behaviors around nutrition, physical activity, sleep, health monitoring (eg, HIV testing),

and other goals identified by the participants. An aspect of the HeLTI *Bukhali* intervention is the provision of multimicronutrient supplements based on participants' anemia status. Women receive a supplement containing, among other micronutrients, 27 mg iron twice per week if they are nonanemic (capillary hemoglobin ≥ 12 g/dL) and daily if they are mildly anemic (hemoglobin < 12 g/dL), with women who are severely anemic (hemoglobin < 7 g/dL) receiving referrals to receive the current standard of care, comprising further assessment, supplementation, and additional management as required. The trial's control group was contacted once a month through telephone, SMS text message, or email to deliver information on *life skills* not directly related to health and had access to standard health services such as HIV and pregnancy testing. The intervention and control arms of the trial were included in the trial program for a total of 18 months and were followed throughout pregnancy and postpartum periods in case of pregnancy within the 18-month time frame [31].

The exclusion criteria for HeLTI *Bukhali* were a diagnosis of type 1 diabetes, cancer, or epilepsy; the presence of an intellectual disability that hinders informed consent; and being unwilling or unable to consent. For this feasibility study, only women recruited into the preconception intervention group of the trial were included. This study evaluated 2 distinct remote media approaches (SMS text messaging and radio combined with Facebook) in the same trial.

As indicated in the timeline in Figure 1, the first 120 women enrolled in HeLTI *Bukhali* between November 1, 2020, and February 2021, who consented to the SMS text messaging substudy, received the SMS text messaging intervention. This *SMS text message-receiving* group was asked to participate in this study's focus group discussions (FGDs), in which the acceptability of the health promotion radio serial was also evaluated.

Figure 1. Timeline of SMS text messaging feasibility study and airing of the radio serial in the context of the COVID-19 pandemic in South Africa. HeLTI: Healthy Life Trajectory Initiative.

In addition, for the preliminary evaluation of the indicative effect of the SMS text messaging intervention, a comparison group receiving the *Bukhali* intervention but not receiving the SMS text messages (*SMS text messaging control group* from here on) comprised the first 120 women who were recruited to the HeLTI *Bukhali* intervention arm from November 2019 onward until the target sample size was attained without any matching the SMS text message-receiving group. The time frame of the SMS text messaging control group recruitment was chosen to avoid seasonal variability in micronutrient status. This also avoided the major hiatus in data collection in response to the COVID-19 crisis that started in March 2020. Follow-ups for participants in the SMS text message-receiving and SMS text messaging control groups were conducted between May and October 2021 and May and December 2020, respectively. The delays in follow-up in both groups were largely attributable to the COVID-19 pandemic.

The HeLTI *Bukhali* Text Messaging Intervention

The HeLTI *Bukhali* SMS text messaging intervention and message bank were developed based on existing evidence and the behavior change theory. [Textbox 1](#) provides an overview of the SMS intervention according to the TIDieR (Template for Intervention Description and Replication) checklist. The Health Actions Process Approach (HAPA) [33] was the main guiding theoretical approach for developing the SMS text message library. The HAPA is a sociocognitive model encompassing 2 phases: the motivation phase, including outcome and risk perception and self-efficacy, and the volitional phase, including action-oriented processes such as action planning and maintenance of self-efficacy. HAPA has previously been shown to successfully inform medication adherence and UK-based SMS text messaging interventions [28,34,35]. The message bank was developed with input from young women in Soweto, including lessons from formative work for HeLTI *Bukhali* around barriers to supplement use [31], and was tested for any content or technical issues before this feasibility study.

Textbox 1. Reporting of the Template for Intervention Description and Replication checklist items for the Healthy Life Trajectories Initiative (HeLTI) Bukhali SMS text messaging intervention.

Template for Intervention Description and Replication checklist item and brief description

- Brief name
 - The brief name is HeLTI Bukhali SMS text messaging intervention.
- Why
 - A lack of adherence to micronutrient supplementation is a prevalent barrier to improving micronutrient deficiencies in the preconception period. SMS text messaging interventions are accessible and have shown potential as a cost-effective avenue to support behavior change in middle- and low-income settings. Therefore, this SMS text messaging intervention aims to improve adherence to and knowledge around micronutrient supplements in women of reproductive age. The intervention development is grounded in behavior change theory, specifically the Health Action Process Approach.
- What (materials)
 - The intervention consisted of comprised 48 SMS text messages delivered over the course of 24 weeks (2 per week). Messages were sent around midday on varying days of the week, as programmed from the day of initial HeLTI Bukhali enrollment. In addition to an introductory message, the 3 main types of SMS text messages were as follows: Health literacy messages: weekly educational messages on the contents and potential benefits of the micronutrient supplement, how they work, potential side effects, the importance of a balanced diet, tips on when to take the supplements, and how to remember them more easily Adherence messages: weekly 2-way messages querying whether participants had taken their supplements in the week (“did you take all your micronutrient pills this week?”); participants could reply “yes” or “no,” prompting a second message asking the main reason for not taking the supplement if the answer was “no” (“I forgot, I ran out of pills, the pills made me feel unwell, other”) Side effect–reporting messages: 2-way messages sent in weeks 2, 8, 13, and 20 instead of the health literacy message, asking participants if they had experienced any side effects from the supplements, to which participants could reply “yes” or “no,” and if they replied “yes,” a second message was sent asking which symptoms were present.
 - The message bank can be accessed from the corresponding author upon reasonable request. Participants were automatically supplied with ZAR 5 prepaid airtime weekly, which sufficiently covered the cost of responding to an SMS text message through any available provider.
- What (procedure)
 - SMS text messages were automatically sent twice a week to participant phone numbers, using Twilio Inc, and airtime was supplied automatically using FlickSwitch Control South Africa (Cape Town). The intervention evaluation was nested in the HeLTI South Africa Bukhali trial, which evaluates a complex intervention (education, social support, behavior change, and micronutrient supplement) [30,31]. Both the SMS text message–receiving and SMS text messaging control groups received the intervention arm of HeLTI Bukhali, although the control arm did not receive the SMS text messaging intervention in any form. As part of the trial, multimicronutrient supplements are provided based on the participants’ anemia status (see Setting and Population section for more details).
- Who provided
 - The SMS text messaging intervention was developed by the research team with input from young women in Soweto during the development phase. The delivery of the SMS text messaging intervention was automated.
- How
 - The mode of delivery was through SMS text messages. In the control group, no SMS text messages were delivered.
- Where
 - The intervention was delivered through SMS text messages. Participants were based in Soweto, a historically disadvantaged township bordering Johannesburg, with approximately 1.3 million residents.
- When and how much
 - The SMS text messaging intervention was delivered to 120 participants newly enrolled in HeLTI Bukhali between November 1, 2020, and February 2021 who additionally consented to the SMS text messaging substudy. The SMS text messaging intervention was delivered twice weekly for 6 months at midday on varying days of the week, as automatically scheduled based on the day of the participants’ initial enrollment in HeLTI Bukhali. For the feasibility study, the last participant received the last message in August 2021. The SMS text messaging control group comprised 120 HeLTI Bukhali participants who enrolled between November 2019 and February 2020, receiving the Bukhali intervention but no SMS text messages.
- Tailoring
 - The SMS text messaging intervention was not tailored to individual participants.
- Modification
 - The SMS text messaging intervention was not modified during the course of the feasibility study.

- How well (planned)
 - The fidelity of the planned intervention in terms of messages received, airtime received, and presence of any technical errors will be reviewed using a log of the automated SMS text messaging and airtime delivery systems.
- How well (actual)
 - See the Results section.

As described in [Textbox 1](#), participants received 2 messages every week for 24 weeks, with messages comprising health literacy, adherence, and side effect reporting. From the time participants were recruited to HeLTI *Bukhali*, SMS text messages were sent and received using an automated SMS text message delivery platform—Twilio Inc. To avoid nonparticipation in the 2-way SMS text messages because of a lack of funds, participants were automatically supplied with 5 South African Rand (ZAR 5, around US \$0.30) prepaid minutes of phone credit (“airtime”) weekly, which sufficiently covered the cost of responding to an SMS text message through any available provider, using FlickSwitch SIMControl South Africa (Cape Town). The successful delivery of the SMS text messages and airtime could be monitored through these respective platforms and was evaluated through qualitative data collection.

The Phila Impilo Yakho Kangcono Radio Serial

The *Phila Impilo Yakho Kangcono* (translating to “Live Your Best Life”) radio serial was designed as media support for the HeLTI trial, and an overview based on the TIDieR checklist is provided in [Textbox 2](#). The weekly radio serial targeted young people and aimed to promote well-being and health. It was aired in isiZulu and English between March and June 2021 on a Sunday youth show on Ukhozi FM, South Africa’s largest radio station, and on Jozi FM, a local radio station popular in Soweto, from July to September 2021. An associated Facebook page was created and referred to in the radio episodes [36]. The content of each episode was designed by an independent production team working with and guided by young adults (both men and women) from Soweto and the research team.

Textbox 2. Reporting of Template for Intervention Description and Replication checklist items for the Phila Impilo Yakho Kangcono radio serial intervention.

Template for Intervention Description and Replication checklist item and brief description

- Brief name
 - The brief name is the Phila Impilo Yakho Kangcono radio serial.
- Why
 - Preconception health and its significance are important knowledge gaps among young women, and radio is one of the most consumed forms of media in South Africa. Therefore, population-based health promotion through radio could be an accessible way of increasing health awareness and well-being among young people in South Africa.
- What (materials)
 - The intervention comprised 11 radio serial episodes of 15 to 20 minutes in English and isiZulu, designed to cover health and well-being topics identified as important by youth, such as mental health (eg, suicide and depression), diabetes, gender-based violence, hypertension, HIV, healthy food, and community gardens. In addition, an associated Facebook page was created to promote the radio serial and for listeners to comment and catch up on missed episodes. Each of the radio serial episodes can be accessed on the Facebook page, which is fully accessible to the public [36].
- What (procedure)
 - The radio serial was aired weekly on 2 radio stations—Ukhozi FM (South Africa’s largest radio station with a listener base of around 8 million people) and Jozi FM (a local radio station popular in Soweto)—with referral to the associated Facebook page.
- Who provided
 - The intervention was delivered over the radio and therefore not provided by individual care providers.
- How
 - The mode of delivery was radio (and Facebook), designed as a media campaign to be delivered on a population level rather than to individual participants.
- Where
 - The intervention was delivered through radio on Ukhozi FM and Jozi FM and through the associated Facebook page.
- When and how much
 - The radio serial aired once a week at 2:30 PM on Sundays from March to June 2021 on Ukhozi FM and at 10:30 AM from July to September 2021 on Jozi FM.
- Tailoring
 - The radio serial was not personalized or tailored.
- Modification
 - The intervention was not modified over the course of the study.
- How well (planned)
 - Not applicable.
- How well (actual)
 - Not applicable.

Ethics Approval

The human research ethics committee (Medical) at the University of Witwatersrand approved this study (M171137 and M1811111). Participants gave written informed consent before enrollment into the study and provided additional written informed consent before participating in the recorded FGDs.

Outcomes

This mixed methods study adopted a parallel-convergent approach, using a combination of quantitative and qualitative data sources to address feasibility outcomes [37]. The framework for evaluating young women’s perceptions of the HeLTI *Bukhali* SMS text messaging intervention and the radio serial and associated Facebook pages are outlined in Table 1 and are based on the existing literature on process evaluation [38,39]. The

main outcomes of interest for evaluating women's perceptions of the SMS text messaging intervention were acceptability, usability and level of interaction, perceived benefit, intervention cost and fidelity, and indicative effects. For the *Phila Impilo*

Yakho Kangcono radio serial and associated Facebook page, the main outcome was the acceptability of the radio serial and the associated Facebook page.

Table 1. Main outcomes and data sources for the study.

Objective	Main question addressed	Data source
Objective 1: feasibility of Healthy Life Trajectories Initiative Bukhali SMS text messaging intervention		
Acceptability	<ul style="list-style-type: none"> To what extent was the intervention delivery agreeable and acceptable to participants? 	Qualitative data from FGDs ^a with participants
Usability and interaction	<ul style="list-style-type: none"> To what extent could the intervention be used and was the intervention used adequately by the participants? Data Collection

HeLTI Bukhali Text Messaging Intervention

Qualitative data on the acceptability, usability, interaction with, and perceived benefit of the SMS text messaging intervention were collected during 5 FGDs, including 2 to 9 participants. These were conducted by trained research staff from Soweto using a topic guide developed by the research team and were organized and attended by LMS. Participants were invited at random from those receiving SMS text message notifications 4 to 8 months after the initiation of the study. Refusals to participate in the FGDs were because of having moved away from Soweto, having other commitments, or being ill on the day of the FGD. Refreshments were provided at the FGD, which took 1 to 2 hours. The FGDs were conducted in English and in the participants' preferred language and were audio recorded (Philips Digital Voice Recorder DVT4110 and DVT1150). The recordings were transcribed verbatim but were anonymized and translated into English where necessary.

To evaluate the indicative effect of SMS text messaging intervention, data were captured and managed using REDCap (Research Electronic Data Capture; Vanderbilt University) [40]. Data were collected by trained research assistants at the research

unit in Soweto. At baseline, a validated questionnaire was used to gather information on participant age, attitudes toward and confidence in supplement use, parity, country in which the participant was born, their home language, education level, employment status, and food security [41]. Participants were categorized as *at risk of food insecurity* if they answered *yes* to one of the 3 questions in the food security questionnaire ("Does your household ever run out of money to buy food?"; "Do you ever cut the size of meals or skip meals because there is not enough money to buy food?"; "Do you go to bed hungry because there is not enough money to buy food?") and as *food insecure* if they answered *yes* to ≥ 2 of the questions, as previously described in our setting [42].

At a follow-up visit conducted approximately 6 months after initial recruitment for both the SMS text message-receiving and SMS text messaging control groups, a questionnaire was used to gather data on self-reported adherence to the micronutrient supplements (1=I never took them to 5=I took them every time), participants' perceived understanding of the condition of anemia, perceived health improvement because of the supplement, fears and side effects related to the supplement, and main reasons for not taking the supplement. At both baseline and follow-up, hemoglobin levels were measured using a Hemocue 201 device. As Soweto is situated >1700 m above

sea level, hemoglobin was altitude adjusted by -0.5 g/dL, according to the World Health Organization recommendation [43], as has previously been evaluated in our setting [44]. The difference in hemoglobin levels from baseline to follow-up (Δ hemoglobin) was calculated (hemoglobin follow-up – hemoglobin baseline).

Data obtained from the log of the automated SMS text messaging system also provided information on participant interaction with the intervention (rate of response to 2-way SMS text messaging features) and intervention fidelity (number of messages successfully received, technical failures, and airtime received by participants). The study records provided information on the total intervention costs per participant.

Phila Impilo Yakho Kangcono Radio Serial

During the 5 FGDs described in detail previously, all participants played 1 to 2 episodes of the *Phila Impilo Yakho Kangcono* radio serial and were shown the associated Facebook page to ensure exposure among all participants. Subsequently, data were collected on the acceptability of the radio serial. These data were recorded and transcribed as described previously.

Data Analysis

Qualitative data analysis was informed by the thematic analysis methods described by Braun and Clarke [45]. The analytic process and presentation of results followed the phases set out in the framework method, which is a codebook approach to thematic analysis [46]. The coding of transcripts combined a deductive approach based on the study objectives and the adapted process evaluation framework [38,39] outlined in [Table 1](#), with inductive analysis to allow for flexibility in incorporating unforeseen findings. LMS read the transcripts to familiarize herself with the data. The initial coding of the transcripts was completed by LMS using MAXQDA software (version 20.4.1; VERBI GmbH), and preliminary themes and framework matrices were reviewed by and discussed with LJW, SK, and MM to refine the analysis.

Quantitative data analysis was performed using STATA (version 13.0, StataCorp). Baseline characteristics and SMS text message response data were described as numbers and percentages for categorical variables and mean and SD or median and IQR for continuous variables. Outcomes at the 6-month visit, including change in hemoglobin from baseline (Δ hemoglobin) and change in anemia status, were compared between the participants receiving SMS text messages and the SMS text messaging control group using the Student *t* test (2-tailed) or Wilcoxon rank-sum test, depending on the normality of the data. The

baseline characteristics of participants lost to follow-up in the SMS text message–receiving and SMS text messaging control groups were described and compared with followed-up participants using statistical significance testing. Mixed linear modeling was used to explore the time point–adjusted association among altitude-adjusted hemoglobin, intervention exposure, time from baseline to follow-up, and the interaction between intervention exposure and time. A second, adjusted model was run adding variables that were statistically significantly different between the SMS text message–receiving and SMS text messaging control groups at baseline.

Results

The HeLTI Bukhali Text Messaging Intervention

Participant Baseline Characteristics

[Figure 2](#) shows the participants of this study. For the SMS text messaging intervention, 72.5% (87/120) of participants in the SMS text message–receiving group and 81.7% (98/120) of participants in the SMS text messaging control group had their data collected at the follow-up visit. Of these, 90.8% (79/87) in the SMS text message–receiving group and 90.8% (89/98) in the SMS text messaging control group had hemoglobin data available from their follow-up visits. Reasons for loss to follow-up included withdrawal from HeLTI *Bukhali* (not specifically from the SMS text messaging substudy; 17/240, 7.1%; 13/120, 10.8%, in the SMS text message–receiving, and 4/120, 3.3%, in the SMS text messaging control group) and relocation or an inability to trace (38/240, 15.8%). The main baseline characteristics in the followed-up versus lost to follow-up group are provided in [Table S1](#) in [Multimedia Appendix 1](#), and the only statistically significant difference between these 2 groups was the number of participants born in South Africa (185/185, 100%, in the followed group vs 53/55, 96%, in the lost to follow-up group).

[Table 2](#) shows the main baseline characteristics of the study participants. The median age was 21.5 (IQR 19–24) years, and 30.8% (74/240) of the participants had anemia (hemoglobin <11.9) at baseline. More SMS text message–receiving participants were unemployed and fewer had graduated from high school than the SMS text messaging control group participants. Moreover, the number of participants with mild or severe anemia at baseline was higher in the SMS text message–receiving group than in the SMS text messaging control group (50/120, 41.7% vs 24/120, 20%).

Objective 1: Feasibility of the Bukhali Text Messaging Intervention**Acceptability**

In terms of acceptability, participants liked receiving SMS text messages on their phones, which they expressed using frequently, and reported that the content was acceptable (Table 3).

The participants suggested changes that would make the SMS text messages more acceptable and useful. For example, participants suggested sending SMS text messages earlier in

the morning and on days when they had to take micronutrient supplements (such as Mondays). Participants taking a daily dose of micronutrient supplements expressed the potential added value of receiving reminder messages every day. However, some participants described adherence messages as repetitive, resulting in them not always being read. Although some participants expressed that the health literacy messages were too long, others liked them and described reading them in full. Participants gave suggestions unique to their personal preferences and needs, such as receiving messages at night or preferring phone calls.

Table 3. Qualitative evaluation of the acceptability of the Healthy Life Trajectories Initiative Bukhali SMS text messaging intervention^a.

Acceptability	Quotes
Timing	
In support (positive)	
The timing of receiving the messages was acceptable	<ul style="list-style-type: none"> • “I think it’s fine, there’s nothing wrong with the timing...It asks you questions about the supplements and then tell you what the supplements provide you with, so I think it doesn’t cause any harm” [FGD^b 1] • “Whatever time I get the notification I read it and see what it contains, then I’m fine, I don’t see anything wrong.” [FGD 1] • “I think it’s the perfect time because they usually send an SMS in the morning.” [FGD 2]
Against (negative)	
Receiving the SMS text message at midday or later in the day was too late	<ul style="list-style-type: none"> • “I think mornings are better because you know that when you wake up, after breakfast you take it [micronutrient supplements].” [FGD 5] • “[I receive the SMS] around 12 and you find that I am in class.”
Participants wanted to receive the message on Monday when they take their supplement	<ul style="list-style-type: none"> • “For me the one that I want for the morning is the Monday one because when I’m from the weekend, I don’t want to lie, I forget.” [FGD 3]
Other participants had personal timing preferences	<ul style="list-style-type: none"> • “I prefer night time because I just take it before bed time then sleep.” [FGD 5]
Suggested adaptations	
To receive the messages early in the morning and on Mondays	<ul style="list-style-type: none"> • “They should input it on time and not input it late, they should send it at around seven” [FGD 3] • “I think they should send them Mondays and Wednesdays around 9, if you forgot, that will be a reminder that ‘I was supposed to take my supplements’” [FGD 1]
Frequency	
In support (positive)	
Receiving messages twice a week was acceptable	<ul style="list-style-type: none"> • “I think it’s fine, because you have to take them twice a week. So yes, it’s OK.” [FGD 4] • “it was actually a good thing getting them twice a week.” [FGD 2] • “I think twice a week it’s perfect.” [FGD 2]
Against (negative)	
Receiving messages twice a week was not enough	<ul style="list-style-type: none"> • “I think it’s too little.” [FGD 3] • “I wish they would send those every day” [FGD 1]
Suggested adaptations	
To receive the messages every day, particularly for those taking their supplements daily	<ul style="list-style-type: none"> • “At least every day, for me.” [FGD 3] • “You should take them every day if your iron is low, so the SMS’s should also come every day. If your iron is OK; they should come in on your designated days to take the supplements.” [FGD 5]
However, some expressed that receiving the same messages every day would be too repetitive	<ul style="list-style-type: none"> • “Sometimes the SMS’s say the same thing; so do you think it’s right that we get those every day?” [FGD 5]
Content	
In support (positive)	
The content was found to be easy to understand	<ul style="list-style-type: none"> • “They are OK; even the explanation is straight forward.” [FGD 5] • “The English they use is simple, they don’t use bombastic...” [FGD 5] • “It is self-explanatory and not complicated English.” [FGD 4] • “The language is understandable” [FGD 2]
Against (negative)	
The repetitive nature of the adherence to SMS text messages was found boring	<ul style="list-style-type: none"> • “They sent the very same thing over and over so...no man!” [FGD 5] • “Sometimes it was boring me, to be honest it was boring me. You do the same thing all the time.” [FGD 3]

Acceptability	Quotes
Suggested adaptations	
To vary the phrasing of the adherence message from day to day (although some repetitiveness is inherent to the nature of these messages)	__ ^c
Length	
In support (positive)	
The length of the messages was acceptable	<ul style="list-style-type: none"> • “The length is not that much, like it’s very convenient, it doesn’t even take much of your time whereby you like now you have to sit down and read.” [FGD 2] • “I think the long information is better.” [FGD 2]
Against (negative)	
The information messages were too long	<ul style="list-style-type: none"> • “What I disliked is that they were lengthy.” [FGD 5] • “When you are tired from school and all the studying then you receive a long text...its draining.” [FGD 1] • “Sometimes they send lengthier ones and maybe you are busy so I didn’t like those.” [FGD 5]
Suggested adaptations	
To shorten the information messages or split them into multiple messages	<ul style="list-style-type: none"> • “They should keep it brief and straight forward.” [FGD 5] • “They should try and limit it and make sure they stick to the relevant key points and not add anything else.” [FGD 5] • “So instead of sending one long message, they could send two different messages, one immediately after the other.” [FGD 1]

^aMain conclusion: The intervention was found to be acceptable, easy to understand, and delivered through an acceptable medium; however, opinions differed according to personal preference and needs on frequency, timing, and length of the messages.

^bFGD: focus group discussion.

^cIndicates a suggested adaptation formulated by the study team inferred from the presented evidence from the FGD but without direct supporting evidence from the participants.

Interaction and Usability

On the basis of quantitative analysis of the data log of participants’ use of the 2-way SMS text messaging system, the participants’ interactions with the 2-way SMS text messaging intervention in terms of response rate were low, with only 59.2% (71/120) of participants replying to any 1 message (Figure 3). Use declined over the 6 months of the intervention, and 10.8% (13/120) of participants still receiving messages replied in week 24.

In the FGDs, participants described their main reasons for not using the reply function as being too busy, lack of interest, lack of airtime, not understanding whether they were required to reply, and a technical error (Table 4). Participants expressed that a fuller explanation of the reply function and the received weekly prepaid airtime was needed. Similarly, participants expressed that being too busy, a lack of interest, and technical issues were the main barriers to receiving and reading SMS text messages. In terms of technical issues, some participants received the message in 2 parts or only received half of the message, possibly because of the length of some of the health literacy messages.

Figure 3. Use of 2-way SMS text messaging system by the number of SMS text message respondents and response rate by week.

Table 4. Qualitative evaluation of the usability of and interaction with the Healthy Life Trajectories Initiative Bukhali SMS text messaging intervention^a.

Usability and interaction	Quotes
Receiving and reading	
In support of (positive)	
The SMS text message reached and was read by participants	<ul style="list-style-type: none"> • “I always read them.” [FGD^b 1] • “Yeah every time I got the message I read everything that is written on it.” [FGD 2] • “If I saw that it is a different message I’d read the message.” [FGD 2]
Against (negative)	
Reasons for not reading the SMS text messages included being too busy, loss of interest, and technical issues in receiving the SMS text messages	<ul style="list-style-type: none"> • “I won’t lie, when I am in class I just look at it and just put it back in my pocket.” [FGD 5] • “I read them in the first week. I had the energy to; I would even sit down for it. But after that, no.” [FGD 5] • “The phone I used to receive the SMS’s is broken, so...I no longer received the SMS’s” [FGD 1]
Suggested adaptations	
To send SMS text messages at a more convenient time (eg, earlier in the morning)	— ^c
To resolve technical problems and unearthing and solving individual participants’ technical problems by asking for regular feedback about this	—
Responding	
In support of (positive)	
The respond function was used by some participants	<ul style="list-style-type: none"> • “Even if I don’t have airtime I make a plan and respond because I know if I don’t respond and I have taken them it won’t be OK.” [FGD 4]
Against (negative)	
There was limited uptake for replying to the SMS text messages	<ul style="list-style-type: none"> • “I only replied twice; all the other times I would just use the airtime for my own good.” [FGD 5] • “I don’t look to check if I can reply or something. I don’t reply anyway.” [FGD 3]
The main reasons for not replying were being busy, lack of interest, lack of airtime ^d , a technical error, and not understanding whether it is necessary to reply	<ul style="list-style-type: none"> • “What prevented me from replying was that I would receive the SMS while I am in class and I can’t reply and by the time I get home; I have lost interest in the SMS.” [FGD 5] • “I didn’t have time. And sometimes it was boring me.” [FGD 3] • “Sometimes the airtime disappears to your airtime advances payments before you can reply” [FGD 5] • “I used to respond but I can’t anymore, it just says error.” [FGD 1] • “That is where I struggle to understand if they really want us to reply or you just leave it like that?” [FGD 1]
Suggested adaptations	
To justify and explain the reply function at the start of the intervention	<ul style="list-style-type: none"> • “I think that you should explain...what should we reply? We must understand, you must give us the explanation.” [FGD 3]
To improve participant knowledge and understanding of the reply function and the airtime received at the start of the intervention, possibly through a short training session	—
To encourage participants to reply later even if they are busy at the moment of receiving the SMS text messages	—
To evaluate the usefulness of the reply function in this setting	—

^aMain conclusion: Although participants reported reading the SMS text messages, technical issues, a lack of time, and missing information were barriers to intervention usability, and participants expressed their use of the reply function was limited.

^bFGD: focus group discussion.

^cIndicates a suggested adaptation formulated by the study team inferred from the presented evidence from the FGD but without direct supporting evidence from the participants.

^dPhone credit per minute.

Perceived Benefits Versus Unintended Consequences

Participants described experiencing benefits from the intervention, including feeling supported by the study team, being reminded to take the micronutrient supplements, and learning new concepts from the health literacy messages (Table 5). Unintended consequences associated with the health literacy messages that were described included feelings of fear about the information in the side effect messages and feeling patronized (made to feel “stupid”) by the messages. This may

be because the SMS text messages reinforce content from the HeLTI *Bukhali* resources, and for participants with limited health literacy, this may feel that it highlights their lack of knowledge and understanding.

In general, participants did not feel the need to respond to the messages, although positive feelings about communicating through the reply function were expressed by one participant. In addition, some participants expressed feeling guilty for not responding to the messages or feeling like they might have been judged if they replied that they had not taken their supplements.

Table 5. Qualitative evaluation of the perceived benefits and consequences of the HeLTI^a Bukhali SMS text messaging intervention^b.

Perceived benefits vs consequences	Quotes
Overall intervention	
In support of (positive)	
The intervention helped participants feel supported by the study team	<ul style="list-style-type: none"> • “They make me feel like they care.” [FGD^c 4] • “I liked it because it showed that you do follow up, you are not just giving us the supplements only.” [FGD 5] • “They show that they want to be a part of this so that they can help us so that we can be focused and remember” [FGD 3]
Suggested adaptations	
To expand the SMS text messaging service to facilitate additional communication to address questions, monitoring of side effects, and delivery of the supplements	<ul style="list-style-type: none"> • “If they can create a WhatsApp number where we can text them.” [FGD 5] • “They must send me an SMS that by this date, we are going to be able to bring you your supplements.” [FGD 3] • “To monitor [side effects] and...where it has boosted you so far” [FGD 3]
Receiving health literacy messages	
In support of (positive)	
The health literacy messages were found to be educational and filled a knowledge gap	<ul style="list-style-type: none"> • “I am happy about it. It teaches me how to balance my diet, supplements and things like that” [FGD 1] • “the SMS’s tell you exactly what they are for and what they do and help with” [FGD 4] • “I actually got to learn the names of vitamins...for me it was exciting” [FGD 4] • “At clinics or wherever they don’t give us that much information. Now you know that even the small things that you can be able to plant yourself you can be able to get iron and be sharp.” [FGD 3] “I think twice a week it’s perfect.” [FGD 2]
Against (negative)	
An unintended consequence of the health literacy messages was feelings of fear about side effects	<ul style="list-style-type: none"> • “I think they should cut out the side effects one because sometimes it’s scarier to know that the medication you are about to take, you might come across this situation and that situation...might stop people from taking the supplements” [FGD 1]
An overlap between the health literacy messages and HeLTI intervention resources was disadvantageous	<ul style="list-style-type: none"> • “Because we already have the pamphlets; you make us feel like we are stupid by repeating the same thing; so I don’t like reading the same thing repetitively.” [FGD 5]
Suggested adaptations	
To review the phrasing of side effect messages for fear-inducing language and adapt where necessary	— ^d
To ensure information messages complement and refer to HeLTI intervention resources	—
To additionally disseminate the health literacy messages through platforms such as social media, television, and word of mouth	<ul style="list-style-type: none"> • “Community health workers...with people, if someone knocks, you open for them and give them your attention, and then they educate.” [FGD 1] • “Everything that there is on Facebook, I look at it.” [FGD 1]
Receiving adherence messages	
In support of (positive)	
Participants expressed that the adherence messages were an effective reminder	<ul style="list-style-type: none"> • “They were helpful because sometimes you forget to take them but when you receive the message you remember.” [FGD 5] • “We don’t receive them anymore and it shows because I forget to take them, but yes, they were a reminder.” [FGD 4] • “And also, our lives are busy, a lot so the SMS sometimes reminds you that you have to wake up, do like this and like this and like this.” [FGD 3]
Against (negative)	
The repetitive nature of the adherence message was not found useful	<ul style="list-style-type: none"> • “The information one I read, but the other one I don’t see it as necessary...because it’s the same thing.” [FGD 3]

Perceived benefits vs consequences	Quotes
Suggested adaptations	
(Please see above for suggestions for improved acceptability for adherence messages)	<ul style="list-style-type: none"> (Please see above for suggestions for improved acceptability for adherence messages)
Responding to adherence messages	
In support of (positive)	
Being able to reply to the messages felt beneficial for some	<ul style="list-style-type: none"> “I also feel good letting them know that I am taking the supplements.” [FGD 4]
Against (negative)	
Other participants did not perceive a benefit to responding to the messages	<ul style="list-style-type: none"> “Why should I have to reply?” [FGD 3] “I felt no type of way.” [FGD 3]
An unintended consequence of the response option was feelings of guilt and judgment for not responding or taking supplements	<ul style="list-style-type: none"> “Because of that part that you cannot answer, you seem like a person who is not cooperative, but you do want to cooperate it’s just that you don’t have what they require [airtime].” [FGD 4] “I felt like they would judge me and say I’d ruin my body...When I didn’t take the supplements I felt a bit odd because I did not want to disappoint them.” [FGD 4]
Suggested adaptations	
To justify and explain the reply function at the start of the intervention	<ul style="list-style-type: none"> “I think that you should explain...what should we reply? We must understand, you must give us the explanation.” [FGD 3]
To assess the need for a reply function in this intervention	—
To thoroughly explain the nonjudgmental nature of the reply function, which is intended to help the participant.	—

^aHeLTI: Healthy Life Trajectories Initiative.

^bMain conclusion: Participants perceived practical, supportive, and educational benefits to receiving SMS text messages; however, there was little perceived benefit for the response option, and feelings of worry and fear were unintended consequences associated with the intervention.

^cFGD: focus group discussion.

^dIndicates a suggested adaptation formulated by the study team inferred from the presented evidence from the FGD but without direct supporting evidence from the participants.

Fidelity and Cost of Intervention Delivery

On the basis of the quantitative data log of received messages, airtime, and technical errors, there was only one participant to whom the SMS text messages were not delivered as intended because of a technical error, which was resolved at week 16 of the 24 weeks after updating the participant’s number and provider. As indicated in [Table 4](#), in the FGDs, participants sometimes reported receiving messages in 2 parts or only receiving half a message, particularly when using nonsmartphone models. Some also reported having technical problems when trying to reply to the message. However, the exact cause or number of cases in which this occurred could not be determined.

In terms of receiving weekly prepaid airtime, a few participants experienced technical problems, with 4.2% (5/120) of participants experiencing repeated technical errors. Of these, 3 were because of the initial recording and use of the wrong cell network by the research team. One was because of a change in the phone number. For these 4 participants, errors were resolved within 2 months of onset. For the fifth participant with a

repeated technical error, technical failure could not be resolved, likely because they had a nonchargeable SIM card.

On the basis of the cost log for the intervention, delivering the SMS text messaging intervention cost ZAR 71.65 (US \$4.65) per participant or, on average, ZAR 245.64 (US \$15.93) per week for the 35 weeks that SMS text messages were sent. When including the weekly prepaid airtime, the intervention cost per participant was ZAR 266.26 (US \$17.27) or ZAR 912.91 (US \$59.21) per week.

Indicative Effect of the Bukhali Text Messaging Intervention

This section reports the results of preliminary, nonrandomized comparisons between the SMS text message-receiving and SMS text messaging control groups. As shown in [Figure 4](#), at follow-up, self-reported adherence was higher in the SMS text message-receiving group (42/63, 67% reported taking supplements every time) than in the SMS text messaging control group (33/85, 39%; $P=.02$). In addition, a larger percentage of the SMS text message-receiving group (32/63, 51%) strongly agreed that the supplements had a positive impact on their health than the SMS text messaging control group (36/85, 42%; $P=.09$;

Figure 5). The main reasons for sometimes or often missing supplements in both groups were traveling (and therefore not having access to the supplement) and forgetting; however, fewer participants in the SMS text message–receiving group reported missing their supplements for these reasons. Moreover, a lower number of participants in the SMS text message–receiving group reported having fears about taking the supplements than in the SMS text messaging control group (4/63, 6% vs 16/77, 21%; $P=.02$), although the number of participants reporting a side

effect in the SMS text message–receiving group was nonstatistically significantly higher than in the SMS text messaging control group (13/64, 20% vs 9/84, 11%). In addition, statistically significantly more participants in the SMS text message–receiving group agreed or strongly agreed that the micronutrient supplements were explained to them well (59/64, 92% vs 66/87, 76% in the SMS text messaging control group; $P=.03$).

Figure 4. Bar graph comparing the SMS text message–receiving and SMS text messaging control group participants’ self-reported adherence at follow-up.

Figure 5. Bar graph comparing the SMS text message–receiving and SMS text messaging control group’s attitudes toward supplements improving their health at follow-up.

The mean difference in hemoglobin from baseline to follow-up (Δ hemoglobin) was negative in the SMS text messaging control group (mean -0.46 , SD 1.59), whereas in the SMS text message–receiving group, Δ hemoglobin was positive (mean 0.52 , SD 2.18 ; $P=.002$). This difference in hemoglobin levels between the 2 groups remained statistically significant when

the 2 participants with severe anemia at baseline were excluded from the SMS text message–receiving group ($P=.003$).

Exploring this finding further with a mixed linear model, we found that the altitude-adjusted hemoglobin increased more between baseline and follow-up in the SMS text

message-receiving group than in the SMS text messaging control group, as indicated by the interaction term in the model (1.03, 95% CI 0.49-1.57; $P < .001$; Table 6), although absolute the hemoglobin level was lower in the SMS text message-receiving group when adjusted for time (-0.70 , 95%

CI -1.13 to -0.28 ; $P = .001$). These results remained statistically significant and were not attenuated after correcting for differences present at baseline (employment status and level of education; Table S2, Multimedia Appendix 1).

Table 6. Linear mixed modeling for altitude-adjusted hemoglobin, adjusting for intervention exposure, time (baseline vs follow-up), and the interaction between time and intervention exposure^{a,b}.

Model	Coefficient (95% CI)	P value
SMS text message-receiving group	-0.70 (-1.13 to -0.28)	.001
Time (baseline to follow-up)	-0.51 (-0.88 to -0.14)	.007
SMS text message-receiving group \times time	1.03 (0.49 to 1.57)	$<.001$

^aNo other covariables other than those shown were included in the model. SMS text message-receiving group \times time indicates the interaction term between the SMS text messaging intervention exposure and time of measurement (baseline vs follow-up).

^bAverage observations per group 1.7; P value model = .001.

The Phila Impilo Yakho Kangcono Radio Serial Intervention

Objective 2: Acceptability of the Radio Serial and Facebook Page

Participants expressed that they found the content of the messages educational and relatable and that they enjoyed the

narrative aspect of the radio serial as a way of communicating health messages (Table 7). The participants reported not having previously heard the radio serial on the national radio station (Ukhozi FM) or on the local station (Jozi FM).

Table 7. Qualitative evaluation of the acceptability of the Phila Impilo Yakho Kangcono radio serial^a.

Acceptability radio serial	Quotes
Delivery	
In support (positive)	
Participants liked the delivery of health messages through a narrative radio serial	<ul style="list-style-type: none"> • “On radio you get to hear people’s voices and emotions and by hearing what they’re saying maybe you can change your diet, your ways.” [FGD^b 2]
Participants liked the associated Facebook page	<ul style="list-style-type: none"> • “It’s informative, it’s youthful.” [FGD 4] • “I find it really inspirational because we learnt about things we did not know about.” [FGD 5]
Participants reported listening to the radio occasionally and in specific situations	<ul style="list-style-type: none"> • “You find that people don’t know how you get diabetes,...so it’s educational.” [FGD 2] • “I personally think it [relationship between characters in serial] is realistic.” [FGD 1] • “she [character] is the one who educates others...She also wants to learn so that she helps her mother, she’s so supportive.” [FGD 1]
Against (negative)	
Participants reported not having previously heard the radio serial	<ul style="list-style-type: none"> • “I listen to radio but have never heard it before.” [FGD 3] • “I don’t listen to radio.” [FGD 1]
Suggested adaptations	
To increase awareness of the radio serial	<ul style="list-style-type: none"> • “And word of mouth will help, just to say there’s this show on the radio.” [FGD 2]
Content	
In support of (positive)	
The content and characters of the radio serial were found to be relatable and acceptable	<ul style="list-style-type: none"> • “You find that people don’t know how you get diabetes,...so it’s educational.” [FGD 2] • “I personally think it [relationship between characters in serial] is realistic.” [FGD 1] • “she [character] is the one who educates others...She also wants to learn so that she helps her mother, she’s so supportive.” [FGD 1]
Suggested adaptations	
To incorporate additional health literacy topics of interest, including exercise, hygiene, sexually transmitted illnesses, cancer, COVID-19, gender-based violence, and mental health	<ul style="list-style-type: none"> • “How to deal with your anxiety. Because with me when I walk the streets, I get scared...I overthink a lot especially with my schoolwork” [FGD 3] • “I think cancer as well because we think it’s only for older people and we also get cancer now.” [FGD 5] • “COVID-19 as well” [FGD 5]

^aMain conclusion: Participants found the delivery radio serial and associated Facebook page acceptable and the content likable and relatable.

^bFGD: focus group discussion.

Advantages and Disadvantages of SMS Text Messaging, Radio, and Facebook Page

An overview of the advantages and disadvantages of the different health messaging media based on the FGD data is provided in [Table 8](#). Although participants expressed concerns

about the accessibility of data-requiring messaging platforms such as Facebook and had not visited the Facebook page associated with the radio serial before the FGD, participants liked that it provided a community with whom they could interact.

Table 8. Qualitative results comparing the advantages and disadvantages of health messaging in the social messaging media, including SMS text messaging, radio, and a Facebook page.

Media	Quotes
Advantages	
SMS text messaging	
Participants frequently use their phones	<ul style="list-style-type: none"> • “The fact that I’m always on my phone and it’s easy to access” [FGD^a 4] • “I always have time [to read the message] because I am always on my phone” [FGD 1]
Does not require access to data	<ul style="list-style-type: none"> • “What if you don’t have data for social media? SMS doesn’t need data.” [FGD 1]
Radio	
Ability to listen to health messages through a story	<ul style="list-style-type: none"> • “On radio you get to hear people’s voices and emotions” [FGD 2] • “I think radio communicates better than the SMS’s because sometimes you are lazy to read SMS’s but listening is better.” [FGD 5]
Does not require access to data and can be accessed anywhere	<ul style="list-style-type: none"> • “On radio it’s an advantage...you can just switch on your radio, headsets and listen, whether you’re in a taxi, whether you’re doing something and you listen” [FGD 2]
Facebook page	
The community associated with the page	<ul style="list-style-type: none"> • “Some people go through a lot...it can actually help people open up about themselves.” [FGD 3] • “I think with this page we can, people can talk and express their feelings.” [FGD 2]
Ability to find past content (eg, past radio serial episodes)	<ul style="list-style-type: none"> • “[I prefer] social media. When you miss this show, nowadays there’s load shedding then when you miss the show they must repeat it so that you can listen to it again.” [FGD 2]
Disadvantages	
SMS text messaging	
Some participants indicated a preference for phone calls	<ul style="list-style-type: none"> • “I prefer that they call; these older models are very problematic...so I prefer them to call, the same way they call when they run sessions.” [FGD 5]
Radio	
Not all participants listen to the radio frequently	<ul style="list-style-type: none"> • “We don’t often listen to the radio so I prefer the SMS” [FGD 4]
Inability to find past content	<ul style="list-style-type: none"> • “Nowadays there’s load shedding [power cuts] then when you miss the show they must repeat it so that you can listen to it again.” [FGD 2]
Facebook page	
Data requiring	<ul style="list-style-type: none"> • “Social media, we always don’t have data.” [FGD 2] • “Not all of us can access the internet.” [FGD 4]
Participants need to proactively log in	<ul style="list-style-type: none"> • “When you get the notification you take your phone and check, but with Facebook, a week might go by without you logging in.” [FGD 1] • “I don’t have Facebook I just deleted it so I prefer to listen to radio.” [FGD 2]

^aFGD: focus group discussion.

Discussion

Principal Findings and Implications

In this nested feasibility study, the HeLTI *Bukhali* SMS text messaging intervention, aimed at improving preconception

adherence to micronutrient supplements, was found to be acceptable, beneficial, and usable by participants. Indicative effect results suggest a promising potential effect of the SMS text messaging intervention on self-reported supplement adherence and changes in hemoglobin from baseline to

follow-up, although these are not based on a randomized comparison. These findings are in line with evidence from high-income countries on the acceptability and potential of SMS text messaging interventions to support behavior change in various life stages and contribute to the existing evidence, although less conclusive, for SMS text messaging interventions from low- and middle-income countries [20,21,27,28]. Finally, the health-promoting radio serial was found to be acceptable for young women.

Although participants reported finding the SMS text messages easy to understand and helpful, we received several suggestions for adapting the SMS text messaging intervention. This included a preference for receiving messages in the early morning on days they were meant to take their supplement. Although personalizing the timing and frequency of SMS text message delivery could negatively affect the scalability of the intervention [47], it may be feasible to send more frequent messages to those participants taking supplements daily, as suggested in the FGDs. As the SMS text messaging intervention was automated, it required few resources and was not demanding on implementation staff, increasing its practicality in limited-resource settings such as ours. However, introducing a nonautomated aspect to the intervention, for example, through a *help desk*, which participants could reach by replying to a number, could help manage the technical challenges experienced by participants and facilitate communication with the study team. Existing evidence also suggests that a nonautomated, personalized element may increase interaction with and the effect size of the intervention, although this remains to be tested from a cost-effectiveness perspective [48]. It is important to establish the feasibility and affordability of such a service in low- and middle-income settings, given that automated systems could be more scalable and sustainable in resource-constrained environments. Furthermore, in the context of the HeLTI *Bukhali* trial, there are likely other intervention priorities that would take precedence over such a service, particularly in terms of the allocation of human resources. However, there could be less resource-intensive ways of integrating these learnings into the intervention implementation, such as reminding those delivering the intervention to follow up more intentionally about the delivery of SMS text messages with participants.

In our study, the 2-way reply function of the SMS text messaging intervention was underused, with only 10.8% (13/120) of participants using the reply function in the final week of the intervention. A study evaluating a 2-way SMS text messaging intervention for weight loss in postpartum women in a high-income setting found good engagement with a comparable *yes or no* SMS text message reply option, with most participants replying to over half of the messages and high engagement contributing to the outcome of interest [28]. In a low- to middle-income setting, some evidence suggests that a 2-way SMS text messaging intervention could be effective if engagement is high enough [49]; however, a study of a 2-way SMS text messaging intervention for improved HIV care in pregnant and postpartum women in Kenya found a similarly low response frequency [50]. Qualitative research from Uganda indicated similar barriers to responding to a 2-way SMS text messaging intervention, as expressed by our participants,

including a lack of airtime, being too busy, and phone-specific issues [51]. Whether these barriers can be minimized through more extensive instructions, explanations, participant encouragement at intervention initiation, or the use of alternative media such as unstructured supplementary service data would require further assessment before this aspect of the intervention can be recommended in our setting. Despite the low response rate, the SMS text messaging intervention was found to be acceptable and showed a potentially indicative effect. Therefore, a 2-way function may not be an essential component of an intervention aimed at improving supplement intake, as opposed to more complex behavior change targets.

In terms of population-level health promotion messaging, our participants indicated a preference for the narrative and accessible nature of the *Phila Impilo Yakho Kangcono* radio serial. Radio health messaging has been found to increase health knowledge and awareness in the context of, among others, maternal health, HIV prevention research, and child health in low- and middle-income settings, including Southern Africa [52-56]. However, we found that not all participants listened to the radio frequently, indicating the need for research on the reach of such a radio-based health promotion campaign among young women in our setting. By combining media, directed health messaging (such as SMS text messaging) could be used to increase young women's awareness of new radio and social media campaigns to improve their reach and effectiveness [57].

Strengths and Limitations

To the best of our knowledge, this is the first study in our setting to evaluate social messaging through individual-level SMS text messaging intervention and population-level radio serial for preconception health promotion. However, a limitation of this study is that more in-depth data on the acceptability, feasibility, and impact of the radio serial were not available as participants' exposure was limited to 1 or 2 episodes, which they heard for the first time during the FGDs. Another limitation is the high rate of loss to follow-up and the presence of missing data, which threatens the validity of the findings regarding the indicative effect of the SMS text messaging intervention. Moreover, the loss to follow-up may indicate that collecting data on these end points might be challenging in the context of a full randomized controlled trial. Although a portion of the loss to follow-up can likely be explained by the unique circumstances of the COVID-19 pandemic, additional methods to limit withdrawal, increase participant motivation for participation, and prevent loss of contact (eg, through community engagement) could be useful to explore. The withdrawal and loss-to-follow-up rates were higher in the SMS text message-receiving group than in the SMS text messaging control group, which could be because of the greater impact of COVID-19 later in the pandemic (with data collected in 2021 vs 2020). Although there was no indication from the participants that they were withdrawing in response to the SMS text messaging intervention, further (randomized) analysis could help confirm this. The evaluation of the indicative effect of the SMS text messaging intervention was not conducted between the 2 randomized groups, and the baseline difference in hemoglobin levels between the SMS text message-receiving and SMS text messaging control groups, although adjusted for in the linear mixed model, may have

affected our results. Therefore, a fully randomized controlled exploration of the effectiveness, as well as the cost-effectiveness, of the intervention is still needed.

The FGDs were moderated by trained research staff from Soweto who were not involved in the development of the intervention. The researcher performing the initial coding and qualitative analysis (LMS) was a cultural outsider as a White European woman, which may have affected nuanced aspects of data interpretation, although the outcomes were reviewed by other members of the research team [58]. LMS was also involved in the study implementation and management (although not the development of either intervention), which may have contributed to observer bias [59]. Nevertheless, this study contributes to the understanding of women's perceptions of preconception health messaging strategies in our setting.

Conclusions

In this feasibility study, young women found that an SMS text messaging intervention aimed at increasing adherence to

preconception micronutrient supplements was acceptable. In addition, mass media health promotion through a radio serial aimed at young people was found to be acceptable and relatable. Participants found the HeLTI *Bukhali* SMS text messaging intervention beneficial and useful. The intervention may also help improve self-reported adherence, attitudes toward supplements, and measured hemoglobin levels at follow-up, although these results are based on a limited, nonrandomized comparison. Although these findings suggest a previously unexplored potential for SMS text messaging interventions to support improvements in preconception micronutrient supplement adherence, further studies in the form of randomized trials are still needed. In addition, some refinements based on participant suggestions and reassessment of the 2-way SMS text messaging component are needed. Social messaging interventions for improving the health and nutrition of young women could consider how directed messaging (such as SMS text messaging) and mass messaging strategies (such as radio) may be used to complement each other to promote the health of young women in the preconception period.

Acknowledgments

The development, implementation, and evaluation of the SMS text messaging intervention were funded by the Queen's University Belfast and the University of the Witwatersrand seed fund. The development and distribution of the radio serial were funded by the South African Department of Science and Innovation-National Research Foundation Center of Excellence in Human Development. LJW, SAN, and LMS were supported by the South African Department of Science and Innovation-National Research Foundation (DSI-NRF) Center of Excellence in Human Development. SK was supported by Koneen Säätiö (grant number 201901846). The funding sources had no role in the study design, statistical analysis, interpretation of the data, writing of the report, or the decision to submit the article for publication.

The authors would like to acknowledge the data management team and data collection team at the Developmental Pathways for Health Research Unit for their contributions to setting up the SMS text messaging intervention and data management for this study.

Authors' Contributions

LJW and MCM conceptualized this project, and LJW, MCM, and AP developed the intervention and focus group topic guides. LJW, CED, and SAN contributed to developing the research methods and implemented the overarching preconception trial. LMS managed the project, contributed to data collection, analyzed the data, and drafted the first version of the manuscript. SK contributed to the qualitative data analysis and interpretation. All authors contributed to writing and editing the manuscript. All the authors approved the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Reliable and consistent social support is associated with the mental health and well-being of persons with severe mental illness, including bipolar disorder (BD). Yet the COVID-19 pandemic and associated social distancing measures (eg, shelter in place) reduced access to regular social contacts, while social media use (SMU) increased concomitantly. Little is currently known about associations between the well-being of adults with BD and different types of SMU (eg, passive and active).

Objective: For this study, we had two goals. First, we report descriptive information regarding SMU by persons with BD during COVID-19 (all platforms). Specific to Facebook, we next developed and tested a hypothesized model to identify direct and indirect associations between BD symptoms, social support, loneliness, life satisfaction, and SMU. Responses were collected during the global spread of the Delta variant and prior/concurrent with the Omicron variant, 20 months after the World Health Organization declared COVID-19 a global pandemic.

Methods: Over 8 weeks, we obtained responses from an international sample of 102 adults with BD using the Qualtrics online platform. Most had previously participated in the BADAS (Bipolar Affective Disorders and older Adults) Study (n=89, 87.3%); the remainder were recruited specifically for this research (n=13, 2.7%). The subsamples did not differ in age ($t_{100}=1.64$; $P=.10$), gender ($\chi^2_2=0.2$; $P=.90$), socioeconomic status ($\chi^2_6=9.9$; $P=.13$), or time since BD diagnosis ($t_{97}=1.27$; $P=.21$). Both were recruited using social media advertising micro-targeted to adults with BD. On average, participants were 53.96 (SD 13.22, range 20-77) years of age, they had completed 15.4 (SD 4.28) years of education, and were diagnosed with BD 19.6 (SD 10.31) years ago. Path analyses were performed to develop and test our hypothesized model.

Results: Almost all participants (n=95, 93.1%) reported having both Facebook and LinkedIn accounts; 91.2% (n=93) reported regular use of either or both. During the pandemic, most (n=62, 60.8%) reported accessing social media several times a day; 36.3% (n=37) reported using social media more often since the emergence of COVID-19. Specific to Facebook, the model we hypothesized differed somewhat from what emerged. The resulting model suggests that symptoms of depression predict loneliness and, inversely, social support and life satisfaction. Social support predicts social Facebook use, whereas passive Facebook use predicts life satisfaction. Symptoms of depression emerged as indirect predictors of SMU via social support.

Conclusions: Our findings suggest that the operational definition of passive-active SMU requires further analysis and refinement. In contrast to theory, passive Facebook use appears positively associated with well-being among certain populations. Longitudinal data collection over multiple points is required to identify associations between BD symptoms, SMU, and well-being over time.

Introduction

Social Support With Bipolar Disorder

Well-being with bipolar disorder (BD) has many facets; for most, this entails routine and consistency, including regular social contact and support [1]. The importance of social support for adults with BD is well documented. It has been shown, for instance, that greater contact with friends and family fosters well-being with BD [2], and those with less social support report more symptoms of mania [3]. The perceived absence of social support is associated with the recurrence of BD mood episodes [4] and slower time to recovery [5].

Isolation and disruption in routine caused by the COVID-19 pandemic have been especially difficult for those with mental health conditions. For instance, one Israeli study showed that those who reported being most lonely during the pandemic were 82% more likely to struggle with depression and anxiety [6]. A similar US study reported that greater loneliness was associated with increased symptoms of depression and suicidal ideation [7].

Initial research on the psychological effects of COVID-19 early in the pandemic reported no significant effects on persons with mental health conditions compared to prepandemic symptoms [8,9]. Some lifestyle changes caused by the COVID-19 pandemic restrictions (eg, lowered access to social support) were less pronounced for persons with BD than healthy controls [10]. This may be due to fewer social contacts at baseline for those with BD (ie, smaller social networks or family estrangement). However, reduced access to social support, along with disruptions to routine, lower income, and unemployment, have a longer-lasting impact on those with BD, leading to longer-term disruptions [11]. This is reflected in recent research [11-13]. In a study from Australia, those with mood disorders (depressive disorder or BD) reported elevated levels of psychological distress (ie, stress, anxiety, or depression) when compared to those free of psychopathology [12].

Social Media Use and Mood Disorders

In the absence of interpersonal contact, many turned to various social media [14]. With an estimated 4.6 billion global users [15], social media (eg, Facebook, Instagram, Twitter, or TikTok) have become platforms, and in some cases replacements, for in-person community building and support [16]. This has been particularly true during the global COVID-19 pandemic [17,18] when in-person social support ceased to be an option for many, particularly those living alone. Yet our understanding of the effects of social media use (SMU) on mental health remains incomplete despite the omnipresence of social media in modern life.

Excessive SMU may well cause or exacerbate symptoms of depression. Among adolescent and young adults, associations between depressive symptoms and SMU are well established

[19-21]. Research on persons with chronic depression suggests that an increase in SMU exacerbates symptoms [22]. Alternatively, depression may predict excessive SMU [23], as those with severe chronic depression are often socially isolated and rely on online interactions [24]. Different facets of SMU may play differing roles, as active versus passive use patterns appear to have opposing associations with social comparison and, in turn, depressive symptoms [25].

Most SMU and mental health research to date has focused on depression and anxiety [26]. The relationship between SMU and other mental health conditions is even less well understood. BD is an especially stigmatized mental health condition as reflected online; tweets relating to BD were found to be more stigmatizing than those pertaining to other mental health conditions [27]. This may create a complex online experience for those with BD. However, research also points to the potential for social media to confer peer support to those with BD, either as a supplement or alternative to in-person support. Qualitative research findings suggest that those with severe mental illness, including BD, seek out opportunities to connect with peers online [28] and that peer support occurs naturally among those who share their experiences online [29]. In intervention research, intentional weight loss was fostered by online support and interaction [30].

Passive and Active Social Media Use

Research conducted with general adult samples underscores that SMU is not a singular behavior [16]; instead, there are various ways in which social media are used, with differential effects on mental health and well-being [31]. Active SMU entails direct engagement with social media, such as posting comments or commenting on posts. Active use includes sharing pictures, opinions, or interests to communicate or connect with friends and family. In contrast, passive SMU entails consuming online information without posting or commenting (eg, scrolling news feeds and viewing posts). This behavior allows the user to observe other people while maintaining relative anonymity.

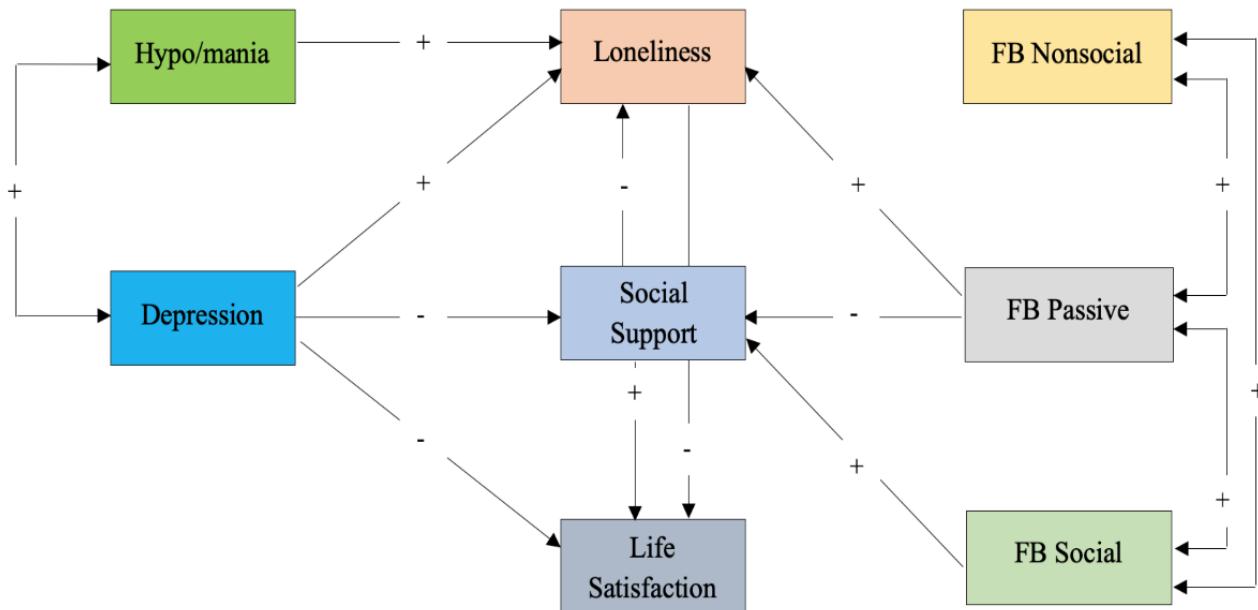

There is no consensus regarding associations between different patterns of SMU and well-being. Multiple studies suggest that active SMU is negatively associated with depressive symptoms [32] and perceived loneliness, and that this relationship is mediated by social support [33,34]. Yet other studies suggest that passive SMU is negatively associated with well-being because it encourages social comparison and feelings of envy [35], and is associated with a depressed mood [36,37]. However, the active-positive and passive-negative dichotomy is not universally accepted. One study performed during the COVID-19 pandemic initially found a positive association between active SMU and meaning in life, yet in a replication study, the opposite was found as well as an association between active SMU and emotional loneliness [38]. There is also evidence that passive SMU is associated with positive well-being such as life satisfaction [39].

This lack of consensus regarding the effects of active and passive SMU may be due in part to different definitions of terms and scales. A meta-analysis found that, of 40 studies of active and passive SMU and well-being, there were 36 different operational definitions of active and passive SMU [40]. Existing scales do not fully differentiate between different nuances of active and passive SMU (eg, public and private use or social and nonsocial use) and are not universally applicable to the range of social media platforms that exist today [35,40]. The effects of social media on the well-being of adults with severe

mental illness are unclear. Additionally, the role of social media in daily life may have become even more prominent as a result of the COVID-19 pandemic.

The aims of this study were twofold. First, we set out to describe general patterns of SMU by adults with BD during COVID-19 (all platforms). Specific to Facebook, we next tested a hypothesized model to identify direct and indirect associations between BD symptoms, social support, loneliness, life satisfaction, and SMU (passive, active social, and active nonsocial; see Figure 1).

Figure 1. Statistically significant associations depicted as paths (directional arrows) or correlated associations (double-headed arrows). Positive (+) and negative (-) directional associations hypothesized a priori. FB: Facebook.

In keeping with previously published research, we hypothesized that:

- Social Facebook use would predict social support
- Passive Facebook use would predict both loneliness and lower social support
- Depressive symptoms would predict lower life satisfaction
- Depressive symptoms would predict loneliness and lower social support
- Symptoms of hypo/mania would predict loneliness

Methods

Online Recruitment and Data Collection

Most (n=89, 87.3%) of the 102 participants previously took part in the Bipolar Affective Disorders and Older Adults (BADAS) study [41]; the remainder were recruited specifically for this study. Subsamples did not differ in age ($t_{100}=1.64$; $P=.10$), gender ($\chi^2_2=0.2$; $P=.90$), socioeconomic status ($\chi^2_6=9.9$; $P=.13$), or country of residence ($\chi^2_3=6.0$; $P=.11$). They also did not differ in symptoms of depression ($t_{100}=.93$; $P=.36$), hypo/mania ($t_{100}=0.95$; $P=.35$), or time since BD diagnosis ($t_{97}=1.27$; $P=.21$). Both subsamples were recruited using microtargeted Facebook advertising. This method has been used effectively to recruit

clinical samples from low prevalence populations, including BD [42].

BADAS participants who authorized future contact provided their email addresses [41,43]. They were sent up to three personalized notices requesting their participation in this study. A first email was sent in early November 2021, a reminder was sent 1 week later (if there was no response to the first), and 3 weeks thereafter (if there was no response to the first or second).

Concurrently, a Facebook page was established, and microtargeted advertisements were sent to prospective new participants using the A/B test method (ie, two versions of the same advertisement compared). The more successful was then used in the third round of advertising. Prospective participants were ≥ 18 years of age, could read and write English, and were members of ≥ 1 online BD advocacy or support group. Responses were obtained during the global spread of the Delta variant and prior/concurrent with the Omicron variant, 20 months after the World Health Organization declared COVID-19 a global pandemic.

Both BADAS and newly recruited participants were directed to an online questionnaire hosted on the Qualtrics platform. Participants were initially asked their age in years and, later, their date of birth in the demographics questionnaire to corroborate candid responding. To facilitate data collection,

participants could enter a lottery to win a single US \$500 prize (ie, an Amazon gift card).

Ethics Approval

Ethics approval was received from the Institutional Review Board at Ben-Gurion University of the Negev, Be'er Sheva, Israel (#2157-2). By clicking to proceed, respondents indicated consent to participate as stated on the study splash page. They were not required to provide identifying information aside from an email address if they wished to receive a study summary or participate in the lottery.

Instruments

The Bipolar Disorder Symptom Scale (BDS_x) was developed to measure symptoms of both depression and hypo/mania (hypomania + mania = hypo/mania: continuum where the point of transition is not immediately apparent) [43-45]. Respondents indicate the extent to which each of the 20 items describes how they feel at this moment, on a Likert scale ranging from *not at all* (0) to *a lot* (2). Internal consistency of BDS_x responses by BD outpatients was reported as $\alpha=.90$ for the depression subscale (cognitive + somatic symptoms) [46] but lower for the hypo/mania subscale at $\alpha=.76$ (affrontive + elation and loss of insight) [47]. This difference may be due to the low frequency of hypo/manic versus depressive symptoms [48].

Concurrent validity of BDS_x responses by BD outpatients has been demonstrated relative to the self-reported Hamilton Rating Scale for Depression and the Altman Self-Rating Mania Scale [47]. Similarly, sensitivity and specificity are high for the BDS_x depression subscale at 88% and 76%, respectively [46]. Sensitivity is lower at 57% for the BDS_x hypo/mania subscale (90% specificity), but sensitivity is higher than for the Altman scale (43%) [46].

The Satisfaction with Life Scale (SLS) [49] measures perceived quality of life based on person-specific criteria [50]. The SLS is composed of five questions (eg, "The conditions of my life are excellent") with response alternatives ranging from *strongly disagree* (1) to *strongly agree* (7). Higher totals are suggestive of greater life satisfaction [51]. Test-retest reliability over 1-month has been reported as $r=0.84$ [52]. Concurrent validity of SLS responses has been demonstrated relative to the Fordyce Global Scale ($r=0.82$) [34]. Among adults with BD, internal consistency has been reported as $\alpha=.89$ [53].

The eight-item UCLA Loneliness Scale (ULS-8) is a brief measure developed to study relationships between loneliness and health-related behavior [54]. Responses are reported along a Likert scale ranging from *I never feel this way* (0) to *I often feel this way* (3). Internal consistency of ULS-8 responses is high ($\alpha=.84$) [55].

The Multidimensional Scale of Perceived Social Support is a 12-item measure of subjective social support from partners, family, and friends [56]. Responses are reported on a Likert scale ranging from *very strongly disagree* (1) to *very strongly agree* (7). High internal consistency was reported in scale development ($\alpha=.88$ [56]) and subsequent research ($.83<\alpha<.93$ [57,58]).

The Passive and Active Facebook Use Measure (PAUM) was developed to distinguish different types of Facebook use [59]. Exploratory factor analyses suggest three distinct patterns: active social, active nonsocial, and passive. Active social use pertains to direct engagement (eg, chatting or commenting to Facebook posts), whereas active nonsocial use does not entail direct interaction with others (eg, post videos or tag photos), and passive use is limited to viewing photos and checking the status of others (ie, no engagement). Internal consistency across subscales ranges from adequate to good ($.70<\alpha<.81$ [59,60]).

We created a self-report questionnaire to collect demographic information. Participants indicated their country of residence (drop-down menu), number of years of education, work or occupation, employment status, and current relationship status. They were asked their gender, ethnicity, if they had been diagnosed with BD by a clinician (eg, psychiatrist), BD subtype if known, and date of BD diagnosis (month, year).

Statistical Methods

Path analysis was performed for this study as a three-step process [61]. A hypothesized model was first tested, nonsignificant paths were deleted, and statistically significant paths not initially hypothesized were added if supported by existing research or theory (see Figure 1).

Path analysis is an extension of multiple linear regression with three significant advantages. Path analysis allows us to simultaneously predict one or more dependent variables (touched by arrowheads in path models). Arrows pointing from independent to dependent variables represent significant prediction (ie, critical ratio values $>|1.96|$, $P<.05$). Path analysis is a multivariate statistical procedure meaning that all significant paths emerged concurrently (ie, over and above other statistically significant results).

Path models allow us to identify both direct and indirect predictors; indirect prediction occurs via other variables (ie, ≥ 2 pathways between variables). In complex or more nuanced models, variables can have both direct and indirect effects on dependent variables; indirect effects can be of equal or greater magnitude than direct effects (total effects = direct + indirect effects).

Computing path analyses with structural equation modeling software allows us to obtain goodness of fit information for the overall model. Good model fit is required to interpret individual results [62]. In accord with convention, we report three goodness of fit indexes to assess overall model fit: an incremental (comparative fit index [CFI]), an absolute (standardized root mean residual [SRMR]), and a parsimonious fit index (root mean square error of approximation [RMSEA]). Ideal SRMR and RMSEA values are less than 0.055, whereas ideal CFI values are greater than 0.95 [61]. Descriptive and comparative analyses were performed using SPSS v28 (IBM Corp), and path analyses were performed using AMOS v28 and maximum likelihood estimation [62].

Results

Descriptive Features

We recruited 102 participants over 8 weeks who were 53.96 (SD 13.22; range 20-77) years of age on average, had completed 15.4 (SD 9.88) years of education, and were diagnosed with BD 19.61 (SD 10.29; range 1-58) years ago. Most participants were women (n=69, 67.6%) and currently married, cohabitating, or partnered (n=56, 54.9%); 27 were single, 11 separated or

divorced, and 4 widowed. Most lived in North America (Canada: n=45, United States: n=15), Western Europe (eg, United Kingdom: n=18, Ireland: n=10), South Africa (n=4), and Australia (n=4) or New Zealand (n=3). [Table 1](#) reports descriptive statistics and the psychometric information for scale responses (eg, internal consistency). Responses are largely within normal limits (limited skewness and kurtosis) with adequate to ideal internal consistency for almost all study measures (see [Table 1](#)).

Table 1. Descriptive features and psychometric statistics for study variables (N=102).

Social Media Use During COVID-19

All participants reported living under government-regulated social distancing or shelter-in-place restrictions, either prior or concurrent to completing the study questionnaire. When asked, 60.8% (n=62) of the 102 participants reported using social media multiple times a day, with Facebook and LinkedIn the most commonly used platforms: 93.1% (n=95) reported accounts on either or both platforms and 91.2% (n=93) reported regular use of either or both. More than one-third (n=37, 36.3%) reported using social media more since the start of the COVID-19 pandemic.

BD Symptoms, Life Satisfaction, and Facebook Use During COVID-19

We performed path analyses to test our hypothesized model of Facebook use (see [Figure 1](#)). Symptoms of depression were assumed to predict loneliness, lower social support, and lower life satisfaction. Use of Facebook was assumed to indirectly predict life satisfaction via social support. Our sample of 102 participants is not large but sufficient to detect medium to large

effect sizes with 7 independent variables (where $\alpha=.05$, $d=0.80$) [[63](#)].

A somewhat different model emerged (see [Figure 2](#)). Goodness of fit for this path model was within optimal parameters for two of three statistics examined ($\chi^2_{17}=15.7$; $P=.55$). That is, the comparative fit index (CFI>.95; CFI=.99) and the root mean square error of approximation (RMSEA<0.055, RMSEA=0.001; 0<RMSEA 90% confidence limits<0.083) were both within ideal limits. The SRMR was within adequate parameters (SRMR<0.055; SRMR=0.06).

Consistent with previous research [[64](#)], symptoms of depression and hypo/mania are positively correlated; only the former, however, significantly predicts loneliness ($\beta=.46$; $P<.001$), social support ($\beta=-.30$; $P=.001$), and life satisfaction ($\beta=-.46$; $P<.001$). Passive Facebook use predicts life satisfaction ($\beta=.15$; $P=.048$), and social support predicts social Facebook use ($\beta=.13$; $P=.048$), not the reverse as originally predicted. Fully 45% of variance in life satisfaction with BD is explained by this model ($R^2=0.45$; $P<.001$; see [Table 2](#)).

Depressive symptoms appear to have a direct and indirect effect on both loneliness and life satisfaction via social support, and depressive symptoms have a small indirect effect on social Facebook use. We assumed that the various aspects of Facebook

use would predict social support and life satisfaction with BD; however, associations appear bidirectional. Facebook use is both a predictor of life satisfaction and predicted by social support.

Figure 2. Direct and indirect predictors of Facebook use and life satisfaction with bipolar disorder during COVID-19. Parameters are expressed as maximum likelihood estimates (standardized solution). Parenthetical numbers indicate significance levels (ie, Critical Ratio [CR] values >|1.96|, $P < .05$; $CR > |2.58|$, $P < .01$). FB: Facebook.

Discussion

Study Hypotheses

As expected, a significant association emerged between social support and Facebook use; however, the direction of this association was opposite than expected, with social support predicting social Facebook use, not the reverse. Additionally, contrary to our hypothesized model, passive Facebook use predicted life satisfaction. These findings suggest bidirectional associations between different facets of SMU and well-being with BD during the COVID-19 pandemic.

As predicted, depressive symptoms were negatively associated with both social support and life satisfaction, and positively associated with loneliness. Though symptoms of hypo/mania and depression were correlated, no direct or indirect associations emerged between hypo/mania and measures of well-being or SMU.

Comparison With Previous Research

These results are consistent with prior research indicating a positive association between symptoms of depression and hypo/mania [65]. Consistent with existing research, our findings confirm that Facebook use is not a singular behavior but multifaceted [66], with differential effects upon social support

and well-being [25]. Our finding that social support predicts active social Facebook use, but not other forms of Facebook use, suggests that those with stronger feelings of in-person social support may be more inclined to use social media to maintain connections online. This positive association may be understood in terms of the outsize role that social media played in providing a substitute for in-person social support during the COVID-19 pandemic; this finding needs to be corroborated with other populations with and without mental illness.

Our result suggesting a positive association between passive Facebook use and life satisfaction is contrary to most prior research with general adult samples [60]. However, this finding is consistent with other research indicating a more complex relationship between SMU types and well-being [44]. The association between passive Facebook use and life satisfaction may indicate that for certain populations, such as older adults or persons with BD, passive behavior is not indicative of social comparison or lack of self-confidence but rather of neutral or positive character traits such as contemplativeness or sense of self. Note that passive and active SMU are defined differently by different scales, thus leading to ambiguity regarding how these facets of SMU are related to well-being. The role of active nonsocial Facebook use on well-being requires further research; no association with measures of well-being emerged for this

study. This may be due to the lower levels of active nonsocial Facebook use in our sample.

SMU has become central to daily life and functioning [67]; over the course of the COVID-19 pandemic, social media became even more deeply embedded in daily life, integral for social networking when opportunities for in-person social interaction were limited or nonexistent. It remains to be seen whether SMU receded once the pandemic began to wane or whether digital relationships continued to take precedence over in-person interactions. There exists a need for both more universal measurement across social media platforms and more comprehensive measurement of all facets of active and passive use.

These questions remain even more pressing for those with severe mental health conditions such as BD. The timing of this study allowed us to explore relationships between SMU and indexes of well-being during a time when in-person social interaction was limited for all, not only for adults with mental health conditions who tend to self-isolate. This provided an opportunity to begin to explore the role of isolation in SMU and well-being. The findings of this study provide preliminary support for the assertion that those with mental health conditions and limited in-person social networks may benefit from certain types of SMU. As indicated by our findings, even passive SMU is suggestive of life satisfaction in this sample of adults with BD.

Limitations and Future Research

This study had several limitations. Both BADAS participants and newly recruited participants were recruited using Facebook. As discussed elsewhere, persons with BD recruited via social media are more symptomatic than psychiatric outpatients [46] and may not be representative of the population of persons with BD. Additionally, persons recruited via social media are likely more regular users than the general population, and participants recruited via Facebook self-reported BD diagnoses (date and BD subtype); this information was not corroborated by chart review or structured clinical interview.

Existing instruments measuring SMU are currently limited [68]. Though developed for use with general adult samples, the psychometric properties of PAUM responses suggest good internal consistency and concurrent validity with adults with

BD. Especially with psychiatric samples, future research is needed examining problematic SMU (eg, addiction) [69]. Though the PAUM appears to be the most widely used measure of SMU, it measures active and passive Facebook use only. Future research is needed examining the effects of other social media platforms on mental health and well-being [35].

The results of this study need to be replicated with larger samples recruited by more traditional methods (eg, psychiatric outpatients). A sample of 102 participants was sufficient to compute a path model with up to seven independent variables; larger samples are required to identify small effect sizes. Longitudinal research in particular is necessary to understand variability in social support and SMU, especially in relation to change in BD symptoms over time.

Conclusions and Summary

The majority of existing research on SMU and well-being has examined young healthy adults. However, social media is today used by most of the world and pervades every population irrespective of age, socioeconomic status, and health. Due to the proliferation of platforms and social media options, different populations may use and relate to social media in distinct ways. To understand the effect of these distinct use patterns and their effects on well-being, it is necessary to study use patterns across diverse populations over time.

The aim of this study was to describe general patterns of SMU by adults with BD during COVID-19 across social media platforms and then to develop and test a hypothesized model specific to Facebook use to identify direct and indirect associations between BD symptoms, social support, loneliness, life satisfaction, and SMU. Contrary to our hypotheses that the patterns of association would conform with the research, indicating active-positive and passive-negative associations with well-being, we found distinct patterns of association.

Our results suggest that adults with BD may use and relate to social media differently than general adult samples. There is a need for further tool development to measure and compare different types of SMU [37] and for longitudinal research examining associations between SMU types and well-being of adults with BD and other forms of severe mental illness (eg, schizophrenia).

Abstract

Background: Pediatric behavioral health needs skyrocketed during the COVID-19 pandemic. Parents and caregivers lacked access to well-established tools to identify risk and protective factors while also experiencing decreased access to treatment options to meet their families' behavioral health needs.

Objective: The aim of this study is to investigate the associations of known pediatric behavioral health risk factors and parents' reports of workplace productivity.

Methods: A clinical research team at Brightline—a virtual, pediatric behavioral health solution—drew on standardized instruments to create a survey designed to understand pediatric behavioral health conditions, child stress, and family resilience and connection during the COVID-19 pandemic. Multivariable linear regression was used to characterize the relationship between these variables and parents' reports of workplace productivity.

Results: Participants (N=361) completed the survey between October 2020 and November 2021. In the multivariable model, higher pediatric stress and time spent managing children's behavioral health needs were associated with greater productivity loss among working parents, whereas higher family connection was associated with lower productivity loss. COVID-19 diagnoses among parents and dependents, financial impact of COVID-19 on households, and family resilience were not associated with parents' workplace productivity.

Conclusions: This survey captured child stress, family connection, and productivity as reported by parents and caregivers during the COVID-19 pandemic. Exploratory studies are the first step in understanding the relationship between these variables. The results from this study can empower parents by providing insights to help manage their child's behavioral health concerns and identify pediatric behavioral health services to aid working parents who are caregivers.

KEYWORDS

adolescent; child, family health; mental health; behavioral health; stress; protective factors; productivity; COVID-19

Introduction

In March 2020, the COVID-19 pandemic was declared in the United States, which set off a flurry of lockdowns, school

closures, and layoffs. The pandemic amplified the already increasing prevalence of mental health conditions for both adults and children, and exacerbated barriers to receiving behavioral health services [1-4]. While the risks for mental health disorders

associated with the pandemic have broadly risen, they have disproportionately affected children and adolescents who already experience even greater barriers to care than adults [5].

As a result, rates of depression and anxiety among children have doubled since the pandemic began. Currently, 1 in 4 children experience increased depression symptoms, and 1 in 5 experience increased anxiety symptoms [6]. Adolescent girls, in particular, have visited emergency departments during the pandemic for eating disorders and tic behaviors at alarming rates [7,8]. Not surprisingly, the decline in children's mental health and well-being during the pandemic is now identified as a major cause of parents' increased stress, job turnover, decreased productivity, and lost income [9].

The prolonged and far-reaching impact of pandemics such as COVID-19 on well-being requires not only increased surveillance of pediatric mental health disorders but also identification of child- and household-level risk and protective factors that may affect pediatric health outcomes [10,11]. For instance, studies have identified risk factors for disaster-related mental health problems among children and adolescents [12-14]. Such factors include both nonmodifiable and modifiable factors, including gender (female), age (younger), ethnic minority, preexisting disabilities, predisaster emotional status, previous trauma history, postdisaster levels of psychological distress, and family resilience [12]. Knowing risk and protective factors can help to predict who may be vulnerable to future disaster-related mental health conditions.

However, because childhood is a time of change and development, it can be challenging for parents to gauge how they and their children are doing with respect to these known risk factors [15]. As such, parents and caregivers often rely on input from schools, day cares, and other caregivers to help them notice potentially problematic shifts and changes in their child's behavior. During calamities such as the COVID-19 pandemic, parents may be cut off from these community resources and support. The lack of access to these support systems and mental health services during the recent pandemic-related closures led to decreased mental health screenings, diminished ability to identify learning disabilities, and less child-protective and mental health referrals [16].

Delays in addressing modifiable risk factors for pediatric behavioral health problems over the past 2 years of COVID-19-related shutdowns have resulted in higher rates of emergency department visits attributed to mental health concerns among children and adolescents [17]. The emergency medical services system, though, is not the optimal point of access for effective treatment due to (1) a shortage of on-site mental health professionals to accurately diagnose or treat conditions, (2) long waits to receive care, and (3) patients failing to continue treatment postdischarge [18]. What follows is a cycle of crisis care, which is ultimately costly, ineffective, and more time intensive than early prevention and intervention. This cycle of crisis care for youth in distress arguably leads to increased parental stress as their children remain undiagnosed or ineffectively treated.

For employed parents, balancing the demands of raising children with behavioral health needs against work commitments can

lead to higher levels of stress and burnout, making it difficult to be a present parent and productive employee—which were amplified when our country overwhelmingly pivoted to work from home [19,20]. During lockdowns and school closures, parents and caregivers lacked access to easy-to-use tools to help identify their children's risk for mental and behavioral health conditions as well as resources to help them manage their children's behavioral health outside of the emergency department. Our clinical research team at Brightline—a virtual behavioral health solution designed for children (aged 18 months up to 18 years) and their families—recognized this gap in support and saw an immediate need to help parents and caregivers who were struggling to understand and meet the mental and behavioral needs of their children.

As a response, we developed a web-based 30-item survey to assess 4 key areas linked to increased risk of behavioral health conditions among children and adolescents: preexisting behavioral health conditions, psychological stress, family resilience, and family connection. As a mental and behavioral digital health company that provides services to children and their families, we were interested in understanding the broad impact that child behavioral health conditions have on other aspects of a parent's life. Therefore, we added questions to ascertain how parents perceived their child's behavioral health impacted their productivity at work. Given the context of the global pandemic, we also included standardized questions about direct household impacts of COVID-19 as they relate to finances and COVID-19 diagnoses of household members.

This exploratory study of survey responses investigated the associations of pediatric behavioral health risk factors and parents' workplace productivity. While the survey was developed during the COVID-19 pandemic, we were not researching the direct impacts of COVID-19 on psychological stress, children's behavioral health conditions, or time spent managing behavioral health. Instead, our aim in creating the survey was to provide parents with feedback on their child's mental and behavioral health based on their survey responses, and to guide them to relevant resources.

Methods

Recruitment

Brightline is a company that offers a technology-enabled behavioral health solution designed for children (aged 18 months up to 18 years) and their families [21]. Brightline delivers self-guided content, coaching services, and virtual care through multidisciplinary care teams, family-focused support, and evidence-based care delivery geared toward helping children and their families across developmental stages. Commonly reported behavioral health needs by Brightline users include anxiety, depression, and disruptive behavior disorders.

The web-based survey was available on a landing page on the Brightline company website between October 2020 and November 2021 and provided an overview of the survey to participants ([Multimedia Appendix 1](#)). A link to the survey was shared on Brightline's social media platforms, such as LinkedIn and Twitter, throughout the survey window. Other than being

shared on social media and through the other avenues, participants were not actively recruited to participate in the survey. Moreover, Brightline membership was not required to access and complete the survey.

Participants

Anyone who visited the Brightline website during the study period could complete the survey. Participants were not compensated for completing the survey. There were no other eligibility criteria or exclusion criteria for participation. While this allowed our survey to be accessible to any interested participant, it also meant that a nonparent could complete the survey.

Procedures

Participants voluntarily completed the anonymous, web-based survey. The survey took approximately 10 minutes to complete. Once participants submitted the survey, they received a summary of each of the 4 survey components ([Multimedia Appendix 2](#)). The participant could then choose to follow a link to resources and a guide to help facilitate a conversation with a pediatric behavioral health care provider ([Multimedia Appendices 3 and 4](#)).

Measures

The survey was designed from 3 standardized clinical instruments, focusing on psychological stress, family resilience, family connection, and preexisting behavioral health conditions. The survey was augmented by a set of questions about parental productivity and time spent managing children's behavioral health, as well as questions related to the direct impacts of the COVID-19 pandemic and participant demographics ([Multimedia Appendix 5](#)). These instruments were selected because they aligned with previous research that identified both nonmodifiable and modifiable risk factors for children's postdisaster mental health outcomes and well-being, such as mass disasters (eg, 9/11 attacks), natural disasters (eg, hurricanes), and previous epidemics [11-14]. Further, these instruments were selected because they do not evaluate for any clinical domains that would require Brightline to intervene in the case of high acuity needs.

Preexisting Behavioral Health Conditions

Preexisting behavioral health conditions were assessed with children with special health care needs (CSHCN) screener [19]. The CSHCN screener is a set of 5 yes or no question sequences used to identify children with special health care needs ([Multimedia Appendix 5](#)). The purpose of including the CSHCN screener was not to evaluate whether COVID-19 was a catalyst for behavioral health conditions in the participants' children but rather to assess for already existing behavioral health conditions.

Psychological Stress

Pediatric stress was measured during the pandemic, specifically at the time of the survey, using the PROMIS (Patient-Reported Outcome Measurement Information System) Pediatric Parent Proxy Psychological Stress Experiences Measure ([Multimedia Appendix 5](#)) [22]. PROMIS has been used in research to study children's stress levels associated with cancer treatment, sickle

cell disease, as well as other chronic illnesses [23-27]. Participants rated the frequency of their child's stress experience on a 5-point Likert scale. Scores were grouped into 4 categories based on general interpretation guidelines: scores less than 50 indicate pediatric stress was within normal limits; scores between 50 and 55 indicate mild pediatric stress; scores between 55 and 65 indicate moderate pediatric stress; and scores greater than 65 indicate severe pediatric stress [22].

Family Resilience and Connection Index

The family resilience and connection index (FRCI) was used to measure family resilience and connection, a 6-item index that comprises 4 family resilience items and 2 additional items that measure parent-child connection and parent coping ([Multimedia Appendix 5](#)) [28]. The FRCI has been used in research to evaluate the connection between family resilience and parenting stress with children's mental health and attention deficit hyperactivity disorder as well as their ability to flourish and engage at school [29-31]. The 4-item family resilience index (FRI) asked parents about their approach to problem-solving and hopefulness. Additionally, the 2-item family connection index (FCI) asked parents about their connectedness with children and perception of how well they are managing the day-to-day demands of child raising. One point was assigned for each time a participant answered "all of the time" to 1 of the 4 FRI items. Moreover, one point was assigned for each time a parent responded "very well" to 1 of the 2 FCI items. Scores were grouped into three categories based on general interpretation guidelines: scores between 0 and 1 indicate low family resilience or connection; scores between 2 and 3 indicate moderate family resilience or connection; and scores between 4 and 6 indicate strong family resilience or connection.

Productivity

Two additional questions written by the research team were added about time spent by parents managing their children's behavioral health concerns, and about its impact on productivity ([Multimedia Appendix 5](#)).

COVID-19 Impact

To determine the potentially adverse effects COVID-19 may have had on participants, a set of 3 yes or no questions from the Coronavirus Aid, Relief, and Economic Security Act was included in the survey ([Multimedia Appendix 5](#)) [32]. These questions asked whether the respondent experienced a COVID-19 adverse event, which includes being diagnosed with COVID-19, a spouse or dependent being diagnosed, or the presence of an adverse financial consequence from COVID-19. The questions about the pandemic were included to ascertain COVID-19 exposure experiences as a facet of participant demographics.

Background and Demographics

The following demographics information was collected: marital status of the parent answering the survey, household income, race or ethnicity, highest educational level achieved, gender, and state of residence ([Multimedia Appendix 5](#)).

Analyses

This retrospective, cross-sectional study analyzed survey responses collected from participants (N=361) between October 2020 and November 2021. All statistical analyses were performed in R version 4.1.2 (R Foundation for Statistical Computing). Prior to analysis, all predictor variables underwent min-max normalization. Multivariable linear regression was used to characterize the associations among productivity interruptions, family stress, family connection, family resilience, and COVID-19–related exposure experiences. This linear regression was adjusted for household income and parental education level. Goodness of fit was performed for linear regressions.

Ethics Approval

This study protocol was approved by the Western Institutional Review Board and the Copernicus Group Institutional Review Board.

Results

Participants

Participant demographics are presented in [Table 1](#). The participants primarily had a White racial background, were married women who were highly educated, and reported high incomes.

Table 1. Participant demographics (N=361).

Variable	Value, n (%)
Gender	
Female	257 (71.1)
Male	62 (17.2)
Nonbinary	10 (2.8)

COVID-19 Exposure-Related Experiences

The direct impact of COVID-19 on participants are presented in [Table 2](#). Over 90% (341/361) of the participants reported neither they nor their spouse had been diagnosed with

COVID-19. The responses to the question “I have experienced adverse financial consequences due to COVID-19” are also summarized in [Table 2](#). A majority of participants (233/361, 65%) said they had not experienced financial consequences as a result of COVID-19.

Table 2. COVID-19 exposure-related experiences (N=361).

Question	“Yes,” n (%)	“No,” n (%)
I was diagnosed with COVID-19.	20 (6)	341 (94)
My spouse or my dependent was diagnosed with COVID-19.	26 (7)	335 (93)
I have experienced adverse financial consequences because (1) I or a member of my household was quarantined, laid off, or had work hours reduced due to COVID-19; (2) I or a member of my household was unable to work as a result of a lack of childcare due to COVID-19; (3) a business owned or operated by me or a member of my household closed or reduced hours due to COVID-19; or (4) I or a member of my household had a reduction in pay (or self-employment income) due to COVID-19 or had a job offer rescinded or start date for a job delayed due to COVID-19.	128 (35)	233 (65)

Survey Results: CSHCN Screener Results

The preexisting behavioral health needs of the participants’ children from the CSHCN screener, which is commonly used to evaluate whether a child already has behavioral health needs prior to evaluation, are presented in [Table 3](#). Approximately

28% (102/361) were described as having an emotional, developmental, or behavioral problem for which he or she needs or gets treatment or counseling, and 21% (76/361) reported their child needing more medical care, mental health, or educational services than is usual for most children.

Table 3. CSHCN^a screener results.

Question	“Yes,” n (%)	“No,” n (%)
Does your child currently need or use medicine prescribed by a doctor (other than vitamins)?	51 (14)	309 (86)
Does your child need or use more medical care, mental health, or educational services than is usual for most children of the same age?	76 (21)	285 (79)
Is your child limited or prevented in any way in his or her ability to do the things most children of the same age can do?	57 (16)	303 (84)
Does your child need or get special therapy, such as physical, occupational, or speech therapy?	56 (16)	304 (84)
Does your child have any kind of emotional, developmental, or behavioral problem for which he or she needs or gets treatment or counseling?	102 (28)	258 (72)

^aCSHCN: children with special health care needs.

The responses for the item “Since Covid began, how much time (on average) are you spending managing your child or children’s behavioral health concerns (including their stress, anxiety, disruptive behaviors)?” are summarized in [Table 4](#). Nearly 50% (155/361) of the participants reported spending between 2 and 4 hours per week managing their children’s behavioral health. The responses to the question “How much is your child’s behavioral health and well-being affecting your productivity and ability to work if you are currently employed?” are also summarized in [Table 4](#). The majority of the participants (307/361, 85%) reported some impact on their productivity and ability to work.

The responses for the PROMIS measure are summarized in [Table 5](#). The mean summed PROMIS raw score was 23.05. The scaled score is approximately 64.4, which indicates moderate pediatric stress reported at the time of the survey among the participants in our study.

The responses for the FRCI measures are summarized in [Table 6](#). The mean summed FRI score was 1.03, indicating low family resilience among participants in our study. The mean summed FCI score was 2.3, indicating moderate family connection among the participants in our study.

Table 4. The impact of child's behavioral health on parents' time and productivity.

Table 6. FRCI^a results.

Variable	Mean (SD)
Family resilience index score	1.03 (0.52)
When your family faces problems, how often are you likely to talk together about what to do?	0.56 (0.36)
When your family faces problems, how often are you likely to know we have strengths to draw on?	0.57 (0.35)
When your family faces problems, how often are you likely to work together to solve our problems?	0.60 (0.29)
When your family faces problems, how often are you likely to stay hopeful even in difficult times?	0.56 (0.31)
Family connection index score	2.30 (1.00)
How well can or do you think you are managing the day-to-day demands of raising children?	0.48 (0.28)
How well can or do you share ideas and talk about things that really matter with your child?	0.55 (0.32)

^aFCRI: family resilience and connection index.

Factors Associated With Productivity Loss

In the multivariable model, there was a strong association between productivity loss and the time spent managing children's behavioral health needs ($\beta=.365$; $P<.001$) as well as Stress Index scores ($\beta=.213$; $P<.001$) (Table 7). There was a

weaker association between productivity loss and FCI scores ($\beta=-.125$; $P=.053$) (Table 7). COVID-19 diagnoses among parents and dependents, financial impact of COVID-19 on households, and family resilience were not associated with parents' workplace productivity (Table 7).

Table 7. Multivariable linear regression of survey items associated with productivity loss ($F^9_{351}=14.97$; $P<.001$; adjusted $R^2=0.2588$).

Independent variables	β	SE β	P value
Time spent managing child behavioral health concerns	.365	.043	<.001
PROMIS ^a pediatric physical stress raw summed score	.213	.075	<.001
Family connection score	-.125	.064	.053
Family resilience score	-.019	.067	.78
COVID-19 diagnosis (self)	-.099	.068	.14
COVID-19 diagnosis (partner or dependent)	.036	.060	.54

Discussion

Principal Findings

Our findings show that parents spend a considerable amount of time managing their children's behavioral health needs. Although we did not find that having a COVID-19 diagnosis among a household member or having a significant financial impact on the household from COVID-19 impacted productivity, this may have been due to the fact that our participants had low rates of COVID-19 infection and were relatively high-income earners. An important extension of this work would be to assess the association of COVID-19 diagnoses and financial consequences of the pandemic on workplace productivity among lower-income earners and those with significant COVID-19-associated illness.

In addition, we found that high pediatric stress and more time spent managing children's behavioral health problems were associated with increased productivity losses for parents regardless of COVID-19-related experiences. While COVID-19 variables were used as predictors in our multivariable regression model, we discovered that COVID-19 exposure-related experiences did not have a significant effect on our outcome. Despite the lack of representation of families affected by COVID-19, we felt it was important to incorporate this variable in our model.

Our findings also showed that enhanced parent-child connection is inversely associated with the parents' productivity loss, even amid adversity [33-35]. This finding is significant because there are known behavioral health interventions that can be mobilized to enhance parent-child connection where parents are trained to support the management of children's behavioral health problems. Our results further support those of previous studies, which show that pediatric stress and family connection are good predictors of pediatric behavioral health outcomes [36-38].

Limitations and Future Studies

As with all survey research, there are limits inherent to this research method. As the survey was completed anonymously and was internet-based, we were unable to control for the chance that a nonparent completed the survey. Moreover, the tool

produced some basic pediatric behavioral health insights that were tailored to the users' answers after completing the survey; therefore, the participants may have been encouraged to take the survey more than once in order to receive different answers. This means that the same participant could have taken the survey multiple times without us knowing. However, allowing for anonymity likely increased the response rate and participation.

In this exploratory study, the majority of respondents represented a well-educated, high-income, female population. Further, participants were only recruited using digital channels (eg, search engines, email, and social media), all of which can potentially limit the generalizability to other populations. The participants may have included parents searching on the web for information related to child behavioral health; therefore, their responses related to perceived child stress and family resilience might not reflect the general parent population. Future studies will share the survey through alternate venues to recruit more diverse participants.

In designing the survey, we did not include questions on the number, age, and gender of children, potentially limiting the ability to draw insights on the differences between children and adolescents across behavioral health needs and impact on stress, family resilience, and family connection. However, research has shown that having a higher number of children is positively associated with a higher level of psychological distress in families [39]. Additionally, the survey did not include questions from the Sickness Index Profile, which evaluates the effect of disease on physical and emotional functioning [40]. There is opportunity to further explore the impact of COVID-19 and other illnesses or stressors on children's behavioral health needs.

Building on our preliminary findings, in future studies, we aim to learn more about the time spent and its impacts on the larger family unit. In this iteration of the survey, we asked parents about their time spent managing their child's behavioral health concerns. What we received is an estimated snapshot. We are interested in developing questions and methods to ascertain changes in time spent to learn whether this is associated with differing productivity and stress levels. Further, this survey includes responses from parents and caregivers on their individual time spent managing their children's behavioral

health (independent of their partner). Collecting data on time spend on the household level would give us greater insight into the impact a child's mental and behavioral health has on the family and measures of productivity more broadly. Lastly, when completing the survey, the participants received recommendations and tools to help support their children's mental and behavioral health needs. In future studies, we aim to collect data on the use of these resources.

Conclusion

Our preliminary findings confirm that measures of increased psychological stress in children and lower family connection are associated with productivity loss regardless of COVID-19 diagnosis, financial consequences of COVID-19, education

level, and income level. These results suggest a continued need for research on family-focused behavioral health benefits that address pediatric stress levels and that offer support to manage children's behavioral health problems and improve parent-child connections. Surveys that integrate standardized and validated measures of known risk and protective factors for children's postdisaster well-being and outcomes can be useful mental and behavioral health points of entry for parents. The feedback that participants receive after completing a survey, for example, can make parents or caregivers more aware of these factors and help them to facilitate conversations with health care professionals about their concerns. This is especially important during crises such as COVID-19, when families have limited access to face-to-face community indicators of well-being.

Acknowledgments

We are grateful to Kendall Leon, Christina Rowell, and Iman Rahim for their contributions in editing this manuscript. DG and JB designed the study and were involved in data collection, analysis, interpretation, and reporting. TL was involved in analysis, interpretation, and reporting. DB was involved in design, interpretation, and reporting. IR, KL, and CR were involved in interpretation and reporting. All authors provided input for the final draft of the manuscript.

Abstract

Background: Interventions to support physical activity participation among individuals with spinal cord injury (SCI) are required given this population's low levels of physical activity and extensive barriers to quality physical activity experiences.

Objective: This study aimed to develop a mobile health intervention, called *SCI Step Together*, to improve the quantity and quality of physical activity among individuals with SCI who walk.

Methods: Our overarching methodological framework was the Person-Based approach. This included the following 4 steps: conduct primary and secondary research (step 1); design intervention objectives and features (step 2a); conduct behavioral analysis and theory (step 2b); create a logic model (step 3); and complete the SCI Step Together program content and integrated knowledge translation (IKT; step 4), which occurred throughout development. The partnership approach was informed by the SCI IKT Guiding Principles. Three end users pilot-tested the app and participated in the interviews.

Results: Step 1 identified issues to be addressed when designing intervention objectives and features (step 2a) and features were mapped onto the Behavior Change Wheel (step 2b) to determine the behavior change techniques (eg, action planning) to be included in the app. The logic model linked the mechanisms of action to self-determination theory (steps 2/3). Interviews with end users generated recommendations for the technology (eg, comparing physical activity levels with guidelines), trial (eg, emailing participants' worksheets), and intervention content (eg, removing *graded tasks*; step 4).

Conclusions: Using the SCI IKT Guiding Principles to guide partner engagement and involvement ensured that design partners had shared decision-making power in intervention development. Equal decision-making power maximizes the meaningfulness of the app for end users. Future research will include testing the acceptability, feasibility, and engagement of the program. Partners will be involved throughout the research process.

Introduction

Approximately 3 million individuals live with a spinal cord injury (SCI) worldwide, with 180,000 new cases of SCI reported each year [1]. Although most individuals who sustain a SCI use a wheelchair for mobility, a small but growing number of individuals retain the ability to walk after their injury [2]. More than half of individuals living with a SCI have an incomplete injury, meaning that motor function and ambulation recovery are possible [3]. A recent study showed that 207 out of 460 individuals with SCI sustained incomplete injuries, of which 47% ambulated some or all the time [4]. However, there is little epidemiological data on the number of individuals who ambulate for their primary mode of mobility, as there is often no follow-up after the acute injury. Individuals with SCI who walk still live with SCI-related impairments that have profound impacts on their physical, psychological, and social health. For instance, individuals with SCI who ambulate have reduced bowel function [5] and experience pain and fatigue during walking due to greater metabolic energy demands [6].

Physical activity is one behavior that can help individuals manage and overcome challenges associated with SCI-related implications. A recent review identified the following benefits of physical activity participation for individuals with SCI who walk: increased cardiovascular fitness, reduced pain and fatigue, improved cognition, and decreased depressive symptoms [7]. Although increasing the amount of physical activity is important, quality physical activity experiences are another valuable aspect of participation. Quality physical activity reflects the subjective perceptions and experiences of individuals [8]. Positive quality physical activity experiences can lead to benefits such as improved well-being, health [9], and sustained participation [10]. Although individuals with SCI who walk participate in less physical activity than those with SCI who use wheelchairs [11], there have been few attempts to help improve the quantity or quality of leisure-time physical activity for this group. Thus, interventions are required to facilitate quality physical activity behavior change among individuals with SCI who walk.

According to a meta-analysis, physical activity behavioral interventions for individuals with physical disabilities have a small to medium effect size on physical activity behavior (mean $g=0.35$, SE 0.07) [12]. Interestingly, most physical activity behavioral interventions for individuals with physical disabilities have been delivered in person or over the telephone, with few using digital platforms (eg, email, texting, and video) [12]. Although apps have been used to deliver other types of health interventions for individuals with SCI (eg, transitional care) [13], to the best of our knowledge, no physical activity interventions have been provided to individuals with SCI through a mobile health (mHealth) format.

mHealth interventions offer a convenient way to deliver physical activity support to individuals with SCI, especially because of the sparse and geographically distant number of individuals with SCI who walk, which makes in-person interventions nearly impossible. In addition, delivering an intervention through an app can alleviate transportation and built environment barriers to access, which are substantial for the SCI population [14].

mHealth interventions are cost-effective, available, accessible, and give users the option of flexible and convenient access to individualized programming (eg, [15]). Among able-bodied adults, a meta-analysis of smartphone-based physical activity interventions demonstrated a significant overall moderate effect size ($g=0.54$ for increased physical activity) [16]. Together, these data indicate the potential value of using mHealth formats (ie, smartphone apps) to deliver physical activity interventions to individuals with SCI who walk.

However, very few physical activity smartphone apps are theory based [17]. Although most existing physical activity apps use the behavior change techniques (BCTs) of goal setting, self-monitoring, and feedback, other valuable theory-based strategies are missing, such as social support, self-talk, and coping planning [18]. Indeed, the more theory-based strategies an app contains, the greater the use rates of physical activity apps [19] and the more effective they are at increasing physical activity in general [20]. In physical activity interventions for people with physical disabilities, the largest effects occurred for interventions guided by the behavior change theory [12]. Accordingly, the development of mHealth interventions to increase physical activity behavior should be explicitly informed by the behavior change theory.

Furthermore, engaging with partners throughout the development process (ie, integrated knowledge translation [IKT]) [21] is important for intervention design. For example, a physical activity counseling intervention for individuals with SCI was developed using an IKT approach and produced the largest effects reported for a behavioral intervention in this population (self-reported physical activity, Cohen $d=1.04$; peak oxygen uptake [$\dot{V}O_2$ peak], Cohen $d=0.54$) [22]. The authors attribute the success largely to the co-development process of intervention development [23]. Indeed, the authors of a recent landmark paper argued that physical activity policies, recommendations, and resources must use an IKT approach to drive greater quantity and quality of physical activity participation experiences for persons with disabilities [24].

Similarly, the Person-Based approach for intervention development provides the groundwork for developing interventions, which account for the context, perspectives, and experiences of end users through mixed methods research [25]. This approach has been used to guide the development of many digital health interventions as a primary goal of this method is to increase the feasibility, acceptability, and engagement of interventions [26]. Notably, the Person-Based approach is used complementarily with theory- and evidence-based approaches [15,26]. However, a limitation is that it does not provide guidance on when and how to include partners in the intervention development process. Greater clarification on how to implement partner engagement using IKT in combination with Person-, theory-, and evidence-based approaches is needed.

Recently, 8 IKT guiding principles for SCI research (refer to Gainforth et al [27] for more details) were developed to address the gap in guidance on partner engagement. These principles help researchers to engage meaningfully in partnered research that is relevant and usable [27]. Using these principles to guide IKT has the potential to reduce experiences of tokenism,

increase the coproduction of knowledge, and create meaningful SCI research partnerships [27].

The purpose of this paper is to describe the 4-step intervention planning and development processes of an mHealth intervention to increase the quantity and quality of physical activity participation among individuals with SCI who walk. This paper provides an illustration of how the Person-Based approach can be used alongside IKT, theory, and evidence to plan and develop an mHealth intervention. Of note, this paper reports on the processes of steps 2 to 4, whereas step 1 is summarized because these details are reported elsewhere [7,28,29].

Methods

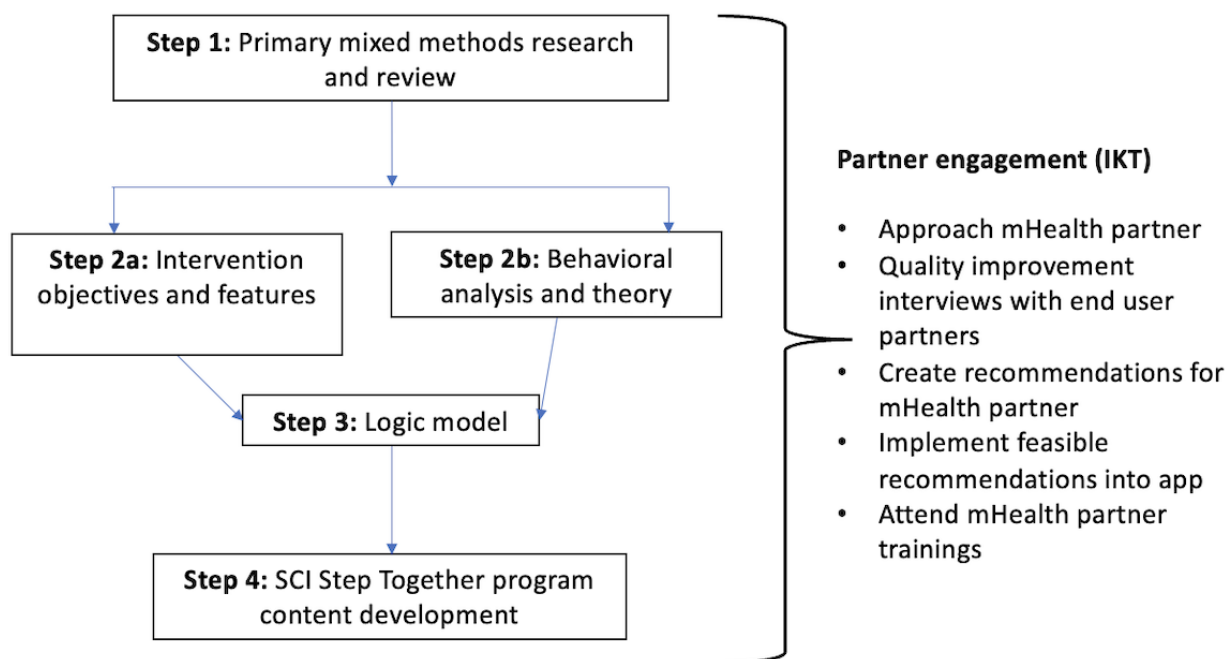

Context

Our intervention, SCI Step Together, was developed as a program within an existing app called *Stronger Together*. The Stronger Together app was created through partnership with Curatio Networks Inc and the University of British Columbia to create communities of peer support for self-management of various chronic conditions (eg, patients who have undergone knee replacement surgery, adults with physical disabilities, and COVID-19 long-haulers). The platform takes a differentiated approach to behavioral change by embedding social connections

into health literacy and management interventions. The platform is privacy and regulatory compliant to meet the requirements of life sciences policy and protocols. The Stronger Together platform has already undergone usability and acceptability testing privately through Curatio Networks Inc. Overall, the app provides users access to educational modules, health tracking, peer support, and individual behavioral support from a live community coach.

In the following sections, we describe the methods for planning, adapting, and developing the SCI Step Together intervention. Adapted from the study by Band et al [15], Figure 1 shows each step in the intervention planning and development process, including partner engagement activities to demonstrate the IKT approach. Importantly, evidence from primary studies and systematic reviews was incorporated throughout the intervention development process, with the intervention development steps being updated and carried out iteratively. This included four steps: (1) conduct primary mixed methods research and review, (2a) design intervention objectives and features, (2b) conduct behavioral analysis and theory, (3) create a logic model, and (4) complete the SCI Step Together program content development. In addition, partner engagement occurred throughout the intervention planning and development process and will be described in step 4.

Figure 1. Steps in intervention planning and development process for the SCI Step Together program. Adapted from Band et al [15]. IKT: integrated knowledge translation; mHealth: mobile health; SCI: spinal cord injury.

Step 1: Primary Mixed Methods Research and Review

Step 1 involved conducting three studies: a scoping review, a quantitative cross-sectional study, and a qualitative study. The purpose of step 1 was to gain an understanding of the background and context of physical activity participation for people living with SCI who walk. The goal was to identify factors to target in the intervention along with recognizing the

context of lived experience for end users. The methods for step 1 are not novel and are only described briefly. Importantly, IKT was incorporated into all 3 studies and is described in detail elsewhere (along with the methods and results) [7,28,29].

Scoping Review

The purpose of the scoping review was to understand the amounts, types, correlates, and outcomes of physical activity

participation for individuals with SCI who ambulate as their primary mode of mobility. IKT was used by consulting individuals with SCI who walk and a provincial SCI organization to determine research questions and search strategies. Using a published method for scoping reviews [30], a systematic search was conducted among academic (MEDLINE, PsycINFO, Embase, CINAHL, Web of Science, and Sport Discus) and gray literature (Open Access Theses and Dissertations and ProQuest Dissertations and Theses) databases, yielding 3257 articles. After a 2-phase screening process by 2 independent coders, 17 articles were selected for inclusion, and the data were charted and summarized, and correlates were coded using the Capability, Opportunity, Motivation-Behavior (COM-B) model [31]. The COM-B model identifies the source of the behavior, which is the first step in the Behavior Change Wheel (BCW; see below in Step 2b for more detail) [31], a theoretically aligned approach to developing interventions.

Primary Mixed Methods Research

Two studies were conducted with a sample of adults with SCI who self-reported that they walked for daily mobility more often than not (ethics board approval time: 52 days). IKT was used by partnering with individuals with SCI, a behavior change theory expert, and a provincial SCI organization to determine measure selection and adaptation, recruitment, and data analysis. The first study (n=43) used a cross-sectional design and required 1.5 hours of time from participants. This study used the Theoretical Domains Framework [32] to identify behavioral change factors related to physical activity participation among ambulators with SCI. The Theoretical Domains Framework is embedded in the COM-B model. The Theoretical Domains Framework domains are used to assess capability-, opportunity-, and motivation-related barriers and facilitators to engage in a behavior [33]. A modified version of the validated Determinants of Physical Activity Questionnaire [34] was used to assess behavioral change factors. We also measured the duration, type, and intensity of physical activity performed during the previous week using the Physical Activity Recall Assessment for individuals with SCI [35,36]. This measure has demonstrated adequate test-retest reliability and evidence of criterion and construct validity [35-37].

The second study used a qualitative approach to explore the conditions and elements involved in quality physical activity experiences. Semistructured interviews were conducted with 22 participants in the cross-sectional study. The interviews lasted for approximately 60 minutes and were transcribed verbatim. Using a philosophically pragmatic approach [38], the data were reflexively thematically analyzed [39] with the goal of informing the SCI Step Together intervention. The data were first inductively coded by 2 independent coders, with feedback from critical friends. Then, the data were deductively coded using the Quality Passport Participation Framework [40] to identify conditions and the Quality Participation Framework [41] to identify elements of quality participation.

Step 2a: Intervention Objectives and Features

An essential component of the Person-Based Approach [25], the purpose of this step was to develop key intervention

objectives and design needs, along with associated intervention features that address these objectives.

First, we stated the objectives of the intervention with respect to behaviors and outcomes and described the relevant aspects of users and their context, as informed by step 1 [25]. In addition, we identified the key behavioral issues, needs, and challenges that the intervention must address. Second, we formulated the intervention design objectives according to the evidence generated in step 1. Third, we generated the design features intended to achieve each objective based on the intervention planning, evidence from step 1, behavioral analysis from step 2b, and logic model from step 3. These objectives and features have been refined throughout the intervention planning and development process based on partner engagement and evidence (eg, inclusion of theory).

Step 2b: Behavioral Analysis and Theory

The purpose of step 2b was to use behavior change theory to identify BCTs to be included in the intervention content as well as to choose a specific theory to inform intervention content.

Behavioral Analysis

The behavioral analysis was conducted using BCW [31], which is a theoretical framework that guides researchers to identify the source of behavior (ie, capabilities, opportunities, and motivations) and then links these to the selection of intervention functions, policy categories, and BCTs. The results from the quantitative study examining the Theoretical Domains Framework behavior change factors (step 1) were used to inform the behavioral analysis. First, the Theoretical Domains Framework domains (predictors of, and barriers to, physical activity) were linked to intervention functions. The most common and feasible intervention functions were identified, and these were linked to common and feasible policy categories. The intervention functions and Theoretical Domains Framework domains were then linked to BCTs, noting the most frequently used BCTs [42]. Finally, 2 reviews of the effectiveness of BCTs in physical activity and self-management interventions among individuals with SCI and physical disabilities generally were consulted [12,43]. These reviews allowed us to decide which BCTs should be included or excluded based on their effectiveness in similar interventions.

Theory

In addition to conducting a behavioral analysis and identifying BCTs for inclusion in the intervention, we selected a theory to inform the intervention. Using theory helps to outline the critical assumptions that underlie the intervention protocol, the primary constructs that are effective, and the causal processes tested by mediators [44]. The first author (SL) reviewed theories on changes in physical activity behavior [45]. In addition, discussions occurred among the first and senior authors (experts in exercise psychology) regarding theory fit and choice. We considered the evidence identified in primary mixed methods studies (step 1; ie, Theoretical Domains Framework domains to target and context from qualitative interviews) in addition to the intervention objectives identified in step 2a.

Step 3: Logic Model

The purpose of developing the logic model was to clarify the hypothesized causal relationships and mechanisms of action that mediate intervention outcomes [46]. The logic model was created in accordance with the Medical Research Council evaluation guidance [46] and process evaluation methods [47]. The logic model included the intervention inputs, processes or actions, outputs, and outcomes. Having clear intervention objectives and features enabled us to understand the problems that needed to be addressed and to select appropriate intervention components. The BCTs identified in the behavioral analysis in step 2 were included as intervention inputs in the logic model, whereas the theory selected in step 2 informed all aspects of the logic model's causal assumptions. The logic model underwent several iterations as the development process continued to include feedback from all partners involved.

Step 4: SCI Step Together Program Content Development and IKT

The partners involved in the development of the SCI Step Together program included 2 SCI physical activity behavior change scientists (SL and KMG); an external project manager at Curatio, Inc, the company that hosts the technology platform (LC); the CEO of Curatio, Inc (LBG); and potential end users of the program (ie, ambulators with SCI; JS, MM, and CJ). The partners included both women (n=5) and men (n=2) and were both over (n=2) and under (n=5) the age of 50 years.

The SCI Step Together program is hosted on Curatio's Stronger Together platform, which was developed and tested among other users with physical disabilities. Six months after the launch of Stronger Together (January 2021), the senior author (KMG) approached Curatio, Inc (LBG), and the 2 partners agreed to create a community for ambulators with SCI using an evidence- and theory-based approach.

One of the original (January 2021) Stronger Together communities is for adults with physical disabilities who want to increase their physical activity. The first author (SL) reviewed the content modules for this community. SL then revised the modules for SCI Step Together, based on the information collected from steps 1 to 3 and content from other physical activity interventions for individuals with SCI, including the ProActive SCI Toolkit [23], Active Homes [48], the Blueprint for Quality Participation [49], and the SCI Physical Activity Guidelines [50].

The first author (SL) and senior author (KMG) wanted to engage end users to receive feedback on the preliminary intervention content and delivery. Accordingly, the first author (SL) developed an interview guide to conduct partnered quality improvement of the program content. Three potential end users (ambulators with SCI) were interviewed, all with different levels of physical activity participation. The purpose of the interviews

was to produce recommendations for the format and general content of this intervention. Before the interviews, the end users were asked to review the original Stronger Together program (physical activity for people with physical disabilities) to understand how the app works and its various components. In addition, end users were sent lay summaries of the (step 1) studies informing intervention development. Finally, we sent the end users the 8 IKT guiding principles for conducting quality and ethical SCI research (Multimedia Appendix 1) [27]. These principles are intended to be used by all partners early and throughout the research process [27]. The IKT guiding principles were discussed with the end users at the beginning of the interview to ensure that all partners were aligned with how the intervention development process would occur. The interviewer (SL) took notes throughout the interview to record recommendations.

Following the interviews, the first author (SL) met the project manager from Curatio. During the meeting, they discussed the project and timelines, and they reviewed the IKT guiding principles. The first author (SL) brought forward technology-related recommendations of the end users on how the original Stronger Together program could be adapted and improved for SCI Step Together. Recommendations were sent to the project manager and software developers who returned a list of what could and could not be changed. Ultimately, the recommendations from end users were incorporated as best as possible for both content and delivery, with the decisions reported in the Results section. These decisions were then communicated back to the SCI end users. Importantly, both the technology and SCI end user partners have been included as authors of this manuscript.

In addition, Curatio invited the first author (SL) to attend trainings on how to engage with participants, technology information, and how to record and manage time in addition to privacy concerns.

Ethics Approval

Ethical approval was not applied for to develop program content as it was completed for quality improvement. Under Article 2.5 of the Tri Council Policy Statement, quality assurance or quality improvement activities are not subject to institutional ethical review.

Results

Step 1: Primary Mixed Methods Research and Review

The results of the step 1 studies have been published elsewhere [7,28,29]. Key issues identified from the primary mixed methods research and scoping review are summarized in Table 1. The implemented intervention features addressing each issue are also reported in Table 1.

Table 1. Key issues from primary mixed methods research and scoping review and associated intervention features.

Issue identified by research	Intervention features addressing the issue
<ul style="list-style-type: none"> Ambulators with SCI^a participate in low levels of leisure-time physical activity, and no interventions exist for this group [7]. 	<ul style="list-style-type: none"> Intervention should be developed to improve physical activity participation.
<ul style="list-style-type: none"> Exercise intervention studies lacking measurement of psychosocial outcomes [7]. 	<ul style="list-style-type: none"> Intervention must address and measure psychosocial constructs related to physical activity participation.
<ul style="list-style-type: none"> Correlates related to physical activity include physical and psychological capability (eg, pain and lack of knowledge), environmental and social opportunity (eg, time and underestimated disability), and reflective and automatic motivation (eg, intentions and boredom) [7] Barriers to physical activity include lack of knowledge, weak beliefs about capabilities, lack of coping planning, and high goal conflict [28]. Coping planning, action planning, goal conflict, and skills significantly predict physical activity [28]. 	<ul style="list-style-type: none"> Intervention must target the following constructs through educational modules, behavioral support, and peer support: <ul style="list-style-type: none"> Physical activity guidelines and benefits (knowledge) Self-monitoring and goal setting (goal conflict) Action planning Coping planning Confidence (beliefs about capabilities) Skills
<ul style="list-style-type: none"> A total of 35 types of physical activity recorded and organized into 10 higher-order categories (eg, walking, resistance training, and rock climbing) [28]. 	<ul style="list-style-type: none"> Intervention content must include educational modules that refer to these types of physical activity when examples are used. A list of these types of physical activity as ideas for participants should also be included.
<ul style="list-style-type: none"> Ambulators with SCI have physical activity experiences, which are shaped by feelings of ableism, feeling sidelined, and the effects of their SCI [29]. 	<ul style="list-style-type: none"> Behavioral support in the intervention must be provided by a person who understands this context for physical activity participation.
<ul style="list-style-type: none"> Conditions and elements of quality physical activity experiences map onto the Quality Participation Framework [41] and Quality Parasport Participation Framework [29,40]. 	<ul style="list-style-type: none"> Conditions and elements of quality physical activity experiences must be included as a separate module for intervention. Quality of physical activity experiences must be referred to throughout the intervention.
<ul style="list-style-type: none"> Ambulators with SCI lack sense of community, especially in physical activity settings [29]. 	<ul style="list-style-type: none"> Peer support must be included and prioritized in intervention delivery.

^aSCI: spinal cord injury.

Step 2a: Intervention Objectives and Features

The objective of the SCI Step Together program, in terms of outcomes, is to increase the quantity and quality of leisure-time

physical activity participation among persons with SCI who ambulate. The implemented intervention objectives and features based on our understanding of the key behavioral issues can be found in [Table 2](#).

Table 2. Intervention objectives and features for the SCI^a Step Together program.

Intervention design objectives	Key features
To increase the quantity of physical activity among individuals with SCI who ambulate	<ul style="list-style-type: none"> Digital intervention to build autonomous motivation through teaching self-regulation skills (eg, action and coping planning) and increasing autonomy, competence, and relatedness Provide educational information on physical activity and self-regulatory behaviors Behavioral coach provides support to individuals through BCTs^b such as feedback on behavior and verbal persuasion.
To enhance the quality of physical activity among individuals with SCI who ambulate	<ul style="list-style-type: none"> Increase intrinsic motivation to participate in activities that align with their desires, needs, and lifestyles through building autonomy, competence, and relatedness Provide resources and support to individuals with SCI who ambulate through behavioral coaching and peer support to offer additional options that may be relevant for their context Provide education on quality participation elements and factors to increase opportunities for experiencing quality in physical activity
To build community among individuals with SCI who ambulate	<ul style="list-style-type: none"> Allow individuals to communicate in the app to offer support to each other and gain an awareness of others in their situation

^aSCI: spinal cord injury.

^bBCT: behavior change technique.

Step 2b: Behavioral Analysis and Theory

The theory chosen to inform the SCI Step Together program was the self-determination theory (refer to the study by Ryan and Deci [51] for a review), which is a theory of human motivation and personality that posits that three basic psychological needs must be met for a person to sustain a behavior (eg, physical activity): autonomy, competence, and relatedness [51]. Self-determined or autonomous motivation occurs when these 3 needs are met and individuals are intrinsically motivated [51]. This theory was chosen to inform the intervention content because the self-determination theory aligns well with not only increasing the quantity but also the quality of physical activity participation. We hypothesized that there is a positive correlation between intrinsic motivation for physical activity and quality physical activity participation.

Importantly, all barriers and facilitators (ie, Theoretical Domains Framework domains) identified in step 1 can be targeted through self-determination theory constructs. For example, beliefs about capabilities and skills are two domains encompassed in the basic psychological need of competence. Furthermore, a recent review of health interventions maps BCTs onto basic psychological needs [52], making it possible to further align the work

completed in step 1 with self-determination theory. Basic psychological needs are incorporated as part of the intervention objectives and features in step 2b. In addition, the included BCTs and the associated Theoretical Domains Framework domains and intervention functions can be found in [Multimedia Appendix 2](#) [31,42,53]. The BCTs, their support for inclusion (or exclusion), and the associated basic psychological needs can be found in [Multimedia Appendix 3](#) [12,43,52,54]. [Multimedia Appendix 4](#) provides the BCTs, related intervention components, and rationale for how they are included in the intervention.

Step 3: Logic Model

The logic model for the intervention is illustrated in [Figure 2](#). The intervention inputs are the BCTs, the processes or actions are the intervention components, the outputs are the fulfillment of the basic psychological needs and motivation, and the outcomes are the quality and quantity of physical activity participation. The logic model presents the causal assumptions and theory of change within the intervention based on self-determination theory constructs and includes BCTs and intervention components identified from steps 1 to 2.

Figure 2. The logic model for the spinal cord injury (SCI) Step Together program. BCT: behavior change technique.

Step 4: SCI Step Together Program Content Development and IKT

No training sessions were provided to end users, as they felt comfortable navigating the app on their own. End users spent 1 to 2 hours using the Stronger Together program to become familiar with app use and engagement required. The initial interview with end users resulted in several recommendations for the final SCI Step Together program ([Table 3](#)). In general, end users (pilot participants) enjoyed the app, found it easy to

use, and experienced no technical issues. They appreciated how the community coaches are real, live people who can provide individualized feedback rather than standardized technological support. End users also liked the inclusion of peer support, noting its importance for participating in physical activity. All end users agreed that asking participants to engage with the program once per week was preferred, rather than daily or biweekly. They thought that the images used in the app were appropriate and the general content included in the educational modules was well done.

Table 3. End user recommendations and changes for the SCI^a Step Together program.

Partner	Recommendation	Curatio feedback	Implemented (yes or no)	How
Technology				
SL	Allow worksheets to be completed inter-actively within the app rather than as a PDF image	Not possible	No	— ^b
SL	Track only exercise (no other behaviors such as smoking)	Not possible	No	—
SL	Include physical activity planners or goal setting in the app instead of tracking medications	Possible to remove medication tracking but not possible to include planner or goal setting	Yes	Removed medication tracking. Participants can set and track physical activity goals in the “Notes” section of the app under “My Info.”
MM	Add the type of physical activity when tracking exercise	Unable to do	No	—
MM	See how your weekly physical activity compares with the guidelines every week	Unable to do within the app platform, but coach can compare	Yes	Coach will note comparisons with SCI physical activity guidelines when providing feedback on their behavior.
JS and CJ	Allow exercise tracking in the SCI Step Together app to sync with your smartphone activity or other fitness apps (eg, Strava)	Not possible from software standpoint	No	—
JS	Create a calendar to plan physical activity that syncs with iCal or Google Calendar	Not possible from software standpoint	No	—
SL	Change intensity from “Low” and “High” to “Mild,” “Moderate,” and “Vigorous” to align with the SCI physical activity guidelines	Not possible	No	—
SL	Allow participants to self-select minutes of exercise rather than choosing “0-10,” “11-20” etc	Not possible	No	—
Trial				
MM	Email participants the worksheets in addition to having them accessible in the app	Possible to do by researchers	Yes	Researcher will ask participants if they would like their weekly worksheet emailed.
MM and CJ	Give people choice in the modules they complete	Possible from research standpoint	Yes	Participants will be encouraged to complete all the modules, but they do not have to complete them all.
MM, JS, and CJ	Allow people to choose how often they would like to be notified by the community coach	Possible	Yes	Community coach will ask participants how often they would like to be reminded of completing the modules
Intervention content				
MM	Provide examples of strategies to be physically active at home	Possible to include in educational content (researchers)	Yes	Educational content uses examples throughout based on physical activity at home
MM, JS, and CJ	Include supportive, motivational, and individualized messages from the community coach	Possible	Yes	Community coach will use autonomy-supportive messages that are individualized to each user’s profile.
JS and CJ	Remove <i>graded tasks</i> BCT ^c —can be overwhelming for individuals new to physical activity	Possible	Yes	<i>Graded tasks</i> BCT removed from educational modules and community coach content

^aSCI: spinal cord injury.

^bNot available.

^cBCT: behavior change technique.

As seen in [Table 3](#), Curatio, Inc could not implement several technology-related recommendations. This is because the platform is already commercially available and hosts several communities in addition to SCI Step Together. Changing this technology would require substantial time, money, and human resources, which are not feasible for the academic or technology partners. As such, these recommendations will be considered in future iterations of Stronger Together communities.

Ultimately, SCI Step Together was designed as an 8-week program that consists of educational modules, peer support, and in-app behavioral support with a live community coach. For SCI Step Together, the first author serves as the community coach. The coach checks in weekly with participants using an autonomy-supportive approach to align with the self-determination theory [51], delivers appropriate BCTs (see the logic model in [Figure 2](#)), and provides support with the educational modules and app technology as needed. The educational modules incorporate BCTs and include links to local resources and worksheets so that participants can put their work into practice. Participants can provide and receive peer support by talking to each other in the app.

Discussion

Principal Findings

This paper provides the stepwise methodology used to develop the SCI Step Together intervention using a Person-, evidence-, and theory-based approach. Importantly, the approach transparently describes how various partners were involved throughout the intervention planning and development process using IKT. The intervention was systematically created with evidence generated from primary mixed methods and review research (step 1), which informed the behavioral analysis and theoretical modeling (step 2) to produce a logic model (step 3). Steps 1 to 3 along with partnership discussions using IKT helped to develop and optimize the Stronger Together program content and delivery (step 4). Overall, this intervention was developed in partnership to provide more meaningful, better-informed, and more relevant resources and support for physical activity participation to individuals with SCI who walk.

This study offers important contributions to the mHealth literature by outlining how programs can be planned and developed in partnership with partners, while using evidence, a Person-Based approach, and theoretical modeling. Although a growing number of physical activity interventions have been developed for individuals with SCI, this is the first intervention delivered in an mHealth format. Furthermore, considering that more than 50% of mHealth interventions do not incorporate theory or BCTs [18,55], this intervention development paper provides guidance on how to incorporate these important elements. The SCI Step Together program not only includes BCTs according to a behavioral analysis using the BCW [31] but is also directly guided by the self-determination theory [51] to inform causal assumptions. BCTs were also included and excluded based on previous reviews of effectiveness [12,43], thus adding confidence in the potential utility of the intervention. BCTs can be delivered and enacted appropriately using mobile technologies [56]. For example, the BCT of self-monitoring

may be easier to implement through mHealth formats because users' phones are ready and accessible immediately after exercising [57]. As such, self-reported physical activity measures may have increased precision [58], allowing participants to set more appropriate goals and coaches to provide better feedback and physical activity behavioral support [59].

This study also contributes to the mHealth literature by outlining an mHealth intervention development method that may be useful in promoting app engagement. Engagement with apps can be defined as "(1) the extent (eg, amount, frequency, duration, and depth) of use and (2) a subjective experience characterized by attention, interest, and affect" [60]. Engagement with mHealth programs is typically poor, which leads to insufficient behavior change (eg, [61]). Factors that increase engagement in mHealth interventions include using BCTs (eg, self-monitoring and action planning) and providing health care practitioner support [60,61]. By conducting a behavioral analysis and working with a technology partner who endorses social support from a health coach, the SCI Step Together program is more likely to support participant engagement. Other factors that influence app engagement include "safety netting" (ie, having the ability to re-engage with the app after disengaging) and tailored content [60,61]. Using IKT allowed us to work with end users to create tailored physical activity content that could be individualized in the app through the health coach. Furthermore, working in partnership with Curatio Inc means that the SCI Step Together program can be sustained after the intervention is tested, providing a "safety net" by allowing individuals to disengage and re-engage with the program whenever they please. As such, by including behavioral analysis and IKT in the intervention development process, participants are more likely to engage positively with the program.

In addition, this is one of the first mHealth interventions to explicitly report IKT activities conducted during intervention development. Similarly, this is the first study to use the IKT guiding principles for SCI research [27] to guide our research partnership. Partners were involved throughout steps 1 to 4 to provide feedback on program content and delivery. The involvement of partners best predicts the translation of research into practice [27,62], and it is becoming increasingly important in physical activity intervention development practices. This study outlines how IKT can add to the Person-Based approach by using principles to guide partnership [27], ensuring partners have shared decision-making power in intervention development, describing who and when partners were involved, and involving partners early and throughout the research process.

Future Directions

This paper describes the formative work of planning and developing an mHealth intervention to increase the quantity and quality of physical activity among persons with SCI who ambulate. As such, the next step, according to the Medical Research Council guidance on developing complex interventions [63], is to pilot-test the acceptability, feasibility, and engagement of the SCI Step Together program among a sample of users. This pilot study is currently underway, and the trial is registered at [ClinicalTrials.gov](https://clinicaltrials.gov) (NCT05063617) [64]. The goal of the pilot study was to gain an understanding of how individuals used the

program, whether they were satisfied with the components, and any areas for improvement before running a larger trial. In addition, we hope to estimate the effects of the intervention on key outcomes to determine a sample size for a future trial. If these feasibility and subsequent effectiveness trials are successful, the next step is implementation, whereby the program will be disseminated among the larger community and long-term outcomes will be monitored [63]. Finally, future research is needed to understand if and how BCTs are enacted by participants in an mHealth format and whether BCT enactment relates to intervention outcomes [56].

Importantly, as we move forward, the Person-Based [25] and IKT approaches [21] will continue to be used to ensure that partners are involved throughout the intervention evaluation process. For example, community and provincial SCI organizations will be involved in participant recruitment for the pilot trial and will be involved in the long-term implementation of the program. In addition, the program will be iteratively updated as mixed methods research continues to be used for program evaluation [25].

Limitations

Some limitations of the intervention planning and development processes should be recognized. First, the studies in step 1 were conducted before the COVID-19 pandemic, and the intervention was released in July 2021. As such, some factors related to the quantity and quality of physical activity participation may differ due to social distancing, facility closures, and other public health measures. We have included several examples of at-home physical activity strategies in the SCI Step Together program, considering pandemic-related restrictions. Second, a relatively

small sample of participants was used in step 1 and for partner interviews in step 4, and their preferences for programming may be limited to this sample. However, we included evidence from larger systematic reviews to inform theoretical content (eg, [43]) and build from previous interventions for individuals with SCI (eg, [23]); thus, we expect the program to be beneficial for a broader sample of individuals with SCI who walk. Third, no studies have been conducted to understand whether and how self-determination theory and quality participation are related. We do not know whether these hypothetical causal assumptions will work as expected, and larger-scale studies are required to test the relationship between self-determination theory and quality participation. Fourth, we acknowledge that many of the cocreated ideas and recommendations developed using the IKT process were not incorporated into the intervention because of the limited capacity of the technology and thus lacked feasibility for implementation. Finally, our partners were limited in racial and ethnic representation, and future partners should include a more diverse sample of individuals with SCI who walk.

Conclusions

This is the first physical activity mHealth intervention for persons with SCI and the first physical activity intervention designed specifically for people with SCI who walk. This study provides an innovative methodology for intervention planning and development that integrates Person-Based approach, evidence, theory, and IKT. The SCI Step Together program was developed in partnership with partners to optimize intervention content and delivery. Accordingly, it is anticipated that the SCI Step Together program will be acceptable, feasible, and have appropriate engagement when pilot testing is underway.

Acknowledgments

The authors would like to acknowledge James Shaw for his important input on this project. This work was supported by a Partnership Grant from the Social Sciences and Humanities Research Council of Canada (SSHRC; grant 895-2013-1021) for the Canadian Disability Participation Project [65]. This work was also supported by an SSHRC Doctoral Fellowship and a WorkSafe BC Doctoral Research Training Award. The supervising author (KMG) holds the Reichwald Family Southern Medical Program Chair for Chronic Disease Prevention.

Conflicts of Interest

LBG is the Chief Executive Officer of Curatio Networks Inc, and LC is a project coordinator at Curatio Networks Inc. Curatio Networks Inc provided in-kind support to back the Stronger Together platform.

Abstract

Background: Over 325,000 mobile health (mHealth) apps are available to download across various app stores. However, quality assurance in this field of medicine remains relatively undefined. Globally, around 84% of the population have access to mobile broadband networks. Given the potential for mHealth app use in health promotion and disease prevention, their role in patient care worldwide is ever apparent. Quality assurance regulations both nationally and internationally will take time to develop. Frameworks such as the Mobile App Rating Scale and Enlight Suite have demonstrated potential for use in the interim. However, these frameworks require adaptation to be suitable for international use.

Objective: This study aims to modify the Enlight Suite, a comprehensive app quality assessment methodology, to improve its applicability internationally and to assess the preliminary validity and reliability of this modified tool in practice.

Methods: A two-round Delphi study involving 7 international mHealth experts with varied backgrounds in health, technology, and clinical psychology was conducted to modify the Enlight Suite for international use and to improve its content validity. The Modified Enlight Suite (MES) was then used by 800 health care professionals and health care students in Ireland to assess a COVID-19 tracker app in an online survey. The reliability of the MES was assessed using Cronbach alpha, while the construct validity was evaluated using confirmatory factor analysis.

Results: The final version of the MES has 7 sections with 32 evaluating items. Of these items, 5 were novel and based on consensus for inclusion by Delphi panel members. The MES has satisfactory reliability with a Cronbach alpha score of .925. The subscales also demonstrated acceptable internal consistency. Similarly, the confirmatory factor analysis demonstrated a positive and significant factor loading for all 32 items in the MES with a modestly acceptable model fit, thus indicating the construct validity of the MES.

Conclusions: The Enlight Suite was modified to improve its international relevance to app quality assessment by introducing new items relating to cultural appropriateness, accessibility, and readability of mHealth app content. This study indicates both the reliability and validity of the MES for assessing the quality of mHealth apps in a high-income country, with further studies being planned to extrapolate these findings to low- and middle-income countries.

Introduction

Use and access to mobile phones and the internet is ubiquitous in many countries [1]. In 2020, there were 4 billion mobile internet users, and this figure is expected to grow to 5 billion by 2025 [2]. In 2017, over 325,000 mobile health (mHealth) apps were available to download across various app stores with the number of app publishers rising by 45% in the same year [3]. This market proliferation has created a challenging task for health care professionals to identify high-quality apps, as many have been created without expert medical involvement, appropriate testing, and validation [4]. A review published in 2020 indicated that most safety concerns about apps related to the quality of their content [5]. Examples of inappropriate app content include a recommendation for people with bipolar disorder to “take a shot of hard liquor an hour before bed” and a suggestion that bipolar disorder is “contagious” [6].

Given the rapid proliferation of mHealth apps, regulation of this sector is challenging for policy makers [7]. Various strategies are being used to tackle shortcomings of mHealth apps especially in high-income countries (HICs). For example, the Food and Drug Administration applies regulatory oversight to a subgroup of mHealth apps regarded as medical devices or that pose patient safety risks [8]. For low- and middle-income countries (LMIC), there is a growing demand to develop and apply assessment frameworks that meet contextual aspects relevant to one’s specific country. While comprehensive, timely, and effective national regulation is awaited, various mHealth app quality assessment methodologies have been proposed for use in the interim. Examples include the Enlight Suite [9], the Mobile App Rating Scale [10], and the App Chronic Disease Checklist (ACDC) [11].

A review of mHealth app quality assessment methodologies indicated the scope for improvement of such methodologies to enhance their comprehensiveness and relevance across resource-diverse settings [12]. The review found that none of the existing generic app assessment methodologies [9-11,13,14] explicitly considered cultural appropriateness. Only two methodologies addressed privacy and security of information [9,13]. Similarly, readability was considered by only two methodologies [11,13]. Only the ACDC [11] addressed the availability of mHealth apps in offline mode. The ability of the apps to facilitate behavior change was only addressed by three methodologies [9-11]. In addition, most existing generic app assessment methodologies only offered some form of face and content validity based on expert opinions [9-11,13] with the reliability of only 2 methodologies reported [9,10]. The construct

validity of all the app assessment methodologies was not evaluated [12].

Although the Enlight Suite was adjudged as thorough and comprehensive, it has limited international applicability because it does not consider attributes that are relevant to the successful uptake of mHealth apps in low-, middle-, and HICs, including cultural appropriateness, readability, and access [12,15]. It is important to consider cultural appropriateness when developing content and designing user interfaces of apps for international and country-specific audiences [16]. If the content or user interface of an mHealth app is not culturally appropriate for a particular audience, acceptability and uptake may be low [16]. Similarly, poor readability may affect the acceptability and uptake of apps among prospective users [17,18]. Previous research revealed that many mHealth apps were written at excessively high reading grade levels, which may not be suitable for users with low levels of literacy especially in LMIC [17-19]. In addition, access to the internet may affect mHealth use especially in LMIC and among deprived communities of HICs [20]. Although the mobile broadband penetration rate has doubled in LMIC over the last decades [21], users continue to experience challenges with the cost and speed of internet services.

The purpose of this study is therefore to modify the Enlight Suite [9] to be more considerate and effective for use internationally. Additionally, this paper serves to provide an initial reliability and validity assessment of the Modified Enlight Suite (MES) in practice.

Methods

Verifying the Content Validity of the Modified Enlight Suite

To formulate the MES and confirm content validity, a two-round iterative Delphi process was undertaken. Delphi techniques are widely used for this type of research with its validity for questionnaire formulation and modification confirmed in past literature [22,23].

Participant Characteristics and Recruitment

Previous research recommends having between 3 and 10 professionals to verify content validity [24]. Therefore, a total of 7 digital health researchers with backgrounds in clinical medicine (n=4), nursing (n=1), clinical psychology (n=1), and information technology (n=1) were recruited in this phase of the study. Of the participants, 3 were affiliated universities in Ireland, 1 was affiliated to a university in Malawi, and 3 were affiliated to universities in the United Kingdom. Although most

of these experts currently reside in HICs, they have varied hands-on clinical (n=2) or research (n=5) experience in LMIC.

Experts were identified based on the following inclusion criteria: hold a professional title in the areas of technology, medicine, health, or clinical psychology; have a minimum of 2 years professional experience in their respective field; be willing to engage in all Delphi phases of this study digitally; and have suitable internet access.

Delphi Process

The panel of experts analyzed the questions in the pre-existing Enlight Suite as well as those proposed by the facilitators (FW and JOD). Version 1 (V1) of the MES contained 7 sections with a total of 33 questions. Of these questions, the facilitators proposed 5 questions based on considerations of a past review of app assessment methodologies indicating potential weaknesses in the Enlight Suite for international mHealth app evaluation practices [12]. Each panelist was asked to examine the suitability of questions within V1 of the MES for mHealth app evaluation practices internationally, both individually and collectively. Participants were asked to consider each of the questions (and proposed questions) with respect to its appropriateness and relevance across all resource-level settings (ie, HICs and LMIC).

During round 1 of the Delphi process, both quantitative and qualitative feedback were gathered. For quantitative evaluation of the content validity, a 3-point scale was used (1="exclude question," 2="include question but modify," and 3="include question as is") to rate each question. Whenever a panelist indicated that a question should be modified, qualitative feedback was requested. Additionally, panelists were asked at the end of each section of the MES if further adaptations to that section were necessary.

Standard methods to determine consensus in Delphi studies are not available [25]. However, for the purposes of this study, consensus was measured via the percentage who agreed with amendments after round 1 ($\geq 4/7$). Following round 1 of the Delphi process, the facilitators (FW and JOD) discussed suggested amendments and reflected on both qualitative and quantitative feedback before formulating Version 2 (V2) of the MES. Results were summarized and panelist feedback was anonymized before round 2 of the Delphi process commenced.

In round 2, panelists were provided with V2 of the MES. During this round, panelists were asked if they accepted or rejected the changes that the facilitators made to V1 of the MES to create V2. Additionally, panelists could review comments and suggestions made by fellow participants, albeit anonymously. The Delphi process would be terminated should the outcome of a round yield "minor" or "out of scope" amendments only. In this case, the facilitators would discuss the feedback and make changes accordingly without another round occurring.

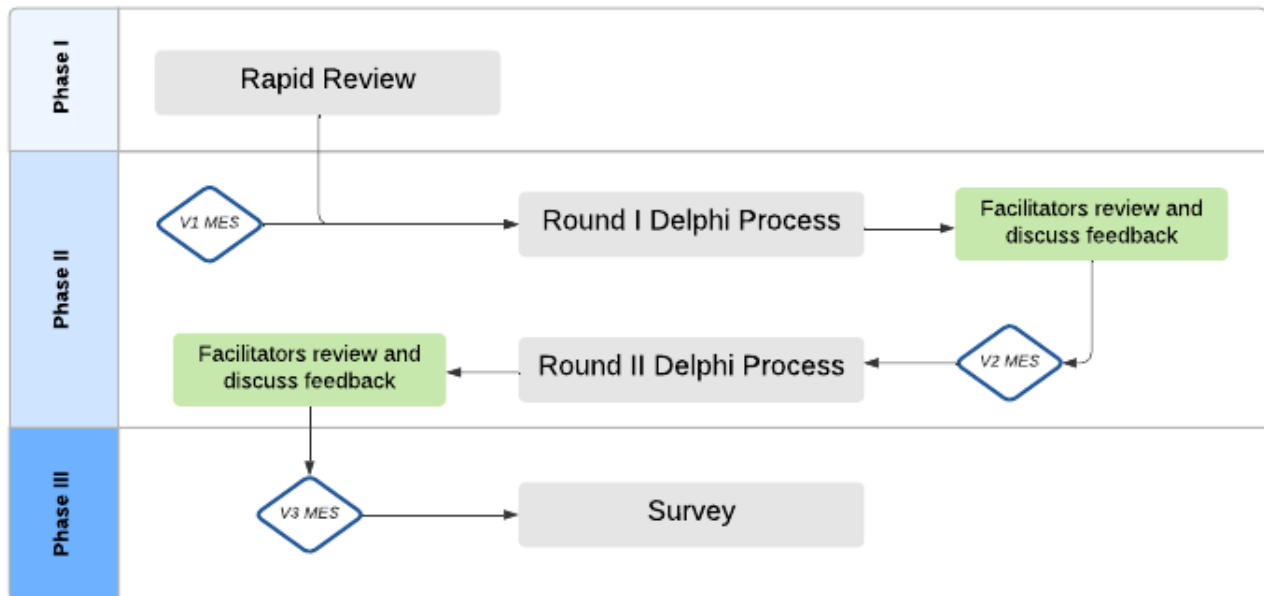

Verification of the Validity and Reliability of the Modified Enlight Suite

To assess the reliability of the MES, the construct was distributed in digitized form to participants who were asked to use it to evaluate the Irish COVID-19 app, a popular freely available mHealth app in Ireland [26]. The MES was tested in Ireland to serve two purposes: (1) to avoid language acting as a confounding variable falsely affecting reliability results and (2) for convenience purposes to promptly identify reliability issues prior to international testing.

The following were inclusion criteria to participate: be a health care professional or health care student with a minimum of 2 years clinical exposure, own a smartphone device, and be familiar with the Irish COVID-19 app.

Convenience sampling was used to recruit participants via targeted social media platforms and through the university emailing list. When validating a questionnaire, there are no fixed rules for an ideal sample size [27]. Some have suggested that a sample size of 50 is considered very poor, 200 as fair, and >1000 being excellent [28]. Larger sample sizes are always more reflective of the population; ergo, the investigators sought as many participants as possible.

The reliability of the MES was assessed using SPSS version 28 software (IBM Corp). The Cronbach α for the overall Enlight scale and each of the seven subscales (usability, visual design, user engagement, content, therapeutic persuasiveness, therapeutic alliance, and general subjective evaluation of the app's purpose) was calculated. A Cronbach α of .7 or above is traditionally regarded as an indication of reliability [29]. The construct validity was assessed using Amos version 26 (IBM Corp) for confirmatory factor analysis. The model for the confirmatory factor analysis was based on the seven pre-existing categories listed above. A flowchart indicating each stage of this research can be viewed in [Figure 1](#).

Figure 1. Flow Chart Indicating Each Phase of the Research Process. MES: Modified Enlight Suite.

Ethical Considerations

The Social Research Ethics Committee of University College Cork Ireland granted ethical approval for this stage of the project (SREC/SOM/19062020/1/25112020/). Prior to engagement, participants were given an information leaflet with details of the study and asked to sign a consent form. All data collected during the study was kept secure on a password-encrypted computer. This research was partly funded by an Irish Health Research Board Scholarship (scholarship SS-2020-089).

Results

Developing the Finalized Version of the Modified Enlight Suite

Round 1

Round 1 of the Delphi study was conducted in July 2020. During this round, the facilitators proposed five questions to be included in the MES. Of these questions, three served to improve the relevance of the MES for quality assessment purposes internationally. These questions were based on the following topics: (1) culture appropriateness, (2) accessibility, and (3) readability. The facilitators also proposed 2 questions that affect a user's ongoing use of an app. These questions were concerned with the following topics: (1) errors and (2) timeliness. Following round 1 of the Delphi process, consensus was reached that each of these questions should be included within the final version of the MES.

Furthermore, the panelists made 47 suggestions/comments. These were categorized by the facilitators into "minor amendments" (n=33), "significant amendments" (n=9), and "other comments" (n=5). Following this round and discussion by the facilitators, 26 of these amendments were accepted and incorporated to create V2 of the MES. An extraction table with categorized feedback from round 1 can be viewed in [Multimedia Appendix 1](#).

Round 2

V2 of the MES contained 7 sections with 32 questions. All amendments made by the facilitators based on feedback from round 1 were accepted by participants in round 2. During this round, participants provided 25 additional comments/amendments that were subcategorized into "minor" (n=18) and "other" (n=7). Of these, 12 were incorporated into the final version (ie, Version 3 [V3]) of the MES ([Multimedia Appendix 2](#)). An extraction table with feedback from round 2 can be viewed in [Multimedia Appendix 3](#).

This multi-round iterative process was terminated after round 2, as modifications in V2 of the MES were accepted by panelists. Given the nature of feedback suggested by panelists during round 2, the facilitators made additional minor amendments as necessary. The comprehensibility of the original Enlight Suite facilitated this short Delphi process. Given the interdisciplinary nature of the professional panel, the Delphi process served to confirm the content validity of the MES for international use.

Reliability of the MES

A total of 800 responses were gathered during this phase to assess the reliability and construct validity of the MES. Of the 800 participants, 91% (n=728) fell within the 18 to 34 years of age category. Health care professionals represented 20% (n=160) of the participants, while the remaining 80% (n=640) were health care students with a minimum of 2 years clinical work experience. The majority (n=712, 89%) of participants identified as being of White/Caucasian ethnicity. Less than half (n=376, 47%) of the responses were complete.

The reliability analysis showed satisfactory internal consistency of the overall scale (Cronbach $\alpha=.93$). Similarly, the subscales demonstrated high reliability except for the user engagement scale (Cronbach $\alpha=.65$), which is slightly lower than the traditionally regarded reliability level (Cronbach $\alpha=.7$) [29]. Deletion of items under user engagement did not improve the reliability of the subscale. The Cronbach α for the scale and the subscales are presented in [Table 1](#).

Table 1. Reliability statistics.

Section	Items, n	Cronbach α
Usability	7	.82
Visual design	3	.77
User engagement	5	.65
Content	5	.80
Therapeutic persuasiveness	6	.78
Therapeutic alliance	3	.73
General subjective evaluation of the app's purpose	3	.76
Overall scale	32	.93

Construct Validity of the MES

The concept of fitness in confirmatory factor analysis refers to the extent to which the empirical data (eg, our survey findings) supports the construct validity of the theoretical model being tested (which is the MES in our study) [30]. The chi-square goodness-of-fit test ($\chi^2_{443}=1045.9$; $P<.001$; $\chi^2 / df = 2.36$) indicates that our model fits modestly with the data [28]. Although a significant P value as in our study indicates a poor fit, this is not unexpected due to our large sample size [30]. For studies with large sample sizes, it is recommended to consider the model as highly fit with data when the χ^2 / df is less than 2 [30]. Although the value in our model is not less than 2, this is still an acceptable value. Similarly, the comparative fit index

(0.89) and Tucker-Lewis index (0.87) show that our model modestly fits with the data, as a value of at least 0.9 is required for the model fit to be deemed acceptable [31]. However, the root-mean-square error of approximation (0.041, 95% CI 0.038-0.043) indicates that our model is a close-fitting model, as it is below the 0.05 cutoff point [32] and all factor loadings are positive and statistically significant (Table 2). In other words, the data from the survey provides support, albeit modestly, for the validity of the constructs (ie, 32 items and 7 categories) of the MES. It is worth noting that the first item in each category does not include significance tests (SE, critical ratio, and P value) because the unstandardized estimate for each first item was fixed at 1 rather than estimated as part of the adopted methodology, hence the empty cells in Table 2.

Table 2. Construct validity.

Discussion

Principal Findings

The objectives of this study were to modify the Enlight Suite and test the reliability and validity of the MES. The Delphi process resulted in a comprehensive MES, which contains 32 questions over 7 sections including additional dimensions not in the original Enlight Suite, including access, cultural appropriateness, readability, errors, and timeliness.

The subsequent survey demonstrated an overall reliability of the MES and its subscales. The confirmatory factor analysis demonstrated a positive and significant factor loading for all 32 items in the MES with a modestly acceptable model fit that is indicative of the construct validity of the MES.

Comparison With Prior Work

The inclusion of cultural appropriateness, readability, and access criteria differentiates the MES from existing methodologies [9-11,13,14], which either considered only one or none of these important criteria. Questions on cultural appropriateness, readability, and access acknowledge the multi-demographic nature of the mHealth market [1]. For instance, there may be a need to present the content of an mHealth app in a local language to enhance its utility in a particular locality [1,33]. Similarly, the consideration of access in offline mode in the MES recognizes that internet access may not be continuous for many users [34]. These newly introduced dimensions (access, cultural appropriateness, and readability) have been identified by previous studies as important aspects of apps that ought to be considered for successful uptake across both HICs and LMIC [12,15]. Thus, the introduction of these dimensions has improved the applicability of the MES internationally.

The overall reliability of the MES was quite high in our study as well as the reliability of the subscales except for the user engagement subscale. However, the original Enlight Suite demonstrated adequate reliability across all domains including user engagement [9]. Interestingly, the major modifications to the Enlight Suite in this study were not in the user engagement category. The difference in the reliability results could be attributed to the variation in the approach used by the two studies. While the reliability of the original Enlight Suite was based on ratings by 2 trained researchers [9], the reliability testing in our study was based on the ratings by 800 health care professionals and students who would be the end users of the MES. Thus, the original Enlight Suite [9] was validated to be used with prior training, while the MES is validated to be used by any health care professional.

The demonstration of construct validity in this study with a modestly acceptable model fit supports the position of the authors of the original tool who regarded it as a suite consisting of multiple scales rather than a single scale whose result could be aggregated [9]. These results should be interpreted with caution due to the possible impact of the missing data in our study on the model fit. Due to missing data, we were only able to use the maximum likelihood estimation approach, which assumes that the variables are normally distributed [35].

Strength and Limitations

This paper builds upon a rapid review that identified shortcomings of mHealth app quality assessment methodologies [12]. The MES was developed with input by international experts in mHealth. Given their diverse background and expertise, the content of this tool could be considered applicable internationally. To the best of our knowledge, the MES is the first mHealth app quality assessment methodology that considers factors known to affect the fundamental usability of mHealth technologies in LMIC.

The reliability and validity assessment of the MES in this study was undertaken in Ireland, an HIC. Of the participants who engaged in the survey, 89% (712/800) identified as either White or Caucasian. This highlights a need for similar studies to test the reliability and validity of the MES in LMIC. For the MES to be reliably effective for all, participants from more diverse backgrounds and ethnicities are needed in the future to extrapolate these findings. The modest construct validity of the MES is also a limitation, and improved modeling could possibly be achieved with less missing data.

Future Work

While this study demonstrates the content validity via an international panel of mHealth stakeholders, health care professionals with no technological background may have been underrepresented in the Delphi process. This is currently being investigated with focus groups in Malawi and South Africa. Additional modifications may be made to V3 of the MES based on feedback from these focus groups. The reliability of the updated Enlight Suite will then be assessed with participants recruited internationally.

The original Enlight Suite provided a comprehensive quality and therapeutic potential tool for both mobile and web-based eHealth interventions. While the focus of this study was to adapt the suite to improve its international relevance for mHealth app evaluation, future works could expand on its web-based potential. This study introduced additional dimensions (access, cultural appropriateness, and readability) that are relevant to international applicability of the Enlight Suite. Future works could look into developing a framework for the international applicability of scales.

Conclusion

The need for quality assessment in mHealth is clear. This study is a key primary step in improving the scope, content, and relevance of mHealth quality assessment methodologies across diverse settings. It is of the authors opinion that the MES is the first quality assessment methodology to also consider factors known to hinder the uptake and continued use of mHealth apps in resource-poor settings. Furthermore, the authors believe that this research improves the validity of the construct while taking measures to enhance its fundamental usability. There is scope that the MES may be adopted by health care professionals internationally to assess the quality and suitability of mHealth apps available to their patients before recommending them. This would help ensure patient safety.

Abstract

Background: HIV/AIDS is now a manageable chronic illness owing to effective antiretroviral therapy (ART), which involves routine follow-up care, including regular physical visits to the clinic. In the recent past, and in wake of the COVID-19 pandemic, there has been increased need for virtual care and intervention delivery, a modality known as mobile health (mHealth), which includes cell phone-delivered services for medical and public health practice.

Objective: Here we describe cell phone use and its relationship with alcohol use in a cohort of persons living with HIV and latent tuberculosis (TB).

Methods: We performed a cross-sectional analysis of baseline data from a cohort of persons living with HIV and latent TB in HIV care in southwestern Uganda. We estimated proportions of cell phone and text message use and evaluated their associations with alcohol use—a common modifiable behavior among persons living with HIV. Cell phone use (primary outcome) was defined as owning a cell phone that is turned on at least half of the day. Any alcohol use was defined as any self-reported alcohol use in the prior 3 months or a phosphatidylethanol (an alcohol biomarker) level of ≥ 8 ng/mL.

Results: A total of 300 participants (median age 40 years; $n=146$, 48.7% male) were included in the analysis. Most ($n=267$, 89.0%) participants had access to a phone and of them, 26 (9.7%) shared the phone with someone else. In total, 262/300 (87.3%) of participants owned a cell phone that is turned on at least half of the time; the majority ($n=269$, 89.7%) rarely or never sent text messages, and over two-thirds ($n=200$, 66.9%) rarely or never received text messages. Most ($n=214$, 71.3%) had any alcohol use in the prior 3 months. In adjusted analyses, any alcohol use was not significantly associated with cell phone use (adjusted odds ratio [aOR] 0.48, 95% CI 0.18-1.25; $P=.13$) or sending (aOR 0.82, 95% CI 0.28-2.37; $P=.71$) or receiving (aOR 1.31, 95% CI 0.70-2.47; $P=.40$) text messages.

Conclusions: There is hope that mHealth interventions in this population can be carried out using cell phones owing to their popularity; however, the interventions may need to employ methods that do not rely on the sending and receiving of text messages only.

Introduction

HIV/AIDS is now a manageable chronic illness owing to the widespread rollout of antiretroviral therapy (ART) [1]. Treatment and prevention of HIV/AIDS involves routine lifelong follow-up care and ongoing interventions to mitigate disease spread and improve treatment outcomes. Follow-up care involves scheduled visits for clinical reviews, medication receipt, laboratory testing, and psychosocial services including counseling and peer support groups. These visits normally involve a physical presence; however, the recent COVID-19 pandemic has made apparent the need for using mobile devices to assist in health and intervention delivery, known as mobile health (mHealth) [2]. mHealth has been studied as both an alternative to and a way to augment physical visits in the chronic care of people living with HIV/AIDS. Recent mHealth interventions for persons living with HIV include cell phone-delivered reminders to promote treatment adherence, motivational messages to encourage clinic attendance and ART adherence, delivery of laboratory tests, and behavior modification messages [3-5]. mHealth interventions may also bridge the service delivery gap during periods of interruptions in valuable HIV/AIDS services including lack of resources for transportation, or more recently, lockdown measures instituted to curb the spread of COVID-19, political unrest, or other epidemic outbreaks including Ebola.

In sub-Saharan Africa where two-thirds of persons living with HIV reside, cell phone access and use has greatly increased over the last decade from an ownership prevalence of 10% in the early 2000s to over 75% in 2019 [6]. In East Africa, cell phone use ranges from approximately 60% in Uganda to over 90% in Kenya [7,8]. Cell phone use gained popularity owing to the widespread coverage quality and ability to reach “everywhere” including resource limited remote areas and the low operational cost. This widespread usage and low cost have been tapped into for mHealth [9]. However, while there has been high enthusiasm for mHealth to improve HIV and other health outcomes, the results of cell phone-delivered interventions among persons living with HIV have been mixed [10,11]. Barriers to the implementation of mHealth interventions may include lack of infrastructure, concerns over privacy and confidentiality, usability issues [12], low level of literacy, low phone ownership, and cost of data to patients [13]. In order to determine the potential for cell phone-delivered interventions for persons living with HIV in low-resource settings, full understanding of cell phone ownership, active use (ie, duration for which a cell phone is kept on and used), and SMS (or texting) use of the targeted intervention population is important as persons living with HIV may differ from the general population in terms of their socioeconomic status and level of literacy [14].

In this analysis, we describe cell phone ownership and use in a cohort of persons living with HIV, who are coinfecting with latent tuberculosis (TB) in southwestern Uganda. We also

describe the association between alcohol use and cell phone use. Alcohol use and HIV are prevalent in sub-Saharan Africa. Alcohol use affects several HIV treatment outcomes, including ART adherence, viral suppression, and the development of opportunistic infections such as the activation of latent TB, all of which may fuel onward transmission of HIV [15-17]. Alcohol use is, however, a modifiable behavior that could potentially be positively impacted using mHealth interventions [18].

Methods

Setting and Population

This was a cross-sectional analysis of baseline data from a study of persons living with HIV who were recruited from a large HIV clinic in southwestern Uganda, entitled the Alcohol Drinkers' Exposure to Preventative Therapy for Tuberculosis (ADEPTT) study (registered under NCT03302299 in the ClinicalTrials.gov registry). The study was a single-arm prospective trial examining the safety, tolerability, and adherence to a 6-month daily isoniazid (INH) regimen among persons living with HIV who were coinfecting with latent TB, who recently consumed alcohol (two-thirds of the sample) or abstained from alcohol consumption (one-third of the sample).

Study Design

We conducted screening for the ADEPTT study using a multistep process. Eligibility criteria at the initial screening step included being an adult (≥ 18 years old) living with HIV, being fluent in Runyankole (the local language) or English, having been prescribed ART for at least 6 months, living within 2 hours' driving distance of or 60 km from the study site, having no plans to relocate from the catchment area, and having no history of active TB or taking TB preventive medications. Alcohol use eligibility additionally included self-reporting current (prior 3 months) alcohol use, or alcohol abstinence (no use in the prior year), with a target of enrolling 200 persons in the former and 100 persons in the latter category. Exclusion criteria are currently taking or having taken nevirapine in the prior 2 weeks, or taking anticonvulsant medications (both contraindications to INH). Further eligibility criteria included alanine transaminase (ALT) and aspartate transaminase (AST) levels being $< 2 \times$ their normal upper limits, being cleared of active TB (for those reporting TB symptoms), and not being pregnant. Finally, participants were screened for evidence of latent TB by research assistants trained in administration and interpretation of the tuberculin skin test (TST), latent TB was defined as a positive TST finding with an induration of ≥ 5 mm read 48-72 hours after injection with purified protein derivative (PPD). Those with positive TST results were invited to participate in the study. Data included in this analysis are baseline data.

All study participants were reimbursed for transport costs following completion of study procedures at each study visit.

Ethics Approval

The study was approved by the University of California, San Francisco Institutional Review Board (16-19093), the Mbarara University of Science and Technology Research Ethics Committee (11/10-16), and the Ugandan National Council for Science and Technology (HS2183). Participants provided written consent prior to study participation.

Measures

Data were collected using an interviewer-administered laptop-based survey using the Computer Assisted Survey Information Collection system. The surveys were conducted in private spaces, for confidentiality reasons, in Runyankole or English, depending on the participants' preference. Baseline blood draws were conducted for testing for a biomarker of alcohol use—phosphatidylethanol [19]. Phosphatidylethanol is a sensitive and specific marker of prior 3 weeks' alcohol consumption.

Outcome Variables

Overview

The primary outcome variable was cell phone use, a self-reported binary outcome defined as owning a cell phone and reporting that it was turned on for at least half of each day. Two secondary outcomes were frequent sending and receiving of text messages. Participants were asked 2 separate questions about how frequently they send and receive SMS text messages: several times per day, several times per week, rarely, or never. These were binary outcomes defined as “yes” if the participant self-reported sending and receiving text messages several times a week or more.

We categorized them as above because for mHealth interventions to be effective, participants need to have a working phone that is turned on most of the time and text messaging several times a week for SMS interventions to be useful.

Main Independent Variable

Alcohol use was assessed on the basis of self-report and Phosphatidylethanol levels. Participants were administered the Alcohol Use Disorders Identification Test—alcohol consumption questions [20], which was modified to ask about drinking in the prior 3 months. A score of ≥ 3 was considered indicative of an Alcohol Use Disorders Identification Test – Consumption positive status for women and ≥ 4 was considered positive for men [21]. For the main analyses, we defined alcohol use as any self-reported alcohol use in the last 3 months or a Phosphatidylethanol level of ≥ 8 ng/mL [22]. In exploratory analyses, we examined the level of alcohol use as a 3-level variable, defined as follows: “none” implying no self-reported alcohol use in the prior 3 months and a Phosphatidylethanol level of < 8 ng/mL, “moderate” implying any self-reported alcohol use in the prior 3 months but an Alcohol Use Disorders Identification Test – Consumption negative status and a Phosphatidylethanol level of ≥ 8 to < 50 ng/mL, and “heavy” implying an Alcohol Use Disorders Identification Test – Consumption positive status or a Phosphatidylethanol level of ≥ 50 ng/mL.

Covariates

We controlled for participant characteristics such as age, sex, literacy, level of education, household asset index, and organized religious activity because of their prior [23–26] or suspected associations with alcohol use and cell phone use. Level of literacy was assessed by asking the participants to read a sentence in the language they are most comfortable with; we considered those who were able to read all or part of the sentence to be literate. The household asset index (HHI) was created using principal component analysis (PCA) [27] and was based on durable goods, housing quality, and available energy sources. Cell phones were excluded from the list of durable goods included in the PCA. We dichotomized this measure as low (bottom 40%) and medium or high (top 60%) because of concern about small cell sizes in multivariable analyses.

We assessed organized religious activity by asking about the frequency of attending religious activities using the Duke University Religion Index [28], and categorized it as weekly or more versus less than weekly attendance of religious activity.

Statistical Analyses

We described sample characteristics using proportions for categorical variables and median (IQR) values for continuous variables. We used unadjusted and adjusted logistic regression models to examine associations with cell phone use (primary outcome), and sending and receiving text messages (secondary outcomes). The multivariable models controlled for the following potential confounders selected a priori: age, sex, literacy, HHI, and organized religious activity. In the multivariable model for frequent sending of text messages, we included education instead of literacy owing to a zero cell (ie, no one in the nonliterate group reported sending text messages frequently). Finally, we conducted exploratory analyses using the 3-level alcohol use variable rather than any alcohol use as the main independent variable of interest.

Results

Results Overview

A total of 1434 people were screened for the ADEPTT study. Main reasons for ineligibility included a history of active TB ($n=26$) or TB medications ($n=42$), elevated AST or ALT ($n=79$), and testing negative on the TST ($n=848$). Of the screened participants, 308 people were found to be eligible for enrollment. Six people declined enrollment, one was later found to be ineligible and was excluded, and one was missing cell phone use data; 300 participants were included in this analysis.

Of the 300 participants included, approximately half of them ($n=146$, 48.7%) were male and their median age was 40 (IQR 33–47) years (Table 1). The majority of the participants ($n=219$, 73.0%) had no more than primary school (6 years) education. Two-thirds ($n=199$, 66.6%) of the participants were either married or cohabiting. Approximately half ($n=158$, 52.7%) of the participants reported attending organized religious services at least once a week. The majority of the participants ($n=263$, 87.7%) were literate. By design, over two-thirds ($n=214$, 71.3%) of participants had consumed alcohol in the past 3 months.

^aAny alcohol use in the prior 3 months was defined as any alcohol use self-reported in the prior 3 months or a phosphatidylethanol level of ≥ 8 ng/mL.

^bLevel of alcohol use in the prior 3 months defined as follows: “none” implies no self-reported alcohol use in the prior 3 months and a Phosphatidylethanol level of < 8 ng/mL; “moderate” implies any self-reported alcohol use in the prior 3 months but an Alcohol Use Disorders Identification Test–alcohol consumption questions (AUDIT-C) negative status and a Phosphatidylethanol level of ≥ 8 to < 50 ng/mL; “heavy” implies an AUDIT-C positive status or a Phosphatidylethanol level of ≥ 50 ng/mL.

^cRisky sexual behavior implies having had unprotected sex with someone who was not a husband, wife, or steady partner during the participant’s most recent sexual encounter.

Cell Phone Use

The majority (n=267, 89.0%) of participants reported they had access to a cell phone; of them, 262 (98.1%) owned the phone and 26 (9.7%) shared the phone. The majority (n=262, 87.3%) of participants used a cell phone (owned a cell phone and had it on for more than half of the day; [Table 1](#)). In unadjusted analysis, any alcohol use was not significantly associated with cell phone use (odds ratio [OR] 0.76, 95% CI 0.34-1.67; $P=.49$)

([Table 2](#)). Adjusted analyses showed lower odds of cell phone use among those who consumed alcohol than among those who did not, although this did not reach statistical significance (adjusted OR [aOR] 0.48, 95% CI 0.18-1.25; $P=.13$).

We observed associations between literacy and cell phone use (aOR 4.15, 95% CI 1.74-9.89; $P<.01$) and also between middle or high HHI and cell phone use (aOR 8.03, 95% CI 3.26-19.79; $P<.01$).

^aLevel of alcohol use in the prior 3 months defined as follows: “none” implies no self-reported alcohol use in the prior 3 months and a phosphatidylethanol level of <8 ng/mL; “moderate” implies any self-reported alcohol use in the prior 3 months but an Alcohol Use Disorders Identification Test–alcohol consumption questions (AUDIT-C) negative status and a Phosphatidylethanol level of ≥8 to <50 ng/mL; and “heavy” implies an AUDIT-C positive status or a Phosphatidylethanol level of ≥50 ng/mL.

Text Message (SMS) Use

Over two-thirds (n=200, 66.9%) of the total participants reported rarely or never receiving text messages and the majority (n=269, 89.7%) reported rarely or never sending text messages (Table 1). Of those who had access to a cell phone (n=267), only one-third (99/267, 37.1%) reported frequently receiving text messages, while only (31/267, 11.6%) reported frequently sending text messages.

In adjusted analyses, any alcohol use was not significantly associated with frequent sending (aOR 0.82, 95% CI 0.28-2.37; $P=.71$) or receiving (aOR 1.31, 95% CI 0.70-2.47; $P=.40$) text messages (Tables 4 and 5).

Age was significantly associated with frequent sending of text messages (aOR 0.93, 95% CI 0.88-0.98; $P<.01$) but not with frequent receiving of text messages (aOR 0.98, 95% CI 0.95-1.00; $P=.09$) (Tables 4 and 5).

Discussion

Principal Findings

We evaluated cell phone ownership and use (frequency of sending and receiving text messages) in a cohort of persons living with HIV in HIV care, who were coinfecting with latent TB in Uganda. We also evaluated the association between alcohol use and cell phone use. The results showed a high prevalence of both cell phone ownership and use in this population. This is consistent with many other studies and surveys of cell phone access and use in Uganda [3,29] and in Africa [30]. This high prevalence of cell phone ownership may be largely attributed to the ease of use and relatively low cost of cell phones [11,31]. Persons living with HIV have been shown to find cell phones convenient as an mHealth tool [32] and have reported that it helps reduce transportation costs and still provides access to much needed health information [3]. We found high levels of cell phone use, indicating the potential utility of cell phone ownership in providing care and treatment for persons living with HIV, and as a tool that can be leveraged for mHealth and interventions.

In this analysis, alcohol use was not significantly associated with cell phone use. This finding held up in exploratory analyses examining the level of drinking. Our findings were different from a study conducted in Uganda among persons living with HIV in a fishing community that found that cell phone use was associated with alcohol use before sexual intercourse, although this was only among young females aged 14-24 years [26]. Other studies, conducted in high-resource settings, in the general population (ie, not focused on persons living with HIV) and among young persons, have found positive associations between alcohol use and cell phone use [33,34]. The differences observed may be due to the fact that in these other studies, the population was much younger than that in our study. In our study, the median age was 40 years while many of these studies were among younger persons. Younger persons may use cell phones for social reasons, including making plans for drinking and entertainment [35] with peers, while older persons may use cell phones more for economic reasons, as they have to provide for families and have more responsibilities; hence, we observed a lack of association with alcohol and instead observed an association with HHI and literacy. These findings suggest the

need to carefully evaluate the target population for cell phone-based interventions, and that these interventions should take into consideration the level of literacy and economic status of the population.

We also found that participants rarely sent or received text messages (approximately 30%). This was different from other studies, especially those conducted in middle- and high-resource countries where sending and receiving of text messages was high (60%) [36], but similar to a study among youths with HIV in Uganda (27%) [5]. A suggested explanation for the low text message use is the loss of novelty of sending or receiving text messages on a mobile phone in Africa [5] and therefore decreased use of the function. A great majority of the participants were literate; literacy was associated with frequent receiving of texts, and none of the persons who frequently sent text messages were nonliterate. While we could not include literacy in the model because no nonliterate person reported sending text messages; there was a strong effect of education with sending of text messages, which is consistent with prior reports [37,38]. We did not observe an association between any alcohol use and frequent sending and receiving of text messages; however, the exploratory analysis suggests that level of alcohol use may be associated with odds of frequent receipt of text messages. While cell phone use was high, using text messages alone as an mHealth intervention may not be effective, especially with interventions that require responses.

Limitations of the Study

This study was limited in the fact that the sample was selected for the main study enrollment purposes (ie, having latent TB); this may limit the generalizability of the study. However, we

did not observe any major differences between patients enrolled and those not enrolled when we analyzed major factors associated with one of the selection criteria (PPD+ skin test) [39]. Another limitation is that this study may have been underpowered to detect associations, as it was not designed to evaluate the relationships being examined. In a post hoc power calculation, we found the study would have approximately 80% power to detect an odds ratio of 0.34 or lower for the relationship between any alcohol use and any cell phone use, assuming 89% cell phone use among those without alcohol use as observed in our sample. The study was, therefore, likely underpowered to detect the magnitude of the association observed in this cohort.

Strengths of the Study

The strength of this study was that alcohol use was measured both by self-report and objectively by use of a biomarker to confirm actual alcohol use.

Conclusions

Many persons living with HIV own cell phones that are turned on for more than half of the day. There is, however, very little use of text messaging among persons living with HIV in this low-income setting.

There is hope that mHealth interventions in this population can be carried out using cell phones owing to their popularity; however, the interventions may need to employ methods that do not rely exclusively on the sending and receiving of text messages. Future mixed methods studies with large sample sizes should be conducted to further evaluate preferred alternatives to text messages such as interactive voice response and the relationship between alcohol use and cell phone use.

Abstract

Background: Hay fever is a highly prevalent, heterogenous, and multifactorial disease. Patients may benefit from longitudinal assessments using mobile health (mHealth) principles. We have previously attempted to establish an effective mHealth platform for patients with hay fever through AllerSearch, our in-house smartphone app that assesses electronic patient-reported outcomes through a questionnaire on hay fever and provides evidence-based advice. To be used by the public, an investigation on its reliability and validity is necessary.

Objective: The aim of this paper is to assess the reliability and validity of subjective symptom data on hay fever collected through our app, AllerSearch.

Methods: This study used a prospective observational design. The participants were patients aged ≥ 20 years recruited from a single university hospital between June 2, 2021, and January 26, 2022. We excluded patients who could not use smartphones as well as those with incomplete data records and outlier data. All participants answered the Japanese Allergic Conjunctival Disease Standard Quality of Life Questionnaire (JACQLQ), first in the paper-and-pencil format and subsequently on AllerSearch on the same day. The JACQLQ comprises the following three domains: Domain I, with 9 items on ocular or nasal symptoms; Domain II, with 17 items on daily activity and psychological well-being; and Domain III, with 3 items on overall condition by face score. The concordance rate of each domain between the 2 platforms was calculated. The internal consistency of Domains I and II of the 2 platforms was assessed using Cronbach alpha coefficients, the concurrent validity of Domains I and II was assessed by calculating Pearson correlation coefficients, and the mean differences between the 2 platforms were assessed using Bland-Altman analysis.

Results: In total, 22 participants were recruited; the data of 20 (91%) participants were analyzed. The average age was 65.4 (SD 12.8) years, and 80% (16/20) of the participants were women. The concordance rate of Domains I, II, and III between the paper-based and app-based JACQLQ was 0.78, 0.85, and 0.90, respectively. The internal consistency of Domains I and II between the 2 platforms was satisfactory (Cronbach alpha of .964 and .919, respectively). Pearson correlation analysis yielded a significant

positive correlation between Domains I and II across the 2 platforms ($r=0.920$ and $r=0.968$, respectively). The mean difference in Domains I and II between the 2 platforms was 3.35 units (95% limits of agreement: -6.51 to 13.2).

Conclusions: Our findings indicate that AllerSearch is a valid and reliable tool for the collection of electronic patient-reported outcomes to assess hay fever, contributing to the advantages of the mHealth platform.

KEYWORDS

hay fever; AllerSearch; smartphone app; mobile health; mHealth; patient-reported outcome; reliability; validity; Japanese Allergic Conjunctival Disease Standard Quality of Life Questionnaire; JACQLQ; questionnaire; allergic conjunctivitis

Introduction

Hay fever is currently believed to be the most common immunologic and allergic disease worldwide, with reports of nearly 30 million cases in the United States and Japan [1-3]. Hay fever symptoms can be chronic and therefore life altering, leading to a decrease in individuals' quality of life and work productivity [3]. This systemic illness targets multiple organs, most commonly manifesting as allergic rhinitis, conjunctivitis, and dermatitis [4,5]. The disease appears to evolve, changing its presentation with varying onsets, levels of severity, and responses to treatment based on the individual [3,4]. Therefore, a deeper understanding of the underlying pathophysiology and establishing an effective strategy to comprehensively assess changing symptoms become imperative to provide tailored, longitudinal care and to improve patients' quality of life [4-7].

Recent findings have increasingly confirmed the advantages of adopting patient-reported outcomes (PROs), which are clinical data grounded in patients' own subjective experiences that are not readily captured by routine medical evaluations [8,9]. With the recent advancements in mobile health (mHealth), a medical discipline centered around health care and support through advanced mobile devices such as smartphones, the electronic adaptation of PROs (ePROs) has been garnering attention as a novel data accrual option for clinical researchers [4,5,10-12].

We have previously taken advantage of the novel mHealth platform and conducted studies through our in-house hay fever smartphone app, AllerSearch, released in February 2018 [4,5]. The app successfully gathered comprehensive medical data related to hay fever without interrupting users' daily lives. By using data collected through AllerSearch, we were able to elucidate various risk factors that could exacerbate the disease, and we stratified the disease into subgroups based on collective symptoms and individual factors [4,5]. In our efforts to implement ePROs via AllerSearch, the app was equipped with features to administer hay fever symptom-related questionnaires, such as the Japanese Allergic Conjunctival Disease Standard Quality of Life Questionnaire (JACQLQ) [4,5,13,14]. Given the ongoing pandemic and the anticipated postpandemic era, the demand for longitudinal, nonintrusive health care continues to increase, and mHealth appears to hold the key to addressing this need. To realize such nonintrusive care that can also engage the principles of participatory medicine through mHealth, a robust validation of mHealth-accrued clinical data on subjective symptoms and their quantification strategies is required.

Hence, we evaluated the reliability and validity of the subjective symptom data collected through our mHealth app by conducting a comparative study between paper-based and app-based versions of the JACQLQ to evaluate the applicability of AllerSearch as a novel clinical tool for assessing hay fever.

Methods

AllerSearch Smartphone App

AllerSearch was initially developed in Japan using Apple Inc's open-source framework, ResearchKit [4,5], and released on Apple's App Store on February 1, 2018, under a consignment contract with Juntendo University Graduate School of Medicine and InnoJin, Inc, both based in Tokyo, Japan. The Android version was released on August 26, 2020. The AllerSearch is freely available on the App Store and Google play.

Design

This study employed a prospective observational design based on previously published validation studies of medical instruments [15,16].

Ethical Considerations

Written informed consent was obtained from all participants prior to the commencement of the study. The study was approved by the Independent Ethics Committee of Juntendo University Graduate School of Medicine (approval number H20-0242-H01, November 6, 2020) and adheres to the tenets of the Declaration of Helsinki.

Enrollment and Participants

The participants were patients aged ≥ 20 years, recruited between June 2, 2021, and January 26, 2022, from the Department of Ophthalmology, Juntendo University Hospital, Tokyo, Japan. We excluded patients who could not use smartphones as well as those with incomplete data records and outlier data.

All participants answered the paper-based JACQLQ at the outpatient service in the Department of Ophthalmology, Juntendo University Hospital. They subsequently answered the same questionnaire on an iOS version of AllerSearch (app-based JACQLQ) on the same day. AllerSearch had been preinstalled on the mobile phones provided for the purpose of this study. Our previous study contained the description of survey items in AllerSearch [4]. Briefly, participants provided electronic consent and basic information on demographics, medical history, lifestyle, hay fever status, and preventive behavior for hay fever. Subsequently, participants performed daily assessments of their conjunctiva and responded to a questionnaire on hay fever that

included the JACQLQ and assessments of nasal symptoms, nonnasal symptoms, daily subjective symptoms, and work productivity.

JACQLQ

The JACQLQ is a well-established metric that enables clinicians to comprehensively assess QOL among patients in the Japanese-speaking population who are affected by allergic conjunctival diseases [13]. The JACQLQ comprises the following three domains: Domain I with 9 items on ocular or nasal symptoms; Domain II with 17 items on daily activity and psychological well-being; and Domain III with 3 items on overall condition by face score. The questionnaire requires participants to rate each symptom on a 5-point Likert scale according to its severity, from “None” (0 points) to “Severe” (4 points). The total score (Domains I and II) for the scale and the total score of each domain was calculated as the sum of Domains I and II and the sum of items in each domain, respectively. Of note is that the default settings of the scale bar in AllerSearch, used to represent the 5-point scale, and the face score were both set to the lowest score, but users were able to adjust their ratings to higher scores as they deemed fit.

Statistical Analysis

The sample size for the Cronbach alpha test was predetermined based on the formula by Bonett [17]. Using these settings—power=90%, significance level=5%, number of items (k)=26, value of Cronbach alpha at null hypothesis=.0, and expected value of Cronbach alpha=.7—the required sample size was calculated to be 17.08 (rounded up to 18) cases. Accounting for 20% dropouts owing to missing data or withdrawal of consent, the final sample size was 22 cases.

Table 1. Participants’ characteristics (N=20).

Characteristics	Values
Age (year), mean (SD)	65.4 (12.8)
Gender, n (%)	
Female	16 (80)
Male	4 (20)
BCVA ^a , logMAR (SD)	-0.04 (0.07)
IOP ^b , mmHg (SD)	13.9 (2.6)

^aBCVA: best-corrected visual acuity.

^bIOP: intraocular pressure.

Scores and Concordance Rate of Paper-Based and App-Based JACQLQ

The median total score for Domains I and II was 6.5 (range: 1.75–13.25) for the paper-based JACQLQ and 4.5 (range: 1–8) for the app-based JACQLQ ($P=.003$). Table 2 shows each item’s

The median scores for the paper-based and app-based JACQLQ were compared using Wilcoxon matched-pairs signed-rank tests [18,19]. The concordance rate of each item and domain between the 2 platforms was calculated. The internal consistency of the app-based JACQLQ was assessed using Cronbach alpha coefficient, with an alpha score of $>.70$ considered acceptable [20]. Concurrent validity was assessed by calculating the correlations (Pearson coefficient) and mean differences (Bland-Altman analysis) [15,21].

Statistical analyses were performed using Stata/MP version 16.1 (Stata Corp) and GraphPad Prism version 9.1.2 (GraphPad Software). Statistical significance was set at $P<.05$.

Patient and Public Involvement

Input on the AllerSearch survey questionnaire was obtained to produce a version that was agreed upon by a committee comprising allergy specialists, ophthalmologists, otolaryngologists, epidemiologists, and the patient and public involvement members [4,5].

Results

Participant Characteristics

In total, 22 participants were recruited for this study. Following the exclusion of an individual with incomplete data records and another with outlier data, the data of 20 (91%) participants were analyzed. Table 1 shows the participants’ characteristics. The average age was 65.4 (SD 12.8) years, and 80% (16/20) were female participants. The mean best-corrected visual acuity value for both eyes was -0.06 (SD 0.05). The mean intraocular pressure was 13.9 (SD 2.6) mmHg.

median score and concordance rate for the paper-based and app-based JACQLQ. The individual total score of Domains I and II was significantly higher in the paper-based JACQLQ compared with the app-based JACQLQ. The concordance rates of each item, subscale, and domain were more than 70%.

Table 2. JACQLQ^a item scores and concordance rate between paper-based and app-based JACQLQ.

JACQLQ items	Paper-based JACQLQ, median (IQR)	App-based JACQLQ, median (IQR)	P value	Concordance rate (%)

^aJACQLQ: Japanese Allergic Conjunctival Disease Standard Quality of Life Questionnaire.

Reliability Between App-Based and Paper-Based JACQLQ

The internal consistency of the total, subscale, and domain scores between the paper-based and app-based JACQLQ is

indicated in [Table 3](#). Our results show satisfactory internal consistency for most questionnaire items (Cronbach alpha>.70), except for nasal symptoms in the app-based version (Cronbach alpha=.331).

Table 3. Reliability between the paper-based and app-based JACQLQ^a.

JACQLQ	No. of items	Cronbach alpha	
		Paper-based	App-based
Domains I and II	26	.964	.919
Domain I	9	.897	.746
Eye symptoms	5	.856	.788
Nasal symptoms	4	.776	.331
Domain II	17	.953	.896
Daily activity	11	.914	.915
Psychological well-being	6	.937	.731

^aJACQLQ: Japanese Allergic Conjunctival Disease Standard Quality of Life Questionnaire.

Correlation Between App-Based and Paper-Based JACQLQ

Figure 1 shows the correlation between the paper-based and app-based JACQLQ. There were significant positive correlations between the 2 measurements (Domains I and II: $r=0.971$, $P<.001$; Domain I: $r=0.920$, $P<.001$; and Domain II: $r=0.968$, $P<.001$). The x-axis indicates the total score for the paper-based

JACQLQ, and the y-axis the total score for the app-based JACQLQ.

Figure 2 shows the Bland-Altman analysis for the clinical agreement between the paper-based and app-based JACQLQ, revealing a difference (bias) with 95% limits of agreement of 3.35 (–6.51 to 13.2) units for Domains I and II, 1.85 (–3.05 to 6.75) units for Domain I, and 1.50 (–4.28 to 7.28) units for Domain II.

Figure 1. Correlation between the app-based and paper-based Japanese Allergic Conjunctival Disease Standard Quality of Life Questionnaires (JACQLQs). The correlation between the paper-based and app-based JACQLQs of Domains I and II, Domain I, and Domain II.

Figure 2. Bland-Altman plot for the paper-based and app-based Japanese Allergic Conjunctival Disease Standard Quality of Life Questionnaires (JACQLQs). The x-axis indicates the average of the 2 methods' scores, and the y-axis indicates the difference between the 2 methods' scores. The central line indicates the mean difference (bias) between the scores from the 2 methods, whereas the superior and inferior lines depict the intervals, which include the 95% limits of agreement. Differences between the JACQLQ of Domains I and II, Domain I, and Domain II.

Discussion

Principal Results

Hay fever, a highly heterogeneous and multifactorial disease, requires personalized assessments to develop effective preventive measures and management strategies. In this study,

we examined the reliability and validity of our smartphone app, AllerSearch, regarding collecting data on hay fever symptoms. Our results indicate that the digital administration of the JACQLQ through AllerSearch shows satisfactory reliability and validity metrics; AllerSearch may therefore be an accessible tool for hay fever management. Its accessibility may prove

advantageous for screening the undiagnosed population and promoting early, personalized interventions. The COVID-19 pandemic accelerated the breakthrough and subsequent growth of telemedicine and effective self-management. AllerSearch's ability to assist in the self-management of hay fever, with its extensive reach, aligns well with the aforementioned changing medical paradigm.

Our results show satisfactory internal consistency for most questionnaire items (Cronbach alpha > .70), except for nasal symptoms in the app-based version (Cronbach alpha = .331). Further, there were significant positive correlations between the 2 measurements (Domains I and II: $r=0.971$, $P<.001$; Domain I: $r=0.920$, $P<.001$; and Domain II: $r=0.968$, $P<.001$). These analyses yielded satisfactory results regarding the reliability and validity metrics of the app-based JACQLQ compared to the paper-based version, suggesting the role of ePROs in the future implementation of mHealth.

Our results also indicate that the app-based collection of nasal symptoms showed low internal consistency, which may lead to a discrepancy between nasal and nonnasal symptom assessments. However, nonnasal symptoms, as well as overall symptoms, maintained a high internal consistency, and the low internal consistency observed for nasal symptoms may be attributed to the small sample size in this study. Future efforts to increase power should be pursued to verify or improve on the observed low internal consistency for nasal symptoms.

Traditionally, in-person assessments have not proved very effective in comprehensive evaluations, mostly owing to the low frequency and time constraints of typical outpatient visits [22]. However, as hay fever presents itself as a heterogeneous, systemic disease with possible long-term detrimental effects, a holistic evaluation through established questionnaires, such as the JACQLQ, becomes crucial in selecting appropriate treatment regimens. Our findings revealed satisfactory internal consistency and a statistically significant correlation between the paper-based and app-based JACQLQ. It is noteworthy that the Bland-Altman plot analysis on the agreement between the paper-based and app-based JACQLQ resulted in a higher mean (bias) of 3.35 units (95% limits of agreement: -6.51 to 13.2) of the latter compared with the former. We believe that this is owing to a carryover effect stemming from the study design, in which a procedure of the study flow affects another downstream result [23]. We administered the app-based JACQLQ after the paper-based version, and future studies should address the discrepancy through a crossover trial with mixed cohorts on the questionnaire administration order.

Another explanation for the 3-point mean difference between the 2 platforms could be the length and order of the questionnaire items in the app-based version. Demographic and medical history questions preceded the JACQLQ, which might

have led to response fatigue [24], a frequently observed phenomenon with survey-type research methodologies. The app-based JACQLQ, by default, positions the scale bar for responses at 0, which may have predisposed fatigued users to quickly answer the JACQLQ items with a low score [25]. This could partially explain the higher score in the paper-based version, as it does not have a "default" score. For further validation of mHealth-driven ePROs and to minimize response fatigue, trials to reduce the number of questionnaire items and reorganize their sequence may be required. Although response fatigue can be addressed, it is practically inevitable; hence, we suggest that the psychological aspects and the resultant discrepancy based on the temporality of the answered items that may have affected the study's results should be considered. Future studies should also address the interface-led bias and discrepancies between the digital and paper questionnaires, one of which may call for a distinct cutoff score in the digital version for diagnoses and severity assessments. The 3-point mean difference, which does not appear highly relevant from a clinical perspective at this stage, and the consistent correlation between the 2 platforms suggest that ePROs collected through AllerSearch may be valid and feasible for assessing hay fever symptoms and advising on self-management.

Limitations

This study has several limitations. First, there may be a degree of selection bias stemming from the participants' demographics, including age and gender. This was also a single-center study, making the selection process prone to selection bias. Further, while there has not been a study, to the best of our knowledge, comparing paper-based and app-based questionnaires, this study had a smaller sample size in comparison to previous studies that investigated discrepancies between digital and paper questionnaires [18,24,26]. Therefore, greater sample sizes are needed for generalization. Lastly, this study did not involve any in-person clinical evaluations on allergic conjunctivitis and did not investigate the correlation of clinical findings with the JACQLQ results obtained through AllerSearch. Therefore, any capability of AllerSearch regarding allergic conjunctivitis diagnosis and screening should not be inferred from our results.

Conclusions

Our findings indicate that the data collected through the AllerSearch app had good internal consistency, with a Cronbach alpha of > .70 and significant positive correlations between the paper-based and app-based JACQLQ (Domains I and II: $r=0.971$; Domain I: $r=0.920$; and Domain II: $r=0.968$), as an instrument for hay fever symptom management. The mHealth-based PRO enables tailored, longitudinal data-based hay fever management and helps improve patients' quality of life.

Acknowledgments

We thank Drs Fujisawa K, Muto K, Nojiri S, Nagao M, and Okano M, and the members of our patient panel for advising us on how to improve our research project, and Medical Logue, Inc (Tokyo, Japan) for developing and releasing the Android and updated versions of AllerSearch.

Data Availability

All data generated or analyzed during this study are included in this published article.

Authors' Contributions

Abstract

Background: Heart failure (HF) is a major cause of frequent hospitalization and death. Early detection of HF symptoms using smartphone-based monitoring may reduce adverse events in a low-cost, scalable way.

Objective: We examined the relationship of HF decompensation events with smartphone-based features derived from passively and actively acquired data.

Methods: This was a prospective cohort study in which we monitored HF participants' social and movement activities using a smartphone app and followed them for clinical events via phone and chart review and classified the encounters as compensated or decompensated by reviewing the provider notes in detail. We extracted motion, location, and social interaction passive features and self-reported quality of life weekly (active) with the short Kansas City Cardiomyopathy Questionnaire (KCCQ-12) survey. We developed and validated an algorithm for classifying decompensated versus compensated clinical encounters (hospitalizations or clinic visits). We evaluated models based on single modality as well as early and late fusion approaches combining patient-reported outcomes and passive smartphone data. We used Shapley additive explanation values to quantify the contribution and impact of each feature to the model.

Results: We evaluated 28 participants with a mean age of 67 years (SD 8), among whom 11% (3/28) were female and 46% (13/28) were Black. We identified 62 compensated and 48 decompensated clinical events from 24 and 22 participants, respectively. The highest area under the precision-recall curve (AUCPr) for classifying decompensation was with a late fusion approach combining KCCQ-12, motion, and social contact features using leave-one-subject-out cross-validation for a 2-day prediction window. It had an AUCPr of 0.80, with an area under the receiver operator curve (AUC) of 0.83, a positive predictive value (PPV) of 0.73, a sensitivity of 0.77, and a specificity of 0.88 for a 2-day prediction window. Similarly, the 4-day window model had an AUC of 0.82, an AUCPr of 0.69, a PPV of 0.62, a sensitivity of 0.68, and a specificity of 0.87. Passive social data provided some of the most informative features, with fewer calls of longer duration associating with a higher probability of future HF decompensation.

Conclusions: Smartphone-based data that includes both passive monitoring and actively collected surveys may provide important behavioral and functional health information on HF status in advance of clinical visits. This proof-of-concept study, although small, offers important insight into the social and behavioral determinants of health and the feasibility of using smartphone-based monitoring in this population. Our strong results are comparable to those of more active and expensive monitoring approaches, and underscore the need for larger studies to understand the clinical significance of this monitoring method.

KEYWORDS

heart failure; mobile device; social interaction; heart disease; mobile health; hospitalization

Introduction

Although there are numerous attempts to monitor heart failure (HF) in an outpatient setting using wearables and other point-of-care devices, compliance is often an issue and prevents monitoring for extended periods [1,2]. One key sensor system many of us carry with us on a day-to-day basis is the smartphone, and this has been shown to lead to longer patient engagement times than has wearables [3]. In this pilot study, we hypothesized that we could leverage the data recorded on the personal smartphones used by a population with HF to predict decompensation.

We defined HF decompensation status based on worsened functional symptoms or physical examination findings suggestive of lower cardiac output or increased intracardiac pressures. This includes but is not limited to fatigue, dyspnea, hypotension, and lower extremity edema [4]. Treatment includes diuretics and vasodilators intended to improve volume status and cardiac function. Unfortunately, even following successful treatment and return to the euvolemic (normal volume status) state, decompensation episodes can continue to occur with increasing frequency [4,5]. Patil et al [6] reported that about 20% of the patient cohort were readmitted within 30 days of initial hospitalization due to HF, with a median readmission time of 12 days. Furthermore, patients with a lower income had a higher readmission rate, indicating that socioeconomic factors could also contribute to the disease's progression. If low-cost monitoring methods identify decompensation episodes developing outside the clinic, medical interventions could be administered proactively to prevent hospitalization or other adverse outcomes.

Various studies have investigated techniques for noninvasively monitoring patients with HF. Packer et al [7] showed that using a combination of clinical variables and impedance cardiography features could be a predictor of a decompensation event in the following 14 days. Previous studies have also investigated the use of wearable devices adhered to the chest. In the "Multisensor Monitoring in Congestive Heart Failure" study [8], the authors propose an algorithm that uses physiological signals, reporting a sensitivity of 63% and a specificity of 92%. However, the authors provide few details and claim it is "proprietary." Inan et al [9] recorded seismocardiogram signals with a noninvasive wearable patch before and after a 6-minute walk test to analyze the cardiac response to exercise. The authors used graph similarity scores between the rest and recovery phases and found a significant difference between compensated and decompensated groups. In another example, similarity-based

modeling was used with physiological signals from a patch on the chest to detect changes from the baseline. This algorithm had a sensitivity of 76% to 88% and a specificity of 85% [10]. Using ballistocardiogram data recorded at home was also investigated [11], and authors demonstrated that collecting high-quality ballistocardiogram data at home is feasible, and an area under the curve of the receiver operator curve (AUC) of 0.78 could be achieved for classifying clinical status.

Other noninvasive approaches include patient-reported outcomes, which could be collected using clinically validated questionnaires such as the Kansas City Cardiomyopathy Questionnaire (KCCQ). The KCCQ assesses the quality of life and predicts readmissions and mortality in patients with HF [12]. In a previous study, Flynn et al [13] reported that KCCQ has modest correlations with exercise capacity measured by the 6-minute walk test in a population with HF.

With the advancement of technology, smartphones have become a ubiquitous part of our daily life. For long-term monitoring, using a smartphone could be advantageous to a solution requiring an additional device by reducing the disruption to patients' normal daily routine. Our research team and collaborators have previously developed the Automated Monitoring of Symptom Severity (AMoSS) app, which is a custom and scalable smartphone-based framework for remote monitoring [14]. Subsequently, we used the passive data from the first 10 participants of this study to estimate the KCCQ surveys collected through the app [15]. The model estimated the KCCQ score with a mean absolute error of 5.7%, providing an entirely passive method of monitoring HF-related quality of life. (The method was passive in the sense that it does not require any active participation by either the patient or clinical staff beyond the everyday use of a mobile phone to monitor activity and behavioral patterns in the background using software.). In subsequent work, motion data were then used to classify decompensation or compensation events [16]. By using a hold-out test randomly sampled from 30% of the events (N=32), the AUC of the classifier was found to be 0.76.

In this study, HF decompensation events were predicted from features derived from passive and active data collected by the smartphone-based framework. Features were extracted from 3 passive data modalities (motion, location, and social interactions) and 1 active (clinical survey data: short KCCQ [KCCQ-12]). Algorithms based on using a single modality and 2 sensor fusion approaches were developed. An analysis of the feature importance in the model is also presented. Finally, a novel late-fusion model that combines the KCCQ-12, motion, and social contact data is proposed.

Methods

Data Collection and Ethical Considerations

Earlier research with the AMoSS app [14] was augmented for use in this study. The app passively collected 3D accelerometer data at a 5-Hz sampling frequency on location, clinical surveys, and digital social contact.

Ethical Considerations

All data were deidentified at the source (on the participants' phones) with hashed identifiers, and random geographic offsets were added to the location data to protect the participants' privacy. The data were stored in HIPAA (Health Insurance Portability and Accountability Act)-compliant Amazon Web

Services data buckets, and the phone app uploaded data periodically (based on connectivity) every few hours. Participants with HF enrolled in the ongoing study at the Veterans Affairs Medical Center and Emory University Hospital in Atlanta, GA, USA, signed a consent form prior to the beginning of the study. The study protocol was approved by the institutional review board (#00075867) at Emory University. The clinical team provided participants with an Android-based smartphone with the app installed during the enrollment. The participant could opt to stop sharing any data type during the study, using switches provided in the app. Figure 1 illustrates the study timeline after the participant is enrolled. The app passively collected data while the clinical team recorded the clinical events, which consisted of hospital visits with compensated or decompensated status during the enrollment.

Figure 1. Illustration of the study timeline. Passive data collection started after the hospital discharge, and the clinical team recorded the clinical events after the enrollment. HF: heart failure.

Data Collection

The data from 28 participants (25 males) who contributed at least 1 clinical event were used in this research. The inclusion criteria for participants in the study were the following: a diagnosis consistent with congestive HF as noted in the electronic medical records within the Emory Health Network, an age over 18 years, the ability to consent to a clinical study,

and English as their primary language. Exclusion criteria were the following: diagnosis with a terminal illness with a life expectancy of fewer than 6 months, enrollment in a hospice program, or enrollment in a clinical study that precluded them from participating in another clinical study. Finally, participants had to be willing and able to comply with the use of their smartphones as indicated in the study. Table 1 shows the detailed information about the participants included in the study.

Table 1. Data set description: if the metric is not available, the participant is excluded from that row.

Participant characteristics	Values (N=28)
Sociodemographics	
Age (years), mean (SD)	67 (8)
Male, n (%)	25 (89)
BMI, mean (SD)	31 (6)
Mean ejection fraction (%), mean (SD)	35 (17)
Employed, n (%)	3 (11)
Race/ethnicity, n (%)	
Black	13 (46)
White	15 (54)
Health factors, n (%)	
History of diabetes	18 (64)
Previous myocardial Infarction	2 (7)
History of hypertension	19 (68)
Previous stroke	4 (14)
Peripheral vascular disease	2 (7)
History of atrial fibrillation	8(29)
Other non-atrial fibrillation arrhythmia	3 (1)
Events	
Compensated, n	62
Decompensated, n	48
Compensated per person, mean (SD)	2 (1.8)
Decompensated per person, mean (SD)	2 (1.7)

Clinical Events

Clinical events consisted of decompensated and compensated events and were collected by the clinical team when the participants visited the hospitals. In the compensated events, the participants visited the hospital for any reason, and their fluid levels were determined to be normal based on the clinician assessment, which includes a history and physical examination. For the decompensated events, the clinical team determined the participant to have functional limitations related to HF. Decompensated and compensated events were assigned to positive and negative classes, respectively.

Passive Data Sources

The raw 3D accelerometer data were converted to activity counts using the Actigraphy Toolbox to reduce the required memory for storing [17]. In the first step, the z-axis of the accelerometer data was filtered using a band-pass Butterworth filter with a 0.25 to 11-Hz passband to eliminate extremely slow or fast movements [18]. The maximum values inside 1-second windows were then summed for each 30-second epoch to obtain the activity counts, following a previously described approach [19]. If the participant shared data for less than 0.1% of the analysis window, that window was considered missing. A common way for visualizing motion data in sleep studies to emphasize shifts

in sleep rhythms is using a “double plot” format (Figure 2). This figure illustrates the motion data for 1 participant over a recording period of 300 days, and the darker colors indicate lower-intensity movement. Each column consists of 2 consecutive days of data stacked together. The first column shows motion intensity levels on days 1-2, and the second column shows days 2-3, and so on. White regions indicate missing data, which could be due to the participant turning off the data sharing or the smartphone running out of battery.

Social contact data included the contact identifier (ID), directionality, and the duration of each call. Each contact was anonymized and assigned a unique ID at the source (on the phone by the app). The age demographics of our population were such that social media was not uniformly used across the population [20], and therefore, we chose not to capture it to avoid bias. We found that phone calls more so than SMS text messaging were used in our population for digital social interactions. Some participants did not use SMS text messaging at all. We therefore chose to focus on call log data. The phone call log is particularly appealing in an older demographic because it reflects the interactions of close and trusted entities, particularly those that may offer advice on health [21]. Moreover, call logs can be generalized beyond phone calls to any communication medium that is the primary social digital interaction point for close and critical contacts.

Figure 2. Double plot representation of actigraphy data illustrating daily motion intensity levels for 1 participant. Darker colors indicate lower intensity movement, and the white color indicates missing data. On the top of the plot, decompensated and compensated clinical events are shown with red and orange squares, respectively. Comp: compensated; Decomp: decompensated.

Figure 3 illustrates 1 participant’s social contact over 300 days for the 10 most frequently contacted IDs. Lastly, location data were collected using the Android location services app program interface, which generally used cellphone tower or Wi-Fi and not GPS for geolocation. Figure 4 shows the location data of a participant, collected from compensated and decompensated windows. High spatial resolution was not required since the aim was to identify the general environment in which a user

was located (eg, home, work, shops). If the smartphone moved at least 100 meters and at least 5 minutes had passed since the last location data update, a new relative location was recorded. These parameters were defined while designing the app to preserve battery life while still providing sufficient temporal and spatial resolution in comparison to the phone’s ability to geolocate without GPS. Figure 5 shows the kernel density estimate of 1 participant’s all-location data updates.

Figure 3. Participants' social contact intensity over 300 days. Each unique contact is assigned a number as shown in the y-axis, and the circle radius is proportional to the call duration to each ID. On the top of the plot, decompensated and compensated clinical events are shown with red and orange squares, respectively. Comp: compensated; Decomp: decompensated.

Figure 4. Location data collected in compensated (comp.) and decompensated (decomp.) windows for a participant shown on the same map with 50 km × 50 km dimensions.

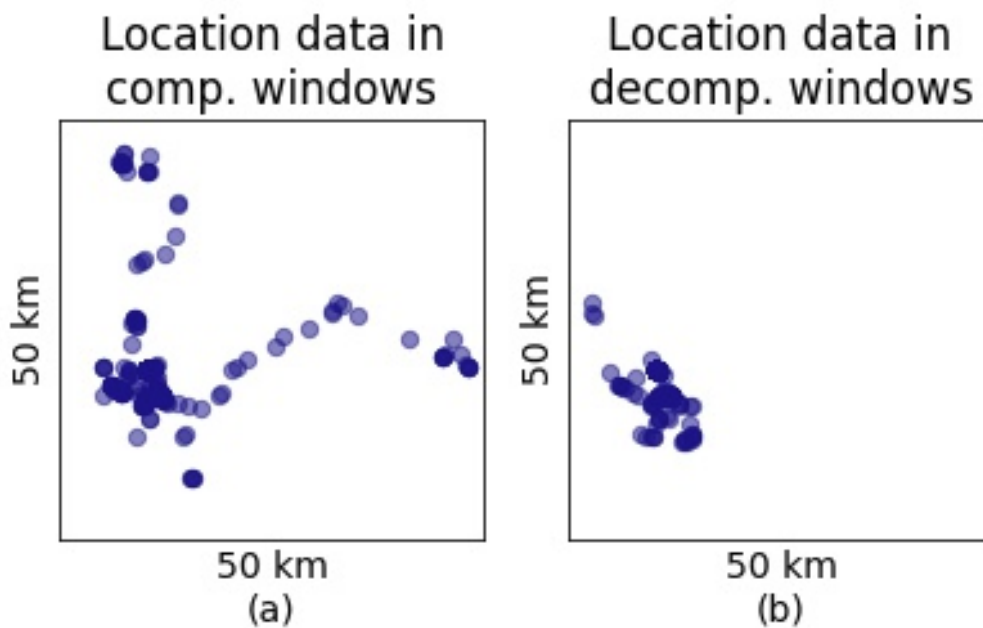

Figure 5. Kernel density estimate for the location data of 1 participant.

Active Data Sources

The active data type, which required user input, was the KCCQ administered through the smartphone app. The scores are lower for severe HF symptoms, and KCCQ scores ≤ 25 correspond to New York Heart Association class IV. In this study, we used the shorter version of the questionnaire, referred to as the

KCCQ-12 [22]. The KCCQ-12 survey had physical limitation, symptom frequency, quality of life, and social limitation domains, and the summary score (ranging from 0 to 100) was the average of all available domains. Figure 6 shows the KCCQ-12 scores administered through the app for a particular participant.

Figure 6. KCCQ-12 summary score over days for a particular participant. A KCCQ-12 score ≤ 25 indicates a transition to severe HF. Decompensated and compensated clinical events are shown with red and orange squares above the plot, respectively. Comp: compensated; Decomp: decompensated; HF: heart failure; KCCQ-12: short Kansas City Cardiomyopathy Questionnaire.

Feature Extraction and Temporal Windows

Several features were extracted for a particular time window from the data collected through the app to construct the motion feature set. A time window of data was the N day period before a clinical event, and the feature extraction was performed for each time window. The window size N was chosen to be 14 days initially since it was also selected by the developers of KCCQ-12 to represent the participant's recent functioning [12]. First, from preprocessed smartphone activity counts, descriptive statistics were extracted. These included mean (act_{mean}), SD (act_{std}), mode (act_{mode}), skewness (act_{skew}), and kurtosis (act_{kurt}). The completeness percentage (act_{comp}) was calculated by dividing the epochs with data by the total number of epochs in the time window. For each time window, the total number of calls ($numCalls$), the sum of the duration of calls ($durCalls$), the SD of the duration of calls ($durCalls_{std}$), the sum of time without any calls ($durNoCalls$), and the SD of time without any calls ($durNoCalls_{std}$) were calculated to be used as social contact features. For these 2 active data feature sets, the performance of using the mean of all surveys inside the window or using the most recent survey was also tested.

Using the participant's location data, the most frequently visited location was determined and defined as the "home" location. The number of times the participant was at the home location was calculated and used as a feature ($atHome$). For the second location feature, Haversine distances [23] between all locations to the home location were summed ($distToHome$). Finally, the area within a 2-km radius from home was defined as zone 1. The area outside of this radius was defined as zone 2. The

number of times the participant contributed from these 2 zones was calculated ($zone 1$ and $zone 2$, respectively).

From the KCCQ-12 data, 2 different sets of features were investigated. First, the summation score ($KCCQ-12_{sum}$) described in the Active Data Sources section was used as a feature. For the second set of features, each domain (physical limitation, symptom frequency, quality of life, and social limitation) of the KCCQ-12 survey was used separately ($KCCQ-12_{all}$).

Machine Learning Models

Logistic regression classifiers were trained to map the feature vector to the compensated or decompensated outcome. All the models were written in Python 3 language (The Python Software Foundation), and the programming code was based on scikit-learn [24]. Since each participant could contribute to more than 1 event, we used leave-one-subject-out cross-validation. The model was trained on the data from all participants except 1 hold-out participant, and this participant's data were used as the test set. This process was repeated for each participant in the data set.

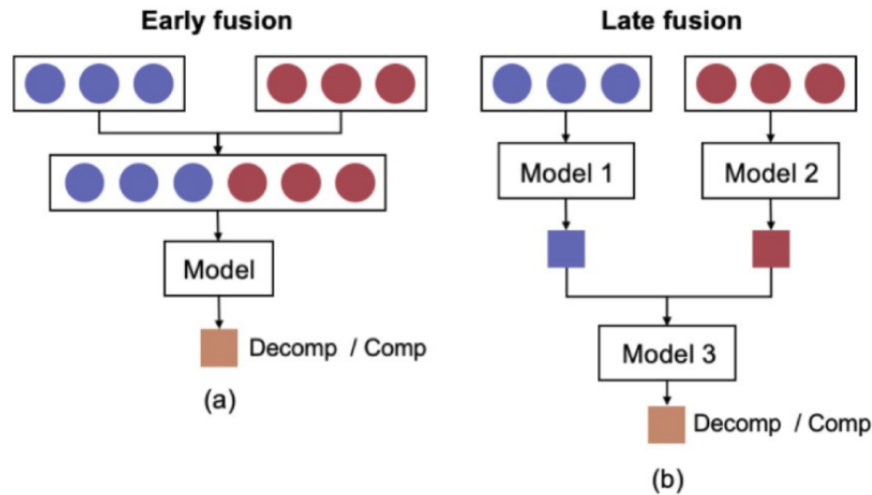

Since the number of compensated and decompensated events were highly imbalanced (Table 1), a majority undersampling was performed on the training set before training the classifiers. During the majority undersampling, all participants from the minority class were used, and the same number of participants from the majority class were randomly selected. Sequential forward feature selection was used to select the 3 most informative features from each modality.

Both early and late fusion approaches combined passive and active modalities (Figure 7). In the early fusion approach,

extracted features were combined at the input level of the classifier to create a single feature vector. For the late fusion approach, all single modality models' output probabilities were concatenated and used as input to another classifier. In all fusion

models, the participants who contributed with all data types were included in the analysis. Each analysis was repeated 50 times with different seeds. The mean and SD of the repeats were then presented as results.

Figure 7. Modality fusion techniques. Purple and red colors indicate 2 different modalities. The left side (a) shows the early fusion approach, and the right side (b) shows the late fusion of the modalities. comp: compensated; decomp: decompensated.

To examine and interpret the features further, Shapley additive explanation (SHAP) values for the early fusion model were calculated [25]. This framework is model agnostic, and SHAP values quantify the contribution and impact of each feature to the model.

Finally, we investigated how early the models can predict an outcome by implementing a time-to-event analysis and a window size analysis. The time-to-event methodology consisted of analyzing the performance of a model using data from only 1 day prior to the event but shifting which day is included in the analysis. The window size methodology consisted of analyzing different intervals of days prior to the event and evaluating the model performance on each window.

Results

Single Modality Model Results

The cross-validation performance for each single-modality model (motion, location, and social contact) is shown in Table 2. For these experiments, the time window was set to 14 days before each clinical event. The number of unique participants and the number of clinical events changed according to the modality since the participants could stop contributing data. For the motion model, 23 participants contributed with 28 decompensated events and 44 compensated events. For the social contact model, there were 21 participants with 27 decompensated events and 45 compensated events. Finally, there were 18 participants with 13 decompensated events and 33 compensated events for the location model.

Table 2. Passive data model performance results presented as the mean and SD of the external folds of each experiment.

Modality	Accuracy, mean (SD)	AUC ^a , mean (SD)	AUCPr ^b , mean (SD)	PPV ^c , mean (SD)	TPR ^d , mean (SD)
Motion	0.66 (0.03)	0.66 (0.03)	0.60 (0.06)	0.55 (0.04)	0.61 (0.06)
Location	0.59 (0.07)	0.56 (0.10)	0.39 (0.11)	0.34 (0.10)	0.49 (0.17)
Social	0.58 (0.05)	0.65 (0.05)	0.56 (0.06)	0.46 (0.06)	0.60 (0.07)

^aAUC: area under the curve of the receiver operator curve.

^bAUCPr: area under the precision-recall curve.

^cPPV: positive predictive value.

^dTPR: true positive rate.

Table 3 provides the single modality results for the active data type, the KCCQ-12 survey. The table shows the performance metrics when the mean of all the questionnaires within the 14-day window was used and when the most recent questionnaire was used for the 2 different active feature sets

(KCCQ-12_{sum} and KCCQ-12_{all}). For this active data type, 20 unique IDs contributed with 23 decompensated events and 32 compensated events. Using the summary KCCQ-12 score and taking the most recent questionnaire resulted in the highest area under the precision-recall curve (AUCPr) score of 0.69.

Table 3. Active data single modality model performance reported as the mean and SD of the external folds of each experiment.

Modality	Accuracy, mean (SD)	AUC ^a , mean (SD)	AUCPr ^b , mean (SD)	PPV ^c , mean (SD)	TPR ^d , mean (SD)
Mean of window

^fKCCQ-12_{sum}: summation scores for all short Kansas City Cardiomyopathy Questionnaire survey domains.

Fusion Modality Model Results

For the fusion model which combines KCCQ-12 and motion data, 17 participants contributed data for both modalities, with 21 decompensated events and 26 compensated events. When 3 modalities were used (KCCQ-12, motion, and social contact), 16 participants contributed with 18 decompensated events and 21 compensated events. Finally, when all data types were merged (KCCQ-12, motion, social contact, and location), there

were data available for 12 participants, with 10 decompensated events and 18 compensated events.

The results for the early fusion models are shown in [Table 4](#). For the late fusion models, the results are shown in [Table 5](#). The highest AUCPr of 0.77 was achieved when KCCQ-12, motion, and social contact modalities were combined with late fusion. For the early fusion models, using the same modalities resulted in an AUCPr of 0.69. The corresponding SHAP summary plot for the early fusion model is shown in [Figure 8](#).

Table 4. Results of early fusion models reported as the mean and SD of the external folds of each experiment.

Modality	Accuracy, mean (SD)	AUC ^a , mean (SD)	AUCPr ^b , mean (SD)	PPV ^c , mean (SD)	TPR ^d , mean (SD)

KCCQ-12 + motion + social + location	0.62 (0.07)	0.72 (0.07)	0.60 (0.11)	0.49 (0.07)	0.68 (0.10)

^aAUC: area under the curve of the receiver operator curve.

^bAUCPr: area under the precision-recall curve.

^cPPV: positive predictive value.

^dTPR: true positive rate.

^eKCCQ-12: the short Kansas City Cardiomyopathy Questionnaire survey.

Figure 8. SHAP summary plot for the early fusion model. Features are sorted by their impact on the y-axis. Each point on the plot shows the Shapley value for 1 instance. The horizontal location shows the feature’s effect for predicting positive class (decompensated) or negative class (compensated), and color indicates the feature value. SHAP: Shapley additive explanation.

Time-to-Event and Window Size Analysis

We investigated how early the algorithms can predict an outcome by shifting the days to the event and using different window sizes in days for each model in each category.

Figure 9 illustrates the AUC and AUCPr change of each model as the time in days to the event is increased. Only participants who contributed data during the time-to-event intervals and event type were included (n=13; with 13 decompensated events

and 18 compensated events). We observed a decrease in performance on the social contact modality when the time to event was 4 days. However, the motion model performance peaked at 4 days to the event. The best model was the late fusion model with a prediction window of 2 days prior to the event (Figure 9). This best model had an AUC of 0.83, an AUCPr of 0.80, a positive predictive value (PPV) of 0.73, a sensitivity of 0.77, and a specificity of 0.88. The 4-days-ahead model had a similar but lower performance with an AUC of 0.82, a AUCPr

of 0.69, a PPV of 0.62, a sensitivity of 0.68, and a specificity of 0.87.

Figure 9. Performance changes as the days to events are shifted. The x-axis indicates the time to event in days, and the y-axis indicates the AUC and AUCPr performance. Early fusion and late fusion models combine KCCQ-12, motion, and social contact modalities. AUC: area under the curve of the receiver operator curve; AUCPr: area under the precision-recall curve; fus: fusion; KCCQ-12: the shot Kansas City Cardiomyopathy Questionnaire.

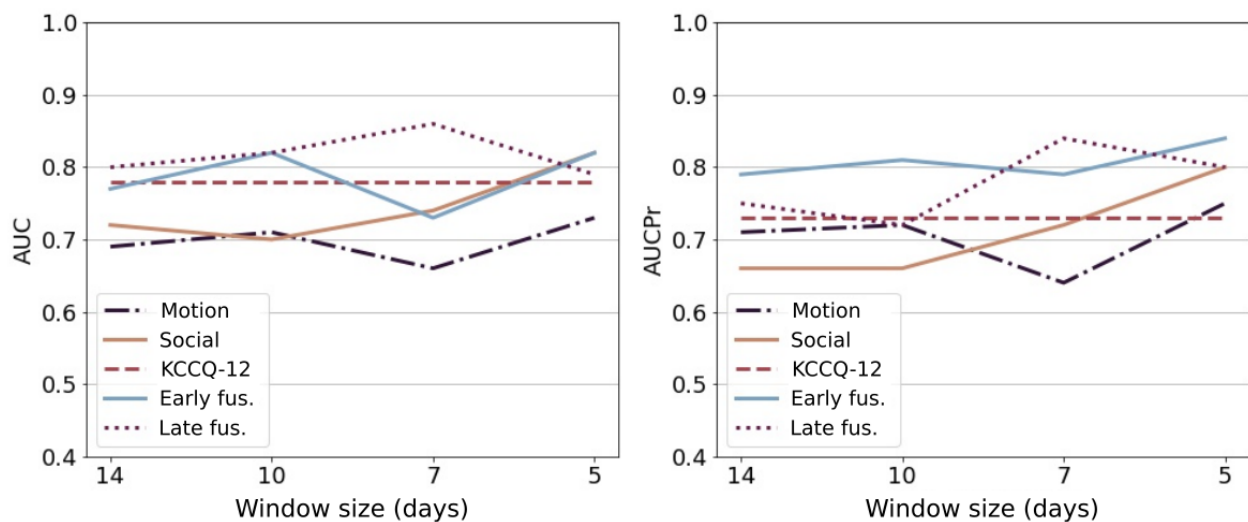

Figure 10 illustrates the performance of the models when the window size is increased. Participants with all the window size data and event type were included (n=11; 12 decompensation events and 15 compensation events). We observed that the

performance of the KCCQ-12 model was similar across all window sizes. However, the performance of the social contact model improved as the window size decreased.

Figure 10. Performance changes as the window size is reduced. The x-axis indicates the time to event in days and the y-axis indicates the AUC and AUCPr performance. Early and late fusion models use KCCQ-12, motion, and social contact modalities. AUC: area under the curve of the receiver operator curve; AUCPr: area under the precision-recall curve; fus: fusion; KCCQ-12: the shot Kansas City Cardiomyopathy Questionnaire; win: window.

Discussion

Overview

In this proof-of-concept study that involved tracking HF status with smartphone technologies, we showed that it is feasible to collect information from self-reported surveys and passive monitoring that are clinically relevant in classifying compensated versus decompensated status. This study is a first of its kind to evaluate 3 passive data modalities (motion, location, and social interactions) and 1 active data modality, the KCCQ-12 survey. We tested both individual and combined

active and passive metrics, and showed that each of them individually and in combination may be potentially useful in helping predict HF decompensation up to 6 days in advance of the clinical encounter.

Principal Findings

Next-day prediction algorithms were built using each modality separately. From the passive data sources, the motion data-based model achieved the highest AUCPr of 0.60. For a model based only on the responses of the KCCQ-12, using the summary of all domains and using the most recent score resulted in the best performance with an AUCPr of 0.74 (Table 3). Combining both

passive and active data modalities achieved a superior performance compared to models based on passive or actively collected data alone (see [Tables 4 and 5](#)). The highest performing model combined KCCQ-12, motion, and social contact data. Using the late fusion approach achieved a 6% higher AUCPr compared to early fusion when 3 modalities were used. Late fusion summarizes each modality and presents a lower-dimensional vector to the final classifier [26]. Therefore, this method could reduce the chances of overfitting and addresses the curse of dimensionality when the sample size is small. An AUC of 0.83, an AUCPr of 0.80, a PPV of 0.73, a sensitivity of 0.77, and a specificity of 0.88 for this model may indicate that the approach could potentially add clinical interventions into the framework and result in a low number of false alarms.

[Figure 8](#) illustrates the feature importance using the SHAP method. Duration and number of calls were among the most informative features, indicating that the dynamics of social interactions could be affected by the disease status. The SHAP summary plot also indicates that a higher duration but fewer calls results in a higher probability of HF decompensation for the model. Another important feature was the KCCQ-12 summary value, and a lower value of this parameter gave rise to higher SHAP values. The SHAP plot also indicated that higher mean smartphone motion intensity resulted in a higher probability of HF, which was unexpected since HF limits daily physical activity and is often associated with fatigue.

When different time-to-event horizons were tested, a general trend of lower performance for longer future predictions was observed. This was expected since symptoms are likely to become more pronounced closer to the event. However, predictions 2 days ahead were actually better than those 1 day ahead, and the performance 4 days ahead was almost as good as that 1 day before the event. This indicates that 1-day, 2-day, and 4-day models could be run simultaneously to identify short- and medium-term risks and result in different levels of intervention. Changes in performance will be affected by the levels of missingness as the event approaches, as well as the intrinsic behaviors, which may explain the performance of the 2-day window.

Comparison With Other Work

Our proof-of-concept study suggests that low-burden, smartphone-based methods of monitoring in HF may offer modest incremental predictive value. The accuracy of our models was similar to earlier work that used mobile health sensors [10] although the lead time was less. We obtained similar results with a late fusion model with a sensitivity of 77% and a specificity of 88% two days prior to the event. However, only a modest reduction in performance was seen for a 4-day prediction window, particularly using motion only, suggesting that running multiple models for different prediction windows may be appropriate. Similarly, the Link-HF study reports a sensitivity of 76% to 88% and a specificity of 85% in a median time of 6.5 (IQR 4.2-13.7) days prior to HF readmission [10]. Although the lead time is lower in our study (2 vs 6.5 days), the costs and burden are lower as well. Two-day advanced alerts may still accelerate care and trigger earlier treatments than may

usual care although more research is needed. Any reduction in delays of care with proactive monitoring and intervention may reduce the overall HF burden; nonetheless, the impact on costs and mortality remain to be explored. Because this is the first study of its kind, our primary focus was on the discovery of novel social and behavioral metrics that help to understand the biopsychosocial mechanisms underlying HF. As such, it underscores the need for larger studies aimed at training and testing models with larger lead times and the potential to reduce HF readmissions with sufficient statistical power.

Limitations

There are several key limitations to this study. First, when the data were missing, the app did not indicate whether this resulted from the participant closing the app voluntarily or if it resulted from the smartphone battery running out. These behaviors have different etiologies, which may be related to impending decompensation in different ways. For example, closing the app may indicate being tired, whereas a battery running out of charge may indicate apathy connected with depression. If an additional label is collected for missing sections, it could be used to learn other behavioral patterns. Second, text messages and social media can provide a more complete picture on social contact. However, due to the age demographics of our population, social contact was quantified using only phone call information [20]. Despite the limited data, our results showed a strong association with decompensated HF status and phone call information. Third, even though each participant contributed many days, the study's sample size was relatively small (N=28 participants), and, therefore, the methods should be further validated in a larger cohort. Finally, the reliance on hospital records rather than on independent examination of participants might have led to misclassification. We cannot rule out the possibility of unmeasured confounders in those who did and did not experience decompensation events, and our limited sample size restricted our ability to examine this as well. The small sample size also restricted our ability to examine differences by age and HF severity. Nevertheless, we were able to show the feasibility of combining passive and active features extracted from a mobile device to predict HF events. Our findings provide good evidence that we should perform a larger confirmatory study.

Conclusions

Our proposed novel smartphone-based approach for noninvasively monitoring patients with HF may help monitor health status changes through changes in movement, location, social interactions, or a combination of these. Many of these features are new discoveries and suggest important mechanisms of disease that have previously been less explored. Due to the ubiquity of smartphones and the ease of scalability of the framework, our method has the potential to facilitate low-cost monitoring of large populations. However, we note that this is a preliminary study on a relatively small population, and before it can be validated, a larger study is required. In addition, other passive monitoring devices (such as movement sensors in the house, electricity usage monitors, and home alarm systems) may provide additional useful information on the changes in behavior leading up to an intervenable event. Moreover, in

future work, the feasibility of combining the proposed method with clinical interventions (such as teleconsultations and drug dose modification) will need to be investigated to measure the potential impact of the framework described in this paper.

Abstract

Background: Self-help interventions have the potential to increase access to evidence-based mental health care. Self-help can be delivered via different formats, including print media or digital mental health interventions (DMHIs). However, we do not know which delivery format is more likely to result in higher engagement.

Objective: The aims of this study were to identify if there is a preference for engaging in print media versus DMHIs and whether there are individual differences in relative preferences.

Methods: Participants were 423 adults between the ages of 18 and 82 years (201/423, 47.5% female) recruited on *Prolific* as a nationally representative sample of the US population, including non-Hispanic White (293/423, 69.2%), non-Hispanic Black (52/423, 12%), Asian (31/423, 7%), Hispanic (25/423, 6%), and other individuals (22/423, 5%). We provided individuals with psychoeducation in different self-help formats and measured their willingness to use print media versus DMHIs. We also assessed participants' demographics, personality, and perception of each format's availability and helpfulness and used these to predict individual differences in the relative preferences.

Results: Participants reported being more willing to engage with print media than with DMHIs ($B=0.41$, $SE\ 0.08$; $t_{422}=4.91$; $P<.001$; $d=0.24$, 95% CI 0.05-0.43). This preference appeared to be influenced by education level ($B=0.22$, $SE\ 0.09$; $t_{413}=2.41$; $P=.02$; $d=0.13$, 95% CI -0.06 to 0.32), perceived helpfulness ($B=0.78$, $SE\ 0.06$; $t_{411}=13.66$; $P<.001$; $d=0.46$, 95% CI 0.27 - 0.66), and perceived availability ($B=0.20$, $SE\ 0.58$; $t_{411}=3.25$; $P=.001$; $d=0.12$, 95% CI 0.07 - 0.30) of the self-help format.

Conclusions: This study suggests an overall preference for print media over DMHIs. Future work should investigate whether receiving mental health treatment via participants' preferred delivery format can lead to higher engagement.

Introduction

Background

Mental health disorders are the leading cause of disability worldwide [1]. However, the demand for mental health services has consistently exceeded the supply, and in recent times, this demand has continued to increase [2,3]. Therefore, innovative delivery of interventions that do not require the presence of a mental health professional may be one way of addressing the supply-demand gap. Cognitive behavioral therapy (CBT), for example, has shown efficacy across a variety of self-help formats [4].

Self-help Interventions

Self-help can be guided (ie, a self-help intervention with support by a trained professional or paraprofessional) or unguided (ie, self-guided, with no support). Guided self-help has been found to be more effective than unguided self-help [4]. However, unguided self-help has a greater potential for large-scale dissemination [5,6], and it is more effective than control conditions including care as usual or being allocated to a waiting list [5]. Self-help CBT can be delivered in many formats, including digital mental health interventions (DMHIs) that use smartphone apps, web pages, or other web-based formats to deliver the intervention. DMHIs can be highly accessible, with a wide range of resources publicly available on the internet [6]. While DMHIs are a promising way to reduce the public health burden of untreated depression and anxiety, users are currently being inundated with information and options for web-based self-help, most of which are not evidence-based [7]. Additionally, internet access and technical difficulties can be barriers to engaging with DMHIs [8,9].

Self-help interventions can also be delivered through written and print media, which is usually known as bibliotherapy. Meta-analytic reviews suggest that self-help delivered via print media is an effective delivery format [10]. Bibliotherapy is a promising model for disseminating CBT and other empirically supported treatments because it is effective, reasonably cheap, and circumvents the technological barriers associated with internet-based self-help interventions.

Although previous studies have established the efficacy of print media self-help and DMHIs when compared to treatment as usual and other controls for reducing depression [11,12], few studies have explored individuals' preferences for different delivery formats. Furthermore, even fewer studies have investigated how individuals might differ in their preference to use one format over the other. Individual differences may be especially relevant for understanding engagement with self-help since these interventions tend to suffer from low engagement rates [4]. Thus, it is essential to understand which factors could increase the likelihood of individuals engaging in self-help interventions.

Treatment Preferences

According to the Theory of Planned Behavior (TPB) [13], attitudes, norms, and perceptions can be used to predict behaviors such as treatment-seeking and engagement. Different studies have tested this theory, confirming a strong relationship

among attitudes, intention, and behavior [14]. In psychotherapy, for example, willingness to engage in treatment has been hypothesized to be a proxy for treatment-seeking [15]. Thus, attitudes toward the use of one format over the other could potentially be used to test which type of self-help format users would be more likely to engage with.

Furthermore, it is possible that certain sociodemographic traits could influence the preference for one treatment format over another. For example, younger individuals might be more strongly influenced by attitudes to engage with newer technologies than older individuals, who are influenced more by perceived behavioral control and subjective social norms [16]. In addition, other variables such as education and race could potentially impact the preference for print media versus DMHIs. For example, prior research has suggested that racial and ethnic minorities are less likely than non-Hispanic White individuals to seek and receive treatment owing to barriers such as stigma, health care engagement, and policies [17]. Thus, self-help might potentially be an alternative for individuals who are less likely to engage in traditional care, though it is unclear whether one self-help format would be preferred to the other. The broader literature on treatment engagement points to the role of variables including the presence of distress, maladaptive emotion regulation strategies, and personality as being predictors of engagement in treatment.

This Study

Our first objective was to explore the relative attitudes of individuals toward the use of self-help in print media (ie, bibliotherapy) versus an internet-based format (ie, DMHIs). We explored this question by providing individuals with psychoeducation on self-help and measuring their willingness to use bibliotherapy versus internet-based self-help, the perceived availability of the format, and its perceived helpfulness. Our second objective was to identify whether demographic and attitudinal variables predicted willingness to use one intervention over the other. We included variables related to treatment outcomes and engagement such as psychological distress, personality, and self-efficacy. We also added a COVID-19–related question to assess whether the pandemic influenced the outcomes.

Methods

Recruitment

Participants were adults over 18 years of age recruited via *Prolific* (N=423)—a web-based participant panel shown to be an effective way of collecting high-quality data from diverse participants for research purposes [18]. The sample was stratified by *Prolific* to be representative of the US population in terms of age, sex assigned at birth, and race/ethnicity according to the US Census Bureau. The study was advertised as being about “preferences for mental health treatments” and hosted on the Qualtrics website.

Ethical Considerations

The study was approved by the internal review board of the University of Pennsylvania (843424). All participants had to consent to the study by reading the informed consent form and

clicking that they consented to participate before commencing the survey. The informed consent form included information on the purpose of the study, future use of the data, possible risks, and researchers' contact information. Participants were compensated with US \$5 for their time.

Measures

Treatment Attitudes

Participants were presented with basic information regarding different treatment alternatives, including print media and internet-based self-help. Print media was described as "self-help books designed by psychologists and mental health professionals that include information and exercises designed to help people learn skills that improve their mental health or well-being." DMHIs were described as "websites, computer programs, or smartphone apps designed by psychologists and mental health professionals. These tools include information and exercises designed to help people learn skills that improve their mental health or well-being. In unguided online self-help programs and smartphone apps, individuals learn content from a website or an app on their own."

After reading about each treatment option, the survey asked about their willingness to try the intervention (ie, "If I were seeking support for my mental health or well-being, I would be willing to try this option"), perceived efficacy (ie, "I believe this option could be helpful for people looking to improve their mental health or well-being"), and perceived availability of the intervention (ie, "I believe this option is available and accessible for people looking to improve their mental health or well-being"). Responses to the questions about willingness, efficacy, and availability were rated on a 7-point Likert scale (1=strongly disagree, 7=strongly agree) [19].

Psychological Distress

We measured psychological distress using the Kessler Psychological Distress Scale (K6) [20]. The K6 is a 6-item scale assessing internalizing distress (ie, nervousness and depression) by asking participants to rate on a 4-point scale how often they have experienced negative affect symptoms over the past month (0=none of the time, 4=all of the time). Scores ranged from 0 to 24, with higher scores indicating higher distress. Specifically, scores of 6 may indicate mild distress, and scores of 13 may indicate more severe distress. The K6 has been validated and demonstrated to have criterion validity [21] and was an internally consistent measure of internalizing distress in a nationally representative sample ($\alpha=.89$) [20,22].

Expressive Suppression

We measured expressive suppression using the suppression subscale of the Emotion Regulation Questionnaire (ERQ-SUP) [23]. This is a 6-item subscale assessing participants' habitual use of expressive suppression by asking participants how much they agree with specific statements (eg, "I keep my emotions to myself") on a 7-point scale (1=strongly disagree, 7=strongly agree). Scores ranged from 4 to 28, with higher scores representing higher habitual use of suppression. The ERQ-SUP has been validated and shown to have criterion validity [24] and internal consistency ($\alpha=.76-.96$) [25].

Personality

We assessed the Big-Five personality traits (ie, neuroticism, extraversion, agreeableness, conscientiousness, and openness) using the Ten Item Personality Inventory (TIPI) [26]. This is a 10-item scale assessing personality traits with 5 bipolar factors representing extraversion, agreeableness, conscientiousness, emotional stability, and openness to experience. The measure contains 2 descriptors for each pole of all 5 personality dimensions. Each of these is rated using a 7-point scale (1=disagree strongly, 7=agree strongly). After reverse coding, the mean for each of the 5 personality dimensions were used as subscales. The TIPI has been validated and demonstrated to have adequate factor structure, convergent validity [27], and internal validity ($\alpha=.40-.73$) [26].

Self-efficacy

We also measured self-efficacy using the General Self-Efficacy Scale (GSF) [28]. This is a 10-item scale assessing participants' general sense of perceived self-efficacy by asking participants how much each specific statement feels true (eg, "I can usually handle whatever comes my way") on a 4-point scale (1=not at all true, 7=exactly true). Scores ranged from 10 to 40, with higher scores representing higher perceived self-efficacy. The GSF has been validated and shown to have criterion and internal validity ($\alpha=.75-.91$) [29].

Effect of the COVID-19 Pandemic

The survey also asked participants how the COVID-19 pandemic has affected their willingness to consider mental health treatment options that are not delivered in person. Participants could choose between "more likely," "less likely," and "no change" regarding their willingness to engage in other forms of treatment.

Statistical Analyses

All analyses were conducted using R [30] with the RStudio graphical user interface [31]. First, we present descriptive statistics to characterize the sample, including mean (SD) values for continuous variables and n (%) values for categorical variables. Our first objective was to determine whether participants, on average, were more willing to use print media or DMHIs. To explore this question, we conducted a paired sample *t* test, which tests if the within-person difference in preferences was significantly different from 0. With a sample size of 423 participants, the study was powered at 80% to detect minor differences (ie, $d=0.14$) at $P<.05$. We also report differences in the perceived efficacy and availability of print media and DMHIs. Our second objective was to determine whether baseline demographic and clinical variables affected the willingness to use print media versus internet-based self-help. Because there is very little theoretical or empirical work on preferences for print media versus DMHIs, we used a machine learning algorithm to select variables that could serve as individual differences in willingness to use print media versus DMHIs. Specifically, we used a model-based recursive partitioning with random forests to help us identify subgroups of observation with different parameters to the basic model, which describes the overall within-person difference in preference for print media versus internet-based self-help. In other words, this procedure allowed us to identify potential

predictors of the difference in willingness to use print media versus DMHIs [32]. A significant moderator of this relationship would imply that different subgroups of individuals differ in the extent to which they prefer print media versus DMHIs. Model-based recursive partitioning using random forests explores potential moderators by bootstrapping to identify the most influential moderators. We tested 1000 bootstrap samples. We used model-based recursive partitioning for variable selection because it has been successfully used in studies of individual differences in psychological interventions. The method is able to assess a large number of variables, test nonlinear relationships, and ultimately corresponds well with our research question (ie, whether the overall difference in preference is moderated by third variables).

The variables that were selected as candidate moderators were then entered into a linear regression predicting differences in willingness. To assess whether other attitudinal variables contributed to differences in willingness, we added differences in perceived availability and perceived helpfulness to the regression model with demographics, personality, and clinical variables.

Results

Demographics

Participants were 423 adults between the ages of 18 and 82 years (201/423, 47.5% female). The sample was representative of the US population, except that we undersampled American Indian or Alaskan Native and Pacific Islander individuals, who were not present in the sample (Table 1).

Table 1. Demographic characteristics of a nationally representative sample of 423 Prolific users.

Variables	Values
Age (years), mean (SD)	45 (16)
Gender identity, n (%)	
Male	213 (50.4)
Female	201 (47.5)
Gender-queer or gender non-conforming	9 (2.1)
Sexual orientation, n (%)	
Heterosexual	361 (85.3)
Not heterosexual+	62 (14.6)
Race, n (%)	
Non-Hispanic White	293 (69.3)
Non-Hispanic Black	52 (12.3)
Asian	31 (7.3)
Hispanic	25 (5.9)
Other	22 (5.2)
Education, n (%)	
Postgraduate	96 (22.7)
Bachelor's degree	163 (38.5)
High school or less	164 (38.8)
Yearly income (US \$), mean (SD)	71,000 (49,000)
Expressive suppression (Emotion Regulation Questionnaire)	2.85 (1.41)
Psychological distress (Kessler Psychological Distress Scale score), mean (SD)	6.77 (5.77)
Self-efficacy (General Self-Efficacy Scale score), mean (SD)	2.13 (.56)
Agreeableness (Ten Item Personality Inventory [TIPI] score), mean (SD)	5.30 (1.28)
Conscientiousness (TIPI score), mean (SD)	5.26 (1.40)
Extraversion (TIPI score), mean (SD)	3.38 (1.64)
Neuroticism (TIPI score), mean (SD)	4.68 (1.70)
Openness (TIPI score), mean (SD)	5.13 (1.27)
Perceived helpfulness of digital mental health interventions, mean (SD)	4.73 (1.33)
Perceived availability of digital mental health interventions, mean (SD)	5.67 (1.27)
Perceived helpfulness of print media, mean (SD)	5.11 (1.21)
Perceived availability of print media, mean (SD)	6.03 (1.07)

Overall Preference

On average, participants reported higher willingness to use print media (mean 4.77, SD 1.82) rather than DMHIs (mean 4.37, SD 1.81). Comparing the within-person difference in willingness to use print media versus internet-based self-help revealed a significant but small preference for print media ($B=0.41$, SE 0.08; $t_{422}=4.91$; $P<.001$; $d=0.24$, 95% CI 0.05-0.43). Most participants reported being more willing to use print media (178/423, 42.1%) than DMHIs or no preference (159/423,

37.5%). Few preferred to use DMHIs than print media (86/423, 20%).

Predictors of Willingness

We explored whether baseline variables moderated the preference for print media over DMHIs using model-based recursive partitioning via random forests. The variable importance plot ranked neuroticism, conscientiousness, expressive suppression, and participants' gender, race, and education as the top predictive variables (Figure 1).

Figure 1. Variable importance plot for variables predicting willingness to engage in print media rather than internet-based self-help, representing mean decreases in accuracy when removing each variable. TGNC: transgender or gender non-conforming.

The variables identified by the MobForest algorithm were then included in a multiple regression as predictors of willingness to use print media over DMHIs. Including these variables yielded a significant overall regression model ($R^2=0.43$, $P=.03$). This model suggested that greater education is associated with a higher willingness to use print media over DMHIs ($B=0.22$, $SE\ 0.09$; $t_{413}=2.41$; $P=.02$; $d=0.13$, 95% CI -0.06 to 0.32). Across all but the lowest education levels (ie, high school or less), participants preferred print media DMHIs, and this preference was strongest among the most educated participants. Furthermore, identifying as Black (vs Non-Hispanic White) suggested a greater preference for print media to internet-based self-help ($B=0.49$, $SE\ 0.25$; $t_{413}=1.92$; $P=.06$; $d=0.29$, 95% CI 0.09 - 0.48).

Attitudes as Predictors of Willingness

We added attitudinal variables, namely differences in the perception of the helpfulness and availability of print media versus DMHIs to the linear model. When adding these variables to the regression model, race and education were no longer significantly associated with willingness to use print media versus internet-based self-help ($R^2=0.40$, $P<.001$). Perceived differences in helpfulness were strongly associated with the willingness to use print media versus DMHIs ($B=0.78$, $SE\ 0.06$; $t_{411}=13.66$; $P<.001$; $d=0.46$, 95% CI 0.27 - 0.66). The perceived availability of print media versus DMHIs also affected willingness to use, though these effects were smaller ($B=0.20$, $SE\ 0.58$; $t_{411}=3.25$; $P=.001$; $d=0.12$, 95% CI 0.07 - 0.30).

Discussion

Principal Findings

Our main findings indicate that most participants were more willing to use print media rather than DMHIs. This preference appeared to be influenced by education level, perceived availability, and perceived helpfulness of the DMHI. Specifically, higher perceived helpfulness had the most

substantial effect on participants' willingness to use print media rather than DMHIs. Furthermore, a higher education level was associated with a stronger preference for print media than for DMHIs.

Sociodemographic Predictors of Willingness to Engage

Previous research has suggested an association between lower education and a higher risk of symptom deterioration when engaging in DMHIs [33]. Thus, regardless of the format, making materials more understandable and engaging for individuals with lower education might be an important avenue for research. It is also important to note that age was not associated with the preference for print media over internet-based self-help. Previous research has suggested that younger individuals may be more likely to engage in newer technologies based on attitudes [16], such as perceived helpfulness or availability. Race was also associated with preferences. Specifically, Black individuals reported a stronger preference for print media than for DMHIs. However, this association was weak and requires further research.

Attitudes

The perceived helpfulness and availability of the self-help intervention format seem to be useful for understanding a participant's willingness to engage in self-help. Our finding alludes to a stronger preference toward print media because participants perceive it as potentially more helpful. These data could be used to improve efforts to engage individuals in treatment and personalize treatment allocation on the basis of individual preferences. In other words, willingness to use internet-based self-help could be optimized by using the information on the efficacy of internet-based self-help versus that of print media. According to the TPB, willingness to engage in treatment can be used as a proxy for treatment-seeking [34,35]. Thus, the relationship between attitudes and willingness to engage in self-help interventions could have potential implications for future efforts to increase use and engagement in evidence-based self-help interventions. Additionally, it is

possible that engagement with DMHIs could be improved if individuals had print media to support their use of DMHIs.

Limitations, Strengths, and Future Directions

Before interpreting the results of this study, several limitations are worth noting. First, although *Prolific* data appear to be of higher quality than those obtained from college student samples and from other web-based panels, the possibility of a selection bias affecting our results cannot be ruled out. Indeed, existing data suggest that individuals in web-based panels tend to be more depressed than the average adult in the United States. It must be noted that while this means that our sample is different from a representative US sample, it is not clear whether this would bias our findings. Our primary question is with regard to the differences between print media and DMHIs. We may nonetheless expect that people in a web-based panel may have stronger preferences for DMHIs than for print media given that they are already engaged with online tools such as *Prolific*.

Additionally, we measured self-reported willingness to use different self-help formats and not actual engagement with the content. Although willingness has been found to predict engagement, it is not a perfect predictor of actual behavior. Furthermore, we did not measure other aspects of the TPB including subjective norms and perceived behavioral control. Finally, although the sample was broadly representative of the US population, it undersampled American Indian or Alaskan Native and Pacific Islander individuals. Nevertheless, several strengths are worth considering. First, the study was powered to detect minor differences that may have practical implications, for example, for large-scale dissemination of self-help resources. Additionally, we measured a variety of individual differences

and used machine learning to identify factors that could be germane to treatment engagement.

One logical future direction is to test whether willingness to engage in treatment can predict actual engagement in treatment and how perceived helpfulness influences this relationship. Therefore, future studies could test whether providing education on the efficacy of interventions could increase participants' willingness to use them. Another alternative would be to test whether allocating patients to their preferred format could lower dropout rates, as our study suggested individual differences in preferences for the different interventions [36]. While DMHIs have received attention over the past couple of years, our results suggest that individuals may be more interested in print media. The combination of DMHIs with print media could be a potential avenue to explore to increase engagement with self-help materials.

Conclusions

Self-help interventions have the potential to improve access to mental health resources. Although there is great excitement for DMHIs, it is essential to remember that this is not the only available format. This study revealed an overall preference for print media over internet-based self-help, which seems to be related to the perceived helpfulness of the format. These findings indicate possible future targets for interventions to increase treatment-seeking and reduce dropout rates. These findings are especially important for self-help interventions that suffer from a high dropout rate [5]. Therefore, to optimize the usability of self-help interventions, we need more studies to confirm the association among self-help delivery formats, attitudes, and engagement in the interventions.

Acknowledgments

We thank the participants for their time and thoughtful responses. This research was partially funded by the National Institute of Mental Health (grant T32 MH103213-06) and grant numbers KL2TR002530 and UL1TR002529 (A. Shekhar, principal investigator) from the National Institutes of Health, National Center for Advancing Translational Sciences, Clinical and Translational Sciences Award, which provided support for LLL. The work was also supported by the Global Mental Health Fellowship through the American Psychological Association (APA) and the International Union of Psychological Science (IUPsys).

Conflicts of Interest

Abstract

Background: Mobile health (mHealth) interventions for self-management are a promising way to meet the needs of patients with chronic diseases in primary care practices. Therefore, an mHealth intervention, TelePraCMan, was developed and evaluated for patients with type 2 diabetes mellitus, chronic obstructive pulmonary disease, high blood pressure, or heart failure in a German primary care setting. TelePraCMan entails a symptom diary, an appointment manager, a manager to document goals, and a warning system. The app should foster the self-management of participating patients.

Objective: We aimed to examine the effects of TelePraCMan on patient activation and quality of life and explored the underlying contextual factors, impacts, and degree of implementation.

Methods: In a prospective observational study design, we collected data by using interviews and written questionnaires from participating patients (intervention and control groups) and primary care workers (physicians and practice assistants). The primary outcomes of interest were patient-reported quality of life (12-Item Short Form Survey) and patient activation (patient activation measure). The quantitative analysis focused on differences between patients in the intervention and control groups, as well as before (T0) and after (T1) the intervention. Interviews were analyzed by using qualitative content analysis via MAXQDA (VERBI GmbH).

Results: At baseline, 25 patients and 24 primary care workers completed the questionnaire, and 18 patients and 21 primary care workers completed the follow-up survey. The patients were predominantly male and, on average, aged 64 (SD 11) years (T0). The primary care workers were mostly female (62%) and, on average, aged 47 (SD 10) years (T0). No differences were observed in the outcomes before and after the intervention or between the intervention and control groups. In the additional interviews, 4 patients and 11 primary care workers were included. The interviewees perceived that the intervention was useful for some patients. However, contextual factors and problems with implementation activities negatively affected the use of the app with patients. The main reasons for the low participation were the COVID-19 pandemic and the target group, which seemed to have less interest in mHealth; the interviewees attributed this to the older age of patients. However, the respondents felt that the app would be better accepted in 5 or 10 years.

Conclusions: Although the TelePraCMan app was rated as very good and important by the participants, few patients used it. The digital intervention was hardly implemented and had limited impact in the current setting of German primary care.

KEYWORDS

telemedicine; multimorbidity; primary health care; symptom assessment; chronic disease; mobile phone

Introduction

Background

An increasing number of people have ≥ 2 chronic conditions (multimorbidity) [1]. Meeting the needs of patients with multimorbidity poses a challenge for health care systems, especially for primary care [2]. Policy makers and health care workers have shown interest in telehealth's potential for the diagnosis, treatment, and prevention of health problems [3] as well as self-management support [4]. Self-management and self-management support for patients with multimorbidity is complex because of the effects of various diseases and emotional distress. Therefore, innovative care delivery models are required. Mobile health (mHealth) interventions are expected to provide self-management support interventions, which can be tailored to individual needs [5].

Previous research in various patient populations has shown mixed effects of mHealth tools for self-management support [4,5]. A review concluded that through enhanced symptom control, the use of mHealth apps has the potential to improve health outcomes in patients with multimorbidity [5]. A metareview concluded that telehealth is seen as a safe option for the delivery of self-management support, especially for the management of heart failure and type 2 diabetes, but the evidence was inconsistent for other conditions. However, they showed that findings of successful components in the interventions were limited and inconclusive [4]. Another review concerning the combination of mHealth and health coaching for improving self-management in chronic care showed that mHealth and health coaching interventions benefit from each other as well as patients still tend to prioritize human contact. The authors thereby concluded that it is desirable to personalize health technology [6]. A systematic review of reviews also showed that most effective technology-based interventions in improving diabetes self-management combined a feedback loop that connected patients and their health care team using 2-way communication, analyzed patient-generated health data, tailored education, and individualized feedback [7]. The results show that although telehealth interventions enhance self-management, communication and interactions with health care professionals are crucial for patients with chronic diseases, and a combination of both is important.

Furthermore, few studies explored the acceptance and actual use of mHealth interventions by older adults in Germany and the effects of their use on patient-reported outcomes such as patient activation and health-related quality of life. Previous studies on older multimorbid patients have shown that further research is needed for a successful integration of the interventions in patients' everyday life and in the workflow of primary care practices [8-10].

Objectives

Therefore, we developed and evaluated the TelePraCMan intervention, which aimed to support the self-management of patients with multimorbidity and enhance their quality of life. We examined the effects of TelePraCMan on patient activation and quality of life and explored the perceptions of practitioners on TelePraCMan. Concomitantly, a process evaluation was

undertaken to understand and explore the context, impacts, and implementation process.

Methods

Study Design

The developed mHealth app TelePraCMan was tested for 12 months (October 2019 to September 2020) as part of a multicenter randomized controlled study in 10 primary care practices in Baden-Württemberg. Patients, physicians, and practice assistants received a questionnaire at baseline and follow-up. As we did not reach the recruitment targets, we report on the outcome evaluation descriptively. In addition, we conducted a process evaluation in the form of a qualitative interview study and further questions in the questionnaire with these three groups alongside the randomized controlled trial, which is the primary focus of this study. For these reasons, we report the results of the randomized controlled study as well as the process evaluation and refer to the study design as a prospective observational study.

Recruitment and Sampling

Only practices using the case management program PraCMan [11] for at least 6 months were invited to participate in the study. Approximately 130 practices were contacted via letter, fax, email, or telephone. These practices were selected based on their geographic location and their practice size as well as on the consisting contacts of the research team. First, they were sent a reply form. After the expression of interest, the practices received an information leaflet, a consultation on the phone, and further information documents on the study implementation. After signing a consent form to participate in the study, an appointment was made for a brief training session lasting approximately 90 minutes, during which the study procedure, patient recruitment, and use of the app in the context of care were explained in detail.

The target group of the study was patients enrolled in the case management program PraCMan. These patients had type 2 diabetes mellitus, chronic obstructive pulmonary disease, high blood pressure, or heart failure. Other inclusion criteria were understanding German, being able to give consent, aged >18 years, and having a smartphone or tablet in the household. Eligible patients in the participating practices were addressed by the practice assistants, informed about the study, and asked for their interest.

If the patients were interested in participation, they were informed about the study verbally and in written form and were asked to sign an informed consent form. Patients were randomly assigned to either the intervention or control group. The patients were then given recruitment envelopes that had been prepared for the practices by the study center in Heidelberg. The envelopes included either the documents for use of the app in the intervention group or documents for study participation in the control group. The randomization was performed by lottery within the study center. The envelopes were constructed to look similar in both groups. The practice staff members were not informed about the order. Both envelopes included information leaflets, bank forms for the expense allowance, an initial

questionnaire (T0) for the baseline survey, as well as a short information on the next steps for patients and the practice team to simplify study conduction.

The process of patient recruitment was documented by the practice staff in screening lists. The day, the number of patients, and the respective outcome of the recruitment (whether the patient participates) were recorded in these lists. If patients did not wish to participate, the reason for nonparticipation was also recorded.

Of the 130 invited practices, a total of 10 practices with 24 physicians and practice assistants in T0 and 21 in T1 took part in the quantitative study. Of the 141 patients who were asked to participate, 25 completed the quantitative survey in T0 and 18 completed the follow-up survey in T1.

Intervention

TelePraCMan Development

TelePraCMan was developed and programmed by the Department of General Practice and Health Services Research at the Heidelberg University Hospital. In addition to PraCMan, an established model for structured management of chronic diseases in primary care [11,12], TelePraCMan was developed to foster self-management and can be used by practices that regularly use PraCMan and their patients who are subscribed within the PraCMan program. Primary care physicians, medical practice assistants with further training (VERAH [Versorgungsassistent/in in der Hausarztpraxis]), and patients were involved in the development of TelePraCMan via focus groups, interviews, and questionnaires. To adapt the app to the demands of the target group, one survey covered smartphone use and technology affinity to gain knowledge of user requirements before and during the app development process [13]. After evaluating the results, the app was adapted and now contains an appointment manager, a manager for target agreements, and the possibility for general practices to access the symptom data via remote access to TelePraCMan, in addition to the initial basic symptom diaries. TelePraCMan is a web-based app. This means that the app is not installed locally on a user's smartphone or tablet. Instead, data processing takes place on independent web servers (of University Hospital Heidelberg) and access is realized via a web browser on the user's smartphone or tablet, which means that an internet connection is required to use the app.

TelePraCMan Features

The main features of this app includes symptom diaries for 4 chronic diseases (type 2 diabetes mellitus, chronic obstructive pulmonary disease, high blood pressure, or heart failure). Patients can record values of blood pressure, blood sugar, weight, or mental health conditions in the symptom diaries. Further features of the app included a decent warning system (including what to do and who to contact in an emergency) whenever one of these symptoms or values exceeded the specified thresholds, an appointment manager, a manager for target agreements, and the possibility for primary care practices to access the symptom data via remote access. Within the home page of the app, a daily overview was provided including shortcuts to quickly get to upcoming tasks. The completed tasks were then automatically ticked off within the daily overview. The app was programmed as a browser-based app, so that it did not have to be downloaded and fulfilled the data protection regulations. Some figures of the main features of the app are included in [Multimedia Appendix 1](#).

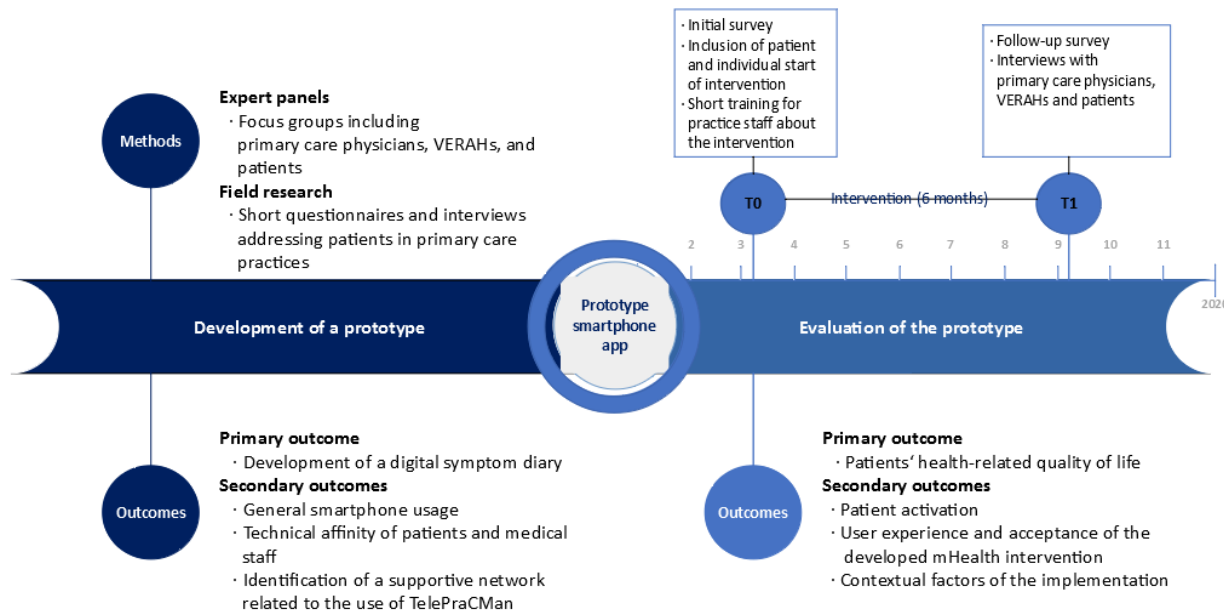

Study Intervention

Patients who were assigned to the intervention group received access to data for using the app in addition to the general study documents. Using a checklist in advance, practice staff and patients determined the frequency and time points at which the patients should document their symptoms or values. Furthermore, the primary care physicians specified thresholds for individualized values (such as the highest or lowest tolerable blood pressure) and documented these in the named checklist. For the first use of the app, the checklist provided guidance on how to individualize the app for themselves.

After the initial setup of the app, patients could use it for 6 months. Patients also continued to receive their usual treatment according to the PraCMan standard guidelines [11]. Before the monitoring appointments, patients could voluntarily transfer the recorded symptoms and values to the practice so that they could be included in the appointments for further treatment planning.

Patients assigned to the control group continued to receive treatment according to the PraCMan standard care guidelines. In addition to regular monitoring appointments, this also included the use of paper-based symptom diaries to document values and symptoms, which is one key element in PraCMan [11]. Patients in the control group were also included in the study for 6 months. [Figure 1](#) presents an overview of the study.

Figure 1. Study overview. VERAH: Versorgungsassistent/in in der Hausarztpraxis. T0: before the intervention; T1: after the intervention.

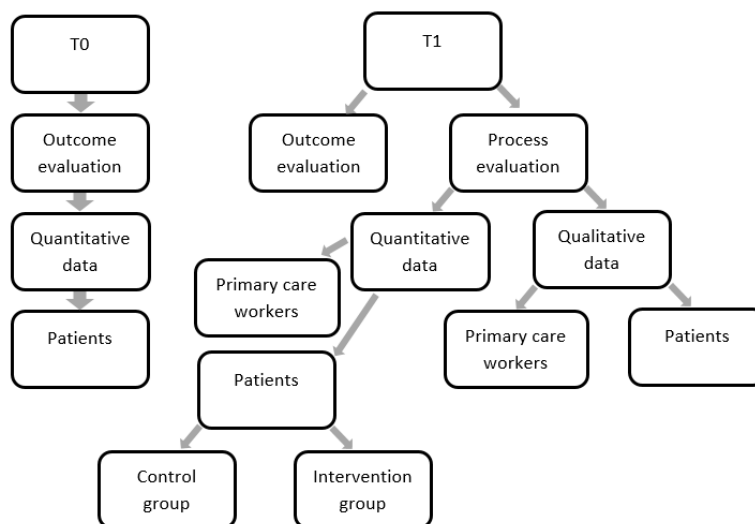

Data Collection and Measures

Overview

Quantitative data were collected before and after the intervention was applied. Data collection at T0 (baseline) took place at the start of the individual intervention for the practices after they had agreed to participate in the study. After the training session, practices received a written survey. Patients also received a

written survey at the start of the intervention together with the study documents. Data collection at T1 (follow-up) was performed at the end of the intervention; that is, after 6 months. For practice staff, the T1 survey was administered at the end of the study in September 2020 or after the end of the intervention when the last patient was included. Patients again received a written survey, which was distributed via the practice at the end of the intervention. Figure 2 visualizes the data collection structure.

Figure 2. Data collection structure. T0: before the intervention; T1: after the intervention.

Outcome Evaluation

For the outcome evaluation, we collected data via a written survey in the patient sample at baseline T0 and T1 (follow-up). We measured health-related quality of life using the 12-Item Short Form Survey (SF-12 [14,15]) and patient activation using the patient activation measure (PAM) [16].

The SF-12 consists of 8 subscales that were transformed to a scale from 0 to 100, and the mean value was calculated in each

case. In a sample [17], which is representative for Germany, the mean value of each scale is 50 points with an SD of 10 points. To improve comparability of data, the scales were standardized by a z-transformation and then transformed linearly (mean 50, SD 10). Using exploratory factor analysis, the 8 subscales were condensed into two superordinate scales: physical health (physical component summary [PCS]) and mental health (mental component summary [MCS]). The two scales were linearly transformed to a mean of 50 and an SD of 10 [15].

Patient activation was measured using the PAM-13D. Each statement is rated by respondents on a response scale of 1 to 4 (German version), where 1 stands for “disagree strongly” and 4 for “agree strongly.” To calculate the PAM scores (from 0 to 100), the German response options were converted to the standardized metric (0-100). Higher scores indicated that the patient is more activated. On the basis of these scores, the patients were divided into levels. At level 1, patients may not understand their role in making decisions about their health and are more passive. Level 4 patients are able to manage their health on their own but may have problems doing so in stressful situations [16].

Process Evaluation

For the process evaluation, we also collected data via the written survey and additional interviews. We measured the evaluation of the TelePraCMan app via the User Experience Questionnaire (UEQ) [18] at T1 in the patient sample. We measured the perceived opportunities and barriers to using TelePraCMan in primary care practices at T0, as well as perception, use, and workload of TelePraCMan in primary care practices at T1 in the primary care worker sample.

Analyzing the user experience data, we used the UEQ Data Analysis Tool version 7 (UEQ Team [19]). The tool calculates the scale means and the mean and SD for each item. It groups the 26 items to create scores for six domains of attractiveness, perspicuity, efficiency, dependability, stimulation, and novelty. The mean scores were calculated for each domain. Values between -0.8 and 0.8 represent a more or less neutral evaluation of the corresponding scale, values >0.8 represent a positive evaluation, and values <-0.8 represent a negative evaluation [18].

A self-administered questionnaire was used to measure the perception and use of TelePraCMan among the practice staff. The questionnaire was based on the technology acceptance model and was tested within the interprofessional study team. It consisted of 21 questions for measurement at T0, which were divided into 5 subscales. The five subscales were as follows: “Perception and use of the VERAH-portal,” “Assessment in relation to the patients concerned,” “Changes brought by TelePraCMan for the patients,” “Workload in the practice,” and “General assessment.” The measurement at T1 consisted of 30 questions, which were divided into 7 subscales. The 5 subscales from the measurement T0 were taken over and extended by the subscales “Ease of use in patients” and “Training”. Each statement was rated by the practice staff from “strongly disagree” (score of 1) to “strongly agree” (score of 5). Mean values were calculated for each subscale, which ranged from 1 (minimum) to 5 (maximum). Values <2.5 stand for a negative evaluation, values of 2.5 to 3.5 for a more or less neutral evaluation, and values >3.5 stand for a positive evaluation.

Additional interviews were conducted with patients and practices after the end of the intervention. The interview guidelines were developed within the project team. Semistructured interviews included questions about the use of the app TelePraCMan, the feasibility of the app, and questions about the integration of the app into everyday (practice) life and about its practicability. All interviews were conducted via telephone between May 2020

and October 2020. The average length of the interviews was 30 minutes (range 13-53). All interviews were digitally recorded with consent of the participants and transcribed verbatim.

Data Analysis

Descriptive statistics were calculated for all variables included in the quantitative analysis to examine means, SD, distribution for continuous variables, and frequencies for categorical data. For this analysis, we excluded the technological affinity questionnaire and a patient support questionnaire.

To examine changes in mean PAM scores and SF-12 scores before and after the intervention, we conducted a paired *t* test (2-tailed). To examine if there is a difference in the control and intervention groups after the intervention, we conducted an unpaired *t* test. $P<.05$ was considered significant in all analyses. All analyses were performed using SPSS (version 25.0; IBM Corporation).

A deductive-inductive content analysis approach was used to analyze the interview data. A preliminary category system was developed deductively based on the CFIR (Consolidated Framework for Implementation Research [20]) and the interview guide used. To inductively identify additional themes, all transcripts were read thoroughly by 3 members of the research team (AB, NL, and LG). Subsequently, all interviews were coded line-by-line using the deductively formed category system, and additional themes were inductively added where appropriate. The analyses of the three coders were compared and modified if necessary. All data were managed and analyzed using MAXQDA (version 20; VERBI GmbH).

The STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) guideline was used for reporting this study [21].

Ethics Approval

Ethics approval was obtained from the Medical Ethics Committee of the Medical Faculty of Heidelberg University (S-092/2019) before the start of the study. All participants provided written informed consent before participating in the study. Research conducted in this study was performed in accordance with the Declaration of Helsinki. The study was registered in the German Clinical Trial Register (DRKS00017320).

Results

Demography

A total of 27 patients were included in the study, of whom 25 completed a questionnaire at baseline T0 and 18 completed the questionnaire at follow-up T1. Of these 18 participating patients who completed the follow-up survey at T1, 9 (50%) were included in the intervention group, which could use the TelePraCMan app, and 9 (50%) patients were included in the control group (Table 1).

The patients were mostly male (T0: 16/25, 64%; T1: 13/18, 72%), with an average age of 64 (SD 11) years at T0 and 66 (SD 12) years at T1. Most participants stated that they had ≥ 2 chronic conditions. Most of them were retired (T0: 15/25, 60%;

T1: 12/18, 67%) and had a low educational background (T0: 16/25, 64%; T1: 10/18, 56%). Nearly all of them owned a smartphone (T0: 22/25, 88%; T1: 16/18, 89%), which they used in daily life mostly often (T0: 6/25, 24%; T1: 4/18, 22%), or very often (T0: 7/25, 28%; T1: 6/18, 33%; [Table 1](#)).

A total of 24 physicians and practice assistants at T0 and 21 at T1 participated in the quantitative study. They were mostly female (T0: 15/24, 62%; T1: 13/21, 62%), with an average age

of 47 (SD 10.1) years (T0) and 49.7 (SD 11.45) years (T1; [Table 2](#)).

The 4 participating physicians and 7 practice assistants in the additional interviews were, on average, aged 50 years (range 28-73 years) and had been working in the surveyed practices for an average of 20 years (range 6-39 years). The 4 patients interviewed were all retired and, on average, aged 71 years (range 66-78 years).

Outcome Evaluation

In 10 primary care practices, a total of 141 patients with multimorbidity were asked to participate in the study. Of these 141 patients, 114 (80.8%) did not want to participate in the study. The reasons for nonparticipation were mainly that patients did not own a smartphone (53/114, 46.5%), had no interest in participation (23/114, 20.2%), or had no access to the internet (16/114, 14% [Table 3](#)).

At date T0, the mean MCS-12 score was 44.1, with a median of 43.1 across all respondents, ranging from 29.03 to 61.17. At T1, the mean MCS-12 score (39.3) was slightly lower, with a median of 39.7 across all patients, ranging from 29.81 to 57.58. On average, all participants had a PCS-12 score of 36.8, with a median of 36.7, ranging from 25.73 to 54.60. Slightly higher, at date T1, the mean PCS-12 score was 39.9, with a median of 37.3, ranging from 30.73 to 54.45 ([Multimedia Appendix 2](#)).

Table 3. Reasons for not participating in the study named by patients and documented by practice assistants (N=114).

Reasons for nonparticipation in the study ^a	Value, n (%)
Technical requirement not met: no smartphone available	53 (46.5)
No interest	23 (20.2)
Technical requirement not met: no internet accessible	16 (14)
Mentally unable	13 (11.4)
No time	5 (4.4)
Language problems	4 (3.5)
Physically unable	4 (3.5)
Need personal contact	1 (0.9)
Spouse is responsible for technical and devices	1 (0.9)

^aMultiple answers were possible.

Across all respondents, the mean PAM score was 77.9, with a median of 76.9 at date T0, ranging from 28.2 to 100. More than half (14/21, 56 %) of all participants had patient activation scores of ≥ 72.5 . Only 1 participant reported lower activation scores at level 1. The PAM score across all patients at date T1 was 82.0, with a median of 82.0, ranging from 61.54 to 100. More than a quarter (14/16, 78%) of the participants had patient activation scores of ≥ 72.5 . None of the patients reported lower activation scores for levels 1 or 2 ([Multimedia Appendix 2](#)).

There was no significant difference in outcome measures SF-12 scores and PAM scores before and after the intervention as well as in the comparison of the intervention and control groups ([Multimedia Appendix 2](#)).

Process Evaluation

The overall perception of physicians and practice assistants regarding TelePraCMan was neutral at the beginning (T0). The

mean score of the perception of TelePraCMan was 3.6, with a median of 3.6 (SD 0.33) across all practices, ranging from 3.05 to 4.52. Looking at the topics of perception in detail, the use and help of the VERAH-Portal were evaluated as the best (mean 4.5, SD 0.34), whereas the perception of the amount of work was evaluated as the worst (mean 2.7, SD 0.73; T0). After using TelePraCMan for half a year (T1), the overall perception was still neutral and slightly worsened (mean 3.3, SD 0.56). The best evaluated topic was again the use and help of the VERAH-Portal (mean 4.3, SD 0.78), whereas the worst evaluated topic was the use in the patients (mean 2.8, SD 0.6). In the free text entries, practices expressed their perception of older adult patients who need primary care and continuity and still tend to feel a general rejection toward digitalization ([Table 4](#)).

Table 4. Perception and use of TelePraCMan among physicians and practice assistants.

	Physicians or practice assistants at T0 (n=24)	Physicians or practice assistants at T1 (n=21)
Perception and use of TelePraCMan (score), mean (SD)		
VERAH ^a -Portal and practice computer	4.5 (0.34)	4.3 (0.78)
Use in target patients	3.0 (0.54)	2.8 (0.60)
Changes for patients	3.7 (0.40)	3.2 (0.80)
Amount of work (VERAH or physicians)	2.7 (0.73)	3.3 (1.32)
General assessment for VERAH or physicians	3.8 (0.79)	4.5 (0.81)
Easy use	N/A ^b	2.9 (1.10)
Training	N/A	3.6 (0.89)
Overall score (all items), mean (SD; range)	3.6 (0.33; 3.05-4.52)	3.3 (0.56; 2.50-4.37)

^aVERAH: Versorgungsassistent/in in der Hausarztpraxis.

^bN/A: not applicable.

Evaluating the UEQ, the 8 patients in the intervention group evaluated TelePraCMan as mainly positive. The mean score in the aspect of attractiveness was 1.39 (SD 0.76), in the aspect of efficiency it was 0.87 (SD 1.12), in the aspect of dependability it was 1.12 (SD 0.76), and in the aspect of stimulation it was 1.13 (SD 0.57). Only the aspects of perspicuity and novelty

were evaluated as neutral. The mean score in the aspect of perspicuity was 0.71 (SD 0.85) and in the aspect of novelty it was 0.75 (SD 0.73).

Interviews

In the interviews, we found that TelePraCMan was perceived as useful for some patients. However, contextual issues and problems with implementation negatively affected the use of the app with patients. Overall, the app and the entire project were rated as very good and important, respectively, by the respondents. However, the respondents agreed that the app would be well accepted in 5 to 10 years, as now the patients who need care still tend to feel a general rejection toward digitalization.

Implementation Activities

Regarding the implementation activities, physicians and practice assistants described the initial training as good and clear. The launching at the practice computers as well as the dealing with the VERAH-Portal were unproblematic. It was described as being easy and user-friendly.

In contrast, recruiting patients for this study was described as difficult and tedious. Practices reported on the COVID-19 pandemic as a reason for low participation of patients. Patients were rarely visiting the practice and it was less time for recruiting owing to other priorities concerning practice management in this time. Nevertheless, the narratives also focused on the fact that the wrong target group was being addressed as a reason for the low participation. Primary care workers reported that PraCMan mainly includes “high-risk” patients with multimorbidity who are commonly old, who often do not own a smartphone, or do not have access to the internet (see the Outcome Evaluation section in Results for reasons for nonparticipation). Practices reported that this group of patients was not interested or had a general rejection of digitalization. The use of smartphones or the internet was not commonplace in this target group:

Then,...came the Corona period. So, our VERAH...assured me that they addressed patients and then had the experience that those they addressed did not react positively to it, i.e., that it was not possible to convey what it was about or that a device was not even used or available. So, to say, the affinity for technology of those addressed was close to zero. But there were only four or five patients that we addressed and then it was Corona chaos anyway.... It was so that the dominance of the urgent pushed it into the background. [Physician 1]

The implementation and setup on the patients’ smartphones were mostly done together with practice assistants or friends and family. Technical problems within the first registration of the patients were observed, which could mostly be solved after consultation of the practice assistants or a project team member.

Patients’ Individual Context: Facilitators and Barriers

Barriers to the use of TelePraCMan were, in the view of the respondents, in some cases too much effort for the patients to learn how to use the app or because of the financial situation of some patients that they could not afford a smartphone. Moreover, they mentioned technical problems such as a mobile phone that was too old, problems with registration or a virus on the smartphone. A lack of patient compliance, a lack of

acceptance, or a lack of skills was also in the forefront of interviewees’ minds:

It was very complicated for those who could actually do it. You could tell that they were maybe a bit familiar with the mobile phone and that they might be able to send a message, but it was difficult to use a special app. So, I think young people up to 60 are fit, not necessarily up to 60. The young people who have just grown up with these smartphones, who know how to use apps.... There are things like health records or video conferences that you can do with your mobile phone. But for those who need a video conference because they have difficulty walking or are multimorbid, they can’t use it. So, I see that as difficult, and everyone wants that. They used to get by without a mobile phone, why should they want to use a mobile phone now? If I explain to them that we can communicate with them, then there is actually an app, or there is a mobile phone and there is an app, and we can communicate with them, no, the older people actually want to have personal contact. [Practice assistant 1]

Patients’ previous experience of using similar apps and a support network in case of technical problems were mentioned as beneficial for them and their use of TelePraCMan. Patients mentioned the simple condition of the app, which did not take much time for them. Patients also articulated enjoying the use of the app:

It may not be the same for everyone, but I had no problem with it at all and honestly, I was pleasantly surprised by the program. It was good, I enjoyed it. [Patient 1]

Impact

Different factors were mentioned regarding the impact of TelePraCMan on health care. The only negative aspect mentioned was that the physician-patient relationship could possibly deteriorate because of the personal contact and the “emotionality” that might be lost. However, one patient also found it positive that small things occurred in the app that can be discussed over the phone; for example, concerning medication.

Physicians and practice assistants also said that TelePraCMan can increase and improve the physician-patient relationship because of the fact of talking on the same information basis. The shared information could also partially change the communication by better involving the patient in the monitoring. However, some practice assistants and physicians did not perceive any changes in communication or in the monitoring appointments.

The release of data to the practice was seen as positive by all respondents. In this context, an aspect that was frequently valued was the quick detection and reaction to situations that require treatment or an intervention from a long distance. Furthermore, respondents described that the app could gain relevance in pandemic situations such as the COVID-19 pandemic because it helps to care for chronically ill patients outside the practice:

And then the person who can react to this has all the values from me and just these two three keywords that I have given to the computer in the evening via TelePraCMan, which can then be looked at by anyone who is important, so that it is not forgotten afterwards. [Patient 2]

Interviewees also supported that TelePraCMan motivated patients and thus promoted self-management and informed them about the actual state of their own health:

Right, for me it was always interesting because I could always see where I stood every week. I knew exactly when I had sinned, what I had done with my cholesterol or my sugar levels, and that was interesting. [Patient 1]

Another positive effect mentioned was that it relieved the workload of the practice assistants and physicians, as the values were directly accessible to them and did not have to be requested by the patient:

Often it's like this, you call the patient, and then the patient says "Oh yes, I'm doing so well," and then you start asking a little bit and then and "Ah yes right, there was something once." I think it would possibly also shorten the time, because you have everything at a glance, you see it, ah ok this and that happened, good, and you can deal with it straight away. And often it's like this, you're on the phone with the patients and you spend an incredibly long time...because you have to pull everything out of their noses. Not that they don't notice that they don't want to tell me, maybe it just doesn't occur to them at that moment. And so, everything would just be listed, it would all be there, this and this and this and this has already happened, the blood pressure was like this and I think that would make the work a lot easier. [Practice assistant 2]

Suggestions for improvement from the respondents were the possibility to enter the values more flexibly in terms of time, a simpler setup and registration, and that the values can be called up in the long term. Enhancements to the app were mentioned in terms of a graphical representation of the values, a pedometer, and a food diary, as well as the inclusion of the medication plan and a plan of what needs to be done if a threshold (eg, blood pressure) is exceeded.

Discussion

Principal Findings

First, the participation rate (27/141, 19.2%) was low in this study. Documentation and respondents in the interviews traced it back to the COVID-19 pandemic, as many patients asked to participate did not have an appropriate smartphone or had no interest in participation. Our quantitative findings indicate no effects on patient activation or health-related quality of life. However, the user experience of patients using the app was mainly positive. Practitioners' perceptions of TelePraCMan was predominantly neutral. Within the qualitative study, we found that the interviewees perceived that the intervention was

useful for some patients. However, contextual issues and problems with implementation negatively affected the use of the app with patients. Overall, the app and the entire project were rated as very good and important by the respondents and will be more accepted in recent years.

According to primary care workers, the COVID-19 pandemic had an impact on recruitment and the low participation rate. However, recruitment took place from November 2019 to March 2020; therefore, only the beginning of the pandemic was part of the recruitment time. Thus, the low participation rate may be due to an interaction of different factors. The primary care workers' narrative as well as the documentation of the reasons for nonparticipation revealed that the addressed target group showed other needs, as older adults commonly do not use smartphones as much as younger people. In terms of figures, 46% (53/114) of the nonparticipating patients did not own an appropriate smartphone. However, the respondents agreed that the app will be well accepted in 5 to 10 years, as now the patients who need the care still tend to feel a general rejection toward digitalization.

Comparison With Prior Work

mHealth interventions such as TelePraCMan are often not used in the "real" world [22]. Therefore, it is crucial to check the development and implementation for understanding and learning for future digital projects. For this purpose, the person-based approach for digital interventions from Yardley et al [23] can be used. The approach reflects the four stages: planning, design, development and evaluation of acceptability and feasibility, and implementation and trialing of an intervention; and offers a systematic means of addressing the user experiences.

The target of the planning phase is to identify the key behavioral needs and issues the challenges have to address, mainly via qualitative research [23]. Within TelePraCMan, primary care physicians, VERAHs, and patients were involved in the development of TelePraCMan via focus groups, interviews, and questionnaires to gain insights to their wishes and needs [13].

In the design phase, it is crucial to create guiding principles for the developers with the features of the intervention [23]. Within TelePraCMan, the evaluations of the previously named data sources were combined in the project team, and a concept for the app was derived. This concept was first translated into a paper prototypes. These paper prototypes served as the basis for further short interviews with patients and teams in primary care practices. These results were then used to design the app in the form of so-called "action sheets." These comprised relevant features, characteristics of the target group, potential barriers and facilitators, and possible variations for each page of the app. This process allows apps to be tailored to the specific target group [24]. The action sheets were given as a list of requirements to the computer scientists who programmed a prototype of the app based on them. Throughout the process, all scientists and programmers worked closely together. In addition, primary care physicians were involved in the process as experts.

In the development and evaluation phases of acceptability and feasibility, the intervention components should be evaluated

and optimized from the user perspective via user reactions to every intervention element and detailed longitudinal mixed methods case studies. Within TelePraCMan, the app prototype was initially tested by employees of the department. After appropriate adjustments, the prototype was tested during an advanced training course of the department with primary care physicians and VERAHs. These test runs were performed without initial explanations or instructions to enable the most intuitive handling. Comments, questions, uncertainties, or technical problems of the test runs were recorded in writing, evaluated, and adjusted in the app together with the computer scientists. With regard to the person-based approach, we realized the analyzing of the user reactions but did not perform an iterative cycle moving between user feedback and changes to the intervention and did not perform longitudinal case studies where the target group could use the app at a certain time on their own. Performing these two aspects may have led to improvements of the app and insights into how the target group of patients with chronic diseases perceive and use the app. We might also gain insights into their internal motivation for using the app and may gain ideas of the target group to motivate other people to participate in the study.

In the implementation and trialing phase, the intervention should be evaluated in real life via mixed methods process analyses to identify further modifications for future implementations [23]. Within TelePraCMan, a randomized controlled trial and a process evaluation were performed, and the results are included here and discussed in comparison with prior work.

Although data from the German Federal Statistical Office showed that the number of people owning a smartphone declines with increasing age [25], the latest survey from the German Federal Statistical Office [26] concerning the use of information and communication technologies in private households showed that in extrapolations, 10,683 of 16,640 (64.2%) people aged ≥ 65 years used the internet for private concerns. Of these 10,683 people, 74% (7905/10683) used a smartphone to access the internet for private concerns, but only 3% used devices connected to the internet for monitoring of blood sugar, blood pressure, or weight [26]. Nevertheless, the data from the German Federal Statistical Office showed that older adults are not commonly averse to use smartphones. In contrast, primary care workers in our study raised concerns that digitalization is widely implemented in the health care sector; still, there are people who need the interventions the most but are not able or not ready to use mHealth interventions. It remains open how to deal with and meet the concerns of this patient group in relation to eHealth and mHealth. Addressing their concerns during the recruitment phase may have enhanced participation.

A study by Steele Gray et al [27] evaluating a tool of electronic patient-reported outcomes in a 4-month trial showed no changes in outcomes of patient activation and quality of life, which was traced back to the small sample size of the study. The authors also explored factors for nonparticipation, these were mainly that patients were overwhelmed with the management of their diseases and patients did not want to add another responsibility, unawareness of having health goals they could facilitate, no self-identification with having a chronic condition, and only in fourth place concerns and less experience with technology [27].

In contrast, the most frequent reason for nonparticipation in our study was the unavailability of an appropriate smartphone or internet access as well as uninterest in participation. The unavailability might be an ostensible reason for patients, so they do not have to tell that they are already overwhelmed with their management of their diseases. It is questionable whether the use of smartphones in our study would have increased participation. A previous study with potential users of TelePraCMan found that older patients with multimorbidity preferred personal support over internet-based support [13]. In every case, the information on the benefits of using an mHealth tool could be facilitated for older patients. This was also found in a larger trial concerning a telehealth service with regular phone calls and standardized scripts, where 609 patients with depression and 641 patients with cardiovascular disease were recruited, showing only modest effect for self-management [10]. In an embedded qualitative study with practitioners and patients, they found that contextual issues in patients' lives, such as motivation to improve their health or the interest in the intervention, as well as some problems with implementation reduced the impact. Furthermore, the authors concluded that to enhance patient engagement in telehealth-motivated staff that offer the intervention with continuity is a crucial factor. Moreover, the intervention should be tailored to individual patients' needs as well as the content, time required, and benefits should be clearly communicated to potential users [10].

Another crucial point discussed in the interviews was the possible loss of the physician-patient connection and the influence on communication. Our findings are supported by a study with nurse practitioners, which found that they believed that it is difficult to communicate by telehealth owing to difficulty in perceiving nonverbal signals. They concluded that interpersonal communication should be a part of their professional training [28]. Some participants in our study feared the loss of the connection, whereas others pointed out that the app could facilitate communication since patients and providers are talking on the same information basis. The aim of the study was not to replace consultations but to make it easier for patients to spend time between appointments, so only the information basis changes, which was described as positive from respondents. A study from China found that face-to-face patient-provider communication had a positive and direct effect on web-based patient-provider communication at a later point. In addition, patient trust and patient satisfaction had a positive impact on the relationship between face-to-face and web-based patient-provider communication [29]. This could also apply to our participants as chronically ill patients who often have a strong connection with their primary care physicians.

We also collected data on practitioners' perceptions on the app. We found that after using TelePraCMan for half a year, the overall perception was neutral. Primary care workers evaluated the use and help of the portal where they could see patients' data the best but were skeptical for the use of patients. Our findings are supported by a systematic review on factors that could facilitate or act as a barrier for health professionals to use mHealth in their work. They found various factors at the individual, organizational, and contextual levels associated with

the use of mHealth tools. The most important factors were usefulness and ease of use of the app in patients [30].

Strengths and Limitations

One strength of this study was the inclusion of different perspectives via primary care physicians, practice assistants, and patients using the intervention in both parts of the study. One of the most important limitations in our study, which we already named, is the small sample size in the quantitative part, which was only partly contingent on the COVID-19 pandemic. Owing to the small sample size, the values had to be interpreted very carefully, as the coefficients may result solely from sampling effects. Furthermore, transferability and comparability with other samples may not be possible. However, the data from the process evaluation served as a possible explanation for the outcome evaluation and provided deeper insight.

Conclusions

This prospective observational study is one of the first studies concerning an mHealth intervention for chronically ill patients in a primary care setting in Germany. The app TelePraCMan was developed involving physicians, practice assistants, and patients and was adapted to their demands. However, this study showed that it was hardly implemented. Owing to the small sample size, the effects on patient activation and quality of life could not be determined. Currently, this app may be a support system for only a few patients in the target group. Future interventions should facilitate the information on the benefits of using an mHealth tool for older patients, and it is crucial to involve motivated staff who offer the intervention with continuity to the patients. Overall, the app and the entire project were rated as very good and important by the participants. However, the respondents agreed that the app would be well accepted in 5 to 10 years, as now the patients who need the care still tend to feel a general rejection toward digitalization.

Acknowledgments

The authors would like to thank all patients, physicians, and practice assistants who participated in this study. The authors would also like to thank Frank Allutis, who programmed the app, and Annika Baldauf, who supported the recruitment process.

The project was funded by the Ministry of Social Affairs, Health and Integration Baden-Wuerttemberg.

Abstract

Background: People with autism spectrum disorder (ASD) frequently experience high levels of anxiety. Despite this, many clinical settings do not provide specialist ASD mental health services, and demand for professional support frequently outstrips supply. Across many sectors of health, investigators have explored digital health solutions to mitigate demand and extend the reach of professional practice beyond traditional clinical settings.

Objective: This critical appraisal and pilot feasibility study examines *heart rate variability (HRV) biofeedback* as an approach to help young people with ASD to manage anxiety symptoms outside of formal settings. The aim is to explore the use of portable biofeedback devices to manage anxiety, while also highlighting the risks and benefits of this approach with this population.

Methods: We assessed the feasibility of using home-based HRV biofeedback for self-management of anxiety in young people with ASD. We adopted coproduction, involving people with ASD, to facilitate development of the study design. Next, a separate pilot with 20 participants with ASD ($n=16$, 80% male participants and $n=4$, 20% female participants, aged 13-24 years; $IQ>70$) assessed adoption and acceptability of HRV biofeedback devices for home use over a 12-week period. Data were collected from both carers and participants through questionnaires and interviews; participants also provided single-lead electrocardiogram recordings as well as daily reports through smartphone on adoption and use of their device.

Results: Pre-post participant questionnaires indicated a significant reduction in anxiety in children ($t_6=2.55$; $P=.04$; Cohen $d=0.99$) as well as adults ($t_7=3.95$; $P=.006$; Cohen $d=0.54$). Participant age was significantly negatively correlated with all HRV variables at baseline, namely high-frequency heart rate variability (HF-HRV: $P=.02$), the root mean square of successive differences in normal heartbeat contractions (RMSSD: $P=.02$) and the variability of normal-to-normal interbeat intervals (SDNN: $P=.04$). At follow-up, only SDNN was significantly negatively correlated with age ($P=.05$). Levels of ASD symptoms were positively correlated with heart rate both before ($P=.04$) and after the intervention ($P=.01$). The majority (311/474, 65.6%) of reports from participants indicated that the devices helped when used. Difficulties with the use of some devices and problems with home testing of HRV were noted. These initial findings are discussed within the context of the strengths and challenges of remotely delivering a biofeedback intervention for people with ASD.

Conclusions: HRV biofeedback devices have shown promise in this pilot study. There is now a need for larger evaluation of biofeedback to determine which delivery methods achieve the greatest effect for people with ASD.

Introduction

Background

Autism is a lifelong developmental disability that affects how people communicate and interact with the world [1]. Substantial changes to how autism is understood and defined have taken place over the years since the term was initially described [2]. Autism is currently viewed as a neurodevelopmental disorder that develops in childhood, and the terms *Kanner autism*, *Asperger disorder*, *childhood disintegrative disorder*, and *pervasive developmental disorder not otherwise specified* have been replaced with the collective term *autism spectrum disorder* (ASD) [3]. All participants in this study had been diagnosed with ASD in specialist health service assessments clinics using standardized measures. None of the participants were diagnosed with a learning disability, and all had attended mainstream education. Although the term Asperger syndrome is still used by both clinicians and some able people with autism, the term ASD will be used throughout this paper to describe the condition.

Approximately 1% of the British population are likely to have some form of ASD, with studies reflecting this prevalence both in children [4] and adults [5]. Epidemiological studies have shown a dramatic increase in the numbers of people being diagnosed with ASD. In the United States, the Centers for Disease Control and Prevention reported a prevalence rate of ASD in children of 1 in 88 [6], which was updated to 1 in 59 in 2018. The reasons for these apparent increases have been debated but may be related to changing definitions of the disorder, increased awareness of the condition in women, and recognition of the condition in people with no learning disability [7].

People with ASD can experience a range of mental health difficulties [8,9] and present with high levels of anxiety [10]. A range of interventions exist to treat anxiety in ASD [11]. There is some evidence for effectiveness of nonpharmacological interventions such as cognitive behavioral therapy adapted for people with ASD [12], but availability of such interventions is limited by poor adoption rates [13] and scarcity of mental health services for people with ASD [14].

There is evidence that digital health interventions can aid compliance with traditional treatments and help to reduce increasing demands on health provision, while extending the reach of professional practice beyond traditional clinical settings [15].

Digital Health Interventions

Digital solutions can be tailored to the needs of people with ASD and can be associated with less stress than that reported in face-to-face interventions [16]. Technology may be used both to deliver interventions and augment communication and social interaction [17]. Emerging digital health interventions are being investigated to help those with ASD to understand and control their reactions [18] and to help them better interpret social situations [19]. A type of intervention that has been found to

reduce symptoms of anxiety in a range of populations makes use of *biofeedback* [20,21], which has been defined as “a self-regulation technique through which patients learn to voluntarily control what were once thought to be involuntary body processes” [22]. Biofeedback actively involves the user, enabling them to change certain physiological responses to improve health [23].

Biofeedback

A variety of biofeedback equipment now exists for both psychophysiological stress profile assessment [24] and for biofeedback training [23], typically categorized into two types: large professional systems and small portable devices intended for personal use. Treatment protocols exist for a wide range of physical and mental health conditions, using either a single sensor or multiple sensors with evaluations of efficacy for each condition [25].

Although biofeedback has been used since the 1970s, there is now growing interest in its use in stress management [26]. Several systematic reviews highlight evidence supporting biofeedback as a cost-effective intervention to help manage anxiety in clinical populations [21,27]. A review of the types of biofeedback modalities and devices currently being evaluated for stress management has been carried out by Yu et al [28]. Many devices have only been tested in nonclinical populations or in laboratory environments, and the importance of testing devices in real-world situations with diverse types of clinical populations has been noted [29].

To date, the most widespread use of biofeedback in individuals with ASD has involved the use of neurofeedback [30,31]. Recent studies show some positive effects in areas such as attention and social skills; however, systematic reviews investigating neurofeedback in ASD have not shown significant results in reducing symptoms such as anxiety [32,33]. An alternative type of biofeedback that has been used to manage anxiety has been termed *resonant frequency feedback*, more commonly known as *heart rate variability* (HRV) biofeedback [34].

HRV Biofeedback

HRV was first recognized 60 years ago as an indicator of fetal distress [35] and then found to be affected by breathing frequency [36]. HRV reflects the activity of both the sympathetic and parasympathetic activities of the autonomic nervous system and is reported in both time and frequency domains [37]. A review of HRV metrics has been produced [38], with population norms identified [39]. HRV is affected by age [40], the environment, breathing rate, and blood pressure, and it is subject to regulation of the autonomic nervous system [41]. HRV is frequently used as a physiological marker in stress detection [42]. It is also an index of adaptability and of the ability to self-regulate behavior [43].

A number of theoretical models have been proposed describing the links between HRV and health, mediated through connections between the heart and the brain [44,45]. The polyvagal theory suggests that impairments in the autonomic

nervous system involving vagus nerve regulation, termed the *social engagement system*, are features of several disorders, including ASD.

HRV has been used in conjunction with sensor technology to develop *HRV biofeedback* [46,47]. Training in HRV biofeedback involves *resonant frequency breathing*, which has been associated with *respiratory sinus arrhythmia* where heart rate acceleration and deceleration rates synchronize with respiration and occur when breathing is slowed to a rate between 4.5 and 7.0 breaths per minute [41]. To support the maintenance and development of resonant frequency breathing, individuals can practice paced breathing or use portable *home trainer* biofeedback devices.

Portable biofeedback devices typically derive HRV using infrared photoplethysmography (PPG), which measures blood flow, usually through either the fingertip or the earlobe. Peripheral blood flow can be used to assess heart rate and to estimate HRV [23]. Several such devices conform with health, safety, and environmental protection standards. They can be adjusted by the user to different breathing rates but are usually set at a default rate of 6 breaths per minute. Assessment of the accuracy of some devices has also been carried out [48,49]. A growing number of research studies have also now investigated their effectiveness when used as stand-alone interventions.

There are wide variations in study design, using different devices, training protocols, and outcome measurements. Nevertheless, systematic reviews and meta-analyses have concluded that HRV biofeedback can be an effective treatment for symptoms in a range of different populations, including both adults [20,21] and children [50]. Providing interventions for symptoms such as anxiety that affect people with ASD has been emphasized as a vital area for research [51], and reviews have acknowledged the need to involve the ASD community directly in research [52,53]. HRV biofeedback has been used in a range of populations for anxiety management. To date, no studies have investigated the feasibility of using portable biofeedback devices as a home-based intervention to help people with ASD manage anxiety.

For people with ASD, biofeedback may provide specific advantages for the management of anxiety. First, it provides a technique for developing control over specific symptoms without the need for verbally based techniques designed for non-ASD populations or behavioral interventions that may be anxiety provoking for people with ASD [54]. Second, biofeedback can present structured visual information in a systematic manner, a factor suited to the typical communication strengths of people with ASD. Third, biofeedback also aims to increase awareness of physiological reactions, which can be reduced or impaired in people with ASD [55].

Finally, people with ASD show a range of different physiological reactions compared with non-ASD peers [56]. The different HRV responses of people with ASD have been debated [57,58]. Further investigation into interventions to help improve *interoceptive ability* or to develop physiological reactions may be particularly important for this population.

Accordingly, we proceeded with an exploratory study to investigate the use of HRV biofeedback outside of clinical settings as a potential intervention to help people with ASD by reducing symptoms of anxiety.

Methods

Overview

The aim of this pilot and feasibility trial comprised two main objectives: first, to explore the use of HRV biofeedback as a suitable methodology to support people with ASD to manage anxiety outside of clinical settings and, second, to assess the risks, benefits, and challenges of using HRV biofeedback within this population.

We involved adults with ASD and professionals working in the field in the initial study development and design. We then recruited a separate group of young people with ASD in an experimental design with appropriate pre- and postintervention outcome measures.

We recorded demographic data and mental health status and used participant anxiety and depression as the primary outcome measures. Statistical analyses were carried out to assess mean group differences in reported anxiety and depression. A per-protocol analysis was used. This led to several participants being excluded after randomization because they met the exclusion criteria, and their pre-post data were therefore not included in the quantitative data analysis. The pre-post data sets were analyzed using a standard statistical package (SPSS software [version 24.0; IBM Corp]). Correlational analyses were also used to review associations between baseline measurements and HRV data.

To assess the risks, benefits, and challenges we used several methods of data collection, including daily monitoring of device use, perceived participant stress levels using a questionnaire delivered through smartphone, standardized interviews, and short debriefing reports. Participants who dropped out early or had continuing difficulties using their biofeedback device or had electrocardiogram (ECG) recording difficulties after randomization had their monitoring data included for further analysis, provided that they had consented for these data to be collected. The aim of the study was to ensure methodological robustness and feasibility, with a focus upon potential risks, problems, or difficulties as well as potential benefits of using HRV biofeedback.

Participants

The sample was drawn from a population of patients with an existing diagnosis of ASD who had attended regional health services for help with anxiety. The young people with ASD were invited to participate in experimental adoption of a portable HRV biofeedback device over a 12-week period. All participants in this study had been diagnosed with ASD in specialist health service assessments clinics using standardized measures. None had a learning disability, and all had attended mainstream education. Additional preassessment screening of participants was carried out using the *Social Communication Questionnaire* [59], yielding a mean score of 20, which is above the cutoff level for diagnosis of ASD. Participants were excluded if they

had pre-existing addiction; a diagnosed cardiac condition; a learning disability; or where suicidal risk, psychosis, or severe eczema or psoriasis had been noted; or if they were taking medications known to suppress HRV, such as benzodiazepines or tricyclic antidepressants [60]. All participants received appropriate information about the study and gave consent or assent in addition to consent from a parent or carer. No incentives were offered for participation.

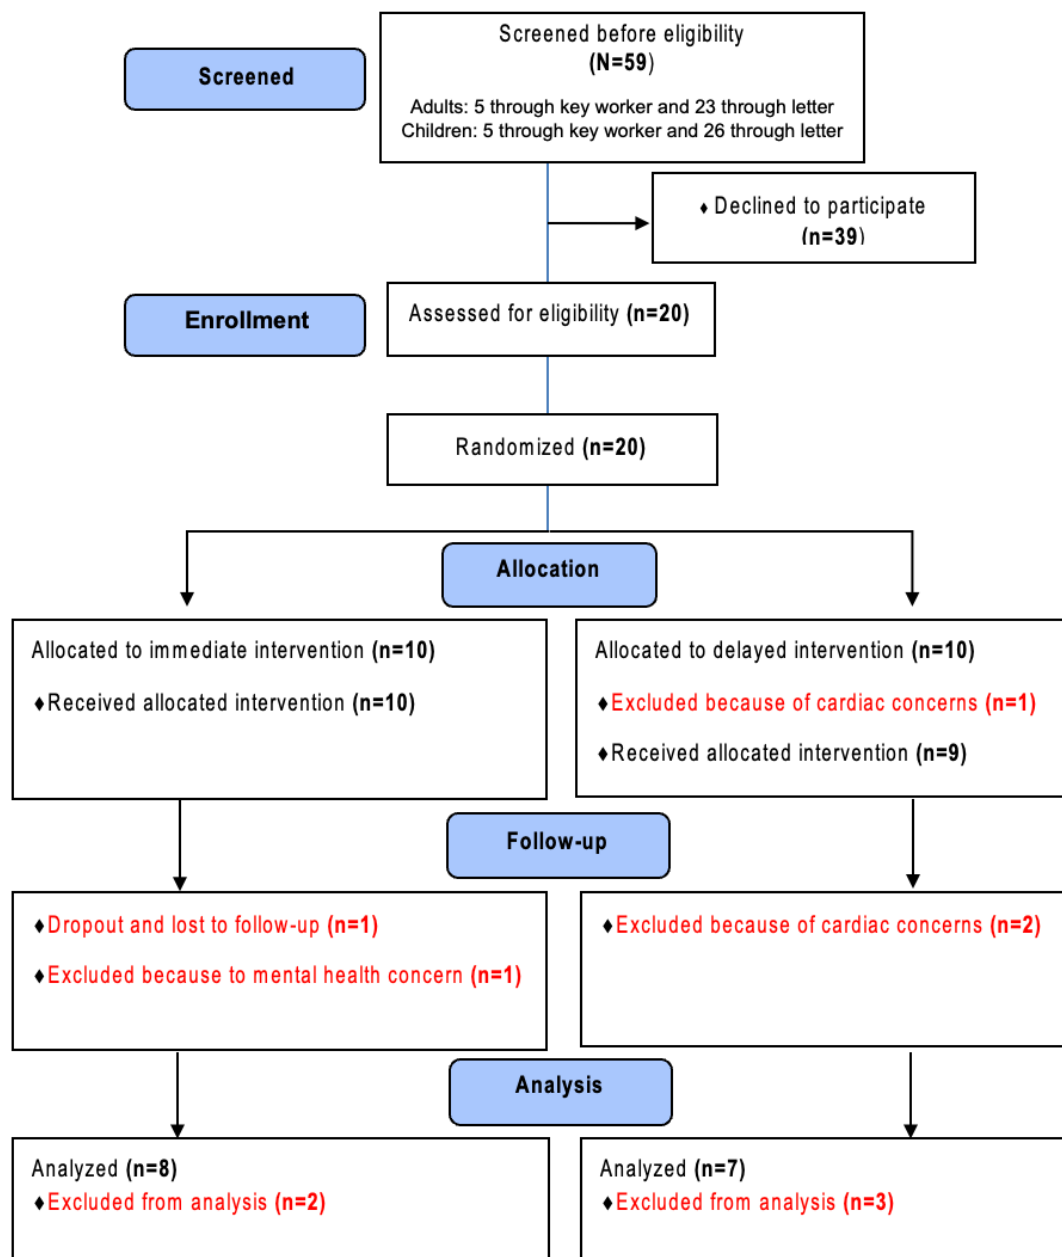

Ethics Approval

Ethics approval was granted by the regional National Health Services ethics committee (15/NI/0255; IRAS: 139122). After review by the regional National Health Services ethics committee, approval was granted under the UK governance arrangements for research ethics committees.

Recruitment

Potential participants were recruited using two methods: either through direct contact with their therapist or through letters sent to patients who were already discharged. It was not possible to determine the exact reasons for nonparticipation in the study because of the ethical constraints regarding contacting those who declined to participate through their therapist or those who did not respond to the invitation letters. Initially, 20 people took part: 16 (80%) male participants and 4 (20%) female participants. Their ages ranged from 13 to 22 (mean 16.2, SD 2.63) years. Detailed demographic information is presented in [Multimedia Appendix 1](#) [61], and participant flow through the study is presented in [Figure 1](#).

Figure 1. CONSORT (Consolidated Standards of Reporting Trials) flow diagram summarizing the processes adopted for screening and enrollment, allocation into groups, follow-up, and final analysis. Participant numbers are provided for each stage.

Randomization

To decrease the risk of group allocation bias, random assignment to treatment group or control group was carried out *after* all preintervention assessments; therefore, the researcher was initially blind to who was allocated to each group during all baseline assessments.

Allocation was made in blocks to ensure that adequate numbers of participants were allocated to each condition. A randomized number sequence was generated through computer.

Between-group comparisons were planned to compare 6 weeks of intervention in the immediate group with 6 weeks of no intervention in the delayed group. The small sample size and additional exclusions from the study prevented these comparisons from being carried out.
