Finding the best time to do the intervention without interruption from my preschooler Vs being too tired to pay it proper attention to get the most out of it. [IFQ001]

Surprisingly difficult to find 20 mins in busy clinical day or family time daily to do game. [IFQ003]

My concern is that staff wouldn’t find the time during the working day to work on the interventions and with shift patterns may struggle to include it in their free time. [IFQ036]

Three of the feedback questionnaire respondents also highlighted how they found it difficult to remember to record and use the intervention, in part because of the lack of time:

Remembering to do the intervention regularly and record the relevant information. During the day, I don’t have time to work on the intervention so I’ve had to work time into my evening to complete the tasks. [IFQ036]

Improvements and Optimizations
Participants were asked about potential improvements or optimizations to the intervention as well as any challenges experienced while using it. The responses were grouped into the following themes, which were found to be relatively frequent and consistent.

Difficult to Focus on Mental Rotation
Overview
Participants emphasized the importance of recognizing that the mental rotation aspect was the focus rather than the Tetris score:

I had to concentrate quite a bit because when I first started using it I just was having fun playing the game [laughs]. [006]

I think we should highlight that when you do the intervention you shouldn’t really. You should focus more on the arrangement rather than aiming for a score or you should stay away from how you usually play Tetris and focus on the future blocks and the arrangement. [014]

Despite recognizing this, participants often found it difficult to concentrate or focus on mental rotation:

I was thinking about myself, my thoughts were just running away, and I wasn’t really concentrating on the Tetris game. [001]

I remember thinking first few times it [speed] increased I started to panic a bit because- And then you do stop focusing on the mental rotation because you just think, oh they’re all coming so quickly. [005]

I think it was the pre-empting the rotation that’s coming, to rotate it in your head before it actually comes onto the screen, that’s the hard bit. [012]
IFQ Data
This difficulty in concentrating was echoed by participants in the feedback questionnaires:

I think 15 mins is enough—my concentration starts to flag after this. [IFQ005]
I found I was bored quickly. [IFQ038]

How to Increase Focus on Mental Rotation
Overview
Participants provided suggestions on how to improve the intervention for future participants. One of the main suggestions was a pop-up message during gameplay to remind participants to focus on mental rotation, as participants had previously mentioned that their focus drifted from mental rotation. Participants also mentioned that the speed at which the blocks fell made it difficult to focus on mental rotation, and they suggested that capping the speed may be helpful:

I don’t know if during the Tetris game some kind of pop up could be coming up, like a reminder. Yes? A kind of- I don’t know what you say on the reminder, but something like- I don’t know, remember to focus on the next pieces. [001]
And maybe cap the speed. When it gets ridiculously fast I think you’re very aware that you’re not doing mental rotations very well. [002]

IFQ Data
Another participant mentioned capping the speed as an improvement suggestion in the feedback questionnaire:

Cap the speed of the blocks to enable proper rotation planning. [IFQ001]

Researcher Support Is Important
Overview
Researchers provided participants with support during the initial session, in which they showed the participants how to identify intrusive memory images and how to use the intervention with mental rotations very well.

I like the fact that I got contacted midway through, because it was obvious that that one was still bothering me more. [005]
Yes, I think so. I think I had a couple of teething issues, but one of the ladies phoned me up, went through it, face-to-face, got me to play it whilst on the phone with me, so it was fine. [004]

IFQ Data
The importance of the initial session with a researcher was also highlighted by a participant in the feedback questionnaire:

Needs 1-1 at beginning when 1st doing intervention so person using it knows exactly what to do. [IFQ045]

How to Access the Intervention Independently
All participants who received the optimized intervention provided suggestions on how to make it more easily accessible independently. For example, they proposed incorporating video demonstrations showing how to autonomously identify their intrusive memory images and playing the intervention while focusing on mental rotation:

Yes, so see someone playing. And what obviously, because you cannot read their mind, but if you put like a bubble say what is doing in their mind. They are turning, they are not focusing on this, they are doing this, this. [015]
Maybe- I guess, maybe giving some examples of how to break those things [intrusive memory images] down, if that makes sense. And the different ones that are just like an image, or something that’s like a little video that plays, that sort of explanation and how to write that, maybe just some sort of video of how to break that down into something. [016]

How to Aid Incorporation of the Intervention Into Participant Lifestyle: IFQ Data
In the feedback questionnaires, a few participants explained how shorter Tetris sessions could help them incorporate the intervention into their daily lives more easily:

Perhaps if the timing the intervention had to be carried out for was shorter - I'm not sure if it would still be effective but feel 10 minutes twice a day rather than one block of 20 minutes would be easier to fit in. [IFQ009]

Is the 20 minutes a specific time or could it be reduced? Sometimes difficult in a busy working day to get full 20 minutes to spend on it. What effect with say 10 minutes? Or 5...? [IFQ021]
I was sometimes deterred from starting the intervention knowing that it would take up 20mins of time. It may seem more accessible if it only required 10 mins for example. It would be possible to do whilst on break at work etc. [IFQ023]
Other Intervention Improvement Suggestions

Overview
In addition, participants expressed a desire for the intervention to be available as an app rather than solely on the web-based platform:

*I think it would have been really good if you could have had an app. And then every time you have a memory, you just tap the app, or something, and then it. Yes, and otherwise you have to, like- By the time you get home, and log it, you’re like, how many did I have? [004]*

*I think it will help if it’s an App that you can download, like Calm or what’s the other one- Then you can just go and open and do for 15, 20 minutes. [014]*

There were mixed views on the use of graphs to display intrusive memory changes, with some participants not liking graphs, whereas others appreciated the ability to track progress in this way:

*I’m not a great fan of graphs to be honest. [013]*

*And not only to see progress but to see- I guess because I could match as well, like they definitely got worse when I was on nights and I could see that, with my shift pattern and also stuff I was doing at work, just certain things that were going on and then I’d be like, I can see how that happened and where that connection is. So, it kind of makes sense to me. [016]*

In general, participants appreciated receiving brief daily reminders to log their intrusive memories and engage with the intervention, as long as the reminders were not excessive and did not prompt participants who had already completed the task. However, as mentioned in a previous subtheme, some participants did find the reminders distressing as they brought the memories of traumatic incidents to mind:

*A quick reminder with may be just a shortcut to the logon is fine for me. [013]*

*[At] least I had that reminder. And I think if I forgot one day, let’s say today, tomorrow in the morning I could go back and do it...Especially when you have so many things on your mind. [015]*

IFQ Data
In addition to requesting that the intervention be available in an app format, a couple of participants in the feedback questionnaire suggested that the intervention use only 1 platform instead of 2 (1 for the intervention and 1 for logging outcome measures):

*I found it difficult to navigate the website, perhaps an app would have been better. [IFQ022]*

*It might be easier to make it all on one platform. Rather than 2 different places. [IFQ028]*

Although some participants mentioned how they appreciated the text message reminders, 1 participant explained in the feedback questionnaires how reminder messages could be confusing:

*I would suggest keeping up the automatic reminders to record and use the intervention. [IFQ025]*

*Infrequent but relevant text message feedback was useful and not overly intrusive. [IFQ032]*

*I get multiple reminders about completing tasks which sometimes confuses me whether I have completed it or not. [IFQ053]*

Discussion
Principal Findings
This qualitative study explored barriers and facilitators to the adoption of a brief digital imagery-competing task intervention (1 guided intervention session of 1 hour, followed by self-guided use of approximately 20 min/session) to reduce intrusive memories of traumatic events from working in an NHS ICU during the COVID-19 pandemic. Overall, on the acceptability questionnaire, the health care staff found the intervention easy to use, helpful, and highly acceptable. They were highly willing to use the intervention and were confident in recommending it to colleagues and their health care organizations for staff exposed to repeated trauma. In the qualitative data collection, participants described many additional positives of the intervention, such as it being easy to use, enjoyable, and encouraging, as participants were able to track intrusive memories and notice reductions in frequency. They could modify the use of the intervention based on the intrusiveness and frequency of the traumatic memories. Compared with sessions of psychological treatment, it was considered less time consuming, more flexible when it could be used, did not require discussing unpleasant memories, and required less effort. Compared with medication, it was more specific in its effect on intrusive memories of traumatic events and did not have adverse effects on weight, sleep, or alertness. It was seen as complementary to psychological and medication treatments in those who needed them.

Although it has its advantages, participants described how the intervention may not entirely replace the need for psychological therapy to talk about the nature of intrusive memories in those who wish to or the need for medication in some instances. A key finding was that some participants preferred not to access the intervention through their workplace or for colleagues to know that they were using the intervention owing to mental health stigma, a factor that is known to affect mental health help seeking among health care professionals [35], including after witnessing trauma in the workplace [36]. An advantage of the GAINS intervention is that although it could be provided through the workplace and introduced as a normal working practice for staff in the ICU, it could also be accessed independently outside of work.

The intervention use data showed that, on average, staff engaged with the Tetris component for the full 20 minutes per session, approximately 7 times over the 4-week period. They were able to target approximately 73% (3.64/4.88) of their intrusive memories through the intervention, that is, on average, participants were able to target 3.64 intrusive memories and had 4.88 intrusive memories listed. This emphasizes that the intervention was extensively used, indicating its significant...
value. When combined with qualitative findings, it appears feasible and acceptable for staff, particularly in the short term. However, there is a need to further investigate how participants use the intervention for a longer term, particularly whether it can easily fit into their daily lives.

Comparison With Prior Work

The findings highlighted barriers that ICU staff experience when accessing support for their mental health, such as stigma, feeling weak for seeking help [37], questioning if they were bad enough to warrant such help, and not wanting colleagues to know that they were struggling. This is consistent with previous findings investigating mental health in health care professionals [35,36] and a culture of not showing weakness in health care work settings [29]. Participants suggested that these barriers could be partially overcome by normalizing intrusive memories after trauma through testimonials from other ICU staff who participated in the GAINS study. In addition, as discussed in the existing literature [35,38], the anonymity of the intervention was important, as it was completely separated from the health care professionals’ workplace or colleagues. This suggests that staff should have the option to access the intervention through routes other than only the workplace. However, participants in the IFQ suggested that health organizations would benefit from the intervention being endorsed by senior staff members. This endorsement could occur during induction and appraisal meetings involving junior colleagues, especially in environments where staff are repeatedly exposed to trauma. If staff did find it acceptable for the intervention to be used in their work environment, it could even be incorporated into staff induction and colleagues could support another through a “buddy system.”

In a previous meta-synthesis of digital health interventions for mental health [39], one of the key barriers to the initial approach was skepticism about how helpful a remote treatment could really be. This was also the case with the GAINS intervention. The initial skepticism was compounded by it being a simple and novel gameplay intervention, with some participants expecting the intervention to be at best a short-term distraction while they played the game. In fact, many participants went on to report long-lasting effects on the frequency and intrusiveness of their traumatic memories. Publicizing research evidence, discussing the mechanism of action of the intervention, and testimonials from ICU staff were suggested as counters to this possible skepticism. This is consistent with the literature, which highlights the importance of users being on board with digital health interventions’ aims and understanding their purpose [40].

The suggestion to publicize research evidence and provide testimonials from ICU staff is of particular importance, as prior findings emphasize that endorsement from health care professionals is valuable and helps digital health interventions’ aims and understanding their purpose [40]. It highlights the importance of users being on board with digital health interventions and suggests that endorsement could occur during induction and appraisal meetings involving junior colleagues, especially in environments where staff are repeatedly exposed to trauma. If staff did find it acceptable for the intervention to be used in their work environment, it could even be incorporated into staff induction and colleagues could support another through a “buddy system.”

Similar to prior findings [41] that integrating a human component into treatment helps retain engagement and reduce dropout, participants reported that researcher support, both before using the intervention (eg, the initial guided session) and throughout intervention use (eg, booster session), was found to be extremely helpful and important. They valued the continuous support provided to ensure they correctly used the intervention and received guidance on making adjustments when necessary. However, providing this level of support can be difficult when scaling up an intervention [41]. Participants provided suggestions on how the intervention could be more easily accessed independently, which would require fewer therapist and researcher resources and enable the intervention to spread more widely and reach a greater number of ICU staff, for example, by providing video demonstrations of someone identifying the intrusive memory images independently and playing the intervention while focusing on mental rotation. Participants’ suggestions around helping to retain a focus on mental rotation while playing Tetris are helpful to identify, as this may be one of the core aspects to the working of the intervention. They also discussed changing aspects of the game itself and whether more frequent but shorter use of the game might be effective and more feasible for staff to continue using it for a longer term.

Limitations

Limitations of the study include the method of recruitment and sample representativeness and the short duration of use of a novel intervention. The trial was a first trial that is being followed by further trial work to test the robustness of the findings of the first trial. Recruitment of participants through advertising in the ICS, a professional organization, may have recruited participants who would be the most receptive and enthusiastic for such interventions. The sample was geographically drawn from many parts of the United Kingdom and was representative of the NHS at large but appears to have been overrepresentative of ethnic minority staff. There were 44% (7/16) staff from ethnic minority backgrounds in our interview sample compared with 20.7% (248,400/1,200,000) in the NHS workforce [42]. However, selective sampling was used for interview recruitment to capture a broad range of experiences of using the intervention from as diverse a sample as possible, rather than to match the sample to demographic characteristics of the NHS population. Any novel intervention, both in format and purpose, may have a large halo effect in
relation to enthusiasm to take it up and use that may not be sustained over time. There is a need to recruit larger representative samples that use this intervention. The aim of this intervention is for most individuals to only need to use it a few times (once for each distinct intrusive memory of trauma). It is designed to be brief each time it is used, and requiring only a few sessions, rather than for prolonged use like a mindfulness app. However, for people with a very large number of intrusive memories and repeated ongoing traumatic events, it would be useful to consider use over a number of months to obtain more robust data on its likely uptake, use, and acceptability, which could be generalized to the staff experiencing repeated trauma in routine health care settings. Furthermore, we were unable to interview any ICU staff who were not able or chose not to participate in the study. Therefore, it is difficult for us to know how typical our sample and findings are of the wider ICU staff population. We also could not obtain important information about any barriers to participating in these individuals and how these barriers could be overcome, as it is likely that our participants were more open to mental health support in general. Furthermore, participants who took part in the trial but did not consent to participating in an interview may have had a different (more negative) experience of the intervention, and we could not obtain information about their experiences.

Nonetheless, our participants described potential barriers to wider participation, and it appears that the intervention was able to overcome some of these to an extent, such as the anonymity of the intervention helping to reduce the impact of stigma. In addition, we used selective sampling to ensure that our sample was as diverse as possible on factors such as profession, background, ethnicity, age, NHS Trust, and baseline intrusive memory frequencies. Therefore, our sample aimed to be as inclusive as possible of our target population. Saturation of themes was reached through the interview and analysis process, suggesting that further barriers would be unlikely to be present if we had recruited more participants.

We attempted to triangulate our data by comparing feedback from the sample that completed the acceptability questionnaire (IFQ) with our qualitative interview data. Certain topics did not lend themselves to completion on the feedback questionnaire, such as discussion of stigma. However, this was often reported in the qualitative interviews with ICU staff, and the themes resonate with previous literature. The feedback questionnaire, which had a very high rate of completion, confirmed most other barriers and facilitators, identifying a new subtheme around highlighting a number of ways staff improved cognitive and emotional coping with trauma through the intervention. A limitation of our analysis is the inability to delve deeper into certain findings. For example, we could not explore how the intervention might induce relaxation nor whether the distraction and improved focus persisted beyond the gameplay or were solely experienced during the game sessions. Bringing awareness to the intrusive memories could be both a positive and a negative experience, as it might help identify a source of stress; however, some people cope with intrusive memories by suppressing them, whereas others believe it adds to distress. The feedback questionnaire provided many additional suggestions to improve the uptake, feasibility, and acceptability of the intervention that the research team and developers of the intervention could explore and consider. A key strength of the qualitative interviews was the chance to iterate findings to adapt the intervention accordingly while it was still being used in the RCT. We also interviewed some participants who received the optimized intervention to gain feedback about their experience with the optimizations so that we could further improve the intervention.

Data gathered from the use of a survey in addition to interviews demonstrate that even when interviews are repeatedly producing the same subthemes and themes, and despite maximum variance sampling on the basis of characteristics available to us, there might still be important themes that might be missed because of the limits on maximum variance sampling imposed by data protection and trial procedures. We could only be made aware of a limited amount of information without fully consenting individuals for the interview. However, the qualitative interview method delves deeper into extracting information that participants might not readily provide in a feedback survey. In addition, it is an iterative process that builds upon multiple interviews. Therefore, if a theme or subtheme is not supported in the survey feedback, it does not mean that it is unimportant or even uncommon, simply not as immediately obvious to the participants.

Future Research

Other potential issues for us to consider in the next phase are related to the practicalities of the intervention, as participants mentioned that the intervention could be difficult to fit into their extremely busy working lives during the pandemic. Health care demands have remained high; therefore, this ability to fit in may be a continued factor to consider. There was also the issue of lack of privacy when accessing the intervention at work and not having access to a personal device in this setting. As highlighted in a previous literature review [43], most intervention frameworks recognize the importance of understanding how well an intervention fits with existing organizational routines to predict its adoption and implementation on a larger scale. As the intervention can be accessed by ICU staff either at work or outside of work, we must also understand how well the intervention fits into their personal lives. Although this aspect was discussed in our findings, it is crucial to further explore the feasibility of long-term intervention use, especially considering that ICU staff regularly encounter work-related trauma. For the intervention to be beneficial, it must integrate as seamlessly as possible into their lives. An advantage of this intervention is that it can be used at any convenient time (eg, at home or on a commute). A further key issue going forward within work, and especially outside work, is data protection of sensitive information that may require training or other safeguards, for example, if staff members are overlooked while examining graphical outputs (eg, a line graph) of the frequency of traumatic memories. We may need to provide alternative ways of presenting the data to ensure that they are more widely accessible, such as through color chart indicators rather than numerical graphs.
Conclusions
Overall, the data suggest that the intervention to reduce intrusive memories after trauma is highly acceptable to ICU staff and has some unique value compared with other current approaches to staff mental well-being. Through additional refinement and gathering evidence regarding outcomes and implementation, this intervention could potentially present a much-needed approach to address the widespread issue of repeated exposure to trauma, which manifesting as intrusive memories significantly impacts on the mental health and emotional well-being of health care staff.

Abstract

Background: Medication adherence and the management of adverse drug reactions (ADRs) are crucial to the efficacy of antitumor drugs. A WeChat applet, also known as a “Mini Program,” is similar to the app but has marked advantages. The development and use of a WeChat applet makes follow-up convenient for patients with cancer.

Objective: This study aimed to assess the usability and utility of a newly developed WeChat applet, “DolphinCare,” among patients with cancer in Shanghai.

Methods: A qualitative methodology was used to obtain an in-depth understanding of the experiences of patients with cancer when using DolphinCare from the usability and utility aspects. The development phase consisted of 2 parts: alpha and beta testing. Alpha testing combined the theory of the Fogg Behavior Model and the usability model. Alpha testing also involved testing the design of DolphinCare using a conceptual framework, which included factors that could affect medication adherence and ADRs. Beta testing was conducted using in-depth interviews. In-depth interviews allowed us to assist the patients in using DolphinCare and understand whether they liked or disliked DolphinCare and found it useful.

Results: We included participants who had an eHealth Literacy Scale (eHEALS) score of ≥50%, and a total of 20 participants were interviewed consecutively. The key positive motivators described by interviewers were to be reminded to take their medications and to alleviate their ADRs. The majority of the patients were able to activate and use DolphinCare by themselves. Most patients indicated that their trigger to follow-up DolphinCare was the recommendation of their known and trusted health care professionals. All participants found that labels containing the generic names of their medication and the medication reminders were useful, including timed pop-up push notifications and text alerts. The applet presented the corresponding information collection forms of ADRs to the patient to fill out. The web-based consultation system enables patients to consult pharmacists or physicians in time when they have doubts about medications or have ADRs. The applet had usabilities and utilities that could improve medication adherence and the management of ADRs among patients with cancer.

Conclusions: This study provides preliminary evidence regarding the usability and utility of this type of WeChat applet among patients with cancer, which is expected to be promoted for managing follow-up among other patients with other chronic disease.

Introduction

Medication adherence is defined by the World Health Organization as the extent to which a person’s medication-taking behavior corresponds with agreed recommendations from health care providers [1]. Medication adherence is crucial to the efficacy of antitumor drugs. Patients with cancer have disproportionately higher burdens of comorbid chronic conditions compared to individuals without a cancer history [2]. For individuals with preexisting chronic conditions, a new cancer diagnosis can lead to tremendous challenges, including the coordination of carers and dependents as well as the management of multiple medications for comorbid conditions alongside cancer treatment [3]. Antitumor drugs are known for their numerous adverse drug reactions (ADRs), which can diminish adherence to treatment and cause medical complications. Several interventions have been developed to improve medication adherence and manage ADRs in patients with cancer [4-6]. However, the effectiveness of these interventions is controversial.

WeChat is a type of social networking software that provides flash messaging services on smart terminals. In 2020, the number of monthly active WeChat users exceeded 1.1 billion, rendering it the most common smartphone app in China. It is no longer a simple social platform but has penetrated into all aspects of people’s lives, including their health [7]. With the constant development of WeChat tools, a new development environment and platform was built for the WeChat applet used by 400 million Chinese users every day [8].

The WeChat applet, also known as the “Mini Program,” is similar to the app but has marked advantages. The steps for using the WeChat applet have been simplified, and the applet can be opened directly without downloading the app package. Interestingly, there is an independent storage space among different WeChat applets. If one no longer uses the applet, one need only close the page without uninstalling the program or clearing the cache, which is convenient for users. In addition, the IT infrastructure of WeChat applets can bring about a rapid transfer of digital data between patients with cancer and doctors or pharmacists, and reduce their burden related to oncotherapy information through real-time communication. All of these make follow-up convenient for patients with cancer by using the WeChat applet.

Norman and Skinner [9] reported that participants who had a high eHealth Literacy Scale (eHEALS) score indicated that they had higher literacy skills in using the internet as a resource to obtain health information. This study selected and interviewed dozens of patients with cancer with high eHEALS scores from a tertiary hospital in Shanghai, who are willing to use an eHealth tool—the WeChat applet. If the WeChat applet can be successfully promoted in Shanghai, it will be spread sequentially in various cities throughout China. At present, the vast majority of WeChat applets are free to use, which can reduce the economic burden of follow-up among patients with cancer. However, the existing WeChat applets were developed without involving relevant stakeholders (such as health care professionals or patients) and were not subjected to mobile health app guidelines [10,11].

Usability is described as the extent to which a product can be used by specified users to achieve specified goals with effectiveness, efficiency, and satisfaction in a specified context of use [12]. Utility is defined as the functionality of the app and how useful it is to users [12]. The development phase consisted of 2 parts: alpha and beta testing. Beta testing was conducted using in-depth interviews. Alpha testing combined the theory of the Fogg Behavior Model and the usability model. The Fogg Behavior Model [13] suggests that 3 core elements—motivation, ability, and trigger—must converge at the same time for a desired behavior to take effect. Motivation and ability can be balanced against each other; for example, patients may be willing to perform a difficult task if they are highly motivated by the promise of better health outcomes. Ability refers to the patients’ skill or dexterity with respect to the simplicity (or otherwise) of using the app. A trigger is a stimulus that prompts patients to adopt and use the app (eg, an acute attack or clinician’s suggestion).

To our knowledge, no study has assessed the usability and utility of a WeChat applet for patients with cancer once it has been developed. This study aimed to assess the usability and utility of a newly developed WeChat applet—DolphinCare—among patients with cancer in Shanghai.

Methods

Study Design

A qualitative methodology was used to obtain an in-depth understanding of the experiences of patients with cancer when using DolphinCare from the usability and utility aspects.

Ethical Considerations

Ethics approval was obtained from the ethics committee of Shanghai Tenth People’s Hospital prior to the study (SHSY-IEC-5.0/22K99/PO1). The study was registered in Chinese Clinical Trial Registry (ChiCTR2200058189). Written informed consent was obtained from all study participants.

eHEALS

The modified eHEALS was used to assess participants’ literacy skills in using their smart devices to find health-related information on the internet (Multimedia Appendix 1).

Participants

We included participants who had an eHEALS score of ≥50% and were taking 2 or more prescribed medications for their tumor treatment and chronic conditions. We excluded participants aged <18 years or those who had mental disabilities. Purposive sampling was used to recruit older (≥65 years of age) and younger (<65 years of age) participants, as we required the experiences of older participants who may have more comorbidities but may not be comfortable using mobile apps, as well as younger participants who may have fewer comorbidities (than older patients) but may be more comfortable using mobile apps. The purpose of recruiting participants based
on age was to obtain wider perspectives when using DolphinCare.

**Alpha and Beta Testing in the Development Phase**

The development phase consisted of 2 parts: alpha and beta testing. Alpha testing involved testing the design of DolphinCare using a conceptual framework (Figure 1), which combined the theory of the Fogg Behavior Model of Motivation-Ability-Triggers and the usability model. Our framework also included factors that could affect medication adherence and ADRs (Table 1).

DolphinCare was then used for beta testing (Figure 2). Beta testing was conducted using in-depth interviews from July to September 2022. The first and second rounds of in-depth interviews were both conducted at the resting area of the ward. In-depth interviews were conducted to explore the views of patients with cancer regarding the usability and utility of DolphinCare when using it for the first time. We supplemented this interview process by observing the participants and documenting these observations as field notes. This allowed us to determine whether they encountered any difficulties and whether they liked or disliked the utility of DolphinCare. In-depth interviews allowed us to focus on the individual, assist the individual in using DolphinCare, and create an environment where the individual would be able to express his or her views without being influenced by others.

**Figure 1.** The conceptual framework for the design and development of DolphinCare based on the Fogg Behavior Model's theory of Motivation-Ability-Triggers and the usability model. AI: artificial intelligence.

The Interview Questions
The following questions were asked to the participants during the interviews:

- What is your initial impression of using DolphinCare?
- What is your feeling about using DolphinCare after a period of use?
- What motivates you to use DolphinCare?
- Can you operate DolphinCare yourself, or do you need help from others?
- Will you continue to use DolphinCare?
- What’s the operation interface of DolphinCare that left a deep impression on you?
- What’s function do you expect DolphinCare to further improve on?
- What do you think are the inconveniences of using DolphinCare?

Data Collection Process
Participants used their mobile WeChat app to acquire the official account of DolphinCare free of charge and then filled in the demographic form. Each participant was interviewed twice. During the interview, the “first impression” of participants in using DolphinCare would be captured. The researcher took detailed notes and observed for nonverbal cues during each interview. Facial expressions and body language subconsciously portrayed by the participants were noted down by the researchers. All interviews were audio recorded. The 8-item Morisky Medication Adherence Scale (MMAS-8) [14-16] is a questionnaire designed to facilitate the identification of barriers and behaviors associated with adherence to medication. The possible answers to questions 1 to 7 are “yes” (0 points) or “no” (1 point). Five of the questions are scored in reverse (ie, yes=1 and no=0). The possible answers to question 8 are “Never” (1 point), “Occasionally” (0.75 points), “Sometimes” (0.50 points), “Often” (0.25 points), and “All the time” (0 points) [17].

Data Analysis
All interviews were transcribed verbatim. An interpretive-descriptive approach was used to identify the themes that emerged from the data. This approach was used to obtain a deeper understanding of the usability and utility of the perspectives and experiences of patients with cancer in using the WeChat applet. The researchers reflected on the data and began constructing an interpretive account of what the codes signified from the participants’ perspectives, and its application in clinical practice [14]. The researchers also referred to the field notes for reflections, facial cues, and body languages observed during the interviews. The research team then met to discuss the coding of the transcripts. Any coding discrepancies were resolved through discussion until a consensus was reached.

Results
Participants
A total of 22 participants were recruited (Table 2) for the first interview. Only 20 participants (12 men and 8 women; 16, 80% of them being patients and 4, 20% being carers) were interviewed consecutively, as 2 (P13 and P14) declined to participate. The mean age of the patients and their carers was 62.4 (SD 10.25) years. The average of the number of medications among patients was 2.7.

\(^a\)eHEALS: eHealth Literacy Scale.

Adoption

We used the motivation, ability, and trigger categories of the Fogg Behavior Model to explore why patients adopted the WeChat applet using data from the qualitative interviews and usage data.

Adoption: Motivation

The key positive motivators described by the interviewers were to be reminded to take their medications, to alleviate their ADRs through monitoring, and to aid in medical research. Some patients had more than 1 motivation for adoption.

_The motivation is to observe if I can improve the medication adherence, and manage my ADRs._ [Patient 10, 68 years, male]

_It [taking part in this research] could be helpful for the medical studies or something. So to advance their work._ [Patient 4, 73 years, female]

_My main motivation is to participate in this research for distracting me from my anxiety about the disease._ [Patient 7, 55 years, male]

Adoption: Abilities

Most of the patients were able to activate and use the WeChat applet by themselves. Some (typically older) patients needed assistance from younger family members.

_I’m not very good with these things but somebody younger in my family would help me for handling it._ [Patient 2, 67 years, female]

_I know how to use it … I think it is quite easy and straight forward because the layout is very clear (while showing the Homepage)._ [Patient 5, 35 years, female]

Adoption: Triggers

Most patients indicated that they would receive follow-up through the WeChat applet if it was recommended by their known and trusted health care professionals.

_My trusted physician recommended me to use this ‘wechat applet’ to improve my medication adherence and better manage ADRs, which makes me willing to use it._ [Patient 8, 62 years, male]
Usability Testing
They were challenges encountered when adding a new medication, with regard to patients’ understanding of their complex medication regimen.

Challenges Encountered When Adding a New Medication
Several subthemes emerged under this theme: confusion by terms used when adding medications into DolphinCare, unfamiliarity with the entered generic name of the medication, and patients’ incomprehension of their complex medication regimen.

Unfamiliarity With the Generic Name of the Medication
When entering medication details into the WeChat applet, most patients knew their medication by brand names but not generic names. DolphinCare requires users to enter the generic name of the medication, as the pharmacy label only contains the generic name.

I am not sure of accurately different names of my medications, and I almost always have my pill boxes with me. [Patient 15, 59 years, male]
I’m not too sure what is the precise name of my medication. I only know it by its brand name. So having the indication automatically linked to the medication name is good to have. [Patient 16, 64 years, female]

Utility Testing
Two themes emerged from the utility testing of DolphinCare: utilities that could improve medication adherence and the management of ADRs.

A Medication Reminder System
All participants found the medication reminder useful, including timed pop-up push notifications and text alerts.

Oh yes this was helpful. It prompted me to remind my mum to take her medications. [Patient 20, 61 years, male]
It would like to set timed pop-up push notifications to depend on what time I wake up in the morning and go to bed in the evening. [Patient 18, 62 years, female]

A Medication Adherence Scoring System
Medication adherence among patients was evaluated using the MMAS-8. When a patient uses the WeChat applet for more than 1 month, a questionnaire to evaluate their medication adherence will be provided to the patient to fill in.

I’m sorry that I wasn’t aware of the MMAS-8 questionnaire until you reminded me. Happily, my medication adherence improved after using the applet. [Patient 9, 47 years, male]

The Management of ADRs
When patients input the antitumor medication they are taking, the applet interface automatically matches the corresponding educational information of ADRs. A week later, the applet provides the corresponding collection information forms of ADRs to the patient to fill out. Health care professionals receive messages or provide web-based medication guidance to the patient based on the severity of ADRs. In addition, the WeChat applet can intelligently recognize the inspection and image reports uploaded by the patient in paper-photo versions. The WeChat applet converts the reports into text formats, and organizes and records them in the patient’s file. When there are obvious abnormalities in indicators of the reports related to ADRs, health care professionals can promptly contact the patient.

The Web-Based Consultation System
The web-based consultation system enables patients to consult pharmacists or physicians in time when they have doubts about medications or have ADRs. There will be a professional exclusively in charge of web-based consultation services during working days.

Oh this is good. This saved me the time and efforts to go to the hospital for consultation, and the response I got from online consultations was equally satisfactory. [Patient 17, 50 years, male]

Discussion
Principal Findings
DolphinCare was designed and developed on the basis of the Fogg Behavior Model. This model comprised 3 phases—motivation, ability, and triggers—which suggests that a patient is able to achieve a target behavior if he or she has high motivation, ability, and an effective trigger simultaneously.

The requirement phase was based on utilities that could improve medication adherence and manage ADRs, which led to the design and development of DolphinCare until the medical personnel and patients were satisfied with the prototype. This paper focused on the usability and utility testing of DolphinCare, for which patients with cancer were recruited to use the WeChat applet and provided feedback.

To our knowledge, no previous study has reported the experiences of patients with cancer when using a WeChat applet. The patients also preferred a summary page of medication, which was accessible by tapping on the medication icon on the home page of DolphinCare; this was useful as it provided a brief overview of their medication regimen. This further enhanced the usability of DolphinCare, as it would be more patient-centered and more likely to be adopted. It is worth noting that there was no particularly negative feedback provided by the participants. This is a limitation of the study, and future research needs explore the negative feedback from patients to better improve DolphinCare.

The steps to add a medication were simplified and displayed in a layered order to prevent cognitive overload [18]. However, some participants struggled when adding a new medication due to the complexity of this task. It is challenging to input data into a small device, as it requires the user to navigate the app on a small screen [19]. Despite the challenges encountered by patients, the process of adding a new medication “manually” benefited patients with regard to their medication knowledge.
Participants had to “learn” the generic name of their medications, their administration frequency, and their purpose, which is beneficial for the patient's treatment process.

Several studies have shown that behavioral change is achievable through active reminders, which strengthens the benefits of medication adherence apps [20,21]. A review by Santo et al [22] in 2016 revealed that only 56% of medication adherence apps adjust flexible scheduling for medication reminders. Medication reminders with flexible scheduling (where users may opt for medication reminders on alternate days or on a weekly basis) allows for personalization of the app to suit their individual needs. Participants also reported that they had a better understanding of the frequency and indication of the medication, which appeared on the reminder, thereby improving their medication knowledge. Improved patient knowledge is known to enhance their medication adherence and clinical health outcomes [23]. However, areas involving strategies to improve patients’ medication knowledge require further investigation [24]. DolphinCare offers a pop-up push notification, with a “single-click” return to the WeChat applet, which was preset every 2 days. Besides a pop-up push notification, weekly text alerts were also provided. These allowed users who were unable to take their medications at a specific time point to take them later, which actively prompted the patients to take their medications properly and on time. DolphinCare required users to acknowledge the reminder that, theoretically, would make the patients more conscious of their adherence to medications.

Symptom monitoring is especially important for patients with cancer because they can experience varying acute and chronic side effects from their treatment regimen [25]. Egbring et al [26] conducted a 3-arm randomized controlled trial for 6 weeks with 139 patients with early-stage breast cancer undergoing chemotherapy. The participants were randomly assigned to a control group, an unsupervised group that used a mobile app to record data without physician review, or a supervised group that recorded data in the app with physician review. The results revealed that participants who had physician collaboration when using the health tracking app demonstrated increased reporting of adverse effects of chemotherapy, more precise health data entries, and stabilization of daily functional activities measured using the ECOG (Eastern Cooperative Oncology Group) scale.

Our study confirmed the importance of symptom monitoring among patients with cancer, as these patients can also experience significant side effects from their treatment regimen, which influence their overall quality of life during and after their course of therapy.

The wide demographic range of the participants of this study delineates the experiences of both young and old users. The usability and utility testing of DolphinCare demonstrated the needs of patients with cancer and their caregivers better and helped tailor the WeChat applet to suit their needs. This ensured that DolphinCare would be a more patient-centered WeChat applet and more likely to be used. Our study suggests that DolphinCare can aid patients with cancer and even those with other chronic diseases to improve medication adherence and manage ADRs.

Conclusions
DolphinCare was designed and developed on the basis of the Fogg Behavior Model. This study provides preliminary evidence of the usability and utility of this type of WeChat applet among patients with cancer. This WeChat applet had usabilities and utilities that could improve the patients’ medication adherence and ADR management.

Abstract

Background: Adult day services (ADS) provide community-based health care for older adults with complex chronic conditions but rely on outdated methods for communicating users’ health information with providers. CareMOBI, a novel mobile health (mHealth) app, was developed to address the need for a technological platform to improve bidirectional information exchange and communication between the ADS setting and providers.

Objective: This study aims to examine the feasibility and acceptability of CareMOBI in the ADS setting.

Methods: A concurrent-triangulation mixed methods design was used, and participants were client-facing ADS staff members, including direct care workers (paid caregivers), nurses, and social workers. Interviews were conducted to describe barriers and facilitators to the adoption of the CareMOBI app. The acceptability of the app was measured using an adapted version of the Technology Acceptance Model questionnaire. Data were integrated into 4 themes as anchors of an informational matrix: ease of use, clinical value, fit within workflow, and likelihood of adoption.

Results: A mix of ADS staff (N=22) participated in the study. Participants reported high levels of acceptability across the 4 domains. Qualitative findings corroborated the questionnaire results; participants viewed the app as useful and were likely to implement CareMOBI in their practice. However, participants expressed a need for proper training and technical support throughout the implementation process.

Conclusions: The CareMOBI app has the potential to improve care management in the ADS setting by promoting effective communication through an easy-to-use and portable method. While the integration of CareMOBI is acceptable and feasible, developing role-specific training modules and technical assistance programs is imperative for successful implementation within the ADS setting.

(JMIR Form Res 2024;8:e49492) doi:10.2196/49492

Introduction

Adult day services (ADS), commonly referred to as adult day care, is a vital but overlooked source of health and social care for the burgeoning population of older adults with complex chronic conditions—particularly those with Alzheimer disease and related dementia (ADRD) [1]. ADS sites are nonresidential, congregate, and community-based facilities that offer interdisciplinary services, including opportunities for socialization, nursing care, and nutritious meals for chronically ill or functionally impaired adults. Each day in the United States, 251,100 adults with complex health and social needs receive care in the ADS setting: 65% have some combination of ADRD, diabetes, depression, heart disease, or other chronic conditions; 72% live below federal poverty lines; and 55% are from a racial or ethnic minoritized group [2]. Clients attend 2 to 5 days per week and may receive assistance with personal care, physical therapy, vital sign monitoring, and medication administration, while also participating in organized group activities [3]. ADS staff are skilled at using their in-depth, serial observations of clients to identify warning signs of acute illness and promote early clinical intervention, which are especially important in persons with ADRD, who may not be able to identify or communicate changes in their health status.

However, ADS sites face numerous barriers in communicating concerning changes in health status to primary care providers [4]. Ineffective communication in health care has been associated with costs exceeding US $10 billion, in addition to adverse outcomes and increased mortality [5,6]. We previously found that communication between free-standing community-based ADS centers is hampered by reliance on antiquated methods of information exchange that challenge information sharing and care coordination [7]. When ADS clients experience acute changes in health status or behavior, information is typically reported to primary care providers through fax or voicemail messages, which often result in nonresponse, delayed diagnosis, referral or treatment, and inadequate follow-up. Primary care providers and ADS staff have agreed that communication between them is infrequent, delayed, incomplete, and unreliable. Primary care providers prefer to communicate using direct messaging systems within their electronic health record; however, 92% of ADS sites in the United States lack the resources for interoperable electronic health record systems that enable e-communication [8]. The lack of resources shifts the burden of communication between ADS sites and primary care to the family caregiver (herein referred to as caregivers) who must deliver the information from the ADS site to the primary care provider at the point of service. Although engaged caregivers are often willing to track medical information and coordinate care, they may lack the necessary time, resources, and health education, resulting in medical errors or delays in care.

We developed CareMOBI (mobile health for organizations to bolster interconnectedness), a mobile health (mHealth) app prototype, to address the consistent need for improved care coordination and communication among care team members supporting care in home and community settings (Figure 1). CareMOBI acts as a centralized hub for families to track and share information about their loved one’s day-to-day health with other care team members (ie, ADS staff, home health aides, and family members). This enables multiple caregivers to support an individual across home and community-based settings. Within CareMOBI, individuals are first invited to a person’s care team. Each member can then record information and share updates about a person’s health, including how they ate, slept, or felt on a given day. They can track vital signs, keep up-to-date medication lists, and track medication administration. They can also track appointments and make notes of observations or questions to ask providers. Most importantly, care team members can report and be alerted when an individual is exhibiting concerning symptoms or experiencing an emergency. Information entered with the app can be summarized and shared via a PDF file to support shared clinical decision-making at appointments or appended to a chart. CareMOBI is a low-cost, portable means of exchanging information between ADS sites, caregivers, and health care providers. It also provides a centralized platform that allows ADS staff, caregivers, and care providers to provide updates and track the health progress of a person who cannot do so independently, as well as share any urgent concerns and observations, such as new or worsening confusion, behavioral changes, or abnormal vital signs. These features are designed to support critical early identification of clinical issues with the goal of reducing costly, traumatic, and avoidable emergency department care or hospitalizations, as well as overall care management for people with complex care needs. The purpose of this mixed methods study was to examine the feasibility and acceptability of CareMOBI in an ADS setting through surveys and interviews with ADS staff.
Methods

We used a mixed methods concurrent triangulation design to (1) assess acceptability and feasibility of the CareMOBI prototype among adult day center staff and (2) identify factors contributing to eventual likelihood of adoption or nonadoption.

Setting and Sample

Participants were eligible if (1) they were paid employees of a participating adult day center and (2) they had a client-facing role that involved daily interaction with persons living with dementia, as these are the target end users of the app in the ADS setting. Examples of client-facing staff are registered nurses, social workers, and program assistants. Individuals were excluded if they had worked in their current position for less than 6 months. Purposive sampling was used to recruit a diverse multistakeholder sample that represented the range of professionals in adult day centers (eg, registered nurses, social workers, and program directors).

Ethical Considerations

Eligible staff members were identified with the help of administrators at participating adult day centers. A research assistant contacted them by email or phone according to their preference, described the study, confirmed participants’ eligibility, and subsequently obtained informed consent. In total, 22 staff members from adult day centers in 3 states (New York, California, and Georgia) enrolled. All enrollees received a US $50 gift card for their participation. The New York University committee on activities involving human subjects provided Institutional Review Board approval for this study (IRB-FY2020-4615).

Procedures

Data collection consisted of one-to-one semistructured interviews and the completion of the Technology Acceptance Model questionnaire, adapted for health care settings [9]. The Technology Acceptance Model was developed 4 decades ago to explore factors that shape workers’ intention to use emerging technology. Rooted in the theory of reasoned action, it explores the beliefs and norms that influence attitudes and expectations that increase the desire to carry out a behavior. Thus, it is a logical and established framework to explore factors determining the likelihood of adoption of CareMOBI in ADS. The Technology Acceptance Model questionnaire provided insight into the acceptability of the app, while subsequent qualitative interviews provided additional insight into concerns around the feasibility of embedding CareMOBI within ADS.

Approximately 1 week prior to the interview, participants received a confirmation email that contained a link to an interactive prototype of CareMOBI. The prototype could be accessed from a smartphone, tablet, or computer. Participants were instructed to watch a 2-minute informational video about the app, also linked in the email, and were then asked to spend approximately 10 minutes navigating through the interactive prototype to complete several relevant tasks, including logging in, adding a new medication, recording day-to-day activities of a typical person living with dementia at their adult day center, as well as any health-related progress notes. They were also asked to use filters within CareMOBI to locate information.
about the person living with dementia in whom they were interested.

**Qualitative Data Collection and Analytic Procedures**

Web-based interviews were scheduled based on participants’ availability and conducted via a secure web-based platform. UX (user experience) and UI (user interface) design professionals, who had extensive knowledge of user-testing, provided input to develop a semistructured interview guide at the product development firm that built the CareMOBI prototype.

Participant interviews lasted 30 minutes on average. Interviews were conducted by either the principal investigator (TS) or a trained research assistant. Both individuals have extensive experience with qualitative interviewing. Open-ended questions allowed participants to elaborate on their reaction to the CareMOBI app and allowed the researchers to elicit information on different factors influencing their perceptions of the app, aspects related to its usability, and potential feasibility issues, including workflow integrations. Sample questions included:

1. What is your overall impression of the app?
2. In what ways do you think this app could help address some of the challenges you face in organizing and communicating information around the needs of person living with dementia?
3. Are there other challenges in caring for person living with dementia that this app doesn’t address? What might those be?
4. What features in the app were most confusing for you to understand/find/utilize?

All interviews were recorded, professionally transcribed, and reviewed for accuracy. Field notes by the interviewer supplemented the tape-recorded interviews. A detailed audit trail documented the rationale for any methodological changes during the interview or analysis (ie, when unique follow-up questions were posed).

Qualitative data were analyzed using a content analysis approach. A preliminary codebook was developed a priori based on the interview guide as a coding scheme for all transcripts. The research team discussed any text that could not be categorized within the codebook to determine if a new category or code needed to be defined or aligned with an existing category or code. The codebook was continuously updated to reflect the iterative process. Initially, 2 coders coded independently in Dedoose, a web-based platform for qualitative and mixed method coding, and met weekly to review coding and resolve any disagreements. To ensure the reliability and consistency of coding, a third independent coder analyzed a subset of 20% (n=5) of the transcripts. The principal investigator addressed any unresolved disagreements, as well as potential new categories or codes, in team meetings. Codes were summarized within cases and then compared across cases to identify emerging themes. Saturation occurred when no new themes emerged. The research team members regularly debriefed to discuss and validate the results of the analysis. Quotations were provided with participant’s initials to maintain anonymity.

**Quantitative Data Collection and Analytic Procedures**

Upon finishing the interview, participants completed a web-based questionnaire. In addition to providing basic demographic information, participants completed an adapted version of the Technology Acceptance Model questionnaire, which was previously validated for use in health care settings [9]. Responses to the 33 survey items enabled further examination of factors that could influence the eventual adoption of CareMOBI, and the anonymous nature reduced the potential for social desirability bias. Respondents rated each item on a 7-point Likert scale ranging from “strongly disagree” to “strongly agree.” Each domain-specific question was averaged to determine scores. Higher scores corresponded to higher perceived acceptability.

Descriptive statistics were used to characterize the sample, with measures of central tendency and spread for continuous measures and frequencies and percentages for dichotomous or categorical variables. Calculations for quantitative statistics were done using Qualtrics software (version May 2023; Qualtrics LLC).

**Integration of Qualitative and Quantitative Data**

Qualitative and quantitative data were integrated in the third and final phase of analysis. We sought to align with the Technology Acceptance Model: perceived ease of use, perceived value in clinical care, fit within existing workflows, and end users’ overall likelihood of adoption. Using the 4 themes as anchors, we developed an informational matrix in which qualitative data were embedded and compared with quantitative data. Using triangulation methods, we sought to understand the overall likelihood of adoption of the app by end users (quantitatively) and factors underpinning this across cases within each stakeholder group (qualitatively).

**Results**

**Overview**

The primary goals of this study were to (1) assess the acceptability of the CareMOBI prototype among adult day center staff and (2) identify factors contributing to the eventual likelihood of adoption or nonadoption. We evaluated the feasibility and acceptability of CareMOBI in an ADS setting quantitatively and qualitatively according to 4 themes: perceived ease of use, perceived value in clinical practice, how the mHealth app fits within existing workflows, and likelihood of adoption.

**Study Sample**

The total sample (N=22) of ADS staff members was majority non-Hispanic (20/22, 91%) and White (16/22, 73%). Most participants (19/22, 86%) were aged between 40 and 69 years. All respondents (100%) identified as women. Among those who responded when asked about their role, the majority (10/18, 56%) identified as direct care workers or professional caregivers (aides) in adult day centers (see Table 1).

**Perceived Ease of Use**

Perceived ease of use describes the effort level associated with understanding and using CareMOBI. There were 5 questions within the Technology Acceptance Model questionnaire that assessed the perceived ease of use: the overall ease of use, the technological skill required to use the app, and the user’s comfort level with the app (Figure 2). The mean score for this domain was 6.48, indicating a high ease of use for CareMOBI. The question with the highest mean score was “I think that I could easily learn how to use the proposed mHealth app” (mean of 6.77 or strongly agree). The lowest scoring question was “I feel comfortable with information and communication technologies” (mean of 6.00 or agree). The qualitative interviews provided insight into what aspects of CareMOBI facilitated the ease of use for the participants (Table 2). Participants reported that the organized layout was simple and easy to navigate. Many expressed appreciation for how they did not have to spend time searching for what they needed, and that all of the features were “at their fingertips” (ADC-LP). However, the qualitative interviews did reveal that while ADS staff found CareMOBI easy to use, they had concerns about family caregivers’ ability to use it. This included challenges with the functionality of some app features and the lack of non-English language options for caregivers and patients with low English proficiency. One respondent stated:
For those who don’t speak English, that’s another issue—because participants here, we have different languages spoken here, more than five, six, seven languages. For caregivers who don’t understand or don’t speak English well, that’s challenging as well. [ADC-AL]

Furthermore, some participants expressed concern that technology-based solutions may not be appropriate methods of communication for some clients due to low technology proficiency and preferences for traditional methods. While many of the features were easy to use, participants noted a few exceptions that were too complex and potentially confusing for them to navigate, particularly the appointment tracking feature. A staff member noted that while navigating the app was “pretty easy,” it might confuse caregivers who could “get mixed up on appointments, whether it’s outside or they’re coming here” (ADC-NF).

</tbody>
</table>

Perceived Value in Clinical Practice

Perceived value in clinical practice is the degree to which CareMOBI could improve patient care and management within ADS. Thirteen questions in the survey assessed this domain (Figure 3). The mean score for this domain was 6.18 out of 7, indicating that participants generally rated the CareMOBI app well in terms of potential value to their clinical practice. The item with the highest average score was “The proposed mHealth app can facilitate the care of my patients/clients/loved ones” (mean of 6.55 or strongly agree). The item with the lowest average score was “The proposed mHealth app can facilitate the care of my patients/clients/loved ones” (mean of 5.70 or agree).

Data from the qualitative interviews suggested that staff felt there was immediate value to implementing the app in the day center (Table 3).

I know how it could help me and my family, so it just lights the torch for me the more. This is so huge because the next wave, they’re gonna be—they’re more technology savvy, so they’re gonna be wanting a lot of this information more so, so we have to keep evolving to be able to help make sure that we are communicating right away and training our staff to use it. Both the people were so excited, like, “Oh, my God, it’s so much easier,” and then they get an alert. I’m like, “Yeah, just to get an alert.” [ADC-NF]
Several features of the CareMOBI app would improve the staff’s ability to manage care for ADS participants. Specifically, study participants appreciated the alert and notifications feature for caregivers and staff and the built-in features that allow easy “communication on a daily basis” for members of the care team. The CareMOBI app has the capacity to track health progress (ie, vital sign trends, medication management, and appointment reminders) beyond ADS through caregiver and health professional portals. These features were viewed as beneficial to augment the traditional emergency communications and to facilitate chronic disease management within the adult day centers. While most features received positive feedback, 1 staff participant noted that the behavioral assessment tool, which used emoticons (or “smiley faces”) to evaluate daily behavior was oversimplified. Generally, both the qualitative and quantitative data indicate that staff participants perceived the CareMOBI app as a potentially valuable clinical tool to augment their practice due to its ability to facilitate communication, consolidate patient information, and organize care management.

**Figure 3.** Quantitative survey answer distributions for perceived value in clinical practice. mHealth: mobile health.

<tbody>
<tr>
<td>Patient monitoring and management</td>
<td>“I know how it could help me and my family, so it just lights the torch for me the more. Both the people were so excited, like, ‘Oh, my God, it’s so much easier,’ and then they get an alert. I’m like, ‘Yeah, just to get an alert.’” [ADC-NF]</td>
</tr>
<tr>
<td>Real time communication among the care team</td>
<td>“I think that the real-time communication makes it useful. What we’re seeing on a daily basis, if we’re able to communicate on a daily basis as opposed to—right now, we have—we will call a family member if there’s an acute episode. If there’s not an acute episode, we’re not gonna just be like, ‘Hey, this is what happened today. This is what we saw. Blah, blah, blah, blah, blah.”” [ADC-DT]</td>
</tr>
<tr>
<td>Updates on health progress</td>
<td>“Even though they might not be able to communicate on a consistent basis when I call, tell me what was happenin’ this week or this weekend. I could at least gather that information and, like I said, with the app there, I could say, ‘Per a neighbor who’s slash the caregiver, this is what they observed.’” [ADC-LSM]</td>
</tr>
<tr>
<td>Trends</td>
<td>“Then visually having the client on-site, it would be able to give me a better way of communicating, ‘Oh, yeah. This is not just a bump. [Laughter] It’s a big bump from the baseline.’ That’s the whole point, being able to look at the trend.” [ADC-LSM]</td>
</tr>
<tr>
<td>Assist caregivers</td>
<td>“We, at adult daycare center, we take care of not only participant, but the caregiver also. When caregiver’s wellbeing are good, our participant are good. They can have quality of life at home instead of ending up in a placement. It’s not their wishes and their goals. That’s very good that in the app.” [ADC-AL]</td>
</tr>
<tr>
<td>Schedules and reminders</td>
<td>“I think it’s very good to have [appointments] on the calendar. It’s forgetful for those who have cognitive impairment and caregiver busy with the schedule. When you have those in place, it’s very good for the keep ongoing with the appointment, with the medication, make sure they take medication on time, don’t miss any doses. That help both caregiver and participant to do the daily tasks appropriately.” [ADC-AL]</td>
</tr>
<tr>
<td>Patient profile information</td>
<td>“Then they sign up their loved one and their pictures, information about themselves, information about their loved one, the medication they’re on, what they, little bit about themselves, a little bit about their loved one’s background.” [ADC-EK]</td>
</tr>
<tr>
<td>Disliked features</td>
<td>“Sometimes behavior issues where someone is having extraordinary anxiety or—then I think that that might be able to be addressed. It would be challenging to properly do that with just the smiley faces, I think. I thought that was very surface-related, very cursory thing. I’m not sure how incredibly helpful that would be unless there’s some depth later somewhere. That would be my only concern about that.” [ADC-HK]</td>
</tr>
<tr>
<td>Health progress logs</td>
<td>“I found that it had, the activities part of it and how their morning started or how they slept, and things that I deal with hands on here.” [ADC-LR]</td>
</tr>
<tr>
<td>Miscellaneous ways the app enhances care</td>
<td>“That is perfect, because then—in outcomes for us or if we utilize it regularly, it would help us with data collection too.” [ADC-BT]</td>
</tr>
</tbody>
</table>

Fits Within the Workflow

New technology should be compatible with the existing workflow of staff and patients and cause minimal disruptions to optimize adoption. A total of 9 questions assessed the extent to which the CareMOBI app could integrate into the existing health records and workflow of ADS staff (Figure 4). The mean domain score was 5.14 out of 7, indicating that most participants agreed that the CareMOBI app would fit within the workflow. The item with the highest average score was “I often use smartphone apps in my work or daily life” (mean of 6.38 or strongly agree), and the item with the lowest average score was “The use of the proposed app may interfere with the usual follow up of my patients” (mean of 3.36 or slightly disagree). Due to the wording of this item, a low rating has a positive implication for the compatibility of the CareMOBI app with ADS staff workflow.

However, data from the qualitative interviews highlighted several caveats that could preclude the successful integration of the CareMOBI app into the current staff workflow (Table 4). Staff recommended prioritizing the interoperability of CareMOBI with existing electronic health record systems (eg, TurboTAR) to avoid duplicitous documentation and streamline their workflow. Congruent with the quantitative data, staff participants cited that the lack of existing mHealth apps used in their routine workflows meant that staff and caregivers were not familiar with this interface and could be problematic when initially integrating the app into use. To ameliorate this, the staff participants emphasized the need for sufficient training using videos and other methods for both staff and caregivers, as many described being intimidated by the complexity of emerging technologies. Participants (ADC-JL) also voiced concern that documentation in the CareMOBI app would just be “one more thing” that needs to be done and believed it could be challenging to “actually utilize it” given their other responsibilities. Many participants also imparted that the benefits provided by improved e-communication and information sharing could encourage integration into their workflows. One staff member stated that the app was “great [for] communication with physicians” and another remarked that the ability to be able to take pictures of medication bottles and export patient information “clears up so much confusion” for them. Both the qualitative and quantitative data show relative support for using the app in the workflow but the qualitative interview data reveal several barriers that could inhibit integration.

Likelihood of Adoption

This domain assesses the extent to which staff participants intended to include CareMOBI in their program and use it with clients and caregivers. Five items assessed this domain (Figure 5) and had a mean score of 5.77, a score that suggests most respondents agreed that they intended to use the app after its release. The highest rated item was “I would use the proposed app if I receive appropriate training” (mean of 6.10 or strongly agree) and the lowest rated item was “I have the intention to
use the proposed app routinely for the care of my patients/clients/loved one” (mean of 5.40 or slightly agree).

The qualitative data revealed that many staff participants were motivated to adopt the CareMOBI app (Table 5). One participant said, “we were already talking about how we would utilize it in our program,” reflecting the high quantitative score for the likelihood of adoption. The app was designed to reflect the interdisciplinary nature of ADS, and staff participants were appreciative of this aspect. One participant (ADC-LR) commented that they were “very impressed with it and how it touched on all of the different disciplines that we have to do with in an adult day health center, social work, health, activities.” To increase the likelihood of adoption, staff participants also suggested new features of the app to improve care and user experience, including the option to print reports and collect education-level data from patients to help allocate activities.

</table>

Discussion

Principal Findings

The results of this study show that the CareMOBI app is highly acceptable to ADS staff, but there were questions about the feasibility of implementation. The high scores in all 4 domains of the survey—perceived ease of use, perceived value in clinical care, fit within existing workflows, and end users’ overall likelihood of adoption—demonstrate that ADS staff members generally considered that the app was easy to use; added clinical value; fit into their workflow; and that if given the option, would likely adapt the app into their system.

Prior to developing the app, members of the study team conducted qualitative interviews nationwide to identify facilitators of effective communication between ADS sites and primary care providers. Results indicated that ADS staff wanted to exchange information bidirectionally with other care team members. They sought technology that would reduce their reliance on fax and voicemail while enabling them to share serial observations of a person living with dementia’s day-to-day health with all members of the care team (eg, ADS staff, health care providers, and caregivers) [7].

In this study, qualitative interviews largely qualified the high scores from survey data; however, interviewees expressed practical concerns about the app’s feasibility, particularly about its fit within the existing workflow of ADS. The feasibility of CareMOBI was threatened by the added workload and documentation burden it has the potential to create, especially for overburdened providers who “already have a thousand things
to document and a thousand things to click and a thousand buttons to do.” This concern is not limited to the ADS setting; other research has shown that increased documentation burden in hospitals is a contributing factor to clinician burnout [10,11]. Notably, cost was not mentioned by any of the participants as a concern or barrier to adoption. This is likely because, with low-cost subscriptions (<$5 US $/month) and little to no investment overhead, mHealth apps are reputed as a cost-effective solution to meet the needs of complex patients.

The potential workflow disruption and incompatibility with existing technology infrastructures have been cited as one of the major barriers to successful eHealth implementation in a systematic review, and our study was no exception [9,12]. As another participant pointed out, “The interoperability, I think that’s the biggie. That we’re entering information one time only.” This could be mitigated by making CareMOBI interoperable with ADS billing software which is what most sites rely on for day-to-day practice management. In a future study, a back-end dashboard for CareMOBI will be designed to integrate with existing ADS practice management systems, like TurboTAR. This will avoid what 1 participant referred to as “double documentation.”

Another key priority for future development will be the translation of CareMOBI into different languages. ADS is the most diverse subset of long-term care, with nearly 60% of participants identifying as a racial or ethnic minority or individual [13]. Studies show that ADS can deliver relevant, person-centered care to diverse populations [3]. Adaptations of CareMOBI into other languages will be necessary to improve adoption and inclusivity and ensure the technology reflects the population it is designed to serve.

Successful adoption of new technology in health care settings requires buy-in from staff. It is, therefore, imperative that technology adds clinical value and does not hinder efficiency. While barriers and facilitators of app use in certain health care settings have been well documented, our study is the first to explore the unique perspectives of staff in ADS settings. Resourcing this setting with low-cost mobile technology is especially innovative because ADS sites provide essential care to persons living with dementia but are often resource-constrained and rarely embedded within health care systems.

CareMOBI was developed as a reaction to the overwhelming sentiment that methods of communication in ADS need to be modernized and streamlined to provide optimal care for their clients. Overall, our results from prototype testing show a high level of acceptability among ADS staff with a need for greater attention to feasibility. Recognized by many of the study’s participants, CareMOBI’s biggest strength is its ability to bring all the members of the care team—ADS staff, caregivers, patients, and health care providers—to the same digital table, managing the complex care of older adults as a true team. Previous research by the Agency for Health Care Research and Quality found that care models emphasizing collaborative care were the only effective, evidence-based care models for persons with dementia [14]. By emphasizing effective communication, CareMOBI, with ongoing refinement and enhancement, has significant potential to help streamline and improve care for participants with dementia and other chronic conditions.

**Limitations**

While this study is the first to our knowledge to document the perceived feasibility and acceptability of an mHealth app in the ADS setting, these results should be interpreted with some limitations. The participants of this study were only furnished with a prototype of the CareMOBI app with a limited set of capabilities. At times, this elicited frustration from the participants due to certain functions not working correctly. Conversely, testing with only a prototype precludes assessment of real-world functionality, particularly in the assessment of integration within the workflow. This study consisted of a relatively small, sample of exclusively women participants representing 3 states. Regulations and documentation requirements for ADS and other community-based services differ greatly between states, and preferences around the design and use of technology can be influenced by gender [15]. These findings, therefore, may therefore not be generalizable. A larger, more representative study sample would have potentially offered more robust results. However, these findings—the emphasis on minimizing disruptions to workflow, training, and institutional support—are consistent with other previous implementation studies in a broad array of health care settings [9,12,14].

**Future Directions**

The feedback gleaned in this study will guide future improvements to the CareMOBI app and on-site implementation of the app. Prior to implementation, the CareMOBI team will aim to develop interactive training modules personalized for each type of end user (ie, a caregiver-specific training module vs an ADS staff or nurse training module). Small-scale implementation studies will help develop a robust framework for successful CareMOBI adoption in ADS settings. Further technological development will be pursued to integrate CareMOBI’s interface with other prominent technologies, like TurboTAR, that are already required in ADS settings.

**Conclusions**

This mixed methods study assessed the feasibility and acceptability of ADS staff toward adopting the CareMOBI app in ADS settings. Overall, staff participants were motivated to integrate CareMOBI into their clinical settings because of its potential to ameliorate long-standing communication challenges between ADS staff and other key members of the care team. However, the qualitative interviews highlighted many important potential barriers to successful implementation that researchers will have to consider as they move forward to the next phase of CareMOBI’s development. The CareMOBI team will continue to leverage this important feedback to develop an app that is optimized to fit the needs of all end users and help bring ADS communication into the 21st Century.

Abstract

Background: Restorative dentistry plays a crucial role in dental practice, necessitating professionals to stay abreast with the latest advancements in the field. The advancement of technology has made web-based learning a widely used method of education delivery in dentistry, providing learners with extensive information and flexibility.

Objective: This study aims to evaluate how effective an online educational course in restorative dentistry is for dental graduates in Syria.

Methods: This study used a pre-experimental study design, with pretest and posttest assessments to measure changes in participants’ knowledge and skills. A total of 21 dental graduates completed the online course in restorative dentistry, which was hosted on Moodle, using the learning management system of the Syrian Virtual University. Participants were provided with a suggested learning sequence and had the flexibility to navigate the course on their own and at their own pace. The course was developed based on the principles of web course design and web-based course development using the ADDIE (Analysis, Design, Development, Implementation, and Evaluation) general instructional design model. The pretest and posttest assessments consisted of 50 multiple-choice questions with a single correct answer, aligning with the course content. Furthermore, participants were asked to complete a course acceptance survey upon finishing the course.

Results: The results showed a significant improvement in the participants’ knowledge of restorative dentistry, supported by a statistically significant $P$ value of less than .05. The effect size of the difference between the pre and posttest indicated that the effect size, as indicated by $\omega^2$, demonstrated a significant 62.1% difference between the pre and posttest, indicating a high and statistically significant effect. Furthermore, the value derived from the Haridy obtained work ratio formula indicated that the educational program was effective, with an effectiveness amount of 3.36%. Additionally, 93% (n=19) of respondents expressed confidence in having gained the expected benefits from the educational course upon its completion.

Conclusions: The findings indicated a notable enhancement in the participants’ understanding of restorative dentistry. The participants’ high satisfaction rate and positive feedback from the course acceptance survey further emphasize the favorable reception of the web-based learning approach. This study highlights the potential of web-based learning in dental education, opening the door for future research in this area. The findings of this study carry important implications for the design and implementation of web-based educational programs in dentistry, suggesting that such programs can serve as an effective tool for continuous professional development in the field.

**Introduction**

Restorative dentistry is a crucial aspect of dental practice, involving the use of various materials and techniques to restore the function and aesthetic appearance of teeth [1]. Continuous education, particularly in restorative dentistry, is essential for dental graduates and practitioners to stay updated with the latest developments in the field [2-4].

In recent years, web-based learning, also known as e-learning, has gained popularity as a method of delivering education in dentistry, thanks to technological advancements [5,6]. This approach provides learners with access to a wealth of information while offering the flexibility to learn at their own pace, overcoming the limitations of time and space [7]. In response to this trend, the dental profession has developed web-based dental courses and web-based continuing dental education programs [8]. The global implementation of web-based learning in dentistry has been further accelerated by the COVID-19 pandemic [9,10].

The transition to new education delivery models, such as web-based education, has reshaped teaching methods into a blended learning methods, particularly in dental education [11,12]. Studies have shown that web-based teaching is perceived as equally as effective as traditional classroom approaches in terms of knowledge acquisition and academic performance [1,13]. Web-based dental education programs and courses have been developed to enhance the knowledge of dental students and practitioners, providing them with easy access to a wide range of information and fostering empowerment [14-16].

Several universities and dental schools worldwide have integrated web-based education into their dental programs, acknowledging its advantages and potential to enhance patient health care outcomes through a patient-centered approach and continuous learning [17-19]. However, while web-based learning offers numerous advantages, careful consideration of technical and pedagogical factors is essential to ensure its effectiveness. Hands-on training with manikins during preclinical education remains crucial [19-21].

This study aims to evaluate the effectiveness of a web-based educational course in restorative dentistry in improving the learning outcomes for Syrian dental graduates. Through assessing the influence of this web-based course, we aim to contribute to the understanding of the benefits and effectiveness of web-based learning in dental education.

**Methods**

**Ethical Considerations**

The ethical approval of this study was obtained from the Syrian Virtual University Ethics Committee (237/0) on January 7, 2023. This study involved a pre-experimental web-based course with human participants. The course did not involve any harmful interventions or interactions that could harm the participants. There is a preprint version of this study [22].

Before their participation, informed consent was obtained from all participants. The consent form, written in Arabic, the first language of all participants, provided a clear description of the research objectives and procedures. Participants were assured that their information would be securely stored and used solely for this research. To ensure confidentiality and privacy, the study data collected from participants were anonymized and protected with appropriate security measures. Access to the participants’ identities was restricted to only one of the researchers involved in the study.

The participation questionnaire was indirectly distributed to approximately 50 graduates, and a voluntary and random selection process was conducted to include participants. Out of the 50 participants contacted individually, a total of 21 participants willingly agreed to take part in the study. The selection of participants was not influenced by any specific criteria or biases, ensuring a representative sample for the research. A total of 21 dental graduates completed the online course in restorative dentistry (OCRD) which used a pre-experimental study design with pretest and posttest assessments.

**Overview**

The course was asynchronous and hosted on Moodle, using the learning management system (LMS) of the Syrian Virtual University. Each participant had an account and full access to the course at any time. The course duration was 3 weeks, and it was available on LMS during this duration with full access for participants, it was divided into 4 thematic units with resources including documents, downloadable articles, presentations, short educational videos, examinations, and surveys.

The OCRD was developed by the principal researcher, RA, based on the principles of web course design [23,24], and web-based course development [25,26], using the ADDIE (Analysis, Design, Development, Implementation, and Evaluation) general instructional design model [27]. The course and its contents were reviewed by several experts from the Faculty of Dentistry at Damascus University.

The course primarily focused on theoretical aspects related to clinical topics. The course provided participants with a comprehensive understanding of various clinical topics within the field of dentistry. It aimed to enhance their theoretical knowledge and conceptual understanding of the principles and practices relevant to restorative dentistry. The course covered a wide range of theoretical aspects, including but not limited to dental materials, treatment planning, occlusion, tooth preparation, and aesthetic considerations. Participants were exposed to evidence-based theories, research findings, and best practices in the field. The course was theory about clinical topics and consisted of four main themes: (1) composite restoration including anterior and posterior composite restoration, (2) diastema closure, (3) direct composite veneer, and (4) tooth whitening.

In addition, we supported the course with clinical applications and clinical cases. The participants were given a suggested sequence for optimal learning but were allowed to access and navigate the course at their own pace. Participant contributions were reviewed daily to guide them in their studies and provide...
feedback. The daily feedback was given by the course tutor. Discussion of any issues related to the revised unit was also allowed, and any doubts were addressed. The study outcomes were based on the structure of the course, which was organized into units, lectures, and educational videos. Tools, methods, and resources were selected for use in the course, which included a set of presentations and related educational short videos.

The participants were informed about the pretest and posttest assessments that would be conducted as part of the study, and they were required to complete both assessments. The pretest was administered before the start of the course, while the posttest was conducted immediately after the course ended.

The study population comprised participants who had graduated from the Faculty of Dentistry. The invitation to the course was sent to a group of graduate students. A total of 21 participants agreed and accepted the invitation to participate in the course, and informed consent was obtained from those who accepted the invitation. The participants have been recruited according to the inclusion criteria including participants who had completed all restorative dentistry courses in their undergraduate studies, had access to a laptop, iPad, or smartphone, had good internet access, and had good knowledge of both Arabic and English, including medical terminology. Participants who did not complete the pretest were excluded from the study.

The pretest and posttest assessments were designed to measure the participants’ knowledge of restorative dentistry. The assessments were based on the course content. The assessments consisted of 50 multiple-choice questions with a single correct answer. The questions were designed to cover the 4 main themes of the course. Each multiple-choice question had 1 correct answer and 3 distractor options. A correct response received 2 points toward a total score of 100, while an incorrect response received zero points. The test was web-based, with limited time access. The duration of the test was 40 minutes.

In addition, participants were also asked to complete a course acceptance survey at the end of the course. The survey consisted of Likert scale questions and open-ended questions. The Likert scale questions were designed to measure the participant’s satisfaction with the course, the quality of the course content, and the effectiveness of the course in improving their knowledge of restorative dentistry. The open-ended questions allowed participants to provide additional feedback and comments about the course.

Data collected from the assessments were analyzed using SPSS (version 25.0; IBM). Descriptive statistics, including means and SDs, were calculated to describe the participants’ demographic characteristics and their pretest and posttest scores. The paired-sample 2-tailed t test was used to compare the mean scores of the pretest and posttest assessments. A P value of less than .05 was considered statistically significant.

Results
Overview
The study included 21 participants, of which 12 (57%) participants were female and 9 (43%) participants were male, with ages ranging from 23 to 30 years. Sixteen (76%) participants graduated from public universities and 5 (24%) participants graduated from private universities. The participants were distributed as follows: 12 (57%) participants were master candidates, 8 (38%) participants were general dentists, and 1 (5%) participant was a specialist. All participants had different years of experience in dental practice with 7 (33%) dentists having only 1 year of experience, 6 (29%) dentists having 2 years of experience, 6 (29%) dentists having 3 years of experience, and only 2 (10%) dentists having more than 3 years of experience.

A total of 21 participants completed the course, with course completion tracked by the LMS, and the time taken to complete the course ranged from 2 to 7 days. The pretest and posttest results were collected and stored in Google Forms and analyzed using SPSS. All 21 participants completed both tests without any significant lack of information. The change in knowledge between pretest and posttest results was analyzed using the paired-sample 2-tailed t test. A P value of less than .05 was considered significant. The P values, mean scores, and SDs for the precourse and postcourse tests for the entire test and each section are shown in Table 1.
### Table 1. Results of paired-sample 2-tailed t test to test knowledge level change.

The normal distribution was tested using the 1-sample Kolmogorov-Smirnov test, which showed that the distribution of the sample was standard. The paired-sample 2-tailed t test was then applied, revealing no statistically significant difference in the post-course test results of the participants, regardless of their age group, gender, academic status, type of university, or prior experience with web-based courses.

**Acceptance Questionnaire**

The internal consistency of the user acceptance questionnaire items, as determined by Cronbach α, was demonstrated to be 0.924, indicating high reliability. In terms of user acceptance, all survey respondents (N=21) reported satisfaction with the web-based course when using a 5-point Likert scale. Moreover, the majority of survey respondents 93% (n=19) believed that they gained the expected benefit from the educational course after its completion.

After analyzing the data, we found that there was no statistically significant difference (with a P value>.05) in the postcourse test results of the participants, regardless of their age group, gender, academic status, type of university, or prior experience with web-based courses.

**Discussion**

**Principal Findings**

This study aimed to evaluate the effectiveness of a web-based educational program in restorative dentistry for increasing the knowledge of Syrian dental graduates. The course was designed based on the fundamental principles of web course design and web-based course development. A total of 21 participants completed the entire course. The results of the study showed a significant increase in the participants’ levels of restorative dentistry knowledge after completing the web-based course, as demonstrated by the postcourse test scores.

The course was also well-received by the participants, as indicated by their positive evaluations. These findings are consistent with previous studies that have investigated the effectiveness of web-based learning in enhancing participants’ knowledge and skills. This success of the course could be attributed to the well-structured presentation and content of the course, as well as the ease of use of the web-based platform (LMS-Moodle) and its flexibility in navigating the course content [29,30].

The highest score in the students’ precourse tests was obtained about composite restoration (first unit), which may be attributed to the fact that composite restoration is widely used and considered the most popular restorative material in dentistry. In contrast, the lowest score in the precourse test was obtained for tooth whitening (fourth unit), because tooth whitening lectures are only given in advanced dental practice programs and postgraduate studies. However, the students’ scores on specific knowledge areas in the postcourse tests showed a notable improvement in all units, including tooth whitening, despite the widespread use of tooth whitening in dental clinics to restore the aesthetic appearance of teeth [31]. This result ensures that the course has been focused on new concepts and interesting ideas that the participants had not been taught before, as well as influencing their daily practice.

The result of this study is consistent with those of Morales - Pérez et al [29], Absi et al [32], and Rosenberg et al [33] regarding the effectiveness of web-based learning and web-based courses in increasing the knowledge of participants.

The current situation in Syria makes attending traditional courses challenging, due to, for example, the lack of transportation, fuel,
and electricity; lack of sufficient and qualified places to hold the courses; and shortage of human resources and staff [34-36].

However, the course offered flexibility in terms of delivery and content review, allowing participants access to the platform 24 hours a day. This approach is similar to previous studies by Murphy et al [37] and Rosenberg et al [33]. Asynchronous web-based learning was also an option that enabled participants to revisit the course materials as needed, based on their commitments and social life as noted by Ruiz et al [38].

Asynchronous web-based learning is considered an attractive, flexible, and convenient option for learners, with lower costs and easy access to information. Similarly, Kenjrawi and Dashash [39] found that asynchronous electronic medical education is an effective and feasible approach for improving the knowledge and attitude of Syrian clinical practitioners [39].

The web-based course proved a valuable option for continuing medical education in Syria given the current circumstances in Syria and after the impact of the COVID-19 pandemic [40]. In dental education, computerized sources of information and virtual reality are increasingly being used as educational tools and have shown promise in training dental students [41]. These technological advancements have the potential to revolutionize dental education and enhance the learning experience of students.

The results of this study indicate that the participants expressed high levels of acceptance and satisfaction with the restorative dentistry course, as evidenced by the questionnaire results. The majority of the cohort (19/21, 93%) reported that the course provided the desired benefit, and all participants reported enjoying it. The well-designed course materials and the instructor’s enthusiasm for delivering the web-based course were also praised by participants. However, there were some areas of the course that needed improvement, such as technical resources and communication methods required to improve the web-based course.

To further assess the effectiveness of the web-based course, future research using larger sample sizes would be beneficial, to evaluate both knowledge and skills in each unit of restorative dentistry separately. Nevertheless, implementing web-based courses of restorative dentistry in continuous medical education programs in Syria is advisable, as it may help dentists stay up to date with minimal requirements.

Limitations
The study did not assess the long-term retention of knowledge or the impact of this web-based course on the participants’ clinical practice. Furthermore, the study focused only on an OCRD. The findings might not apply to other areas of dentistry or other forms of web-based learning.

Conclusion
This study provides evidence that web-based learning can be an effective tool in improving the knowledge and skills of dental graduates about restorative dentistry. The high satisfaction rate expressed by the participants and the positive feedback received through the course acceptance survey indicate that the web-based educational program was well-received by the participants. These findings support the potential of web-based learning in dental education and suggest that it can be a valuable tool for providing continuous education to dental professionals, as it can help dental professionals stay up to date with the latest advancements in their field, which can ultimately benefit the patients they serve.

Acknowledgments
The authors would like to thank Syrian Virtual University for its assistance and all the participants who agreed to take part in this study. All authors declared that they had insufficient or no funding to support open access publication of this manuscript, including from affiliated organizations or institutions, funding agencies, or other organizations. JMIR Publications provided APF support for the publication of this article. Artificial intelligence was not used in writing this manuscript.

Abstract

Background: The artificial intelligence (AI) analysis of chest x-rays can increase the precision of binary COVID-19 diagnosis. However, it is unknown if AI-based chest x-rays can predict who will develop severe COVID-19, especially in low- and middle-income countries.

Objective: The study aims to compare the performance of human radiologist Brixia scores versus 2 AI scoring systems in predicting the severity of COVID-19 pneumonia.

Methods: We performed a cross-sectional study of 300 patients suspected with and with confirmed COVID-19 infection in Jakarta, Indonesia. A total of 2 AI scores were generated using CAD4COVID x-ray software.

Results: The AI probability score had slightly lower discrimination (area under the curve [AUC] 0.787, 95% CI 0.722-0.852). The AI score for the affected lung area (AUC 0.857, 95% CI 0.809-0.905) was almost as good as the human Brixia score (AUC 0.863, 95% CI 0.818-0.908).

Conclusions: The AI score for the affected lung area and the human radiologist Brixia score had similar and good discrimination performance in predicting COVID-19 severity. Our study demonstrated that using AI-based diagnostic tools is possible, even in low-resource settings. However, before it is widely adopted in daily practice, more studies with a larger scale and that are prospective in nature are needed to confirm our findings.
Introduction

Background

Humans have been learning to adapt to the COVID-19 pandemic. While vaccine development has mitigated the spread, mortality, and morbidity associated with COVID-19, waves of COVID-19 cases are still reported. The main driver of these cases is viral mutation, with the latest mutant, the XBB omicron subvariant, reported to be more virulent and responsible for another COVID-19 wave in Singapore [1]. As of November 1, 2022, a total of 4,707 new cases have been reported throughout Indonesia [2]. This is the highest number of new cases reported since September 1, 2022, and might be attributed to SARS-CoV-2 variants. Importantly, at the time this study was conducted, the number of new daily cases reached 14,518 confirmed cases per day at its peak (January 30, 2021) [3].

Currently, the World Health Organization (WHO) endorses the use of the nucleic acid amplification test, including reverse transcription–polymerase chain reaction (RT-PCR), as the gold-standard diagnostic method for COVID-19 cases [4]. Nonetheless, at the height of the pandemic, the weaknesses associated with the test are accentuated, thus increasing the false-negative rates [5,6]. This is similar to the situation we experienced in Indonesia during our study period.

Therefore, another alternative is needed to help with the COVID-19 triage process. Imaging modalities, primarily chest computed tomography (CT) scan and chest x-ray (CXR), are widely available in most health care facilities. Lung CT is the most effective and sensitive method for diagnosing lung lesions during early disease progression [7]. While CXR is less sensitive than lung CT, it is easier to perform, is more cost-effective, is faster, is more portable, has less radiation exposure, has simpler decontamination, and is more widely distributed. Hence, the latter is the initial radiographic modality of choice amid the COVID-19 pandemic [8].

Several scoring systems have been developed to increase CXR’s diagnostic accuracy and reliability in diagnosing COVID-19. The Brixia scoring system (BSS), one of the most commonly used scoring systems, is a semiquantitative CXR scoring system for COVID-19 diagnosis [9]. However, this system is complicated because of the issue of ground truth, which is influenced by rater experience, interobserver agreement, CXR quality, the facility, and the environment surrounding the scoring process. Moreover, additional work burden is imposed on the radiologists as the system relied on manual, subjective scoring and became a less-interesting option at the height of the pandemic [10].

Fortunately, artificial intelligence (AI) is available to ease the workforce burden amid the COVID-19 pandemic. In the past decade, AI has been advancing rapidly, especially in radiology, with applications mainly to diagnose respiratory diseases such as tuberculosis [11]. With the help of AI and machine learning, diagnostic precision can be optimized through computing algorithms for image identification and analysis, resulting in quantitative image scoring [12]. Another important AI role is to determine COVID-19 severity [13], especially in the setting of limited medical resources, equipment, and hospital beds. The correct identification of disease severity can facilitate efficient, adequate, and prompt treatment for those who need it the most.

One of the most used AI software in the COVID-19 pandemic is CAD4COVID x-ray, which detects and scores COVID-19 pneumonia through the color heat map method. This software has been shown to be significantly superior in diagnosing COVID-19 pneumonia through CXR in 454 participants compared with 6 radiologists with an excellent area under the curve (AUC) [14]. However, studies that examined this software utility for disease severity classification remained scarce, especially in low- and middle-income countries such as Indonesia.

Similar to the study mentioned earlier, our study aimed to compare AI performance against that of radiologists. However, in our study, the radiologists used the BSS.

Objectives

The research questions are two-fold: (1) How does the AI scoring system, using the color heat map methodology, compare to the BSS when assessing CXR in correlation with SARS-CoV-2 RT-PCR results among participants suspected of having COVID-19 pneumonia? (2) What is the effectiveness of the AI scoring system in comparison with the BSS for classifying disease severity in participants suspected of having COVID-19 pneumonia?

The rationale for our research questions is in alignment with the WHO’s guidelines, which recommend the use of chest imaging for the diagnostic evaluation of COVID-19 in scenarios where (1) RT-PCR testing is available but results are delayed or in cases where (2) initial RT-PCR testing returns negative results but there is a strong clinical suspicion of COVID-19 [15]. Our practical experience indicates that these delays in RT-PCR results can extend up to a maximum of 2 weeks. In addition, during periods of high COVID-19 prevalence, the occurrence of false negatives in RT-PCR tests can be notably elevated. A meta-analysis revealed that under conditions of a 50% disease prevalence rate, the rate of misdiagnosis reached 290 out of 1000 participants [16].

Moreover, the wait for a positive RT-PCR result can significantly disrupt the triage system and the clinical flow for patients suspected with COVID-19 infection, consequently leading to delays in the allocation of appropriate treatments. To the best of our knowledge, this is the first study to examine these questions in an Indonesian population.
Methods

Study Design
This retrospective cross-sectional diagnostic study used secondary data from medical records and picture archiving and communication system chest radiography repositories. This study was conducted at the Rumah sakit Dr. Cipto Mangunkusumo (RSCM) National Referral Hospital, Jakarta. This study included adults (aged ≥18 years) hospitalized with suspected COVID-19 and RT-PCR–confirmed COVID-19 infection, with or without comorbidities, from April 2020 to April 2021. This study excluded cases with substandard chest radiography qualities, large lung cavities on CXR, concurrent mediastinal or lung mass, and an interval between RT-PCR and CXR acquisition of >7 days. Data were extracted from inpatient medical records from the RSCM department of internal medicine from April 2020 to April 2021 that met the inclusion criteria. Sampling was performed consecutively until the minimum number of samples was obtained.

Ethical Considerations
This study protocol was reviewed and approved by the Faculty of Medicine, University of Indonesia’s Ethical Board (approval number Nomor KET-588/UN2. FI/ETIK/PPM.00.02/2020). Written informed consent was waived because of the retrospective nature of the study and amid the COVID-19 pandemic. All medical records and CXRs were deidentified and anonymized to ensure patient confidentiality and compliance with privacy standards. No compensations were given to the participants because of the nature of the study.

Operational Definition
Vaccination data were ascertained from history taking and medical records and ordinarily stratified into not vaccinated, vaccinated once, and vaccinated twice. COVID-19 disease severity was determined on hospital admission by emergency medical doctors and was stratified according to the local Indonesian guideline, which adopted the WHO COVID-19 disease severity stratification (Table S1 in Multimedia Appendix 1) [17]. Oxygen saturation data were measured using the transmittance pulse oximeter. They were ordinarily stratified according to normal oxygen saturation (94%-100% on room air), mild to moderate hypoxia (90%-93% on room air), and severe hypoxia (<90% on room air). The RT-PCR data were ascertained from the medical records and used naso- oropharyngeal specimens. Specimen handling and processing for RT-PCR have been described elsewhere [18].

Diabetes was defined according to the American Diabetes Association and the Indonesian Guidelines for the Management and Prevention of Diabetes [19]. Hypertension was defined according to the Indonesian Society of Hypertension Guidelines and the Eighth Joint National Committee [20,21]. Chronic obstructive pulmonary disease and asthma were determined according to the Global Initiative for Obstructive Lung Disease and the Global Initiative for Asthma guidelines, respectively [22,23]. Finally, pulmonary tuberculosis was defined according to the WHO guideline. It was deemed positive if there was a previous history of tuberculosis or active pulmonary tuberculosis [24]. Acute respiratory distress syndrome was defined according to the Berlin criteria [25].

BSS Measurement
The BSS is a semiquantitative method used to measure the severity of lung lesions on CXR. The method has been described in detail elsewhere [9]. Briefly, the lung image on CXR is divided into 6 zones, and each zone can have a score of 0 to 3 with a total maximum score of 18. A total of 2 observers, both board-certified radiologists, measured the score. The third radiologist acted as the ground truth, with >20 years of experience. Each CXR was anonymized before the scoring was performed, and radiologists were blinded to the clinical data. In this study, we focused on the overall CXR score domain of BSS for comparison. We did not establish a predefined BSS cutoff for the classification of positive SARS-CoV-2 RT-PCR results and for the disease severity classification in advance.

AI System for CXR Interpretation
For AI-based CXR interpretation, we used the CAD4COVID x-ray software. It is an advanced AI system built upon deep learning techniques designed for the identification of COVID-19 indicators in frontal CXRs. This cutting-edge system, an extension of the commercially available CAD4TB software (version 6; Thirona), primarily developed for tuberculosis detection in chest radiographs, undergoes initial preprocessing steps, including image normalization and lung segmentation via U-net software. Subsequently, the system uses a patch-based analysis with a convolutional neural network and concludes with image-level classification using an ensemble of networks [14].

The following steps were performed on the software:

1. Digital CXR (Digital Imaging and Communications in Medicine) of patients suspected with COVID-19 infection was pseudoanonymized before image upload with the picture archiving and communication system INFINITT software (INFINITT Healthcare).

2. CXR scoring was performed in 4 consecutive steps, which are as follows:
   - Normalization: this step was to normalize the CXR scale from CXRs with larger or smaller sizes and to be generalized by AI so that it can be processed uniformly.
   - Lung fields segmentation: the AI automatically did this step to delineate the lungs and distinguish them from the rest of the image.
   - Texture analysis: this step was to determine relevant abnormalities in lung segments.
   - Finally, area analysis was done to estimate the percentage of involved lung parenchyma.

3. All filter weights were calculated. The average filter weight was used as a mask on the CXR image to generate a color heat map, which was visualized only in the lung area previously segmented by the previously trained model.

4. The color heat map produced different colors corresponding to its weight. Red, yellow, green, and blue correspond to high,
medium, low, and very low probability of abnormality on the CXR, respectively.

5. The digital CXR was uploaded to the CAD4COVID software to generate 2 AI scorings. First, the affected lung area (ALA) score, with a scale from 0 to 100, was determined according to the total lung volume with abnormalities detected on the CXR. A higher value indicates more lung area that is affected. Second, the COVID-19 probability score, with a scale from 0 to 100, was determined according to the average final weight of all layers. A higher value indicates a higher probability of COVID-19.

The CAD4COVID cutoff for a positive SARS-CoV-2 RT-PCR result and disease severity classification were determined during the study.

Data Analysis

Descriptive Statistics

We summarized baseline characteristics, presenting categorical variables as frequencies (n) and proportions (%). Continuous variables were described as means with SDs for normally distributed data and as medians with IQRs for nonnormally distributed data. The normality of continuous data was assessed using the Kolmogorov-Smirnov test.

Interobserver Reliability

Interobserver reliability was evaluated using the intraclass correlation coefficient (ICC) with a 2-way mixed-effect model (k=2) and consistency. We categorized ICC values as poor, moderate, good, or excellent reliability. Estimated means with their respective 95% CIs were reported for each respective ICC. ICC values of <0.50, 0.50 to 0.75, 0.75 to 0.90, and >0.90 were interpreted as poor, moderate, good, and excellent reliability, respectively. In addition, we also evaluated interobserver reliability based on CXR projections, that is, posteroanterior (PA) and anteroposterior (AP).

Receiver Operating Characteristic Analysis

To assess the diagnostic performance of both AI scoring and Brixia scoring, we used receiver operating characteristic curves and AUC analyses. AUC values of <0.60, 0.60 to 0.70, 0.70 to 0.80, 0.80 to 0.90, and 0.90 to 1 were classified as failure, poor, fair, good, and excellent, respectively. The results were calibrated and internally validated using the Hosmer-Lemeshow test and bootstrapping. A comparison between the AUCs was performed using the DeLong test. A P value of <.05 indicates significant difference.

Optimum Cutoff Values

We determined the optimum cutoff values for AI scoring (probability score and affected lung score) and the BSS to distinguish the RT-PCR results and classify disease severity. The Youden Index method guided our selection process, aiming for the highest sensitivity with a specificity of ≥50% (Tables S2 to S4 in Multimedia Appendix 1).

Diagnostic Performance

We calculated sensitivity, specificity, accuracy, positive predictive value, and negative predictive value based on the chosen cutoff values. The reference standard for COVID-19 diagnosis was RT-PCR, as it is the diagnostic modality needed to confirm COVID-19. The reference standard for disease severity classification was the BSS.

Agreement Tests

The agreement between AI and Brixia scoring in relation to RT-PCR results and disease severity was assessed using the kappa statistic. Kappa values of 0 to 0.20, 0.21 to 0.40, 0.41 to 0.60, 0.61 to 0.80, and 0.81 to 1 were classified as slight, fair, moderate, substantial, and near-perfect agreement, respectively.

We adhered to the Standards for Reporting of Diagnostic Accuracy statement in our reporting of results. Statistical analyses were performed using SPSS for Macintosh (version 27; IBM Corp), MedCalc for Windows (version 20.114; MedCalc Software Ltd), and Stata Statistical Software for Macintosh (version 14; StataCorp LP)

Results

From April 2020 to April 2021, there were 1145 hospitalized patients with COVID-19 in RSCM National Referral Hospital, Jakarta, with complete clinical data, CXR, and RT-PCR. Only 26.2% (300/1145) of the participants met the inclusion and exclusion criteria. The study outline is presented in Figure 1.
Baseline Characteristics
A total of 300 participants (refer to the Methods section) were enrolled in this study. Demographics, comorbidities, clinical data, and radiology scoring are presented in Table 1.

In this study, most hospitalized patients with COVID-19 were aged <60 years (211/300, 70.3%), with a median population age of 52 (IQR 39.0-61.0) years and male gender preponderance (159/300, 53%). In total, >two-thirds of the patients had a negative RT-PCR result (203/300, 67.7%). Moderate disease severity dominated COVID-19 disease severity. Moreover, the 3 most common comorbidities were hypertension, diabetes, and pulmonary tuberculosis.

j Higher AI scores of affected lung area are commensurate with a larger affected lung area.
Interobserver Reliability of Lung Lesion Severity on CXR With the BSS

The analysis showed no statistically significant difference for every lung zone evaluation and the total score in Brixia scoring between the 2 observers (Table 2).

The ICC score for the BSS for every lung zone was >0.75, with good to excellent reliability for zone A (right upper lobe [RUL]) and zone D (left upper lobe [LUL]). Excellent reliability was noted for zone B (right middle lobe), zone C (right lower lobe), zone E (left middle lobe), zone F (left lower lobe), and for the overall CXR score. The Brixia score for each lung zone and the overall CXR score had similar proportions for both AP (187/300, 62.3%) and PA (101/300, 33.7%) CXR projections. The AP had a lower ICC score with a wider 95% CI (Figure S1 in Multimedia Appendix 1).

Performance Comparison Between Color Heat Map–Based AI Scoring Performance and the BSS on CXR Against SARS-CoV-2 RT-PCR Results of Patients Suspected With COVID-19 Infection

Of the 300 participants suspected with COVID-19 infection, only 32.3% (97/300) had a positive RT-PCR result. Owing to the small number of RT-PCR–positive cases and its large measurement error, no scoring system was able to statistically discriminate between patients who had a positive RT-PCR result and those who had a negative RT-PCR result.

Performance Comparison Between Color Heat Map–Based AI Scoring and the BSS on CXR Against COVID-19 Disease Severity

All scores were higher among 86% (258/300) of cases of moderate to critical disease, when compared with 14% (42/300) of cases of mild disease (P<.001). The receiver operating characteristic analysis showed that the AI probability score, AI ALA score, and BSS had excellent discrimination against COVID-19 disease severity (Table 3; Figure 2).

Compared with the performance of BSS to discriminate disease severity (sensitivity 75.7% and accuracy 79.3%), the AI ALA score had better sensitivity and accuracy (Sn 84.5% and accuracy 83.0%), while the AI probability score did not (Sn 68.2% and accuracy 69.7%). The kappa statistic showed there were moderate agreements between AI probability score (κ=0.271±0.050; P<.001), AI ALA score (κ=0.452±0.063; P<.001), and BSS (κ=0.456±0.053; P<.001) against COVID-19 disease severity (Table 3). However, there was no significant difference between the AUC for the AI probability score (AUC 0.787) and the BSS (AUC=0.863), with a difference of 0.076 (SD 0.034, 95% CI 0.010-0.142; P=.04). Similarly, no significant difference was observed between the AI ALA score (AUC 0.857) and the BSS, with a negligible difference of 0.006 (SD 0.023, 95% CI –0.039 to 0.052; P=.76), indicating that both AI scores were comparable to BSS in discriminating disease severity (Table 4).

The Hosmer-Lemeshow test shows good calibration and internal validation for the AI probability score ($P=.90$) and AI ALA score ($P=.99$). Calibration and internal validation of the BSS could not be performed.

**Discussion**

**Principal Findings**

In this study, we demonstrated that the BSS had excellent interobserver reliability (ICC $>0.75$) to determine the severity of lung lesions on CXR (ICC $0.950$, 95% CI $0.937$-$0.960$). Our findings are in agreement with previous studies by Mruk et al [26] (ICC $=0.847$, 95% CI $0.816$-$0.848$) and Chaudhari et al [27] (ICC $=0.920$, 95% CI $0.880$-$0.950$). Our study also aligns with that of Mruk et al [26], who reported that PA projection had higher interobserver agreement and reliability than AP projection. Thus, it can be assumed that PA CXR projection has better image quality and thus can affect the interpretation.

In the context of lung anatomy, zone A (RUL) and zone D (LUL) had lower ICC values than the other zones. These findings were similar to those of a previous study by Monaco et al [28], who also reported that LUL had the lowest ICC, followed by the right lower lobe and the RUL. A hypothesis explaining these findings is that the upper zone sparing phenomenon seen in COVID-19 pneumonia, that is, infiltrates rarely develop on the LUL and the RUL. Moreover, anatomical structure juxtaposition with the clavicles and scapula influences the scoring subjectivity of these zones.

Although the interobserver reliability was excellent and the mean difference in the overall CXR score was low, the interobserver score had a very wide range ($Δ$ Overall CXR score $=0.0$-$16.0$). This difference was influenced by a myriad of factors that were not studied in this research. Similarly, van Assen et al [29] reported poor interobserver agreement when assessing disease severity. The disease severity classification was different in 82% of CXR, with 59% showing a 1° difference in disease severity. The differences were primarily observed in the intermediate group (mild and moderate severity), which can greatly affect clinical decision-making for patient management.

While the semiquantitative method may be seen as more convenient, the subjective nature of this scoring system can give rise to multiple problems, including how to determine the ground truth. Thus, supporting data is needed to justify its use [10]. Moreover, the BSS can contribute to health care workers’ burnout, especially radiologists, as the system relies on them to manually sum up the score.

No scoring system was able to statistically discriminate between which patients had a positive RT-PCR result and which ones had a negative RT-PCR result. These findings might be explained by the low prevalence of positive RT-PCR results ($97/300$, 32.3%), which might have been caused by a high false-negative rate, considering the true COVID-19 prevalence during the participant enrollment was 47.6% ($143/300$).

False-negative RT-PCR results can be explained by numerous factors, including exposure time, symptom onset, SARS-CoV-2 virulence, and specimen handling and processing [30-35]. Lai and Lam [31] showed that the interval between the day of exposure and the day of RT-PCR specimen sampling contributed to false-negative rates. False-negative rates of RT-PCR for the 0-, 5-, 8-, and 21-day interval were 100%, 35%, 20%, and 66%, respectively. Viral virulence also contributed to a false-negative rate, as reported in studies by Alteri et al [34] and Petrillo et al [35]. They showed that the false-negative rates of participants infected with low viral virulence were approaching 20% to 30%.

Another possible contributor to an increased false-negative rate was specimen transportation, considering that the viral specimen should be kept at a minimum of $–70$ °C to maintain viral isolation and viability [36]. This factor is crucial owing to the unavailability of an in-house RT-PCR facility in our hospital because it was centralized in the early days of the COVID-19 pandemic. Our hospital is a national referral hospital, which might have led to referral bias. Therefore, most patients referred from lower-tier health care facilities with COVID-19 may have negative RT-PCR results as they may have passed the virulence period and many days have passed since the first onset of symptoms. Finally, according to the Indonesian COVID-19 guidelines, the RT-PCR test did not have to be repeated, contrary to the WHO and European Center for Disease Control guidelines, which state that before discharging patients, 2 negative RT-PCRs are needed [4,37]. Therefore, in our circumstances, solely relying on RT-PCR can lead to an underestimation of the COVID-19 diagnosis, which will impact the decision-making and clinical management of COVID-19. In retrospect, as the RT-PCR turnaround time is high with a high operating cost, at the height of the COVID-19 pandemic, another screening modality that is fast, inexpensive, practical, reliable, and noninvasive is needed for triaging, diagnosing, and quarantining suspected COVID-19 cases as measures to curb the pandemic. Nonetheless, this modality will act as an adjunct to conventional CXR and should be incorporated while waiting for the RT-PCR results [38]. Therefore, we preferred CXR rather than CT scan as the modality that we researched because it is widely available, inexpensive, and has low radiation exposure.

Although our findings found that AI and Brixia scoring were poor COVID-19 diagnostic modalities, they were similar to previous studies that also reported that AI and manual radiologist scoring had similar performance. Murphy et al [14] showed that the AI system (AUC $0.810$) gave similar scoring results and was even superior compared with 6 radiologists ($P<.001$). This was likely because of the heterogeneous lung lesions seen on CXR in patients with COVID-19, including peripheral and diffuse opacities, which made distinguishing COVID-19 from other pulmonary diseases more challenging. In contrast, Chamberlin et al [39] stated that radiologists had a superior diagnostic ability for COVID-19 (AUC $0.936$, 95% CI $0.918$-$0.960$) compared to AI (AUC $0.890$, 95% CI $0.861$-$0.920$), despite similar discriminatory abilities between them.

However, the AI scoring system has several advantages over manual evaluation for CXR interpretation. First, an automated
and quantified AI scoring system will decrease radiologists’ overall work burden. Second, with the help of the AI scoring system, radiologists can increase their accuracy up to 99.05%, which is comparable to that of RT-PCR [40,41]. Moreover, as nonradiologists, especially medical doctors who work on the front line, are the first ones to see the CXR before interpretation by the radiologists, AI use can increase the diagnostic agreement. Hwang et al [42] showed that AI scoring gave similar results to radiologists (AUC 0.714 vs 0.712) but was superior to nonradiologists (AUC 0.714 vs 0.584). Furthermore, hybrid AI use increased diagnostic agreement significantly for both groups (radiologists’ Fleiss κ=0.688, 95% CI 0.665-0.710; nonradiologists’ Fleiss =0.510, 95% CI 0.488-0.533) [42].

In our assessment of AI and BSS performance against disease severity in patients suspected with COVID-19 infection participants, the AI ALA score exhibited higher sensitivity and diagnostic accuracy compared with the BSS, although the difference was not statistically significant. This can be explained by the fact that CAD4COVID can eliminate the technical limitations of conventional CXR, such as its quality. Furthermore, before generating scores, the software normalized the CXR image and segmented lung fields, which optimized CXR image quality [14]. Considering the limited size of our data set, it is not possible to definitively assert the superiority of the AI system over human Brixia. Nonetheless, our analysis indicates a 95% CI that the AI system’s performance is not statistically distinct from that of human Brixia. This finding serves as a promising safety signal, warranting additional comprehensive testing and assessment of AI scoring systems in larger subsequent studies aimed at real-world implementation. Regardless, both had excellent discrimination without significant differences in AUC.

In the context of evaluating AI and Brixia scoring in assessing disease severity among patients suspected with COVID-19 infection participants, both AI scoring systems demonstrated notably higher sensitivity and diagnostic accuracy when compared with the BSS. This superiority can be attributed to the capacity of CAD4COVID to overcome the inherent technical limitations often associated with conventional CXR imaging, including variations in image quality. Notably, CAD4COVID effectively normalized CXR images and meticulously segmented lung fields before generating probability and ALA scores, thereby enhancing overall image quality. Notably, both AI and human Brixia scoring exhibited excellent discrimination without significant disparities in the AUC.

To the best of our knowledge, this is the first study to compare the AI scoring performance using the CAD4COVID software based on AI probability and AI ALA score with the BSS against disease severity in patients suspected with COVID-19 infection participants. Our findings align with those of Guiot et al [43], albeit with a different modality. In their research, CAD4COVID-CT, through the ALA and CT severity score (CT-SS), was able to predict the length of stay, the odds of intensive care unit admission, the odds of mechanical ventilation, and the odds of in-hospital mortality [43]. The cutoff value chosen for odds of intensive care unit admission was CT-SS 14 with an AUC of 0.84 (95% CI 0.79-0.90) and, for odds of mechanical ventilation, it was CT-SS 16 with an AUC of 0.71 (95% CI 0.63-0.78).

The sensitivity, specificity, and accuracy of the BSS were 75.6%, 100%, and 78.4%, respectively. These values were lower than reported by Abo-Hedibah et al [44]. In their study, the BSS sensitivity, specificity, and accuracy in diagnosing moderate disease were 90.4%, 100%, and 94.6%, respectively, whereas in diagnosing severe disease, they were 100%, 84.5%, and 86.7%, respectively. Nevertheless, they referred to disease severity stratified by the WHO, whereas our study referred to the Indonesian national guidelines.

The clinical implications of these findings are 2-fold. First, with the help of AI scoring, a clinician can more confidently exclude moderately to critically ill patients with COVID-19. However, the AI scoring system is image based and not clinically applicable. Thus, it will generate conflicting results when the disease severity classification relies on clinical criteria, as seen in the WHO and Indonesian guidelines [17,45]. In contrast, the US National Institutes of Health COVID-19 guidelines do not solely rely on clinical data [46]. For example, moderate COVID-19 infection can be diagnosed if there are pulmonary infiltrates on imaging. As COVID-19 pneumonia can be asymptomatic or without typical signs and symptoms of pneumonia, we argue that disease severity should be stratified according to the National Institutes of Health guideline [46].

Second, minimal pulmonary lesions on the CXR that are sometimes undetected by manual readers could be identified by AI. The AI probability and the ALA score had higher sensitivities than the BSS to rule out moderate to critical disease. The AI probability and the ALA score can mitigate drawbacks when relying on clinical judgment and conventional radiographs. These findings are significant, as the downstream effect will include patient management, that is, outpatient or inpatient treatment.

According to our study results, we propose the incorporation and clinical application of AI use on CXR as an ancillary diagnostic tool for patients suspected with COVID-19 infection in a structured algorithm. We hope that for future COVID-19 outbreaks, this algorithm can shorten triage and diagnostic time and shorten clinical decision-making as to whether the patients need to be quarantined or hospitalized. As AI and Brixia scoring did not have discriminatory ability against RT-PCR results in suspected COVID-19 cases, we hope that with the addition of clinical and laboratory data, a more precise diagnostic model can be developed. In contrast to the RT-PCR results, the AI and Brixia scoring had an excellent ability to discriminate disease severity in patients suspected with COVID-19 infection, with superior sensitivity and accuracy observed for the former. Thus, AI scoring can be considered for CXR interpretation because of the clinical–radiological incompatibility that can sometimes be observed in patients with COVID-19 pneumonia.

Our study showed that the AI scoring system has the potential to become a disease severity classifier for patients with suspected COVID-19 infection. As the AI scoring system was generated through machine learning, with more data available to train the system, the AI scoring accuracy will continue to increase. We proposed an algorithm for AI incorporation and...
AI application on CXR as an ancillary diagnostic test for patients with COVID-19 (Figure 3).

Figure 3. Proposed algorithm of artificial intelligence (AI) incorporation and AI application on chest x-ray as an ancillary diagnostic test on patients with COVID-19. ALA: affected lung area; CXR: chest x-ray; Prob: probability; RT-PCR: reverse transcription–polymerase chain reaction.

Limitations
Our study has several limitations. First, the study population is relatively small compared with the COVID-19 prevalence during the participant’s enrollment, owing to missing data and the study’s exclusion criteria. Second, as our hospital is a national referral hospital, most patients came with moderate to critical disease and presented with other pulmonary lesions. Furthermore, several study variables could not be retrieved as they were not incorporated into the patient’s medical record. Finally, in the early days of the pandemic, our hospital did not have an in-house RT-PCR facility because of the centralized specimen processing, so the specimen had to be delivered to another facility, which could further compromise RT-PCR results.

Conclusions
The AI score for the ALA and the human radiologist Brixia score had similar and good discrimination performance in predicting COVID-19 severity. Our study demonstrated that using AI-based diagnostic tools is possible, even in low-resource settings. However, before it is widely adopted in daily practice, more studies with a larger scale and prospective in nature are needed to confirm our findings.

Acknowledgments
The authors thank Delft Imaging for providing CAD4COVID free of charge. The research team institutions have also signed a joint research arrangement between Universitas Indonesia, Dr. Cipto Mangunkusumo National Referral Hospital, and Delft Imaging System, encompassing rights and obligations for each party on data confidentiality during and after the research period. This study was supported by Universitas Indonesia PUTI Q1 2022 Research Grant NKB-429/UN2. RST/HKP:05.00/2022. The code for CAD4COVID is not publicly available as it is proprietary software. Abstract

Background: Polycystic ovary syndrome (PCOS) represents a significant global health burden requiring urgent attention. This common chronic endocrine and cardiometabolic condition affects around 1 in 10 women and individuals assigned female at birth, with significant adverse effects on well-being, quality of life, and mental health, as well as serious and complex long-term health consequences. International guidelines for best health care practice recommend the provision of comprehensive cognitive behavioral interventions to support self-management and improve health outcomes for those living with PCOS. Web-based health interventions have the potential to meet this need in an accessible and scalable way.

Objective: We aim to identify barriers to self-management and psychological well-being in women with PCOS and adapt a web-based self-management program to provide a prototype digital support intervention for them.

Methods: We adapted an existing support program (HOPE) for PCOS using the antecedent target measure approach. We conducted qualitative interviews with 13 adult women living with PCOS, 3 trustees of a patients with PCOS advocacy charity, and 4 endocrinologists to identify “antecedents” (barriers) to self-management and psychological well-being. Framework analysis was used to identify potentially modifiable antecedents to be targeted by the novel intervention. At a national conference, 58 key stakeholders (patients and health professionals) voted for the antecedents they felt were most important to address. We used research evidence and relevant theory to design a prototype for the PCOS intervention.

Results: Voting identified 32 potentially modifiable antecedents, relating to knowledge, understanding, emotions, motivation, and behaviors, as priorities to be targeted in the new intervention. A modular, web-based prototype HOPE PCOS intervention was developed to address these, covering six broad topic areas (instilling HOPE for PCOS; managing the stress of PCOS; feeding your mind and body well; body image, intimacy, and close relationships; staying healthy with PCOS; and keeping PCOS in its place).

Conclusions: We identified barriers to self-management and psychological well-being in women with PCOS and used these to adapt a web-based self-management program, tailoring it for PCOS, which is a comprehensive group intervention combining education, empowerment, lifestyle management, peer support with cognitive behavioral tools, and goal-setting (to be delivered by peers or codelivered with health care professionals). The modular structure offers flexibility to adapt the program further as new clinical recommendations emerge. The intervention has the potential to be delivered, evaluated for feasibility, and, if effective, integrated into health care services. Self-management interventions are not designed to replace clinical care; rather, they serve as an additional source of support. The HOPE PCOS program conveys this message in its content and activities. Future research should evaluate the prototype intervention using primary outcomes such as measures of psychological well-being, self-management self-efficacy, depression, anxiety, and PCOS-related quality of life. They should also assess the intervention’s acceptability, scalability, and cost-effectiveness.
Introduction

A Complex Condition With Serious Physical and Mental Health Consequences

Polycystic ovary syndrome (PCOS) represents a significant global health burden requiring urgent attention [1]. It is a common chronic cardiometabolic condition affecting around 1 in 10 women and individuals assigned female at birth. PCOS has diverse symptoms, for example, acne, alopecia, hirsutism, obesity, impaired glucose metabolism, menstrual disturbances, and subfertility [2-4]. It has significant adverse effects on well-being, quality of life, and mental health. For example, compared with healthy controls, women with PCOS have lower health-related quality of life and higher scores on symptoms of depression and anxiety [5-9], and appear to be at risk for disordered eating [10-14] and unhealthy weight management practices [15]. There is also evidence that women with PCOS may experience impaired sexual satisfaction [16], which may impact relationship satisfaction for those in intimate relationships [17]. The adverse mental health impact of PCOS may have been worsened during the COVID-19 pandemic, as patients faced an uncertain risk of contracting COVID-19, more limited access to health care services, and barriers to using their normal support strategies [18].

PCOS has serious and complex long-term health consequences [19,20]. Women with PCOS are at increased risk of sleep disturbances [21] and obstructive sleep apnea [22,23] and appear to have an elevated risk for postpartum depression [24]. They also have an increased risk of developing type 2 diabetes and cardiovascular complications [4]. Hospital admission rates for patients with PCOS have been reported to be twice as high as those without the condition [25].

The Need for Self-Management Support

PCOS is a long-term condition with no cure, having a wide range of treatment options but no single treatment that targets every symptom or concern. Treatments are often complex and multifaceted and often include recommendations for lifestyle change, for example, altering diet and increasing physical activity [4]. Considerable self-management is required on the part of those living with PCOS, including adherence to treatment. There are wide disparities in adherence, with 1 review suggesting adherence rates ranging from 21.7% to 86% [26]. A large-scale survey suggests women with PCOS are open to adjusting their diet and physical activity to improve their health, but few achieve their goals [27].

Recent qualitative research [28-33] has identified that women with PCOS face a range of barriers to following health professionals’ lifestyle advice, including limited access to credible information, time, cost, and lack of access to safe exercise spaces, with some women lacking adequate social support, having unsupportive partners, or struggling to prioritize their own health because of responsibilities for feeding children [29]. In addition, women’s motivation and capability to adhere to recommended lifestyle changes may be impacted by the complex and multifaceted nature of PCOS, including fatigue, anxiety, depression, difficult emotions, disordered eating, the impact of stress, sleep disturbances, and a lack of critical health literacy [28,29,31-33]. Features of PCOS itself may add to the burden of following lifestyle advice, especially around weight management. For example, altered regulation of gut hormones and energy expenditure may affect women’s capability to follow diet and exercise regimes [28].

The Need for Comprehensive, Evidence-Based, Coproduced Interventions

Patients with PCOS value specialized, integrated health care services [34], and it has been argued that the ideal model of care would be “evidence-based, patient-centered, codeveloped by consumers and health professionals” [35]. International guidelines advise (in addition to appropriate medical treatment) “Comprehensive health behavioral or cognitive behavioral interventions could be considered to increase support, engagement, retention, adherence, and maintenance of a healthy lifestyle and improve health outcomes in women with PCOS.” [4]. There is therefore scope for developing new interventions that combine education and cognitive behavioral approaches with peer support to promote physical activity, healthy eating, and emotional well-being in women with PCOS. This multifaceted approach reflects the tradition of long-term self-management that is well established in other endocrine conditions, such as diabetes [36]. Self-management is arguably broader than lifestyle change, referring to what patients must do to manage their own health in collaboration with health professionals [37,38]. This may include behavior change but also requires emotional regulation, coping, and maintaining general well-being, such as self-worth, a positive outlook, and hope [39].

Objectives for This Study

The first aim of the study was to identify barriers to self-management and psychological well-being in women with PCOS. The second aim was to combine insights from these data to cocreatively adapt an existing web-based program to offer a prototype peer-delivered, self-management intervention to empower and support women with PCOS to enhance their psychological well-being and, if they chose to, to make appropriate lifestyle changes to self-manage their condition.

To develop our novel self-management intervention for PCOS, we selected an existing intervention that has been researched and evaluated with multiple patient groups. The HOPE program [40] is a complex intervention for long-term condition self-management with a distinctive theory and evidence base from positive psychology [41]. The HOPE program has reduced anxiety and depression and increased positive well-being for...
people with a range of health conditions and support needs, for example, people living with multiple sclerosis [42], parents of children with developmental disorders [43], and people living with and after cancer [44].

Methods

Approach to Intervention Development

The UK Medical Research Council’s (MRC) guidance on developing complex interventions [45,46] recommends that intervention development should be “a dynamic iterative process, involving stakeholders, reviewing published research evidence, drawing on existing theories, articulating program theory, undertaking primary data collection, understanding context, paying attention to future implementation in the real world, and designing and refining an intervention using iterative cycles of development with stakeholder input throughout” [46]. The most recent framework commissioned by the National Institute of Health Research and the MRC [47] further emphasizes the importance of developing interventions that are “implementable, cost-effective, transferable, and scalable in real-world conditions.” This may include adapting existing interventions and using existing, for example, digital infrastructure, rather than developing wholly new interventions ab initio. We chose to adapt and tailor an existing intervention to build on its previous successes and use its proven, scalable digital infrastructure to offer a PCOS intervention that would be as implementable, transferable, and scalable as possible.

The HOPE cancer program from which this intervention was adapted [44] was developed following the MRC recommended processes and continues to undergo refinements as each cohort or variant of the program is completed. In adapting HOPE for PCOS, we conducted an initial needs assessment with key stakeholders, reviewed published research evidence from primary sources, review papers, and international clinical guidelines, and drew on established and emerging theories about psychological well-being to produce a prototype digital intervention [48] that could be subjected to feasibility testing.

Underpinning Theory and Evidence: Self-Management Versus Behavior Change

Interventions in the field of health behavior are more likely to be successful if they are theory-based [49]. A number of different approaches were considered for adapting the existing HOPE program, including the behavior change wheel [50] and intervention mapping [51]. However, both of these approaches require very clear specification at the outset of the intervention design of what the target behavior is that the intervention seeks to increase, decrease, promote, or modify. “Lifestyle change” is recommended as a first-line treatment in relation to the management of PCOS, and this often refers to changes to diet and physical activity. However, there is as yet no international consensus as to what precise optimal self-management behaviors might be in PCOS, and it was felt that the groundwork was lacking for the development of a behavior change intervention per se. Given the diversity of the PCOS population, for example some are lean, some are living with overweight and obesity, some are trying to conceive, others are not, some are physically active, some are more sedentary, some have issues around eating, and others are not, the development of a behavior change intervention to meet the needs of all these was beyond the scope of this study. As our objective was to adapt the existing HOPE program to support self-management, reduce depression and anxiety, and promote psychological well-being rather than develop a completely new intervention from scratch, we used the design process outlined in the following sections.

Cocreation Process

An iterative process of cocreation was used to develop the intervention, using a mixed methodology. An initial needs assessment was conducted with key stakeholders, following the antecedent target measure (ATM) approach [52,53]. This is a flexible model that has been used in the development of previous self-management interventions, for example, for people living with cancer or dementia [54,55].

Initial Data Collection

Semistructured interviews were conducted with women living with PCOS, trustees of the Verity UK PCOS charity who themselves had PCOS, and endocrinologists who provided services to patients with PCOS at a large publicly funded teaching hospital.

Participant Characteristics

Those with lived experience of PCOS were 13 adult women recruited through purposive sampling from social media. All had received a formal diagnosis of PCOS from health professionals at least 6 months before the study and took part in individual interviews. The Verity trustees were 3 adult women, all diagnosed with PCOS by National Health Service (NHS) clinicians, who volunteered to be interviewed to assist with the “cocreation” of the new intervention. The health professionals interviewed in December 2016 were 4 endocrinologists working for a large UK NHS teaching hospital, which has a specialist clinic for PCOS.

Procedure

Interviewees were presented with the problem statement “Some women with PCOS struggle to cope and self-manage effectively” and asked if they agreed and, if so, to give all the reasons why. The reasons given (“antecedents” in the terminology of ATM) were typically difficulties women experience with PCOS and in self-managing their condition. Interviews continued until participants felt they had exhausted all the antecedents they viewed as relevant for PCOS. Antecedents and the conversation through which they were generated were audio recorded and transcribed verbatim for the patient interviews. Antecedents were transcribed contemporaneously for the trustee and health professional interviews.

Analysis

All the antecedents generated across interviews were collated and analyzed thematically following the framework analysis approach to theme development [56] to identify potential targets for intervention. When targets were chosen for intervention, only those considered to be potentially amenable to change by a self-management intervention were selected. For example,
the following antecedents were excluded: endocrine characteristics of PCOS itself, social and environmental factors such as stigmatizing behavior from others, and issues with the health care system such as general practitioners’ awareness of PCOS. Once antecedents judged to be unsuitable targets for the intervention were excluded, 36 potentially modifiable antecedents remained.

**Stakeholder Voting on Priorities for Intervention**

A web-based survey was created listing the 36 modifiable antecedents, and delegates at a national public engagement conference were asked to rate each of these on a 5-point scale of how important they would be to target in a self-management intervention (0=not at all important, 1=somewhat important, 2=important, 3=extremely important, and 4=crucial). Conference delegates included patients with PCOS and advocates and some health professionals treating PCOS, of whom 58 voted in the survey. All modifiable antecedents scoring 2.5 or above were retained as intervention targets; antecedents scoring below 2.5 were discarded.

**Literature Searches for Intervention Targets**

Literature searches were conducted, and clinical guidelines were consulted to generate further intervention targets. Review and systematic review papers [2,16,57-68] were reviewed alongside an international clinical guideline for the management of PCOS [4]. No new targets were generated from the literature, which confirmed the findings from the needs assessment with key stakeholders.

**Adaptation of Existing Digital Intervention and Consultation With Stakeholders**

The existing HOPE program has previously been specified using the Practical Reviews in Self-Management Support (PRISMS) self-management intervention taxonomy [69], and new intervention components were mapped onto or added to the program specification. New program content specific to the prototype PCOS program was created to complement the existing HOPE program materials. A paper prototype was presented to key stakeholders from the PCOS support charity, and following discussion, the new program materials were created and uploaded into the secure web-based platform that hosts the HOPE program. This produced a 6-week web-based intervention ready for feasibility testing.

**Ethical Considerations**

This study received clearance from the Coventry University Research and Ethics Governance Committee (approvals P40730, P44631, and P45355). For the data collection from health care professionals, NHS Research Ethics Committee approval was not required. A letter of access for research was provided by the Research, Development, and Innovation office of the University Hospitals Coventry and Warwickshire NHS Trust. Participants provided written, informed consent before being interviewed. Patients with PCOS and health care professionals at the public engagement event completed a digital informed consent statement before completing the web-based voting survey. Interview transcripts were anonymized for analysis. No personally identifiable data were collected in the voting survey. No compensation was offered to any participants.

**Results**

**Stakeholder Needs Assessment and Voting**

Table 1 shows the list of modifiable antecedents presented in the next stage of the intervention design. Figure 1 shows a diagrammatic representation of the logic model developed from the PCOS self-management needs assessment done with stakeholders.
Table 1. Modifiable antecedents of polycystic ovary syndrome (PCOS) self-management and psychological well-being in order of priority, as voted on by patient and health care professional delegates at the public engagement event.

^Potential antecedents scoring below 2.5 were discarded as intervention priorities. This left 32 antecedents that were targeted by the new intervention, 10 of which were thematically categorized in the framework analysis under behaviors, 9 under emotions, 8 under knowledge and understanding, 8 under motivation, and 1 under skills.
In a typical ATM design, logic models are often presented as linear processes in which 1 antecedent, such as knowledge or understanding, is represented as preceding another, such as motivation or behavior. We have selected the metaphor of interlocking gears for our schematic logic model on the assumption that knowledge, understanding, skills, motivation, emotions, and behavior interlock and may drive or impede each other, at times facilitating or hampering effective self-management. For example, a person might gain helpful knowledge about their condition, but without developing skills to apply this to practice, they might be unable to engage in effective self-management behaviors. Similarly, a person might have adequate knowledge, understanding, and skills to manage their condition, but difficult emotions might adversely impact their motivation and prevent effective self-management. This logic model was used to inform the adaptation of the existing HOPE program framework to produce a specific version for PCOS.

Mapping Modifiable Antecedents Onto Intervention Content

Table 2 shows how the antecedent “problems” derived from the logic model were mapped onto solution-focused content across 6 sessions of the prototype intervention.
### Table 2. Mapping of antecedents of polycystic ovary syndrome (PCOS) self-management and psychological well-being onto new PCOS self-management intervention session content.

#### Choosing Theory- and Evidence-Based Intervention Components to Address Modifiable Antecedents of Self-Management

The HOPE program framework used to develop the PCOS intervention includes the following self-management intervention components: information about available resources, safety netting, training and rehearsal to communicate with health care professionals, training and rehearsal in psychological strategies, social support, and lifestyle advice and support [69].

Below, we outline how specific intervention content was selected to address the antecedents identified in the logic model for PCOS self-management.

#### Information and Activities to Target Knowledge and Understanding for Self-Management

Women with PCOS have unmet information needs [63,70-72] and may lack knowledge of how to manage their condition, for example, how to eat well to manage insulin resistance [33,73]. Unmet information needs may adversely impact...
self-management, including adherence to treatment [26,28,32,74,75]. PCOS-specific information is valued by patients with PCOS and may address unmet psychosocial needs [76-78], potentially enhancing understanding, reducing anxiety, and promoting quality of life [79]. There is a plethora of information sources available on the web, of varying quality, making it difficult for women with PCOS to select trustworthy material [71,80-83]. Signposting to trustworthy information sources may support patient activation and self-management. In the prototype intervention, factual information is provided about PCOS, including androgen excess and food intake, blood sugar and insulin resistance, eating well, and managing weight.

The needs assessment and previous research [84,85] indicate women may have concerns about the long-term health sequelae of PCOS. Motivation to adopt healthy lifestyles may be impacted by perceptions of the health risks associated with PCOS [28]. In the prototype intervention, content is provided on focusing on future health and ways to manage emerging health concerns and worries. Information about specialist health professionals, the range of support, and some potential treatment options is designed to empower participants to be active partners in their health care. The intervention seeks to empower participants to engage in health protective behaviors, for example, exercise, healthy eating, self-monitoring of their health, managing worries to alleviate health anxiety, and future help-seeking as any new health issues arise. Links to further information and resources are provided, for example, Verity (a UK PCOS charity), the NHS Choices website, the NHS Improving Access to Psychological Therapies service, and the AskPCOS app [86].

**Goal Setting and Feedback to Target Self-Management**

**Motivation and Behavior**

Women with PCOS may struggle to achieve the goals they set for lifestyle change [27], may lack the ability to identify and resolve barriers [32], experience tiredness, feel unrewarded, or have depressive and defeating thoughts that act as barriers to achieving their goals [29]. Goal setting is a widely used and effective component of self-management support [87,88]. Goal-oriented care, emphasizing patient priorities and values, may be particularly appropriate for patients with chronic or multifaceted health concerns [89]. Goal-setting theory and research recommend paying attention to multiple goal factors and multiple phases in the goal process [90].

Goal setting and solution-focused goal feedback are included in every session of the prototype intervention, with weekly and long-term goals chosen by participants themselves based on their personal priorities and values rather than set or recommended by program facilitators. The goal-setting and feedback processes are facilitated by peer facilitators, with attention to goal difficulty, goal specificity, goal proximity, goal commitment, and solution-focused feedback.

**Psychoeducation and Activities to Target Emotions**

Women with PCOS are prone to higher perceived stress [91], and stress may also impact women with PCOS differently and have an impact on the physiology of the condition [92,93]. Stress may be a barrier to lifestyle change [32]. Mindfulness-based stress reduction activities have been effective in reducing stress, depressive, and anxiety symptoms in PCOS [94] and in increasing self-efficacy for physical activity and nutrition behaviors [95]. Physical activity has well-recognized benefits for mood and perceived stress [96,97], including in women with PCOS [98,99]. In the prototype intervention, content is provided on managing stress, including mindfulness, soothing rhythm breathing, guided imagery, and “get active, feel good.” Because interviews with health professionals during the needs assessment suggested that some women with PCOS may exercise in dysfunctional ways in order to lose weight, the PCOS prototype intervention does not promote exercise for weight loss per se but rather for stress management and general well-being.

Psychological comorbidities may be a barrier to lifestyle change [32]. Interventions using aspects of cognitive behavioral therapy (CBT) have shown promise for improving fatigue, quality of life, weight loss, and depressive symptoms in women with PCOS [100-103]. In the prototype intervention, CBT-informed content is provided on managing common unhelpful thinking patterns. Compassionate mind approaches (sometimes referred to as part of a “third wave” of CBT) are particularly relevant to disordered eating, emotional eating, and weight management [104-107]. In the prototype intervention, a compassionate mind approach is taken to eating well, including eating mindfully, overeating, binge eating, and self-soothing.

Self-compassion activities, compassionate mind training, and compassion-focused therapy have been demonstrated to be particularly beneficial in improving anxiety, depression, shame, and self-criticism [106,108-111]. These issues have been identified as common in populations with PCOS. In the prototype intervention, content is provided on self-compassion, including, for example, compassion for perceived flaws, toward feelings of embarrassment or shame, and “getting to know your inner critic.”

Women with PCOS may have reduced relational and marital satisfaction [17,112], sexual satisfaction, function, and sense of sexual attractiveness [16,113-119]. Body dissatisfaction may be a barrier to lifestyle change [28]. The prototype intervention discusses and seeks to normalize the topic of common body changes and associated distress, for example, acne, alopecia, hirsutism, obesity, and associated low self-esteem, frustration, and depression, which have been identified in previous research [84,120-123], and in the needs assessment. Content is provided on common body changes in PCOS and associated difficult emotions. The potential impact of PCOS on intimate relationships and sexuality is explored, along with suggestions for ways to cope and adjust.

The population with PCOS is diverse, including women who will be more or less concerned about visible or invisible body changes. Interventions may empower them to respond and adjust in ways that are personally appropriate, including accepting changes, making adaptations, or seeking treatment, for example, for obesity or hirsutism. Previous research, including the needs assessment, indicates that embarrassment or shame may lead women to conceal the extent of their bodily changes, even from health professionals [124-127]. In the prototype intervention,
content is provided on responding to change, including acceptance, treatments and adaptations, and overcoming embarrassment to get help for body changes. The PCOS intervention takes an autonomy or body acceptance approach [128,129]. Unrealistic female body standards and body-positive activism are discussed in the program materials.

Women may struggle to manage and control their PCOS symptoms, especially if they have comorbidities, sometimes feeling controlled by their condition [84]. Motivational imagery interventions are widely used in sports psychology, with benefits for motor performance, motivational outcomes, and affective outcomes [130] and found to be motivating by a number of different populations, including people trying to manage their weight or type 2 diabetes [131,132]. Emotional mental imagery interventions have shown promise for reducing anxiety and depression [133,134]. Prospective (future-focused) mental imagery interventions are particularly relevant to fostering optimism in people with depression [135]. In the prototype intervention, content is provided on life priorities and motivational imagery—“keeping PCOS in its place”—and future-focused mental imagery.

Positive psychology interventions, such as character strengths and gratitude diaries, which focus on function rather than dysfunction, have shown promise in treating anxiety, depression, low mood, and low self-esteem and in promoting positive well-being [136-138]. In the prototype intervention, content is provided on maximizing psychological resources, for example, by focusing on character strengths and gratitude diaries rather than focusing purely on psychological deficits and dysfunctions.

Activities for Development of Self-Management Communication Skills

Being able to communicate the need for practical and social support is essential for effective self-management. Communicating with friends, family, peers, and health professionals may be particularly difficult for women with PCOS because of its sometimes visible, sometimes invisible nature and associated taboos and stigma [139-142]. In the prototype intervention, content is provided on communication, including communicating concerns with friends, family, peers, and health professionals.

The intervention explicitly acknowledges the issue that some women with PCOS may lack trust in, or feel dismissed or stigmatized by, health professionals [70,71,143-147]. Some health professionals treating PCOS recognize that “lifestyle change,” especially around weight, is a sensitive topic [148], but some patients report a lack of trust in and perceived lack of empathy from health professionals. Intervention materials in the prototype explore and deconstruct health communication around weight to foster shared understanding and trust.

People with long-term health conditions need a range of knowledge and skills to navigate health care systems and participate actively in consultations and care [149]. In the prototype intervention, content is provided on maximizing support from health services and health professionals, including health care specialists who treat PCOS, treatments, “why it may sometimes sound like health professionals are being preachy or judgemental,” summarizing concerns and requesting a referral, shared agenda setting at health care appointments, and communicating clearly and assertively with health professionals.

Building on Therapeutic Peer Group Factors and Collective Advocacy

Women with PCOS are interested in group educational interventions [150]. Group psychosocial and psychoeducational interventions provide particular therapeutic factors, for example, instillation of hope, universality, imparting of information, and opportunities for altruism and catharsis [151]. A lack of social support may be a barrier to lifestyle change [32,33]. Group and peer support, provided face-to-face or on the web, have been beneficial for those living with PCOS [76,78,152-154]. Peers delivering interventions may be well placed to express empathy and to act as realistic role models, supporting self-management [155-157].

Peer group factors are emphasized and facilitated throughout the prototype PCOS intervention, including, for example, self-management, “your PCOS journey,” getting peer support, open space forums, support from health professionals, peers, and the UK PCOS charity, and signposting to ongoing participation with PCOS-related groups and networks. The intervention is delivered in a web-based group format with secure digital social sharing features, for example, a gratitude wall, hopes and dreams, goal sharing, and delivery by trained peer facilitators who themselves had PCOS. Group delivery allows the intervention to be made available to multiple participants, saving time and resources for facilitators.

Improving health care access and outcomes for PCOS is not simply a matter of individual patient assertiveness. Collective collaborative action between patients, health professionals, and powerful others is needed to bring about change. In the prototype intervention, content acknowledges the limits of personal assertiveness and emphasizes the value of collective action. For example, we signpost to activism by Verity [158] and other women’s health organizations.

Modular Web-Based Format for Accessibility And Scalability

Digital health interventions offer considerable scope for accessibility and scalability [159]. The prototype PCOS intervention is designed to be delivered digitally through a secure social platform developed by the social enterprise community interest company Hope for the Community (H4C) [160]. The social enterprise company hosts the intervention and has a track record of scaling up the existing HOPE interventions for a range of commissioners. The H4C web-based intervention platform allows peers to support each other and engage in synchronous or asynchronous therapeutic activities in a web-based space without the logistical and practical difficulties of travel and finding venues and times suitable for all.

Program Specification

Textbox 1 shows the content of the 6-week prototype intervention program. Solution-focused goal setting and feedback, open forum discussions, and further resources are provided in every session.
The H4C team uploaded the additional content and created a working prototype intervention that was checked and tested, ready for a pilot study with women living with PCOS.
Textbox 1. Content of polycystic ovary syndrome (PCOS) intervention.

**Session 1: Instilling HOPE for PCOS**
- Welcome and introductions
- Responsibilities and ground rules
- Instilling HOPE
- Diaphragmatic breathing
- Gratitude diary
- Your PCOS journey
- Support from health professionals, peers, and Verity (UK PCOS charity)
- PCOS basics: androgen excess & insulin resistance
- Test your PCOS basics: quiz
- Factual information about PCOS
- Self-management
- Self-compassion

**Session 2: Managing the stress of PCOS**
- Gratitude diary
- Managing stress
- Mindfulness
  - Physical activity for stress management: “get active, feel good”
  - Managing common unhelpful thinking patterns (cognitive behavioral therapy [CBT])
  - Mindfulness: and am I doing this “right”??
  - Why self-compassionate mindfulness?
- Compassion-focused therapy

**Session 3: Feeding your mind and body well**
- Gratitude diary
- Eating well in PCOS: role of food intake, blood sugar, and insulin
- Why being insulin resistant is a problem for the whole body
- Why it may sometimes sound like health professionals are being preachy or judgmental
- Eating well without depriving yourself, losing weight in PCOS
- Eating mindfully to eat well in PCOS
- Overeating and binge eating in PCOS: some helpful tips for reducing the chances of overeating
- Feeding your mind and body well
  - Ways to soothe yourself without over- or undereating
  - Getting to know your inner critic, developing a compassionate ideal

**Session 4: Body image, intimacy, and close relationships**
- Gratitude diary
- Body changes, sexuality, and intimacy
- Communication
- Common body changes in PCOS
- Difficult emotions that can come with body changes
- Getting ready to be self-compassionate
- Compassion for your perceived flaws
Discussion

Principal Results
We cocreatively identified and prioritized barriers to self-management and psychological well-being to adapt a successful web-based self-management program and tailor it for the needs of adult women with PCOS. We developed a web-based prototype program for the PCOS program, ready for testing with this population.

Comparison With Previous Work
Women with PCOS value specialized, integrated, evidence-based, patient-centered health care services, ideally codeveloped with consumers and health professionals [34,35]. The new HOPE PCOS intervention has been co-developed by combining input from patients, patients with PCOS’ advocates, and health care professionals. It is a comprehensive intervention integrating education and empowerment with lifestyle management, cognitive behavioral tools, and peer support, ready to be delivered by trained peer facilitators or codelivered by peers and health care professionals.

Developed following MRC guidance for the development of complex interventions [45,47], the intervention is evidence-based, underpinned by relevant theory, and designed to support a collaborative approach to care. Subject to evaluation, the new intervention could be integrated as part of PCOS services to support self-management and the model of collaborative, patient-centered health care advocated by international guidelines [4,161].

The intervention deploys an existing secure web-based social platform that has been used successfully to scale up other self-management support programs for other populations and conditions [40,44]. The multicomponent and modular structure of the program offers flexibility in adapting it further as new clinical recommendations and patient information emerge. The intervention is therefore well placed to be delivered and evaluated at scale.

The HOPE PCOS intervention is designed to support self-management and promote psychological well-being, rather than as a behavior change intervention per se. Since we started the process of cocreating the HOPE PCOS intervention, a different team has undertaken development work for a behavior change lifestyle intervention using a different intervention design.
model [28,31-33]. That work has not yet, to our knowledge, resulted in a prototype intervention. However, the findings from the needs assessment work conducted by that team for their lifestyle intervention concurred considerably with our own needs assessment results, showing that women living with PCOS may often experience barriers of capability, opportunity, and motivation, for example, a lack of credible information, difficulty managing multiple health conditions, limited access to resources, adequate social support, and issues such as health expectancies and emotional eating affecting their motivation to engage in lifestyle change [33].

Limitations
The current HOPE PCOS intervention is based on a needs assessment conducted with adult women. As part of the iterative cocreation process, further needs assessments may be required to adapt and tailor future versions of the intervention for other populations, for example, adolescents with PCOS, as concerns, distress, and intervention format preferences may differ [162]. There is scope to develop variants of the intervention for specific adult populations, for example, perimenopausal, menopausal, or postmenopausal women with PCOS who may have specific concerns [163-165]. The intervention might also be tailored to support trans and nonbinary people with PCOS, those with particular concerns such as weight management, comorbid conditions, or those actively trying to conceive. More cocreation and development work could be done to ensure the intervention is culturally appropriate. The intervention is intended to provide extra support and not to bypass what is recommended by a clinician. Women with PCOS are not advised to rely fully on this self-management intervention and are advised to consult a clinician as appropriate.

Cocreative intervention development is an iterative process, and, in addition to tailoring the HOPE PCOS intervention for different populations, future iterations may need to develop new content or place greater emphasis on some components, depending on how participants and health professionals evaluate the program. If consensus emerges about specific target behaviors for self-management in PCOS, it may be necessary in the future to adapt the intervention to promote specific behavior change. For example, the current content promoting physical activity could be modified and refined to promote a target level of physical activity, or the current material on healthy eating could be modified to promote specific changes in eating behavior.

Although the prototype intervention has been collaboratively co-designed to support self-management and psychological well-being, further feasibility research is needed with patients with PCOS using the program. This should evaluate the program’s acceptability as well as its impact on key outcomes such as measures of self-management, depression, anxiety, and psychological well-being. Future work is also needed to assess the intervention’s scalability, cost-effectiveness, and suitability for integration with standard care.

Conclusions
The development of the novel HOPE PCOS intervention contributes to ongoing efforts to support patients with long-term conditions to self-manage effectively and is, to our knowledge, the first such program for patients with PCOS. This study has demonstrated that comprehensive intervention programs can be co-developed with patients with PCOS, patient advocates, and health care professionals to address multiple barriers to self-management and psychological well-being. A person-centered, holistic approach, organized around the self-reported needs and priorities of patients, may produce interventions that complement services provided by health care professionals and patient advocacy and support organizations. This study demonstrates that the use of a remote digital platform with preloaded, evidence-based intervention content may offer economies of scale in that complex self-management support interventions might be delivered to many patients in parallel, potentially saving clinic resources for one-to-one care. A key message for those working to develop lifestyle or self-management support interventions is the potential value of adapting an existing program and reusing existing digital infrastructure to provide a tailored intervention without the additional resource implications of developing an entire intervention from scratch.

Acknowledgments
The HOPE Program is delivered by Hope for the Community, a community interest company of Coventry University. The intervention development work for this polycystic ovary syndrome intervention was supported by a short-term temporary research sabbatical for CP funded by Coventry University. The patient interviews were conducted by CO as part of her master’s study in Health Psychology at Coventry University.

Data Availability
The data sets generated or analyzed during this study are not publicly available due to participants’ consent being given for anonymized extracts only (not whole transcripts) to be used in published reports, but data are available from the corresponding author upon reasonable request.

Conflicts of Interest
AT is the co-inventor of the original HOPE Program, co-founder, and nonexecutive director of Hope For The Community (H4C).

Abstract

Background: Vancomycin pharmacokinetics are highly variable in patients with critical illnesses, and clinicians commonly use population pharmacokinetic (PPK) models based on a Bayesian approach to dose. However, these models are population-dependent, may only sometimes meet the needs of individual patients, and are only used by experienced clinicians as a reference for making treatment decisions. To assist real-world clinicians, we developed a deep learning–based decision-making system that predicts vancomycin therapeutic drug monitoring (TDM) levels in patients in intensive care unit.

Objective: This study aimed to establish joint multilayer perceptron (JointMLP), a new deep-learning model for predicting vancomycin TDM levels, and compare its performance with the PPK models, extreme gradient boosting (XGBoost), and TabNet.

Methods: We used a 977-case data set split into training and testing groups in a 9:1 ratio. We performed external validation of the model using 1429 cases from Kangwon National University Hospital and 2394 cases from the Medical Information Mart for Intensive Care–IV (MIMIC-IV). In addition, we performed 10-fold cross-validation on the internal training data set and calculated the 95% CIs using the metric. Finally, we evaluated the generalization ability of the JointMLP model using the MIMIC-IV data set.

Results: Our JointMLP model outperformed other models in predicting vancomycin TDM levels in internal and external data sets. Compared to PPK, the JointMLP model improved predictive power by up to 31% (mean absolute error [MAE] 6.68 vs 5.11) on the internal data set and 81% (MAE 11.87 vs 6.56) on the external data set. In addition, the JointMLP model significantly outperforms XGBoost and TabNet, with a 13% (MAE 5.75 vs 5.11) and 14% (MAE 5.85 vs 5.11) improvement in predictive accuracy on the inner data set, respectively. On both the internal and external data sets, our JointMLP model performed well compared to XGBoost and TabNet, achieving prediction accuracy improvements of 34% and 14%, respectively. Additionally, our JointMLP model showed higher robustness to outlier data than the other models, as evidenced by its higher root mean squared error performance across all data sets. The mean errors and variances of the JointMLP model were close to zero and smaller than those of the PPK model in internal and external data sets.
Conclusions: Our JointMLP approach can help optimize treatment outcomes in patients with critical illnesses in an intensive care unit setting, reducing side effects associated with suboptimal vancomycin administration. These include increased risk of bacterial resistance, extended hospital stays, and increased health care costs. In addition, the superior performance of our model compared to existing models highlights its potential to help real-world clinicians.

critically ill; deep learning; inflammation; machine learning; pharmacokinetic; therapeutic drug monitoring; vancomycin

Introduction

Vancomycin is frequently used for severe infections caused by gram-positive bacteria (including methicillin-resistant Staphylococcus aureus), such as pneumonia, skin and soft tissue infections, and other sepsis or septic shock in patients with critical illnesses. For vancomycin, because of the narrow therapeutic range and individual differences in pharmacokinetic parameters, therapeutic drug monitoring (TDM) is recommended to minimize toxicity and improve therapeutic efficacy. Although various pharmacokinetic indicators related to the antibacterial action of vancomycin have been suggested, the most recent guideline [1] recommends that a ratio of the area under the curve (AUC) over 24 hours to the minimum inhibitory concentration (MIC) of ≥400 should be the primary pharmacokinetic and pharmacodynamic (PK/PD) predictor of vancomycin activity [2]. However, in the real world, especially in intensive care units (ICUs), a more practical method of vancomycin monitoring is evaluating with trough concentrations since calculating the AUC requires multiple blood samples per patient [3-5].

There are different methods to determine the vancomycin AUC, such as the Bayesian approach or equation-based methodologies such as the trapezoidal model. The Bayesian approach uses population data to estimate individual patient pharmacokinetic parameters, called Bayesian priors. However, this method requires complex mathematical calculations to estimate the posterior distribution of model parameters and relies on certain assumptions, such as the normality of errors and data independence. Violating these assumptions can result in biased results, and using the Bayesian approach requires expensive commercial software programs [6,7]. On the other hand, equation-based approaches, like the trapezoidal model, do not require specialized software but need multiple blood sampling to achieve 2 steady-state levels. Since it is done under steady-state conditions, it cannot account for potential changes in AUC due to ongoing acute physiological changes. The pharmacokinetic profile of vancomycin exhibits linear pharmacokinetics over a range of therapeutic doses, is highly variable, especially in older people or people with critical illnesses, and is different for adults with normal renal function [8,9].

Population pharmacokinetic (PPK) models of vancomycin required to determine the AUC have very limited robustness beyond the specific population studied. The training and experience of the clinician or clinical pharmacist are still vital in achieving adequate vancomycin TDM, especially in patients with critical illnesses with high heterogeneity. A more multidimensional and consistent decision-making system is needed in such a clinical decision-making system because differences inevitably influence the results of individual clinicians’ abilities. Machine learning algorithms have emerged as a promising approach for improving decision-making on specific questions related to rich multidimensional data and for medical research and clinical care [10-12]. In previous studies, machine learning techniques such as decision trees [13] and extreme gradient boosting (XGBoost) [14,15] were used to make better predictions on vancomycin concentrations. In addition, various deep learning models have had great success in various fields [16], including clinical practice. These might help solve more complex clinical problems. In this study, we aimed to establish an ideal model by comparing and integrating methods that have been successful so far in the decision-making system that predicts the vancomycin TDM level in patients in the ICU.

Methods

Study Population

This retrospective study involved 2406 patients with critical illnesses admitted to medical ICUs, including 1 each at Dongguk University Ilsan Hospital (DUIH) and Kangwon National University Hospital (KNUH) between January 1, 2010, and February 28, 2022. We used the data collected from DUIH and KNUH as the internal and external validation data sets. The internal validation data set contained 977 patients, while the external validation data set contained 1429 patients.

Patients with critical illnesses (>18 years) with intravenous vancomycin treatment history and who had at least 1 test for vancomycin TDM were eligible for this study. Vancomycin TDM was investigated for trough-level information. If the TDM was checked multiple times, only the first TDM value was selected. However, in patients with normal renal function, if the interval between stopping vancomycin and readministering it was 2 weeks or more, it was considered an independent TDM value and used for analyses. Patients who received oral vancomycin or were aged 18 years or younger were excluded. The total serum vancomycin concentrations were determined using a fluorescence immunoassay (VANC3, Cobas c 702; Roche Diagnostics).

The data set was split into training and testing groups in a 9:1 ratio, with 879 and 98 cases representing the internal data set, respectively. For external validation, 1429 cases from KNUH were used. To evaluate the model's generalization and the range of expected errors of the classifiers, 10-fold cross-validation was performed on the internal training data set, with a 9:1 ratio and 791 and 88 cases, respectively. The model was tested on...
both the internal and external test data sets for each fold and the metrics obtained were used to calculate the 95% CI over the 10 folds. The internal and external data sets remained constant across all folds. To evaluate the generalization ability of the joint multilayer perceptron (JointMLP) model, we used 2394 cases from the Medical Information Mart for Intensive Care–IV (MIMIC-IV) [17] as a US critical care database used for large-scale multi-institutional research for external validation.

Experimental Model

We proposed a JointMLP to predict the vancomycin TDM level in patients in the ICU. The JointMLP model is an ensemble model, meaning it combines the predictions of multiple individual MLPs (multilayer perceptrons) to generate a final prediction. The MLP is an artificial neural network. The MLP consists of multiple layers of interconnected nodes (also known as neurons) that perform mathematical operations on the input data to generate an output. In the case of the JointMLP model proposed for vancomycin TDM prediction, each MLP in the ensemble consists of 3 hidden layers with a hidden unit size of 32, and the LeakyReLU activation function is used to introduce nonlinearity into the model (Figure 1). Using an ensemble helps reduce the risk of overfitting and improves the accuracy and robustness of the model. In this case, the JointMLP model comprises 100 different MLPs, each with its own set of weights learned during the training process. To find the best set of hyperparameters for the JointMLP model, grid search is used, which systematically tests different combinations of hyperparameters to find the combination that yields the best performance on a validation data set. In this case, the tuned hyperparameters included the number of MLPs, the number of hidden layers, and the size of the hidden units. In a JointMLP model, the MLPs are trained independently in parallel. During training, each MLP in the ensemble receives a randomly selected subset of the training data and learns to make predictions based on that subset. The individual MLPs are then combined to generate a final prediction, typically by taking the average of their outputs or using a weighted combination. The MLPs are trained independently of each other and in parallel. Our JointMLP model is available on the websites [18] for predicting TDM levels and recommending the frequency and dose.

Figure 1. The architecture of joint multilayer perceptron (JointMLP). The JointMLP model was built with 100 different multilayer perceptrons (MLPs) consisting of 3 hidden layers with a hidden unit size of 32 and LeakyReLU as an activation function.
We compared 4 other models: the PPK model [19], XGBoost, TabNet, and 300-layer MLP. The PPK is a pharmacokinetic model used to assess the relationship between drug concentration and time in the body. XGBoost is an open-source library for decision tree–based gradient-boosting machine learning. The XGBoost model especially works well on tabular data learning. It is a vital model for distributed training or regularization. TabNet is a deep learning model specialized for tabular data set analysis. TabNet could be optimized by automatically transforming input variables and using additional validation data to select the required variables.

For XGBoost, the hyperparameters are eta (learning rate), gamma (minimum loss reduction required to make a further partition on a leaf node of the tree), and max_depth (maximum depth of a tree). The grid search was performed to find the best combination of these hyperparameters. The eta, gamma, and max_depth values were 0.2, 0.001, and 6, respectively.

For TabNet, the hyperparameters are n_d (width of the decision prediction layer), n_a (width of the attention embedding for each mask), n_steps (number of steps in the architecture), gamma (coefficient for feature reuse in the masks), and verbose (verbosity for notebook plots). The grid search was performed to find the best combination of these hyperparameters. The values chosen for n_d, n_a, n_steps, gamma, and verbose were 8, 8, 3, 1.3, and 0, respectively.

The 300-layer MLP model was constructed to verify the performance of the JointMLP model. The hyperparameters for the MLP model were chosen to have the same depth as the JointMLP model, which is 100 horizontal MLPs times 3 hidden layers. The number of hidden layers was set to 300, and the number of hidden units was set to 32.

Data Processing

Variables that are associated with vancomycin PK/PD were selected. These variables included the total dose of vancomycin from start to end, the usage of the loading dose at the first use, the total number of vancomycin infusions, the dose of vancomycin per infusion, the mean infusing interval of vancomycin, the interval from the start of vancomycin administration to the measurement of vancomycin serum levels, age, sex, height, weight, serum creatinine levels, serum vancomycin levels, dialysis, and the total volume of transfusion from the start of vancomycin administration to the measurement of vancomycin levels. Patients with impaired kidney function may have issues with the metabolism and elimination of vancomycin. The estimated glomerular filtration rate (eGFR), which represents renal function, was calculated using the Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) formula and used as a variable. For the normalization of the data, for both the input and target variables, all values were scaled in the range (−1 to 1) using the minimum-maximum scaler. Moreover, we only had binary categorical variables in the model. Therefore, no special categorical variable encoding was performed in the model but a simple change to 0 and 1. To select significant input variables, we grouped variables into 5 categories. Each variable was classified as (1) baseline demographics—age, sex, body weight, and height; (2) drug administration-related variables; (3) variables related to the volume of distribution; (4) eGFRs using serum creatinine levels; and (5) variables related to the amount of transfusion. With the above-grouped categories, first, we have selected the default variables that would be used throughout all scenarios: the baseline demographics and the drug administration–related variables. Then, from the remaining 3 categories, with the clinician’s consultation, we tried to minimize the redundancy of the variables that would have the same meaning. Moreover, in accordance with the feature importance of each variable, we were able to find the best combination of model input variable sets. Furthermore, the contribution of the input data to the model in the test set was determined through the Shapley value of Shapley Additive exPlanations (SHAP) [19]. A high mean absolute estimated Shapley value indicates that the variable has a stronger impact on the output value.

Statistical Analysis

The primary end point was the predictive performance of the vancomycin level within the therapeutic range. The baseline variables and patient characteristics of internal and external data sets were presented as frequencies with percentages or mean values with SDs. Between–data set comparisons were performed using the paired 2-tailed t test for continuous variables or the chi-square test for categorical variables. The measured serum vancomycin levels were used as true values. The predictive abilities of 4 kinds of models for vancomycin trough concentrations, using the PPK model on the website of the infectious diseases management program at the University of California, San Francisco [20], machine learning models (XGBoost) [21], and deep learning models (TabNet [22] and JointMLP), were evaluated for bias and precision by calculating the mean absolute error (MAE), root-mean-square error (RMSE), R², and adjusted R². The paired t test on MAE was used [23,24] to confirm significant differences in prediction performance between models. P values of <.05 were considered statistically significant. All analyses were performed with R software (version 3.4.4; R Foundation for Statistical Computing) and Python (version 3.8.12; The Python Software Foundation) using the SciPy 1.9.1, PyTorch 1.10.2, and PyTorch Lightning 1.6.4 libraries.

Ethical Considerations

This study involved a retrospective analysis of medical records and did not involve collecting prospectively obtained data. As such, the study was considered to pose minimal risks and did not directly affect patients’ rights, welfare, or clinical care while offering recognized social benefits. To protect patient confidentiality during data collection and record review, all investigative records were securely stored in an encrypted database, and published results did not include any participants’ names or identifiers. The study received ethical approval from the institutional review board of Dongguk University Hospital (DUH 2021-08-015) and Kangwon National University Hospital’s Institutional Review Board (KNUH-2022-03-020). This study was performed per the principles of the Declaration of Helsinki.

Results

Overview

Out of the 977 patients included in the DUIH data set, the testing data set was composed of 98 (10%) patients, with the other 879 patients belonging to the training data set. All 1429 patients included in KNUH were for external validation. The baseline characteristics did not differ significantly between the testing and training groups (Table 1). However, there were more older patients and shorter heights in the external validation set. The estimated renal function by the CKD-EPI method was worse in the patients for external validation. The patients included in MIMIC-IV showed significant differences in sex distribution compared to internal data sets or patients in other ICUs in Korea, and the proportion of non-Hispanic White patients was over 66.4% (n=1591).

Compared to the PPK model, the XGBoost model only significantly improved the predictive performance of external data sets (20.43 vs 11.59, a 76% change by RMSE and 11.87 vs 8.75, a 36% change by MAE; Table 2) when evaluated by RMSE and MAE. Although statistical significance could not be determined, the predictive power of internal data sets also improved by 8% (10.38 vs 9.58 by RMSE) and 16% (6.68 vs 5.75 by MAE).

aRMSE: root mean squared error.  
bMAE: mean absolute error.  
cPPK: population pharmacokinetic.  
dXGBoost: extreme gradient boosting.  
eMLP: multilayer perceptron.  
fJointMLP: joint multilayer perceptron.  

The proposed JointMLP model significantly outperformed XGBoost and TabNet with a 13% (5.75 vs 5.11) and 14% (5.85 vs 5.11) improvement in predictive accuracy under MAE on the internal data set, respectively. Additionally, our trained JointMLP showed better performance not only on the internal data set but also on the external data set that consisted of 1429 patients with critical illnesses by 34% (8.75 vs 6.56) and 14% (7.50 vs 6.56) when compared with XGBoost and TabNet. Furthermore, JointMLP’s RMSE performance is higher than that of other models on all data sets, which means that the proposed model is more robust than theirs against outlier data.

Within the external data set, we clearly see that all models are statistically significant among themselves (Figure 2). However, the P value of JointMLP within the internal data set expressed a trend more robust than all other models while showing statistical significance only when compared with PPK with MAE. The mean error and variance of the JointMLP model were nearer to zero and smaller in both internal and external data sets than in the PPK model (Figure 3).
Figure 2. $P$ value heat map by paired t test on all the combinations of prediction models. The $P$ value for each comparison of the mean absolute error for predictive performance on (A) the internal validation data set (B) and the external validation data set. 300MLP: 300-layer multilayer perceptron; JointMLP: joint multilayer perceptron; PPK: population pharmacokinetic; XGB: extreme gradient boosting.

Scatter plots of (A) the internal data set and (B) the external data set with the predicted value against a target value. The error histograms of (C) the internal data set and (D) the external data set with a predicted value against a target value. TDM: therapeutic drug monitoring.

The most influential variables in TDM prediction were eGFR CKD-EPI, the average dose of vancomycin, and the average volume of distribution in both internal and external data sets. These variables consistently had high SHA $P$ values in both data sets (Table 3).

**JointMLP Versus 300-Layer MLP**

The purpose of Table 2 was to compare the predictive performances of the 300-layer MLP model and the proposed JointMLP model. The results showed that JointMLP outperformed the 300-layer MLP model in both the internal (8.27 vs 9.94, a 23% improvement by RMSE, and 6.98 vs 5.11, a 37% improvement by MAE) and external (9.50 vs 9.94, a 5% improvement by RMSE, and 7.45 vs 6.56, a 14% improvement by MAE) data sets, indicating the effectiveness of the boosting ensemble approach used in JointMLP. Figure 2 shows the $P$ value analysis of the comparison between JointMLP and the 300-layer MLP model. The analysis revealed that the difference between the 2 models was statistically significant ($P<.001$) within the external data set. However, compared to other models, the difference between JointMLP and the 300-layer MLP model was not statistically significant ($P=.09$) within the internal data set.

**Model Comparisons in the MIMIC-IV Data Set**

The findings presented in Table 4 clearly indicated that the JointMLP model performed better than both the PPK and 300-layer MLP models by a significant margin of 160% and 25%, respectively, when evaluated using the RMSE metric. This improvement in predictive performance was observed even in the MIMIC-IV data set, which included patients from multiple centers and races. The JointMLP model also demonstrated superior performance compared to the XGBoost and TabNet models, with improvements of 5% and 4%, respectively. When examining the MAE metric, the JointMLP model significantly outperformed the PPK model by 90%, with further improvements of 8%, 6%, and 5% over the XGBoost, 300-layer MLP, and TabNet models, respectively.

<sup>e</sup>XGBoost: extreme gradient boosting.
<sup>f</sup>MLP: multilayer perceptron.
<sup>g</sup>JointMLP: joint multilayer perceptron.

All models, except for the 300-layer MLP, were statistically significant in the MIMIC-IV data set (Figure 4A). The most influential variables in TDM prediction using the JointMLP model were consistent with eGFR CKD-EPI, average vancomycin dose, and average distribution volume, which were variables identified in the internal data set (Figure 4B). The 300-layer MLP was statistically significant ($P<.001$) compared to the PPK model. Additionally, the JointMLP model had a mean error and variance that were close to zero and smaller than those of the PPK model in the MIMIC-IV data set (Figure 4C and D).

(A) The $P$ value for each comparison of the mean absolute error for predictive performance on the MIMIC validation data set; (B) the Shapley Additive exPlanations (SHAP) values of the joint multilayer perceptron (JointMLP) model on the MIMIC validation set; (C) scatter plots of the MIMIC data set with the JointMLP predicted values against target values; and (D) the error histograms of the MIMIC data set with the JointMLP predicted values against target values. 300MLP: 300-layer multilayer perceptron; CKD-EPI: Chronic Kidney Disease Epidemiology Collaboration; eGFR: estimated glomerular filtration rate; PPK: population pharmacokinetic; TDM: therapeutic drug monitoring; XGB: extreme gradient boosting.

Discussion

Principal Findings

The PPK method is widely used for predicting vancomycin TDM levels. However, it is population-dependent, leading to inappropriate results for some patients. Therefore, this study proposes a consistent decision-making system that is population-independent and unaffected by clinicians’ abilities by applying a joint MLP model that integrates various successful deep learning models and decision trees. The proposed JointMLP showed the best performance for predicting vancomycin trough concentration in all data sets compared to other models. Significantly, in the MAE metric, the JointMLP model improved performance by 90% over the PPK model. Results mean that the proposed model can be applied to predict appropriate vancomycin trough concentrations in patients with critical illnesses who require vancomycin treatment in various situations.

Comparison to Machine Learning Model

In our study, we compared the performance of 3 machine learning models for predicting vancomycin levels: JointMLP, XGBoost, and TabNet. XGBoost is a popular gradient-boosting algorithm known for its high accuracy and flexibility, while TabNet is a newer deep-learning model specifically designed for tabular data. Compared to XGBoost and TabNet, ourJointMLP model outperformed both in terms of predictive accuracy. One of the main reasons for this is that our model was designed to handle noisy data samples, a common characteristic of medical data sets. A deep neural network architecture accomplishes this with multiple layers, which allows the model to learn complex relationships between the input features and the output variable. In contrast, XGBoost and TabNet are both tree-based models, which may need to be more effective at handling noisy data.

Compared to previous studies [15,24-26], our proposed JointMLP model performs better in accurately predicting vancomycin levels. Specifically, our model outperforms XGBoost and TabNet, 2 well-known models in analyzing tabular data and predicting drug concentrations. Moreover, our JointMLP model is designed to handle noisy data samples effectively, a crucial feature for real-world applications in the medical domain where data quality can be highly variable. Our model’s robustness is demonstrated by comparing it to a
300-layer MLP, confirming the effectiveness of our model structure in handling vancomycin TDM predictions. Importantly, our model is trained on a larger and more diverse data set than previous studies and tested on an unseen data set, demonstrating its generalizability and suitability for predicting drug concentrations. Overall, our findings highlight the potential of deep learning models in improving the accuracy and reliability of drug concentration prediction, which can lead to better treatment outcomes and improved patient health. Overall, our findings suggest that the JointMLP model is a promising approach for predicting vancomycin levels, particularly in the presence of noisy data. However, the choice of which model to use may depend on the specific characteristics of the data set being analyzed and the goals of the analysis.

Limitations and Future Work
When considering implementing our approach in clinical settings, there are several factors to consider. First, although we extended our model to validate across diverse ethnic groups by including patients from Asia and other regions in the MIMIC-IV data set, we acknowledge that there is still room for improvement in this regard. We used a larger data set than previous studies, with 977 samples as the internal data set and 1429 samples as the external data set. Additionally, we sought to develop a generalized model by applying the MIMIC-IV data set, which includes 2394 samples. However, additional validation with external data sets is necessary to enhance further the generalizability of our model for predicting vancomycin levels. Second, our comparison of the predictive performance with the PPK method was based on the trough-based target method, which is easily used in the treatment of patients with critical illnesses, rather than the AUC/MIC-specific range that is currently recommended. Therefore, further research is needed to compare the AUC/MIC range with our approach. Despite these limitations, our deep learning model, if implemented in actual clinical practice, could significantly improve the treatment outcomes of ICUs by supporting clinical decision-making in a more standardized and consistent manner. Our proposed JointMLP model will continue to evolve and update its performance to mimic the human brain better and determine the optimal vancomycin dose.

Conclusions
In this study, proposing the JointMLP approach in clinical settings has significant implications for public health, as it can help optimize treatment outcomes for patients with critical illnesses in ICUs. By providing a more accurate and consistent method for predicting vancomycin levels, the model can reduce adverse events associated with suboptimal vancomycin dosings, such as the increased risk of bacterial resistance, longer hospital stays, and higher health care costs. Furthermore, the ongoing development and improvement of the JointMLP model through continuous learning and updating can lead to more effective treatments and better health outcomes for patients, improving the accuracy and reliability of other clinical prediction models in the future. Overall, the implementation of the JointMLP approach has the potential to improve public health outcomes and benefit patients worldwide.

Abstract

Background: Atrial fibrillation (AF) represents a hazardous cardiac arrhythmia that significantly elevates the risk of stroke and heart failure. Despite its severity, its diagnosis largely relies on the proficiency of health care professionals. At present, the real-time identification of paroxysmal AF is hindered by the lack of automated techniques. Consequently, a highly effective machine learning algorithm specifically designed for AF detection could offer substantial clinical benefits. We hypothesized that machine learning algorithms have the potential to identify and extract features of AF with a high degree of accuracy, given the intricate and distinctive patterns present in electrocardiogram (ECG) recordings of AF.

Objective: This study aims to develop a clinically valuable machine learning algorithm that can accurately detect AF and compare different leads' performances of AF detection.

Methods: We used 12-lead ECG recordings sourced from the 2020 PhysioNet Challenge data sets. The Welch method was used to extract power spectral features of the 12-lead ECGs within a frequency range of 0.083 to 24.92 Hz. Subsequently, various machine learning techniques were evaluated and optimized to classify sinus rhythm (SR) and AF based on these power spectral features. Furthermore, we compared the effects of different frequency subbands and different lead selections on machine learning performances.

Results: The light gradient boosting machine (LightGBM) was found to be the most effective in classifying AF and SR, achieving an average $F_1$-score of 0.988 across all ECG leads. Among the frequency subbands, the 0.083 to 4.92 Hz range yielded the highest $F_1$-score of 0.985. In interlead comparisons, aVR had the highest performance ($F_1=0.993$), with minimal differences observed between leads.

Conclusions: In conclusion, this study successfully used machine learning methodologies, particularly the LightGBM model, to differentiate SR and AF based on power spectral features derived from 12-lead ECGs. The performance marked by an average $F_1$-score of 0.988 and minimal interlead variation underscores the potential of machine learning algorithms to bolster real-time AF detection. This advancement could significantly improve patient care in intensive care units as well as facilitate remote monitoring through wearable devices, ultimately enhancing clinical outcomes.

Introduction
Atrial fibrillation (AF) is the most prevalent cardiac arrhythmia, impacting an estimated 33.5 million people worldwide [1]. This severe cardiac condition heightens the risks of stroke and heart failure [2]. Clinicians typically detect and diagnose AF through the noninvasive electrocardiogram (ECG) method. However, ECG interpretation relies heavily on the expertise of the medical professional, creating a need for automated ECG classification to support clinicians. Machine learning, a subset of artificial intelligence, has shown great potential in improving the detection and management of AF through automated ECG analysis [3], risk stratification [4], or treatment planning [5].

The 2020 PhysioNet Challenge data sets offer 12-lead ECG recordings that can be used to evaluate machine learning techniques for ECG interpretation [6]. Compared to machine learning approaches based on small and homogeneous data sets, algorithms using PhysioNet data are likely to be more representative of realistic clinical scenarios, thereby making them better suited for practical implementation. Various machine learning techniques have been used to detect AF using ECG data. Some of the widely explored methods include support vector machines, decision trees, random forests, and deep learning approaches like convolutional neural networks and recurrent neural networks. These techniques have demonstrated promising results in classifying normal sinus rhythm (SR) and AF, with fair accuracy and $F_1$-scores [4].

The performance of machine learning algorithms depends on the quality of the input features. Common feature extraction methods in AF detection include time-domain analysis, frequency-domain analysis, and wavelet transform. Power spectral density (PSD) is a popular frequency-domain feature that has been used to differentiate SR from AF. PSD analysis reveals information about the distribution of a signal’s power and frequency components. An ECG signal comprises various frequency components, including those related to the sinus heartbeat as well as atrial and ventricular activity. The PSD distribution of these frequency components may alter heart conditions that affect the cardiac contraction cycle, making it a potential indicator for identifying cardiac arrhythmias. Consequently, we developed an automated machine learning algorithm based on PSD to differentiate normal SR from AF based on a large-scale data set from PhysioNet 2020.

Methods

ECG Data

We used the 2020 PhysioNet Challenge data sets (Table 1) [6], comprising the China Physiological Signal Challenge (CPSC) Database (men: n=3699, women: n=3178, total: n=6877, and sampling rate: 500 Hz), CPSC-Extra Database (men: n=1843, women: n=1610, total: n=3453, and sampling rate: 500 Hz), St Petersburg Institute of Cardiological Technics INCART 12-lead Arrhythmia Database (total: n=72 and sampling rate: 257 Hz), Physikalisch Technische Bundesanstalt (PTB) Diagnostic ECG Database (men: n=377, women: n=139, total: n=516, and sampling rate: 1000 Hz), Physikalisch Technische Bundesanstalt extra large (PTB-XL) electrocardiography Database (men: n=11,379, women: n=10,458, total: n=21,837, and sampling rate: 500 Hz), and Georgia 12-lead ECG Challenge Database (men: n=5551, women: n=4793, total: n=10,344, and sampling rate: 500 Hz). The PhysioNet Challenge data sets can be accessed publicly [7], and data access is licensed under the Creative Commons Attribution 4.0 International Public License [8].

From these data sets, we initially selected data featuring a 500 Hz sampling rate. Next, we identified ECG diagnoses using the Systematized Nomenclature of Medicine—Clinical Terminology codes 426783006 and 164889003 for SR and AF, respectively. This led to the identification of 20,766 SR and 3458 AF ECG recordings. After excluding recordings corresponding to multiple diagnoses, the final data set comprised 9102 SR and 1088 AF ECG recordings.

**Ethical Considerations**

This study was approved by the institutional review board of Taipei Veterans General Hospital (2022-04-004BC).

**ECG Preprocessing and Feature Extraction**

The ECG patterns associated with AF exhibit greater variability compared to those of SR. To explore this distinction, we used the Welch method [9,10] to estimate PSD and determine the frequency composition of the ECG signals. The recording durations of the ECG data ranged from 6 to 60 seconds, with 10 seconds being the most common. This variability could lead to differences in PSD resolution. To address this issue, we used the frequency bin method to ensure consistent frequency resolution across our PSD features. We set the frequency resolution to 1/6 Hz and calculated the arithmetic mean of the PSD frequencies within this resolution to represent the midpoint of each envelope. The data we used had a sampling rate of 500 Hz. Based on Nyquist-Shannon sampling theorem, the highest frequency information we can get is 250 Hz. After observing several data plots of the original PSD graph, we can see that most of the power of the signal is within 0 to 25 Hz. Thus, for a 10-second ECG recording, we selected a frequency of 0 to 25 Hz which was converted to 0.083 to 24.92 Hz. Figure 1 presents an example of original PSD plots and explains why we chose the PSD from 0 to 25 Hz. For further segmentation, it was just reasonable to separate the whole frequency segment into 5 smaller segments since the whole frequency ranges from 0 to 25 Hz. Figure 2 presents example ECG signals and PSD plots, highlighting notable differences in PSD between SR and AF; narrower harmonic frequency components can be observed in SR, while AF patterns display more erratic frequency components. We used these PSD features as inputs for our machine learning algorithm.

Figure 1. Initial results of PSD for SR and AF in lead 1. The original frequency information we got from PSD is 0 to 250 Hz. From the figure, we can see that the power of the signal concentrates within 0 to 25 Hz. Thus, we selected 0 to 25 Hz as our main frequency band. AF: atrial fibrillation; PSD: power spectral density; SR: sinus rhythm.
Figure 2. A comparison of the ECG and PSD for SR and AF in lead V4. While there is a discernible difference between SR and AF in the ECG representation, it remains challenging to distinguish them in this format. In contrast, the PSD figure demonstrates the harmonic nature of SR and the chaotic nature of AF, making it much easier to differentiate between the two. As a result of these observations, we have chosen to use PSD as the primary feature for our machine learning algorithms. This decision is based on the enhanced clarity and distinction provided by the PSD representation, which allows for more accurate and effective differentiation between SR and AF in our analysis. AF: atrial fibrillation; ECG: electrocardiogram; PSD: power spectral density; SR: sinus rhythm.

Machine Learning Methods
Supervised machine learning is a type of machine learning where the algorithm is trained on a labeled data set, and the goal is to make predictions for new, unseen data. There are several types of supervised machine learning methods used in this study, including (1) discriminant analysis: a method for modeling the relationship between a dependent variable and one or more independent variables (used for continuous target variables); (2) logistic regression: a method for modeling the probability of a binary outcome based on one or more independent variables; (3) decision trees: a method for making predictions by creating a tree-like model of decisions and their potential consequences; (4) random forests: an ensemble method that combines multiple decision trees to make a prediction; (5) support vector machines: a method for classifying data by finding the best boundary (or “hyperplane”) that separates the classes; (6) neural networks: a method inspired by the structure and function of the human brain (can be used for a wide range of tasks, including classification and regression); and (7) naive Bayes: a probabilistic method for making predictions based on Bayes’ theorem (often used for text classification).

Additionally, we used a gradient boosting decision tree algorithm, namely light gradient boosting machine (LightGBM) [11]. It is one of the most efficient algorithms in recent years, known for its speed and accuracy. Boosting is an approach for combining multiple base models into a composite one. One of the ensemble tree algorithms of LightGBM is a “leaf-wise” tree algorithm, wherein the tree grows vertically; most of the others are “level-wise” tree algorithms, wherein the trees grow horizontally. The leaf-wise structure reduces time complexity and offers a favorable balance of accuracy and efficiency, especially for large-scale, high-dimensional data. Thus, it is useful in classification problems.

Perceptrons are single-neuron models and the precursors to larger neural networks; now, they are the building blocks of neural networks. A deep neural network (DNN) is a supplement of a feed-forward neural network and consists of 3 types of layers: the input layer, the output layer, and the hidden layer. The input layer receives the input signal to be processed. The output layer performs the required task, such as prediction or classification. The true processing engine is the hidden layers, placed between the input and output layers. In a DNN, data flow from the input layer to the output layer, just as in feed-forward neural networks. The neurons are trained through back propagation. DNNs are widely used in various applications, including automated diagnosis using ECG data [12].

Statistical Analysis
Data Imbalance
We used the synthetic minority over-sampling technique [13] to filter the data and reduce the imbalance between the numbers of SR and AF recordings (n=9102 and n=1088, respectively).

F1-Score
To mitigate bias resulting from data imbalance, we used the F1-score as the primary metric for evaluating machine learning models. F1-scores treat false-positive and false-negative errors equally and are more useful than accuracy in cases of class
imbalance. The $F_1$-score is the harmonic mean of precision and recall, which measures the errors contributed by false positives and false negatives, respectively.

**Training, Validation, and Testing Data Sets**

We divided our data sets into training, validation, and testing sets. The training set was used to develop the models, the validation set for model tuning, and the testing set for model assessment. In this study, 60% of the data comprised the training set, 20% the validation set, and 20% the testing set. For model tuning, we used ensemble learning to identify optimal parameters for each model based on the validation set.

**Results**

**Comparison of the Performance of Various Machine Learning Algorithms**

We evaluated various machine learning methods, including extra tree, LightGBM (Microsoft Corporation), CatBoost (Yandex), XGBoost (The XGBoost Contributors), decision tree, k-nearest neighbors, stochastic gradient descent, gradient boosting, random forest, naive Bayesian, logistic regression, and DNN. Our analysis reveals that machine learning algorithms with boosting methods outperform those without boosting. In particular, LightGBM outperformed the other methods, achieving the highest average $F_1$-score of 0.988 across all 12 ECG leads and the lowest computation time for features within the entire frequency range (0.083-24.92 Hz). Conversely, our results indicate that the naive Bayesian algorithm performs poorly in classifying SR and AF. Despite its simplicity, naive Bayesian appears to be less suited for this specific task, and alternative approaches should be considered for better accuracy and reliability. Thus, we focused solely on LightGBM for subsequent analyses.

**Effect of Frequency Band on Model Performance**

We examined the contributions of various frequency subbands of ECG PSD features to model performance in detecting AF (Table 2). The entire frequency range was divided into 5 subbands (0.083-4.92, 5.083-9.92, 10.083-14.92, 15.083-19.92, and 20.083-24.92 Hz). The highest overall $F_1$-score was achieved by the model using the full frequency range (0.083-24.92 Hz), and the frequency subband of 0.083 to 4.92 Hz yielded the highest $F_1$-score among the subbands. Generally, the $F_1$-score for each subband was around 0.9, indicating that every subband contains valuable information for ECG classification.

**Interlead Differences in Model Performance**

In lead comparisons, aVR demonstrated the highest performance across all frequency subbands, although the differences between leads were minimal (Table 3). Specifically, for the entire frequency range, using aVL resulted in the lowest classification performance ($F_1$-score=0.980), while using aVR achieved the highest performance ($F_1$-score=0.993).

**Discussion**

**Principal Findings**

In this study, we found that the LightGBM algorithm was the most effective machine learning model for our purposes. Notably, all frequency subbands contained distinct information, achieving independent $F_1$-scores of approximately 0.9. Consequently, using the entire frequency range (0.083-24.92 Hz) provided the most comprehensive features and yielded the highest $F_1$-score of 0.988. Interestingly, among the limb leads, aVR produced the best result, which was marginally superior to the outcomes of chest leads and lead II. This finding is unexpected, as lead aVR is rarely used in real-world scenarios for detecting arrhythmia. The contributions of different frequency bands to classification performance showed that even though each subband contains unique features, the dominant frequency subband (0.083-4.92 Hz) is sufficient for distinguishing AF from SR.
In terms of the contributions of frequency bands to classification performance, it is important to note that the normal human heart beats between 60 to 100 times per minute (1-1.67 Hz), whereas the dominant frequency in AF ranges from 3.8 to 8 Hz [14]. Given the differences in frequency components between SR and AF, they can be used to distinguish one from the other. As demonstrated in Figure 1, multiple frequency peaks are observed within the 0 to 25 Hz range for both SR and AF. Consequently, frequency subbands containing distinct features may yield different results.

Initially, we hypothesized that the subband containing the dominant frequency (0.083-4.92 Hz) would result in the optimal classification of SR and AF, similar to the whole frequency range (0.083-24.92 Hz), while other subbands would struggle to classify SR and AF effectively. Indeed, models using the dominant frequency subband performed well, with results closely resembling those of models using the whole frequency range. However, other subbands also demonstrated high performance independently (Table 2), with $F_1$-scores exceeding 0.854. The dominant frequency subband (0.083-4.92 Hz) yielded an $F_1$-score of 0.985, which is comparable to that of the whole frequency range ($F_1$-score=0.988). These findings suggest that although each subband contains unique features and cannot be replaced by other subbands, the dominant frequency subband alone is sufficient for differentiating AF from SR.

In this study, we explore the variations in AF classification performance across different ECG leads. Each ECG lead has unique physiological applications, which in turn influence the preference of medical professionals in identifying specific types of arrhythmias. For instance, lead 1, aVF, or V1 are frequently used in diagnosing right ventricular hypertrophy. Routine clinical practice suggests that lead 2, which is typically the focus of medical professionals when examining AF, would yield the most accurate results. Surprisingly, our findings revealed that all leads, within the frequency range of 0.083-24.92 Hz, generated $F_1$-scores in close proximity to 0.985. Among these, lead aVR achieved the highest $F_1$-score at 0.993. We believe this can be attributed to the visibility of AF in the majority of leads and the comprehensive features encompassed by the entire frequency range.

Contrary to our initial expectations, lead aVR, which is not a common choice in clinical settings, produced the most optimal results when using subbands [15]. This finding may potentially shed light on the reentry mechanism that underlies AF [16,17]. It is worth noting that lead aVR captures data from the right ventricle outflow tract and the basal portion of the septum, whereas AF predominantly manifests in the left ventricle. Consequently, the reentry mechanism emerges as the most plausible explanation for this observed phenomenon.

In a prior study [18], the 2020 PhysioNet Challenge data sets were used alongside the LightGBM machine learning algorithm. However, the approaches to signal extraction and processing in that study differed from those used in our research. The previous study implemented filtering techniques and wavelet multiresolution analysis, while our investigation used PSD and the Welch method. Another key distinction between the 2 studies is the scope of the classification task. While our research focused solely on differentiating AF from SR, the previous study attempted to identify 24 different diseases. Due to the varied physiological information provided by each ECG lead, we opted to compare the performance of LightGBM for each individual lead, rather than inputting data from all 12 leads into the LightGBM simultaneously. Furthermore, our study identified the most critical frequency subband within the total frequency range. We determined the dominant frequency subband to be 0.083-4.92 Hz, which played a significant role in our analysis.

There are several limitations to be addressed in this study. One notable constraint is our selection of 10-second ECG recordings, which may not accurately represent the full spectrum of real-world clinical scenarios. The data sets used in this study were predominantly clean, while actual clinical situations may involve data contaminated by noise, potentially affecting the results. Moreover, our study focused exclusively on single-diagnosis data, representing either AF or SR. This approach, however, does not account for the possibility of a patient experiencing multiple arrhythmias concurrently. Consequently, our findings were derived under simplified conditions that may not fully reflect the complexity of real-life cases. In light of these limitations, it is essential to interpret our results with caution and consider further research that incorporates a broader range of ECG recordings, addresses potential noise-related challenges, and examines cases with multiple coexisting arrhythmias to enhance the generalizability and applicability of our findings to real-world clinical settings.

In summary, LightGBM proves to be a highly effective algorithm for distinguishing AF from SR. Our study demonstrated that when dividing the entire ECG frequency range into subbands with fewer features, lead aVR delivered the best performance. This outcome could potentially be associated with the underlying pathological mechanisms of AF. By incorporating adequate frequency band features, lead 2 ECG data can achieve an $F_1$-score of approximately 0.99. This level of accuracy and efficiency of the LightGBM model renders the algorithm suitable for implementation in clinical practice and integration into commercialized electronic devices, such as the smartwatch with the ECG functionality, for a range of health care applications. This study’s findings suggest that leveraging the power of LightGBM could enhance arrhythmia detection and monitoring, ultimately improving patient care and outcomes.

Literature Review

In this review, we will talk about studies that introduce techniques for AF detection, analyzing their methods, results, and potential implications in the field of cardiology. First, one study [19] proposed a feature extraction method based on a gradient set for AF detection, which features simplicity, noise tolerance, and adaptability to various classifiers. However, we can still improve the feature extraction method in the future, such as improving AF detection performance by proposing a more representative feature set or combining it with other types of features. This approach shows the potential for streamlined, efficient feature extraction, providing a solid foundation for further research in the domain.
Next, the Transposed Projection–Convolutional Neural Network (TP-CNN) method was introduced in another study [20], aiming to use “compressed ECG signals” for AF detection. The approach demonstrates promising results in accurately detecting AF in wearable application scenarios while addressing energy consumption concerns. It shows the effective use of compressed signals and a highly accurate algorithm. Yet, its data sources only contain 25 patients. More patients should be included in further studies.

Another study [21] demonstrates a unique method using multiple parameters, including the average number of f waves in a TQ interval, showing robust real-time AF detection capabilities. This approach not only differentiates between AF and normal ECGs but also outperforms distinguishing AF from other arrhythmias. However, they can discuss more about how their algorithms will be implemented in clinical situations.

There is another study [22] focusing on low-complexity algorithms for AF detection, a method based on RR interval features. This approach demonstrated reasonable feature selection while maintaining a low computational cost, making it suitable for low-power devices. However, in future studies, it should focus on getting a better $F_1$-score.

In addition to ECG AF detection, there is also a signal called photoplethysmography common in wearable devices for AF detection, while we usually use ECG in clinical situations. This Fitbit Heart study [23] provides an algorithm that exhibited a high positive predictive value for concurrent AF, highlighting the potential of consumer wearables for large-scale AF identification. Though the result is nice, we hope we can know more about photoplethysmography comparison with ECG.

In conclusion, these studies collectively contribute to the evolving landscape of AF detection methods. While each approach offers unique advantages, further research should focus on refining these methods, exploring real-time applications, and enhancing the overall accuracy and efficiency of AF detection algorithms. Potential limitations should also be emphasized in future studies.

Abstract

Background: The unmet need for mental health care affects millions of Americans. A growing body of evidence in implementation science supports the effectiveness of task sharing in the delivery of brief psychosocial interventions. The digitization of training and processes supporting supervision can rapidly scale up task-shared interventions and enable frontline health workers (FLWs) to learn, master, and deliver interventions with quality and support.

Objective: We aimed to assess the perceived feasibility and acceptability of a novel mobile and web app designed and adapted to support the supervision, training, and quality assurance of FLWs delivering brief psychosocial interventions.

Methods: We followed human-centered design principles to adapt a prototype app for FLWs delivering brief psychosocial interventions for depression, drawing from an app previously designed for use in rural India. Using a multimethod approach, we conducted focus group sessions comprising usability testing and group interviews with FLWs recruited from a large health system in Texas to assess the feasibility and acceptability of the app. The positive System Usability Scale was used to determine the app’s overall usability. We also calculated the participants’ likelihood of recommending the app to others using ratings of 0 to 10 from least to most likely (net promoter score). Focus group transcripts were coded and analyzed thematically, and recommendations were summarized across 4 key domains.

Results: A total of 18 FLWs varying in role and experience with client care participated in the study. Participants found the app to be usable, with an average System Usability Scale score of 72.5 (SD 18.1), consistent with the industry benchmark of 68. Participants’ likelihood of recommending the app ranged from 5 to 10, yielding a net promoter score of 0, indicating medium acceptability. Overall impressions of the app from participants were positive. Most participants (15/18, 83%) found the app easy to access and navigate. The app was considered important to support FLWs in delivering high-quality mental health care services. Participants felt that the app could provide more structure to FLW training and supervision processes through the systematic collection and facilitation of performance-related feedback. Key concerns included privacy-related and time constraints regarding implementing a separate peer supervision mechanism that may add to FLWs’ workloads.

Conclusions: We designed, built, and tested a usable, functional mobile and web app prototype that supports FLW-delivered psychosocial interventions in the United States through a structured supervision mechanism and systematic collection and review of performance measures. The app has the potential to scale the work of FLWs tasked with delivering these interventions to the
hardest-to-reach communities they serve. The results of this project will inform future work to evaluate the app’s use and efficacy in real-world settings to support task-shared mental health programs across the United States.

Introduction

Background

In the United States, 22.8% of adults have a mental illness, and 5.5% have a serious mental illness [1]. Following the COVID-19 pandemic, the percentage of adults with symptoms of anxiety or depressive disorders has increased substantially, with preliminary data reporting a prevalence of 20% to 32.3% [2,3], although the extent of the increase is still unclear [4]. In 2021, in the United States, only 65.4% of adults with serious mental illness and 47.2% with any mental illness received mental health services [1], and the proportion receiving “minimally adequate” treatment [5], defined as treatment minimally sufficient for common mental disorders, is low [6,7]. In addition to the direct impact on health and well-being, the economic cost of mental illness is high [8]. Worldwide, 418 million disability-adjusted life years and an economic burden of US $5 trillion are associated with mental health disorders [8]. In the United States, the federal government spent US $280 billion on mental health services in 2020 [9]. Despite significant efforts, access to mental health services remains highly limited owing to barriers such as cost and availability of services [9].

The rate of untreated mental health conditions is a major concern. Although psychosocial interventions have shown remarkable effectiveness in supporting individuals with mental conditions [10,11], barriers to accessing services limit the number of people benefiting from such interventions [12]. Access to mental health support varies widely across the country. According to a 2018 study, over 60% of rural counties reported lacking access to a psychiatrist or psychologist [13]. Studies have reported long delays in appointment scheduling [14], with clients sometimes having to wait many months before they are seen; this is especially true for scheduling first-time appointments [15] and has thus become a common issue for mental health care [16,17]. The COVID-19 pandemic has exacerbated the gaps between a need for and access to mental health services [18], with renewed calls to address the shortage of mental health professionals in the United States [19].

To address the gap in providing adequate services for mental health conditions, the World Health Organization and other institutions have advocated for task-sharing approaches, including screening and treatment protocols that frontline health workers (FLWs) can follow to extend the role of mental health specialists wherever possible, particularly in areas where specialist support is nonexistent or inaccessible [20]. Worldwide, there is growing evidence of the effectiveness of psychosocial interventions delivered by FLWs who are not behavioral health specialists [21-24]; frontline interventions have demonstrated effectiveness and cost-effectiveness in addressing mental health in high-income and low-income countries worldwide [25-29].

Task-sharing programs with trained FLWs were initially pioneered and have since been broadly evaluated across various low- and middle-income countries, many with <1 psychiatrist per 100,000 people, rendering specialist access a near impossibility for much of the world’s population [30-33]. Following the concept of “reciprocal innovation,” in which mutual benefit and learnings are derived from innovations demonstrated to be effective in low-income settings and then applied to high-income settings and vice versa [34], task-sharing programs are now being advocated for use in high-income countries experiencing critical shortages of mental health providers and a need for equitable, culturally competent, and value-based care [21,25,35]. Task-sharing programs show great promise for increasing the health system’s capacity to meet the overwhelming demand for mental health care in the United States, particularly in areas with already limited access to specialized care. They can further allow specialists to focus on more complicated cases, potentially reducing delays for those who require more specialized care [36,37]. Scaling up such task-shared programs requires innovative strategies to ensure quality delivery of interventions and support FLWs’ skill enhancement. Using digital tools for training and supervision of FLWs is a promising next step [21] to enhance FLW skills, deliver psychosocial interventions effectively, and provide supportive supervision. Here, we define an FLW as any health worker without specialized training in mental health care who may be tasked with providing mental health support to clients in their communities, which in the United States can include primary care providers, physician assistants, community health workers (CHWs), lay therapists, peer navigators, nurses, midwives, and health coaches [38]. FLW-delivered interventions often have brief core elements (eg, behavioral activation [BA] [21,39]) and are intended to be conducted during FLW visits with clients in the community or primary care settings.

We built an app prototype guided by the principles of measurement-based care and supportive supervision based on an earlier app designed to facilitate supervision for CHWs in rural India [40] to facilitate skill enhancement of FLWs and effective delivery of FLW-led interventions in Texas. Measurement-based care includes methods of monitoring and improving the quality of psychosocial intervention delivery through objective, measurable metrics generated through systematic data collection to monitor client progress and directly inform care decisions [41-43]. Supportive supervision shifts the focus from the supervisor-supervisee dyad to the entire workforce by including self-assessments and assessments by peers, community members, and supervisors [44]. By digitally supporting measurement-based care and supportive supervision, the app can provide scalable access to measurable, evidence-based metrics that can guide assessments by peers as well as oneself and one’s supervisor. The app is designed to
support FLWs trained to implement a psychosocial intervention and who can benefit from a metrics-driven, supportive supervision approach to enhance individual performance and ensure intervention fidelity.

**Goal of This Study**

In this study, we aimed to assess the feasibility and acceptability of an adapted version of this prototype app in preparation for potential implementation in the United States following the technology acceptance model [45] and learnings from prior work using similar technology in India and other global settings [46].

**Methods**

We used human-centered design principles to adapt an app for FLWs in the United States and used a multimethod approach combining usability testing and group interviews to yield collective interpretations of the feasibility and acceptability of the app among potential target end users [47].

**Prototype Design**

The design of the app was based on learnings from implementing an existing app in the Promoting Effective Mental Healthcare Through Peer Supervision (PEERS) project built on the CommCare platform and developed as part of a large-scale randomized controlled trial in India to understand whether the quality of mental health care offered by FLWs can be improved through a scalable measurement-based peer supervision model [46,48]. This study builds on evidence that an allied peer supervision model can provide a scalable approach to improve the quality of mental health care available to populations in low-resource settings [46,49]. As of late 2023, over 200 non-specialist providers or lay counselors in Madhya Pradesh and Goa with appropriate training and supervision in mental health care but no formal mental health qualifications continue to use the app to support the peer supervision component of their work.

In this study, following the PEERS model, we adapted an Android and web app using an iterative prototype design with feedback from an advisory panel of stakeholders and subject matter experts with backgrounds in clinical professional development education, mental health policy, clinical social work, and development and implementation of CHW programs in Texas. Members of the study team held 4 rounds of discussions with 5 advisory panelists to assess face validity and help ensure that potential target users’ input was directly incorporated throughout the design and development process. Through a series of in-depth interviews, advisory panel members initially provided commentary on the original PEERS app, current supervision practices in the United States, and the app’s potential to support the supervision process. Subsequent in-depth interviews probed feedback on the usability of the prototype and considerations for its implementation within the United States. The advisory panel’s feedback included inputs for the design and development of the app and considerations for future implementation.

After incorporating preliminary advisory panel feedback, a final app prototype and study materials were created and prepared for usability testing with target end users. The final app was designed to support the following FLW activities: (1) registering clients, conducting and audio recording intervention sessions, and entering session-related notes; (2) reviewing and rating audio-recorded intervention sessions they conducted themselves using a validated scale (eg, the Behavioral Activation Quality Scale [44]); (3) reviewing and rating audio-recorded intervention sessions conducted by peers; (4) reviewing data visualizations of self-ratings as well as those given by their peers and supervisors for reviewed sessions; and (5) accessing related training materials. A screenshot of the app’s menu and the details of each module are shown in Figure 1.

**Figure 1.** Screenshot of the peer supervision web application menu with descriptions of each menu item.
Previous Mental Health Training
To assess the feasibility and acceptability of this prototype app, we identified participants who had completed a 2-part training on foundational skills and BA interventions for depression and received access to measurement-based peer supervision training developed by a nonprofit program, EMPOWER, that leverages digital tools for training and supervising FLWs worldwide [46]. The FLWs in this study had been trained as part of efforts to build workforce capacity and scale up access to brief psychosocial interventions for depression in primary care and community settings across Texas [46].

Recruitment
FLWs from a large health system in Texas (ie, Baylor Scott & White Health) were recruited via email by an experienced human subjects–trained member of the study team to participate in remote focus group sessions. Candidates who met the following eligibility criteria were invited to participate: (1) aged ≥18 years, (2) fluent in English, and (3) having completed training on foundational skills and BA interventions for depression and having access to the measurement-based peer supervision training course developed by EMPOWER. Informed consent was obtained before participation.

Onboarding to the App
After completing the aforementioned training courses, which included a brief introduction to the app and brief video tutorials on how to use it, participants were invited to join a remote focus group session comprising usability testing and a group interview. All sessions were conducted via Zoom (Zoom Video Communications) and lasted approximately 1.5 hours. Participants who did not own an Android device were mailed a study tablet with the app preinstalled for use during the usability testing portion of the focus group session. Study team members trained in user experience and qualitative methods moderated the sessions (YXH and DML).

Usability Testing
To assess the app’s usability, a set of 11 usability tasks and related scenarios were created based on tasks we anticipated FLWs would commonly perform if they were to use the app in practice (see the task list in Multimedia Appendix 1). One moderator (DML) introduced each task to the participants, who then performed each task independently at their own pace. The next task was introduced once everyone had completed the preceding one unless the task took much longer than anticipated, in which case the moderator then moved participants to the next task. Moderators observed and noted participants’ task performance while providing minimal assistance with task instructions when needed.

Surveys
In addition to usability testing, each participant independently completed a series of surveys via Qualtrics (Qualtrics International Inc) to collect information on participant demographics; experience with technology; and perceived ease of use, usefulness, and user satisfaction. We used the positive System Usability Scale (SUS) [50], a 10-item Likert scale survey to assess general usability, with possible scores ranging from 0 to 100, where higher scores indicate higher usability. We also calculated the net promoter score (NPS) [51], a single-item user-reported questionnaire to rate the likelihood of recommending the app to others to assess market viability. To generate an NPS, respondents provide scores between 0 (not at all likely) and 10 (extremely likely); scores of 9 or 10 are considered “promoters,” scores of 7 or 8 are considered “passives,” and scores of 0 to 6 are considered “detectors.” The NPS is then derived by subtracting detractors from promoters (both calculated as the percentage of total respondents), with possible NPS scores ranging from −100 to 100.

Group Interviews
All participants engaged in semistructured interviews following usability testing and survey completion. An interview guide was developed and used to collect feedback on user experience with probes on the overall impressions of the app, current supervision mechanisms, and barriers to and facilitators of the broader implementation of the app. A trained and experienced moderator (YXH) followed the guide to probe feedback on the app’s perceived feasibility, acceptability, and usefulness.

Data Analysis
The focus group sessions were audio recorded, transcribed, and anonymized before coding and analysis. The COREQ (Consolidated Criteria for Reporting Qualitative Research) checklist is included in Multimedia Appendix 2 [52].

We used both deductive and inductive approaches to coding. We first defined usability, feasibility, and acceptability following definitions published by Ginsburg et al [53]. In total, 2 coauthors (YXH and DML) who moderated the focus group sessions independently read 2 transcripts and generated codes from the data. YXH, AP, and DML then finalized the codebook, which was used to direct the coding process. We used a systematic thematic coding approach [54] to generate key themes based on a priori codes and emergent codes: (1) perceived feasibility of the app, (2) acceptability of the app, (3) perceived usefulness of the app, and (4) barriers to and facilitators of scalability. Textbox 1 summarizes the definitions of the themes as used in this paper. Following thematic coding, we developed code summaries or preliminary narratives describing each theme. YXH, AP, and DML then discussed and refined the code summaries to ensure depth and breadth across all participants. The final code summaries were used to describe the findings in this paper. An intercoder agreement was calculated between 2 coders (YXH and DML) on a portion of coded data until a κ value of 0.61 was achieved. All interview transcripts were double coded and analyzed using the qualitative research software Dedoose (version 9.0.107; SocioCultural Research Consultants) [55]. SUS and NPS scores were calculated following the focus group sessions.

Ethical Considerations

The institutional review boards at Baylor Scott & White Health (388136) and Harvard Medical School (IRB22-0692) approved the study.

Results

Overview

A total of 18 FLWs—including clinical managers, CHWs, social workers or social work students, research assistants, nurses, and medical assistants—participated in 1 of 6 focus group sessions. Participants were aged between 21 and 70 years. Most identified as female (15/18, 83%), were not Hispanic/Latino (11/18, 61%), and had bachelor’s degrees (8/18, 44%). Table 1 summarizes the demographic characteristics of the participants.

Most participants (11/18, 61%) did not have mental health training before the EMPOWER training but interacted with individuals with mental illness regularly during their work (Table 2). None of the participants had experience delivering structured BA therapy.

Overall, participants found the app usable, with an average SUS of 72.5 (SD 18.1) compared with the industry benchmark of 68, which has been found to be the average SUS for digital health apps and used in previous digital health studies [56,57]. The average SUS scores from older participants (aged >50 years) were lower than those from younger participants (Table 4). The NPS was 0 (neutral), with an equal distribution of promoters, detractors, and passives (6/18, 33% per NPS category).

Perceived Feasibility of the App

In this section, we discuss the perceived feasibility of the app, which includes structural factors such as the current administrative and operational capabilities of health systems that could influence the introduction of the app. The participants discussed their current client-provider engagements and supervision mechanisms that could affect the potential introduction and incorporation of the app into current workflows and across the existing health system.

**Client-Provider Engagement**

Participants described how they worked with clients, which revealed potential considerations of how the app may need to be flexibly designed to support the ways in which FLWs meet with clients today. First, although in-person visits were still common, many participants shared that they engaged with their clients via telehealth. Furthermore, when meeting remotely with clients, participants shared that they may not necessarily have a quiet, private space to speak with clients and connectivity may be less reliable. Thus, obtaining high-fidelity recordings of sessions conducted in settings with frequent disruptions is an important consideration. Second, FLWs have limited time to interact with clients, and some participants shared that additional time would be needed to deliver a brief psychosocial intervention. Third, in some cases, screenings such as the Patient Health Questionnaire–9 for depression are currently administered and updated in electronic health record (EHR) systems such as Epic, and it may not be the FLW’s role to access, collect, or update these data even though such screening data may be needed for the delivery of a psychosocial intervention such as BA. When discussing client engagement, one participant noted the following:

...the social worker is the first person that meets with the patient because she talks to the patient to see what barriers they have to their personal care, which would involve depression screening, and any kind of behavioral health barriers that they may have going on. So that’s how we get our information about what the patient is kind of going through and what they need as far as behavioral health management. [P04; nurse]

The integration of the app into existing EHR systems was reported as another important consideration.

Finally, although we did not specifically collect feedback on supervisors’ perceptions of the app, participants in supervisory roles suggested that additional time would be needed not only to review all the recordings but also to actually deliver the intervention—time that FLWs may not have:

From my role, like I said before, I don’t know that I would have the time to incorporate something like this into a patient encounter just because, like I said, we’ve got about 15, 20 minutes to see a patient for whatever issue is happening. And generally, when I see a patient for depression, anxiety, or something mental health, we certainly talk about it, talk about the role of treatment, maybe some options for counseling, not necessarily just medication. But I feel like when they get to me, it’s more about treatment and not so much about talking through things just because they’re not going to have as much time with a physician or a nurse practitioner because of their schedules. [P08; nurse practitioner]

**Supervision Structure**

According to the participants, the current supervision structure includes structured supervisor-supervisee meetings scheduled as a part of annual performance reviews. In most settings, although they are not perceived as part of supervision and are not standardized, peer support groups are also available. Although the existing peer support mechanisms are informal and do not follow a structure similar to the supervisor-supervisee meetings, they function as a good support mechanism for team members in which “a doctor can support a doctor, a manager can support a manager, or even their employees” (P06; clinical manager). A participant noted the following:
We do huddles where we kind of discuss different things that are going on and changes within our settings and our clinical practice that are similar, but we don’t necessarily do any ratings. [P16; certified medical assistant]

Thus, introducing the app would mean integrating these traditionally siloed supervisor-supervisee and peer support mechanisms and potentially introducing a new workflow that allows additional time and resources to be invested in supporting FLWs.

Acceptability of the App

On the basis of feedback from the focus group sessions, participants’ overall impressions of the app were mainly positive. Participants reported that they found the app “easy,” “useful,” and overall “important” to their current workflows. The app could provide a much needed structured platform to support peer supervision and overall training of FLWs. A participant with no training in mental health care delivery before the BA training program noted the following:

I don’t have to be a licensed professional counselor, and I can actually use it myself to help and...get supervision from my other peers to help me along the way. [P07; certified medical assistant]

Another participant described the app and process as an “objective way to actually hear the session and hear how much each person reacted, how they delivered the information to the person, how the patient received it” (P08; nurse practitioner). She added that, as a supervisor, she could instruct the trainee to “go ahead and do it, and then we’ll listen, and we can talk about feedback together.”

Even though most participants did not necessarily review or remember information from the app-related training materials provided to them before the focus group sessions, they considered the app easy to use. Participants who accessed the app on their devices found it easy to install. Most respondents also found the app navigation to be easy and self-explanatory. Nonetheless, it was noted that it could be a bit confusing at first “because you don’t know where to click,” (P02; social worker or social work student) and there were a few features within the app that the participants found more challenging to navigate. Participants needed time to familiarize themselves with the app and use it comfortably as they had never used a similar app before. One FLW reported the following:

I watched the (training) videos a long time ago and didn’t remember exactly everything that was talked about in the videos. And so, there’s a little bit of difficulty at first, but it’s pretty intuitive [as to] where everything is and how to use it. Or at least for me, it was, and so I could be able to grasp onto it pretty easily. [P03; social worker or social work student]

The features that participants needed the most time to navigate included accessing recordings, graphs, and self-ratings.

Perceived Usefulness of the App

Participants generally perceived the app to be potentially useful for a few reasons. One respondent shared that such an app would be useful to have now to address gaps in care because of limited access to and availability of mental health specialists:

For me, it would be a great thing to refer someone to if this was—if this was available because I think right now our psychiatrists are scheduling out next year. I think it’s a year before you can get the next appointment. So obviously, mental health is a big problem. [P08; nurse practitioner]

The app could also help enhance FLWs’ job performance, highlight their areas for growth, and ensure overall intervention fidelity. The app’s ability to record and allow users to review and rate sessions can allow for more tailored feedback on performance enhancement, highlighting areas of growth:

I think as a supervisor, being able to record sessions could be really impactful if you have group supervision that you’re doing. Because if you have the consent from the patient and you’re able to kind of play this recording for everybody, you could kind of talk about what things went good [sic], areas of growth, basically. And so being able to use a recording, I think, could be helpful, as well as peer ratings and getting the ratings from your supervisor to kind of also see what areas of growth that you might have for behavioral activation or any other skills that you’re using at your place of employment. [P03; social worker or social work student]

In addition to individual performance enhancement, the app could ensure intervention fidelity. A CHW shared that counseling sessions were often interrupted in the hospital setting; therefore, audio recording or rating could verify that the sessions were comprehensive despite disruptions. Reviewing the recording asynchronously could also help FLWs ensure that their sessions adhere to the intervention protocol.

Finally, most participants mentioned how their current peer support groups lacked structure and did not use systematic guidance or frameworks such as ratings for peer supervision. Respondents highlighted the potential of this app to fill that gap; however, the challenge would be in how to systematically incorporate the use of the app across the health systems currently implementing or planning to implement task-shared mental health interventions. As aptly summarized by a CHW, “to say that we need something like this, we definitely do. It’s just ‘where-do-we-put-it type’ of situation” (P17; CHW).

Barriers to and Facilitators of Scalability

Following discussions on the app’s perceived feasibility, usefulness, and acceptability, we probed considerations that could help the app’s broader implementation, including its fit into the FLWs’ current workflows and recommendations for future implementation.

Addressing Privacy Concerns

Protecting client privacy was expressed as a top priority for most respondents. Although feedback was mixed about clients’
apprehension toward audio-recorded sessions, it was generally agreed that obtaining proper client consent before recording was critical and necessary. Participants shared that consent from both FLWs and clients would be essential to ensure transparency and that all parties were informed of and agreed to how recordings would be used. Suggestions for increasing client comfort and obtaining adequate consent included building a trusted relationship with the client before asking to record sessions. By doing this, clients may be less hesitant to be recorded and more comfortable sharing their potential concerns.

Finally, regarding physical infrastructure, as noted previously, there is not always a private, physical space for FLWs to engage with clients and conduct peer supervision activities. One participant shared the following:

...we would probably talk about a lot of stuff that people would really want to be kept private with no real chance of anyone else hearing it, but that space is a big issue. We have a lot of shared offices—a lot of people in the same room at the same time...it might be better for us to, say, record a session so that we can make sure we’re getting everything, make sure I’m not missing something because that person’s over here, this person’s doing this, this person interrupted me, that person bumped into me. Yeah, we would just need to find a way to do it where we could minimize distractions, interruptions, and that kind of stuff. [P17; CHW]

Another participant agreed, stating the following:

I’m in a room that can accommodate 25 people. And I have people all around me, and we’re all talking about different things. And it’s really hard. [P18; CHW]

Ensuring the App Fits Workflow and Time Capacity

Although the app was perceived as an important addition to support their work, some participants raised concerns about finding time to deliver brief interventions and reviewing their sessions. It was suggested that the ability to review and rate recordings anytime and anywhere is an advantageous feature of an app accessible from any device and that FLWs may prefer different device types depending on their environment or workflow. For example, one FLW noted the following:

I think mostly it would be done at a computer because we have very set clinic hours where I’m at. But in some other environments, I could see somebody trying to access it from a car or something like that. [P16; certified medical assistant]

Another commented that, for her role, “...these (tasks) would be more flexible in very small devices, like iPad or phone, rather than recording it and everything, doing it in a computer” (P10; nurse). Asynchronous review would also allow for more flexibility in completing these follow-up activities:

I think being able to kind of reference the sessions that you’ve recorded will kind of allow for being a little more flexible in the schedule. Right now, you just have to go with each patient as it is, but this will allow...you to refer back. So, you don’t always have to just do it all at one time. [P16; certified medical assistant]

Collecting and managing data offline would also be critical for FLWs working in areas with limited connectivity.

Providing Structured, Supportive Supervision

Respondents noted how the app could help supervisors give structured feedback to their staff, identify and highlight areas of growth, and delegate appropriate tasks to FLWs based on their performance and expertise. Similarly, peer supervision could allow for more structured feedback from peers in workplaces that currently have informal peer support groups. Respondents confirmed that structured supervisor feedback could help with performance enhancement and quality assurance, particularly during the training phase, when workers need the most support. One participant noted the following:

...it would be good to be able to listen to how we interact with the patients. And it would be good to listen to it with the provider so...the nursing staff would know what we could do different, if we did well, just to get an idea of how we’re doing and how the patients are reacting to what we do. [P09; medical assistant]

Participants felt that current app-supported supervision could allow for a more consistent feedback mechanism, systematic tracking of gradual performance improvement, and a constant feedback loop to enhance learning opportunities for FLWs.

Similarly, although respondents reported that informal peer feedback is available in some settings, it is largely unstructured. Most participants agreed that having their peers listen to their sessions and provide feedback is beneficial. Respondents were generally receptive to their peers being involved in supervisory processes, primarily as the participants viewed peer supervision more as “feedback” rather than a performance appraisal. However, it was suggested that it would be important, if not critical, to ensure that peers provide constructive and positive feedback to each other; concerns were raised about how the care team culture may be affected by peers giving and receiving negative ratings and critiques on performance. When asked how they would feel about their peers listening and rating their sessions, one participant noted that it is “beneficial to have another set of ears as long as it’s constructive criticism or constructive help” (P18; CHW). Regarding constructive criticism, “I think it’s all in bettering us so that we can better our patients, so that’s good” (P16; certified medical assistant). For some, ratings were only associated with yearly performance reviews with a supervisor. Respondents emphasized the importance of a nurturing and supportive peer group rather than a competitive one. Finally, participants agreed that the app had the potential to help with more structured self-assessments as well. The ability to record and review sessions could allow for more flexible self-evaluation and help with self-improvement and retrospective performance assessment.
Discussion

Principal Findings

We conducted this study to assess the feasibility and acceptability of a prototype app developed for FLW supervision using objective, metric-based performance evaluation and supportive feedback mechanisms in the United States. Participants found the app easy to use and acceptable. It was considered useful for supporting task sharing of mental health care services, enhancing FLWs’ skills, ensuring intervention fidelity, and providing structure to the traditionally unstructured peer support groups by introducing peer ratings and structured feedback mechanisms. Some key feasibility issues revealed in discussions with FLWs and stakeholders included (1) how the ability to record sessions with high fidelity may depend largely on the nature of the client encounter, (2) the potential need to integrate the app into an existing EHR system (eg, Epic), and (3) the introduction and integration of a new app-supported peer supervision workflow into existing supervisor-supervisee processes and peer support mechanisms. Among areas of improvement for scalability were privacy considerations both on recording and rating the session and ensuring the availability of private space in the health facility to conduct the mental health intervention successfully. Other areas of improvement included focusing on the additional time commitment required of FLWs and supervisors when introducing the app, including time to record and rate the sessions. Findings from our study highlight the app’s potential to catalyze the existing traditional supervisor-supervisee dyad model by shifting focus to a supportive supervision model that incorporates feedback not just from supervisors but also from peers and through self-assessments [44].

We would like to highlight 2 key findings that affect the scalability of the current app and similar digital tools that aim to support the monitoring of psychosocial intervention delivery through objective, measurable metrics. The first is the utility of the current app for supportive supervision of FLWs in the United States. Given the current focus on the scalability of task-shared mental health interventions and the need to ensure the quality delivery of task-shared psychosocial interventions, digital solutions such as the one proposed in this study are crucial [46,58]. Worldwide, digital interventions have shown great promise in supporting FLWs [59], and studies are now exploring digital supportive supervision more extensively [60,61]. The current app can rapidly scale this process, standardize performance measures, and account for evolving training needs with great flexibility. In this study, we demonstrated that an app based on work with nonspecialist providers in Madhya Pradesh and Goa, India, was found to be usable and potentially useful for FLWs in Texas and shows promise for supporting the scale-up of services delivered by FLWs in similar settings across the United States.

Another key finding of this study is the potential of the app to help merge traditionally siloed supervisor-supervisee and ad hoc peer feedback approaches to build a more unified, structured supervision process across existing health systems. This requires effort beyond adding the app to the existing workflow; rather, it may be necessary to develop a new workflow entirely. Participants expressed concerns about the additional time commitment required to use the app as a part of their job. However, it is important to note that the time constraints mentioned were not necessarily related to the use of the app itself but to adding objective, measurable metrics to assess FLWs’ performance. Introducing measurable metrics to evaluate performance requires recording, rating, and discussing sessions; additional time; and skill sets often beyond the FLWs’ job description. The time commitment required can constrain effective supervision in task-shared projects [29]. Therefore, the app’s scalability depends greatly on creating a workflow that benefits FLWs and communicating its need to support FLWs and task-sharing mental health care across health systems. Creating protocols that outline how to record sessions safely and securely for quality assurance is also critical, particularly in light of the privacy concerns associated with recording internet-based sessions [62]. Ensuring readiness for a systematized supportive supervision process guided by infrastructure and protocols contextualized for a particular type of setting is crucial for the success of task-shared mental health care delivery [63]. More importantly, the current app must flexibly align rather than conflict with existing supervision models and diverse FLW workflows to ensure that it truly supports FLW skill enhancement, effective feedback mechanisms, and adequate fidelity in task-shared interventions [64-66].

Recommendations for Future Implementation

On the basis of the feedback collected in this study, there are several key considerations, challenges, and proposed solutions for the future implementation of this app. Table 5 summarizes the key considerations raised during the preliminary prototype design of the app, including advisory panel discussions, usability testing, and focus group session interviews. We propose solutions for each consideration that can inform future studies aimed at introducing similar digital tools to assist FLWs. These recommendations will also facilitate organizations’ development of supportive and structured supervision mechanisms.

| Available resources in the implemen ting health facilities | • Inadequate physical space for conducting private and secure counseling sessions  
• Lack of current protocols on supportive supervision to guide FLWs  
• Need for structured peer supervision to implement the app | • Assess the availability and accessibility of facilities’ resources before implementing the app  
• Facilitate the development of protocols or updates to current protocols to promote the use of the app  
• Set up or use the existing structured peer supervision mechanisms to support app integration |
| Peer supervision model              | • More structured peer supervision could be cumbersome and time-consuming, especially for FLWs who are used to feedback from supervisors and are more comfortable with informal peer feedback mechanisms | • Include specific training and guidance on delivering and receiving peer feedback  
• Ensure supervisor buy-in and system support |
| Hybrid workflow                     | • Both in-person and remote (telehealth) client visits are common            | • Ensure the app can flexibly support recordings either directly in-app or via integration with other tools that may already be used |
| **App related**                     |                                                                             |                                                                                                                                                    |
| Peer ratings                        | • Introducing a mechanism for peers to rate and critique each other may feel uncomfortable | • Include positive and encouraging language and features (eg, badges) to support improvement in performance  
• Include space for qualitative feedback to provide more context for ratings |
| Navigation                          | • Navigation through parts of the app remains cumbersome                   | • Enhance the app to support the following:  
  • Unnested features (eg, client or patient lists)  
  • An easy way to view completed self-ratings  
  • A way to flag incomplete self- and peer ratings  
  • locating a session recording via multiple search parameters, such as client or patient ID, peer, or date |
| Data visualization                  | • Graphs and self-ratings are not intuitive                               | • Simplify current features such that graphs are more easily accessed and usable across device screen sizes  
• Highlight and indicate change in performance over time, noting specific areas that may need improvement |

aFLW: frontline health worker.
Conclusions

In summary, we demonstrated the feasibility and acceptability of a usable and functional mobile app prototype to support FLW-delivered psychosocial interventions in the United States. However, the success of future implementation hinges on further development of the app to ensure its adoption by both FLWs and their supervisors and overall readiness to adopt a novel peer supervision model of care. Feedback from stakeholders and target end users (FLWs) suggests that the app can help structure supervision mechanisms and systematize the collection and review of performance metrics in task-shared mental health interventions. With appropriate organization- and system-level support coupled with strong FLW training programs, the proposed app has the potential to scale up the delivery of high-quality, evidence-based mental health interventions in the United States through the critical role of FLWs who are already connected with and best positioned to serve some of the hardest-to-reach communities with the greatest needs for psychosocial support and care.

Acknowledgments

The authors would like to thank their colleagues at Dimagi, Akshita Sharma, and Surabhi Dubey, who assisted with app building and provided helpful inputs throughout this study. They would also like to thank Dr Daisy Singla, who has been leading the related study in rural India on which this study is based. Finally, they express their deepest gratitude to their advisory panelists from the Meadows Mental Health Policy Institute, Baylor Scott & White Health, the University of Texas at Arlington, and all the study participants for their time and contributions to this work. This project was supported by the National Institute of Mental Health award R43MH130305-01A1. AP has received support from the National Institute of Mental Health T32 on Social Determinants of HIV (T32MH128395-01). The development and testing of the app previously deployed in rural India were supported by Grand Challenges Canada under grant TTS-2109-47591 in collaboration with Sangath and the Sinai Health System.

Data Availability

The data sets generated during and analyzed during this study are available from the corresponding author on reasonable request.

Conflicts of Interest

YXH, DML, LM, and NL are employed by Dimagi, Inc, whose revenue is derived from the open-source platform on which the digital app described in this paper was built and studied. VP is a co-founder of the EMPOWER At Scale company in the US. He has zero income from this company.

Abstract

Background: The construction, chemical, aviation, medical, and health care industries have used serious games for safety training. To our knowledge, serious games have not been developed focusing on behavioral change to improve safety through the use of verbal commands and instilling players with heightened awareness of their spatial proximity to other people in their surroundings.

Objective: We aimed to develop a theory-driven serious game for improving safety behavior using verbal commands and validate the implementation of the theoretical frameworks used for game development. The game developed, KitchenSpeak, was a first-person character (FPC) game where users respond to in-game prompts to use loud verbal commands when they are approaching another employee’s blind spot.

Methods: In addition to using the SERES framework in guiding the general game design and development, and the Reflection, Engagement, Choice, Information, Play, Exposition (RECIPE) framework to inform the design of the game mechanics, we also applied gestalt laws of perception for graphic design to guide the design of the game’s user interface. We conducted 2 evaluative tests (alpha and beta) to collect end user and stakeholder feedback on the implementation of the theoretical frameworks, as well as to collect relevant information for full-scale implementation and a future validation study.

Results: The alpha and beta tests had 8 and 40 participants, respectively. The alpha test results revealed that the theoretical frameworks were adequately applied; however, suggestions were also made to modify and improve the game. The beta test results suggested further improvements for the game design and found no differences in the perception of ease of play between participants with and without previous FPC gaming experience (P=.47; Kruskal-Wallis). Results suggested that the game met its design and theoretical requirements, and it would be easily playable by all players regardless of their previous experience in FPC games.

Conclusions: A theory-driven and evidence-based FPC game titled KitchenSpeak was developed to teach the use of kitchen-speak terms in commercial kitchens. Evaluative tests were conducted to validate the implementation of the theoretical frameworks. Our main contributions are creating and validating game-based training to improve behavioral-based safety in the workplace and the incorporation of gestalt laws of perception for graphic design in the game’s user interface.

Introduction
Overview
In recent times, serious games have been used in industries and various occupations as training tools for employee safety. Serious games combine elements such as visual and auditory effects and the euphoria of overcoming challenges to facilitate user engagement to motivate the user to transfer gained knowledge to real-life experiences [1]. Serious games are effective tools to improve safety knowledge in the construction [2-8], chemical [9-11], medical and health care [12-15], and aviation [16-18] industries. However, to our knowledge, serious games have not been used in improving behavioral-based safety. In addition to acquiring safety knowledge, behavioral-based safety requires employees to repeat safe behavior over a period of time. Using verbal commands to alert fellow employees of their proximity is a safety practice that is important in high-traffic workplaces, where struck-by injuries can occur. Consistently using verbal commands is a behavior-based safety practice.

Verbal commands are used in various work settings, and this study used a commercial kitchen as a representative workplace to develop and validate our serious game. Verbal commands given in a commercial kitchen environment are generally called “kitchen-speak,” and they are widely used in commercial kitchens as a safety behavior aimed at reducing the risk of accidents due to collisions between employees. Existing methods to train employees to use verbal commands in the workplace using traditional training methods (lectures or videos with quizzes) have been ineffective. This study developed a theory-driven and feedback-based serious game for teaching and training employees to use verbal safety commands within a commercial kitchen.

KitchenSpeak Game Overview
KitchenSpeak is a first-person character (FPC) game where users respond to in-game prompts to use loud verbal commands when they are approaching another employee’s blind spot. These verbal commands to alert other employees of their proximity are called kitchen-speak, the namesake of this game.

Commonly used verbal commands in a commercial kitchen include “corner,” “behind,” “hot,” “sharp,” and combinations of these commands, such as “hot corner” and “sharp behind.” In our game, the player will use the keyboard and mouse to navigate the game environment. Whenever a scenario to use a verbal command occurs, a pop-up text message will inform the player of the verbal command required to be yelled. Upon successful yelling of the command, the game will display another pop-up to inform the player. The player will not be able to proceed through the scenario until the proper command is verbally completed.

KitchenSpeak game consists of 4 stages, where players will progressively learn a new command in every stage while applying the commands learned in previous stages. The last stage is a free-roam stage, where players will have to use a combination of the commands they have learned without any pop-up window to indicate the place of use. The players should now be able to identify the safety situation and act without a prompt. In each stage, a minimum of 4 verbal commands are required for completion, and the players are allowed 1 manual override per stage to minimize frustration and game abandonment.

Prior to starting the game, the player will have to enable the microphone on their computer. The voice recognition module used in this game is Google’s speech-to-text application programming interface which is trained with Google’s speech recognition models. The players do not calibrate or train the speech recognition module.

Significance of the Research
This study contributes to the body of knowledge on serious games by focusing on behavioral change to improve safety through the use of verbal commands and instilling the player with a heightened awareness of their spatial proximity to other people in their surroundings. Existing research in using serious games to improve safety has mainly focused on knowledge such as the proper use of tools [4,5] and proper procedures to perform high-risk tasks [19]. None of the existing serious games for safety focus on behavioral change and using verbal commands. The development and beta testing of the game from this study can be adapted to other training scenarios where behavioral change is needed and incorporate verbal commands as part of the gameplay.

Methods
Ethical Considerations
This study was reviewed by Oregon State University (OSU) institutional review board (IRB-2021-1174) and was determined to be exempt from review.

Methods Overview
The SERES framework [20] for developing serious games was used to guide KitchenSpeak’s development. Nicholson’s [21] Reflection, Engagement, Choice, Information, Play, Exposition (RECIPE) framework was used to guide the design of the game mechanics within the design foundation stage of the SERES framework. KitchenSpeak’s user interface (UI) was designed according to the 6 gestalt laws of perception as proposed by Smith-Gratto and Fisher [22]. An effective UI is important for game development as it ensures that the game players engage with the game in the intended manner [23].

SERES Framework
Overview
The five stages in the SERES framework are (1) scientific foundations, (2) design foundations, (3) development, (4)
validation, and (5) implementation. This study applies the first 3 stages of the framework to KitchenSpeak game development. The last 2 stages of the framework involve evaluating the effectiveness of the training tool, which is planned for a follow-up study. The following subsections present a summary of how the first 3 stages of the SERES framework were applied, as well as the plan for implementing the last 2 stages.

**Scientific Foundations**

There were 4 aspects of this stage. First, the target audience was Marketplace West Dining Center (MWDC) student employees (84% of the MWDC employee population). Second, the outcome objectives were to increase the use and knowledge of kitchen-speak among student employees. Third, the theoretical basis was our hypothesis that kitchen-speak use and knowledge will increase among people who play the game. Fourth, the tool evaluation will be performed in future work prior to implementation.

**Design Foundations**

**Game Mechanics**

We designed the game mechanics according to the RECIPE framework for gamification. Please see the RECIPE Framework for Game Mechanics section for further details.

**Design Requirements**

We modeled the virtual environment after the real-world MWDC environment to motivate reflection and foster immersion. A plug-in was used to transcribe verbal inputs from the players. For easy access, KitchenSpeak was designed for a web browser platform. MWDC management advised that the game’s completion time should be between 5 and 10 minutes.

**Game Authoring Tools**

Based on the design requirements, the following software and services were used to develop the game: (1) Unity-3D game engine for WebGL, (2) Autodesk 3ds Max for object modeling, (3) Google’s speech-to-text plug-in for speech transcription, and (4) PHP database hosted on OSU servers for game data storage.

**Trial Design**

Two validation tests (alpha and beta tests) were used to validate the implementation of the theoretical frameworks.

**Development**

**Genre**

KitchenSpeak was modeled to be a FPC game. The FPC perspective camera model was used since it encourages user immersion more than games in the third-person camera perspective [24].

**Content**

KitchenSpeak had 4 game stages: Corner, Behind, Hot Corner, and Free Roam stages. Each user must use kitchen-speak terms at least 3 times in the Corner and Behind stages, and at least 5 times in the Hot Corner and Free Roam stages. Each stage has a simple narrative where users are asked to complete tasks assigned by their supervisor. While navigating the virtual kitchen to complete tasks, the player is prompted to use kitchen-speak in blind areas. Figure 1 shows the “yell corner” prompt shown to a user as they approach a blind area. Learned kitchen-speak words cascade in each stage, that is, the Behind stage includes “corner” and “behind” kitchen-speak, the Hot Corner stage includes “corner,” “behind,” and “hot-corner,” and Free Roam includes all previously used kitchen-speak, with an additional “sharp-corner” kitchen-speak.

![Figure 1. Prompt to use kitchen-speak in the Corner stage.](https://formative.jmir.org/2024/1/e48080)
Rules
There are three general rules: (1) All game stages must be completed to complete the game. (2) Within the Corner, Behind, and Hot Corner stages, a player must use kitchen-speak terms when prompted; otherwise they do not advance through the blind area and cannot complete their assigned task (“enforced-use rule”; the Free Roam stage does not have this rule). (3) In the Corner, Behind, and Hot Corner stages, users are allowed to override the prompt to use kitchen-speak if they are stuck in the blind area for over 30 seconds; users are allowed a maximum of 3 overrides throughout the 3 game stages (override rule).

Visuals and User Experience
Gestalt laws of perception for graphic design were applied to guide the design of the UI elements. User experience was tested and modified through the alpha test.

Figure 2. KitchenSpeak virtual environment and Marketplace West Dining Center (MWDC) kitchen.

Validation and Implementation
Validation and implementation, the last 2 elements of the SERES framework, will be performed in future work.

RECIPE Framework for Game Mechanics
The six elements of the RECIPE framework were implemented in KitchenSpeak game mechanics as follows.

Reflection
This was implemented by modeling KitchenSpeak environment and activities after the MWDC kitchen environment, as well as the activities that occur within the MWDC kitchen. Figure 2 shows a scene of the virtual environment from KitchenSpeak compared to the MWDC environment.

Exposition
This was implemented by including simple narratives, such as “Your colleague John put some Teriyaki chicken into the oven, and it is now ready to be checked and served. Go and pick up the chicken from the oven.”

Choice
This was implemented by (1) allowing users to choose different navigating routes to complete an activity and (2) giving users the ability to choose when they want to complete a task. They may decide to free-roam within the game before completing the task.

Information
This was implemented by creating 3 tutorial stages that allow the user to practice the game controls before the main game stages. Informational texts highlighting the objectives of each stage are displayed at the start of each stage. A quick message is also shown to alert the player if they correctly use kitchen-speak, and if they have started, completed, or are in the process of completing a task.

Play
This was implemented by allowing players to restart each stage from within the game. If a user fails to complete certain tasks within a stage, the user is permitted to restart that stage an infinite number of times until they have completed the stage or feel satisfied with their progress. A player is always informed on their progress through the informational text during task progress and completion. Allowing the user to fail and restart within the learning environment creates an opportunity for the user to self-reflect and discuss their experiences with other players, thus improving long-term learning [25].

Engagement
This was implemented through interaction by including activities within the game that require the user’s response. The user is made to provide verbal input as a form of response to the kitchen-speak prompts and is asked to provide keyboard input while completing activities.

Gestalt Laws of Perception for Graphics Design
Gestalt laws of perception for graphics design leverage the laws of perception to develop a comprehensible screen design that is aimed at aiding viewers to interpret and remember the
presented materials [22, 23]. The gestalt laws were applied to the UI elements within KitchenSpeak; however, the Controls menu and Stage Select menu in Figure 3 are used as examples to show how the laws were applied. The 6 gestalt laws of perception for graphics design applied in this game are as follows.

**Figure 3. Controls and stage select menus.**

**Figure-Ground Contrast**
This law states that the figure and background must be distinct so that viewers can easily distinguish the figure from the background. In the Controls and Stage Select menus, the primary background color is dark orange (#FF8000) while the text color on the primary background is white (#FFFFFF). This color combination creates high contrast, which improves its legibility.

**Simplicity**
This law states that people simplify their perceptions based on previous experiences. The UI should be designed with simple and familiar designs so that viewers may easily understand it. In KitchenSpeak, unrelated information is shown in separate UI objects, while related information is shown in a single UI object.

**Proximity**
This law states that objects that are close together in space are generally perceived to be grouped together. Similar game UI objects were placed together to reduce the mental load that a player uses to identify game objects. In the Stage Select menu, the game stages and tutorial stages buttons are arranged in close proximity so that the player can easily identify that those buttons represent the game stages and training stages, respectively.

**Similarity**
This law states that objects that possess similar characteristics are generally perceived as a whole. KitchenSpeak game objects that were similar in function were designed to have similar appearances. In the Controls menu, the same background color was used for the subheadings Controls and Stages to signify that these 2 texts were subheadings and not parts of the instructions. In the Stage Select menu, the game stage buttons are made the same color apart from the Free Roam stage button. The Free Roam stage button turns green after the player successfully completes the 3 other stages.

**Symmetry**
This law states that objects with an unbalanced symmetry are perceived to be incomplete and could be distracting to viewers. In the Controls menu, the white vertical line between the Controls and Stage subheadings was designed to create a symmetrical design in the UI. Symmetry was also applied in the Stage Select menu to guide the arrangement of the game stage buttons.

**Closure**
This law states that open shapes are perceived as incomplete. Important figures should have closed shapes so that viewers do not have to be distracted from trying to close the shape. In the Controls menu, the message “Successfully complete all stages to finish the game” conveys information that is different from the information that the other UI objects convey. As a result, its UI object was designed to have a closed red rectangular figure that distinguished it from the other UI objects, thus reducing ambiguity and making the information easier to read.

**Trial Design**
Two evaluation tests (alpha and beta tests) were conducted. The alpha test was conducted as a qualitative test in the form of an open-ended discussion where participants played KitchenSpeak version 1.0 and were asked to provide their verbal feedback on their gameplay experiences. Our focus for the alpha test was the game content, navigation, UI, speech recognition, realism of environment, narrative, choice, information, and the restart and override rules.

The beta test was conducted by releasing KitchenSpeak version 2.0 to MWDC staff and collecting their (1) game completion times, (2) perception of ease of play, (3) gameplay engagement, and (4) experience with bugs and glitches during gameplay. A 5-point Likert scale survey was used to collect user perception of ease of play, while a survey with predetermined questions was used to collect users’ experience with bugs and glitches.

**Results**

**Alpha Test Results**
We recruited 8 participants, including 5 MWDC management staff and 3 nonmanagement staff with varying gaming experience, who were recruited by MWDC management.
Participants played the game one after another with the debugging window opened to observe how the speech recognition model transcribed the participant’s speech input. The results from this qualitative test are provided in Table 1.

Table 1. Results from the alpha test.

<th>Aspects of the game</th>
<th>Results</th>
<th>Suggestions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Realism of game environment</td>
<td>Participants deemed the game environment design was similar in appearance to the MWDC\textsuperscript{a} kitchen.</td>
<td>Include more details to reflect real-world execution of activities, for example, while a player is picking up a hot pot from the gas oven top, they should turn off the gas and use heat-resistant gloves.</td>
</tr>
<tr>
<td>Content and narrative</td>
<td>Game narratives were perceived as short, but it was explained that they were intentionally kept short to avoid confounding the narrative with the game’s purpose. All participants agreed that the content and narrative were sufficient.</td>
<td>No suggestions for improvement.</td>
</tr>
<tr>
<td>Navigation</td>
<td>Difficulty in navigating for participants with no previous FPC\textsuperscript{b} gaming experience.</td>
<td>Limit the vertical camera viewing angle such that it cannot go above the game character’s horizontal line of sight. That is, FPC cannot look up, but only downwards.</td>
</tr>
<tr>
<td>Information</td>
<td>Instructions in the Stage Select menu were not easy to understand, and participants did not know how to start playing a stage.</td>
<td>Include descriptive instructions on how participants could access game stages.</td>
</tr>
<tr>
<td>UI\textsuperscript{c}</td>
<td>UI elements were without clutter, simple, and easy to understand.</td>
<td>No suggestions.</td>
</tr>
<tr>
<td>Speech recognition usability</td>
<td>Single-word kitchen-speak (ie, “corner” and “behind”) was transcribed correctly, but the “hot corner” phrase was often transcribed as “hot burner” and “hot porter.”</td>
<td>Include “hot burner” and “hot porter” phrases into a similar keyword dictionary such that they will be accepted as correct alternatives to “hot corner” when transcribed.</td>
</tr>
<tr>
<td>Choice</td>
<td>Participants enjoyed the liberty to explore the game environment while completing tasks. One participant mentioned that exploring the kitchen environment reminded them of the MWDC kitchen.</td>
<td>No suggestions.</td>
</tr>
<tr>
<td>Game rules</td>
<td>Two overrides per game session were too little given the accuracy of the speech recognition module. Participants agreed that the restart rule was good as it would allow users to practice within each stage.</td>
<td>Increase the allowable number of overrides per session to 3.</td>

Beta Test Results

Overview

Feedback from the alpha test was used to release version 2.0, which was used for the beta test. The beta test had 40 participants; 34 of them played and responded to the FPC experience and the ease of play surveys, and 32 responses were valid. A total of 21 participants indicated they were in the 15-to-24-year age group, while 11 participants did not respond to the age question; 7 participants were male, 11 were female, 1 was nonbinary, and 13 did not indicate their gender. The age group and gender proportions were representative of the student population in MWDC. A total of 13 participants responded to the Bugs and Glitches questionnaire.

Ease of Play

We looked at the difference in perception of ease of play between participants with previous FPC experience and those without previous FPC experience. Table 2 shows the summary of the ease of play results. The average ease of play of all 32 participants was 3.91 (SD 1.12). There was no significant difference in the user’s perception of ease of play between players who had previous FPC experience and players who had no previous FPC experience at a .05 significance level.

\(^a\)Significant at 5% significance level.

**Gameplay Engagement**

At least 160 prompts were shown to all 32 players (minimum of 5 kitchen-speak prompts per player). We measured disengagement by the ratio of the number of times a user did not use kitchen-speak when prompted to the minimum number of times a prompt to use kitchen-speak was shown in the Free Roam stage (5 prompts). The results revealed that out of more than 160 prompts that were shown to all 32 players, 11 (6.9%) prompts did not receive valid user responses, while at least 149 (93.1%) prompts received valid user responses.

**Bugs and Glitches**

A total of 13 participants completed the Bugs and Glitches questionnaire. A total of 8 reported no issues, 5 had bugs in the Free Roam stage, and 2 had speech recognition issues. One participant found the game realistic. While the speech recognition module was adjusted to reduce recognition errors after the alpha test, issues with speech recognition were still expected.

**Discussion**

**Overview**

As part of this discussion, we will examine implications of this study and implications for future game developers based on our results. The major topics of discussion will be the frameworks used for game development, the results of the alpha and beta tests, and the development of serious games for behavioral safety.

**Frameworks for Game Development**

The frameworks used for our game design were SERES and RECIPE frameworks. In addition, we used gestalt laws of perception to design an effective UI for a serious game. In evaluating our implementation of the RECIPE framework, we found that evaluating player engagement was challenging. We measured engagement through the lack of disengagement, and we found our approach to be lacking. Engagement is a multiconstruct measurement [26] and as such must use a triangulation method using more than 1 input. For future game development, developers should consider including multiple measurements for engagement during the design phase.

Effective UI design can improve the gaming experience for inexperienced players, and the gestalt laws of perception can bridge the gap for game developers in designing an effective UI. Previous gaming experience affects user experience as inexperienced players report less positive experiences than experienced players [27]; however, effective UI design can be used to improve user experience and aid effective learning in electronic learning platforms [23]. Gestalt laws of perception for UI design are effective because they provide a holistic perspective that considers humans’ perception and interpretation of information [23]. We applied gestalt laws of perception to design the UI and evaluated the UI’s usability. The alpha test results showed that the UI design was without clutter, simple, and the information was easy to understand. We encourage serious game developers to incorporate the laws of perception to improve their game design by reducing clutter and improving information retention with players.

**Alpha and Beta Testing**

The alpha tests showed us the importance of receiving feedback to improve the game. Including the players, the most important stakeholders, is key to successful game deployment. In our case, we used a qualitative method that provided rich feedback for version 2. Our methods here show that a full testing regime that includes quantitative methods such as A/B testing is not always required. Receiving qualitative feedback to make quick improvements is an effective and agile methodology we suggest for serious game developers.

Our analysis of game completion time showed players without FPC gaming experience completed the game significantly more slowly than those with prior experience. Even though we had a tutorial for inexperienced players, the difference in completion time results was significant. This shows that additional training is required. Players with no prior FPC experience must be eased into gameplay by observing player behavior and receiving real-time feedback. Failure to ease players into the game may cause frustration and game abandonment.

In terms of bugs and glitches, voice recognition was an area of interest. There was variability due to factors such as background noise levels and user-specific characteristics. User accent and voice pitch are factors that will inherently affect the accuracy...
of a speech recognition module. Accent recognition is a problem of particular interest that requires further exploration.

KitchenSpeak game used the Unity3D WebGL. We used Unity3D’s profiling tool to review game assets and memory usage. The results showed that CPU memory was mostly used by rendering game object textures and audio data. To improve overall game performance, similar textures were applied to different game objects to reduce the number of times a type of texture was rendered. We encourage game developers to consider this aspect while developing a game and to use this technique to promote game performance.

**Serious Game for Safety Behavior**

Prior work in serious games for safety mainly focused on safety knowledge training. There are a few challenges in developing a serious game for behavior change from the safety behavior theoretical perspective. Safety behaviors are defined as acts that can be observed by other employees. Existing theories on changing safety behaviors are rooted in changing values, attitudes, and motivations, and emphasize providing consequences for not practicing the behavior [28].

The first challenge we encountered was finding the balance between providing sufficient exposition in the game to affect the value, attitude, and motivations of the players and managing the length of the gameplay. Our current approach to exposition is a pop-up text box to provide context. If the pop-up window is text-heavy or if we use too many consecutive pop-up windows, based on our own gameplay experience, it can lead to players skipping the pop-up windows or abandoning the game. We have opted to minimize the text in exposition, but have the player repeat the same behavior (verbal commands) multiple times for each play, each with a different exposition.

Second, the literature on safety behavior states that behavior must be observable by other employees; we included nonplayer characters (NPCs) into the scenes within our game. For future work, we plan to collect the gameplay information of actual players and create NPC movements based on actual players’ gameplay data to increase the realism of the NPCs. In either case, we are still looking into methods to assess whether the NPCs create the effect of observers.

Third, in terms of consequences to players when they did not perform the safety behavior, we considered adding consequences, and we evaluated two potential approaches. One is to create and display virtual scenes of accidents such as the spilling of hot food content after the collision and another is to use a pop-up window to inform the player that an accident had happened due to them not providing verbal commands. We decided against the pop-up window as we used it for exposition and did not want to overload the players and have them ignore it. Due to time constraints, we were not able to implement the actual scene of the accident for this study.

For safety behavior, using verbal commands consistently throughout an entire work shift is a relatively new concept to many employees who have never worked in a commercial kitchen. The behavior change we initiated through this study can serve as the baseline for future work to assess whether a change in value or attitude or motivations, a need for observers, and a need for consequences are necessary in a serious game to initiate behavior change.

**Conclusion and Future Work**

Serious games and other e-learning modules could be used as a cost-effective method for training as employers do not have to deal with the costs of face-to-face in-person training [29]. A serious game is a game that achieves an additional goal that is not for entertainment purposes [30]. By this definition, KitchenSpeak is a serious game. This study aimed to advance the serious games research field by developing a game aimed at changing behavior, specifically, instilling the behavior of consistently using verbal commands in blind areas within high-traffic workplaces.

KitchenSpeak development was successful; however, a new study should evaluate its effectiveness in improving the use of verbal commands and its effect on accidents that lead to struck-by injuries. In order to assess how effective KitchenSpeak is in enhancing the use of verbal commands, we need to compare the frequency of verbal command terms used in a commercial kitchen where the game is deployed to the frequency of kitchen-specific terms used in a commercial kitchen where the game is not deployed. To evaluate KitchenSpeak’s effect on accidents that lead to struck-by injuries, we will compare safety records on struck-by injury frequency before and after the game’s deployment in a commercial kitchen.

In this study, we discussed and validated the implementation of 3 theoretical frameworks that were used to develop the KitchenSpeak serious game for commercial kitchen safety. A serious game’s effectiveness is improved by incorporating theoretical concepts and principles that intend to achieve the desired results [30]. While theoretical concepts and principles serve as relevant tools for guiding serious game development, their effectiveness is linked to their success in application and implementation. In addition to testing the effectiveness of a serious game in achieving its desired outcomes, developers may also evaluate the implementation of their foundational theoretical principles, as they may provide relevant information on the cause of their game’s effectiveness or ineffectiveness.

**Acknowledgments**

We are grateful to Christopher Anderson, Kent Hildebrandt, Suzi Kritikos, and Michael Meeker of University Housing and Dining Services at Oregon State University for their assistance and input in the game’s development and validation. We are also grateful to Dan Kermoyan, MPH, and Tom Doyle, MBA, of Environmental Health and Safety at Oregon State University. There was no funding for this study. We used Google’s speech-to-text plug-in for transcribing users’ speech input to text, as well as a PHP database hosted on OSU’s servers for gathering all game-related data. The authors attest that there was no use of generative artificial intelligence technology in the generation of text, figures, or other informational content of this study.
Data Availability
The data sets generated during and analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions
EHN was responsible for the conceptualization of this study. CA wrote the study, developed the game, and provided data for all tables in the study. EHN and GN provided administration and supervision of the project. All authors reviewed the final study.

Abstract

Background: Primary care plays a key role in the management of type 2 diabetes. Sodium-glucose cotransporter 2 (SGLT2) inhibitors have been demonstrated to reduce hospitalization and cardiac and renal complications. Tools that optimize management, including appropriate prescribing, are a priority for treating chronic diseases. Future Health Today (FHT) is software that facilitates clinical decision support and quality improvement. FHT applies algorithms to data stored in electronic medical records in general practice to identify patients who are at risk of a chronic disease or who have a chronic disease that may benefit from intensification of management. The platform continues to evolve because of rigorous evaluation, continuous improvement, and expansion of the conditions hosted on the platform. FHT currently displays recommendations for the identification and management of chronic kidney disease, cardiovascular disease, type 2 diabetes, and cancer risk. A new module will be introduced to FHT focusing on SGLT2 inhibitors in patients with type 2 diabetes who have chronic kidney diseases, cardiovascular diseases, or risk factors for cardiovascular disease.

Objective: The study aims to explore the barriers and enablers to the implementation of an SGLT2 inhibitor module within the Future Health Today software.

Methods: Clinic staff were recruited to participate in interviews on their experience in their use of a tool to improve prescribing behavior for SGLT2 inhibitors. Thematic analysis was guided by Clinical Performance Feedback Intervention Theory.

Results: In total, 16 interviews were completed. Identified enablers of use included workflow alignment, clinical appropriateness, and active delivery of the module. Key barriers to use were competing priorities, staff engagement, and knowledge of the clinical topic.

Conclusions: There is a recognized benefit to the use of a clinical decision support tool to support type 2 diabetes management, but barriers were identified that impeded the usability and actionability of the module. Successful and effective implementation of this tool could support the optimization of patient management of type 2 diabetes in primary care.

Introduction

Type 2 diabetes places a significant burden on both people with this condition and the Australian health system. An estimated 1.3 million Australians older than the age of 15 years have diabetes [1], with an associated Aus $14 billion (US $12.9 billion at 2010 rates) [2] of health spending. This creates an enormous social and economic burden. General practitioners

https://formative.jmir.org/2024/1/e50737
(GPs) play a vital role in reducing the impact of diabetes as most people receive their medical care in general practice. Guidelines produced by the Australian Diabetes Society [3], The Royal Australian College of General Practitioners [4], and the Living Evidence for Diabetes Consortium [5] provide support to GPs to inform both pharmacological and nonpharmacological management decisions.

Sodium-glucose cotransporter 2 (SGLT2) inhibitors have been included in Australian guidelines for years, but their place in therapy has evolved as recent evidence demonstrates secondary prevention benefits for cardiovascular disease (CVD) and chronic kidney disease (CKD) irrespective of glycated hemoglobin [6-11]. Prescribing of SGLT2 inhibitors remains low [12], and reported barriers include a lack of knowledge of its nonglycemic benefits and concerns about side effects [13]. This can be mitigated if appropriate and relevant education is available [14]. However, education alone is not likely to have a significant impact on changing prescribing behavior.

Future Health Today (FHT) is a co-designed quality improvement and clinical decision support technology platform aimed at the detection and management of conditions in general practice. FHT integrates with the electronic medical record to provide two components: (1) a clinical decision support tool active at the point of care (PoC) and (2) a web-based dashboard that facilitates practice-wide audit and quality improvement activities, including patient recall. Wraparound activities are also included with links to the latest guidelines and access to educational resources. Following initial optimization in 12 general practices, using guidelines for CKD, CVD, and cancer prevention, it is now in use in 55 general practices across Australia. A new module was introduced to FHT practices in July 2022 recommending SGLT2 inhibitor prescribing in patients with type 2 diabetes who also have CKD, CVD, or risk factors for CVD consistent with the Australian Evidence-Based Clinical Guidelines for Diabetes [5]. If a patient is suitable for prescribing, the statement “Consider initiation of SGLT2 inhibitor to reduce CVD and CKD risk” will appear in the PoC. The objective of this paper is to report on the evaluation of the implementation of this new SGLT2 inhibitor module in FHT.

**Methods**

Study Design
Fifty-two practices in Victoria (n=51) and Tasmania (n=1) had access to the SGLT2 module between July 2022 and January 2023. A qualitative evaluation exploring the use of the module was undertaken using the Clinical Performance Feedback Intervention Theory (CP-FIT), a theory for designing, implementing, and evaluating feedback [15]. CP-FIT was chosen as it incorporates and builds on 30 pre-existing theories and was developed specifically for the health care context. The theory proposes 42 variables that influence a feedback cycle with each step vital for successful feedback to occur. The theory postulates that the cycle is affected by 3 variables: feedback, recipient, and context. In the context of FHT, CP-FIT outlines the steps that users move through when guideline-based recommendations are communicated to users. Algorithms are applied to electronic medical records (data collection and analysis); recommendations are delivered to users (feedback); and they are received (interaction), interpreted (perception), and interrogated (verification). If users find the recommendations appropriate (acceptance), they will respond to them (intention and behavior) and ultimately leads to changes in patient care (clinical performance improvement).

Participants were recruited through expression of interest to participate in semistructured interviews, from those who had at least 1 month access to the SGLT2 inhibitor module. Expressions of interest were sent via email to practices encouraging participation in an interview. Advertisements in the department and practice-based research network newsletters were also used to promote the study. Interviews were conducted between September and December 2022. All participants had access to the FHT software for between 6 and 18 months prior to the use of the SGLT2 inhibitor module in clinical practice.

Data Collection
Semistructured interviews using CP-FIT as a guide were conducted with GPs, general practice nurses (GPNs), and clinical health assistants (CHAs) to explore their perspectives on using the module and recommendations for improving the tool. CHA are administrative staff who use patient data for health research and quality improvement. The aim was to gather as many perspectives as possible until saturation was reached. Participants participated in one-to-one interviews that occurred via telephone or Zoom (Zoom Technologies). Interviews were conducted by MS, a male academic GP registrar with the University of Melbourne. An interview guide was developed to focus on questions regarding the clinical usefulness of the recommendations, the impact on clinical workflow, and perceived changes in clinical performance. Data were uploaded to NVivo (version 12; QSR International) and coded by MS to identify themes using CP-FIT as a coding framework. A second researcher (CM) reviewed the data to ensure the reliability of the analysis.

Ethical Considerations
This study was approved (23269) by the Faculty of Medicine, Dentistry and Health Sciences Human Ethics Subcommittee at The University of Melbourne. Consent was taken through a signed consent form prior to the interview, and verbal consent was also gained to record the audio component of the interview. Participation was voluntary, and participants were compensated with an Aus $50 (US $32) voucher for their time. Participants’ names and practice locations were deidentified and replaced by a pseudonym only known to MS and CM to ensure the protection of their privacy.

**Results**

Overview
Invitations for interviews were sent out to clinics that had at least 1 month of experience with the SGLT2 inhibitor module. There was interest from 14 general practice clinics, and 16 interviews were completed with participants from 11 clinics (Table 1). The sex of the interviewee was confirmed during the interview. A further 3 interviews were not completed as the
The interviewees used FHT and previous modules but not the SGLT2 inhibitor module. Interviews ranged from 15 to 42 minutes. The themes were mapped across the 3 variables: context, feedback, and recipient. Barriers and facilitators related to these variables are summarized in Figure 1.

Feedback Variables

Goal: Evidence-Based Nature, Relevance, and Importance

Common across all interviews were goals relating to the importance, relevance, and evidence-based nature of the SGLT2 recommendations. Users had confidence that the recommendations were accurate knowing they were based on the latest guidelines. Some incorporated FHT and the module in their conversation with patients by highlighting and explaining to patients the background and concept of FHT to instill patient confidence and acceptance of SGLT2 inhibitor prescribing.

> I can say to people that the reason I’m suggesting the change in medicine or the increase in dose is because there is a little point of care prompt, it’s telling me there are advantages in doing this, in making a change. [GP2]

Feedback Delivery: Active Delivery, Frequency, and Function

Active delivery was demonstrated through the PoC but not the dashboard. Participants found the PoC user friendly as it would automatically pop up once the patient file was opened. They also enjoyed the flexibility of being able to minimize and scroll through the recommendations in the PoC. In contrast, a majority indicated the need to log in to the dashboard to access it was a barrier to its use.

> Well it [PoC] comes up automatically every time we enter a patient where it’s relevant and it’s a very good prompt to double check that we’re following the guidelines. [GP8]

Practices using the SGLT2 inhibitor module also had access to over 20 recommendations within FHT relating to other chronic diseases. With the multiple modules available, prompt fatigue was highlighted as a barrier, especially with time constraints during consultations. Several participants highlighted the possibility of a behavioral norm of not checking the PoC recommendations when they pop up. Despite this, most still believed the recommendations were helpful in identifying patients who would not have been highlighted if it was not for the prompt, reiterating the tool as an additional safety net.

> It comes up on every patient when we open the file but because we’re so busy during a consultation...and it comes up so often. [GP2]

Context Variables

Organization and Team Characteristics: Workflow Fit, Intraorganizational Networks, and Competing Priorities

Many users reported using the PoC function before or during the consultation to guide clinical decision-making when talking broadly about FHT. They indicated that they referred to it when the consultation was diabetes focused but would otherwise flag it for future reference or disregard it. “I have a look at the point of care and see what kind of recommendations are popping up” (GP1).

The SGLT2 module encouraged collaboration between the staff. With the use of the cohort function, CHA and GPNs were able to generate recall list and book appointments for GPs to review patient suitability. This reduced the workload for GPs. In addition, GPNs felt comfortable initiating a conversation about the benefits of the medications, although they also acknowledged the final decision lay with the GP.

> The autonomy is given to be able to do recalls without having to have the GP absolutely check through every little detail of the patient. [CHA1]

Competing priorities were identified as barriers to fully use FHT with a flow on effect to the SGLT2 inhibitor module, especially with the use of the dashboard. Multiple GPs commented that they used the PoC as the recommendations came to them once the patient file was open. This is in contrast with the dashboard which involved creating patient lists, recalling patients, and filling quality improvement forms. Time pressure was highlighted as a barrier, with many GPs commenting about having time constraints and an increased in workload due to workforce shortages, particularly in rural and regional clinics.

> As with all of those things in a busy practice, the catch is putting time aside [to use FHT]. I never get around to doing so. [GP8]

Participants believed a lack of familiarity and knowledge with SGLT2 inhibitors hindered their use of the module. This stemmed from a lack of time for users to upskill. They were aware of the education resources and support offered through FHT, but time pressures did not allow them to review these resources. For the feedback cycle to be completed, GPs must show leadership in engaging with the module as they are the ones that make the decision on whether the recommendation is clinically appropriate. Practice staff have commented that due to time constraints and competing priorities, GPs were unable to prioritize the use of FHT.

> I think our GPs, you need to actually show them and go through it with them [FHT], then there’s always that “I’m time poor, not right now, can’t do it too much.” [CHA1]

Patient Population: Clinical Appropriateness and Choice Alignment

Participants recognized that the recommendations were a guide only and still required the use of clinical acumen. Although they acknowledged the accuracy, they may not be clinically appropriate at the individual patient level due to factors such as age, health literacy, comorbidities, and likely compliance.

> They’re [GPs] not willing to introduce stricter control for a 70 year old that’s got diabetes and he’s well controlled and everything else.... It’s just a little bit reassessment and the individualisation of the knowing your patients. [Practice nurse 7]

Implementation Process: Cost, Training, and Support

The main cost attributed to the use of FHT was time. For GPs, the time spent on the use of PoC before and during consultations was appropriate for the benefit given as the recommendations...
could be actionable at the time or delayed. However, the dashboard was unused by GPs as they did not have time to use it. In contrast, practice nurses and the CHA found the dashboard function useful to create recall lists and as a quality improvement tool.

Would I love to have more of an opportunity to look at the online module and setting up cohorts and doing things? I’d love to have more time doing that. [GP2]

Participants reported that more support and training would increase their familiarity of confidence in discussing and prescribing SGLT2 inhibitors. They were aware of the educational materials offered to them through FHT, but time constraints prevented them from using them. Practice nurses noted that the resources provided specifically for the SGLT2 inhibitor module were tailored more to GPs for prescribing with broader education on the topic likely to be more beneficial for them. While feedback for these resources was positive, participants believed other modes of education would be beneficial for the broader use of FHT.

I suppose maybe just some how to put it into practice, maybe. Like some scenarios or that type of thing. See while these patients come in, this has popped up, this is what we should be talking about and discussing. [Practice nurse 6]

Recipient Variables

Many found it useful to prompt and raise awareness of the benefits of prescribing SGLT2 inhibitors but found the overcapture of patients an issue. While commenting they were confident with the accuracy of the recommendations, the guideline-based recommendations did not take the patient’s personal history and suitability into account. Participants believed that to maximize the potential of the module, they are still needed to use their own clinical judgment to interrogate and decide if the recommendations were appropriate. Some commented that by following the recommendations blindly, it would reduce the “patient centredness” of the clinical decision and remove shared decision-making with the patient. “I wouldn’t have thought of it without the popup.... It’s making medicine more recipe-like” (GP3).

After seeing the recommendations, users identified their own need for further education on SGLT2 inhibitors and diabetic management in general. This stemmed from the need for more knowledge on the topics for them to confidently discuss these medications with patients. While they were aware of the resources offered through FHT, time constraints for education were again noted.

It’s improved my ability...my little areas of where I need to hone my education skills... I probably didn’t do it that well until we had the popup that forced me to think about why am I telling this patient. [Practice nurse 2]

The recommendation is shown every time the patient file is opened independent of the reason for presentation. Users have commented that it would be difficult to introduce the recommendations if the patients presented for a nondiabetes-related consultation and to steer the conversation toward diabetes. Some users would take note of it and often suggest making a subsequent appointment to discuss SGLT2 inhibitor prescribing. Others used the recommendation as a prompt to change their consultation style to incorporate the module in their consultations.

If I was to see a diabetic who wasn’t on a SGLT2 and had cardiovascular risks, then I would - I would in time change my plan. But as you would well know, best practice is hard to change because you’ve got to learn a new mental routine. [GP6]

Discussion

Principal Findings

The overall response to the use of the SGLT2 inhibitor module in FHT was positive. Enablers and barriers to the use of this module were explored. Enablers of the module’s use included users’ confidence about the accuracy of the recommendations and that they found it easy to incorporate into appropriate consultations and comfortable introducing the topic to patients. They felt the recommendations were proactive and a useful prompt for users to consider prescribing the medication. Unfamiliarity with SGLT2 inhibitors is a known barrier to its prescription [16], and GPs’ awareness of the nonglycemic benefits is low [14]. The inclusion and presentation of SGLT2 inhibitors in guidelines are relatively new, and they have also encouraged users to upskill on knowledge for them to feel more comfortable discussing it with patients.

The role of the GP and GPN and both vital to the management of diabetes in the primary care setting [17], and the module has helped define these roles. GPNs used the module to create lists from the dashboard to recall patients to initiate a conversation about possible SGLT2 inhibitor prescribing and optimization of diabetes management in general with the final decision made by the GP to determine suitability. The main barrier to the use of the module was time pressure and competing priorities during the consultations. Many users stated that the heavy workload prevented them from using the full function of FHT.

By mapping against the CP-FIT framework, the PoC function allowed users to move through the feedback cycle successfully. It has led to better recordkeeping (data collection and analysis) to maximize the efficacy of the algorithms to produce accurate recommendations. They still required to use their clinical acumen to decide whether the recommendation was appropriate for the patient (feedback, interaction, and perception). If appropriate (acceptance), they would initiate a conversation with the patient about prescribing SGLT2 inhibitors and discussing the benefits of improved glycemic control and better patient outcomes (clinical performance improvement). The expanding number of modules has led to prompt fatigue causing users to reduce their interaction with PoC and not initiating the feedback cycle.

There were several limitations to this study. Approximately half of the users of this module were the practice champions for FHT in their workplace. This may lead to responder bias with their enthusiasm for FHT making them more likely to participate and have a better understanding of the program. The study was

https://formative.jmir.org/2024/1/e50737

Suen et al JMIR FORMATIVE RESEARCH

(422x43)
conducted during the COVID-19 pandemic, which may prevent potential users from engaging with the program as the effects of the pandemic caused disruption to workflow, especially with staff and resource shortages. We aim to conduct follow-up interviews in the future to see if the pandemic had any significant effect on the use of FHT.

The use of clinical decision support systems (CDSSs) in diabetes has previously been shown to improve patient outcomes [18], although studies are focused on the hospital setting and glycemic control [19,20]. Literature has consistently reported a gap between optimal diabetes care practice and recommended care standards. Previous CDSS studies have found high clinician satisfaction with its use to facilitate the intensification of glucose control [21]. There is strong evidence that users of CDSS consistently recommend its use to others [22] and is appropriate for general practice use [23].

Previous barriers with CDSSs previously reported include increased workload and time constraints [24], which align with the findings of this study. A previous study showed that the implementation of a CDSS alone did not improve quality of care but required multifaceted strategies including continuing education and feedback mechanisms, organizational changes, and patient-orientated strategies [25]. While these strategies were made available to participants, engagement and uptake of the SGLT2 inhibitor module recommendations were variable.

With the increasing burden of type 2 diabetes on the Australian health care system, early diagnosis and treatment will no doubt reduce the risk of developing and delaying comorbidities and improve the quality of life for diabetics. CDSS can assist clinicians in diagnosing and optimizing the management of chronic disease beyond type 2 diabetes.

Conclusions

This study highlights the benefit of a clinical decision support tool to improve appropriate prescribing and increase clinician awareness of SGLT2 inhibitors for their diabetic and cardiorenal effects. Successful implementation of this module could be used to detect patients who will benefit from the effects of SGLT2 inhibitors in primary care and assist in reducing all-cause mortality and morbidity with guideline-concordant prescribing.

Acknowledgments

The authors would like to acknowledge the contributions of the Future Health Today project team and investigators. We would also like to acknowledge the time and commitment of all participants. The project was supported by the Australian Government’s Targeted Translation Research Accelerator program and the Paul Ramsey Foundation.

SGLT2: sodium-glucose cotransporter 2
Background: Hot flashes are associated with a lower quality of life and sleep disturbances. Given the many consequences of hot flashes, it is important to find treatments to reduce them. Hypnotherapy, the use of hypnosis for a medical disorder or concern, has been shown in clinical trials to be effective in reducing hot flashes, but it is not routinely used in clinical practice. One solution to close this implementation gap is to administer hypnotherapy for hot flashes via a smartphone app. Evia is a smartphone app that delivers hypnotherapy for hot flashes. Evia has made hypnotherapy more widely accessible for women who are experiencing hot flashes; however, the app has yet to undergo empirical testing. Additionally, research on user characteristics is lacking.

Objective: This study aims to (1) determine the average age, stage of menopause, and length of menopause symptoms for users of the Evia app; (2) determine the characteristics of hot flashes and night sweats for users of the Evia app; (3) determine the self-reported sleep quality of users of the Evia app; (4) determine the self-reported mental health of users of the Evia app; and (5) determine the relationship between hot flash frequency and anxiety and depression for users of the Evia app.

Methods: This study analyzed data collected from participants who have downloaded the Evia app. Data were collected at 1 time point from a self-report questionnaire that assessed the demographic and clinical characteristics of users. The questionnaire was given to users when they downloaded the Evia app. Users of the Evia app fill out a questionnaire upon enrolling in the program and prior to beginning the intervention. This included 9764 users.

Results: Results showed that the mean age of users was 49.31 years. A total of 41.6% (1942/4665) of users reported experiencing 5 or more hot flashes per day, while 51.2% (1473/2877) of users reported having difficulty falling asleep each night and 47.7% (1253/2626) of users reported their sleep quality to be terrible. In addition, 38.4% (1104/2877) of users reported that they often feel anxious or depressed. There was a small, significant, and negative correlation between hot flash frequency and self-report frequency of anxiety and depression ($r = -0.09$).

Conclusions: This study showed that the average age of app users is in line with the median age of natural menopause. A large percentage of users reported experiencing 5 or more hot flashes per day, while 51.2% (1473/2877) of users reported having difficulty falling asleep each night and 47.7% (1253/2626) of users reported their sleep quality to be terrible. In addition, 38.4% (1104/2877) of users reported that they often feel anxious or depressed. There was a small, significant, and negative correlation between hot flash frequency and self-report frequency of anxiety and depression ($r = -0.09$).

Introduction

Hot flashes are common during menopause, which is marked by 12 months of amenorrhea or absence of the menstrual period. It is estimated that approximately 75% of women experience hot flashes during menopause [1]. During the transition into menopause, hormone levels fluctuate, and this leads to many physical changes and symptoms, with hot flashes being known as the “hallmark” symptom of menopause. Hot flashes are distressing for women who experience them, and they are associated with a lower quality of life [2] and psychological well-being [3]. Hot flashes are also associated with sleep disturbances [4-6]. Given the many consequences of hot flashes, it is important to find treatments to reduce them.

The most effective treatment for reducing hot flashes is hormone therapy; however, this has been shown to increase the risk of breast cancer and its use is contraindicated in many situations such as in breast cancer survivors [7]. Other treatments for hot flashes such as selective serotonin reuptake inhibitors, selective norepinephrine reuptake inhibitors, clonidine, gabapentin, cognitive behavioral therapy, and mindfulness-based stress reduction have not been found to be as effective as hormone therapy, and they often include side effects that make their long-term use undesirable [8-13]. Therefore, effective and safe nonpharmacological treatment options are needed to relieve hot flashes.

Hypnotherapy, the use of hypnosis for a medical disorder or concern, has been shown to be effective in reducing hot flashes [14,15]. In a clinical trial that examined the efficacy of hypnotherapy for reducing hot flashes among breast cancer survivors, it was found that hypnotherapy reduced hot flashes by approximately 68% from baseline to intervention end point and this was significantly greater than controls [14]. In another clinical trial that examined the efficacy of hypnotherapy for reducing hot flashes among postmenopausal women, hot flashes were reduced by approximately 80% from baseline to week 12 and these reductions were significantly greater than the structured attention control condition [15].

Although hypnotherapy has been shown to be effective in clinical trials, it is not routinely used in clinical practice. Very few clinicians are trained to administer hypnotherapy for hot flashes. One solution to close this implementation gap is to administer hypnotherapy for hot flashes via a smartphone app. Evia is a smartphone app that delivers hypnotherapy for hot flashes. It is based on a hypnotherapy protocol that has been rigorously tested in randomized clinical trials [14,15] and was developed in consultation with an expert in the field of hypnotherapy for hot flashes. Evia includes a 5-week hypnotherapy intervention with daily tasks that include listening to the audio-recorded hypnotherapy session, tracking hot flashes, and psychoeducational readings. Evia has made hypnotherapy more widely accessible for women who are experiencing hot flashes; however, the app has yet to undergo empirical testing. Additionally, research on user characteristics is lacking. This is the first study to report the characteristics of users of Evia. The information gathered from this study will allow for the Evia app to be tailored and optimized toward its users. This study will also tell us whether individuals who seek relief from hot flashes via a smartphone app are different from those who seek treatment in a clinical setting or a clinical trial, and will allow us to better understand who is downloading and engaging with the digital hypnotherapy intervention. Some previous research has shown that smartphone app users are generally younger [16], and this study will explore whether users of Evia are younger than women who seek treatment in a clinical setting or clinical trial. Additionally, the study will explore how app users may differ in the length of time they have experienced menopause symptoms or symptom severity. In addition, this study is a first step to conducting further research on the Evia app, including clinical trials to evaluate efficacy.

This study analyzed data collected from participants who have downloaded the Evia app. These data were collected by Mindset Health, the developers of the Evia app. Users of the Evia app fill out a questionnaire upon enrolling in the program and prior to beginning the intervention. These data will be analyzed to achieve the study’s aims. This study aims to (1) determine the average age, stage of menopause, and length of menopause for users of the Evia app; (2) determine the characteristics of hot flashes and night sweats for users of the Evia app; (3) determine the self-reported sleep quality of users of the Evia app; (4) determine the self-reported mental health of users of the Evia app; and (5) determine the relationship between hot flash frequency and anxiety and depression for users of the Evia app.

Methods

Overview

Data were collected at 1 time point from a self-report questionnaire that was given to users when they downloaded the Evia app between October 5, 2021, and July 8, 2022. Users filled out the self-report questionnaire directly on the Evia app. These data were collected prior to the user beginning the intervention and were analyzed retrospectively.

Participants

Participants included individuals who downloaded the Evia app between October 5, 2021, and July 08, 2022. Participants are users of the Evia app and were recruited via Facebook advertisements and the app. Any person who downloaded the Evia app during this time period was prompted to fill out a questionnaire with demographic and clinical information prior to beginning the intervention. This included 9764 participants.

Measures

Aim 1

Participants were asked to fill in their age. Participants were asked, “How would you classify your stage of menopause?” Response options included “perimenopause,” “menopause,” “postmenopause,” “I’m not menopausal,” and “I’m not sure.” To determine the amount of time that users have been experiencing menopause symptoms, participants were asked, “How long have you been experiencing menopause symptoms?” Response options included “0-6 months,” “6-12 months,” “1-2 years,” “2-3 years,” “3-5 years,” “5-10 years,” and “10+ years.”
**Aim 2**
Participants were asked, “How many hot flashes do you experience each day?” Response options ranged from “0” to “5+.” To assess the severity of hot flashes that users are experiencing, participants were asked, “How severe are your hot flashes?” Response options included “very mild”, “mild”, “moderate”, “severe”, and “very severe.” To assess the characteristics of users’ hot flashes, they were asked, “What do your hot flashes feel like?” Response options included “sudden feeling of warmth,” “perspiration,” “flushed appearance,” “rapid heartbeat,” “anxiety/an aura,” “dizziness/weakness,” “nausea,” and “other.” Users were able to select multiple responses for this item. To assess the number of night sweats that users experience, they were asked, “How many night sweats do you experience each night, on average?” Response options ranged from “0” to “5+.”

**Aim 3**
Users were asked to report sleep difficulty with 1 self-report item that reads, “Many women also struggle with sleep during menopause. Do you find it difficult to fall asleep each night?” Response options include “no,” “a little bit,” and “yes.” Users were also asked to rate their sleep quality with 1 self-report question that read, “How would you rate the quality of your sleep?” Response options included “terrible,” “fair,” “good,” and “excellent.”

**Aim 4**
Users were asked 1 self-report question that read, “Some women also struggle with mental health during menopause. How often do you feel anxious or depressed?” Response options included “never,” “sometimes,” “often,” and “constantly.”

**Aim 5**
Users were asked, “How many hot flashes do you experience each day?” Response options ranged from “0” to “5+.” Users were asked, “Some women also struggle with mental health during menopause. How often do you feel anxious or depressed?” Response options included “never,” “sometimes,” “often,” and “constantly.”

**Ethical Considerations**
This study was reviewed by the institutional review board at Baylor University and was considered to be exempt. The institutional review board determined the study to be secondary research for which consent is not required. The data analyzed were deidentified.

**Data Analyses**
Descriptive statistics (means, SDs, and frequencies) were calculated for the variables of interest. For aim 5, which was to determine the relationship between hot flash frequency and self-report frequency of anxiety and depression, a Pearson correlation analysis was used.

**Results**

**Aim 1: Age, Stage of Menopause, and Length of Menopause Symptoms**
The mean age of users was 49.31 (SD 6.69(1,973),(92,999)) years. Out of 9103 valid responses, 0.5% (n=49) of users reported being not menopausal, 31.2% (n=2837) of users were perimenopausal, 14.2% (n=1293) of users were menopausal, 13.1% (n=1188) of users were postmenopausal, 7.6% (n=688) of users were uncertain, and 33.5% (n=3048) of users reported unknown (see Table 1). Out of 3127 valid responses reporting length of experiencing menopause symptoms, 20.4% (n=639) of users reported 0-6 months, 20.9% (n=655) of users reported 6-12 months, 20% (n=624) of users reported 1-2 years, 13.5% (n=421) of users reported 2-3 years, 11.3% (n=354) of users reported 3-5 years, 9.3% (n=290) of users reported 5-10 years, and 4.6% (n=144) of users reported 10+ years (see Table 1).
Table 1. Stage of menopause and length of menopause symptoms for Evia users. This table lists the frequencies and percentages of Evia app users who are in each stage of menopause and their length of menopause symptoms. These data were collected from Evia app users who downloaded the Evia app. Data were collected via a questionnaire given on the Evia app to users prior to beginning the intervention and were analyzed retrospectively. These data were collected between October 5, 2021, and July 8, 2022. The Evia app includes a hypnotherapy intervention to help reduce hot flashes.

Aim 2: Hot Flash Characteristics

Out of 4665 valid responses, 13.5% (n=630) of users reported experiencing 0 hot flashes per day, 9.4% (n=437) of users reported experiencing 1 hot flash per day, 13% (n=607) of users reported experiencing 2 hot flashes per day, 12.8% (n=595) of users reported experiencing 3 hot flashes per day, 9.7% (n=454) of users reported experiencing 4 hot flashes per day, and 41.6% (n=1942) of users reported experiencing 5+ hot flashes per day (see Table 2). Out of 4183 valid responses, 1.9% (n=80) of users reported that their hot flashes were very mild, 30.4% (n=1273) of users reported that their hot flashes were mild, 40.9% (n=1710) of users reported that their hot flashes were moderate, 20.3% (n=851) of users reported that their hot flashes were severe, and 6.4% (n=269) of users reported that their hot flashes were very severe (see Table 2). Out of 4180 valid responses, 83% (n=3469) of users reported that their hot flashes felt like a sudden feeling of warmth, 59.2% (n=2474) of users reported perspiration, 47.5% (n=1987) of users reported a flushed appearance, 34.5% (n=1442) of users reported rapid heartbeat, 32.7% (n=1367) of users reported anxiety or an aura, 24.5% (n=1023) of users reported dizziness or weakness, and 16.4% (n=686) of users reported nausea (see Table 2). Out of 321 valid responses, 13.4% (n=43) of users reported experiencing 0 night sweats, 25.5% (n=82) of users reported experiencing 1 night sweat, 23.1% (n=74) of users reported experiencing 2 night sweats, 21.8% (n=70) of users reported experiencing 3 night sweats, and 16.2% (n=52) of users reported experiencing 4 night sweats (see Table 2).
Table 2. Number, severity, and characteristics of hot flashes for Evia users. This table lists the frequencies and percentages for Evia app users’ number of hot flashes, severity of hot flashes, hot flash characteristics, and number of night sweats. These data were collected from Evia app users who downloaded the Evia app. Data were collected via a questionnaire given on the Evia app to users prior to beginning the intervention and were analyzed retrospectively. These data were collected between October 5, 2021, and July 8, 2022. The Evia app includes a hypnotherapy intervention to help reduce hot flashes.

**Aim 3: Sleep**

Out of 2877 valid responses, results demonstrated that 18% (n=519) of users reported no to having difficulty falling asleep each night, 30.8% (n=885) of users reported a little bit of difficulty falling asleep each night, and 51.2% (n=1473) of users reported yes to having difficulty falling asleep each night. Out of 2626 valid responses, results also demonstrated that 47.7% (n=1253) of users reported their sleep quality to be terrible, 44% (n=1155) of users reported their sleep quality to be fair, 7.8% (n=206) of users reported their sleep quality to be good, and 0.5% (n=12) of users reported their sleep quality to be excellent.

**Aim 4: Mental Health**

Out of 2877 valid responses, 5.9% (n=169) of users reported that they never feel anxious or depressed, 38.4% (n=1104) of users reported that they often feel anxious or depressed, and 16.2% (n=465) of users reported that they constantly feel anxious or depressed.

**Aim 5: Relationship Between Hot Flash Frequency and Anxiety and Depression**

There was a small, significant, and negative correlation between hot flash frequency and self-report frequency of anxiety and depression ($r(2875) = -0.09, P<.001$).
**Discussion**

**Principal Findings**

Results demonstrated that the average age of app users (49.31 years) is in line with the median age of the beginning of perimenopause (47.5 years) and the median age of natural menopause (51.3) [17]. Although previous studies have shown that, overall, app users are generally younger [16], users of Evia are the age we would expect based on the age of menopause onset and symptoms emerging. Additionally, a large percentage of users (2837/9103, 31.2%) reported being in perimenopause, and this is oftentimes when menopause symptoms, including hot flashes, begin. An unexpected finding in this study was that a large percentage of users did not know their stage of menopause (3048/9103, 33.5%). This shows that users of Evia may not be aware of the various stages of menopause and what the menopause transition entails. This suggests that it may be beneficial for the Evia app to include some psychoeducational components about the menopause transition and stages of menopause. These psychoeducational components may help users of Evia better understand their menopause transition and experiences. Many users reported experiencing menopause symptoms for 0-6 months (639/3127, 20.4%), 6-12 months (655/3127, 20.9%), or 1-2 years (624/3127, 20%) with users less commonly reporting experiencing menopause symptoms for 5-10 years (290/3127, 9.3%) or 10+ years (144/3127, 4.6%). These results demonstrate that users are starting to use Evia toward the beginning of menopause symptoms. It is possible that those who have been experiencing symptoms for longer have learned how to cope with or treat their symptoms.

The largest percentage of users reported experiencing 5 or more hot flashes per day and reported that their hot flashes were moderate intensity. This finding is in line with previous studies that assessed hot flash frequency at baseline [15]. In a clinical trial by Elkins et al [15], participants experienced approximately 10 hot flashes per day on average at baseline. This study showed that, on average, Evia app users experience 5 or more hot flashes per day, which is in line with participants in previous clinical trials.

In line with previous studies regarding hot flashes and sleep, a majority of users (1473/2877, 51.2%) reported difficulty falling asleep each night and reported their sleep quality to be terrible (358/2877, 12.5%) or poor (316/2877, 11.0%). There were also limitations regarding how variables in the study were measured. For example, sleep quality and frequency of anxiety and depression were measured. For example, sleep quality and frequency of anxiety and depression were measured using single items. There are limitations to using single-item scales, including that they may not accurately or fully capture the construct. In addition, the items may have been worded in a suggestive manner. For example, “Many women also struggle with sleep during menopause. Do you find it difficult to fall asleep each night?” By starting the item with, “Many women also struggle with sleep during menopause...” it may be suggested for the individual to respond in a certain way. By identifying these limitations of measurement, this study will help to inform the optimization of data collection and measurement with the Evia app.

The results of this study will inform the optimization of the hypnotherapy intervention delivered via the Evia app. The results of this study will also inform the optimization of data collection via the Evia app. Once the Evia app is optimized, users will be better able to report their symptoms and experiences. This study also provides valuable information for future research.

**Limitations**

This study has several limitations that should be addressed. First, several characteristics of users remain unknown and were not addressed by this study. For example, information about geographic location and race or ethnicity was not reported. The study was not able to describe several important demographic factors of the sample, including race or ethnicity and education level.

There were also limitations regarding how variables in the study were measured. For example, sleep quality and frequency of anxiety and depression symptoms were measured using single items. There are limitations to using single-item scales, including that they may not accurately or fully capture the construct. In addition, the items may have been worded in a suggestive manner. For example, “Many women also struggle with sleep during menopause. Do you find it difficult to fall asleep each night?” By starting the item with, “Many women also struggle with sleep during menopause...” it may be suggested for the individual to respond in a certain way. By identifying these limitations of measurement, this study will help to inform the optimization of data collection and measurement with the Evia app.

**Future Directions**

The results of this study will inform the optimization of the hypnotherapy intervention delivered via the Evia app. The results of this study will also inform the optimization of data collection via the Evia app. Once the Evia app is optimized,
further research is warranted. Future studies should first examine the feasibility of the Evia app in a randomized controlled trial design. Then, future studies should examine the efficacy of the Evia app in comparison to a control group or even a face-to-face delivery.

Conclusions
This was the first study to report on the characteristics of users of the Evia app, which delivers hypnotherapy for hot flashes. Results showed that the average age of app users is in line with the average age of menopause onset. Results also showed that the largest percentage of users reported experiencing 5 or more hot flashes per day and reported that their hot flashes were moderate intensity. In line with previous research regarding hot flashes and sleep, a majority of users reported difficulty falling asleep each night and reported their sleep quality to be terrible or fair. In addition, a majority of users reported that they sometimes or often feel anxious or depressed. The results of this study will help to inform the optimization and tailoring of the hypnotherapy intervention delivered via the Evia app.

Acknowledgments
The authors would like to acknowledge Mindset Health and its employees for their collaboration in this project, as well as Clair Hall and Hanna Burrows for assistance with data collection.

Data Availability
The data set analyzed during this study is not publicly available due to confidentiality but is available from the corresponding author upon reasonable request.

Conflicts of Interest
GRE is a consultant to Mindset Health but was not involved in data collection. GRE discloses that he receives a consultant salary from Mindset Health and holds stock options within the company. However, this salary and equity were not dependent on the results of this research.

Abstract

Background: The high prevalence of mental illness is a critical social problem. The limited availability of mental health services is a major factor that exacerbates this problem. One solution is to deliver cognitive behavioral therapy (CBT) using an embodied conversational agent (ECA). ECAs make it possible to provide health care without location or time constraints. One of the techniques used in CBT is Socratic questioning, which guides users to correct negative thoughts. The effectiveness of this approach depends on a therapist’s skill to adapt to the user’s mood or distress level. However, current ECAs do not possess this skill. Therefore, it is essential to implement this adaptation ability to the ECAs.

Objective: This study aims to develop and evaluate a method that automatically adapts the number of Socratic questions based on the level of detected psychological distress during a CBT session with an ECA. We hypothesize that this adaptive approach to selecting the number of questions will lower psychological distress, reduce negative emotional states, and produce more substantial cognitive changes compared with a random number of questions.

Methods: In this study, which envisions health care support in daily life, we recruited participants aged from 18 to 65 years for an experiment that involved 2 different conditions: an ECA that adapts a number of questions based on psychological distress detection or an ECA that only asked a random number of questions. The participants were assigned to 1 of the 2 conditions, experienced a single CBT session with an ECA, and completed questionnaires before and after the session.

Results: The participants completed the experiment. There were slight differences in sex, age, and preexperimental psychological distress levels between the 2 conditions. The adapted number of questions condition showed significantly lower psychological distress than the random number of questions condition after the session. We also found a significant difference in the cognitive change when the number of questions was adapted based on the detected distress level, compared with when the number of questions was fewer than what was appropriate for the level of distress detected.

Conclusions: The results show that an ECA adapting the number of Socratic questions based on detected distress levels increases the effectiveness of CBT. Participants who received an adaptive number of questions experienced greater reductions in distress than those who received a random number of questions. In addition, the participants showed a greater amount of cognitive change when the number of questions matched the detected distress level. This suggests that adapting the question quantity based on distress level detection can improve the results of CBT delivered by an ECA. These results illustrate the advantages of ECAs, paving the way for mental health care that is more tailored and effective.

Introduction

Background

Cognitive behavioral therapy (CBT) is an established and effective therapeutic approach for treating a wide range of mental illnesses, including depression and anxiety disorder [1,2]. This approach, rooted in the cognitive model of emotional responses, posits that our thoughts, feelings, and behaviors are interconnected. Its central principle asserts that negative automatic thoughts must be corrected because they deleteriously affect emotions and behaviors [3]. CBT has been widely adopted in clinical practice and in preventive health care for the general public [2,4]. Despite its efficacy, broad dissemination faces challenges [5,6]. The World Health Organization [5] asserts that factors such as a shortage of trained therapists, geographical and financial limitations, and societal stigma toward mental health contribute to a substantial treatment gap.

Researchers have attempted to provide CBT through embodied conversational agents (ECAs) to address social issues [7-9]. ECAs are computer-programmed interfaces that simulate human-like conversations with users by using natural language processing techniques. Examples include messaging app–like chatbots [10,11], robots [12,13], and ECAs displayed as computer graphics on a screen [14]. Text-based agents or chatbots are especially widespread and commercially available as smartphone apps. Inkster et al [11] and Fitzpatrick et al [10] are 2 examples of such agents whose ability has been extensively validated for targeting and helping individuals who are experiencing mild to moderate symptoms of depression and anxiety. These agents provide therapy for daily mental health care rather than intensive clinical treatment. Studies have shown their effectiveness in reducing symptoms of depression and anxiety, increasing mental well-being, and fostering user resilience [15].

ECAs, or chatbots, increase accessibility, affordability, and anonymity, potentially reaching a broader population that might benefit from CBT. However, the effectiveness of these digital therapies depends on several factors, including therapeutic techniques, empathy, user interface, and personalization. Asay and Lambert [16] categorized the factors affecting therapy effectiveness into four major groups: (1) extratherapeutic changes, which include clients’ personality and environmental factors that support recovery, independent of therapy participation; (2) common factors such as empathy and therapeutic alliance, which are found in various therapy approaches; (3) expectancy, which involves improvement resulting from clients’ anticipation of assistance and their belief in the therapy’s rationale and effectiveness; and (4) techniques, which are specific factors unique to particular therapies and adjusted to address specific issues. Among these 4 groups, the techniques are crucial for enhancing the quality of therapy. One critical CBT therapeutic technique strategically uses Socratic questioning [17]. On the basis of the pedagogical style of the ancient Greek philosopher Socrates, this method is a form of guided discovery that encourages clients to critically examine and articulate their thought patterns to facilitate cognitive change and distress reduction [18,19]. Socratic questioning helps clients deeply contemplate their problems and perspectives. Questions such as “Why do you think that way?” “What evidence supports this perspective?,” and “Have you considered other perspectives?” can be adjusted to specific problems or situations. These flexible templates can be applied to various concerns and situations. The process involves carefully considering the content, timing, and sequence of questions adjusted to an individual’s cognitive processes and emotional state, emphasizing the quality of queries when engaging the client in Socratic questioning [2,4,20]. Therapists observe the content of clients’ utterances, changes in their voices, and facial expressions to understand changes in their mood [2,4].

Recent studies have started to investigate the application of Socratic questioning in automated CBT systems such as ECAs. Kimani et al [14] and Shidara et al [21] explored ways to implement Socratic questioning in CBT delivered by ECAs. The former work provided Socratic questions according to a dialogue context using a flowchart of selectable inputs and reduced the specific anxiety about giving a presentation. The latter study set up 2 dialogue scenarios, with and without Socratic questioning, and evaluated them in a comparative experiment. The group with the scenario containing Socratic questioning showed a larger reduction in negative moods. Both studies suggest that Socratic questioning by ECAs promotes cognitive changes and distress reduction.

However, there is a significant gap in current research. Existing studies have not explored how to automatically adapt Socratic questioning. Ideally, ECAs should adapt CBT strategies according to users’ psychological states, just like human therapists do. Specifically, there is limited research on this topic. We must focus on the adjustment of the number of questions or its types. Therefore, we set our goal to personalize CBT strategies based on an individual’s current psychological state.

This study addresses this gap by introducing an adaptive method to improve the effectiveness of CBT using ECAs. This method adjusts the number of questions during a therapy session based on the detected level of psychological distress. The main goal is to provide questions according to the user’s level of distress to improve the therapeutic interaction. To achieve this goal, we formulated the following research questions:

1. Research question 1: Can modifying the number of questions based on the user’s level of psychological distress lead to better therapeutic outcomes?

To address this question, our system uses a machine learning model with natural language processing techniques to estimate a user’s psychological state during a CBT session. Our system can automatically detect psychological distress, allowing it to adapt to the user’s mental state without using psychological...
scales such as the Kessler Psychological Distress Scale (K6) in each session. Furthermore, by integrating the distress detection model, our system can estimate the user’s distress in real time during the CBT session. This functionality is intended to improve the effectiveness of CBT with an ECA. In this sense, we present the hypothesis 1.

Hypothesis 1: In a condition with the adaptive number of questions, improvement in distress and emotion and cognitive change will be better than in a condition with a random number of questions.

2. **Research question 2**: Is there a clear benefit to modifying the number of questions to match the user’s specific psychological state rather than setting a fixed optimal number for all?

For this question, we emphasized the value of customization, recognizing that the most effective balance of questions may vary from user to user. Therefore, we aimed to clarify the therapeutic benefit of determining the distress reduction moments. Through this investigation, we aimed to identify the most effective strategy: changing the number of questions or setting a user-specific number of questions. Therefore, we propose hypothesis 2.

Hypothesis 2: The adapted question amount has better improvement than both the too few questions amount and the too many questions amount in terms of the users’ distress improvement, emotion improvement, and cognitive change.

To validate these hypotheses, we tested it experimentally by comparing 2 conditions: the adapted number of questions condition and the random number of questions condition. We assessed the reduction of psychological distress and negative emotional states and cognitive changes in both conditions. We also analyzed the influence of deviations in the number of questions from the model’s estimated value on the effectiveness of the ECAs.

The incorporation of a distress detection model into an ECA system is essential to our method. In the Psychological Distress Detection and Conversational Scenario section, we describe our psychological distress model and the design of the agent architecture.

**Psychological Distress Detection and Conversational Scenario**

**System Overview**

Figure 1 shows the overview of our system, including the abstract scenario. The detailed scenario can be found in Multimedia Appendix 1. This ECA uses an ECA toolkit called Greta (Institut des Systèmes Intelligents et de Robotique in Paris) [22]. Its animation’s appearance uses a version identified as more acceptable to Japanese people [23]. We used the ja-JP-Wavenet-B of Google’s Text-to-Speech service to generate the synthesized speech of a Japanese female voice. We used a laptop (i7, 32GB RAM, Dell Inc) for the ECA implementation and recorded the participants’ facial expressions and speech with its built-in camera. A microphone and a speaker were built into a headset (Sennheiser). Figure 2 shows a conversation between a user and our ECA.

---

Figure 1. A framework of an embodied conversational agent and a conversational scenario for cognitive behavioral therapy. MPEG-4: Moving Picture Experts Group Phase 4.
In this study, we developed a question scenario based on the principles of cognitive restructuring [2,4], a key component of CBT. The scenario was supervised and reviewed by a psychiatrist to ensure clinical accuracy and relevance. The CBT process involves 3 main steps: identifying automatic thoughts, correcting them, and examining new balanced thoughts.

The first step in the scenario involves identifying automatic thoughts by describing the situation, the mood, and the automatic thoughts themselves. Typically, the situation and mood are described first, followed by identifying the automatic thoughts that occur between the situation and the mood. When describing mood, participants also report the intensity of their moods using a score, which is a percentage ranging from 0 (not stressed at all) to 100 (the most stressed they have ever felt). In this step, the users select their strongest automatic thought. Although multiple automatic thoughts may arise from a single situation, focusing on the strongest thought allows for the largest reduction of mood score.

Once the automatic thoughts have been identified, participants correct their thoughts by comparing them with the facts of the situation. The CBT system poses questions designed to increase participants’ awareness of overlooked facts and provides distance from their automatic thoughts to view them more objectively. After correcting their automatic thoughts, the participants were asked to state their new balanced thoughts. This step involved considering the insights gained while correcting automatic thoughts and generating new balanced thoughts. At the end of this process, participants reported their mood score again to confirm a reduction of their negative mood scores after deriving new balanced thoughts.

**Adaptation of Number of Questions**

In our developed scenario, multiple questions were included for correcting automatic thoughts. This step ensured that the standardized scenario effectively improved participants’ mood by incorporating multiple questions. In actual CBT sessions, questions are adjusted according to an individual patient’s condition and level of distress.

Our ECA posed questions aimed at helping participants notice overlooked facts and gain distance from their automatic thoughts.
to view them more objectively. In the developed scenario, multiple Socratic questions were included for correcting automatic thoughts. This step ensured that the standardized scenario effectively improved participants’ mood by incorporating multiple questions. The number of questions posed for correcting automatic thoughts was adapted based on the detected level of the participant’s psychological distress. After posing questions that correct an automatic thought, the participant’s responses were used to identify their current psychological distress state. If distress is detected, the system continues to pose additional questions that prompt the participants to correct their thinking from various perspectives. This process gently nudges participants to reconsider their automatic thoughts, offering them the opportunity to alter their perspective and reduce their distress. The system was designed using a pool of 21 Socratic questions to prompt the correction of automatic thoughts. If a participant continues to exhibit high levels of psychological distress, the agent can pose up to 20 additional questions to assist them in working through their distress.

If the estimated value of the detection model is nondistressed, the agent proceeds to the next step, where the participant composes a balanced alternative thought. This step was based on the insights gained in the previous step, which is the correction of automatic thoughts. After this process, the participant again reported a negative mood score, which was expected to confirm a less negative mood.

**Pretraining of Detection Models to Address Japanese Conversation**

In our quest to dynamically adapt the number of questions asked during a CBT session, psychological distress in users must be accurately detected. In this context, machine learning models have been developed to estimate psychological distress [25-29], often using publicly available data sets, such as the Distress Analysis Interview Corpus/Wizard-of-Oz (DAIC-WOZ) database [30]. Unfortunately, this data set primarily contains English language data focused on assessing depressive tendencies rather than providing mental health care. Therefore, our challenge is to adapt these models to suit a Japanese language context, especially for the CBT domain.

To address this challenge, we first applied a deep learning architecture of the depression detection model proposed by Li et al [31]. Their model identifies depressive tendencies in interactions with ECAs by classifying presence or absence into 2 categories. It combines recurrent neural network and long short-term memory networks and uses multitask learning for depression detection. Multitask learning enables simultaneous training on multiple tasks, leveraging shared knowledge to improve generalization, use relationships between tasks, and reduce overfitting. In the study by Li et al [31], the model achieved a high $F_1$-score of 0.71.

Figure 3 [30,32] shows the training flow of the psychological distress detection model [30,32]. For the training process, we used a combination of pretraining and transfer learning. First, we translated the original training data in the study by Li et al [31] from English into Japanese using machine translation software and pretrained the model with reference to the settings in the study by Li et al [31]. We then constructed a Japanese CBT data set using crowdsourcing and conducted transfer learning on the detection model.
We retained the original implementation details of the study by Li et al [31]. We trained the model for a maximum of 100 epochs with early stopping based on the macro \( F_1 \) metric for depression classification. We used cross-entropy loss and a batch size of 1 for the DailyDialog and DAIC-WOZ. Tokenization was performed using the MeCab library [36], and we constructed word embeddings with a default dimension of 128. The turn-level encoder consisted of 1 hidden layer and 128 output neurons. We tuned the document-level recurrent neural network layers within a range of \([1, 2, 3]\) and the hidden size within a range of \([128, 256, 512]\). The model parameters were optimized using the Adam optimizer [37] with a learning rate of 0.001. Dropout rates were set to 0.1 for both the turn and document encoders.

Transfer Learning for Real-Time Distress Detection in CBT

After pretraining the model with the translated data, we implemented transfer learning by replacing the fully connected layer. This transfer learning process allowed us to leverage the original model architecture while shaping it to our specific distress detection task in CBT. In this transfer learning phase, we incorporated only 3 types of user utterances corresponding to the situation, mood, and automatic thought responses within the CBT process. This approach was adopted to enable real-time distress detection during CBT sessions with the ECA. When the detection model makes inferences, it inputs the 3 most recent utterances. In this way, the distress detection model enables real-time detection in a CBT session.

Our crowdsourced data set was initially collected from 100 crowd workers from the general public. However, upon visual inspection of the data, it became apparent that the responses from some participants were not adequately informative or valid for our purpose. Therefore, we excluded data from 6 participants as likely outliers or nonresponsive. Thus, the final data set for our analysis consisted of responses from 94 participants. In the data collection, we assessed the level of psychological distress in our crowdsourced data set with the Japanese version of K6 [38] (Japanese version [39]). This scale is a concise and reliable self-report tool that assesses the level of psychological distress experienced by individuals in the previous 30 days. This 6-item scale measures the frequency of symptoms related to anxiety and depression, making it a valuable instrument for detecting and evaluating mental health disorders in both clinical and research settings. The items are rated on a 5-point Likert scale, from 0 (none of the time) to 4 (all of the time), leading to a total score range of 0 to 24. Higher scores indicate greater psychological distress. In this study, following Sakurai et al [40], a K6 score of \( \geq 5 \) was considered distressed, and a score of \( <5 \) was considered nondistressed. We constructed a psychological distress detection model that classified these 2 classes. Of the 94 participants, 63 (67%) were categorized as distressed (K6 score of \( \geq 5 \)) and 31 (33%) as nondistressed (K6 score \( <5 \)). We used stratified sampling to automatically split the data into training, validation, and testing subsets. We used 55% (52/94) of the participants for training, 19% (18/94) of the participants for validation, and 26% (24/94) of the participants for testing.

Methods

Ethical Considerations

The research ethics committee of the Nara Institute of Science and Technology reviewed and approved this study (2019-1-24-3). We engaged a human resources company to advertise and recruit participants. All participants provided written informed consent before participating in the experiment. The participants were compensated with an honorarium, which was paid by the human resources company. Study data were anonymized.

Participants

This study was conducted in February and March 2023. Eligibility criteria for the experimental participants were as follows: (1) aged between 18 and 65 years, (2) having no hearing impairments, and (3) ability to speak Japanese. For the analysis of this research, 49 participants were allocated into 2 conditions to assess the impact of varying the number of Socratic questions based on detected levels of psychological distress during CBT sessions with an ECA.

In addition to these participants, a separate group (of 26 participants) was involved in a distinct experimental condition, designed for a different research focus. Although data for this separate group were collected concurrently with the main study, the data from this separate group are not relevant to the current analysis and have not been included in this paper. The objective of collecting the data from this separate group was to analyze whether an extreme number of questions were stressful and discouraged cognitive changes. It is expected that participants in this separate group might experience or perceive the system rather than personal emotional challenges such as depression or anxiety. Specifically, participants may be dissatisfied with how the system works or interacts rather than with their internal struggles. Although this system-related dissatisfaction is also important, it is beyond the scope of this study. Only the 2 conditions were used in this study to focus on the person’s nonadaptive thoughts and moods regarding their problems.

Table 1 shows the demographics and baseline characteristics of the participants who were recruited through an external participant recruitment service. We also included 1 participant with a history of a mental health issue in the adapted number of questions condition. This participant was currently in remission and not taking any medication. This participant was recruited through a company that provides employment transition services for people with a history of mental health issues.
Table 1. Participants’ demographics and baseline characteristics (N=49).

\(^a\)K6: Kessler Psychological Distress Scale.

To confirm whether there was any bias in the age of the participants and the preexperiment K6 scores between the 2 conditions, we conducted a 2-sided Welch t-test and calculated Cohen d values. As a result, for age, Cohen d was 0.21 and the P value was .48; for preexperiment K6 scores, Cohen d was −0.08 and the P value was .78. These results indicate that there was no significant bias in age and preexperiment K6 scores between the 2 conditions.

**Experimental Conditions**

Figure 4 illustrates the conversation scenarios for our 2 experimental conditions: the adapted number of questions and the random number of questions. In the adapted number of questions condition, the ECA used a distress detection model. This model continuously estimated the participant’s level of distress after each answer for a thought-correction question. If the model detects distress, it prompts the agent to ask a new question to correct the automatic thought. This process is repeated until the model detects no distress or the maximum number of questions is reached. In contrast, the condition of a random number of questions does not use the distress detection model. Instead, the system randomly determines the number of questions without considering the participant’s distress state. In both conditions, the number of questions asked to correct automatic thoughts varied from a minimum of 1 to a maximum of 21.

![Figure 4. Diagram of the experimental conditions. The adapted number of questions condition, which includes the psychological distress detection model, versus the random number of questions condition, which does not include the distress detection model.](image-url)

The condition assignment was not concealed from the experimental examiner. Participants were automatically assigned to conditions based on their age, sex, and K6 scores (a self-reported psychological distress scale). The day before the experiment, the participants responded to these 3 items using a questionnaire administered through Google Forms. On the basis of the questionnaire results, the conditions were divided such that no imbalance existed between the conditions in terms of K6, age, and sex. The participants conducted the experiment according to their predetermined condition assignments. They were unaware of their condition assignment and were not informed of the differences between the conditions.
Before the experiment, an experimenter explained this to the participants who signed the consent forms. They then completed the K6 questionnaire and read a publicly available leaflet explaining CBT [41]. The experiment consisted of the same questions as those in the ECA dialogue scenario created in our previous study [21]. The experiment was completed within 1 hour, including its briefing and preparation.

**Measures**

**Psychological Distress**

K6 was used as the rating scale to assess the psychological distress of our participants. Before the experiment, we obtained the K6 results for the previous 30 days. After the experiment, the participants were asked if any of the K6 items had changed after the CBT. The postexperimental measures differed from the original protocol, and we asked about the changes solely for analyzing our experiment. We calculated the change in psychological distress using equation 1.

\[
\text{Change in psychological distress} = \text{K6 score (pre)} - \text{K6 score (post)} \quad (1)
\]

Before the session, we measured the Quick Inventory of Depressive Symptomatology [42] (Japanese version [43]), which assesses depressive tendencies.

**Cognitive Change**

The Cognitive Change-Immediate scale [44] is a 5-item self-report measure that assesses the extent of the cognitive changes experienced by users during a single CBT session within therapy sessions. Items were rated on a scale from 0 (not at all) to 6 (completely), yielding a total score ranging from 0 to 30. Higher scores indicate a greater degree of cognitive change experienced by the participants.

**Mood Change**

A mood score is a numerical representation of the intensity of self-reported negative emotions experienced by the participants. The scores ranged from 0 to 100, with higher scores indicating more severe distress. Participants verbally provided their mood scores at 2 time points during scenarios involving CBT sessions with the ECA. The initial mood score was used for prethought correction, and the subsequent score was used for postthought correction. Specifically, participants were asked, “On a scale of 0 to 100, where 0 is no problem at all and 100 is a huge problem, how intense is that feeling?” These questions are commonly used to assess relief from negative moods [2,4]. Participants provided their responses verbally during the CBT. The participants’ moods were characterized using such language as anxiety, depression, sadness, feelings of inferiority, and fatigue. In this study, these negative emotional states were collectively assessed under an umbrella term, negative mood. In this study, these negative emotional states were collectively assessed under an umbrella term, negative mood.

This calculation is a measure of the degree of change in a participant’s negative mood, where a larger positive value indicates a decrease in negative mood.

**State–Trait Anxiety**

The State–Trait Anxiety Inventory [46] (Japanese version [47]) is a validated, self-report questionnaire that assesses both state anxiety (temporary and situational anxiety) and trait anxiety (general and stable anxiety) in adults. The State–Trait Anxiety Inventory consists of two 20-item scales: the State–Trait Anxiety Inventory-State (STAI-S) and the State–Trait Anxiety Inventory-Trait (STAI-T). The STAI-S measures the respondent’s current anxiety levels and feelings of apprehension, tension, and nervousness. It assesses the extent to which an individual is experiencing anxiety in response to a specific situation or event. Items are scored from 1 (not at all) to 4 (very much), where higher scores indicate more severe state anxiety. The STAI-T evaluates a respondent’s general tendency to experience anxiety as a stable personality characteristic. It focuses on the feelings of anxiety that are not associated with a particular event or situation; instead, it reflects an individual’s overall tendency to become anxious. Items are scored from 1 (almost never) to 4 (almost always), where higher scores represent greater trait anxiety levels. Both STAI-S and STAI-T scores can range from 20 to 80, and higher scores denote greater anxiety. We calculated the change in STAI-S using equation 3.

\[
\text{Change in STAI-S} = \text{STAI-S (pre)} - \text{STAI-S (post)} \quad (3)
\]

This calculation is a measure of the degree of change in a participant’s state anxiety, where a larger positive value indicates a decrease in state anxiety.

**Statistical Analysis**

We conducted an investigation to address hypothesis 1. This hypothesis states that an adaptive selection of the number of questions based on detected psychological distress would have superior effects in improving mental states. This approach was compared with the one in which the number of questions was randomized. For this investigation, we focused on several metrics, including K6 scores, mood scores, STAI-S, and cognitive change. Both within-condition and between-condition comparisons were conducted within these metrics. Owing to the inability to confirm the normal distribution of these measures in both the adapted number of questions condition and the random number of questions condition, we chose to use nonparametric tests for our analyses.

For within-condition comparisons, we assessed the differences in scores before and after the CBT session for each measurement in both conditions. The Wilcoxon signed-rank test was used to analyze these within-condition differences, illustrating the effect of the session on the adapted and random number of questions conditions individually.

For between-condition comparisons, we compared the pre- and postsession scores for each measurement between the adapted and random number of questions conditions. The Mann-Whitney U test was used for this analysis. In addition, we conducted a comprehensive analysis across 4 key parameters: change in psychological distress, cognitive change, mood change, and...
change in the STAI-S. This analysis involved multiple 1-sided Mann-Whitney \( U \) tests under the assumption that the adapted number of questions condition would show higher effects on each measure than the random number of questions condition.

We conducted a subgroup analysis to examine hypothesis 2, which asserts that adapting the number of questions according to the participant’s psychological distress is more effective. We categorized the participants into 3 subgroups based on the difference between the number of questions asked and the distress detection model’s estimation: the same group (participants who were asked the same number of questions as determined by the distress detection model), the fewer group (fewer questions were asked than determined by the distress detection model), and the more group (more questions were asked than determined by the distress detection model). In this analysis, we combined participants from both the adapted number of questions condition and the random number of questions condition. We did this because we expected too few participants in the same group within the random number of questions condition. We compared the same group with the fewer and more groups, expecting superior outcomes for the same group. This comparison used a 1-sided Mann-Whitney \( U \) test to compare the cognitive change, mood change, change in K6 scores, and change in the STAI-S across the subgroups.

In addition, we conducted further analysis to validate hypothesis 2. In this step, we examined the differences in various measurements across specific question counts. We focused on groups divided by question amount, such as 10, in the condition of a random number of questions. These were then compared with the participants in the adapted number of questions condition. Owing to the limited sample size in each category, we restricted our examination to qualitative analysis. In this comparative analysis, we did not conduct statistical testing. Furthermore, we reported the number of nondistressed and distressed values automatically detected for each individual question. These analyses aimed to demonstrate the effectiveness of a flexible approach to the number of questions presented.

Although we collected usability questionnaires and subjective evaluation feedback from the participants, this information was not included in the primary analysis of this study.

## Results

### Model Construction Results

Pretraining our detection models to address Japanese conversation yielded the following results: for the English data set (original condition and reproductive experiment), the accuracy was 0.72, precision was 0.67, recall was 0.58, and \( F_1 \)-score was 0.62. When the data set was translated by an automatic translation model into Japanese, the models achieved an accuracy of 0.64, precision of 0.59, recall of 0.60, and an \( F_1 \)-score of 0.59, demonstrating that we maintained equivalent performance levels despite the change in language.

We further applied transfer learning to the pretrained model with Japanese conversation for real-time distress detection in CBT. The results of implementing this transfer learning are as follows: In the condition where only pretraining was applied, the model achieved an average accuracy of 0.55, precision of 0.47, recall of 0.48, and an \( F_1 \)-score of 0.48 across 5 evaluation trials. When both pretraining and transfer learning were implemented, the average scores improved, with the model achieving an accuracy of 0.70, precision of 0.60, recall of 0.63, and an \( F_1 \)-score of 0.61. The model that demonstrated the highest performance during these trials, exhibiting an accuracy of 0.75, recall of 0.69, precision of 0.72, and an \( F_1 \)-score of 0.70, was selected for integration into the conversational scenario.

aK6: Kessler Psychological Distress Scale.

bNot available.
cSTAI-S: State–Trait Anxiety Inventory-State.
dQIDS: Quick Inventory of Depressive Symptomatology.
eSTAI-T: State–Trait Anxiety Inventory-Trait.

The average time spent on the dialogues in the adapted number of questions condition was 494.96 (SD 161.10) seconds, whereas the random number of questions condition spent an average of 661.40 (SD 289.20) seconds. However, it should be noted that owing to system issues, we were unable to record the time spent by one participant in each condition. As a result, the reported mean and SD for time spent exclude the data from these 2 participants. All other measurements were successfully recorded for these participants.

The average number of questions asked to correct an automatic thought was 4.76 (SD 4.48) for the adapted number of questions condition and 8.83 (SD 6.52) for the random number of questions condition.

We evaluated the distress detection model’s performance in the adapted number of questions condition. Specifically, we evaluated its accuracy in correctly identifying the nondistressed states, indicating when to stop asking Socratic questions. The model’s performance was measured by comparing its output (0 denoting nondistressed) with the participants’ actual postexperiment psychological distress states. The model correctly identified nondistressed state in 72% (18/25) of the instances.

In the presession phase, the K6 scores did not significantly differ between the 2 conditions. However, a significant difference was observed in the postsession phase; the adapted number of questions condition recorded a notably lower K6 score, indicating a substantial reduction in distress compared with the random number of questions condition. On other measures, the pre- and postsession scores were not significantly different between the 2 conditions.

A closer look at the within-condition comparisons revealed that the adapted number of questions condition experienced a decrease in scores across several metrics following the session, albeit to varying degrees. The adapted number of questions condition showed more marked improvements, especially in the K6 and mood scores, with significant reductions after the session, as evidenced by Cliff delta values of −0.49 (P=.01) and −0.66 (P=.001), respectively. In contrast, although the random
number of questions condition also showed a reduction in the mood score, characterized by a medium effect size (Cliff delta=-0.44; \( P=0.03 \)), the change in the K6 score was negligible between the pre- and postsession periods.

Table 3 presents the comparative results of changes in each measurement. We conducted a 1-sided Mann-Whitney \( U \) test to compare the cognitive change, mood change, change in the K6 scores, and change in the STAI-S between the adapted number of questions condition and the random number of questions condition. The results indicated that there was no significant difference in the change in psychological distress, mood change, and change in STAI-S between the 2 conditions, with \( P \) values of .11, .16, and .54, respectively. However, for cognitive change, a relatively large effect size was observed with a Cliff delta of 0.12, and the \( P \) value was .07, showing a trend toward significance, suggesting that the adapted number of questions condition exhibited a tendency for greater cognitive change compared with the random number of questions condition.

Table 3. Comparative results of changes in each measurement using nonparametric analysis of 1-sided Mann-Whitney \( U \) test for differences between conditions.

\( a \)STAI-S: State–Trait Anxiety Inventory-State.

To investigate hypothesis 2, we conducted a subgroup analysis as described in the Statistical Analysis subsection. We categorized the 49 participants from the adapted and random number of questions conditions based on the deviation between the differences in the questions asked and the estimated value of the model. Of the 21 participants, 7 (14%) received fewer questions than estimated and 14 (29%) received more questions than estimated, and for 28 (57%) participants, the number of questions matched the estimated value, denoted as the same group.

Table 4 shows the mean and SD for each subgroup. For cognitive changes, comparisons between the same and fewer groups showed a small effect size (Cliff delta=0.24; \( P=0.03 \)), indicating a significant difference. In contrast, comparisons between the same and more groups showed a negligible effect size (Cliff delta=0.04; \( P=.65 \)), indicating no significant difference. For the change in psychological distress, the comparisons between the same and fewer groups showed a negligible effect size (Cliff delta=0.03; \( P=.40 \)), indicating no significant difference. Similarly, comparisons between the same and more groups showed a negligible effect size (Cliff delta=0.04; \( P=.34 \)), indicating no significant difference. For mood changes, the comparisons between the same and fewer groups showed a negligible effect size (Cliff delta=0.08; \( P=.26 \)), indicating no significant difference. Similarly, the comparisons between the same and more groups showed a negligible effect size (Cliff delta=0.01; \( P=.44 \)), indicating no significant difference. Finally, for changes in the STAI-S, comparisons between the same and fewer groups showed a negligible effect size (Cliff delta=−0.03; \( P=.46 \)), indicating no significant difference. The comparisons between the same and more groups also showed a negligible effect size (Cliff delta=−0.07; \( P=.77 \)), indicating no significant difference.

\( a \)STAI-S: State–Trait Anxiety Inventory-State.

Table 5 illustrates the mean changes in various measurements such as distress, cognitive change, and mood change across different numbers of questions. As indicated in Table 4, the mean changes for the adapted number of questions condition were 1.04 for change in psychological distress, 16.3 for cognitive change, 0.22 for mood change, and 3.00 for change in STAI-S. The bar graphs of these data can be found in Multimedia Appendix 2. For the random number of questions condition, it was observed that in most instances, the mean change was lower compared with the overall average of the adapted number of questions condition. However, a notable exception was observed at a question count close to the average question count for the adapted number of questions condition (mean 4.76, SD 4.48), specifically at 5 questions. At this count, the random number of questions condition exhibited...
slightly higher scores in both distress change and cognitive change compared with the adapted number of questions condition. Furthermore, a trend was observed in cognitive change, where an increase in the number of questions correlated with a larger change, indicating a potential area for further exploration and validation in subsequent studies. Despite these observations, it was consistently found that the adapted number of questions condition manifested superior effectiveness across various numbers of questions, indicating robustness in its application regardless of the question count.

Table 5. Mean change in each questionnaire across different numbers of questions posed to participants in the random number of questions condition. Instances where the mean is “not available” indicate that the number of participants (n) is 0. Instances where the standard SD is “not available” are due to the number of participants (n) being either 0 or 1.

<sup>a</sup>STAI-S: State–Trait Anxiety Inventory–State.

<sup>b</sup>Not available.

Table 6 displays the number of detected values classified as nondistressed and distressed for each question aimed at correcting automatic thoughts. The bar graphs of these data can be found in Multimedia Appendix 3. In the adaptive question amount condition, questioning concluded with the detection of a participant’s first nondistressed value. Conversely, the process continued regardless of the values detected in the random question amount condition. Consequently, the total number of participants decreased as the number of questions increased. A significant proportion of participants were identified with nondistressed values, particularly within the initial 4 questions. However, as the number of questions reached a certain amount, the frequency of nondistressed value detection decreased, with none identified from questions 16 to 21. Meanwhile, distressed value detection persisted, with at least 1 individual exhibiting distressed values through the 21st question.
Table 6. Number of nondistressed and distressed values detected for each question aimed at correcting automatic thoughts, including only those participants who were presented with the same or a greater number of questions.

Discussion

Principal Findings

The primary aim of this study was to evaluate a method that adapts the number of questions in a CBT session based on the user’s level of distress, aiming to enhance the session’s effectiveness.

Hypothesis 1 posited that an adaptive approach to the number of questions selection, based on detected psychological distress, would lead to superior cognitive change and reduce psychological distress as well as negative emotional states compared with the random number of questions condition. The results partially supported this hypothesis. We observed a reduction in psychological distress from before the session to after the session in the adapted number of questions condition, whereas no such reduction was evident in the random number of questions condition. Furthermore, the level of distress after the session was significantly lower in the adapted number of questions condition than in the random number of questions condition. In contrast, no significant difference was observed in the changes in each measurement between the 2 conditions. These findings overall indicate that our approach contributed to optimizing the health care process and its outcomes.

A plausible reason for the significant improvement observed only in distress is that the deep learning model incorporated in this study was designed to detect the presence or absence of psychological distress. This suggests that although the CBT system’s adjustment of the number of questions was adjusted for distress, it was not necessarily adjusted for other measures. In cognitive models, cognition, including automatic thoughts, and reactions such as distress are considered distinct entities [2]. Relevant studies [19,44,45] explore the ways in which cognitive shifts can influence stress levels. Moving forward, it might be necessary to analyze the content of CBT and propose methods that enhance both cognitive and distress changes.

Hypothesis 2 proposed that better improvement would occur when the number of questions corresponded with the model’s estimated value. The data partially supported this, indicating more significant cognitive changes when the number of questions was aligned with the model’s estimate compared with when fewer questions were asked. This insight suggests the importance of precision in the number of questions selected to enhance the effectiveness of CBT delivered by ECAs. It was also implied that a large number of questions does not necessarily work effectively. Table 6 (Multimedia Appendix 3) shows that none of the participants were detected as nondistressed from questions 16 to 21. This result suggests that further questioning might not lead to significant improvements when there is no improvement in distress after a certain number of questions. Therefore, it would be prudent to set an upper limit on the number of questions that the system can ask.
We personalized the therapeutic process by ensuring a timely adjustment of the number of questions when the distress alleviation was projected to be insufficient. Our experimental data suggest that this approach significantly bolsters the effectiveness of ECAs in integrating thought-correction techniques into the therapy process. The data also revealed that maintaining a balance in the number of questions was critical for improving CBT’s effectiveness. Our findings highlight the potential of dynamic and personalized strategies in enhancing mental health care.

**Comparison With Prior Work**

The field of mental health care has significantly evolved owing to advancements in artificial intelligence. Among these advancements, using ECAs to deliver mental health care services is particularly promising. Influential studies in this domain, including the work of Fitzpatrick et al [10], DeVault et al [48], and Fulmer et al [49], investigate the effectiveness of these text-based conversational agents or ECAs in mental health care. Furthermore, research by Inkster et al [11], Ghandeharioun et al [50], and Murali et al [51] has revealed the importance of these agents’ ability to convey empathy.

These empathetic elements are crucial for creating a therapeutic alliance and supportive mental health care. Among these advancements, using ECAs to deliver mental health care services is particularly promising. Influential studies in this domain, including the work of Fitzpatrick et al [10], DeVault et al [48], and Fulmer et al [49], investigate the effectiveness of these text-based conversational agents or ECAs in mental health care. Furthermore, research by Inkster et al [11], Ghandeharioun et al [50], and Murali et al [51] has revealed the importance of these agents’ ability to convey empathy.

In addition, research endeavors by Kimani et al [14] and Shidara et al [21] initiated the exploration of the application of Socratic questioning in CBT delivered by ECAs. These studies have shown promising results in fostering cognitive changes and reducing distress. However, they have not explored the dynamic adjustment of Socratic questioning based on users’ psychological states. This study aims to address this gap.

The integration of such adaptive strategies in mental health care, as demonstrated by our study, underscores the substantial contribution of our research in advancing the field. Our study introduces a novel component that modulates the number of questions according to the degree of the user’s psychological distress. The results of our study indicate that adapting to a user’s psychological distress by modulating the number of questions significantly reduced psychological distress compared with a random number of questions. This finding is in alignment with psychiatric insights suggesting that the modification of automatic thoughts through questioning may not yield sufficient effectiveness if such thoughts remain superficial [2].

**Limitations**

When interpreting the results of this study, several limitations must be addressed. First, the cross-sectional design used in our research did not capture the long-term effects of ECAs on psychological distress. A long-term experiment is important to gain a deeper understanding of the lasting effects of ECAs and their potential role in improving mental health outcomes. Another limitation of our study is the small number of participants who exhibited high depressive tendencies. To enhance the generalizability of our findings, future research should involve a more diverse sample of participants, covering a broad range of psychological distress levels. This sample should include individuals with varying degrees of depression and other mental health concerns, ensuring that the results are more widely applicable to different populations that are experiencing various psychological issues. In addition, further research is needed on the effective selection of the number of Socratic questions to maximize the effectiveness of CBT. Techniques such as the WOZ method, in which a therapist operates an ECA, might shed light on this aspect [52].

**Conclusions**

Our study provides evidence that adjusting the selection of questions based on an individual’s distress levels can significantly enhance CBT effectiveness. This adjusted approach allows for a more personalized health care, which can improve the therapeutic outcomes for individuals who are struggling with mental health issues, including anxiety and depression.

Our research highlights the importance of timely and appropriate reactions when an individual’s distress levels improve during therapy. By carefully monitoring and responding to these changes in distress, the ECAs can better support users’ progress. Overall, our study highlights the value of personalized and adaptive approaches in CBT, paving the way for more effective and responsive mental health care.

Abstract

Background: People living with multiple sclerosis (MS) face a higher likelihood of being diagnosed with a depressive disorder than the general population. Although many low-cost screening tools and evidence-based interventions exist, depression in people living with MS is underreported, underascertained by clinicians, and undertreated.

Objective: This study aims to design a closed-loop tool to improve depression care for these patients. It would support regular depression screening, tie into the point of care, and support shared decision-making and comprehensive follow-up. After an initial development phase, this study involved a proof-of-concept pilot randomized controlled trial (RCT) validation phase and a detailed human-centered design (HCD) phase.

Methods: During the initial development phase, the technological infrastructure of a clinician-facing point-of-care clinical dashboard for MS management (BRIDGE) was leveraged to incorporate features that would support depression screening and comprehensive care (Care Technology to Ascertain, Treat, and Engage the Community to Heal Depression in people living with MS [MS CATCH]). This linked a patient survey, in-basket messages, and a clinician dashboard. During the pilot RCT phase, a convenience sample of 50 adults with MS was recruited from a single MS center with 9-item Patient Health Questionnaire scores of 5-19 (mild to moderately severe depression). During the routine MS visit, their clinicians were either asked or not to use MS CATCH to review their scores and care outcomes were collected. During the HCD phase, the MS CATCH components were iteratively modified based on feedback from stakeholders: people living with MS, MS clinicians, and interprofessional experts.

Results: MS CATCH links 3 features designed to support mood reporting and ascertainment, comprehensive evidence-based management, and clinician and patient self-management behaviors likely to lead to sustained depression relief. In the pilot RCT (n=50 visits), visits in which the clinician was randomized to use MS CATCH had more notes documenting a discussion of depressive symptoms than those in which MS CATCH was not used (75% vs 34.6%; $\chi^2 = 8.2; P = .004$). During the HCD phase, 45 people living with MS, clinicians, and other experts participated in the design and refinement. The final testing round included 20 people living with MS and 10 clinicians including 5 not affiliated with our health system. Most scoring targets for likeability and usability, including perceived ease of use and perceived effectiveness, were met. Net Promoter Scale was 50 for patients and 40 for clinicians.
Conclusions: Created with extensive stakeholder feedback, MS CATCH is a closed-loop system aimed to increase communication about depression between people living with MS and their clinicians, and ultimately improve depression care. The pilot findings showed evidence of enhanced communication. Stakeholders also advised on trial design features of a full year long Department of Defense–funded feasibility and efficacy trial, which is now underway.

Introduction

Background

Approximately 50% of people with multiple sclerosis (MS) have a depressive disorder, and people living with MS are 2-3 times more likely to be diagnosed with a depressive disorder than the general population [1]. However, depression in MS remains underreported, underevaluated [2], and undertreated [3,4], despite the prevalence of depression in people living with MS, low-cost tools available to screen for depression, and evidence-proven, society-recommended pharmacologic and nonpharmacologic treatment modalities [5,6]. In clinical practice, common barriers to these clinical goals include time constraints during clinical visits (Nelson, M, unpublished data, August 2020), stigma and discomfort discussing psychiatric symptoms [7], insufficient antidepressant medication dose, duration or mechanism of action [8], inadequate attention to other MS symptoms (fatigue, cognitive impairment, and urinary retention) that could interfere with mood and worsen symptom burden [2,9], and patient difficulty following treatments owing to difficulties with access, insurance, or finding specialists close to home [10], as well as the many competing demands on their time. Solutions to address these gaps in reporting, screening, and treatment are needed.

A closed-loop intervention could close these gaps in care and represent a pragmatic approach to address the suboptimal treatment of depression in real-world MS settings. Closed-loop interventions in health care refer to systems that minimize gaps in communication between patients and clinicians; these have been implemented effectively for a number of medical conditions [11-13]. For the purpose of improving depression care in MS, such an intervention would support relevant clinical information flow from patients to clinicians at the point of care and back to patients to support patient-centered care. Such a system would not focus on a specific “one size fits all” treatment or intervention modality (eg, social intervention) or on a specific proprietary mood app, but could support developing a complex plan individualized for each patient’s symptoms, goals, and capability. To accomplish this, the tool should efficiently deliver patient-reported mood symptoms to clinicians in line with the “5 rights” [14] (right information, to the right person, in the right format, through the right channel, and at the right time in the workflow). Further, the tool must promote the behaviors (eg, reporting, screening, treatment recommendations, and following through with timely refills or referral scheduling) that are likely to lead to mood improvements. Finally, this tool should seek to streamline workflows and streamline care within an existing care team (neurologist, nurse, and interprofessional staff) and system of care (informatics, care delivery, and payment structure). Once developed, even after extensive multidisciplinary stakeholder input, a digital health solution must be thoroughly socialized within a health system to increase adoption.

Some prior studies support the feasibility of monitoring patient mood longitudinally in people living with MS as well as the possible effectiveness of a closed-loop approach. There is good concordance between patient reports and clinical depression, supporting the use of patient-reported tools for depression monitoring [15]. The 3-month pilot CoachMS randomized controlled trial (RCT; NCT03335618; n=21; people living with MS; [16]) showed that it was feasible, and acceptable, to monitor patients' bothersome symptoms (mood, ambulation, and bladder) and to act on them clinically in near real time (coaching patients to address these) [16]. This intervention showed some preliminary efficacy in supporting behavioral change [17,18] likely to address depression, including in one case, recognition of and urgent hospitalization for suicidality. A proposed closed-loop intervention could further deliver data on patient function directly to the clinician at the point of care to support effective response.

Objectives

This study details a 3-phase endeavor designed to develop a comprehensive, closed-loop system for monitoring and thoroughly treating depression to be tested in real-world clinical settings: MS CATCH (Care Technology to Ascertain, Treat, and Engage the Community to Heal Depression in people living with MS). In phase I, a prototype was developed. In phase II, it was piloted in a clinical setting to obtain preliminary cross-sectional efficacy data on a fundamental premise, namely that visualization of patient mood during the clinical encounter would improve clinical attention to mood during that visit. In phase III, having ensured that the tool was satisfactory to patients and clinicians and that its use did indeed improve attention to depression in the pilot study, the tool was then refined using an extensive process of human-centered design (HCD) [19,20].

Methods

Phase 1: Initial Technical Build

Overview

Members of the primary research team led earlier engagement efforts that informed MS CATCH development, namely,
creating the BRIDGE dashboard concept [21], testing the acceptability of patient-reported outcomes (PROs) in a point-of-care MS clinical dashboard (MS NeuroShare; [19]), and developing a closed-loop reporting system that collects and synthesizes data at the point of care (MS Falls Insight Track; MS-FIT); [22]). Each of these design processes informed the current technical build.

**BRIDGE**

BRIDGE [21] is a technologically scalable, institutionally approved, workflow friendly, cross-disease, modular precision medicine platform [23]. BRIDGE launches from within a patient’s encounter from the Epic electronic health record (EHR) at the University of California, San Francisco (UCSF) using industry standard integration (Figure 1; Table S1 in Multimedia Appendix 1 [24]), delivering a seamless experience for clinicians [21]. BRIDGE was designed using an extensive process of HCD [19,20]. The tool accesses and visualizes data that are currently available in various disparate sources (EHR, patient diaries, and publicly accessible websites), with the substantial innovation that they are presented here in one comprehensive and streamlined format. A disease-specific version of BRIDGE is live within multiple clinics at the UCSF, with the MS clinic BRIDGE used as a point-of-care dashboard for the current project.

**Figure 1.** Components of the MS CATCH (Care Technology to Ascertain, Treat, and Engage the Community to Heal Depression in people living with multiple sclerosis) tool, including the (A) patient-facing survey and log, (B) the clinician-facing dashboard, and (C) the closed-loop system, with in-basket alerts for the clinician.

**MS NeuroShare**

This closed-loop prototype designed for a collaborative health system integrated a patient-facing PRO app with an EHR-based clinician-facing dashboard [25]. Patient participants cited the perceived value of thinking about and recording information before their appointments, noting how it impacted discussions with their clinicians, adding that coviewing information with the physician put physicians and patients on the same page and promoted a conversation of equals. Clinicians perceived patients’ prospectively collected mood scores as more sensitive, accurate, and comprehensive than a patient’s recall during the visit, and felt that these could improve value and promote clinician engagement [25].

**MS-FIT Tool**

A closed-loop system to prospectively record, report, and prevent falls in people living with MS was designed using HCD in a process analogous to that intended for MS CATCH [22]. MS-FIT includes low-burden regular falls ascertainment that patients can access with one click from any computer, tablet, or device, triggering a clinician’s inbox message for new or serious falls. Clinicians can then access and launch, from the medical record, a comprehensive version of BRIDGE refined
MS CATCH Prototype

The prototype for MS CATCH used in this study was refined for the specific purposes of depression monitoring and treatment by the study team using the BRIDGE and MS-FIT technical scaffolding, and informed by the MS NeuroShare and MS-FIT design processes and experiences. The MS CATCH prototype used in this study is shown in Figure S1 in Multimedia Appendix 1.

Phase 2: Proof-of-Concept Pilot Randomized Controlled Trial

Research Setting and Participants

Design

This was a cross-sectional, randomized controlled pilot study.

Setting

The primary clinical setting was the UCSF Center for MS and Neuroinflammation, which specializes in providing care to >5000 adults with MS annually, and has an extensive track record of pivotal trials for MS [26,27], remote monitoring [28,29], and treatment [16].

Participants

MS clinicians were invited to participate in the study during the center’s monthly research meeting, and a convenience cohort of 6 clinicians was enrolled using a signed electronic consent form. Then, from the participating neurologists’ practices, adult patients with an MS diagnosis scheduled for upcoming in-person and video neurology visits were contacted before the clinic visit by the study coordinator via email and phone call. Interested patients were scheduled for an enrollment visit whether in-person, or via telephone, or Zoom (Zoom Video Communications, Inc; an institutionally approved, Health Insurance Portability and Accountability Act–secure, televideo platform). During this visit, they provided detailed informed consent via DocuSign (DocuSign, Inc). Once patients signed the informed consent form, they were asked to complete a series of PROs, including the 9-item Patient Health Questionnaire (PHQ-9) scale, via a secure REDCap (Research Electronic Data Capture; Vanderbilt University) link. Patients with scores of ≥5 (mild depression: 5-9, moderate: 10-14, moderately severe: 15-19, and severe: 20-27) met the study criteria and were seen in the clinic. For participants with PHQ-9 scores of ≥19, even if their clinician was not asked to use BRIDGE, the clinician was informed of their score near the conclusion of the clinic visit to ensure safe treatment of the patient. At the conclusion of the study visit, both clinician and patient feedback regarding the tool were solicited. During the proof of concept pilot, MS CATCH was used once during the visit in real time. For the full RCT, the patient-facing mood survey will be completed monthly, as described in the results for phase III.

Trial Outcomes

Usability: Participant Feedback on Tool

At the end of the study visit, patients were asked to provide feedback on the tool. There were 2 main prompted questions: “Tell us (with illustrative examples) of what worked well and what didn’t, with regards to BRIDGE, during your appointment.” This question was asked to both patients and clinicians, whereas “Please explain in detail, why it was or wasn’t useful for you to report your mood symptoms before the visit” was just addressed to the patients. Then, 2 questions informed from the System Usability Scale [30,31] and the health IT usability evaluation model [32] were completed, assessing likeability and perceived usefulness of the tool.

Efficacy: Effect of the Tool on Attention to Depression

At the end of the study, each clinical encounter was reviewed by a team member with an eye to whether mood was mentioned during the clinical visit. After the review was completed by one team member, another team member blinded to the treatment assignment audited the report. Only the second team member was blinded to treatment assignments. Any disagreements were resolved by a third party.

Ethical Considerations

This study was approved by the UCSF institutional review board (#18-26148).

Statistical Analysis

The participant demographics and usability outcomes were analyzed using descriptive statistics. The main efficacy outcome, percentage visits where depression was mentioned in the clinic notes, was compared for visits with and without the use of MS CATCH using chi-square analysis [33].

Phase 3: MS CATCH Tool Refinement (Stakeholder Engagement and Intended User Input Over 6 Months)

Study Design

HCD is a process that holds at its center the needs of the intended users. During the MS CATCH refinement phase, the overall goal was to fine-tune and optimize the intervention by partnering with patient and clinician users and multidisciplinary stakeholders in a sequence of iterative feedback sessions to inform and validate design decisions (Figure 2). To our knowledge, features assembled into the MS CATCH prototype

were reminded to launch BRIDGE via text or email before the patient appointment when applicable, and neither clinician nor patient participant were blinded to the intervention. Patients continued to be recruited until a target (n=50) had met the inclusion criteria and were seen in the clinic. For participants with PHQ-9 scores of ≥50, even if their clinician was not asked to use BRIDGE, the clinician was informed of their score near the conclusion of the clinic visit to ensure safe treatment of the patient. At the conclusion of the study visit, both clinician and patient feedback regarding the tool were solicited. During the proof of concept pilot, MS CATCH was used once during the visit in real time. For the full RCT, the patient-facing mood survey will be completed monthly, as described in the results for phase III.
had never before been available at the point of care in a clinically actionable format for depression treatment in MS. It was important to verify that the workflow and displays promoted behavioral change likely to improve depression care and to simplify the display into the features most likely to drive adoption of the tool and support depression care. Here, the “capability, opportunity, and motivation model for behavioral change” (COM-B) [18] was used. COM-B is a hub in the center of Michie’s behavioral change wheel [18] and can help inform a patient’s intention to engage in a planned behavior, which is considered the best predictor of that behavior [34,35]. The COM-B approach, and individual intervention functions, have been successfully applied to facilitate behavioral change in people living with MS [17].

<tr>
<td></td>
<td>Meeting 2 when tool is ready for clinical trial: Review the tool optimization and feedback scores (see below) and confirm that the intervention is ready for launch in the trial.</td>
</tr>
<tr>
<td></td>
<td>Meeting 3 following trial start: Review enrollment and early qualitative feedback on clinical trial activated and develop a roadmap for the transition plan.</td>
</tr>
<tr>
<td>Discovery Interviews</td>
<td><strong>Process:</strong> Members of the primary research team with expertise in engagement and HCD conducted 1:1 interviews with patients and clinicians separately, via the UCSD* Zoom platform. The sessions were recorded to ensure that all feedback was captured.</td>
</tr>
<tr>
<td></td>
<td><strong>Goals:</strong> To identify new features and map all features and data types to COM-B principles to facilitate behavioral outcomes (reporting, evaluating, treating) [15] likely to support depression reduction.</td>
</tr>
<tr>
<td></td>
<td><strong>Outcomes:</strong> Feedback was used to generate a list of features to be modified (e.g., enhanced, clarified, removed, and simplified) by the developer. Clarifying feedback was also elicited on perceived ease of use and usefulness to ensure that only the components most likely to be effective would be used.</td>
</tr>
<tr>
<td>Think aloud Session</td>
<td><strong>Process:</strong> Members of the primary research team conducted 1:1 sessions where the tool was launched and tested with patients and clinicians. Patients were presented with specific scenarios for entering data into the platform (e.g., using the tool after a difficult life event vs for monitoring during periods of emotional stability) and the way they engaged with the tool was observed. Clinicians were exposed to interactive live demonstrations.</td>
</tr>
<tr>
<td></td>
<td><strong>Goals:</strong> Validate modifications made following discovery interviews and further refine and clarify each feature.</td>
</tr>
<tr>
<td></td>
<td><strong>Outcomes:</strong> Both patients and clinicians were asked to prioritize the individual data types by scoring their “perceived usefulness,” so that only the key drivers of behavioral changes were retained. If any specific data scored low (i.e., not perceived as useful), then they were either removed or modified in the visualization.</td>
</tr>
<tr>
<td>Final Tool Scoring</td>
<td><strong>Process:</strong> The final version of MS CATCH was scored by 20 diverse patients with MS and 10 MS clinicians using established scales such as the SUS, Health IT USES, and NPS.</td>
</tr>
<tr>
<td></td>
<td><strong>Goals:</strong> Assess clinician perception of usability with the System Usability Scale (SUS), Assess patient and clinician perceptions of usefulness and ease of use with Health IT USES-based questions, and perceptions of likeability with a single-item question and the Net Promoter Score (NPS). [26, 27, 28]</td>
</tr>
<tr>
<td></td>
<td><strong>Outcomes:</strong> Any domains scoring below target as defined in Table 3 would trigger another round of iterative edits, with input from the Stakeholder Advisory Group.</td>
</tr>
</tbody>
</table>

To maximize the likelihood that the tool would be adopted and effective, it was evaluated using the health IT usability evaluation model [32]. This model integrates multiple usability theories including the Technology Acceptance Model and evaluates both subjective and objective outcomes. Although refining the critical data and visualization elements, as well as technological and clinical workflow aspects, the 4 key variables proposed by Mathews et al [36] for digital health tool validation were examined to determine whether the tool (1) reflects HCD principles and (2) is likely to engage patients. These factors include usability, effectiveness, learnability or ease of use, and likeability. Usability was defined using the System Usability Scale, learnability and ease of use were measured with a subset of the Health Information Technology Usability Evaluation Scale–based questions, and likeability was assessed with a single Likert scale question: “Do you like the tool?” and the net promoter score (NPS). Effectiveness was determined based on the pilot study visit notes outcomes.

**Sequential Methods With Iterative Technological Modifications**

Over a 9-month period between September and June, sequential activities were conducted as outlined in Figure 2.
**Stakeholder Advisory Group**

This group was convened and led by members of the primary research team. The primary research team comprised investigators with a track record of collaboration as well as expertise in both scientific and technological aspects of this project, including MS clinical trials (RB), digital tools to evaluate and treat cognition and mood in MS [16] (RB and AF), psychiatric care for underserved populations and innovations in treatment of psychiatric conditions in diverse settings (CM) [37-44], implementation science (CM), statistics (Ann Lazar), patient engagement (RB and JR) [20,21,25], HCD of digital tools (JR, RB, NS, and NM) [20,21,25], and launching an institutionally and technologically sophisticated, scalable, cross-disease platform from the EHR at UCSF (RB and BRIDGE team). The stakeholder advisory group included the research team listed above, as well as a patient champion JS, patient advocacy group leader Linda Glassel, National Multiple Sclerosis Society, Northern California Chapter President, MS nurse expert AM, Registered Nurse, social worker MD licensed independent clinical social worker, and MS neurologist CYG.

**Participants**

MS clinicians and other experts (degrees including Doctor of Medicine, Nurse Practitioner, Registered Nurse, and Masters in Social Work) were identified within the UCSF MS clinic and the investigators’ broader professional network. Adults with MS were recruited from the UCSF MS center by the study team (convenience sampling). All participants provided informed consent to test the tool and provide preliminary data. Furthermore, 31% (10/32) of the patients participated in the phase II pilot study.

**Ethical Considerations**

Activities during this phase (HCD phase) were approved by the UCSF institutional review board (#22-36620).

**Results**

**Phase 1: Initial Technical Build**

The MS CATCH prototype used for the current phase II and phase III study phases, informed by prior HCD processes (BRIDGE, MS NeuroShare, and MS-FIT), is shown in Figure S1 in Multimedia Appendix 1. A patient-facing mood survey was selected to be administered via a secure REDCap link that could be accessed on any device with Wi-Fi or cellular data capabilities. The validated, self-administered PHQ-9 scale was then connected to the BRIDGE platform so that it could be visualized at the point of care and interpreted in BRIDGE in addition to the other elements of the patient’s MS history, as well as a list of resources including psychotherapy and psychiatry, available in the patient’s home area (California only). The PHQ-9 survey also triggered a clinician’s inbox message for worsening mood. The mechanism by which MS CATCH is postulated to work is by facilitating communication flows that are likely to support intended users’ COM-B behaviors (patient: reporting and follow through and clinician: evaluating and recommending) likely to lead to symptom improvement. With regard to usability, the intended users, that is, both clinicians and patients, can each access it with one click.

**Phase 2: Proof-of-Concept Pilot Randomized Controlled Trial**

**Participants**

Of the 200 patients contacted, 106 (53%) agreed to participate in this study. Of these, 50 (47.2%) met the inclusion criteria of a PHQ-9 score >4 and were cared for by 6 participating physicians. Distribution of PHQ-9 scores was as follows: 52% (26/50) mild depression (5-9); 32% (16/50) moderate depression (10-14); 10% (5/50) moderately severe depression (15-19); and 6% (3/50) severe depression (20-27). Patients were then randomized to visits where the BRIDGE dashboard was used (24/50, 48%) or not used (26/50, 52%). All participants were contacted before their clinical visit, which was conducted between May and December, 2021. This visit was where the MS CATCH intervention was used. The cohort included 40 (80%) females and 10 (20%) males, aged 25-75 (mean 50.46, SD 13.0) years, including individuals with all MS subtypes (32 relapsing remitting MS, 9 primary progressive MS, 1 progressive relapsing MS, 6 secondary progressive MS, 1 unspecified, and 1 MS likely).

**Tool Usability**

The mean likeability score was 4.3/5 for patients (93% of the patient participants agreed or strongly agreed that they liked the tool) and 4.4/5 for clinicians (100% of the clinicians agreed or strongly agreed that they liked the tool).

For perceived usefulness [30,31], among clinicians, 100% of them reported that the tool increased their attention to the patient’s mood, particularly for patients with mild to moderate symptoms that might otherwise have been missed. Clinicians provided some specific feedback on how to further customize the dashboard, suggesting that it would be better to have the categorical components of the PHQ-9 rather than just the raw score (3/6, 50%).

Among patients, 71% (20/28) reported feeling that it was useful to report their mood-related symptoms before the visit. In qualitative feedback, many patients reported that filling out the mood survey ahead of time gave them the opportunity to reflect on their own feelings: “It set the tone, upfront, about how I was feeling.” “It’s helpful for me to think about assessing my mood in a structured way,” “was useful because it made me stop and reflect,” and “it opened the door to explain how...new MS symptoms are affecting my mood.”

**Tool Effectiveness**

For the patients with a PHQ-9 score of ≥5, visit notes documented a discussion of depressive symptoms in 75% of the visits where MS CATCH was used versus 35% of the visits where it was not used (N=50; χ² = 8.2; P = .004; Table 1). One patient was referred to a psychiatrist for suicidal ideation.
### Phase 3: MS CATCH Tool Refinement

#### Study Participants

Overall, 45 individuals provided feedback on the tool during successive phases of development. The results are summarized in Table 2.

#### Discovery and Think-Aloud Sessions: Selected Findings

Detailed findings and scores from each round of engagement, as well as iterative development steps, are presented in Multimedia Appendix 1 and summarized here. During the discovery interviews (N=5 patients, N=5 clinicians), each tool component was found to be useful and usable. A number of features and data types were identified that mapped to the COM-B principles of behavior change, and these resulted in design changes and interventions promoted to address potential boosters or blockers (Table S2 in Multimedia Appendix 1). For example, patients universally felt that the PHQ-9 should be delivered monthly if not more often, despite concerns by the study team that it would be too burdensome. The patient-facing survey was edited to support free-text entry and addition of language at end of survey informing patients who scored >15 to seek care urgently, as their care team may not see the score for 36 hours, and instructing patients to seek immediate care if experiencing a mental health crisis. During the think-aloud sessions (N=7 patients, N=5 clinicians), some patients articulated concern for how answers might be interpreted by their clinicians, for example, concern about sending up unnecessary “red flags” with their survey answers as symptoms addressed on the survey can overlap with MS symptoms. Relatedly, the free text box proved to be a popular design feature as it presents an opportunity to offer context for potentially concerning or MS symptom-related survey answers. Additional features were noted to be of value; for example, neighborhood walkability was specifically identified by patients as useful context for their clinicians to have within the clinical decision support view. Patients also universally expressed interest in having dashboard views available in a summary display for reference following appointments. All surveyed participants preferred an electronic summary format distributed through the patient portal (MyChart) as opposed to an alternative format that was not integrated with their EHR portal. Clinician feedback led to a reduction in the visual “wordiness” of the original clinical decision support widget. One decision that could not be accommodated was the ability to include patient insurance information, which substantially influences prescribing choices and referral decisions, as there is unfortunately no “ground truth” source for this information.

#### Final Changes Made to Tool Before Scoring

The patient survey was further developed to include an in-survey pop-up directing patients who screened positive for suicidal intent to seek immediate medical care (with contact information), a catalog of mental health resources at the end,
and a companion patient-facing mood tracker displaying the patient’s longitudinal mood survey results. On the dashboard side, the clinical decision support screen was further refined to be less “visually overwhelming.”

**Qualitative Feedback on the Closed-Loop System**
Clinicians’ qualitative feedback on the potential impact of MS CATCH on the care delivery experience and quality of conversations with patients and caregivers ranged from appreciation for the intervention’s holistic approach to concern that limited visit times will constrain the dashboards’ seemingly limitless potential.

- “Patients will feel empowered to make decisions using the information.”
- “The value comes from physicians being able to see the patient’s trajectory, and from patients being able to have a longitudinal view.”
- “It will allow me to come into visits with more of a plan.”
- “While [BRIDGE] may not be useful for every problem, it can be valuable for high stakes symptoms (depression, falls).”
- “Feel like it gives me more to offer my patients.”
- “Reinforces what we should do.”
- “Helps to have an objective measure of symptom worsening. Is more reliable than past notes.”

**Description of the Final MS CATCH Prototype**
The final prototype is displayed in Figure 1. The patient-facing survey is easily accessible via email. Along with receiving the short monthly survey via email, the patient’s response history and resources relevant to depression self-management can be viewed at the end of the survey (Figure S2 in Multimedia Appendix 1). PHQ-9 scores of 15 or higher or any suicidal intent trigger an alert to the patient’s MS clinician’s EHR in-basket. This is a critical feature allowing for timely follow-up within the usual care workflow, including an urgent referral to psychiatry. The clinician-facing dashboard (Figure 1) has a comprehensive mood evaluation and treatment dashboard that launches from the EHR. This dashboard can be copied and pasted into the clinical notes as well as the patient’s after visit summary to be accessed at the end of the visit and between visits. The tool uses a closed loop system, diagramed in Figure 1, which integrates the patient survey, in-basket messaging, and clinical dashboard tools.

**Final Tool Scoring**
A convenience sample of adults with MS (n=20) and clinicians (n=10) participated in the final tool testing. Of the participating clinicians, 5 (50%) practiced at external (non–UCSF-affiliated) institutions, and 5 (50%) were affiliated with UCSF. The target and achieved results are presented in Table 3.

Patient assessment ratings exceeded the goals in approximately all categories. Despite a patient NPS of 50, which is considered one point below excellent, slightly fewer (75%) than the goal of 80% agreed or strongly agreed that the tool was likeable (mean 4.25, SD 1.12). Of those (n=5) who scored the tool ≤4 with regard to likeability, approximately all (n=4, 80%) were neutral (score=3). Reasons varied from lack of personal applicability, “Mood symptoms are due to MS, not depression,” and “I have a lot of anxiety, but not depression”; to survey design, “I don’t like the multiple-choice options”; and to formatting, “Font is small.” Concrete follow-on actions taken by the development team in response to this feedback were as follows:

- Increasing the default survey font size, in addition to giving patients the option to adjust the font independently.
- Adding a note above the free text box indicating it can be used to add comments or clarify answers.
- Coaching physicians on how to communicate with patients about the survey, including how it can help detect anxiety and mood symptoms that may or may not be MS-related.

Similarly, clinician ratings exceeded the goals in approximately all categories. A clinician NPS of 40 indicated strong favorability in terms of recommending to peers. Perceived usefulness was slightly under goal at 95%. Although all but 1 clinician agreed or strongly agreed that the tool was useful (mean 4.35, SD 0.75) and 1 rated the tool ≤4 citing concerns about limited bandwidth and lack of financial incentives or reimbursable mechanisms for clinicians to address mood between clinical encounters. This feedback echoes concerns noted during discovery interviews about visit time limitations and the need for complementary workflows to ensure that patient mood issues can be monitored in a timely fashion, with the assistance of multidisciplinary staff (registered nurse and masters in social work) and elevated to physicians as needed.
Psychiatric and nonpsychiatric care in the EHR is often low, and better integration is associated with improved psychiatric care [51]. In this study, we showed that viewing patients’ self-reported mood at the point of care improved attention to depression in the clinical notes. This of course does not inform follow through on this intention. To that end, our 3-month pilot CoachMS RCT (NCT03335618; 21 people living with MS) showed that monitoring and responding to patients in real time [16] was feasible, acceptable, and showed preliminary effects on behavioral change [17,18] suggesting that sustained monitoring and feedback can promote behavioral change [16].

After development, implementation into clinical workflows represents the final goal of health-related tools. From prior experience in developing platforms for the clinical encounter, it was clear that socialization of a tool is a critical step. For patients, knowing that information about their mood will tie back to their care team and translate into improved attention to their care is an important component of tool use, as is the ability to self-monitor using the survey results. Furthermore, direct actionable steps were implemented based on patient feedback, such as providing a list of resources at the end of the survey to reduce the activation energy required to access resources during a depressive episode. Similarly, clinicians are more likely to use and recommend a tool if they know that patients will have completed their surveys [25] and are more likely to want access to patient-generated data if it is clinically actionable. Integrating comprehensive management resources will support individualization of the treatment plan rather than “one size fits all” treatment interventions.

Many treatment trials for depression have to date focused on “one size fits all” approaches testing a specific intervention or combination of interventions. Novel approaches tested within

### Discussion

Depression is a serious comorbidity in MS that is associated with an increased risk of disability progression [47], yet it remains severely undertreated; by one estimate, two-thirds of individuals meeting the clinical criteria for major depressive disorder receive no antidepressant medications [48]. Depression is often missed altogether by neurologists, even when it is severe and accompanied by suicidal ideation [49,50]. We iteratively and extensively piloted and developed a closed-loop intervention designed to improve reporting, screening, and treatment of depression in a cohort of clinical patients with MS. The preliminary data presented here support our key premise underlying this closed-loop approach [11] that delivering reliable information about a patient’s mood in an interpretable, visual format to the clinician would increase the likelihood that depression was detected (including, in one case, suicidality) and addressed in the clinical encounter. Further, our robust process of HCD and tool evaluation allowed us to maximize the likelihood that this tool would be adopted by ensuring that it met the stringent goals of being likeable, easy to use, and perceived as being effective.

We are not aware of other closed-loop tools developed to support depression care in MS that are integrated with the EHR. Distinct from other mood apps on the market, the patient self-report app directly connects to the clinician’s in-basket so that the information can be efficiently streamlined. In full clinical use, the patient-facing survey would be distributed once per month, and clinicians will not be reminded to launch BRIDGE. Studies have generally shown that integration between psychiatric and nonpsychiatric care in the EHR is often low, and comprehensive management resources will support individualization of the treatment plan rather than “one size fits all” treatment interventions.

Many treatment trials for depression have to date focused on “one size fits all” approaches testing a specific intervention or combination of interventions. Novel approaches tested within...
MS include sequential blocks of medications [52] as well as combinations of behavioral and pharmacological interventions [53]. Extending beyond the usual screening and care components (such as asking about moods retrospectively), MS CATCH will comprehensively visualize the other functions contributing to depression, including other conditions (eg, sleep) and unmet social needs (eg, substance use counseling, neighborhood unsafe for walking exercise). These will support customized action prompts to help patients self-manage, and clinicians will tailor treatments, anticipate challenges, and make social and behavioral health referrals.

Some limitations were evident in the design and compromises had to be made. For example, the PHQ-9, which is widely adopted as a screening tool, may not be particularly specific. For example, in response to the “constant bother” question, one participant responded “MS is a constant bother.” However, this tool was selected because of its brevity, extensive validation across multiple conditions including MS, and because it comprised the 9 criteria that are identified in the diagnosis of depressive disorder per the DSM-IV [45]. Another limitation is the lack of information regarding insurance acceptance by mental health professionals. Unfortunately, this limits actionability in terms of referrals to mental health professionals in the United States. For the resources map, we chose to focus on mental health professionals near the patient who were considered to have expertise for individuals with MS, but we also included a link to a website that includes insurance information to allow cross-checking. A third challenge is scalability. Key technological and clinical features were intentionally selected to ensure that the tool’s modular infrastructure could be scaled to other symptoms, conditions, and clinical settings. Technological factors designed to support scalability include (1) the quality and content of static visualizations that can be disseminated broadly regardless of a clinic’s technology and (2) optimizing the industry technological standards used for the build so that the code can be shared by clinicians in other health settings (eg, other MS centers using Epic EHR). However, the integration of the build into other health systems ultimately depends on governance and motivation internal to that system.

MS CATCH is a comprehensive, low-burden, closed-loop platform designed to reduce depression severity and prevalence in people living with MS by supporting real-time communication and alerts, shared decision-making, and action prompts for comprehensive, personalized interventions. The research findings summarized here suggest that MS CATCH scores well on likeability and usefulness scales and that it improves attention to mood in individual clinic visits. In a complementary pilot study, we previously showed that remote monitoring of mood can lead to timely intervention [16]. Altogether, these findings support the results of a planned randomized single-center clinical trial evaluating its effect on behaviors that support depression reporting, ascertainment, and care. A similar model can be used to improve other clinical symptoms in MS and for managing other chronic medical conditions with high prevalence of depression.

Acknowledgments
This trial is funded by a Department of Defense US Army Medical Research Acquisition Activity Clinical Trials Award (project #W81XWH2210894; principal investigator: RB).

Authors’ Contributions
KH drafted the manuscript. KK and JW collected preliminary data and revised the manuscript. JR was involved in trial design, conducted interview and interpreted results, and revised the manuscript. AF, CM, MD, AM, CYG, and LO contributed expertise from their respective fields through stakeholder feedback sessions and other avenues and revised the manuscript. NS and NM were involved in tool iterative development and revised the manuscript. RB was involved in trial design, obtained study funding, and drafted the manuscript. KPR and SS revised the manuscript.

Conflicts of Interest
The authors report no disclosures relevant to this clinical trial. KH, JR, KK, JW, NS, NM, MD, AM, JS, LO, and KPR had no conflicts of interest to disclose. CYG reports personal advisory board or consulting fees from Genentech and Horizon. AF received grant support from Multiple Sclerosis (MS) Society of Canada, Canadian Institutes of Health Research, book royalties from Johns Hopkins University Press, and speaker’s honoraria from Novartis. CM is supported by several grants from the National Institutes of Health (NIH; National Institute of Mental Health, National Institute on Minority Health and Health Disparities, National Institute of Allergy and Infectious Diseases, and National Institute on Drug Abuse), Health Resources and Services Administration, Doris Duke Charitable Foundation, California Health Care Foundation, Genentech, Gilead, and United Health Group. RB received research support from NIH, Department of Defense, National Multiple Sclerosis Harry Weaver Award, Biogen, Novartis, and Hoffman-La Roche. RB has received personal advisory board or consulting fees from EMD Serono, Horizon, Janssen, and TG Therapeutics. SS receives research funding from BioMarin Pharmaceutical.

Abstract

Background: The 6-minute walk test (6MWT) is a commonly used method to assess the exercise capacity of people with many health conditions, including persistent pain. However, it is conventionally performed with in-person supervision in a hospital or clinic, therefore requiring staff resources. It may also be difficult when in-person supervision is unavailable, such as during the COVID-19 pandemic, or when the person is geographically remote. A potential solution to these issues could be to use GPS to measure walking distance.

Objective: The primary aim of this study was to assess the validity of a GPS-based smartphone app to measure walking distance as an alternative to the conventional 6MWT in a population with persistent pain. The secondary aim of this study was to estimate the difference between the pain evoked by the 2 test methods.

Methods: People with persistent pain (N=36) were recruited to complete a conventional 6MWT on a 30-m shuttle track and a 6MWT assessed by a smartphone app using GPS, performed on outdoor walking circuits. Tests were performed in random order, separated by a 15-minute rest. The 95% limits of agreement were calculated using the Bland-Altman method, with a specified maximum allowable difference of 100 m. Pain was assessed using an 11-point numerical rating scale before and after each walk test.

Results: The mean 6-minute walk distance measured by the GPS-based smartphone app was 13.2 (SD 46; 95% CI −2.7 to 29.1) m higher than that assessed in the conventional manner. The 95% limits of agreement were 103.9 (95% CI −107.7 to −71.1) m and −77.6 (95% CI −107.7 to −61) m, which exceeded the maximum allowable difference. Pain increased in the conventional walk test by 1.1 (SD 1.0) points, whereas pain increased in the app test by 0.8 (SD 1.4) points.

Conclusions: In individuals with persistent pain, the 2 methods of assessing the 6MWT may not be interchangeable due to limited validity. Potential reasons for the differences between the 2 methods might be attributed to the variation in track layout (shuttle track vs continuous circuit); poor GPS accuracy; deviations from the 30-m shuttle track; human variability in walking speed; and the potential impact of a first test on the second test due to fatigue, pain provocation, or a learning effect. Future research is needed to improve the accuracy of the GPS-based approach. Despite its limitations, the GPS-based 6MWT may still...
have value as a tool for remote monitoring that could allow individuals with persistent pain to self-administer frequent assessments of their functional capacity in their home environment.

**Introduction**

**Background**

Persistent pain affects 20% of the Australian population, has fueled the opioid epidemic, and cost the Australian government Aus $73.2 billion (US $54.7 billion) in 2018, the latest year for which figures are available [1,2]. People with persistent pain report that their pain negatively affects their ability to exercise and their physical functioning [3].

The 6-minute walk test (6MWT) is a standard method for measuring submaximal exercise capacity, which measures how far a person can walk over 6 minutes (6-minute walk distance; 6MWD). Conventionally, the 6MWT involves the participant walking multiple laps of a straight path that is 30 m in length [4]. Track length can influence the results of the 6MWT [5-8], likely due to a difference in the number of 180-degree turns, each necessitating acceleration and deceleration. Standard instructions are given and standard encouragement prompts are provided at preset intervals, as it is known that changes in instructions or encouragement can affect the performance during this test [9,10].

The 6MWT has been used in a range of conditions including chronic heart failure [11], peripheral artery disease [12], and chronic obstructive pulmonary disease [13]. It has also been used for older adults more generally [14]. Within the context of pain conditions, the 6MWT has been used as an outcome measure in both observational studies [15] and clinical trials [16,17]. The average 6MWD for people with persistent pain upon entry into pain programs has been reported to be 389 (SD 94) m [18] or 427 (SD 127) m [19]. In comparison, the reference values of the 6MWD for healthy men and women aged between 50 and 60 years are approximately 578 m and 534 m, respectively [20].

The minimum clinically important difference (MCID) for the 6MWD has been estimated for various conditions: 25 to 80 m in people with chronic obstructive pulmonary disease [21-23]; 22 to 42 m in people with lung cancer [24]; 33 m in people with pulmonary arterial hypertension [25]; 36 m in people with chronic heart failure [26]; 25 m in people with coronary artery disease [27]; and 18 m in older adults at risk of falls [28]. However, estimates in the population with persistent pain are less well defined, with different studies providing a range of estimates from a distance between 15 m and 30 m used in a clinical trial [16] to a distance between 156 m and 167 m calculated in fibromyalgia (a persistent pain disorder) [29]. Benaim et al [19] used an anchor-based approach to estimate MCID values of 60 m for chronic musculoskeletal pain of the spine and 75 m for chronic musculoskeletal pain of the lower limb. On the other hand, a recent study was unable to calculate an MCID in people with persistent pain undergoing a pain rehabilitation program due to a lack of correlation between the 6MWD and patient-reported outcome measures [18]. Therefore, further studies are needed to determine a more precise and consistent estimate of MCID values for the 6MWD in the population with persistent pain.

The conventional 6MWT is typically performed in a clinic or hospital. However, this is a significant limitation if patients cannot attend the facility due to distance or lack of access to transport. In addition, it can be difficult for some facilities to locate a straight section of corridor that is at least 30 m in length and largely free of obstacles and interruptions from other users of the corridor. The 6MWT can be performed outdoors, as an outdoor 6MWT appears to be comparable to an indoor 6MWT when the standard 30-m track is used [30], although outdoor testing can be limited by weather at the time of the test. The 6MWT can also be conducted at a participant’s residence, but this requires the clinician to travel to the patient, which increases the requirement for staff time and resources. In addition, locating a suitable 30-m track inside a house or in a backyard can be difficult. Holland et al [31] attempted to perform the 6MWT using the longest length of track that was practicable in the home environment but achieved an average track length of just 13 (SD 7) m for indoor tests and 20 (SD 10) m for outdoor tests. As such, the 6MWD estimates obtained from 6MWTs conducted inside or outside a home underestimated the 6MWD by an average of 30 (SD 69) m compared to the standard in-clinic tests using a 30-m track [31]. The variability in track length also contributed to wide limits of agreement (LoAs) between a conventional 6MWT conducted at a hospital and a 6MWT conducted at home (95% LoA 167 m-102 m). Finally, any method of performing the 6MWT that requires a clinician to assess the participant in person may be precluded if in-person contact needs to be limited, such as occurred worldwide during the COVID-19 pandemic. This has highlighted the need for alternative methods of performing the 6MWT.

Performing the 6MWT remotely would eliminate the problems associated with travel or in-person contact. Several studies have reported the use of accelerometers in smartphones or consumer-level wearable activity monitors to perform 6MWTs by detecting the number of steps or number of turns [32-38]. For instance, in a study conducted among healthy adults, the mean difference between accelerometer-based measurement and simultaneous clinician observation of a conventional 6MWT was 0, although the SD was 42 m [32]. However, this has not been replicated in clinical populations, and the app is not publicly available. Other accelerometer studies required their participants to use a holster or harness to affix their smartphone to a specific location on their body [38] or to wear a wrist-worn activity tracking device [33], both of which are potential barriers...
to use or uptake in a home environment. Furthermore, the 6MWT assessed via an app would ideally be undertaken on a 30-m-long track to best replicate the clinical setting, but it is unlikely that people with persistent pain would have access to such a length of track or the equipment to precisely measure its length in the home environment.

A potential solution to these issues could be to use GPS to measure the walking distance [39]. Modern smartphones include GPS receivers, and GPS-based walk tests can be conducted during an outdoor walk over level terrain (given this walk is free from the obstructions of tall buildings and does not involve many sharp turns). Although changing the 6MWT from the conventional shuttle to a continuous walk introduces some bias due to the removal of acceleration and deceleration when turning around, this might be less than the bias that would occur from using very short track lengths. For instance, in a population with respiratory problems, when compared to a 6MWT performed on a 30-m shuttle track, a 6MWT performed on a continuous circular track of 40-m circumference overestimates the 6MWD by 3% [40], but decreasing a shuttle track to 10 m underestimates the 6MWD by approximately 9% to 10% [8]. Furthermore, it may be possible to use an algorithm to compensate for the overestimation associated with continuous walking if it is consistent, but this is unlikely for the variable error that is associated with using tracks of varying and imprecisely measured lengths in a home environment.

Salvi et al [36] recently developed an app, called Timed Walk, which could use either an indoor algorithm using smartphone sensors or an outdoor algorithm using GPS. To the best of our knowledge, this is the only purpose-built app for conducting a 6MWT that is available on both Android and Apple iOS smartphones and the only app that uses GPS. This app has been tested in a population with pulmonary arterial hypertension in 2 studies that estimated the bias (the average difference between the app’s measurement and a reference) and the variability of the differences (given as SD of the differences). In the first study, Salvi et al [36] used a distance wheel as the reference measurement and found a larger bias but smaller variability when using the indoor algorithm (mean −2.0, SD 7.8 m) than when using the outdoor algorithm (mean −0.80, SD 18.6 m). However, in their later pilot trial, the indoor algorithm differed by 14.6 (SD 75) m when compared to the simultaneous performance of a conventional 6MWT in a clinic. This difference and SD is greater than that of the outdoor algorithm (mean 2.5, SD 47 m) compared to a clinic-based test performed within a 7-day period (before or after) [41]. The authors believe that much of this variation can be attributed to the app being used incorrectly, such as using the outdoor test on a tightly curved path. However, these studies compared the outdoor GPS mode of the app to a distance wheel [36] or to a conventional 6MWT performed within a 7-day period (before or after) [41]. Thus, interday variation in submaximal exercise capacity could also have contributed to the variation between these measurements. A comparison between the GPS-based test function of this app and a conventional 6MWT performed on the same day has not been attempted. In addition, this app has not been validated in the population with persistent pain.

**Aims and Hypothesis**

The primary aim of this study was to evaluate the concurrent validity of the GPS-based 6MWT using the Timed Walk smartphone app in an outdoor setting and conducted on the same day as the conventional 6MWT using a 30-m straight path. The secondary aim of this study was to estimate the difference between the pain evoked by the 2 test methods.

It was hypothesized that the agreement between the results of the 2 methods will be within the nominated maximum allowable difference and that the 2 methods will demonstrate an excellent level of correlation.

**Methods**

This was an observational study comparing 2 methods of estimating the 6MWD: a conventional 6MWT with a clinician and a 6MWT using a smartphone app with GPS.

**Participants**

The sample comprised a combination of participants recruited from 2 sources, to ensure a broad sample of people with persistent pain. The first recruitment method involved outpatients from a persistent pain clinic located in a large, tertiary public hospital in Australia. Potential participants were invited to participate in the study by their treating clinician. The second method of recruitment involved advertising the study via social media (Facebook and Twitter).

Participants were screened via an in-person or telephone conversation with a member of the research team. Individuals were eligible for inclusion if they were aged >18 years, had persistent pain (>9 months in duration), claimed that they were able to walk at least 100 m on flat ground, and owned a compatible smartphone on which they were willing to install the Timed Walk app. Individuals were excluded from participating if they had comorbidities impacting their ability to walk on flat ground (and did not have medical clearance to participate), were unable to speak English, or did not possess a compatible smartphone.

**Data Collection**

Participants performed 2 6MWTs: one in the conventional manner with a clinician and another with the Timed Walk app (version 0.2.0 or 0.3.0, depending on the date of the test).

The app test was conducted outdoors to use the GPS signal. Participants were instructed to walk either in a circuit around the paths of a local park or around the perimeter of a hockey playing field for the app test. Care was taken to select a mostly level path and to avoid sharp turns. As walking alongside a researcher walking at a comfortable distance behind each participant to provide supervision. The Timed Walk app automatically announced the standard encouragement prompts at appropriate times.

The 6MWT assessed in the conventional manner was completed in accordance with existing guidelines [4], using a straight track of 30 m in length, with the ends of the track marked with cones and the starting line marked with a clearly visible line on the
ground. A researcher (JS) conducted all the tests and provided the standard encouragement prompts.

For practical reasons and to minimize differences between the testing methods, the conventional 6MWT was also conducted outdoors at the same location as the GPS test. Outdoor testing has been shown to be no different to indoor testing in individuals with pulmonary disease [30]. Outdoor testing was only performed when weather conditions were mild (temperature of 10 °C-30 °C, no rain, and wind speed <20 km/h).

To account for potential fatigue or learning effects, the sequence in which the participants performed each form of the 6MWT was randomized on the day of testing. Urn design randomization was used [43]. Participants were randomized using a simulated urn initially containing 2 balls, with 1 ball representing each test method. After drawing a ball to allocate each participant to their starting test method, the ball was returned to the urn and an additional ball added for the opposite test method. To further minimize the effect of fatigue, participants were rested in a shaded location for 15 minutes between tests. Participants were instructed to wear comfortable clothing and appropriate footwear, to be well hydrated (and bring a water bottle), and to not perform any vigorous exercise 2 hours before and after the test.

Neither the participants nor the researcher performing the conventional 6MWT were blinded to the study hypothesis or to the methods of assessment being received.

**Outcome Measures**

The primary outcome of this study was the 95% LoAs between conventionally measured and GPS-measured 6MWD.

Secondary outcomes included the following: (1) the intraclass correlation coefficient (ICC) between the conventionally measured and GPS-based 6MWD and (2) the difference between the change in pain for the 2 types of 6MWTs. Pain intensity data were collected at four time points: (1) immediately before the first 6MWT, (2) immediately after the first 6MWT, (3) immediately before the second 6MWT, and (4) immediately after the second 6MWT. Pain was assessed on an 11-point numerical rating scale (NRS), verbally delivered to the participant at the abovementioned time points. This scale ranged from 0 (indicating no pain at all) to 10 (indicating pain as bad as it could be or worst pain).

Additional demographic data collected included participant age, gender, employment status, primary diagnosis (including pain source or body region), and years since diagnosis of the persistent pain condition. These data were collected using a paper-based questionnaire on the day of testing.

**Statistical Analysis**

The Bland-Altman method of analysis was used to estimate the 95% LoAs between the conventionally measured and GPS-measured 6MWD. The exact parametric 95% CIs for the upper and lower limits of the 95% LoAs, considered together as pairs, were calculated using the methods proposed by Carkeet [44]. The maximum allowable difference between measures was set at 100 m, approximately in between the 60-m to 75-m site undergoing occupational rehabilitation [19] and 156-m to 167-m MCID in people with fibromyalgia [29].

Outliers were excluded from the analysis if the difference between the 2 test methods was >3 SDs from the mean difference.

Assumptions of normality and homoscedasticity were assessed through visual inspection of quantile-quantile plots and residual plots. The ICC was calculated using a 2-way random-effects model for both absolute agreement and consistency, with values >0.8 considered to be good and those >0.9 considered to be excellent. The difference between the mean change in pain due to each test was presented with paired-sample CIs.

Several exploratory analyses that were not initially planned were conducted after the results for the main outcome measures were inspected. The exploratory analysis of the variance between recruitment groups was conducted using an F test. Welch 2-sample CIs were used for the exploratory comparisons between the 2 smartphone operating systems (Android and iOS) and the 2 sequences in which the tests were conducted (in-person test conducted first and app test conducted first). Paired-sample CIs were used to present the results of an exploratory comparison between pain at the start of the first test and pain at the start of the second test.

**Sample Size and Power**

The sample size required for the Bland-Altman analysis was calculated using the method outlined by Shieh [46]. A difference of 2.5 m was used for this calculation, based on a study comparing an unsupervised test using the GPS-based Timed Walk app performed at home and a clinic-based test conducted within a 7-day period (before or after) [41]. However, with the assumption that the tests performed on the same day and under supervision would result in slightly less variability, sample size calculation assumed an SD of 40 m rather than the previously reported value of 47 m. The maximum allowable difference between measures was set at 100 m as previously stated. Additional assumptions include the following: 90% power, α of .05, and a null central portion of 0.95 (ie, 95% of measurements lie between the 100-m maximum allowable difference boundaries). This calculation resulted in a requirement for 34 participants, which was increased to 38 participants to account for potential dropouts.

**Ethical Considerations**

All participants were provided with a participant information sheet that explained the study, and they provided their written consent to participate. Participants were compensated with a voucher worth Aus $20 (US $14-15) for their time and travel expenses. All data were deidentified. The study was approved by the Royal Brisbane and Women’s Hospital Human Research Ethics Committee (reference number HREC/2021/QRBW/75331) and ratified by the University of...
Queensland Human Research Ethics Committee (reference number 2021/HE001471).

Results

Sample Description

A total of 38 participants (n=17, 45% from the community and n=21, 55% from the outpatient pain clinic) were eligible and consented to participate. Of the 38 participants, 1 (3%) withdrew due to illness, 1 (3%) was excluded for no longer meeting the inclusion criteria, and 1 (3%) participant, whose GPS-based 6MWD was 88% more than their conventional 6MWD, was considered as an outlier and excluded from the analysis. The first participant was tested on October 27, 2021, and the final participant was tested on August 27, 2022 (reflecting issues with recruitment during the COVID-19 pandemic). A full description of the final sample of participants (N=35) is presented in Table 1.

After randomization, of the 35 participants, 17 (49%) participants performed the GPS-based 6MWT first and the conventional 6MWT second and the remaining 18 (51%) participants performed the tests in the reverse order. The results for the 2 types of 6MWTs, according to the order of the tests, are presented in Table 2.

Concurrent Validity

The mean 6MWD measured by the GPS-based smartphone app was 13.2 m (SD 46 m; 95% CI −2.7 to 29.1) higher than the 6MWD assessed in the conventional manner. The 95% LoAs were 103.9 (95% CI 87.4-134.1) m and −77.6 (95% CI −107.7 to −61.0) m, which are not entirely within the maximum allowable difference of 100 m. A Bland-Altman plot is presented as Figure 1. As the distribution of the differences was leptokurtotic (an excess kurtosis of 2.2), an alternative, nonparametric Bland-Altman approach was applied, which yielded a median difference of 25.1 m and 95% LoAs (at the 2.5% and 97.5% quantiles) of −86.9 m and 76.4 m.
The ICC for agreement (2-way random-effects model) between the 2 6MWTs was 0.94 (95% CI 0.88-0.97) and the ICC for consistency (2-way random-effects model) was 0.94 (95% CI 0.89-0.97), both of which indicate good to excellent agreement.

The average of the two 6MWD measurements differed based on recruitment source, with those recruited from the community having a higher 6MWD (527 m, 95% CI 489-564) compared to those recruited from the outpatient clinic (368 m, 95% CI 304-431). The mean difference between the two 6MWD measurements also differed based on recruitment source, with outpatient measurements only differing by –4 m (95% CI –30 to 23) compared to a much higher difference of 33 m (95% CI 22-44) in the community sample. The apparent trend of overestimation by the GPS-based 6MWT relative to the conventional 6MWT with increased walking distance seems to be attributable to participants from the community displaying greater values than outpatients for both the average 6MWD and the difference between GPS-based and conventional 6MWD measurements (Multimedia Appendix 1). An exploratory comparison suggests that the difference between the two 6MWTs in the outpatient sample had a variance that was 6.5 (95% CI 2.3-17.4) times higher than the variance in the community sample (3009 m$^2$ vs 461 m$^2$).

In addition, an exploratory comparison found that the mean difference between the two 6MWT methods (GPS 6MWD minus conventional 6MWD) was 34.9 m (95% CI –5.29 to 75.2) greater when Android smartphones were used compared to that when Apple smartphones were used. The difference in 6MWDs when the GPS-based 6MWT was performed on Android smartphones was 34.2 (SD 61.6) m, whereas the difference in 6MWDs when the app test was performed on Apple smartphones was –10.8 (SD 57) m.
Another exploratory comparison suggests that the order in which the 2 tests were conducted has no clear effect on the difference between the tests. The mean difference between the two 6MWT methods (GPS 6MWD minus conventional 6MWD) when the GPS-based 6MWT was conducted first was 13.4 (SD 45.5) m, and the difference between the methods when the conventional 6MWT was performed first was 13.0 (SD 48.4) m. Therefore, when the app 6MWT was performed first, the mean difference between the tests was increased by 0.3 m (95% CI –31.9 to 32.6) versus when the conventional 6MWT was performed first.

**Change in Pain**

Pain increased in the conventional walk test by 1.1 (SD 1) points, whereas pain increased in the app test by 0.8 (SD 1.4) points. The conventional walk test produced a change in pain score that was 0.26 (95% CI –0.20 to 0.73) points higher than that produced by the app test.

An exploratory comparison suggests a statistically significant difference between pain at the start of the first test compared to pain at the start of the second test (t_{34}=2.969; P=.005). The pain rating before the first test averaged 4.1 (SD 2.5) points, and the pain rating before the second test (after the rest period) averaged 4.7 (SD 2.6) points. On average, pain at the beginning of the second test was 0.57 (95% CI 0.18-0.96) points higher than pain at the beginning of the first test. However, the median difference in pain was 0 (range –1 to 4) points. Approximately half (17/35, 49%) of the participants reported a pain level at the start of the second test that was identical to the level reported at the start of the first test. Figure 2 illustrates the distribution of individual differences between pain ratings at the start of each test.

**Discussion**

**Principal Findings**

This study investigated the validity of a GPS-based 6MWT smartphone app (Timed Walk) compared to that of the conventional method of conducting a 6MWT in people with persistent pain. To the best of our knowledge, this is also the first study to compare the Timed Walk app to a conventional 6MWT conducted on the same day in any population.

Participants walked an average of 433.6 (SD 129.9) m during the conventional 6MWT, which is typical of people with persistent pain [15,19,47]. The mean pain score at baseline for
participants of this study was 4.1 (SD 2.6), which is moderately lower than the averages of 6.0 and 6.4 noted during enrollment into a pain program in the literature [15,47]. This is likely due to our inclusion of participants from the community, who would be expected to have lower pain scores than those enrolled in a rehabilitation program. However, the baseline pain scores of the outpatients included in this study was 5.2 (SD 2.5), which is more consistent with previous estimates. Therefore, we can still be confident that the study sample was representative of people with persistent pain.

The results of the Bland-Altman analysis indicated uncertainty about the agreement between the 2 methods of measuring 6MWD. The 95% LoAs were 103.9 (95% CI 87.4-134.1) m and −77.6 (95% CI −107.7 to −61.0) m. These CIs are consistent with LoAs that are fully outside or within our a priori 100-m maximum allowable difference. Therefore, there is uncertainty about whether 95% of the differences will lie within this 100-m threshold. These LoAs are also larger than the estimated MCID in the 6MWT for chronic musculoskeletal pain, which is estimated to be 60 m for chronic musculoskeletal pain of the spine and 75 m for chronic musculoskeletal pain of the lower limb [19], but are within the much larger MCID estimate range of 156 m to 167 m for fibromyalgia [29]. Therefore, agreement between methods might not be sufficient for clinicians to use these two 6MWT methods interchangeably and still be able to reliably detect clinically important differences in the 6MWD for people with chronic pain of the limbs and spine. It is possible that the level of agreement is sufficient to detect clinically significant differences in people with fibromyalgia; however, this study was not performed specifically among people with fibromyalgia.

There are several potential reasons for differences between the two 6MWD measurements. First, the tests differed in how they were conducted, with one using a 30-m shuttle track and the other using various circuits around a public park. The GPS-based 6MWT involved fewer and more gradual turns, without the requirement to decelerate and accelerate with short turns on a shuttle track. Previous studies have demonstrated that continuous (circular or rectangular) tracks result in 6MWD estimates that are 3% to 10% higher than those obtained from a straight shuttle track [7,40,48]. Therefore, this is a likely explanation for the observed 6MWD derived from the Timed Walk app in this study being 13.2 m (95% CI −2.7 to 29.1) higher than that obtained from the conventional 6MWT—approximately a 3% increase. However, the CIs for the mean difference in the 6MWD between tests are wide enough to include both the possibility of no difference between the tests and a difference as large as approximately 30 m or approximately 7% of the total 6MWD. The 2 tests also differed in how encouragement phrases were delivered—by a researcher or through audio from the smartphone app—which could also impact walking distance. In addition, although the 30-m track was consistent for all conventional 6MWTs, the exact walking route used for the GPS-based 6MWT for each participant varied in terms of potentially influential factors such as the number of turns, radius of turns, and number of laps performed. It is possible that differences in the walking routes used could also partially explain the variability between the 2 tests.

Second, the tests differed in how they were measured, which could have introduced errors that could be observed as either systemic bias or as variability in the results. Inaccuracy of measurement in the conventional 6MWT might occur due to inaccurate measurement of the length of the track (or partial final lap), the participant not being able to stop instantly at 6 minutes, and the participant deviating from the track during walking or making wider turns around the markers. Although none of these issues are present for the GPS method of measurement, other sources of inaccuracy likely exist. In their initial 30 tests with 8 different smartphones, Salvi et al [36] compared the GPS-based algorithm of the Timed Walk app to a simultaneous measurement of distance with a trundle wheel, thereby eliminating variability between separate walking tests. Although the mean difference between those 2 measurements was minimal at 0.8 m, the SD was 18.6 m (or approximately 4.2% of the mean 6MWD of 438 m). As the Bland-Altman method calculates 95% LoAs as 1.96 SDs from the mean, approximately 36-m wide 95% LoAs (or 8.4% of the 6MWD) might be expected based on measurement error alone. This measurement error could be related to a poor-quality GPS signal (due to tree coverage or cloud cover), inaccurate GPS receivers in smartphones, and issues with the app’s algorithm. GPS accuracy is typically assessed in a static (nonmoving) condition or while driving [49,50], both of which differ significantly from a walking test. The accuracy of GPS measurements in the context of a dynamic, real-world activity such as walking is influenced by various factors, including signal processing and filtering algorithms specific to each app. Some previous studies suggest that the GPS receivers have different levels of accuracy across different models of smartphones [51]. The difference we observed between Android and Apple smartphones suggests some role for the hardware or operating system, which, as participants’ devices were effectively random, could introduce an additional source of variability.

Conducting 2 separate walking tests introduces an additional source of variability due to normal human variability in walking speed, in addition to the measurement error discussed previously. The conventional 6MWT, when performed 1 week apart, has a minimum detectable change (at 95% confidence) of 86 m in people with persistent pain [18] and from 50 m to 80 m in adults aged >60 years [52]. The minimum detectable change at 95% confidence is equivalent to the difference between the 95% LoA and the mean difference [53,54]. This suggests that the conventional method of assessing a 6MWT is only barely able to reliably detect a change of the same magnitude as our nominated 100-m maximum allowable difference. The test-retest reliability of the Timed Walk app has only been reported once in the literature. Salvi et al [41] have reported data about the test-retest reliability of the Timed Walk app in pulmonary hypertension, based on 89 pairs of outdoor tests performed 7 days apart in 10 patients. That study also reported a mean difference of 1.8 m (0.7% of the 6MWD) and an SD of 37 m (or 10.1% of the 6MWD) between pairs of GPS-based 6MWTs, giving a 95% LoA of approximately 74 m on either side of the mean. Therefore, this evidence suggests that it can be difficult to reliably detect a change of 100 m between two 6MWTs, even when both 6MWTs are conducted

https://formative.jmir.org/2024/1/e46820  JMIR Form Res 2024 | vol. 8 | e46820 | p.1341 (page number not for citation purposes)
using the same methods (either the conventional method or the GPS-based method).

Finally, there could be some effect of the first test on the results of the second test. For instance, performance might have decreased during the second test due to the provocation of fatigue or pain. Although a 15-minute rest period is sufficient for people with cardiac disease to recover from fatigue induced by walking [55], this may not be the case for recovery from pain. We found that some (15/35, 43%) of participants reported higher pain scores at the start of their second test than at the start of their first test. This residual pain could have altered their performance during the second test, as pain can increase the energy cost of walking [56,57]. On the other hand, a learning or practice effect whereby 6MWD increases for a second 6MWT conducted on the same day has been demonstrated in several studies in healthy adults [58,59] and people with respiratory disease [60] and chronic heart failure [61]. This learning effect may be due to decreased anxiety (more willingness to walk faster if they see that it does not provoke as much pain or fatigue) or improvements in technique (optimum stride length or pacing) during subsequent tests [4]. In addition, a learning effect may still occur regardless of the rest period between tests conducted on the same day. As the order in which the 2 tests were conducted was randomized in this study, any effect of test order would manifest as variance in the difference between the 2 methods. However, when the difference between 6MWD measurements was compared between the subgroup randomized to perform the app test first versus the subgroup performing the app test second, there was no clear evidence of a difference. As the 2 walk tests investigated in this study were very dissimilar, a learning effect may have been less likely to occur. Alternatively, a learning effect could have been countered by an approximately equal and opposite effect of pain or fatigue. Interestingly, the greater variability between the 2 tests seen in the outpatient subsample, who also had higher pain scores and more widespread pain than the community subsample, may also suggest that those who are experiencing greater pain have more variable walking speeds in general. This could be related to spatiotemporal gait mechanics, which are known to be affected by pain conditions [62,63].

Validity, as assessed by the ICC for agreement (2-way random-effects model) between the 2 6MWTs, was good to excellent at 0.94 (95% CI 0.88-0.97), suggesting that approximately 12% of the variation between the 2 measurements is due to bias or error. ICC for consistency was also good to excellent at 0.94 (95% CI 0.89-0.97). The near equality of these ICC values indicates that the validity is mostly being affected by random error rather than systemic error (bias). Despite the variability introduced by the previously mentioned differences between the GPS-based and conventional 6MWTs, the ICC for agreement in this study is similar to previously reported ICC values (agreement) of 0.91 and 0.92 for the test-retest reliability (with 1 day or 7 days between tests) of the conventional 6MWT in fibromyalgia [64,65]. Similarly, it is comparable to the ICC of 0.91 reported by Salvi et al [41] for the test-retest reliability of the Timed Walk app in pulmonary hypertension, based on 89 pairs of outdoor tests performed 7 days apart in 10 patients.

Pain

Secondarily, the study also compared the 2 methods to examine the differences in the degree of pain evoked by the test. Pain increased by approximately 1 point on NRS in both tests. Therefore, there is no indication of any additional advantage or disadvantage to either method with respect to pain provocation. However, this sample comprised people with a variety of different pain conditions. It is possible that a population with only hip or knee pain would have experienced a difference between the 2 tests, perhaps due to the increased frequency of turning in the conventional 6MWT. Moreover, pain was only assessed immediately after the walking tests, and both tests were completed 15 minutes apart; therefore, potential differences in pain experienced in the hours or days after the tests are beyond the scope of this study.

Strengths and Limitations

This study compared Timed Walk against a conventional 6MWT on the same day. People with persistent pain can have variability in day-to-day pain [66,67], which may result in variations in walking speed. Conducting the tests 15 minutes apart removed this source of variability. However, the pain caused by the first 6MWT was clearly still a factor during the second 6MWT for some individuals. It is unclear whether extending the rest period to 30 minutes or an hour would have been sufficient for this pain to resolve completely. Moreover, only pain intensity was assessed and not the quality of the pain. Recording descriptors of the quality of pain (such as sharp, dull, throbbing, or aching) or assessing pain-related fear of movement might have provided deeper insights into why some participants with significant pain increases did not exhibit changes in walking distance but others did.

The study used the Timed Walk app on participant’s own smartphones. Similarly, this study used a wide variety of heterogeneous walking tracks on grass or paved surfaces at a local park, with this heterogeneity precluding any analysis of the effect of walking track on the results. Although the observed agreement between methods may have been higher if a single smartphone and a set walking track were used consistently for all GPS-based walking tests, the results of this study have more practical relevance to people using their own smartphone in real-world environments. Similarly, as GPS is reported to have issues in measuring distances around sharp corners, a linear track for GPS may have been a more accurate measure of distance walked but would have been practically more difficult for participants to replicate at home and thus would be of less practical relevance.

This study calculated the 95% LoAs and their CIs under the assumption that the data were normally distributed. However, due to noticeable kurtosis (excess kurtosis of 2.2), the calculated 95% LoAs may be a slight overestimate. Although a nonparametric approach found that the 2.5% and 97.5% quantiles of the sample fell just within the nominated maximum allowable difference, it did not provide CIs to represent the uncertainty in the 95% LoAs. To obtain these CIs, the data could have been transformed to better approximate a normal distribution, or a bootstrap approach could have been used. However, regardless of the approach used, it is likely that the
95% LoAs or the associated CIs would be outside the maximum allowable difference.

The maximum allowable difference nominated in this study was selected in the absence of clearly established values for clinically relevant differences in the 6MWT in persistent pain conditions. A value of 100 m was selected as a compromise between the existing MCID estimates for the 6MWT in people with chronic pain of the back and lower limbs (60 m and 75 m, respectively) [19] and in those with fibromyalgia (which range from 156 to 167 m) [29]. The lack of knowledge about clinically acceptable differences for the 6MWT significantly limits the interpretation of the Bland-Altman analysis.

Implications for Future Studies and Clinical Practice

Future studies are required to develop more accurate methods for remotely performing the 6MWT in populations with chronic disease including persistent pain. This may involve accelerometer-based methods, GPS-based methods, or a combination of both. Future updates to the Timed Walk app will require reassessment of concurrent validity. In addition, future studies could further elucidate the sources of variability between the GPS-based 6MWT and conventional 6MWT. This could entail performing a GPS-based 6MWT with the additional use of a trundle wheel as a third measurement of the 6MWD, simultaneous measurements derived from multiple smartphones from various manufacturers, and a systematic comparison of specific walking tracks. It may also be wise for future research studies to ensure that participants unfamiliar with the 6MWT are given a practice test to minimize the potential learning effect. Finally, more research is needed to establish a more precise estimate of the MCID in persistent pain to allow for future studies to better define the maximum allowable difference between 6MWT methods.

As both tests in this study were performed under supervision, future investigations should consider the effect of unsupervised use of the GPS-based 6MWT app. Tests that are self-administered may be even more variable if care is not taken to avoid sharp turns, tall buildings, uneven terrain, or inconsistencies in weather conditions. Future studies are also required to investigate whether the test-retest reliability of the GPS-based 6MWT, when used unsupervised in people with persistent pain, is sufficient for use as a tool for remote monitoring. It is feasible that the imprecision in the estimates from the GPS-based app may be less of an issue if testing is conducted more frequently, as the average of a series of tests may provide a more stable estimate of the participant’s functional status over time.

Although conventional and GPS-based 6MWT methods do not demonstrate sufficient agreement to be used interchangeably in people with persistent pain, the ability to perform the test remotely using the GPS-based app may still have benefits in a clinical context. The ability for patients to perform the GPS-based assessment at home without the need for a clinician’s presence may increase patient autonomy and reduce the burden of frequent clinic visits. In addition, for individuals who are unable to regularly attend in-clinic evaluations, obtaining an approximate measurement of functional capacity more frequently via a GPS-based 6MWT may still be clinically useful, even if the estimate is imprecise, as it provides some information, which is better than a complete lack of data. GPS-based measurements may also offer more ecologically relevant assessments of functional capacity than in-clinic testing, better reflecting a patient’s natural walking abilities and providing an opportunity for training walking capacity in the patient’s everyday environment. Overall, although the in-clinic standard 6MWT performed by experienced personnel remains as the gold standard, the GPS-based app may still be considered as a complementary tool.

Conclusions

This study demonstrated that the concurrent validity between the GPS-based 6MWT using the Timed Walk app and the conventional 6MWT may not be sufficient for the 2 methods to be used interchangeably in people with persistent pain while still being able to detect clinically significant differences in the 6MWD. Despite limited validity, the GPS-based 6MWT may still have clinical application as a complementary tool to the conventional 6MWT performed in the clinic, especially for remote monitoring. In addition, the GPS-based 6MWT makes it possible to conduct more frequent assessments of functional capacity, which are self-measured without the presence of a clinician and conducted in a more ecologically relevant environment. Future studies are needed to improve the accuracy of the GPS-based 6MWT for remote monitoring.

Acknowledgments

The authors would like to thank the participants for their participation in this study. In addition, the authors would like to thank D Salvi for answering their questions regarding previous investigations of the Timed Walk mobile app. Finally, the authors acknowledge the use of ChatGPT (version 3.5; OpenAI; February 2023) as a writing assistant, specifically for rephrasing and summarizing content.

Data Availability

The data sets generated during and analyzed in this study are not publicly available due to lack of ethical clearance to disclose data to third parties.

Abstract

Background: Advances in health have highlighted the need to implement technologies as a fundamental part of the diagnosis, treatment, and recovery of patients at risk of or with health alterations. For this purpose, digital platforms have demonstrated their applicability in the identification of care needs. Nursing is a fundamental component in the care of patients with cardiovascular disorders and plays a crucial role in diagnosing human responses to these health conditions. Consequently, the validation of nursing diagnoses through ongoing research processes has become a necessity that can significantly impact both patients and health care professionals.

Objective: We aimed to describe the process of developing a mobile app to validate the nursing diagnosis “intolerance to physical activity” in patients with acute myocardial infarction.

Methods: We describe the development and pilot-testing of a mobile system to support data collection for validating the nursing diagnosis of activity intolerance. This was a descriptive study conducted with 11 adults (aged ≥18 years) who attended a health institution for highly complex needs with a suspected diagnosis of coronary syndrome between August and September 2019 in Floridablanca, Colombia. An app for the clinical validation of activity intolerance (North American Nursing Diagnosis Association [NANDA] code 00092) in patients with acute coronary syndrome was developed in two steps: (1) operationalization of the nursing diagnosis and (2) the app development process, which included an evaluation of the initial requirements, development and digitization of the forms, and a pilot test. The agreement level between the 2 evaluating nurses was evaluated with the κ index.

Results: We developed a form that included sociodemographic data, hospital admission data, medical history, current pharmacological treatment, and thrombolysis in myocardial infarction risk score (TIMI-RS) and GRACE (Global Registry of Acute Coronary Events) scores. To identify the defining characteristics, we included official guidelines, physiological measurements, and scales such as the Piper fatigue scale and Borg scale. Participants in the pilot test (n=11) had an average age of 63.2 (SD 4.0) years and were 82% (9/11) men; 18% (2/11) had incomplete primary schooling. The agreement between the evaluators was approximately 80% for most of the defining characteristics. The most prevalent characteristics were exercise discomfort (10/11, 91%), weakness (7/11, 64%), dyspnea (3/11, 27%), abnormal heart rate in response to exercise (2/10, 20%), electrocardiogram abnormalities (1/10, 9%), and abnormal blood pressure in response to activity (1/10, 10%).

Conclusions: We developed a mobile app for validating the diagnosis of “activity intolerance.” Its use will guarantee not only optimal data collection, minimizing errors to perform validation, but will also allow the identification of individual care needs.
Introduction

In recent decades, the ability to produce, collect, and communicate data around the world has increased exponentially with access to technologies such as smartphones. These technologies have improved data storage as well as its handling and analysis [1]. In the field of health, electronic record systems facilitate data collection that can be used for various purposes, allowing data retrieval that promotes the improvement of research processes such as identification and recruitment of patients for clinical projects [2,3].

In addition to obtaining individual data from each patient, the collection of large amounts of data can be useful to obtain information that more effectively supports the exploration of diseases, treatment, and rehabilitation. This creates the need to develop research platforms that optimize the capacity to conduct informative and innovative research and enable scientific approaches where objective data can be obtained with a minimum of errors and expended resources [4].

As part of the health staff providing care to cardiovascular patients, nurses can be the first to identify individual needs. To aid this, tools are available such as the NANDA (North American Nursing Diagnosis Association) taxonomy, which identifies the response of a person, family, or community to real health problems and potential vital processes. However, these diagnoses and their respective defining characteristics must be validated according to the context where they will be assessed, which constitutes a challenge in research into the use, implementation, and dissemination of technologies of information [5-7]. For this purpose, the use of digital platforms has demonstrated its applicability from the early stages of research, such as the assessment of care needs [8,9].

Mobile apps in health, education, and work in Colombia are applications of medical informatics apps; mobile app; mobile applications; nursing diagnosis; nursing research; research data; software; validation

Methods

Overview

This was a descriptive study conducted with 11 adults (aged ≥18 years) with a suspected diagnosis of coronary syndrome who attended a health institution for highly complex needs between August and September 2019 in Floridablanca, Colombia. An app for clinical validation of the “activity intolerance” diagnosis (NANDA code 00092) in patients with acute coronary syndrome was developed in three steps, outlined in the following sections.

Step 1: Operationalization of the Nursing Diagnosis

The first step consisted in the operationalization of the defining characteristics of the nursing diagnosis [11] of activity intolerance (NANDA code 00092), defined by NANDA-I [6] as “the lack of sufficient physiological or psychological energy to tolerate or complete the required or desired daily activities.” This diagnosis is categorized as “Domain 4: Activity / Rest, Class 4: Cardiovascular / pulmonary responses Need: Move and Pattern Activity-exercise.” It is also related to an imbalance between oxygen supply and demand, a sedentary lifestyle, immobility, and bed rest; it has defined characteristics [12].

Through an extensive search of the literature, we selected scales or instruments to standardize the measurement of each defining characteristic of this nursing diagnosis [11]. An interdisciplinary group that included 2 nurses, an epidemiologist, and a cardiologist verified the face validity of the operationalization.

Step 2: App Development Process

Initial Requirements Evaluation

Health professionals, along with a systems engineer, carried out the structural design of the data collection forms or case report forms. The digitization process was carried out using CommCare [7], which is an open source, cloud-based platform that helps researchers develop data capture tools using mobile devices. An open source tool was also used to create an Android-based mobile app for a low-income setting. Mobile apps can be used as a tool to track beneficiaries through a service lifecycle and can also streamline data collection [13]. Our app used the HTTPS protocol, which made it cryptographically secure. Access to data was password protected. The CommCare [7] platform was selected because it has been widely used for health projects all over the world and because of its ease of use and compatibility with older versions of Android. CommCare is a platform that works on Android mobile phones from version 2.3, but the platform recommends reviewing the documentation for these older versions because they may have limitations in terms of functionality and compatibility with the latest features developed by CommCare, so it is recommended to have at least Android version 4.0.3 or later, a storage space of at least 100MB.
a minimum of 1GB of RAM, and a processor with at least 2 cores for a better user experience.

Finally, we did not use any programming language because we used a platform that prevents us from reaching that level. We worked directly with CommCare, which allowed us to create data collection applications without touching or programming source code (Figure 1).

CommCare requires the use of a password to access the app and the data stored on the platform. This helps to ensure that only authorized users can access information. The platform uses the secure HTTPS communications protocol, uses role-based access, and is in compliance with data security regulations and standards such as the European Union’s General Data Protection Regulation (GDPR). This ensures that the platform follows good practices in terms of privacy and personal data protection.

Figure 1. Commcare platform design.

Development and Digitization of the Forms
The principles of the Scrum methodology for agile software development were applied. This is a regularly applied process that includes a set of best practices to work collaboratively in teams and obtain the best possible outcome of projects. It is characterized by a strategy of incremental development, boosting the quality of the result by getting to know people in self-organized teams and matching the different phases of development, rather than doing one after the other in a sequential or cascading cycle [14]. Through this methodology, an app was developed to gather data. This phase included the following six steps: (1) specifying the forms to be digitized, which contained the questions or variables to be obtained in the field; (2) dividing the various sections of the form into smaller subforms, depending on the size of the questionnaire or the time of application; (3) defining the variables as the simple question-and-answer type or as more complex ones containing calculations, depending on others, or having a different logical flow; (4) building the form on the CommCare platform; (5) generating app versions (eg, test versions); and (6) testing the app with health professionals who simulated data from possible patients and followed the flow of questions within the app to check if the different flows worked correctly; if errors or possible improvements were found during the process, the entire procedure was repeated from step 4.

Ethical Considerations
The Ethics Committee of Universidad Cooperativa de Colombia thoroughly reviewed and approved the research (report 003; April 16, 2018), as did the Fundación Cardiovascular de Colombia ethics committee (report 450; May 22, 2018). The study was carried out in strict adherence to the established protocol, regulatory requirements, Good Clinical Practice, the Declaration of Helsinki, and the clinical investigation guidelines of Universidad Cooperativa de Colombia. All participants provided their informed consent by signing a form. Participation in this study was entirely voluntary, and no financial compensation or reimbursements were offered to the participants.

The information obtained has been securely stored in the archives of the Universidad Cooperativa de Colombia to safeguard the privacy of individuals. Each patient was assigned a code to ensure that their names or identification did not appear in the database. Access to the collected data was restricted to the researchers, and the data will be used exclusively for the study’s intended purposes. Personal information is being protected in compliance with Colombian Law 1581 of 2012, which pertains to the right of “habeas data.”

Results
After repeatedly performing the entire process and correctly digitizing all the forms proposed in advance, the last version of the app (the production version) was generated. The result of the development process was an app that allowed obtaining information using the forms shown in Table 1.

Table 2 shows the scales and instruments used for the operationalization of the defining characteristics of nursing. The resulting app allowed the simultaneous collection, data entry, and follow-up of patients in different stages of investigation. Two previously trained nurses conducted a pilot test with the first 11 patients included in the research. Taking

https://formative.jmir.org/2024/1/e33868
into account the inclusion and exclusion criteria, a cardiologist selected potential patients. Subsequently, the patient received an explanation of the study; if they agreed to participate, they provided informed written consent. The information was filled out on tablet-type mobile device. Once the data were collected, a process of sending or synchronizing the data with the database in the cloud was carried out, for which it was necessary to have an internet connection (Wi-Fi network).

Later, the systems engineer reviewed the database obtained through the web platform CommCare, which allows downloading information as a flat file or in spreadsheet format. In this way, the research team verified the correct operation of the app and its use in the field, obtaining positive results that allowed the continuity of the investigation with more patients. Figures 2-4 show 3 screenshots of the app.

The pilot test yielded descriptive data (n=11). The participants had an average age of 63.2 (SD 4.0) years, 82% (9/11) were men, and 18% (2/11) had incomplete primary schooling. We found that 64% (7/11) had a history of hypertension and 73% (8/11) had ever smoked. The defining characteristics present in this group of patients were exercise discomfort in 91% (10/11), electrocardiogram abnormalities in 9% (1/10), abnormal heart rate in response to exercise in 20% (2/10), dyspnea in 27% (3/11), weakness in 64% (7/11) and abnormal blood pressure in response to activity in 10% (9/10) (Table 3). The k agreement index ranged from 73% to 100%.

Discussion

Principal Findings

We describe the development process of a mobile app for collecting health research data in an easy, agile, and practical way. This strategy may be used for the complete collection of samples in the process of clinical validation of the nursing diagnosis “activity intolerance.” In addition, a good rate of agreement was found among the evaluators thanks to the standardization used in the app.

In recent years there has been an increase in the use of computer technologies to replace paper records by means of mobile apps, web forms, and specialized software; likewise, it has become evident that these are key tools to improve quality in health care [22]. However, it is still a challenge to continue implementing new strategies, achieve their efficient use by health professionals, and make their implementation easier and more accessible.

This process enabled us to validate the app’s use for identifying prevalent nursing diagnoses, such as activity intolerance, in patients with acute myocardial infarction. Among the 9 defining characteristics we evaluated, there was an agreement of over 80% among the evaluators for 5 of them. This, in turn, helped us identify the most prevalent characteristics, namely dyspnea on exertion and heart rate alteration in response to activity. It is also noteworthy that none of the evaluators identified fatigue in any of the users.

Mobile Apps

We evaluated this strategy for identifying nursing diagnoses that require an objective definition of their characteristics and clinical judgment [23]. The precise operationalization of the defining characteristics through a predefined registry structure, as seen in this mobile app, enhances the precision of nursing diagnoses [1]. In this sense, it enables the evaluation of these characteristics, which can improve documentation for nursing staff, thereby aiding in the inference and evaluation of diagnoses [2]. Therefore, this app aims not only to enhance the quality and safety of care processes but also to promote the adoption of standardized nursing language, addressing the limitations in its use.

Another possible use of this app is in education, where it would potentially help to strengthen the precision of documentation in nursing diagnoses [3]. This strategy is adapted to current conditions, in which the use of virtual methods and mobile technologies has been shown to be a new basic input for the teaching process, making it necessary for professionals and trainers to make an adequate use of this type of strategy.

A relationship where nurse and patient can contribute to improving administrative processes that benefit others has been described in settings such as outpatient care [5]. This is expected to contribute to research scenarios that promote improved caregiving. Apps can assist in the assessment and generation of nursing diagnoses in hospital practice [24], and they have been used in research studies such as clinical trials for the self-management of angina [25].

Limitations

This work was limited to a specific nursing diagnosis. Future work should include other prevalent diagnoses in patients with cardiac disease. An evaluation of usability among end users could help improve our strategy, and more data is also needed to better specify the large-scale feasibility and cost of this strategy with other nursing diagnoses.

Other aspects to improve in the design of future research are to include scales and instruments used in health care to measure different variables. These sources of information should be updated according to the context, clinical conditions, and even environmental conditions. An additional challenge is the integration of these types of apps to existing health systems. A recent review with the objective to provide an overview of studies that have collected patient data using an app-based approach indicated that using mobile technologies could help to overcome challenges linked with data collection in epidemiological research. However, further feasibility studies need to be conducted to test the applicability and acceptance of these mobile apps for epidemiological research in various subpopulations [26].
Conclusions
We developed a mobile app for use in the validation process of the nursing diagnosis activity intolerance. This app enabled the evaluation of defining characteristics, which can enhance documentation for nursing staff, facilitate more effective inference and evaluation of diagnoses, and reduce errors in information recording. One significant potential of this app lies in its impact on education, as it aids in improving the precision of nursing diagnosis documentation and, as a result, enhances the quality of care planning.

Data Availability
The data sets generated during and/or analyzed during this study are available in the Mendeley repository [27].

Abstract

Background: The overall prevalence of cigarette smokers in China is very high, and China’s total cigarette consumption makes up more than 40% of the world’s consumption. In view of the lack of smoking cessation services and social support in China and the effectiveness of mobile phone apps for quitting smoking in other countries, we carried out a smartphone app–based smoking cessation trial in China.

Objective: This study aimed to evaluate the efficacy of a cognitive behavioral therapy (CBT)–based smoking cessation smartphone app among smokers seeking treatment in China.

Methods: We conducted a randomized controlled, web-based pilot clinical trial in China between February 23 and June 27, 2021. Eligible participants were randomly assigned to the smoking cessation app intervention group or the control group in a ratio of 1:1. The intervention group received the CBT smoking cessation intervention using a smartphone app, and the control group received a “thank you” message. The intervention was 4 weeks long, and the patients were followed up for 4 weeks. The primary outcome was self-reported continuous smoking abstinence at week 4 after the quit date. The secondary outcomes included self-reported 7-day point prevalence of smoking abstinence; reduction of the number of cigarettes smoked per day at weeks 1, 2, 3, and 4; and program acceptability.

Results: A total of 973 people were recruited to quit smoking, of whom 262 completed basic information, 56 were excluded, and 206 were randomized and included in the final analysis. There were 189 (91.7%) men and 17 (8.3%) women, with an average age of 34.46 (SD 7.53) years and an average daily smoking rate of 15.93 (SD 7.10) cigarettes/day. We found 30 (29.7%) of the 101 participants in the intervention group and 7 (6.7%) of the 105 participants in the control group reported continuous smoking cessation after the quit date at week 4 (odds ratio 5.92, 95% CI 3.78-9.26; \( P<.001 \)). The 7-day point prevalence abstinence rate of the intervention group varied from 42.6% (43/101) to 46.5% (47/101) after 1, 2, 3, and 4 weeks, while the control group varied from 18.1% (19/105) to 26.7% (28/105). Compared to the control group, continued smokers consumed 1.5-3.0 fewer cigarettes per day in the intervention group. The overall program got positive user feedback with a high satisfaction rate (66/87, 76%) and an average Mobile Application Rating Scale user version score of 3.46.

Conclusions: Our pilot study provided preliminary evidence that the CBT-based smoking cessation smartphone app led to improved smoking quit rates versus control in Chinese smokers. The study demonstrated the CBT-based smartphone app may be an effective and feasible digital treatment model to help smokers quit, which may improve smoking cessation service quality and accessibility in China.

Trial Registration: ClinicalTrials.gov NCT04421170; https://clinicaltrials.gov/study/NCT04421170
International Registered Report Identifier (IRRID): RR2-10.1136/bmjopen-2020-041985
Introduction

Tobacco smoking remains one of the leading causes of preventable death [1]. More than 8 million smokers worldwide die each year from smoking-related causes, of whom about 7 million die of diseases caused by smoking and about 1.2 million die from diseases caused by secondhand smoke exposure [2]. More than 1 million people in China lose their lives due to smoking every year. If effective action were not taken to significantly reduce the smoking rate, the number of deaths due to smoking would increase to 2 million per year by 2030 and 3 million per year by 2050 [3]. Since 1978, cigarette production in China has grown from 20% to over 40% of the world’s cigarette products [4]. Tobacco has caused a huge economic burden to society and individuals, including the high cost of medical care, more diseases, and premature death [5]. According to survey results on adult smoking prevalence in China in 2018, the smoking rate of people aged 15 years or older in China was 26.6% [6], which was still higher than in many other countries.

One of the key reasons for China’s low smoking cessation rate is limited smoking cessation services. The 2018 China Adult Tobacco Survey demonstrated that 90.1% of smokers who tried to quit in the past 12 months did not use any form of cessation aid [6]. A report in 2019 showed that 366 hospitals and primary health care institutions in China set up smoking cessation clinics, of which only 43% provided smoking cessation medications [7]. Few smokers were willing to go to the smoking cessation clinic for help [5], and most self-help cessation attempts failed [8,9]. Most smokers tend to relapse in the first few weeks after trying to quit smoking [10]. The success rate of quitting smoking after 1 year was 3%-5% for those without support, 7%-16% when smokers received behavioral intervention, and as high as 24% when smokers received drug treatment and behavioral help [11]. At present, it is necessary and meaningful to find accessible, effective, and scalable smoking cessation intervention methods to improve smoking cessation services in China.

Nowadays, mobile phone–based smoking cessation support provides a new channel for those who cannot get access to or lack the willingness to use face-to-face support [12]. About 45% of mobile phone subscriptions worldwide were related to smartphones, and this number continues to grow as 75% of new mobile phone sales were smartphones [13]. Around the world, mobile phones are becoming more and more useful in health information and health care service delivery [14]. Digital medical service has the advantages of economy, easy access [12], and easy promotion, which provides an opportunity for developing cost-effective smoking cessation digital interventions [15]. We previously carried out a study on smoking cessation intervention based on SMS text messaging (Happy Quit) in China, which supported the effectiveness and feasibility of digital medical services [16]. Smartphone apps for health and health care are increasing rapidly, but there are few in the smoking cessation area [17]. Smartphone apps can enable diverse functions, including audio and video materials, and can provide additional resources through the network [18]. Besides, smartphone apps could be more powerful than SMS text messaging programs for digital intervention because they have the potential to increase user engagement through diversified user interfaces and user experiences [19]. A study has found that under the same intervention content, the effect of a smartphone-based smoking cessation intervention app was stronger than that of a non–mobile device–based web page intervention. Mobile devices have the potential to make it easier for smokers to get smoking cessation support [20]. However, most of the currently available smartphone smoking cessation apps on the market have the problem of low compliance with standard clinical practice guidelines [21]. In 2018, a study of smoking cessation apps for the UK mobile phone app market found that most smoking cessation apps had low theoretical adherence, and the overall quality of smoking cessation apps was still unsatisfactory [22]. A review showed that there was insufficient evidence of the smartphone app’s effectiveness on smoking cessation support; thus, more randomized controlled trials (RCTs) were recommended to validate the smartphone-based digital smoking cessation interventions [12]. Specifically, as far as we know, there has been no mobile smoking cessation app with sufficient clinical evidence in China.

As an indispensable part of psychotherapy, cognitive behavioral therapy (CBT) plays an important role in the field of psychological and behavioral intervention [23]. One of the roles of CBT involves challenging behaviors that may trigger or sustain difficulties, such as smoking. CBT has been proven to help reduce cravings and promote smoking cessation by changing participants’ thoughts and behaviors [24]. The CBT quitting method consists of several parts, generally including preparation before quitting smoking, starting quitting smoking, and maintaining or preventing the recurrence treatment stage [25]. CBT may be a good choice for people who want to quit smoking, especially for those who want to quit smoking through nondrug methods [25,26]. Our previous study on “Happy Quit” SMS text message smoking cessation in China found that a CBT-based smoking cessation intervention can effectively improve the 24-week continuous smoking cessation rate [16,27]. As far as we know, there is little research to explore the effect of CBT-based mobile apps on smoking cessation intervention. Therefore, we are committed to designing a CBT-based mobile app for Chinese smokers who want to quit smoking, so as to find more effective ways to quit smoking.

Considering the above factors, in order to provide more feasible and effective smoking cessation services, we developed a scientific mobile smoking cessation app based on clinical practice guidelines. Smoking is an unhealthy behavior that can be altered, and CBT can help solve a wide range of smoking cessation problems. Various forms of interventions were developed in the app based on CBT to help smokers learn new...
skills, resist smoking cravings [28], and better deal with emotional disorders [29].

This Mandarin mobile smoking cessation app, based on CBT, integrates smoking cessation support and social skills training and finally achieves the goal of cognitive behavior change. A previous 1-arm study on the feasibility and acceptability of this CBT-based smartphone app was carried out for Chinese smokers who wanted to quit and showed that the smoking cessation app may become a new digital therapy model and have the potential to provide support for smoking cessation services in China [30]. We hypothesized in this study that the CBT-based smoking cessation app is feasible and acceptable and can significantly increase the quit rate.

**Methods**

**Objectives**

In the current trial, the objectives were to evaluate the feasibility and acceptability of this Chinese CBT-based app in a direct-to-participant clinical design and preliminarily evaluate the efficacy of the CBT-based app for smoking cessation in China. Given that CBT [23] is the current standard in behavioral intervention for smoking cessation, we tested the hypotheses that participation in this intervention will lead to significant improvement in the self-reported continuous smoking cessation rate at 4 weeks; self-reported 7-day point prevalence smoking abstinence and reduction of the number of cigarettes smoked per day at weeks 1, 2, 3, and 4; and that the program would be acceptable to participants.

**Study Design**

This was a randomized controlled, direct-to-participant clinical trial conducted in China. Researchers conducted preliminary conditional screenings for each participant. In the baseline assessment, all eligible participants were required to fill out a baseline questionnaire that included demographic information, motivation to quit smoking and willingness.

Using a randomization method by electronic data capture system, participants were randomly assigned to a smoking cessation app intervention group or to a control group in a 1:1 ratio after the completion of the screening, consent, and baseline questionnaires. No changes have been made to the trial design since its commencement. Participants in the intervention group received the CBT-based smoking cessation app, while those in the control group were encouraged to quit but were not provided with the CBT-based smoking cessation app. A control group was used since this was an exploratory study designed to assess both the feasibility, acceptability, and initial efficacy of the app intervention. Participants were required to complete the program acceptability assessment, including the App Satisfaction Assessment Scale and the Mobile Application Rating Scale, user version (uMARS; including engagement, functionality, aesthetics, information, and the average score of the uMARS total score), 4 weeks after the quit date. Each item is scored from 1 to 5, with a maximum total score of 5.0. The higher the score, the better the satisfaction [31]. Follow-up visits were conducted at weeks 1, 2, 3, and 4 after the participants started smoking cessation. The study design is depicted in Figure 1.
Figure 1. Flowchart of the study.

Procedures

Sample Size
A sample size of about 200 participants was calculated to give 80% power and a 2-sided 5% significance for detecting a beneficial difference in the self-reported continuous smoking cessation rates between the CBT app intervention and the control intervention. These assumptions were made based on our previous RCT of CBT-based SMS text messaging interventions for smoking cessation [16] and other previous RCTs of smartphone app interventions for smoking cessation [15], as well as the consideration of the better efficacy of the CBT-based app than the non–CBT-based app for smoking cessation [32].

Recruitment
From February 23 to June 27, 2021, a total of 206 participants were recruited through advertisements on social media, such as WeChat (Tencent), Weibo, the website, and the principal investigator–affiliated hospital WeChat official account. Potential participants were screened through a mobile phone or WeChat phone contact. Of the 973 screened, 711 did not meet the preliminary inclusion and exclusion criteria. Of the 262 baseline assessments completed, 56 were deemed ineligible to participate. Therefore, a total of 206 participants were randomized and included in the analysis according to the intention-to-treat (ITT) principle.

Stratified Block Randomization
Randomization was conducted by an electronic data capture system, a computerized system designed for the collection of clinical data in electronic format for RCTs and other clinical trials. Randomization was at the level of the individual participant with a 1:1 ratio by the method of minimization stratified by balancing for (1) with or without previous quit attempts and (2) 10 cigarettes or more per day. The study investigators were blinded to participants’ treatment allocation until all data were collected. The investigators who analyzed the data were also blinded to participants’ allocated groups until analysis completion.

Interventions

Overview
Following randomization, participants set a smoking cessation day. On that day, participants began receiving personalized messages to help quit smoking through either a smartphone app (intervention group) or by simply receiving SMS text messages (control group). The intervention group also logged into the smoking cessation app, started a smoking cessation journey, completed tasks, and sought personalized smoking cessation assistance under the automatic guidance of the app, while the control group received regular SMS text messages.

Control Group
Participants in the control group received information to thank them for their participation and to remind them to complete their smoking status at each point.

Intervention Group
Participants from the intervention group were invited to download the CBT-based app. The app integrates cognitive-behavioral principles and tailored behavior-change skills in Chinese. More descriptive details of this smartphone app were available elsewhere [33]. Participants who were randomly assigned to the intervention group were instructed on how to access and use the app, including a schedule of intervention activities, tasks during the pre- and postpreparation stages, and expected completion dates. Participants could begin their assigned tasks immediately after completing the pretest assessment. The system limited participants to 3 tasks each day during the preparation stage. To encourage completion, SMS text message reminders were sent each week after the quit date.

Both Groups
All participants earned CNY 20 (US $2.8) phone top-ups for the completion of pre- and posttest questionnaires. Participants from both groups received a reminder by SMS text message to complete questions about their smoking status during weeks 1, 2, 3, and 4 after the quit date by electronic Patient Reported Outcomes (ePRO) software.

Outcome Measures

Participant Demographics and Smoking Behaviors at Baseline
Participant demographic and smoking behaviors at baseline, including gender, age, height, weight, education, cigarettes per day, quit history, motivation, self-efficacy to quit, quitting smoking gradually or abruptly, smoking craving, and severity of nicotine dependence, were evaluated using the Fagerstrom Test for Nicotine Dependence (FTND).

4-Week Continuous Smoking Abstinence
Continuous smoking abstinence for 4 weeks is defined as smoking no more than 5 cigarettes in the past 4 weeks since quitting, measured through response to the following item: (1) “How many cigarettes have you smoked in the past 4 weeks?” Response choices were “0,” “1–5,” or “more than 5”; and (2) “If more than 5, recorded the number of smoked cigarettes per week.” Within 4 weeks, participants who smoked more than
5 cigarettes indicated a recurrence [34]. This was the primary outcome measure.

**7-Day Point Prevalence Smoking Abstinence**

Self-reported abstinence of at least 7 days before the assessment day was assessed 1, 2, 3, and 4 weeks after each participant’s quit date. It is defined as smoking no more than 5 cigarettes in the past 1, 2, 3, and 4 weeks since quitting.

**Reduction of the Number of Cigarettes Smoked Per Day**

Daily cigarette consumption among participants who were still smoking after quitting days (participants who smoked more than 5 cigarettes in total but less than 1 cigarette per day were considered to have smoked 1 cigarette per day).

**Program Acceptability**

A questionnaire of program acceptability was assessed at 4 weeks post quitting, including the App Satisfaction Assessment Scale and the uMARS. Questions are shown in the Results section.

**Safety**

The safety of this program was evaluated by the collection and analysis of spontaneous adverse events reported by participants. No serious adverse events were reported by participants in our trial.

**Intervention Effects**

The primary outcome was the self-reported continuous smoking abstinence rates at 4 weeks after the quit date. Secondary outcomes included self-reported 7-day point prevalence smoking abstinence at weeks 1, 2, 3, and 4, reduction of the number of cigarettes smoked per day from week 1 to week 4, program acceptability, and the association of outcomes with baseline data. In all analyses, participants who dropped out or were lost to follow-up were considered treatment failures and smokers. Participants using smoking cessation methods not allowed in this study were not included in the efficacy analysis.

**Statistical Analysis**

Statistical analyses were conducted with R software (R Foundation for Statistical Computing) and SPSS (version 23; IBM Corp). All baseline data comparisons, including participant demographics and smoking behaviors, were conducted using a chi-square test. A total of 206 participants were included in the analysis according to the ITT principle. In both groups, nominal and ordinal demographics were compared using chi-square tests, and continuous variables were compared using independent samples 2-tailed t tests. The number of average cigarettes smoked per day was compared using a 2-sample t test between groups. The mixed-effects model was used to test the self-reported smoking abstinence rates in intervention groups and control groups. Program acceptability (treatment satisfaction ratings) for participants with the app intervention was evaluated by tallying the proportion of users answering each item on the usability measure. If the smoking status was not available after quitting, the participant was considered to have smoked the same number of cigarettes per day as before quitting. The odds ratio was used as a measure of outcomes in the intervention group compared to the control group. Multiple imputations will be used in chained equations. A 2-sided P<.05 was used to determine statistical significance.

**Ethical Considerations**

The study protocol was approved by the ethics committee of Sir Run Run Shaw Hospital, an affiliate of Zhejiang University School of Medicine (protocol number 20200129-33), and was published [33]. The trial was performed in accordance with the Declaration of Helsinki. Informed consent was obtained from all participants. The purpose, procedures and measurements, potential risks, and benefits of the trial were explained to each participant before recruitment. The investigators who analyzed the data were also blinded to participants’ allocated groups until analysis completion.

**Results**

**Follow-Up Rate**

Figure 1 shows the process of screening, grouping, and follow-up of participants in this study. A total of 206 participants were recruited from February 23 to June 27, 2021. Of the 973 screened, 711 did not meet the preliminary inclusion and exclusion criteria. Overall, 262 completed baseline assessments, but 56 were deemed ineligible to participate. Therefore, a total of 206 participants were included in the analysis according to the ITT principle.

**Participant Characteristics**

Demographics and smoking characteristics at baseline for all participants are presented in Table 1. There were no statistically significant differences in the baseline characteristics of the 2 groups of participants (P>.05). A total of 206 participants were enrolled in the trial. There were 189 (91.7%) men and 17 (8.3%) women, with an average age of 34.46 (SD 7.53) years and an average daily smoking rate of 15.93 (SD 7.10) cigarettes per day.

The Outcome of Abstinence Rates

**The Primary Outcome**

Compared with 7/105 (6.7%) participants in the control group, self-reported continuous smoking abstinence at week 4 was higher (30/101, 29.7% participants) in the intervention group (odds ratio 5.92, 95% CI 3.78-9.26; \(P<.001\); Table 2).

The Secondary Outcomes

Table 2 details the results of self-reported 7-day point prevalence of smoking abstinence at weeks 1, 2, 3, and 4. It was shown that the self-reported 7-day point prevalence of smoking abstinence at weeks 1, 2, 3, and 4 of the intervention group were 46.5% (47/101), 42.6% (43/101), 42.6% (43/101), and 44.6% (45/101), respectively, while 7-day point prevalence of smoking abstinence in the control group was 26.7% (28/105), 18.1% (19/105), 20% (21/105), and 19% (20/105), respectively. The differences were statistically significant at all time points. Compared to the control group, continued smokers consumed 1.5-3.0 fewer cigarettes per day in the intervention group (Table 3).

Table 3. Cigarettes consumed per day in nonabstinent participants (only those who self-reported smoking more than 5 cigarettes [reaching the standard of relapse] after the quit date were included).

The Acceptability and Feasibility of the CBT-Based Smoking Cessation App Program

Participants were required to complete the program acceptability assessment, including the App Satisfaction Assessment Scale and uMARS, 4 weeks after their quit date. All participants (n=101) in the intervention group were contacted to evaluate the program based on their experience, and we finally obtained responses from 87 people, including 87 on the App Satisfaction Assessment Scale and 84 on the uMARS. The overall program satisfaction was 76% (66/87) and the percentage of dislikes was less than 10% (9/87). The uMARS included the average scores of 5 items scored 1-5, namely, engagement (2.96), functionality (3.73), aesthetics (3.56), information (3.6), and the average score of the uMARS total score (3.46). More details are available in Tables S1 in Multimedia Appendix 1 and Table 4.

**Discussion**

**Principal Findings**

In this study, our main results indicate that (1) the 4-week continuous smoking cessation rate of the intervention group participants (30/101, 29.7%) was statistically significantly higher than that of control group participants (7/105, 6.7%); (2) the self-reported 7-day point prevalence smoking abstinence rate in the intervention group at the weeks 1, 2, 3, and 4 was higher than that in the control group (43/101, 42.6% to 47/101, 46.5% vs 19/105, 18.1% to 28/105, 26.7%); (3) compared with the control group, those who continued to smoke in the intervention group smoked 1.5-3.0 fewer cigarettes a day; (4) the app had high overall satisfaction rating (66/87, 76%) and average uMARS scores (3.46). These findings suggest that the CBT-based smartphone app is effective for smoking cessation, and it could be an effective, feasible, and easy-to-access quitting app in China. It is hopeful for this app to be introduced to a large-scale Chinese population to intervene in smoking cessation.

The effectiveness of this CBT-based smartphone app intervention on short-term smoking cessation rates was encouraging. About half (47/101, 46.5%) of participants in the intervention group and about a quarter (28/105, 26.7%) in the control group reported 7-day abstinence in the first week after quitting, which was comparable to the preliminary results of other randomized controlled digital intervention studies on smoking cessation [35,36]. Previous research results for smartphone apps and SMS text messaging smoking cessation programs were similar to ours [16,37]. Participants in the intervention group reported point prevalence that was 3 to 4 times higher than that in the control group from 1 to 4 weeks, and self-reported continuous abstinence at 4 weeks in the intervention group was similar to that in previous smartphone smoking cessation app studies [37,38].

The results of this study show that the smoking cessation rate is high, and there have been some similar or inconsistent studies in the past, although there are some differences in smoking cessation standards. A systematic evaluation of smartphone apps for quitting smoking found that the results of 11 RCTs were not consistent. Among these 11 studies, the abstinence rate of the test group was significantly higher than that of the control group in 4 studies, the abstinence rate of the test group was not significantly higher than that of the control group in 5 studies, and there was no difference between the test and control groups in 2 studies [1]. The social environment in China is still quite tolerant of smokers and appears less supportive of quitting behavior, so potential quitters in China may be more resistant to personal intervention than smokers in other countries [16]. As far as we know, there are no mobile smoking cessation platforms developed under the theoretical guidance of professional medical institutions in the domestic software development market, and most of the smoking cessation apps in China are developed by individuals or companies that may not have knowledge of clinical smoking cessation practice. Those apps comply less with the recommendations from the China clinical smoking cessation guidelines (2015 edition), and their smoking cessation effect is limited [21]. Therefore, for most Chinese smokers, using apps to quit smoking is a new way to quit smoking that needs further improvement.

China has introduced some smoking control measures, but the choice of a mobile smoking cessation service is relatively limited. The earliest method of smoking cessation based on mobile phones was mainly SMS text messages [39]. Our team previously carried out an SMS text message smoking cessation project, and the effect of smoking cessation was relatively significant [16]. China’s smoking cessation services are inadequate. An authoritative national survey found that in 31 provinces, only 366 hospitals and primary care centers offered smoking cessation clinics [7]. Among them, smoking cessation clinics are mostly attached to tertiary or secondary hospitals, but population-level interventions rely heavily on primary care settings [40], where fewer clinics exist. In addition, the limited use of smoking cessation medications in China is also a serious problem [7]. Additionally, many smokers who want to quit smoking have low awareness of and use of smoking cessation support services [41].

It is noteworthy that the overall program satisfaction (66/87, 76%) and the average score of the uMARS total score (3.46) were high. About 80% (69/87) of the participants would happily recommend the app to others, which was consistent with the results of a randomized clinical trial of a smartphone app based on acceptance and commitment therapy for quitting smoking [37]. In this study, except for engagement, the software’s functionality, aesthetics, information, and the average score of the uMARS total score were all around 3.5, indicating that the participant’s overall satisfaction level was relatively high. Similar to our results, a study showed that participants made suggestions, including making features more ramified and integrating with some social media platforms to increase app and user interactivity, although some smartphone smoking cessation apps were widely accepted [41].

This pilot study provided valuable learning for future research. A review study showed that the certainty of evidence comparing smartphone apps to very low-intensity smoking cessation support was very low, and more RCTs were needed to test these interventions [12]. Also, the recruitment of participants in the intervention and control groups of RCTs related to smartphone apps for smoking cessation was not easily supported [41]. It is worth mentioning that we recruited eligible participants in this preliminary study and carried out RCTs in accordance with the norms, obtaining relatively accurate data and also providing a reference and basis for subsequent RCT studies. These preliminary data still provide sufficient and reliable information for our subsequent larger, robust trials.

**Limitations and Strengths**

There are some limitations to our study. First, this study was a pilot study with a small sample size, and the results may be biased. At present, our large-sample trial has begun, which will help to further confirm our preliminary research results. Second, due to the need to master the basic ability to use the app, the enrolled smokers were relatively younger and had a higher education level, so the smoking cessation effect of the smoking cessation APP is uncertain for older or less educated smokers.
and more caution needs to be exercised if the results are
generalized to older or less educated smokers. Finally, some
important subgroup analyses, such as smoking cessation rates
between men and women, tobacco users, and e-cigarette users,
were not considered in this study. Although we matched the 2
groups of quitters on factors such as gender and smoking status,
these differences could potentially have an impact on smoking
cessation outcomes. Despite these limitations, this study’s
strengths included its conduct in China, the direct-to-participant
design, and the use of an RCT.

Conclusions
This pilot study of a CBT-based smartphone smoking cessation
app provided preliminary evidence that the app led to improved
smoking cessation rates versus control in Chinese smokers. This
study demonstrated that the CBT-based smartphone app may
be an effective and feasible digital treatment model to quit
smoking, which may improve smoking cessation services in
China.

Acknowledgments
We sincerely thank all participants, their families, and all workers for their support. We are grateful to Johnson & Johnson
Pharmaceutical Company for providing critical comments and suggestions for the study design and development of the digital
intervention app. The source of funding had no impact on the data collection and analysis of the study or the writing and submission
of the manuscript.

The research is supported by Johnson & Johnson Pharmaceutical Company (K-20201478). The funder was collaboratively
involved in the study design, development of the data collection tool, and app software development, but the company had no
involvement in enrollment, providing an informed consent form, contacting participants, addressing safety issues, or monitoring
and collecting data.

Data Availability
All data in this study will be available from the corresponding author on reasonable request and upon completion of the data user
agreement.

Authors' Contributions
YL and JT developed and designed the study, and SC collected and analyzed the data. SC and YL took the lead in drafting the
manuscript protocol, with contributions by JT, who advised on the study design and coordinated study approval. YL and JT read
and proposed critical comments, as well as approved the manuscript for publication. All authors read and approved the final
manuscript.

Conflicts of Interest
YL received funding from Johnson & Johnson Pharmaceutical Company for the study. SC, JT, CW, GZ, IZ, and YL have no
potential conflicts of interest to declare.

Abstract

Background: WA Notify was Washington State’s smartphone-based COVID-19 digital exposure notification (EN) tool, which was used to help limit the spread of COVID-19 between November 30, 2020, and May 11, 2023. Following the 2022 Washington State Public Health Association Annual Conference, attendees who had WA Notify activated began receiving ENs alerting them to a possible COVID-19 exposure during the conference. A survey was emailed to all conference attendees to measure WA Notify adoption, mechanisms through which attendees received ENs, and self-reported engagement in protective behaviors postexposure.

Objective: This study aimed to learn more about the experiences of WA Notify adopters and nonadopters who may have been exposed to COVID-19 at a large group gathering.

Methods: A web-based survey administered through REDCap (Research Electronic Data Capture; Vanderbilt University) was sent to all attendees of the Washington State Public Health Association conference. Self-reported demographic information and characteristics of respondents were summarized. Regression models were used to estimate relative risks to compare WA Notify adoption and testing behaviors between groups.

Results: Of the 464 total registered attendees who were sent the survey, 205 (44%) responses were received; 201 eligible attendees were included in this analysis. Of those, 149 (74%) respondents reported having WA Notify activated on their phones at the time of the conference. Among respondents with WA Notify activated, 54% (n=77) reported learning of their potential exposure from a WA Notify EN. Respondents who reported that they did not have WA Notify activated and learned of their potential exposure via the event-wide email from conference organizers were 39% less likely to test for COVID-19 compared to respondents with WA Notify activated who learned of their potential exposure from the email (relative risk 0.61, 95% CI 0.40-0.93; \(P=.02\)), and this gap was even larger when compared to respondents who learned of their exposure from a WA Notify EN. The most commonly cited reason for not having WA Notify activated was privacy concerns (n=17, 35%), followed by not wanting to receive ENs (n=6, 12%) and being unaware of WA Notify (n=5, 10%).

Conclusions: Digital EN systems are an important tool to directly and anonymously notify close contacts of potential exposures and provide guidance on the next steps in a timely manner. Given the privacy concerns, there is still a need for increasing
transparency surrounding EN technology to increase uptake by the public if this technology were to be used in the future to slow the spread of communicable diseases.

### Introduction

#### Background

Smartphone-based COVID-19 digital exposure notification (EN) tools were developed at the beginning of the COVID-19 pandemic to help limit the spread of the SARS-CoV-2 virus. These tools alert users of possible exposure to COVID-19 based on Bluetooth-based proximity to other users’ devices and other users informing the system of a positive COVID-19 diagnosis [1]. According to the Association of Public Health Laboratories, which helped support EN systems across the United States, 28 states have implemented a digital EN tool, including Washington State, which launched its EN system, WA Notify on November 30, 2020 [2,3]. Like most of these tools, WA Notify was built using the Google-Apple Exposure Notification (GAEN) Bluetooth system and its GAEN Express platform [1-4]. GAEN-based digital COVID-19 EN tools preserve the users’ privacy; adoption or activation of the tool is anonymous, users and their locations are not tracked, and data protections ensure ENs are distributed anonymously. As of April 11, 2023, WA Notify had been activated on smartphones over 3.92 million times. During the period in which WA Notify was operating, approximately 230,000 positive COVID-19 cases were reported to the system and an estimated 1.94 million ENs were shown to users [5].

The effectiveness of EN tools like WA Notify is presumed to include providing rapid notification of possible exposure to users [6] and using effective strategies to encourage individuals shown an EN to engage in behaviors to reduce further spread, such as testing and isolating [7,8]. While direct observation of WA Notify users’ protective behaviors after being shown an EN is not possible, we can ask users who were shown an EN about their anticipated and completed protective behaviors through optional, anonymous surveys. The results from these surveys suggest that ENs do influence behavior, and it has been estimated that digital EN tools such as WA Notify have averted thousands of new COVID-19 cases in the states in which they have been deployed and widely adopted [9-11].

In October 2022, the Washington State Public Health Association (WSPHA) held its Annual Conference. Several conference attendees tested positive for COVID-19 either during or following the conference. In the week following, WA Notify users who attended the conference began receiving ENs of possible exposure during the time period when they were attending the conference. This event presented a unique opportunity to capture WA Notify user interactions in the context of a large public gathering as well as the experiences of public health professionals—a population potentially more likely to both adopt digital EN tools and engage in protective behaviors—undertaking protective health behaviors in response to receiving an EN. We describe the results of a postconference web-based survey emailed to all attendees to measure WA Notify adoption, mechanisms through which attendees were alerted to a possible COVID-19 exposure (digital EN, personal communication, etc), and self-report of engagement in protective behaviors after learning of the exposure.

#### Objectives

We aimed to learn more about the experiences of WA Notify adopters and nonadopters who may have been exposed to COVID-19 at a large group gathering.

#### Methods

##### How WA Notify Works

WA Notify (and other similar EN systems) can be activated either through the settings on iPhones or downloaded as an app on Android phones [3,5]. When in close proximity to another activated phone, the devices will exchange random, anonymous cryptographic Bluetooth keys. If the owner of either device later tests positive for COVID-19, they may anonymously confirm their positive result using the tool. Depending on the length and proximity of the phones’ interaction, ENs will be shown on phones belonging to individuals who have exchanged Bluetooth keys with the infected individual. While ENs may be displayed on phones for exposures happening up to 10 days earlier, the average time between exposure and the EN alert was 4.6 days in October 2022. The examples of EN messages from WA Notify can be found in Multimedia Appendix 1.

##### Survey Instrument

A web-based survey was designed to capture WA Notify engagement (adoption and reasons for not having WA Notify activated), awareness that someone who attended the conference later tested positive for COVID-19, respondents’ COVID-19 status (presence of symptoms, testing, and result), vaccination status, and demographics (race or ethnicity, age, gender, and state residency). The survey was piloted internally to assess clarity, question order, and timing. The final survey was programmed and administered through REDCap (Research Electronic Data Capture) [12]. A copy of the survey can be found in Multimedia Appendix 2.

Survey invitations were distributed via email to a list of all WSPHA conference attendees on October 28, 2022, a total of 15 days after the conference, by the conference organizer. Reminders were sent on November 6, 2022, and the survey closed on November 10, 2022.
Inclusion Criteria
Only respondents who attended the WSPHA Annual Conference on October 11 through 13, 2022, were included. Reports of ENs distributed outside of October 11 through 23 were excluded since these ENs fall outside of the 10-day window for ENs plausibly resulting from interactions at the WSPHA conference.

Statistical Analysis
Survey responses were tallied and stratified by the primary outcome of interest, WA Notify activation status. Variables of interest included how respondents learned that someone who attended the conference later tested positive for COVID-19, the development of COVID-19 symptoms, engagement in protective behaviors after being shown an EN, and vaccination status. Univariate Poisson regression models were used to estimate relative risks (RRs) of having WA Notify activated and postconference testing behavior between groups.

Ethical Considerations
The University of Washington institutional review board determined that this project was a public health quality improvement or surveillance project and nonhuman subjects research. The data used in this study were obtained from a voluntary survey that did not provide any compensation for participation and did not collect any personally identifiable information.

Results
Respondent Demographics and Characteristics

Demographics
Of the 464 total registered attendees who were sent the survey, 205 (44%) responses were received. Four surveys were excluded because the respondents did not attend the conference in person. A total of 201 completed surveys were included in the analysis, of which 149 (74%) reported having WA Notify active on their phones during the conference (Table 1).

The majority of the sample identified as female (n=158, 79%), White (n=156, 78%), and non-Hispanic, any race (n=174, 87%). Sixty-four percent (n=128) resided in Western Washington and 92% (n=184) reported having completed the primary COVID-19 vaccination series and receiving at least 1 booster.
Table 1. Respondent characteristics by WA Notify activation status (N=201).

**WA Notify Adoption**

Reported WA Notify adoption was highest among younger age groups, with 86% (n=55) of those 18-34 years old having WA Notify activated on their smartphones compared to 38% (n=3) of those 65 years and older (Table 2). We found that those aged 35-44 years were 22% less likely to have WA Notify activated than those aged 18-34 years (RR 0.78, 95% CI 0.63-0.97; P=.03).

Reported adoption also varied across racial groups. Respondents who identified as Asian were 29% more likely to have WA Notify activated compared to those who did not identify as Asian (RR 1.29, 95% CI 1.13-1.49; P<.001). Respondents who identified as “other” race were 35% more likely to have WA Notify activated compared to those who did not identify as “other” (RR 1.35, 95% CI 1.24-1.47; P<.001). We found no statistically significant association between WA Notify adoption and Hispanic ethnicity of any race.

Respondents living in Eastern Washington were 22% less likely to have WA Notify activated compared to those living in Western Washington (RR 0.78, 95% CI 0.61-1.00; P=.05).

b Respondents could select more than 1 answer. The reference category for each comparison was those who did not select each respective response.

**COVID-19 Vaccination Status**
Only 2 respondents reported being unvaccinated (Table 2). Respondents who reported receiving only the primary vaccination series were 45% less likely to have WA Notify activated than those with at least 1 booster, although this association was not statistically significant (RR 0.55, 95% CI 0.30-1.02; P=.06).

**EN Receipt**
The WSPHA Annual Conference took place from October 11 through 13, 2022, in Wenatchee, WA. From October 13 through October 23, there were 42 conference attendees who reported receiving their first WA Notify EN. Figure 1 illustrates the dates of the first reported WA Notify EN among participants who remember the date of the EN and who had WA Notify activated during this period. We do not know when attendees tested positive or confirmed their positive tests using WA Notify.
However, due to the 10-day storage period for keys used to determine exposure, the plausible dates for an EN shown due to a potential exposure during the conference were between October 11 and 23. Three respondents reported ENs outside of this range (October 2, 10, and 31), and these ENs were not included in the analysis.

The only EN dates collected with this survey were for the first WA Notify EN shown to those who reported having WA Notify activated and who reported being aware that someone who attended the conference later tested positive for COVID-19. Dates for other ENs were unavailable, except for the WSPHA conference organizer email EN sent to all attendees on October 17.

**Figure 1.** The plausible dates for an exposure notification shown because of potential exposure during the conference were between October 11 and 23 due to the 10-day storage period for keys used to show exposure notifications. Data were only available for respondents with WA Notify activated who remembered the date of the first WA Notify exposure notification received. Three respondents reported exposure notifications outside of this range (October 2, 10, and 31), and these exposure notifications were not included in the analysis. WSPHA: Washington State Public Health Association.

**Symptoms, Testing, and WA Notify Adoption**

Following the conference, 17% (n=35) of respondents reported experiencing at least 1 symptom and 63% (n=126) took a test for COVID-19 (Table 3).

Among those who tested, 92.1% (n=116) reported taking an “at-home” rapid antigen test for COVID-19, while the others received a polymerase chain reaction test. Testing was most frequently prompted by receiving an EN from WA Notify (n=58, 29%) or email notification from WSPHA conference organizers (n=56, 28%), although many respondents also reported testing being a routine behavior when they travel (n=44, 22%). Respondents who reported having WA Notify activated were 74% more likely to test for COVID-19 following the conference compared to those who did not have WA Notify activated (RR 1.74, 95% CI 1.22-2.47; P=.002). Nine (7%) respondents reported testing positive following the conference.

Pathways for Receiving First EN

Most respondents (n=194, 97%) reported that they were aware that someone who attended the conference later tested positive for COVID-19 (Table 4). Respondents learned about the attendees who tested positive for COVID-19 through a variety of pathways. Among those who were aware, respondents most frequently reported learning of the COVID-19–positive attendees via an event-wide email notification from WSPHA conference organizers (n=93, 48%) or receiving a WA Notify EN (n=77, 40%). A small number of respondents learned about the COVID-19–positive attendees via personal communication from another attendee who tested positive for COVID-19 (n=7, 4%), communication from someone else who had been exposed (n=6, 3%), or an internal email notification from the Washington State Department of Health (n=4, 2%). Among respondents with WA Notify activated, 54% (n=77) reported learning of their exposure from WA Notify, while 33% (n=48) learned of their exposure from the conference organizer email. It is possible that some portion of the 33% (n=48) of respondents with WA Notify activated who received the email notification first were not considered exposed based on Bluetooth proximity or the risk score used in WA Notify. Alternatively, this group may have also been shown a WA Notify EN after the email notification, but data were not collected on additional notifications.

\textsuperscript{e}Reasons included communication from someone else who was exposed (n=6), Washington State Department of Health email notification (n=4), and cannot remember (n=2).

**Associations Among Pathway of First Received EN, Symptoms, Vaccination History, and Testing**

Respondents who reported that they did not have WA Notify activated and learned that someone who attended the conference later tested positive for COVID-19 via the email from conference organizers were 39% less likely to take a test for COVID-19 than respondents with WA Notify activated who learned of their potential exposure from the email (RR 0.61, 95% CI 0.40-0.93; \( P=.02; \) Table 5).

Respondents with WA Notify activated who learned of their potential exposure from a WA Notify EN were slightly more likely to test compared to those with WA Notify who received the email notification first, although this association was not significant (RR 1.14, 95% CI 0.90-1.45; \( P=.28 \)).

The number of symptoms experienced was associated with testing for COVID-19 following the conference. Respondents who reported experiencing 1 symptom were 62% more likely to test than those who experienced no symptoms (RR 1.62, 95% CI 1.28-2.05; \( P<.001 \)), and those who experienced 2 or more symptoms were 78% more likely to test than those who experienced no symptoms (RR 1.78, 95% CI 1.55-2.06; \( P<.001 \); Table 5). With the exception of 1 person who reported a sore throat, everyone who reported symptoms also reported testing for COVID-19.

Reasons for Not Activating WA Notify

Among those who reported not having WA Notify activated (N=49), there were a variety of reasons reported with some respondents (n=7) reporting multiple reasons. The most commonly cited reason was privacy concerns (n=17, 35%), followed by not wanting to receive ENs (n=6, 12%), and being unaware of WA Notify (n=5, 10%). Other reasons for not activating WA Notify included not understanding it (n=3, 6%), thinking it is cumbersome or bothersome (n=3, 6%), not getting around to it (n=3, 6%), having limited phone storage (n=3, 6%).
Discussion

Overview

This analysis allowed us to compare the characteristics of WA Notify adopters and nonadopters among those attending the WSPHA Annual Conference. It also explored testing behavior following a possible exposure and factors that may influence EN tool uptake. Our survey population consisted of public health professionals who, compared to the general public, are likely to be more aware of COVID-19 risks and prevention measures and are more inclined to use digital EN tools.

Principal Results

Our findings indicate that respondents who identified as WA Notify users were more likely to be younger compared to their counterparts, although this is unsurprising as younger age groups may be more comfortable with digital tools and technology in general. WA Notify users were also more likely to receive COVID-19 vaccinations relative to their counterparts, which would align with a higher likelihood of taking health precautions in general. Key findings included high levels of reported privacy concerns among nonadopters, that the majority (n=77, 54%) of WA Notify users reported first learning about their possible exposure from the tool, and that WA Notify users were more likely to test for COVID-19 compared to nonusers regardless of how they were first notified about their exposure.

Among nonusers, the most common reason for not having WA Notify activated was privacy concerns (n=17, 35%), despite stringent privacy protections, which make it nearly impossible for any government agency or corporation to obtain individual-level information [13,14]. We recognize that social desirability bias may have led nonusers to more frequently cite privacy concerns for not adopting WA Notify and assume that the general public, whose affiliation with public health is lower, likely has equal or greater privacy concerns than our sample. Still, this finding underscores the need for improved communications surrounding the privacy and data security of digital EN systems.

WA Notify users were significantly more likely to test for COVID-19 irrespective of how they first learned of their potential exposure. It is possible that testing was encouraged by the more personalized WA Notify EN or receiving multiple notifications or the combination of these 2 factors. Unfortunately, we cannot determine the extent to which WA Notify ENs encouraged testing. It is possible individuals with WA Notify activated were also more likely to test for COVID-19 regardless of whether they received an EN.

However, our findings indicate that WA Notify played an important role in distributing timely ENs to conference attendees following COVID-19 exposures at the WSPHA conference. Additionally, we believe a proximity-based digital EN system could be particularly useful in other large gatherings to alert close contacts of their exposure and reduce further transmission. The WSPHA conference was unique in that the attendees were public health professionals, and the sponsoring organization’s mission focused on health and public safety. Organizers in other event contexts may not be informed about infectious individuals attending the event, and if informed, organizers may be unable to or choose not to distribute their own EN to attendees.

Our results add to the evidence of the value of digital EN systems, but work remains to encourage adoption and engagement with these systems. The adoption of these systems is influenced by how easy they are to use (which is improved by the GAEN Express platform). Additionally, conducting pilot studies of the system, strong advertising campaigns, and engaging a wide array of stakeholders all likely contributed to WA Notify’s successes and can improve the adoption of similar systems in the future [3].

Limitations

There are several limitations to our findings. The survey population was a subset of individuals from the WSPHA conference and thus could have limited generalizability to the general population since the survey respondents are likely highly invested in public health and public health measures. These individuals could be more likely to use EN tools and take additional precautions against COVID-19 infection compared to the population of all WSPHA conference attendees or the general public.

There are also limitations to our survey design. The survey did not ask about prior COVID-19 infection, so natural immunity could not be accounted for. The question about vaccination status allowed an option for primary series booster; respondents who selected that response may have received either 1 booster or multiple boosters because the new bivalent booster had recently become available. We did not assess the respondents’ role within public health, such as if they worked at the state or local level or were a student. Knowing these characteristics may have provided more insight into the differences between these groups. When assessing the type and number of ENs received, data were only collected regarding the first EN method. The EN date information was only available for those who reported receiving a WA Notify EN; dates of other ENs were unknown if multiple were received.

Conclusions

Digital EN systems are important tools that have been used to notify close contacts of potential COVID-19 exposures. Our data suggest that having WA Notify activated encouraged individuals to engage in postexposure protective behaviors relative to those who did not have the tool activated. For digital EN technologies to sustain and expand their use in slowing the spread of communicable diseases moving forward, more work must be done to encourage uptake in groups less comfortable with the technology. Developing clear, consistent, and transparent messaging around the privacy and data security protocols built into these tools is needed to reduce these barriers to adoption. Additionally, understanding how to communicate evidence of public health value both to the general public and within the public health community is needed. Investment in future digital public health tools would benefit from an improved evidence base that includes systematic research on the impact of tailored messaging and the attributes and components of such
messaging for encouraging the adoption and sustained use of public health digital tools like WA Notify.

Acknowledgments
The work described in our manuscript was supported through an Interagency Agreement between the Washington State Department of Health and the University of Washington (HED 25742).

Authors’ Contributions
JGB, NLB, DR, LMW, AH, WBL, and BTK conceptualized, reviewed, and implemented the survey. CMD analyzed the data with support from BLG and ASE. CMD wrote the manuscript with support from BLG, ASE, DR, and JGB. All authors reviewed and approved the final version of the manuscript for publication.

Abstract

Background: Alcohol misuse is the fourth leading cause of death in the United States and a significant problem in the US military. Brief alcohol interventions can reduce negative alcohol outcomes in civilian and military populations, but additional scalable interventions are needed to reduce binge and heavy drinking. SMS text messaging interventions could address this need, but to date, no programs exist for military populations.

Objective: We aimed to develop an SMS text messaging intervention to address binge and heavy drinking among Airmen in Technical Training in the US Air Force.

Methods: We implemented a 2-phase, mixed methods study to develop the SMS text messaging intervention. In phase 1, a total of 149 respondents provided feedback about the persuasiveness of 49 expert-developed messages, preferences regarding message frequency, timing and days to receive messages, and suggested messages, which were qualitatively coded. In phase 2, a total of 283 respondents provided feedback about the persuasiveness of 77 new messages, including those developed through the refinement of messages from phase 1, which were coded and assessed based on the Behavior Change Technique Taxonomy (BCTT). For both phases, mean persuasiveness scores (range 1-5) were calculated and compared according to age (aged <21 or ≥21 years) and gender. Top-ranking messages from phase 2 were considered for inclusion in the final message library.

Results: In phase 1, top-rated message themes were about warnings about adverse outcomes (eg, impaired judgment and financial costs), recommendations to reduce drinking, and invoking values and goals. Through qualitative coding of suggested messages, we identified themes related to warnings about adverse outcomes, recommendations, prioritizing long-term goals, team and belonging, and invoking values and goals. Respondents preferred to receive 1 to 3 messages per week (124/137, 90.5%) and to be sent messages on Friday, Saturday, and Sunday (65/142, 45.8%). In phase 2, a total of 283 respondents provided feedback about the persuasiveness of 77 new messages, including those developed through the refinement of messages from phase 1, which were coded and assessed based on the Behavior Change Technique Taxonomy (BCTT). For both phases, mean persuasiveness scores (range 1-5) were calculated and compared according to age (aged <21 or ≥21 years) and gender. Top-ranking messages from phase 2 were considered for inclusion in the final message library.

Conclusions: This study involved members from the target population throughout 2 formative stages of intervention development to design a BCTT-informed SMS text messaging intervention to reduce binge and heavy drinking, which is now being tested in
an efficacy trial. The results will determine the impact of the intervention on binge drinking and alcohol consumption in the US Air Force.

**Introduction**

**Overview**

Alcohol misuse contributes to 140,000 deaths per year, making it the fourth leading cause of death in the United States [1]. Alcohol use also contributes significantly to the epidemic of *deaths of despair*, both as a primary cause of death and as a contributor to approximately 25% of opiate overdose deaths and suicides [2,3]. Deaths from alcohol have increased by 37% since 2005 [4]. Binge drinking and the associated health and social consequences are substantial public health concerns, with a high prevalence among young adults [5,6].

Alcohol misuse is a significant problem in the US military because of its impact on military functioning and readiness and its effect on the health and careers of service members. The Millennium Cohort Study, sampling >77,000 troops (active duty and reserve/guard), indicated that 18.5% of respondents reported a history of alcohol problems, and 7% to 8% reported current weekly heavy drinking (ie, >14 and >7 drinks per week for men and women, respectively) [5]. In 2018, overall, 34% of all Department of Defense (DoD) service members reported binge drinking at least once a month, defined as ≥5 drinks per sitting for men and ≥4 drinks per sitting for women, with significant differences based on gender (35.2% and 28.2% for men and women, respectively, P<.05) [7]. Specifically, in the Air Force, 24.1% reported binge drinking in the past month. Overall, young adults drink more than any other age group, and on average, young adults in the military drink 22% more than demographically similar civilians (33.1% vs 27.1%) [5,8].

Fortunately, brief alcohol interventions (BAIs) have been validated in college students and community-dwelling young adults who report elevated drinking levels and alcohol-related health or social problems. Overall, BAIs (typically 1-2 individual counseling sessions that include personalized feedback on drinking that are delivered in a motivational interviewing style) result in 30% to 50% reduction in binge drinking, with positive treatment effects reported up to 4 years after the intervention [9-11].

While individually delivered BAIs are effective, they are challenging to implement in large populations, such as the US military, due to logistics and cost. Therefore, scalable and cost-effective approaches for reducing the prevalence of binge and heavy drinking in this population are needed. One very promising approach to cost-effectively disseminate BAI content to many thousands of at-risk service members is through the use of automated SMS text messages sent at key times during training or when participants may be at the greatest risk for binge drinking. For example, Cadigan et al [12] evaluated specific personalized feedback during football tailgating, an event heavily associated with binge drinking. College students (N=130) who reported a history of tailgating and binge drinking were randomized to 1 of 2 SMS text message groups: an event-specific SMS text message or generic alcohol education messages. At the 1-month follow-up, those in the event-specific SMS text message group reported lower estimated peak blood alcohol concentration than those who received generic alcohol education messages.

In another study, 765 young adults who screened positive for hazardous drinking were randomized to SMS text message assessments and feedback group, SMS text message assessments only group, or a no SMS text message control group over a 12-week period [13,14]. Overall, there were decreases in the number of self-reported binge drinking days from baseline in the SMS text message assessments and feedback group, whereas there were increases in binge drinking days in the SMS text message assessments only and no SMS text message groups. Overall weekend bingeing was also lowest in the SMS text message assessments and feedback group.

Finally, Teeters et al [15] tested a mobile phone–based intervention with personalized SMS text messages to determine its impact on driving after drinking. Participants included 84 college students who endorsed driving after drinking ≥3 drinks at least twice in the past 3 months. Participants were randomized to either information about driving after drinking (eg, how alcohol affected the brain and nervous system) or mobile phone–based BAI related to driving after drinking that included personalized feedback and interactive SMS text messaging. The mobile phone–based interventions included personalized feedback delivered via secure SMS text message (eg, normative feedback about drinking level and frequency of drinking and driving). The feedback was delivered in the context of a 15- to 20-minute, SMS text-based “session” that included open-ended, motivational interviewing–style SMS text messages asking participants about their reaction to the feedback, the potential personal and professional costs of being arrested for driving under the influence of alcohol (eg, losing their college scholarship), and their plans for avoiding drinking and driving in the future. The study clinicians made tailored empathic reflections about the participants’ reactions and encouraged specific goal setting/planning. The primary outcome variable was self-reports of driving after drinking at a 3-month follow-up. Results indicated that students receiving the mobile phone–based BAI reported significantly greater reductions in the likelihood
of driving after drinking and the number of drinks consumed before driving than those in the information group.

While these findings suggest a potentially promising impact of SMS text message interventions on hazardous drinking outcomes, 2 recent meta-analyses in specific settings have shown potentially less robust efficacy of SMS text message interventions on heavy drinking when delivered as the only intervention [16] and when delivered as a preventive intervention [17]. For example, when delivered as the only intervention, Bendtsen et al [16] determined that while heavy episodic drinking and weekly alcohol consumption were low among participants who received the SMS text message intervention, the CI of these estimates both included the null, indicating a lack of a statistically significant association. In addition, the included studies were judged to be of low quality [16]. Therefore, more studies are needed to fully understand the potential impact of SMS text message interventions on binge and heavy drinking.

To date, the few studies that evaluated SMS text messages for binge drinking have been conducted in civilian settings. However, a large percentage of military personnel are also similar in age to college populations, making them potentially similarly receptive to mobile health interventions. Military personnel may also have confidentiality and health stigma concerns, which mobile health interventions are well suited to mitigate. Furthermore, military populations have expressed general interest in digital interventions [18,19]. As mentioned previously, the military has a particular problem with binge and heavy drinking. In all service branches, there is a protracted ban of alcohol in Basic Military Training and the first part of Technical (advanced) Training. In the Air Force, the ban is for approximately 12 weeks and tolerance to alcohol, even if the Airman (note that Airman is the term used by the Air Force for its service members, regardless of gender or position in the Air Force) used to drink alcohol before basic training, tolerance is low at the completion of training. Our research team has successfully implemented a group-based BAI and observed a significant reduction in the odds of an alcohol-related incident (ARI: getting in trouble while drinking) over the year of the intervention compared to the previous year (odds ratio 0.56, 95% CI 0.38-0.81; P=.002) [20]. Implementing an SMS text message intervention to complement this group-based BAI when Airmen begin to be allowed to leave base and access alcohol for the first time in approximately 3 months has enormous potential.

As the types of messages that civilians find persuasive may not be persuasive to military personnel, it is crucial to develop messages using feedback directly from Airmen in Technical Training to find messages that will be compelling and influential for this population. While individually tailoring the messages is often presumed to be beneficial in targeting addictive behaviors, there are also benefits to having universally acceptable messages. Nontailored messages require no information about the recipient, potentially diminishing the service members’ concerns regarding anonymity. In addition, nontailored messaging can increase feasibility and future dissemination if the intervention is determined to be effective.

**Objectives**

This paper describes a 2-phase mixed methods study designed to develop an SMS text message intervention to reduce binge and heavy drinking among Airmen in Technical Training. Specifically, the aims of this study were to (1) determine the persuasiveness of SMS text messages suggested by experts and Airmen designed to discourage binge and heavy drinking, (2) obtain data about the dose and timing of messages, and (3) create a final message library for efficacy testing.

**Methods**

**Phase 1**

**Study Population**

Participants included 149 Airmen in Technical Training located across 4 US Air Force bases who were attending, as part of standard training, a squadron-level group BAI session. Surveys were administered in each squadron at the end of the BAI session.

**Procedures**

**Message Development**

An initial set of 49 messages were created by content and population experts (eg, military, retired military, and nonmilitary psychologists and health behavior change experts). To reduce participant burden, the 49 messages were divided randomly into 3 sets, with 16 to 17 messages in each set.

**Message Evaluation**

All Airmen were asked to provide their age, gender, and past-month binge drinking frequency (“During the past 30 days, how many times did you have 4 (for women)/5 (for men) or more alcoholic drinks on one occasion?” with response options, “never,” “1 or 2 times,” “3 to 5 times,” “6 to 10 times,” and “11 or more times”). Overall, 3 questions assessed general beliefs about the importance of being successful in Technical Training, perceived impact of receiving a punishment related to alcohol while in the Air Force, and level of concern about having problem drinking, all of which used a 5-point Likert-type scale ranging from 1 (strongly disagree) to 5 (strongly agree). The Airmen were then presented with their set of messages to be evaluated. All 3 sets of messages were included equally in each survey administration, so that all 49 items were assessed evenly within each squadron. For each message, the Airmen responded to 2 items (ie, “This statement makes me concerned about the impact of drinking while in Technical Training” and “This statement discourages me from wanting to drink alcohol excessively”) using a 5-point Likert-type scale ranging from 1 (strongly disagree) to 5 (strongly agree) [21]. Following message rating, the Airmen were asked, “What might be a good text message that you can think of that might discourage an Airmen from drinking too much during Technical Training?” and provided space for a write-in response. Finally, the Airmen were asked about message timing and frequency and for specific points during their training when information of this nature might be particularly useful to receive.
Data Analysis
Following data entry, all responses were summarized using descriptive statistics. The Airmen’s age was dichotomized to <21 years or ≥21 years to reflect US legal drinking limits. Airmen who reported any binge drinking in the past month were coded as binge drinkers. To explore the messages’ persuasiveness, means, medians, and SDs were calculated for the persuasiveness item. “This statement discourages me from wanting to drink alcohol excessively” for each message. The messages were ranked based on persuasiveness and compared according to age and gender using Wilcoxon rank sum tests to identify the top-ranked messages with no statistically significant differences in rating based on age or gender. The resulting top messages were qualitatively coded for themes by 3 study authors (CAA, DGC, and JME). The frequency and timing of message delivery was explored using frequencies and percentages. Finally, messages suggested by Airmen were qualitatively coded for themes.

Phase 2
Study Population
Participants included 283 Airmen in Technical Training located across 4 US Air Force bases who were attending, as part of standard training, a squadron-level group BAI session. Surveys were administered in each squadron at the end of the BAI session.

Procedures
Message Development
Messages suggested by Airmen from phase 1 were refined, often by reformatting them into Airmen quotes, and coded based on the Behavior Change Technique Taxonomy (BCTT). Highly rated messages from phase 1 were also refined and coded based on the BCTT. Informed by the study by Michie et al [22], additional expert-created messages were developed to ensure a pool of messages that addressed key behavior change techniques (BCTs) previously identified to successfully reduce alcohol consumption. The final pool of 77 messages covered the following BCTs: problem solving, goal setting (outcome), action planning, discrepancy between current behavior and goal, review outcome goals, self-monitoring of behavior, information about consequences, information about social and environmental consequences, anticipated regret, social comparison, behavior substitution, comparative imagining of future outcomes, future punishment, reducing negative emotions, restructuring the social environment, avoiding/reducing exposure to cues for the behavior, identification of self as a role model, valued self-identity, and verbal persuasion about capability. To reduce participant burden, the 77 messages were divided randomly into 5 sets, grouped according to BCTs, with 15 to 16 messages in each set.

Message Evaluation
All Airmen were asked to provide their age, gender, and past-month binge drinking frequency (“During the past 30 days, how many times did you have 4 (for women)/5 (for men) or more alcoholic drinks on one occasion?” with the following response options: “never,” “1 or 2 times,” “3 to 5 times,” “6 to 10 times,” and “11 or more times”). Overall, 8 questions were included to assess general beliefs about the importance of being successful in Technical Training, perceived impact of receiving a punishment related to alcohol while in the Air Force, level of concern about having problem drinking, perceived culture of drinking in the Air Force, and opinions about alcohol reduction strategies and not drinking while in Technical Training, all of which used a 5-point Likert-type response scale ranging from 1 (strongly disagree) to 5 (strongly agree). The Airmen were then presented with their set of messages to be evaluated. All 5 sets of messages were included equally in each survey administration, so that all 77 items were assessed evenly within each squadron. For each message, the Airmen responded to 4 items to assess persuasiveness (ie, “This statement makes me concerned about the impact of drinking while in Technical Training”; “This message makes me think about how to be successful in Technical Training”; “This statement discourages me from wanting to drink alcohol excessively”; and “This message would be useful if I wanted to reduce or limit my drinking”) using a 5-point Likert-type scale ranging from 1 (strongly disagree) to 5 (strongly agree) [21]. Following message rating, the Airmen were asked to select 3 messages from their set that they believed would be most likely and least likely to help Airmen make good choices about alcohol.

Data Analysis
Following data entry, all responses were summarized using descriptive statistics. The Airmen’s age was dichotomized to <21 years or ≥ 21 years to reflect US legal drinking limits. Airmen who reported any binge drinking in the past month were coded as binge drinkers. To determine message suitability for inclusion in the final message pool, means, medians, and SDs were calculated for each item regarding message persuasiveness. The messages’ persuasiveness was compared according to age and gender using Wilcoxon rank sum tests to identify any messages with statistically significant differences in rating based on age or gender. The messages in phase 2 were ranked based on persuasiveness and considered within each BCT and overall to develop a final message pool that could address multiple BCT targets. Any messages that were statistically different based on age or gender where 1 group had a mean score below a threshold of 3.5 were excluded from consideration.

Ethical Considerations
In both phases, participants were asked to complete an anonymous survey. Both surveys were approved by the Joint Base San Antonio institutional review board as quality improvement, and thus, a full review was not required. The voluntary, fully informed consent of participants was obtained as required by 32 Code of Federal Regulations (CFR) 219 and Department of Defense Instruction (DODI) 3216.02. The study staff emphasized that participation in the survey was optional and anonymous, and >99% of the population consented to participate. No information was obtained about the individuals who did not choose to participate.
Results

Phase 1
Among the 149 respondents, 113 were men, 76 were aged <21 years, and 131 reported no heavy drinking in the 30 days before starting military training (Table 1). Approximately all (140/148, 94.6%) reported agreement with the statement, “Being successful in Technical Training is extremely important to me.” Motivation to be successful in Technical Training was also high; 89.9% (133/148) agreed to the statement, “Receiving punishment for an alcohol related incident (ARI) in Technical Training could harm or end my career,” and 91.2% (135/148) agreed that “Whether I drink alcohol or not, it is very important to me to NOT have a problem related to my drinking” (data not shown).

The values do not add up to 100% owing to missing data.

The 10 expert-created messages with highest median persuasiveness scores and statistically similar responses based on age (<21 years and ≥21 years) and gender (man and woman) are shown in Table 2. Qualitative coding indicated that 9 of the 10 (90%) top-rated messages had a theme related to warning about adverse outcomes, with specific adverse events related to the following: impaired judgment (4/9, 44%), career or receiving an ARI (3/9, 22%), assault (1/9, 11%), and financial costs (1/9, 11%). Of the 10 top-rated messages, 5 (50%) also included recommendations, with specific recommendations related to the following: planning (3/5, 60%), moderation (1/5, 20%), and low-risk drinking (1/5, 20%). Of the 10 top-rated messages, 1 (10%) invoked values and goal reminders.

• Recommendation (prioritize long-term goals) |
| “Your career could be in that bottle.” | • Warning about adverse outcomes (career) |

Most Airmen preferred to be sent 1 to 3 messages per week (124/137, 90.5%), followed by 4 to 6 messages per week (10/137, 7.3%). The most frequently selected days to receive messages were Friday, Saturday, and Sunday in combination (65/142, 45.8%) and Thursday, Friday, and Saturday in combination (20/142, 14.1%). Most respondents preferred messages to be sent in the early evening (84/149, 56.4%) or late evening (80/149, 53.7%; data not shown).

Phase 2
Among the 283 respondents, 189 were men, 125 were aged <21 years, and 204 reported no heavy drinking in the 30 days before starting military training (Table 1). Approximately all (243/259, 93.8%) reported agreement with the statement, “Being successful in Technical Training is extremely important to me.” Motivation to be successful in Technical Training was also high, as 90.3% (233/258) agreed to the statement, “Receiving punishment for an alcohol related incident (ARI) in Technical Training could harm or end my career,” and 88.7% (228/257) agreed that “Whether I drink alcohol or not, it is very important to me to NOT have a problem related to my drinking” (data not shown).

The final messages selected for inclusion in the SMS text message intervention are shown in Table 4. The final message library includes 28 BCTT-informed messages across 13 different BCTs and 5 messages (not shown) directly referencing content originally introduced in the group BAI. The program is designed to be delivered over 6 weeks, sending 3 to 4 messages per week, and most messages are sent on Friday and Saturday in the late afternoon and early evening. Mean scores for the included messages ranged from 3.31 (SD 1.29) to 4.21 (SD 0.90). Of the top 5 highest-rated messages in the final message library, 4 were categorized into 2 BCTs: valued self-identity and information about health consequences. Specific recommendations for behavior differ for those who are and those who are not legally allowed to drink in the United States, as those with ARIs and aged <21 years face harsher disciplinary action. Therefore, while designed to be a universally delivered program, for Airmen aged 21 years or those who will be aged 21 years during the intervention period, safe drinking–related messages were prioritized, whereas for Airmen aged <21 years, abstinence-related messages were prioritized. The total number of messages received by each Airmen is the same. Therefore, the distribution of BCTs differs according to age, with most action planning messages (3/4, 75%) only being sent to Airmen aged <21 years.
aged ≥21 years. Messages for Airmen aged <21 years have a high percentage of messages addressing the consequences of alcohol use. The inclusion of targeted messages based on age also resulted in 2 new messages needing to be created that were informed by phase 2 results but not evaluated by Airmen. Of the final 28 messages, 8 (28.6%) were informed by messages suggested by Airmen from phase 1.
Table 4. The final message library of an SMS text message intervention to prevent binge and heavy drinking among Airmen in Technical Training, with coding based on Behavior Change Technique Taxonomy.

*DU: driving under the influence of alcohol.
ARI: alcohol-related incident.
Only sent to Airmen who are of US legal drinking age or who will be before the end of the intervention period.
Only sent to Airmen who are younger than the US legal drinking age.
Indicates a message that was not included in phase 2 testing.
Original source was a message suggested by Airmen from phase 1.

**Discussion**

**Principal Findings**

This 2-phase study developed an automated SMS text message intervention designed to reduce binge and heavy alcohol use among young adults entering the military. In phase 1, a sample of US Air Force Technical School trainees rated the messages created by experts and provided suggestions. In phase 2, the messages suggested by Airmen and those that were highly rated in phase 1 were refined and rated alongside additional expert-created messages. These phases culminated in the creation of a BCTT-informed SMS text message program for Airmen in Air Force Technical Training and highlight an approach for message testing and program development, which incorporates mixed methods feedback from the target population. This approach allowed us to have a final program that was directly informed by the target population and led to more than one-fourth (8/28, 28.6%) of the final messages being in the Airmen’s own words.

Top-rated, expert-created messages from phase 1 included recommendations for planning or drinking in moderation and warnings about adverse outcomes associated with drinking in excess (eg, career impact, risk for sexual assault, and impaired judgment associated with drinking). In particular, most (9/10, 90%) of the top-rated messages in phase 1 were loss-framed messages. Messages suggested by both experts and Airmen included warnings about adverse outcomes, especially pertaining to one’s career. Other themes of the messages suggested by Airmen were reminders to prioritize long-term goals and values over short-term “fun” and emphasis on belonging to the same collective team. In phase 2, an expanded set of items organized based on BCTs allowed for a more nuanced analysis of the potential message pool. Specifically, it also allowed for the inclusion of more gain-framed messages. As in phase 1, the highly rated messages in phase 2 were related to themes such as adverse outcomes and long-term values and goals. The 2 highest-rated messages in the final program were related to the topics of valued self-identity (“Remember why you joined the Air Force. [link to inspirational video]. Don’t let alcohol be what stops you from achieving these goals.”) and comparative imagining of future outcomes (“Take a moment to reflect on what you hope to achieve in the next year, academically, professionally, or athletically. How could alcohol get in the way?”), which both had loss-framed messages around alcohol getting in the way. Thematic consistency of top-rated messages across both phases of the study suggests that the messages ultimately included in the final message pool are likely to resonate with the target population. The real-world effectiveness of these messages are being empirically evaluated in an ongoing clinical trial.

The final intervention is targeted at Airmen of the US legal drinking age, while also being designed to be uniformly acceptable across genders. Therefore, message ratings were
considered overall and according to age and gender. This allowed for a program that can still be scaled up easily while providing relevant content for specific subsets of the population.

If tailoring based on other factors becomes necessary, for example, the Airman’s specific role in the Air Force, this study provides a framework through which messages can be developed and evaluated with specific tailoring needs in mind. It will also be important to explore the potential moderators of program success after completion of the currently underway clinical trial. The presence of a strong effect modifier would suggest a potential need to tailor based on specific Airmen characteristics and would help justify the collection of additional personal information at the time of program sign-up.

Phase 1 also identified Airmen’s preferences for receiving SMS text messages, which were incorporated into the final intervention. Specifically, the Airmen preferred to receive messages at a frequency of approximately 3 to 5 times per week, in the evenings and on weekends. This could be an ideal window to receive a timely prompt in the form of an SMS text message, given that Airmen are most at risk for binge drinking from Friday evening to Sunday evening when they become able to leave their base (approximately 10-12 weeks after starting Basic Military Training). Having information about message timing and frequency preferences allowed us to develop an SMS text message program that should fit within each Airman’s daily routine and maximizes the number of messages sent at times when the Airmen may be considering and planning off-base activities, where alcohol is more readily available.

Across both phases, respondents reported interest in being successful in Technical Training, believed that an ARI would be detrimental to their careers, and did not want to have a problem associated with their drinking. These results should be interpreted with some caution, as respondents had just completed the group BAI; therefore, the Airmen might have been having heightened feelings regarding the potential harms of alcohol use. It could also show the potential of the group BAI to be a teachable moment, which the SMS text message intervention will attempt to capitalize on to sustain self-reflection and opinions about alcohol use and the desire for success during Technical Training. The sentiment of success during Technical Training is also referenced in the SMS text message intervention to increase the potential salience of the messages.

In addition to being developed specifically for a noncivilian population, there are other differences between the SMS text message intervention described in this paper and the previously developed alcohol reduction SMS text message interventions [12,13]. For example, the 2 previous studies designed to address binge drinking included assessments of drinking behavior. Specifically, Cadigan et al [12] collected information about participant drinking behavior while tailgating at baseline to provide normative feedback to participants during the intervention, which referenced back to the information each participant provided. Suffoletto et al [13] asked participants to report anticipated drinking behavior and the highest number of drinks consumed over the weekend, and responses were used to tailor other intervention messages. Owing to confidentiality concerns within the military, actual alcohol use behavior is not able to be captured by Airmen within the SMS text message intervention described in this paper. Thus, direct normative feedback cannot be delivered to participants. However, there is a message included to allow for social comparison. Despite this difference, there are also similarities between the proposed intervention and previous studies, such as sending messages when participants are at the highest risk of drinking (ie, weekends) and not tailoring the messages based on other personal characteristics.

In addition to the programmatic differences described previously, to the best of our knowledge, the SMS text message intervention described in this paper is the first to use BCTs to guide intervention development within the context of alcohol reduction [22,23]. The use of BCTs is helpful for understanding the hypothesized mechanisms of action through which the SMS text message intervention may reduce binge and heavy alcohol use. In addition, it allows for the testing of active components in future evaluations. This SMS text message intervention includes content that covers 13 distinct BCTs, which is more than the average number seen in previous behavior change interventions to reduce alcohol use (mean 9.1 BCTs) [24], but less than another SMS text message intervention that was coded based on BCT after its development and evaluation (23 BCTs) [23]. However, there may be other BCTs that could prove to be valuable. A future study could evaluate the impact of adding content that addresses additional BCTs. Moreover, the SMS text message intervention could be separated into unique BCT components and compared directly [25] to better understand which BCTs are most important for addressing binge and heavy drinking in this population.

Limitations
A limitation of this study is that this pool of messages is based solely on the Airmen’s predictions about which messages will influence future drinking behavior. Consequently, the final message pool must be empirically tested to determine its impact on alcohol-related behavior. This study is the first to develop an SMS text message intervention to reduce binge and heavy drinking within a US military population, specifically, the US Air Force. However, it is possible that the results of this mixed methods approach are not generalizable to other military settings.

Conclusions
This study included the involvement of members from the target population throughout the formative stages of intervention development, to design an SMS text message intervention to reduce binge and heavy drinking in the US Air Force. Message content was anchored to evidence-based behavior change techniques according to the BCTT in conjunction with integration of feedback from Airmen regarding SMS text messaging language, timing, and frequency, thus increasing the odds of a robust intervention effect.

Abstract

Background: Stress is an emotional response caused by external triggers and is a high-prevalence global problem affecting mental and physical health. Several different digital therapeutic solutions are effective for stress management. However, there is limited understanding of the association between relaxation components and stress levels when using a digital app.

Objective: This study investigated the contribution of relaxation tools to stress levels over time. We hypothesized that participation in breathing exercises and cognitive behavioral therapy–based video sessions would be associated with a reduction in stress levels. We also hypothesized a significant reduction specifically in participants’ perceived sense of burden and lack of productivity when engaged with breathing exercises and video sessions.

Methods: Stress levels were evaluated in a real-world data cohort using a behavioral health app for digital intervention and monitoring change. This retrospective real-world analysis of users on a mobile platform–based treatment followed users (N=490) who started with moderate and above levels of stress and completed at least 2 stress assessments. The levels of stress were tracked throughout the first 10 weeks. A piecewise mixed effects model was applied to model the trajectories of weekly stress mean scores in 2 time segments (1-6 weeks and 6-10 weeks). Next, a simple slope analysis was used for interpreting interactions probing the moderators: breathing exercises and video sessions. Piecewise mixed-effects models were also used to model the trajectories of specific perceived stress item rates in the stress questionnaire in the 2 segments (1-6 weeks and 6-10 weeks) and whether they are moderated by the relaxation engagements. Simple slope analysis was also used here for the interpretation of the interactions.

Results: Analysis revealed a significant decrease in stress symptoms (β=−0.25; 95% CI−0.32 to −0.17; P<.001) during the period of 1-6 weeks of app use that was maintained during the period of 6-10 weeks. Breathing exercises significantly moderated the reduction in stress symptoms during the period of 1-6 weeks (β=−0.07; 95% CI−0.13 to −0.01; P=.03), while engagement in digital video sessions did not moderate stress scores. Engagement in digital video sessions, as well as breathing exercises, significantly moderated the reduction in perceived sense of burden and lack of productivity during weeks 1-6 and remained stable during weeks 6-10 on both items.

Conclusions: This study sheds light on the association between stress level reduction and specific components of engagement in a digital health app, breathing exercises, and cognitive behavioral therapy–based video sessions. Our findings provide a basis for further investigation of current and moderating factors that contribute to the personalization of digital intervention. In addition, results may aid in developing a more comprehensive understanding of how digital intervention tools work for mental health and for whom they are most effective.

Introduction
Stress is defined as an emotional or physical reaction typically caused by an external trigger [1,2] and is known to be a high-prevalence global problem, negatively affecting mental and physical health [3]. According to Gallup 2019 Global Emotions Report, the percentage of the American population who experienced stress (55%) is one of the highest in the world, as compared to the global average of 35% [4,5]. Furthermore, it is reported that distress levels have only increased during the COVID-19 pandemic due to health concerns, altered everyday life routines [6], and the unpredictability of its future implications [3]. A recent US stress survey conducted, reports an elevated average reported stress level from prepandemic levels [7]. Moreover, an alarming proportion of adults reported that stress has an impact on their day-to-day functioning, with more than a quarter (27%) saying that most days they are so stressed they cannot function [7].

Stress has a major impact on managing daily life, as everyone experiences it in varying forms every day [8]. According to the American Psychological Association’s 2014 Work and Well-Being Survey, 31% of employed adults indicated that they felt tense or stressed out during the workday [9]. Several studies investigating the understanding of how employee health impacts work performance have found stress can cause burnout, absenteeism, and reduced efficiency and performance [10], which can negatively impact the organization [11]. Yet, some resources can be implemented to help meet the pressures and demands faced at work [12].

There is evidence of improvements in health status due to workplace wellness programs for mental health [13,14]. In the past decade, the delivery of digital interventions has become increasingly popular; these interventions target common mental health illnesses [15] within the workplace due to their easy implementation [16]. Web-based interventions are shown to offer several advantages that may overcome some of the limitations of face-to-face approaches [17] as they are accessible through any internet-connected device. Among the working population, these interventions could especially benefit those who do not seek regular mental health treatment because of negative perceptions of mental health needs in the workplace [14].

It is reported that a substantial proportion of adults with common mental disorders fail to receive treatment [18]. The barriers thought to impede appropriate mental health care seeking have been well documented in the literature [18,19]. Many patients experience accessibility issues such as prolonged wait times, cost, clinic location, and transportation [20]. Others report that the stigma associated with mental illness diagnosis is the main reason that decreases their willingness to seek treatment [19].

Thus, digital interventions have the potential to overcome many of the barriers associated with seeking and accessing mental health care [18] and to provide increased convenience for patients allowing them access to care at any time.

Furthermore, digital health solutions aim to foster patient empowerment [21,22] by encouraging them to be proactive in the care process. These interventions allow people the right guidance and support for self-management, consequently addressing their own health-related goals [23]. Digital solutions also enable users to be better informed about their health, share experiences, assess and monitor specified health states, reach treatment, and improve communication between them and health care professionals [24].

In recent years, there has been an increase in the delivery of digital therapeutics targeting common mental health conditions [25,26]. Depression and anxiety, which have the highest prevalence among mental health conditions, are at the forefront of these targeted programs [26]. Previous research has demonstrated the efficacy of web-based interventions on the prevention and management of these conditions [27,28] and these conditions were even reported as efficacious as traditional face-to-face treatments [29].

Most treatment provided in behavioral health apps uses module-based sessions and the teaching of coping and management strategies based on cognitive behavioral therapy (CBT) principles, problem-solving therapy, and psychoeducation [20,26]. The digital application of CBT is showing promising results in the treatment of depression and anxiety disorders [30]. Additional research suggests that a successful approach to addressing digital health interventions is through a multicomponent design [13], using features such as tailored messages, reporting of thoughts, feelings, or behaviors [31]; relaxations features [5]; integrated therapist contact and other supplementary worksheets and engagements [20].

Notwithstanding that stress itself is not defined as a disorder, it can lead to major psychological and physical implications that could place people at risk for illness [17,32]. Given that stress represents a major threat to public health, effective and scalable solutions to accommodate the demand for stress-management interventions are needed [17]. The concept of “stress management” refers to the emotional, psychological, and behavioral methods used to develop skills to manage and reduce stress [33]. Several types of stress management interventions have been reported to be effective at reducing stress levels, such as CBT, time management, relaxation, and meditation exercises [34]. However, applying these self-help skills to achieve improvement requires motivation and self-discipline.

One of the easiest methods for managing stress-related symptoms is deep breathing exercises [3]; these exercises have been proposed as first-line and supplemental treatments for emotional disorders [35]. Several studies reported that the use of different breathing techniques showed significant improvement in mood states and perceived stress [36,37].

Jmir Form Res 2024 | vol. 8 | e50506 | p.1397

(page number not for citation purposes)
resulting in an effective improvement in the management of stress in daily life [36]. Slow and deep breathing can have a significant impact on reducing stress feelings and activating the relaxation response. This exercise is efficient as it reduces the ventilation in the dead space of the lungs and decreases the effect of stress and strain on the body by shifting the balance toward the parasympathetic system [38].

In recent years, the number of studies on digitally delivered stress management has been rising, yet the overall effect of specific formats of treatment delivery remains unclear [17]. Moreover, existing web-based stress management programs differ in various aspects such as type, content, and guidance, and this may influence their efficacy [17].

A recurring element described in the literature is video-based self-administered intervention programs, which are mainly rooted in a CBT framework [39,40]. Previous studies reported that video-based CBT has shown effectiveness for anxiety, sexual pain, and insomnia [39-41]. However, these video-based programs have not yet been integrated into the treatment of stress in a digital form. This method is described as a third waveform of CBT [40], which is characterized by concepts such as acceptance and mindfulness that focus on the person’s relationship to thought and emotions [42].

In their meta-analysis review of digital mindfulness-based interventions, Spijkerman et al [43] suggested that these interventions can be effective in reducing perceived stress. Mindfulness is a complete therapy that can minimize stress levels and improve psychological well-being because it includes various components of relaxation, such as yoga, deep breathing techniques, and focusing attention [44]. However, despite the abundance of digital mindfulness-based interventions and considering the structured variability [45], it is presently unknown whether different components of these interventions are effective.

In summary, although there has been an established body of research evaluating the efficacy of mobile app platforms for stress management, there has been less focus on the effectiveness of engagement with specific components and relaxation strategies for stress reduction. The purpose of this study is to evaluate the effect of a relaxation engagement digital behavioral health app on perceived stress. Our primary hypothesis is that in users with moderate-to-high stress levels, improvements in stress scores will be observed during the initial weekly period of the intervention and will be followed by maintenance for several weeks after. We hypothesized that engagement with certain digital components would moderate the reduction in stress levels. Specifically, we hypothesized that breathing exercises and video sessions would moderate stress levels’ reduction. We also anticipated a significant reduction in the perceived sense of burden and perceived level of productivity ranking as these measures were designed to reflect a change in perceived stress levels over time.

### Methods

#### Behavioral Health App

The Dario Health behavioral health app is essentially a modular tool delivering emotion-focused support designed to apply to a range of mental health conditions. Members generally have access to the Dario Health behavioral health platform as part of their employee or health plan benefits. A clinically based screening tool assesses each person’s needs and guides users to the most efficient support. The app provides several CBT programs including depression, anxiety, anger, stress, and substance use, and can be used as a self-guided intervention or with the help of a certified coach. The structure of each program includes conceptual videos, textual skills, breathing exercises, and monitoring progress tools. This study focuses on tracking cohorts of users with stress scores measured by their responses to the stress questionnaire.

The stress program begins with a psychology education module about stress, identifying symptoms, as well as how it presents itself physically, mentally, and emotionally. The program includes short CBT-based and empirically supported whiteboard educational videos, introducing skills such as understanding the impact of stress, coping strategies, identifying stress signs and symptoms, and stress-related behaviors. By increasing the awareness of the individuals’ thoughts and feelings and gradually explaining specific situations leading to stress, these modules provide a way to promote stress self-management. During these skills-based sessions, various techniques are introduced to assist with reducing stress such as relaxation exercises, breathing exercises, monitoring progress, and coaching. The content is delivered to engage the users and appealingly convey information. Relaxation exercises provide a digital experience including audio or video sessions of mindfulness, muscle relaxation techniques, and automatic thoughts and emotions regulation.

The breathing exercises are instructed as a short up to 5-minute audio guide; each one educates about a different technique, that is, progressive muscle relaxation, diaphragmatic breathing, or 4-7-8 breathing.

Coaching is introduced to users for support and assistance and people who choose to obtain coaching services via the app.

#### Measures

Stress levels were assessed over 10 weeks using a stress questionnaire. The questionnaire that objectifies the degree of stress severity is a 5-item self-reported, in-app delivered questionnaire. Each of the 5 items is scored from 0 (not at all) to 3 (nearly every day; Table 1). The questionnaire aims to assess an individual’s level of stress and the factors contributing to it. The questionnaire items reflect perceived stress such as a sense of burden, lack of productivity, and symptoms of stress such as lack of sleep, body tension, and irritability. As a severity measure, scores range from 0 (absent of stress symptoms) to 15 (severe stress levels). Stress scores of ≤5, 6-10, and >10 represent low, moderate, and high stress levels, respectively. Internal reliability testing of the questionnaire demonstrated an acceptable internal reliability with a Cronbach α of 0.73 [46].
Table 1. The components in the stress questionnaire grading stress severity.

Independent variables were included in the analysis as potential moderating factors such as app sessions, videos, breathing exercises, and coaching interactions.

All data were transferred and stored in compliance with HIPAA (Health Insurance Portability and Accountability Act) requirements, using MongoDB or BigQuery database services. All data were anonymized before extraction for this study.

Users

A retrospective data evaluation study was performed on the Dario database.

The stress cohort consisted of a group of 490 users who used the Dario Behavioral Health platform between 2019 and 2022. The population included users who started at a moderate and above level of stress (stress questionnaire score >5) and those who completed at least two stress assessments. The sample included 388 (79%) women, 95 (19%) men, and 7 (2%) others. The age distribution was as follows: ≤35 (38%), 36-55 (49%), 56-65 (12%), and 66-76 (1%) years. The average baseline score of the stress questionnaire was 9.8 (SD 2.7; median 10, IQR 4). The weekly average time of app use observed in this cohort was 26.4 minutes (SD 39.2; median 14, IQR 21)

Ethical Considerations

All data used for the analysis were anonymized before extraction for this study. This study received an exemption from the institutional review board. Ethical & Independent Review Services [47], a professional review board, issued the institutional review board exemption for this study (21235 - 01#).

Statistical Analysis

A classical linear longitudinal model assumes a single-slope growth pattern for changes in an outcome variable across time. In contrast, piecewise - based mixed effects models allow flexibility in the modeling of variable change trajectories across time [48]. Previous studies consistently demonstrated a 2-stage dynamic of clinical outcomes associated with digital interventions: an initial improvement is followed by stabilization of the outcome [49,50].

Following a visualization of the distribution of the stress estimates over time, a piecewise cutoff point for the model slopes was chosen at 6 weeks of product use, assuming a change in the time-related stress severity level trajectory after 6 weeks considering previous research as well [51,52]. Such a behavior including 2 trajectories is in line with our previous research on digital follow-up measures in chronic conditions management [53,54].

Here, a piecewise mixed effects model was conducted to model the trajectory of the stress questionnaire mean score in 2 segments to allow the data to exhibit different linear trends over different periods. We tested whether digital engagement moderated 2 piecewise time trajectories in stress (1-6 weeks and 6-10 weeks). The model included a person-based random intercept and random slope for the time trajectory after the piecewise cutoff. Simple slope analysis was used for the interpretation of the interactions probing the moderators at 1 SD below (low engagement) and 1 SD above (high engagement) the average.

Next, we used mixed model analysis to model the trajectory of questions 1 and 2 rates (Table 1) in the stress questionnaire in
the 2 segments (1-6 weeks and 6-10 weeks). Moreover, we tested whether these scores were moderated by engagement with specific components in the app. The models included a random intercept and random slope of the time trajectory. Simple slope analysis was used for the interpretation of the interactions probing the moderators at 1 SD below (low engagement) and 1 SD above (high engagement) the average.

**Results**

**First Analysis: Stress Score Reduction Is Associated With Breathing Exercises**

In total, 90% (441/490) of the users improved or maintained their stress level over this study’s period, that is, remained at a moderate level or improved from moderate or high to a low level of stress.

Piecewise mixed model analysis revealed a significant decrease in stress levels ($\beta = -0.25; 95\% \text{ CI} -0.32$ to $-0.17; P < .001$) during the period of weeks 1-6. There were no significant time-related trends in stress during the period of weeks 6-10 ($\beta = 0.00; 95\% \text{ CI} -0.21$ to 0.22; $P = .98$). **Figure 1A** demonstrates time-related fluctuations in stress levels.

Breathing exercises significantly moderated the reduction in stress score during the period of weeks 1-6 ($\beta = -0.07; 95\% \text{ CI} -0.13$ to $-0.01; P = .03$). The weekly average number of breathing exercises completed is 1.55 (2.34 SD). Users with increased breathing exercise completion (+1 SD) demonstrated stronger reduction in stress score ($\beta = -0.45; 95\% \text{ CI} -0.64$ to $-0.25; P < .001$) compared to users who completed fewer breathing exercises ($-1 \text{ SD}$), that was not significant ($\beta = -0.13; 95\% \text{ CI} -0.32$ to 0.05; $P = .15$). Breathing exercise did not moderate the time trajectory of stress levels during the period of weeks 6-10 ($\beta = -0.02; 95\% \text{ CI} -0.23$ to 0.19; $P = .87$).

**Figure 1B** presents low and high levels of breathing exercise engagement, showing a significant reduction in stress levels only for users with high engagement, while the decrease for users with low engagement was not significant.

The engagement in digital video sessions did not significantly moderate stress score during both segments of time ($\beta = -0.01; 95\% \text{ CI} -0.03$ to 0.00; $P = .14$ and $\beta = -0.03; 95\% \text{ CI} -0.11$ to 0.04; $P = .37$ to week 1-6 and 6-10 accordingly).

**Second Analysis: Improvement in Perceived Stress Is Moderated by Digital Video Sessions**

**Overview**

The perceived stress level was reflected by items 1 and 2 in the questionnaire.

**Question 1: “Have you felt overwhelmed or stressed about important responsibilities?”**

Piecewise mixed model analysis revealed that breathing exercises significantly moderated the reduction in question 1 ranking during the period of weeks 1-6 ($\beta = -0.02; 95\% \text{ CI} -0.04$ to $-0.01; P = .009$). Breathing exercises did not moderate the time trajectory of question 1 ranking during weeks 6-10 ($\beta = -0.00; 95\% \text{ CI} -0.06$ to 0.06; $P = .91$). The weekly average number of breathing exercises completion is 1.55 (2.34 SD). Users with increased breathing exercise engagement (+1 SD) demonstrated a stronger reduction in perceived stress prompted by important responsibilities ($\beta = -0.13; 95\% \text{ CI} -0.19$ to $-0.08; P < .001$) compared to users who were less engaged in breathing exercises ($-1 \text{ SD}$), that was not significant ($\beta = -0.02; 95\% \text{ CI} -0.07$ to 0.03; $P = .40$).

Further piecewise mixed model analysis revealed that engagement in digital video sessions significantly moderated
the reduction in question 1 ranking during the period of weeks 1-6 (β=-0.01; 95% CI –0.01 to –0.00; P=0.02), yet no significant reduction was seen during the period of 6-10 weeks (β=0.00; 95% CI –0.02 to 0.02; P=0.91). The weekly average number of video session completion is 6.38 (8.59 SD). In addition, it was found that users who completed a higher number of video sessions (+1 SD) demonstrated a greater reduction in question 1 ranking (β=-0.13; 95% CI –0.19 to –0.07; P<0.001) compared to those who were less engaged (–1 SD) with video sessions (β=0.02; 95% CI –0.08 to 0.03; P=0.38).

**Question 2:** “What about feeling as though you were not as productive as you should’ve been?”

A piecewise mixed model has shown that the completion of breathing exercises has also significantly moderated the reduction of question 2 ranking in the stress questionnaire during the period of weeks 1-6 (β=-0.02; 95% CI –0.04 to –0.00; P=0.04); however, the period of 6-10 weeks was not significant (β=0.01; 95% CI –0.05 to 0.07; P=0.64). The weekly average number of breathing exercises completion is 1.55 (2.34 SD). Users with an increased number of completed breathing exercises (+1 SD) displayed a significant reduction in the question 2 ranking (β=-0.07; 95% CI –0.13 to –0.01; P=0.02), while in users who completed fewer breathing exercises (–1 SD), the reduction was not significant (β=0.02; 95% CI –0.04 to 0.07; P=0.55).

Here as well, an additional piecewise mixed model has demonstrated that engagement in video sessions significantly moderated the reduction in question 2 rank during weeks 1-6 (β=-0.01; 95% CI –0.01 to –0.00; P=0.01), yet no significant reduction was found in weeks 6-10 (β=0.00; 95% CI –0.02 to 0.02; P=0.84). The weekly average number of video session completion is 6.38 (8.59 SD). Furthermore, results from the simple slope analysis showed that users with increased engagement in video sessions (+1 SD) were significantly associated with improvement in question 2 rank (β=-0.08; 95% CI –0.14 to –0.02; P=0.01), compared to users with lower engagement (–1 SD) to video sessions (β=0.03; 95% CI –0.02 to 0.08; P=.27).

**Discussion**

**Principal Results**

The Dario Health behavioral health stress program delivers an optimized solution that combines videos, textual skills, breathing exercises, and interaction with a coach to improve the users’ emotional wellness. The goal of this study was to assess changes in stress outcomes over time among users with moderate and above levels of stress scores at baseline. This study tested the effect of digital therapeutic use on stress levels over time, using a specific engagement instrument for stress conditions. Piecewise mixed model analysis indicated a significant decrease in stress levels during the period of the first 6 weeks of product use and maintained during the period from 6 to 10 weeks with no significant time-related trends. Engagement in breathing exercises significantly moderated the reduction in stress levels during weeks 1-6. During the period of 6-10 weeks, the reduced level of stress was maintained, and there were no significant time-related trends. An additional piecewise mixed model revealed that engagement in video sessions significantly moderated the reduction of perceived stress as shown by a decreased sense of burden (question 1) and a decreased lack of productivity (question 2), during weeks 1-6. It is worth noting that stress can have various causes and effects, and everyone experiences stress differently. However, a sense of burden and lack of productivity are commonly associated with stress, and identifying and acknowledging them can help individuals take steps to manage their stress levels and improve their well-being.

This real-world analysis presents new evidence regarding the dynamic efficacy of digital therapeutic solutions for people with moderate to high stress levels. The results are consistent with previous research that observed improvements in mental health metrics following digital, app-based interventions [26,29,33]. Our findings also provide insight into the nonlinear nature of stress level reduction during the first 10 weeks of a digital behavioral health program by showing the direct association with breathing exercises during the improvement stage in the first 6 weeks and emphasizing the key role of breathing exercises on stress reduction. In the next 6-10 weeks, the reduced levels of stress are maintained indicating that experiencing the use of a behavioral health digital program is a sustainable approach that may create a positive environment leading to a meaningful change. A nonlinear effect of digital therapeutics has previously been demonstrated in studies of mental health recovery via digital therapeutic intervention [50,55]. Additionally, the nonlinear effect of chronic condition management has been previously demonstrated in studies of chronic condition management such as glucose levels in diabetes, blood pressure, and pain level changes over time [53,54,56].

The study of nonlinear change requires multiple assessments over time and examination of the individual trajectories of variables [55,57]. If the variables of interest are assessed frequently over the course of product use, processes can be examined to better understand what facilitates and inhibits change. In this study, we examined time course data moving beyond the question of whether stress level change occurs and toward an understanding of how change occurs. A piecewise mixed model analysis indicated a significant decrease in stress level during the period of the first 6 weeks of product use and maintained during the period from 6 to 10 weeks with no significant time-related trends. This real-world intervention may have captured how change in coping may occur. In other words, people initially improve by learning to cope more effectively with stress but that needs to be incorporated, so this change can occur over only a limited period before it can be truly integrated.

Based on current findings it appears that it takes 6 weeks to learn and then 6-10 weeks to integrate before becoming a changed behavior.

Although this real-world study does not relate to gender-specific experiences, it is notable that the gender ratio predominantly consists of women by 79% (388/490). Per previous studies, women are more likely to use e-mental health programs, designed features, and practices to reduce symptoms of stress or depression although they do not differ in terms of their general internet use [58]. The prevalence of major depressive episodes in women is about 2 times higher than that in men [59]. This could be explained by the existence of gender norms,
men are less likely than women to disclose mental health symptoms and often delay seeking help until symptoms become severe [60,61]. From the social role perspective, women often have a multitasking agenda hence, efficiency and convenience of treatment may be more regarded [62,63].

In terms of physiological aspects, men and women were not seen to differ in terms of breathing practice and integrative body-mind training for dealing with stress conditions [64].

To date, there have been very few large-scale studies examining the effectiveness of digital therapeutic interventions for emotional disorders delivered in real-world settings [65-67]. There is also limited quantitative literature on the associations between the program components and direct methods with clinical outcomes [68].

We hypothesized that breathing techniques may be an enhanced method to address and reduce the bodily and mental processes associated with stress. Breathing exercises are an easily taught and practiced direct method, and they can realize almost immediate benefits and therefore allow for greater behavioral change. Stress causes sympathetic activation; the sympathetic nervous system is 1 of the 2 branches of the autonomic nervous system [35]. The sympathetic nervous system plays a critical role in the body’s response to stress. When it is activated, it triggers the “fight or flight” response, which prepares the body for immediate action in response to a perceived threat or danger [69]. The sympathetic nervous system is activated by the hypothalamus in response to a threat, which triggers the release of hormones such as adrenaline and noradrenaline [70]. Therefore, various physiological responses are caused such as increased heart rate, blood pressure, and respiratory rate, as well as the release of glucose from the liver to provide energy for the body’s response [71]. Our findings demonstrated that engagement with breathing exercises significantly moderated the reduction in stress levels during the period of weeks 1-6. Slow and deep breathing is known to activate the parasympathetic nervous system.

Stress can have various causes and effects, and everyone experiences stress differently. However, a perceived sense of burden and a perceived lack of productivity are commonly associated with stress. Identifying and acknowledging these stress-related feelings are the first steps in taking proactive measures to address them. Therefore, we also hypothesized that the ranking of the two items in the questionnaire, that is, (1) “Have you felt overwhelmed or stressed about important responsibilities?” and (2) “What about feeling as though you were not as productive as you should’ve been?” would be associated with engagement with certain digital components. We assumed that an improvement in perceived stress is reflected by the ways those 2 items would be linked to product use when combining video sessions with digital tools. Our findings showed that both items’ rankings 1 and 2 were moderated by engagement in video sessions as well as in breathing exercises. Engagement with CBT-based video sessions has the potential to be effective and efficient in treating symptoms of mental health conditions in real-world settings [72-74]. Managing stress and handling challenges are obtained by learning how to cope with stress in day-to-day life and adjusting it to the level of stress necessary for optimal functioning. The video sessions explain the core concepts of problem-solving and decision-making to reduce burden and modulate perceptions of responsibilities.

One of the strategies that helped to manage stress and improve well-being is setting realistic goals and prioritizing tasks [75]. Offering content and recommendations about breaking down tasks into manageable steps and setting realistic goals that combat the style of perfectionistic thinking possibly helped individuals to reduce feelings of burden and increase productivity reflected in items 1 and 2 in the questionnaire.

It was consistently demonstrated in our findings that breathing exercises moderated the improvement of the general stress score and the ranking of items 1 and 2 as well. Breathing exercises have a significant impact on reducing perceived stress and promoting relaxation [64,76]. Deep breathing exercises, such as diaphragmatic breathing or belly breathing, engage the diaphragm muscle and stimulate the parasympathetic nervous system. The parasympathetic nervous system is the other branch of the autonomic nervous system, and it is responsible for promoting rest, relaxation, and digestion [35]. It has been demonstrated that during respiration, inspiration inhibits sympathetic nervous system activity [77]. Therefore, breathing techniques could be used as first-line and supplemental treatments for stress and emotional disorders [35,78].

Deep breathing exercises can help slow down the heart rate, bringing it closer to a calm and regular rhythm, contributing to a feeling of relaxation [79]. By consciously focusing on deep breaths and consciously relaxing the muscles, breathing exercises help release tension and promote a sense of physical relaxation [79]. During breathing exercise oxygen supply is increased supporting better delivery of oxygen to the body’s tissues, including the brain [80]. It can improve mental clarity, focus, and overall well-being. Lastly, engaging in breathing exercises requires focusing attention on the breath. This helps shift the focus away from stressors, worries, and racing thoughts, promoting a mindful state of being in the present moment. Mindfulness has been shown to reduce stress and enhance overall psychological well-being [81].

Recent reviews in the field of mental health programs highlight the need for research that goes beyond examining the overall effects of such programs. Instead, there is a call for more nuanced investigations that delve into the associations between specific components or building blocks of these programs and the clinical outcomes observed. This approach aims to comprehend the relative contributions of various activities within digital health management protocols. Researchers and digital health organizations can gain a deeper understanding of what works best in digital health management protocols and improve the effectiveness of mental health interventions [65,68].

Our findings indicate that breathing exercises and CBT-based video sessions help people lower their stress levels. These findings suggest that increasing digital engagement to specific activities in a lower engaged population may be an efficient way to optimize digital platforms supporting patients with moderate levels of stress. New models of care and digital tools have the potential to transform health care by increasing
accessibility, promoting patient-centered care, improving
timeliness, enhancing equity, and optimizing efficiency. Digital
tools can empower patients to take an active role in their health
care journey. This shift toward patient-centered care promotes
collaboration and empowers individuals to make informed
choices about their health [82,83].

We expect that the analytical approach applied in this study will
be beneficial for personalizing interventions and optimizing
incentivization planning. This information could be used to
further personalize outreach to encourage users to maintain their
personal critical level of mental health activities. More research
is required to further understand the current and potential
moderating factors of digital intervention tools for mental health
and how independent use of these tools facilitates the care of
patients with day-to-day stress levels.

Limitations
In this study, we used a single-arm design that analyzed
retrospective real-world data that lacked a comparison group
or control group, contained a self-selection bias, and lacked
randomization. While this design allowed us to explore the
association between digital relaxation tools and stress levels,
we acknowledge the limitation of not having a control group.
The lack of a control group restricts our ability to establish
causal relationships and control potential confounding variables.
Future research efforts could consider incorporating a control
group to further validate and extend the implications of our
findings. Additionally, we acknowledged the gender distribution
predominantly consisting of 79% (388/490) women that may
potentially influence the results and interpretation of the results.
However, women have higher rates of anxiety and depression
and use more digital treatment [58,59], therefore our results
may be specifically applicable to the real world. In other words,
the real-world population of women who have more anxiety
and depression may be better served with the use of a mobile
app. Although this study’s research topics are not related to
gender-specific experiences, future research should strive for a
more balanced gender representation. It is also possible that
people who chose to use digital therapeutic instruments were
those who were most motivated to make a change in their
conditions. These factors could limit the generalizability and
create a challenge for drawing causal conclusions. The time
scale was designed to reflect a weekly interval change over 10
weeks; however, the relationships of interest in this study could
be potentially investigated in different scales emphasizing daily
or monthly outcomes. Owing to the difficulty in tracking daily
changes in stress levels, most real-world studies focus on weekly
fluctuations.

Stress level was the key outcome assessed in this study by using
a stress questionnaire constructed by our internal experts. This
questionnaire demonstrated a Cronbach α value of 0.73, an
adequate reliability coefficient, as >0.70 is considered a measure
of internal consistency [84,85]. It was decided to use our stress
questionnaire although the Perceived Stress Scale-14, a 14-item
scale, is the most widely used for measuring perceived stress
[86] since it has fewer items and may be more useful in
increasing the answer rate among platform users.

Conclusions
This study provided evidence that an increase in mental health
management via digital engagement, specifically with relaxation
tools, can help reduce stress levels over time. Although stress
can be experienced in various forms, it is established that using
an app as an integrated part of the health self-management
process significantly improves clinical outcomes. It was
demonstrated that breathing exercises have a significant impact
on promoting relaxation. From a behavioral perspective,
engaging with CBT content helps recognize stress causes and
provides strategies to self-manage the feelings of burden,
ultimately improving well-being. These findings provide a basis
for encouraging users to take an active role and make informed
choices about their health. Future work is needed to investigate
current and other potential moderating factors and to develop
a more comprehensive understanding of the importance of the
app, how digital intervention tools work for mental health, and
for whom they are most effective. This knowledge will guide
the development and implementation of personalized and
evidence-based digital interventions, ultimately improving
mental health outcomes for individuals in a variety of contexts.

Abstract

Background: Individuals can experience difficulties pursuing their goals amid multiple competing priorities in their environment. Effective goal dynamics require flexible and generalizable pursuit skills. Supporting successful goal pursuit requires a perpetually adapting intervention responsive to internal states.

Objective: The purpose of this study was to (1) develop a flexible intervention that can adapt to an individual’s changing short to medium-term goals and be applied to their daily life and (2) examine the feasibility and acceptability of the just-in-time adaptive intervention for goal pursuit.

Methods: This study involved 3 iterations to test and systematically enhance all aspects of the intervention. During the pilot phase, 73 participants engaged in an ecological momentary assessment (EMA) over 1 month. After week 1, they attended an intervention training session and received just-in-time intervention prompts during the following 3 weeks. The training employed the Capability, Opportunity, Motivation, and Behavior (COM-B) framework for goal setting, along with mental contrasting with implementation intentions (MCII). Subsequent prompts, triggered by variability in goal pursuit, guided the participants to engage in MCII in relation to their current goal. We evaluated feasibility and acceptability, efficacy, and individual change processes by combining intensive (single-case experimental design) and extensive methods.

Results: The results suggest that the digital intervention was feasible and acceptable to participants. Compliance with the intervention was high (n=63, 86%). The participants endorsed high acceptability ratings relating to both the study procedures and the intervention. All participants (N=73, 100%) demonstrated significant improvements in goal pursuit with an average difference of 0.495 units in the outcome (P<.001). The results of the dynamic network modeling suggest that self-monitoring behavior (EMA) and implementing the MCII strategy may aid in goal reprioritization, where goal pursuit itself is a driver of further goal pursuit.

Conclusions: This pilot study demonstrated the feasibility and acceptability of a just-in-time adaptive intervention among a nonclinical adult sample. This intervention used self-monitoring of behavior, the COM-B framework, and MCII strategies to improve dynamic goal pursuit. It was delivered via an Ecological Momentary Intervention (EMI) procedure. Future research should consider the utility of this approach as an additional intervention element within psychological interventions to improve goal pursuit. Sustaining goal pursuit throughout interventions is central to their effectiveness and warrants further evaluation.

Introduction

Background
We have all experienced difficulties in developing, pursuing, and achieving our goals. This can be influenced by our internal state (eg, mood and motivation), environmental factors (eg, competing goals or demands), and resources (eg, skills and opportunity). We need the ability to prioritize goal pursuit in a dynamic environment, determining how much effort to allocate and deciding when to shift our attention to other goals [1]. Managing this is a dynamic, within-person process that varies over time based on how much progress one has made toward their goals. These goals or tasks related to goals vary in how demanding they are, and our ability to pursue those goals will be influenced by capacity. Pursuing goals requires effort, both physical and mental, not just due to the difficulty of the task [2] but also for maintaining a mental representation of the goal [3]. Moreover, we need to make decisions around the allocation of resources to the task (eg, breaking down a task or abandoning it), affecting successful pursuit. Effort can be considered synonymous with motivation when measured objectively [4], with motivation influenced by expectancy or certainty and value attributed to the outcome. People exert more effort if the outcome is perceived to be more likely, important, and rewarding [5,6]. In addition, mood, particularly anhedonia, has been associated with behavioral reward processing deficits [4]. The application of theory to intervention suggests a need for a “perpetually adapting” intervention [7].

Successful goal pursuit involves numerous steps: option generation, cost-benefit decision leading to option selection, initiation, and pursuit [8]. Failure at any point can reduce the likelihood of pursuit, and there is a need to anticipate obstacles [9]. By considering obstacles, the individual is better able to anticipate and plan for challenges that may arise as they work toward their goal [10]. The individual must also be able to employ metacognitive strategies such as planning, self-monitoring, and flexibility to overcome challenges, and they may benefit from prompts and support to facilitate these strategies [11].

People’s intentions do not always translate into action: medium-to-large changes in intentions only lead to small-to-medium changes in behavior [12]. Most interventions focus on altering specific behaviors within specific contexts, and the results are not conclusive. Personalized feedback, goal setting, and self-monitoring appear promising, but they are not consistently effective across behaviors and contexts [13]. It is also unclear whether these skills generalize to other behaviors and contexts. Simple strategies or microinterventions can provide easy access and low-effort solutions to increase or maintain engagement in behavior change [14,15]. These strategies may be simple but difficult to sustain without practice.

Ecological Momentary Intervention (EMI) involves providing feedback or intervention to participants in real time based on the data collected from Ecological Momentary Assessment (EMA). The deployment of interventions via mobile devices (eg, smartphones) provides the opportunity to deliver intervention on scale as either a standalone or adjunct intervention. EMA alone can act as a form of self-monitoring, facilitating an awareness of thoughts, emotions, and behavior. Interventions can be personalized, based on momentary assessments, and delivered in anticipation of a change in the target behavior. In the context of adaptive ecological momentary interventions, push/pull strategies involve delivering interventions either proactively by the system (push) or in response to a user's request (pull), while just-in-time interventions are provided at opportune moments when they are likely to be most effective, based on a real-time assessment of the individual’s context and state [17]. This method can benefit the generalization of skill acquisition, where the just-in-time intervention prompts the individual to allocate increased resources toward skill acquisition.

We propose an intervention that aims to bolster skill acquisition (ie, effective goal pursuit) through a combination of evidence-based strategies and EMI implementation. These strategies include frequent self-monitoring, shown to improve goal attainment [13]; mental contrast with implementation intentions (MCI) [18], shown to produce a moderate effect on health behaviors [19]; and the Capability, Opportunity, Motivation, and Behavior (COM-B) framework [20] for goal setting. In addition, the intensive measurement of relevant goal-pursuit processes can be used to model the dynamics in daily life [21]. To develop an intervention for implementation within the clinical sample, we optimized the design following a research model for developing digital health interventions through iterations [22].

Study Aim
This study aimed to develop, evaluate, and implement a just-in-time adaptive intervention to improve goal pursuit. The intervention sought to provide training for a goal pursuit strategy that could easily be incorporated into participants’ daily lives in terms of time and effort. The goal was for this intervention to serve as an adjunct to behavioral interventions (whether psychological or health-related) in future research.

The aim was addressed by (1) developing a personalized approach to implementing a goal pursuit intervention in daily life; (2) identifying barriers and facilitators and monitoring the implementation process of the intervention through several iterations; and (3) piloting the intervention to evaluate its feasibility and acceptability, efficacy, and individual change processes by combining intensive single-case experimental design (SCED) and extensive methods. Figure 1 outlines the procedure for optimizing and piloting the ecological momentary intervention via 3 iterations.

Figure 1. Procedure for optimizing and piloting the ecological momentary intervention, outlining the steps undertaken within each iteration.

**Methods**

**Study Design**

This study involved 3 iterations to test and gradually improve all features of the intervention to ultimately inform a randomized control trial evaluation of the intervention. Two iterations focused on optimization, while the third iteration was an uncontrolled pilot study. After each iteration, feedback was used to improve the design and intervention to increase the feasibility and acceptability. Questionnaires and strategy training were delivered via Qualtrics and EMA/EMI using the m-path platform [23].

**Ethical Considerations**

Ethical approval was granted by the University College London (UCL) Research Ethics Department (21883/001). All participants were provided with details of the study, confirmed eligibility, and provided informed written consent. The study data were deidentified. All participants (including those who chose to withdraw partway through) were entered into a prize draw to win a £50 (US $64) voucher. They received £20 (US $25) and a personalized report outlining their results if they reached 70% completion of the EMA at the end of the study.

**Recruitment**

The participants were recruited through a convenience sampling approach from various social media platforms. Individuals were eligible if they (1) were over the age of 18 years; (2) able to read and understand English; (3) were based in the United Kingdom; and (4) had a personal smartphone with Android or iOS operating software. Because we were seeking to pilot in a “healthy” sample, our exclusion criteria were (1) current mental health difficulties, including anyone scoring above 15 on the 9-item Patient Health Questionnaire (PHQ-9) or >1 on the suicidal ideation item and 12 on the Generalized Anxiety Disorder 7 (GAD-7); and (2) anyone undergoing psychotherapy at the time the study was conducted. Figure 2 shows the study flowchart.

EMA studies require commitment from participants over a long period (up to 6 times a day for 28 days); therefore, dropout rates can be high. Appropriate incentives can encourage compliance. Therefore, we created a 2-fold incentive as outlined in the previous section. Participants were also incentivized through app functions such as earning badges and data visualization.
Developing the Intervention

Developing the intervention relied on adapting existing evidence-based strategies for goal pursuit. We aimed to develop an intervention that was adaptable to each participant’s goals and generalizable enough to accommodate shifts and changes in goal focus during their daily lives. A self-guided training session was developed and supplemented with abbreviated prompts that could be delivered throughout the intervention period (Multimedia Appendix 1).

Feasibility Assessment

Within each iteration, we collected information relating to the experience of participating in the study, specifically undertaking EMA and the intervention. This included Likert scale questions assessing the ease, helpfulness, and intrusiveness of the EMA; perceived effectiveness and utility of undertaking the intervention; and helpfulness of the strategy training guide. Participants could also provide qualitative feedback on their goal progress and experience. Feasibility was assessed through data relating flow of participant recruitment and retention throughout the intervention. Acceptability was assessed post intervention. This feedback took the form of a questionnaire assessing how feasible and acceptable the EMA schedule was for them; whether it was easy, helpful, or enjoyable; or whether it was intrusive and impeded optimal goal pursuit.

Assessment of Outcomes

Primary Outcome

Goal pursuit was used as the primary outcome to test the preliminary efficacy of our intervention, goal. This was measured using EMA, and participants were also asked about goal attainment post intervention.

Secondary Measures

To test whether the intervention influenced goal pursuit–related processes, we assessed participants’ pre-post changes on 5 goal pursuit–related measures, which are outlined in Textbox 1.
1. **Action orientation**: The Action Control Scale (ACS-90) [24] is divided into 3 subscales: Hesitation (8 items), the ability to initiate a task; Preoccupation (8 items), the ability to actively work on the task; and Volatility (6 items), the ability to stay action-oriented until completion.

2. **Defeatist Performance Beliefs**: The 15-item Defeatist Performance Beliefs (DPB) scale [25] measures overgeneralized negative thoughts in goal-striving.

3. **Prospective imagery**: The Prospective Imagery Test (PIT) [26] measures the ability to vividly imagine positive and negative future-orientated scenarios.

4. **Intertemporal choice**: The 27-item Money Choice Questionnaire (MCQ) [27] measures preferences between small immediate rewards and large delayed rewards. A general delay discounting parameter (“k”) is estimated, wherein greater k values represent steeper delay discounting.

5. **Difficulties in Emotion Regulation**: The 18-item Difficulties in Emotion Regulation Scale (DERS) [28] measures participants’ emotion regulation abilities.

### Ecological Momentary Assessment
The participants completed a series of questions numerous times a day over 28 days. The number changed across iterations. The questions aimed to (1) track mood and motivation; (2) assess goal characteristics such as reward, meaning, and importance; and (3) estimate the extent to which people are acting toward a goal, can visualize it, and feel self-efficacious.

In terms of goal pursuit, “I am acting toward a goal” was the primary outcome. Other questions measured mood, such as “How do you feel right now?” (smiley visual analog scale), anhedonia (“I’m enjoying what I am doing”), motivation (“I feel motivated”, expectation (“I feel hopeful”), energy (“I feel energized”), and questions related to goals, domain (“What I am doing is related to recreation/relaxation, education, relationships, work or health”), difficulty (“What I am doing is difficult”), importance (“What I am doing is important”), reward (“What I am doing is rewarding”), meaning (“What I am doing is meaningful”), implementation (“I know how I am going to reach this goal”), and representation (“I can picture myself achieving this goal”).

### Ecological Momentary Intervention
The study design was guided by the Risk of Bias in N-of-1 Trials (RoBiNT) scale to ensure the methodological quality of intervention studies employing single-case methodology (Multimedia Appendix 2). Details of each iteration and adaptation can be found in Multimedia Appendix 3.

### Pilot Component
Following the completion of baseline measures, the participants completed a 7-day EMA monitoring period, during which they completed 4 EMA surveys per day, occurring at semirandom intervals within an individualized 12-hour waking period (baseline). Following the completion of 7-day monitoring, the participants completed the self-guided COM-B/MCII training via the internet.

During the intervention period (the subsequent 21 days), all participants received a prompt at the start of each day, following which the goal pursuit variable alone was used to trigger prompts (falling 1 SD below their rolling average). If the individual indicated low goal pursuit, they were not asked subsequent questions relating to the goal (domain, difficulty, importance, reward, meaning, implementation, and representation), as this was considered aversive in previous iterations.

### Statistical Analyses

#### Acceptability / Feasibility
To evaluate the acceptability of study procedures, participants’ experiences were assessed in the postintervention questionnaire and analyzed descriptively.

#### EMA Analysis: Preprocessing Period
Participants with less than 48 time points were removed from the EMA analysis. In addition, participants were excluded when there was a baseline trend (ordinary least squares standardized beta coefficient >+/–0.3) on the basis that differences between phases can be difficult to interpret if improvement trends are observed in phase 1 (ie, due to natural improvement unrelated to the intervention).

#### SCED Analysis
The data obtained from the single-case experimental phase design used in this study have a hierarchical 2-level structure with observations (level 1) nested within individuals (level 2). We estimated design-comparable between-case standardized mean differences (BC-SMD) using restricted maximum likelihood methods [29]. We modeled baselines including both fixed and random effects for each level. The treatment phase was modeled with linear trends with both fixed and random effects at the level and slope. Assumptions were set around the likelihood methods [29]. We modeled baselines including both fixed and random effects for each level. The treatment phase was modeled with linear trends with both fixed and random effects at the level and slope. Assumptions were set around the session level error structure—an autoregressive model of order 1 (AR1) with variance differing by phase.

In addition, we estimated the differences in scores between the 2 phases using Ruscio A [30]. This metric reflects the probability that a randomly selected time point in phase 2 is larger than a randomly selected time point in phase 1 (calculated via Monte Carlo simulation: 10,000 runs) [31]. We also estimated the unstandardized difference in scores between the median values in the 2 phases.

#### Pre-Post Change
Differences between baseline and postintervention assessment measures were estimated using paired-sample t test.

#### Network Modeling
To explore the theoretical conceptualization of goal pursuit dynamics, we estimated a temporal network analysis. We
generated 2 models, the first with mood-related variables (mood, motivation, energy, hope, and interest) and goal pursuit (as these were captured at each time point), along with a separate model with goal-specific variables (difficulty, meaning, reward, importance, implementation, and representation) and goal pursuit. These were assessed separately, as the participants only rated the goal-specific variables if their goal pursuit was >1 SD below their rolling average.

We estimated multilevel vector autoregression networks via the mlVAR package on R software (R Foundation for Statistical Computing) [32], using the method lmer (sequential univariate multilevel estimation) with orthogonal estimation. We then visualized the autoregression networks with the qgraph package [33].

Both a temporal network (how the variable is predicted by all other variables after controlling for all other temporal effects) at the previous time point and a contemporaneous network (how variables are associated at the same time point, controlling for the influence of all other variables and temporal effects) were used within the results. The model assumes stationarity; as such, all items were detrended before including them in the network.

Results
Overview
As the purpose of the initial 2 iterations was to inform the optimization of the EMI, only data from iteration 3 (the pilot) are reported in this section.

Participant Characteristics
Sample characteristics are presented in Table 1. The total sample size was 73 participants (participants undertaking the EMI), with 65 (89%) completing postintervention measures. There were more female than male participants. While there was variation in ethnicity, there were no Black participants, and most of the sample were students. This was a healthy sample with low to no symptoms of depression (PHQ-9: mean 3.71, SD 3.73; range 0-15) and anxiety (GAD-7: mean 3.45, SD 3.65; range: 0-12).

| Table 1. Sociodemographic characteristics of the study sample (N=73). |
|--------------------------|-------------------|
| Characteristics          | Value             |
| Age (years), mean (SD)   | 25.05 (7.49)      |
| Female gender, n (%)     | 46 (63)           |
| Ethnicity, n (%)         |                   |
| Asian                    | 27 (37)           |
| Chinese                  | 15 (21)           |
| Mixed                    | 1 (1)             |
| Other                    | 4 (5)             |
| White                    | 26 (36)           |
| Employment status, n (%) |                   |
| Employed                 | 25 (34)           |
| Student                  | 46 (63)           |
| Unemployed/unable to work| 2 (3)             |

Acceptability Assessment
Post intervention, the participants completed a survey on the acceptability of the intervention (Figure 3, Multimedia Appendix 4). A total of 22 (35%) respondents stated they achieved the goal “a little better than expected,” 16 (25%) reported that they achieved the goal “much better than expected,” and only 2 (3%) reported not achieving the goal or experiencing a decline in their ability to reach a desired objective. When asked to assess the general ability to effectively pursue goals, 14 (22%) participants said it became much better and 33 (52%) reported a slight improvement. Moreover, 2 (3%) participants indicated that their overall competence in accomplishing goals had deteriorated. One participant’s goal was to get a promotion, and they did not get it; it wasn’t clear why the other participant thought their competence had deteriorated.

Open feedback on user experience was largely positive. In general, participants endorsed the simplicity and interactivity of the app, which had a visualization component to help track their responses. They suggested decreasing the number of notifications during the day and making a more varied list of EMAs to avoid respondent fatigue. The participants stated the MCII strategy was helpful, and engaging with the app helped them become more aware of their own goal-related behaviors:

...Helped to keep reminding myself what I needed to accomplish and keep it in the forefront of my mind. [Participant #15]

Whenever I see a reminder from the app, I seem to be persuaded to do something to change the current situation, even though I might have answered the questions with a negative emotion. [Participant #32]
Feasibility Assessment
To assess feasibility, we examined compliance with the EMA. Among all those who started the EMA (N=73), 10 (14%) were excluded from statistical analysis due to low compliance. Participants were sent 112 EMA surveys. On average, all 73 (100%) participants completed a mean of 85 (SD 33) or 76% of the EMAs across the month. While the strategy was presented at the first beep of each day, the prompt was also triggered by changes in mood on average 18 (SD 13) times per participant over a 21-day period.

Primary Outcome: Goal Pursuit SCED Analysis
We assessed changes in goal pursuit between the baseline and intervention phases for 73 participants (Multimedia Appendix 5). Throughout the experiment, the participants’ goal pursuit domains were recreation/relaxation (1024 observations, 29%), education (882 observations, 25%), relationships (559 observations, 16%), work (581 observations, 16%), and health (508 observations, 14%). There was a small effect size (BC-SMD 0.15, 95% CI 0.03-0.27). The intervention had an immediate significant effect, increasing the participants’ goal pursuit by 0.495 units (standard error: 0.152) (P<.001) but no significant additional improvement during the intervention period, at an intervention trend of 0.002 (P=.002). The probability of superiority (Ruscio A) was 0.59 (95% CI 0.54-0.63). There was a large amount of heterogeneity (I² =78.2%; H²=4.6), with 20 (27%) participants demonstrating CIs >0.5, 3 (4%) below 0.5 (suggesting poorer performance during the intervention phase), and the remaining 50 (69%) unclear (CIs crossing 0.5). The median difference between phases was 0.41 (SD 1.29).

Secondary Outcomes
A total of 65 (89%) participants completed the postintervention measures. No significant pre-post changes were noted for Defeatist Performance Beliefs (DPB) (t_{64}=0.36, P=.72), Prospective Imagery Test (PIT) (t_{64}=0.47, P=.64), DERS (t_{64}=0.47, P=.64), MCQ (t_{52}=1.36, P=.19), PHQ-9 (t_{61}=1.65, P=.10), and GAD-7 (t_{64} = –0.24, P=.81). GAD-7 and PHQ-9 were affected by floor effects. On the Action Control Scale (ACS) subscales, hesitation was significant (t_{61}=2.1121, P=.04) but not volatility (t_{63}= –0.76017, P=.45) or preoccupation (t_{61}=1.0326, P=.31). There was no significant change between baseline and intervention phases for the other EMA variables: mood (BC-SMD 0.03, 95% CI –0.07 to 0.13), motivation (BC-SMD 0.03, 95% CI –0.08 to 0.14), energy (BC-SMD –0.01, 95% CI –0.13 to 0.11), anhedonia (BC-SMD 0.01, 95% CI –0.12 to 0.10), and expectancy (BC-SMD 0.06, 95% CI –0.07 to 0.19).

Contemporaneous Networks
To elucidate dynamic processes during goal pursuit, we also estimated the network of associations between variables (Figure 4). The contemporaneous network visualized the partial correlations between variables at the same time point (controlling for the influence of all other variables and temporal effects). In the primary network, mood-related variables were associated as expected (mood, motivation, energy, and expectation) and anhedonia, motivation, and energy directly were associated with goal pursuit (explained variance for goal pursuit: $R^2= 0.24$). Meanwhile, in the secondary network, goal-specific variables were strongly associated, with representation, implementation, importance, and reward directly associated with goal pursuit (explained variance for goal pursuit: $R^2= 0.07$).
**Temporal networks**

The temporal network demonstrated how the variables predicted each other from 1 time point to the next. Within the primary temporal network, all variables demonstrated strong autocorrelations; only motivation predicted pursuit at the next time point, with motivation predicted by energy. There was a bidirectional relationship between expectation and anhedonia, with anhedonia negatively predicting mood. Expectation and mood both influenced each other at the next time point. Within the secondary network, there were strong autocorrelations for all variables except implementation and reward. Pursuit was predicted by implementation but had a stronger influence on implementation. Representation also predicted implementation at the next time point, as well as importance and meaning. Meanwhile, implementation negatively predicted meaning at the next time point. Reward negatively predicted difficulty, while difficulty only predicted itself.

**Discussion**

**Principal Findings**

This study aimed to develop, evaluate, and implement a just-in-time adaptive intervention to improve goal pursuit. Overall, the results suggest that the digital intervention was feasible and acceptable to participants. Our results show that participants endorsed high acceptability ratings relating to both the study procedures and the intervention. While there was a high level of attrition between baseline measures and those setting up the app, there was also a high level of retention and completion for those who did begin the EMI. There was a significant improvement in goal pursuit (between baseline and intervention) with most participants achieving their primary
goal and reporting that they would continue using the strategy, supporting its potential effectiveness in promoting positive behavior change. There was no improvement in pre-post measures measuring processes associated with goal pursuit.

This study focuses on the dynamics of goal pursuit including the reality that people will switch between multiple goals. There is little in the intervention literature that covers dynamic within-person processes that help individuals pursue their goals over time. Similar digital intervention studies have examined the use of employing within-person dynamic data to inform prompts. Korinek et al [34] used dynamical systems modeling within their adaptive intervention to increase walking behavior in participants who were overweight to set an “ambitious but doable” goal for themselves. Fallon et al [35] used a microrandomized control design to randomize participants to an intervention option (providing goal or social feedback relating to a physical activity goal) based on each participant’s specific state. Notably, their results suggested that the effectiveness of the intervention depended on the stage of their goal pursuit (how close they were to attainment). This study contributes to the literature by using the within-person variation on goal pursuit to prompt the intervention, leading to improved goal pursuit over time.

The only change in the associated goal pursuit measures was for hesitation—the ability to initiate intended actions. This construct appeared to align with implementation intentions, looking to improve the ability to translate specific intentions into behavior. This construct has been suggested to be particularly important for goal-striving across numerous domains [36]. Given the emphasis on mental representation within the strategy, it was surprising that there was no improvement in representation. This may be due to the sensitivity of the measures, where similar measures have not been associated with task performance [37]. The measures did not capture the vividness or intensity of the imagery, which would be important phenomena underpinning scene construct [38], and were expected to be targeted. While we assessed processes related to goal pursuit, we did not assess the mechanisms of change related to all strategies. Self-monitoring, for instance, is thought to improve mental health and well-being by increasing emotional self-awareness [39,40]. Future studies should endeavor to identify measures related to the mechanisms of change.

The network analysis can inform our understanding of dynamic goal pursuit highlighting a complex cyclical process involving interdependence, influence, and self-sustaining processes. There were no changes in the associated goal pursuit measures, either in terms of pre-post measures or EMA items. Contemporaneously, motivation and reward were directly associated with goal pursuit, while anhedonia was negatively associated with it. In terms of goal-specific constructs, representation, implementation, importance, and reward were directly associated with goal pursuit. Only motivation and implementation (knowing how the goal could be achieved) predicted goal pursuit at the next time point, with goal pursuit itself being the strongest predictor of goal pursuit. This would seem to suggest that the intervention directly targets goal pursuit rather than indirectly through an associated process (eg, motivation). Indeed, within the sample, motivational levels were high. Pursuit also predicted implementation, suggesting that goal pursuit is self-sustaining and boosts confidence in knowing how to achieve the goal. This is in line with the GOAL (goal-orientated action-linking) architecture, where motivation arises from the individual’s perception that their actions can impact the likelihood of achieving a goal [1]. Self-monitoring behavior and implementing the strategy may aid goal reprioritization, where the goal pursuit itself is a driver of further goal pursuit (within or between goals), as noted by the bidirectional relationship between pursuit and implementation.

**Strengths and Limitations**

The study had a few strengths and limitations. The development of the study procedure over multiple iterations facilitated adjustments including short momentary assessments, an efficient reporting process, low attrition, and high compliance. In addition to the app, the researchers provided consistent support through the intervention period, with reminder emails appearing particularly useful for improving compliance. For EMA technology to be successful in gathering accurate data and sustaining user interest over time, it is essential to engage users effectively. This is especially important when considering the translational application to mental health, where it can facilitate individuals taking a more active role in their recovery [41,42].

While there is an indication of an impact on goal pursuit, the single-case design reveals that while it might prompt change for some individuals, its effects remain unclear for the majority and entirely absent for others. In addition, the trend over the intervention did not indicate an incremental benefit; however, it may have been a sustaining pursuit, and without prompts, we may have seen a decline. Without a follow-up, it is also unclear whether the changes were maintained over time without prompts. Self-report requires self-awareness; indeed, we viewed the EMA as an active component enhancing awareness, but this could affect the measurement (either through meaning associated with items or change consequential to EMA), and this reactivity may interfere with causal claims [43].

This study aimed to personalize the just-in-time adaptive intervention. In the second iteration, we aimed to personalize the approach by identifying predictors of goal pursuit during the baseline period. However, this approach was hampered by poor compliance. In the pilot, we adopted a more conservative approach focusing solely on variation in goal pursuit; however, further studies may be able to improve the design by reinstating this approach. Finally, in relation to strategy training, the results from the initial iteration indicated that the web-based self-facilitated guide was considered optimal over video. There is evidence that the mode of learning may affect the effect size, where facilitator-led is stronger than self-facilitated [44]. Behavioral interventions that can be delivered via an app can address barriers that typically hamper engagement in intervention and may aid in study retention. Strategies for user engagement are a key aspect of EMI design. In this study, reducing participant burden was an important consideration; through iterations, we reduced the number of assessments and introduced branching of responses when not pursuing a goal. The number of assessments was still an issue for some participants, and this reduction comes at a cost to the availability.
and validity of data—for instance, nonrandom missing data (we had far fewer responses to model the secondary network). Passive monitoring helps reduce the burden but relies on proxy measures of goal pursuit and associated psychological processes, and it may not be as relevant for some goals as others [45].

Further research will need to consider piloting this EMI within a clinical sample before proceeding to a larger trial. The design has been optimized for easy integration into an individual’s daily life in terms of time and effort, with the intention that it could serve as an adjunct to behavioral interventions (psychological or health-related) in future research. Further considerations will need to be given to whether this should be tested as a standalone or an adjunct within an established intervention—for instance, facilitating behavioral activation for depression, or with cognitive behavioral therapy targeting the negative symptoms of psychosis. In this study, the participants were required to have enough motivation to pursue their goals. There is the question of whether this would be appropriate for those who lack motivation, as experienced in depression or psychosis. It is also unclear which aspects of the study design may need to vary, as it has been suggested that while compliance is related to fewer prompts in nonclinical samples, more frequent prompts led to higher compliance in studies with clinical samples [43]. Further research will need to carefully consider the design, intensity, and appropriateness of this EMI intervention for use within different clinical samples, while also accounting for differences in the mechanism of change between nonclinical and clinical samples.

**Conclusion**

This pilot just-in-time adaptive intervention used behavior self-monitoring, COM-B, and MCII strategies to improve dynamic goal pursuit. It was delivered via an EMI procedure and shown to be feasible and acceptable among a nonclinical adult sample. Given the potential feasibility, these results provide a foundation from which future research may implement a more rigorous methodology to assess efficacy within clinical populations that experience goal pursuit deficits. There was preliminary evidence of an effect on goal pursuit. However, this should be tested in a fully powered trial before drawing conclusions. Future research should consider the utility of this approach as an additional intervention element within psychological interventions to improve goal pursuit. Sustaining goal pursuit throughout interventions is central to their effectiveness and warrants further evaluation.

Abstract

Background: There has been an increased need to provide specialized help for people with depressive and anxiety symptoms, particularly teenagers and young adults. There is evidence from a 2-week intervention that chatbots (eg, Woebot) are effective in reducing depression and anxiety, an effect that was not detected in the control group that was provided self-help materials. Although chatbots are a promising solution, there is limited scientific evidence for the efficacy of agent-guided cognitive behavioral therapy (CBT) outside the English language, especially for highly inflected languages.

Objective: This study aimed to measure the efficacy of Fido, a therapy chatbot that uses the Polish language. It targets depressive and anxiety symptoms using CBT techniques. We hypothesized that participants using Fido would show a greater reduction in anxiety and depressive symptoms than the control group.

Methods: We conducted a 2-arm, open-label, randomized controlled trial with 81 participants with subclinical depression or anxiety who were recruited via social media. Participants were divided into experimental (interacted with a fully automated Fido chatbot) and control (received a self-help book) groups. Both intervention methods addressed topics such as general psychoeducation and cognitive distortion identification and modification via Socratic questioning. The chatbot also featured suicidal ideation identification and redirection to suicide hotlines. We used self-assessment scales to measure primary outcomes, including the levels of depression, anxiety, worry tendencies, satisfaction with life, and loneliness at baseline, after the 2-week intervention and at the 1-month follow-up. We also controlled for secondary outcomes, including engagement and frequency of use.

Results: There were no differences in anxiety and depressive symptoms between the groups at enrollment and baseline. After the intervention, depressive and anxiety symptoms were reduced in both groups (chatbot: n=36; control: n=38), which remained stable at the 1-month follow-up. Loneliness was not significantly different between the groups after the intervention, but an exploratory analysis showed a decline in loneliness among participants who used Fido more frequently. Both groups used their intervention technique with similar frequency; however, the control group spent more time (mean 117.57, SD 72.40 minutes) on the intervention than the Fido group (mean 79.44, SD 42.96 minutes).

Conclusions: We did not replicate the findings from previous (eg, Woebot) studies, as both arms yielded therapeutic effects. However, such results are in line with other research of Internet interventions. Nevertheless, Fido provided sufficient help to reduce anxiety and depressive symptoms and decreased perceived loneliness among high-frequency users, which is one of the first pieces of evidence of chatbot efficacy with agents that use a highly inflected language. Further research is needed to determine the long-term, real-world effectiveness of Fido and its efficacy in a clinical sample.

Introduction

Background

The interest in digital mental health apps has largely increased in recent years [1]. Their growing popularity results mainly from the pressure to use technology during the COVID-19 pandemic, which coincided with a fast deterioration in public mental health and the increasing quality of digital health technologies. Therapy applications have been proven to be helpful for clients not able to afford traditional therapy and for therapists seeking solutions to increase client engagement in therapy [2]. A recent meta-analysis [3] showed that using an internet-based intervention can be as effective as face-to-face therapy. Nevertheless, applications that are available on the market often lack appropriate scientific evidence of feasibility or efficacy [4].

One solution that seems to be especially promising is agent-guided cognitive behavioral therapy (AG-CBT [5]), in which interventions are provided by chatbots—applications backed by machine learning algorithms that mimic natural conversation while communicating with users via a chat interface [6]. The development of such applications has been approached in many different ways, but one bot that seems to be the most advanced so far is Woebot. Woebot is a self-help chatbot using CBT techniques such as psychoeducation, goal planning, and mood tracking to lower the levels of depression, anxiety, substance abuse, and, recently, postnatal depression [5,6].

In a randomized controlled trial (RCT), the use of Woebot for a period of 2 weeks has been proven to be more effective at reducing symptoms of anxiety and depression than the use of self-help materials prepared by the World Health Organization (WHO) [6]. Further studies have provided evidence that users can develop a bond with the Woebot on a similar level as the one that is built between the client and therapist during group CBT [5,7].

Previous experiences with English-speaking mental health care chatbots (eg. Woebot, Wysa, Youper [8-10]) have encouraged attempts to develop chatbots in other language versions, such as German [11], Chinese [12], Spanish [13], and Ukrainian [14], or even multilingual chatbots [15]. Currently, the development of such applications varies among high-income and low-income countries due to cross-cultural differences and specific obstacles [16]. In Poland, there is still a limited number of digital therapeutic solutions, although the need for them is growing. In the last few years, there has been a visible decline in mental health among Polish teenagers and young adults, which became especially severe during the COVID-19 pandemic [17].

To address that need, our team initiated the development of Fido—the first Polish therapy chatbot—that aims to provide mental health support to adolescents and young adults struggling with anxiety and depression. Our previous research on the interaction between humans and Fido showed that it is considerably user-friendly [18]. However, Fido still required an efficacy study, which is presented in this article along with the exploratory analysis of human–therapy chatbot interactions. We hope that this study will extend previous research in this field and enrich the discussion on agent-guided mental health treatment.

Objectives

A previous study on human-chatbot interactions using Fido provided satisfactory results, suggesting that Fido is pleasant to use; however, it hasn’t been optimized yet and required further development in the area of user experience (UX) [18]. After its UX optimization, Fido has been ready to use in an efficacy study. Therefore, we performed the first RCT aimed at testing the effects of using Fido to reduce subclinical depression and anxiety symptoms and compared them with the use of self-help materials from the book “Mind Over Mood” [19].

Based on previous clinical research of chatbots [6,8-10], we aimed to investigate the direct intervention effects and their stability. We hypothesized that, after a 2-week intervention and a 1-month follow-up, the following would occur:

1. The chatbot group reports lower depression, anxiety, and worry symptoms than those with the self-help book only.
2. The chatbot group has higher satisfaction with life than those using the self-help book only.
3. The positive affect is higher, and negative affect is lower than prior to intervention. Furthermore, this change is greater in the chatbot group than in the group with the self-help book.

Based on previous research on the chatbot-user interaction [8,18], we also hypothesized that:

1. Loneliness is lower in the chatbot group than in the group with the self-help book.
2. Participants form a bond with the chatbot, scoring at least 4 on the Working Alliance Inventory-Short Revised (WAI-SR) scale.
3. The users’ assessments of the chatbot's linguistic pragmatics correlate positively with the level of UX.

Methods

Trial Design

We used a 2 x 3 mixed factorial design with 2 intervention arms (Fido chatbot vs self-help book) and 3 time points (before the intervention [T1], immediately after the intervention [T2], and at a follow-up 1 month after the previous measurement [T3]).
The primary intervention lasted 2 weeks. After the intervention, the use of the technique was not obligatory (but it was not forbidden). For an overview of the procedure, see Figure 1.

**Figure 1.** Procedure flowchart with measures and time points (T0-T3).

---

**Participants**

Participants were recruited via Facebook and Instagram advertisements from May 2022 to June 2022 and screened using a Qualtrics online survey (measurement at T0). The estimated sample size was 80 participants, with an estimated dropout of around 15%. The sample size was based on previous studies of chatbot interventions [6,9], in which the estimated sample size (ie, N=70) allowed for detecting a moderate-large effect for depression. We increased the sample size to 80 due to the high dropout rate in previous studies (average of 7 participants per group) [6,9].

Eligibility criteria included (1) age between 18 years and 35 years; (2) not undergoing psychotherapy, coaching, nor psychopharmacological treatment; (3) no diagnosis of a neurological disorder; (4) declaring at least mild depressive or anxiety symptoms by achieving a total score of at least 16 points on the Center for Epidemiologic Studies Depression Scale Revised (CESD-R) [20,21] or at least 50 points on the Penn State Worry Questionnaire (PSWQ) [22,23]; and (5) being able to visit the study site in Poznań (Poland) to complete the follow-up measurements. Computer literacy and proficiency in Polish were implicitly presumed as all participants completed an online screening survey written in Polish.

After enrollment, the research team members performed simple randomization with a 1:1 ratio (via Python script). Because the intervention involved either using the chatbot or the book, participants were informed about their assignment. To reduce the effect of expectation bias, we intentionally masked our hypotheses about the superiority of chatbot-supported therapy. The research team members remained unblinded as well.

During the onboarding for the intervention, the participants were asked to use the assigned intervention technique as needed (ie, with no prespecified minimal time of use per day or week). The uptake of the intervention was monitored via regular commitment checks delivered by email, which could serve as a reminder to use the assigned intervention technique.

All participants received compensation for their involvement: ZŁ 90 (US $22.57) directly after the intervention and ZŁ 70 (US $17.56) at the follow-up.

---

**Ethics Approval and Informed Consent**

The study received approval from the Ethical Review Board at SWPS University of Social Sciences and Humanities (opinion no. 2022-158) and was registered during participant enrollment in the Open Science Framework (OSF) Registries [24].

We retrospectively registered the protocol and analysis plan under the clinical trial number NCT05762939. Participants were informed about each intervention, step-by-step procedure, their right to withdraw, and research data confidentiality. All participants expressed their consent via a checkbox on a screening survey. Should one of the interventions have proved more beneficial, we ensured the participants from the other arm could gain access to that intervention’s materials.

Due to the Messenger chatbot policies [25], the research team members were hypothetically able to access individual participant messages from the chatbot conversations. This limitation is due to the fact that, formally, Messenger chatbots are an interface to send messages to Facebook pages. Participants from the experimental condition were informed of this potential privacy breach via a consent form explicitly presented in the chatbot and Meta’s Data Policy [26].

**Interventions**

**Chatbot Intervention—Fido**

For the experimental group, we used a free, prerelease version of a therapy-supporting Polish-language chatbot, called Fido [27], integrated into Facebook Messenger. Participants were added as testers in Meta’s development website and accessed the chatbot via links embedded in individual emails. They were given no special training (apart from the initial email instructions) but were offered technical assistance in case of any problems.

The chatbot uses machine learning models for intelligent user intent detection and close-ended input methods (such as choosing 1 option from a list). It was developed using iterative co-development with focus groups consisting of therapists and potential users (for more information, see [18]). Moreover, external therapists provided quality assurance for all therapeutic methods used by the chatbot, while software engineers used standard testing procedures. During the trial, none of the features underwent any changes.
During the onboarding procedure, participants indicate their gender and receive information on user terms and data protection, as well as basic training in cognitive biases because understanding them is crucial for interaction with Fido. After onboarding, users can try different therapeutic techniques implemented in Fido using a tree-based structure.

The primary functionality of Fido is providing dialogue focused on intelligent recognition of cognitive biases and their subsequent modification using Socratic questioning. It also recognizes suicidal ideation and reacts to it by redirecting users to emergency hotlines.

To maximize Fido’s performance, one of its machine learning models implements the so-called ABC technique (known from CBT), which helps patients organize and differentiate between activating events, beliefs, and their emotional or behavioral consequences [28], as presented in Figure 2. Fido also provides psychoeducation about depression, anxiety, and emotions. Last, it embraces gratitude practice exercises [19].

**Figure 2.** An example of a Fido-patient conversation (translated from Polish to English): ABC technique and cognitive distortion recognition.

---

**Control Intervention—Materials From “Mind Over Mood”**

Chapters 1-6 and 12 from the Polish translation of “Mind Over Mood” [19,29] were used to familiarize control participants with similar content and tasks as those provided to the experimental group. The book contains psychoeducation content with self-help exercises and is a well-established therapist’s guide to depression.

**Outcomes**

**Primary Outcomes Measures**

**Overview**

Primary outcomes were assessed at the 3 time points: T1, T2, T3. All questionnaires were implemented in Qualtrics and administered mostly offline at the study site; when participants could not visit the lab, they were given a link to an online version of the survey. Participants completed validated Polish adaptations of the scales. For primary analyses, we used sum scores of every single primary outcome measured at 1 time point (not change scores).

**CESD-R**

Depression symptom severity was measured using the CESD-R [20,21]. It is a 20-item screening tool for major depressive disorder. The scale uses 9 symptom groups defined in the Diagnostic and Statistical Manual (DSM)-5 [30]: sadness, anhedonia, appetite, sleep, thinking/concentration, guilt, fatigue, agitation, and suicidal ideation.

**Patient Health Questionnaire-9**

Another measure used to assess participants’ depression was the Patient Health Questionnaire-9 (PHQ-9) [31,32] from the...
self-administered version of the Primary Care Evaluation of Mental Disorders (PRIME-MD) inventory [33]. This brief, 9-item scale is based on DSM-IV criteria for depression. It is used mainly for symptom severity monitoring in primary care.

**PSWQ**

We used the PSWQ [22,23] to measure worry tendency, which is the primary component of generalized anxiety disorder. The 16-item scale addresses worry excessiveness, generality, and uncontrollable dimensions.

**State-Trait Anxiety Inventory**

The State-Trait Anxiety Inventory (STAI) [34,35] is another questionnaire used to measure anxiety, both as a temporary state and as a relatively fixed trait of an individual. We used the 20-item trait scale of STAI.

**Positive and Negative Affect Schedule**

The Positive and Negative Affect Schedule (PANAS) [36,37] was used to measure the general affect during the last 2 weeks. We calculated 2 subscale sum scores: 1 for positive feelings (9 items) and 1 for negative affect (9 items). The last 2 items of the original scale were not administered due to human error in the online survey implementation.

**Satisfaction With Life Scale**

Primary measures also included a brief, 5-item Satisfaction With Life Scale (SWLS) [38,39], which was used to assess global life satisfaction in a cognitive-judgmental aspect. Together with positive and negative affect, life satisfaction is an important component of subjective well-being.

**Revised UCLA Loneliness Scale**

We used the 20-item Revised UCLA Loneliness Scale (R-UCLA) [40,41] to assess other specific aspects of well-being, namely subjective feelings of loneliness and social isolation.

**Secondary and Other Outcome Measures**

**Overview**

During the 2-week intervention, participants received 5 engagement check surveys, each containing a single question: “How much time have you spent on therapeutic chatbot/book use during the last 48 hours?” Answers were in 10-minute increments. We calculated the sum score of the engagement checks as the total amount of declared time spent on book or chatbot use in minutes. Each survey had to be completed in less than 24 hours.

After the intervention (T2), all participants also were asked an open-ended question: “How many times have you used the chatbot / read the book in the past two weeks?” If a participant declared a range of values (eg, “10-12 times”), we recoded their answer as the median value in this range.

Another secondary measure used in both arms at T2 was a 12-item test that assessed the participants’ acquired knowledge of psychoeducation topics covered both by Fido and the “Mind Over Mood” book (see Multimedia Appendix 1). The test was administered in a paper-and-pencil format at the study site.

Participants from the chatbot arm were also asked to complete several additional scales at T2, including the WAIS-R and UX.

**WAIS-SR**

The WAIS-SR [42] is a 12-item scale that measures therapeutic alliance in 3 key areas defined by Bordin [43], which are (1) agreement on the tasks and (2) goals of the therapy and (3) overall patient-therapist affective bond. As agent-guided therapy also requires some form of therapeutic chatbot–user alliance, we adapted this scale to be used in our study. All items were first translated to Polish using a forward and backward translation with reconciliation. Next, we modified phrases related to human-led therapy to increase their relevance for the chatbot therapy (see Multimedia Appendix 2 for the original WAIS-SR items and their adaptation for this study). Items from the tasks and goals subscales were not as relevant to this study (because Fido does not establish these elements of the intervention; they are determined ad hoc by the user), so alongside the total average scale score, we also made use of the average of the bond subscale.

**UX**

For the general assessment of UX, we included nonmandatory items from several scales used in other studies: Acceptability E-scale, Human-Agent Interaction Scale (HAIS), Language Pragmaticality Scale (LPS).

The Acceptability E-scale [44] is used to measure the overall acceptability and usability of health-related computer applications. The team prepared its Polish translation using a similar procedure to our adaptation of WAIS-SR (see Multimedia Appendix 3 for both the original and the translation). The original scale included 5 items. One of the items regarded the functionality of the program. We used this item 4 times, as we wanted to check the functionality of 4 different techniques (psychoeducation, cognitive bias recognition, suicidal thought recognition, and gratitude practice). This way, we ended up with 9 items and used their sum as a total score.

The HAIS [45] has answers that range from 1 to 7 (see Multimedia Appendix 4). The calculated sums from 6 subscales were used: Supportive Anthropomorphic Traits (3 items), Unsupportive Anthropomorphic Traits (4 items), Behavioral Traits (7 items), Uncanny Valley (6 items), Competence (6 items), Warmth (6 items).

We previously used the LPS [18] to assess the perceived ability of Fido to communicate in a pragmatically sound manner. The scale consists of 4 separately scored items with answers on a percentage scale (0%-100%): “What percentage of overall chatbot statements were adequate?” “What percentage of overall chatbot statements were neutral (neither adequate nor inadequate)?” “What percentage of overall chatbot statements were inadequate?” “In what percentage have you been feeling understood by a chatbot?”

The preregistered plan of the study also included chatbot metadata (frequency of use or time spent in the conversation) for each user after the intervention (T2). However, due to technical and ethical reasons, we could not link the questionnaire data with anonymous chatbot metadata. Therefore, we only used the metadata (frequency of use) at a group level.

https://formative.jmir.org/2024/1/e47960

Karkosz et al
Analytical Methods

For baseline, we conducted contingency analyses on the nominal and ordinal data and 2-tailed Welch $t$ tests on the continuous data, to measure whether groups were different in any way at the beginning of the study.

To assess the direct treatment effects on each primary outcome, we conducted repeated measures ANOVA with arm (experimental/control) as a between-group factor, as well as time point (T1/T2) as a within-group factor. We repeated the analyses to test treatment stability, including the scores obtained before versus 1 month after the intervention (T1/T3).

After the intervention (T2), we calculated descriptive statistics on human-agent interaction measures as well as the frequency of use (subjective measures and metadata), declared time spent on the intervention, and knowledge test scores. We also analyzed Pearson correlations between the human-agent interaction measures.

Results

Participants

Of the 245 people screened, 81 were admitted to the study. For an overview of participant flow, see the CONSORT (Consolidated Standards of Reporting Trials) diagram (Figure 3). Basic demographic characteristics as well as screening scores (CESD-R and PSWQ at T0) are presented in Table 1. Participants from the chatbot and control conditions did not differ in terms of age, sex, education, employment, university student status, or screening scores (at T0). Moreover, there was no major difference between the groups in any primary outcome measures at baseline ($t_{72}<1.57, P_s>.12$). Detailed $t$ test results are presented in Multimedia Appendix 5.

Efficacy After 2 Weeks

We analyzed the efficacy of the intervention, comparing the data from baseline (T1) and after the 2-week intervention (T2). Only the main effects of time were significant at α=.05. For the between-subject and interaction effect results, see the tables in Multimedia Appendix 5.

For depressive symptoms, there were moderate effects of time. Scores for the CESD-R ($F_{1.66}=62.58, P<.001; \omega^2=0.08$) and PHQ-9 ($F_{1.66}=34.18, P<.001; \omega^2=0.06$) decreased in both groups.

In terms of anxiety and worry tendency, there was a small decrease in symptom severity in both groups, as measured with the PSWQ ($F_{1.66}=10.78, P=.002; \omega^2=0.01$) and STAI ($F_{1.66}=25.87, P<.001; \omega^2=0.03$).

For both study arms, we also detected small increases in satisfaction with life (SWLS: $F_{1.66}=13.59, P<.001; \omega^2=0.01$) and positive affect (PANAS-P: $F_{1.66}=16.54, P<.001; \omega^2=0.04$), while negative affect decreased (PANAS-N: $F_{1.66}=24.02, P<.001; \omega^2=0.05$). The decrease in feelings of loneliness was very small and not significant ($F_{1.66}=3.47, P=.07; \omega^2=0.00$; see Table 2). For a visual representation of treatment efficacy and stability, see Figure 4 [46].

<sup>a</sup>CESD-R: Center for Epidemiologic Studies Depression Scale Revised.
<sup>b</sup>PANAS: Positive and Negative Affect Scale.
<sup>c</sup>PHQ-9: Patient Health Questionnaire-9.
<sup>d</sup>PSWQ: Penn State Worry Questionnaire.
<sup>e</sup>R-UCLA: Revised UCLA Loneliness Scale.
<sup>f</sup>STAI: State-Trait Anxiety Inventory.
<sup>g</sup>SWLS: Satisfaction With Life Scale.
Figure 4. Mean (95% CI) scores at screening, at baseline (Pre), after the intervention (Post), and at the 1-month follow-up for the following primary outcomes: (A) Center for Epidemiologic Studies Depression Scale Revised (CESD-R), (B) Penn State Worry Questionnaire (PSWQ), (C) Satisfaction With Life Scale (SWLS), (D) State-Trait Anxiety Inventory (STAI), (E) Patient Health Questionnaire-9 (PHQ-9), (F) Revised UCLA Loneliness Scale (R-UCLA), (G) Positive and Negative Affect Scale (PANAS)-Positive, (H) PANAS-Negative. Confidence intervals were difference- and correlation-adjusted using the superb R library described by Cousineau et al [46].

Treatment Stability After 1 Month

The measurements from the follow-up (T3) were compared with those at baseline (T1) to determine if previously observed therapeutic effects were stable.

Depressive symptoms remained at a reduced level, as observed in both the CESD-R ($F_{1,57} = 32.10, P < .001; \omega^2 = 0.11$) and PHQ-9 ($F_{1,57} = 26.58, P < .001; \omega^2 = 0.07$) scores. A similar effect was found in anxiety (PSWQ: $F_{1,57} = 12.14, P < .001; \omega^2 = 0.01$) and
worry tendency (STAI: \( F_{1,57} = 18.12, P < .001; \omega^2 = 0.03 \)) scores. Stability in the therapeutic effect was also observed for satisfaction with life (SWLS: \( F_{1,57} = 7.22, P = .009, \omega^2 = 0.01 \)), positive affect (PANAS-P: \( F_{1,57} = 14.87, P < .001; \omega^2 = 0.04 \)), and negative affect (PANAS-N: \( F_{1,57} = 21.67, P < .001; \omega^2 = 0.06 \)). There was not sufficient evidence to conclude that loneliness (as measured using R-UCLA scores) changed from baseline to follow-up (\( F_{1,57} = 1.19, P = .28; \omega^2 = 0 \)).

As discussed previously, no group and interaction (of group and time) effects were detected for any primary outcomes measures (for detailed results, see Multimedia Appendix 5).

**Human-Agent Interaction Effects**

In terms of human-agent interaction characteristics, Fido achieved a mean 2.71 (SD 0.94) points on the WAI-SR scale, with an average score of 3.25 (SD 1.14) on the bond subscale. We detected a moderate correlation of language pragmaticality (item 1: % of messages rated as adequate) with the general UX level measured using the Acceptability E-scale (\( r = 0.60, 95\% \) CI 0.32 to 0.78; \( P < .001 \)).

Groups were similar in terms of the frequency of use they reported after the intervention (\( t_{50} = 1.44, P = .15; d = 0.36, 95\% \) CI -0.13 to 0.84) and scores on the knowledge test (\( t_{50} = 0.02, P = .99; d = 0.01, 95\% \) CI -0.51 to 0.52). However, the analysis of the time spent on the intervention via regular commitment checks suggested that the control group (mean 117.57, SD 72.40 minutes) actually spent more time reading the book than the chatbot group (mean 79.44, SD 42.96 minutes) spent on the interaction with Fido (\( t_{50} = 2.75, P = .008; d = 0.64, 95\% \) CI 0.17 to 1.11).

**Exploratory Analyses**

We extended our preregistered analyses after gaining insight into the data. The therapeutic alliance score (WAI-SR) correlated positively with the subjective sense of being, as understood from the LPS (\( r = 0.79, 95\% \) CI 0.60 to 0.89; \( P < .001 \)), overall acceptability (\( r = 0.77, 95\% \) CI 0.57 to 0.88; \( P < .001 \)), and scores for competence (\( r = 0.71, 95\% \) CI 0.48 to 0.85; \( P < .001 \)) and behavioral traits (\( r = 0.45, 95\% \) CI 0.12 to 0.69; \( P = .01 \)) from the HAIS.

We also detected a moderate, negative correlation between the WAI-SR score and age (\( r = -0.37, 95\% \) CI -0.63 to -0.03; \( P = .04 \)), which motivated us to split the experimental group into 2 subgroups by median (younger and older participants) and compare them using the Student t test. Younger participants formed a stronger human-chatbot bond (mean 3.59, SD 0.97) than older participants (mean 2.79, SD 1.23; \( t_{31} = 2.11, P = .04; d = 0.74, 95\% \) CI 0.02 to 1.45).

Moreover, in the chatbot group, loneliness (R-UCLA) scores after the intervention (at T2) were negatively correlated with the declared frequency of use (\( r = -0.48, 95\% \) CI -0.71 to -0.16; \( P = .006 \)). This finding motivated us to split the observations by median into subgroups of high- and low-frequency chatbot users. Repeated measures ANOVA of the R-UCLA scores with low-frequency and high-frequency users as the between-subjects effect and 2 time points (T1-T2) as the within-subjects effect yielded a statistically significant interaction of frequency and time point (\( F_{1,66} = 7.417, P = .01; \omega^2 = 0.01 \); see Figure 5). After 2 weeks, only high-frequency users reported lower levels of loneliness (\( t_{16} = 3.69, P_{\text{Bonf.}} = .005; d = 0.44, 95\% \) CI 0.07 to 0.81).

**Figure 5.** Revised UCLA Loneliness Scale (R-UCLA) scores for the high-frequency and low-frequency users at baseline and after the intervention. Confidence intervals were difference- and correlation-adjusted using the superb R library described by Cousineau et al [46].
Qualitative Feedback

The team also collected informal, qualitative data through individual in-depth interviews and an open-ended survey question after the intervention (T2). Volunteers (n=16) from the chatbot group answered questions about the perceived advantages and pitfalls of Fido, as well as other unintended effects that had not been assessed by the previously administered questionnaires. The most common response about the negative aspects of using Fido was that there were many failures in recognizing the user’s intent, which resulted in the chatbot telling the user that it did not know what they are talking about. Regarding the positive side effects, the most prominent was that using Fido encouraged the user to make a decision about starting traditional therapy.

Discussion

Principal Findings

This study is one of the few that presents an RCT of chatbot therapy efficacy in comparison with an active control, to the best knowledge of authors—the first one for the Polish language. Fido was effective in terms of reducing depression, anxiety, and worry symptoms, as well as for increasing satisfaction with life during the 2-week intervention. We also detected an increase in positive affect, along with a decrease in negative affect, after the intervention using Fido. All effects were stable for at least one month following the interventions. In contrast to some previous findings [6] about agent-guided therapy, we did not detect expected differences in the effectiveness between the intervention based on Fido and the one in which the book chapters were used.

Although there were no between-group effects in terms of symptoms or affect, or for obtained psychoeducational knowledge or the frequency of use, we did detect some other differences. Worth consideration is that the chatbot users spent less time on the intervention than the control group. Thus, although the effects of working with Fido were comparable to those achieved using self-help materials, they were achieved in a shorter period of time, which is an obvious benefit considering the concentration and motivation problems of patients in mental health crises. The differences in time spent on the 2 interventions may be related to differences in the form of the presented content: Even though both techniques are text-based, reading an ebook may be challenging, in contrast to absorbing shorter messages from the chatbot.

Contrary to our expectations, we did not detect a superior decrease in loneliness levels in the chatbot group when compared with the control group. However, we observed a drop in loneliness among participants who used the chatbot with higher frequency, an effect that did not occur either among participants who used Fido with low frequency or in the control group. Interestingly, although loneliness is linked to well-being, we did not detect a decrease in loneliness in the control group, but we did observe a therapeutic effect on all other primary outcome variables. In the face of this result, it is difficult to relate a decline in loneliness observed in high-frequency chatbot users to the decrease in depression or anxiety. A dissociation between treatment effects on loneliness versus anxiety and depression was observed in a study investigating the efficacy of internet-delivered CBT [47]. Some authors consider loneliness as a transdiagnostic phenomenon that can vary in intensity across different diagnoses [48]. It is possible that loneliness was differentially represented as a factor related to depressiveness and anxiety in our study sample, and we, therefore, did not observe a stable relationship between the effects observed for loneliness and those for the anxiety and depression levels. It is also possible that the duration of our study was simply too short to capture this relationship, as changes in levels of loneliness and depression seem to occur with different temporal dynamics [49]. Future studies should try to track the effects of therapy chatbots for longer time periods and replicate our findings regarding loneliness using nontherapeutic agents, as the interaction with such chatbots may also have a direct effect on loneliness with or without any effect on the mental health condition.

Younger participants formed a stronger relationship with Fido, bonding at an average score of 3.59 (on a 1-to-5 positively scored scale), which is higher than the bond reported for internet interventions but lower than Woebot or human-involved therapy (Woebot formed a bond at 3.8, traditional CBT formed a bond at 4, and group CBT formed a bond at 3.8 on the same scale [8]). Participants used the chatbot as frequently as the book in the 2-week intervention period, but the book readers declared spending more time using their psychoeducation materials than chatbot users.

Comparison With Prior Work and Limitations

We did not replicate the findings from the study on Woebot that demonstrated better treatment effects for the chatbot-based intervention than those for the self-help materials [6]. In addition, the alliance built with Woebot was higher than with Fido. This may suggest that, at this stage, Fido is less effective and user-friendly than Woebot.

However, we would argue that the lack of group differences in this study do not result from Fido’s insufficiency but is rather related to the fairly high effectiveness of the self-help materials that we used and the differences in our experimental procedure. First, the materials used in the study by Fitzpatrick et al [6] were mostly psychoeducation, and the materials used in the previous study required not only getting acquainted with psychoeducation but also performing a few cognitive exercises. Second, the materials used for the control group in the Woebot study were provided by the WHO, and those included in our study were derived from a CBT handbook that was empirically proven to be efficient [50]. Third, our study differed in the experimental protocol from the Woebot protocol; that is, in our study, engagement checks were sent to participants every 3 days, which may have served as a reminder to use the intervention. Although it provided valuable insight into participants’ behaviors, it may have also increased the treatment effects, making the 2 studies difficult to compare.

Even though we did not replicate the outcomes from the Woebot study [6], our data are in line with the results of other studies on digital therapeutics. Studies of mental health–supporting applications yield high efficacy mostly when compared with waiting list control samples but not with active control groups.
The lack of differences between the 2 groups investigated in this study prompts us to ask whether the interventions that we used would also be more efficacious when compared with a passive control group (ie, waiting control) and if they would match traditional CBT. To gain a deeper understanding of the patient-reported outcomes, further assessment methods could be used, such as clinical interviews [3] or even psychophysiological methods, that were previously used for human-agent interaction studies [45].

Another important factor when we consider the lack of replication of previous effects is the kind of intervention used in our control group, as different effect sizes are reported depending on the kind of intervention. In our study, the well-established handbook materials were used for the control condition, and the procedure ensured that participants used them regularly, which might have increased the effects of the control intervention [3]. It seems important for the entire area of intervention research to systematize the issue of the control condition in the future and to enable thoroughly selected active control conditions to a greater extent.

There are some other limitations. Our experimental procedure does not allow us to completely exclude the influence of the time factor. It may be that all participants improved only as a result of the passing time or regression toward the mean. The use of a waiting control group could enable control over this aspect of our study, providing information about differences in the outcome data without any intervention. However, if we compare the recruitment and baseline data, we can see that waiting for the beginning of treatment did not change the levels of depression and worry, which suggests that the overall affect and well-being were stable over time and changed only after the intervention.

Last, some elements of this study would be different in a routine application setting. The standard use of Fido or other self-help materials may not include frequent commitment checks or psychological assessments and certainly would not involve financial compensation. All of these factors could have influenced intervention uptake, effectiveness, and side effects. The generalizability of the results is also limited by the fact that subsequent free versions of Fido will use improved machine learning models (ie, achieving better precision and recall scores in intent recognition) while offering the same set of conversation functionalities. However, the level of human involvement and support should be very similar in the standard use of Fido.

**Future Research**

Prospective studies should try to replicate the effects presented here. One future direction would be to extend the timing of the intervention, as 2 weeks are relatively short. Thus, it would be beneficial to conduct at least a 4-week intervention and a 3- or 6-month follow-up to assess whether the effects are sustained after a longer period of time. Furthermore, future studies should consider using other control groups such as waiting lists or traditional CBT.

This article focused mainly on the therapeutic effects; however, during this experiment, we used several measures linked to human-chatbot interaction, which may be further explored. Future studies may provide insight not only into the quantitative measures linked to the use of chatbots but also into qualitative measures, as well as deep analysis of metadata, such as the distribution of cognitive biases and their relationship with the mental health condition. Those studies may extend our knowledge linked to digital therapeutics and provide a theoretical background for the development of further therapy applications.

**Data Availability**

The data sets generated during and/or analyzed during this study are available in the Open Science Framework repository [24].

**Acknowledgments**

This work was supported by a Ministry of Science and Higher Education grant (grant number 012/RID/2018/19). The authors would like to thank Norbert Szczepaniak and Iwona Gawrycka for their continuous contribution to the development of Fido, as well as Barbara Konat, who worked with us at the beginning of the project. It is worth noting that Fido was implemented by Emplocity and runs on natural language processing technology provided by this company.

**Conflicts of Interest**

All authors are actively involved in the development of Fido at a pre-release stage. Fido was commercialized in April 2023 in the form of a spin-off company, in which SK, KS, and JM have stock options.

Abstract

Background: The eCOVID19 Recommendations Map & Gateway to Contextualization (RecMap) website was developed to identify all COVID-19 guidelines, assess the credibility and trustworthiness of the guidelines, and make recommendations understandable to various stakeholder groups. To date, little has been done to understand and explore parents’ experiences when accessing and using the RecMap website for COVID-19 health decision-making.

Objective: To explore (1) where parents look for COVID-19 health information and why, (2) parents’ user experience when accessing and using the RecMap website to make health decisions, and (3) what knowledge mobilization activities are needed to increase parents’ awareness, use, and engagement with the RecMap website.

Methods: We conducted a qualitative descriptive study using semistructured interviews and a think-aloud activity with parents of children aged 18 years or younger living in Canada. Participants were asked to provide feedback on the RecMap website and to “think aloud” as they navigated the website to find relevant COVID-19 health recommendations. Demographic information was collected using a web-based questionnaire. A hybrid deductive and inductive thematic approach guided analysis and data synthesis.

Results: A total of 21 participants (13/21, 62% mothers) were interviewed and participated in a think-aloud activity. The data were categorized into four sections, representative of key elements that deductively and inductively emerged from the data: (1) parent information seeking behaviors and preferences for COVID-19, (2) RecMap website usability, (3) perceived usefulness of the RecMap website, and (4) knowledge mobilization strategies to increase awareness, use, and engagement of the RecMap website. Parents primarily used the internet to find COVID-19 information and focused on sources that they determined to be credible, trustworthy, simple, and engaging. As the pandemic evolved, participants’ information-seeking behaviors changed, specifically their topics of interest and search frequency. Most parents were not aware of the RecMap website before this study but found satisfaction with its concept and layout and expressed intentions to use and share it with others. Parents experienced some barriers to using the RecMap website and suggested key areas for improvement to facilitate its usability and perceived usefulness. Recommendations included a more user-friendly home page for lay audiences (separate public-facing user interface), improving the search and filter options, quicker navigation, clearer titles, more family-friendly graphics, and improving mobile-friendly access. Several strategies to disseminate the RecMap website were also expressed, including a mix of traditional and nontraditional methods (handouts and social media) in credible and high-traffic locations that parents frequent often.
Conclusions: Overall, parents liked the concept of the RecMap website but had some suggestions to improve its usability (language, navigation, and website interface). These findings can be used to improve the RecMap website for parents and offer insight for the development and dissemination of effective web-based health information tools and resources for the general public.

Introduction

During the COVID-19 pandemic, digital information sharing and exchange exploded as disease information emerged and messaging around various restrictions, such as lockdowns and physical distancing, came into effect. While this generated a wealth of web-based COVID-19 information, it presented challenges for the public, including parents and families, when navigating and recognizing trustworthy health recommendations [1,2].

In response, the eCOVID19 Recommendations Map & Gateway to Contextualization (RecMap) website was developed [3]. The overall aim of the RecMap is to identify and collate all COVID-19 guidelines, assess the credibility and trustworthiness of the recommendations, and make the recommendations understandable to various stakeholder groups. The RecMap was developed by Cochrane Canada in collaboration with the World Health Organization’s (WHO) Collaborating Center for Infectious Diseases, Research Methods and Recommendations at McMaster University, the GRADE (Grading of Recommendations Assessment, Development and Evaluation) centers, the Norwegian Institute of Public Health, the Guidelines International Network, the National Institute of Health and Care Excellence (NICE), WHO and the Pan American Health Organization (PAHO), and many other organizations [3,4]. The living catalogue of COVID-19 guidelines is freely accessible, in English and French [5].

On the RecMap website, the recommendations, which are typically written for health care professionals, are currently being adapted into plain language products. These products have been developed as easy-to-understand summaries of health recommendations [6,7]. Our group’s previous findings suggest that parents prefer and better understand plain language versions compared to standard language recommendations [8].

It is critical that the evidence-based information available to parents is effectively communicated, understandable, and engaging for lay audiences. This is necessary to guide uptake and create actionable impact [9-11]. However, previous anecdotal data have suggested that parents are unaware of the RecMap website when seeking COVID-19–related health information or recommendations. There is also little information about the RecMap website’s usability from the perspective of parents. Usability and perceived usefulness are key criteria to consider when developing effective web-based health information tools [12-15].

To address this gap, we aimed to explore (1) where parents look for COVID-19 health information and why, (2) parents’ user experiences (including barriers and facilitators) when accessing and using the RecMap website to make health decisions, and (3) what knowledge mobilization activities are needed to increase parents’ awareness, use, and engagement with the RecMap website. The results of this study can be used to inform the enhancement and knowledge mobilization of a web-based COVID-19 tool for the general public, as well as the future development of web-based resources on other health topics.

Methods

Ethical Considerations

Approval was received from the University of Alberta Health Research Ethics Board and the McMaster Research Ethics Board (Pro00126429, Pro15646), and all participants gave informed consent before any data collection. After study completion, participants were compensated with a CAD $50 (a currency exchange rate of CAD $1 = US $0.6518 is applicable) electronic gift card for their time.

Overview, Sampling, and Recruitment

We conducted a qualitative-descriptive study [16]. Participants were eligible and self-identified for study enrollment if they were a parent, legal guardian, or grandparent of a child aged 18 years or younger, were aged 18 years or older themselves, lived in Canada, could read and speak English, had access to email and the internet through a computer, tablet, or smartphone. The study was advertised nationwide on the web between February and April 2023 through our collaborators (eg, the RecMap Team, Pediatric Parent Consultancy Network, and Pediatric Parent Advisory Group), and networks (eg, Cochrane Canada, Translating Emergency Knowledge for Kids, and Children’s Healthcare Canada) through email, as well as on social media through Instagram, Twitter, and Facebook. Purposive sampling (based upon parenting role and ethnicity) was used to gather an in-depth understanding of Canadian parents’ experiences with the RecMap website [17]. Results are reported following the Consolidated Criteria for Reporting Qualitative Research checklist [18].
Sample Size
Sample size was shaped by data saturation, which was assessed concurrently throughout data collection and analysis to assess data comprehensiveness, variation, richness, and redundancy [19].

Study Components
Semistructured Interview and Think-Aloud Activity
Participants were invited to attend a web-based, one-on-one, semistructured interview using Zoom video conferencing software. The interview guide was field tested and adapted over 2 nonrecorded interviews using in-house research staff and a parent volunteer (Multimedia Appendix 1). Interviews were conducted by SC (a woman), who is a research coordinator with a Master of Science and has previous experience conducting qualitative interviews. Consenting participants had no previous relationship with the coordinator and were informed of the study objectives at the beginning of the interview. There were no other individuals present during each interview besides the participant and the research coordinator. Interviews were audio-recorded, deidentified, and transcribed verbatim using a third-party transcription service (SimplyTranscription). Field notes were made throughout the interviews, including during the think-aloud activity, in which the parent was observed navigating the website and shared their screen so the interviewer could ascertain the steps and clicks they used to complete the different tasks. The first part of the interview focused on understanding where parents look for COVID-19 information and for what purpose. Participants were then asked to visit the RecMap website on their electronic device of choice (eg, computer, tablet, or smartphone). The second part of the interview asked participants to provide feedback about the RecMap website and to “think aloud” as they were asked to navigate the website to find relevant health recommendations for children. The think-aloud activity is based in cognitive and psychological research, where participants talk aloud while performing a task to verbalize their thoughts that come to mind [20-22]. Think-aloud interview methods have formerly been used in combination to explore usability and perceived usefulness [12]. Participants were also asked to share possible knowledge mobilization strategies to increase parents’ awareness, use, and engagement with the RecMap website. No participants withdrew from the study, no repeat interviews were conducted, and transcripts were not returned to the participants for corrections or to provide feedback on the findings.

Demographic Questionnaire
Participants were asked to complete a short web-based demographic questionnaire (eg, parenting role, age, education, ethnicity, and child’s age) after finishing the interviews. Quantitative data were collected and managed using REDCap (Research Electronic Data Capture), hosted at the University of Alberta [23,24].

Data Analysis
Thematic Analysis
Thematic analysis was used to synthesize and identify common behaviors, processes, and preferences described in the semistructured interviews. Data management and analysis were facilitated using NVivo 14 Software (version 14.23.1; QSR International).

Data collection and analysis occurred iteratively, with data collection occurring until data redundancy was achieved. Interviews were coded by SC (the primary coder) and categorized to facilitate the development of themes. A hybrid deductive and inductive approach guided analysis in which data were categorized into 4 components. An established framework, the Technology Acceptance Model, was used to deductively organize the data, and additional codes were inductively gathered as they emerged from the data [12-15,25]. The analysis was guided by the following six main steps: (1) comparing the transcript with the recording and revising to ensure alignment (data cleaning); (2) reading transcripts and data familiarization; (3) generating initial codes (using a code manual and testing the reliability of codes through verification by a second reviewer [SAE]); (4) summarizing data and identifying initial themes guided by the model (deductive) and coding themes that extend beyond the model (inductive); (5) connecting the codes, identifying themes, and generating a “thematic map;” and (6) corroborating and legitimating coded themes. The coding system was refined throughout the iterative data collection and analysis stages, using a secondary coder (SAE) to code approximately 10% of the transcripts and compare them to maintain intrarater reliability [26]. Any discrepancies between the reviewers were discussed and resolved through consensus. The focused codes were further refined through collaboration between the 2 authors into themes and subthemes that identified common factors contributing to parental preference, usability, and perceived usefulness. All codes and transcripts were then re-examined to ensure the consistency and accuracy of the interpretation. Preliminary findings and interpretations were continuously reviewed and discussed among the research team. Other strategies for maintaining rigor were followed, such as detailed study logs and audit trails to ensure transparency [26].

Demographic Analysis
Demographic data were downloaded from REDCap into Microsoft Office Excel (2019; Microsoft Corp), and frequency distributions were used to describe the study sample.

Results

Sampling and Demographics
A total of 21 parents, mostly mothers (13/21, 62%) living in Canada, participated in interviews lasting between 30 and 60 minutes from February to April 2023. Participant demographics are presented in Table 1. Briefly, all parents reported a postsecondary education, with 57% (12/21) having a graduate or postgraduate degree. Parents identified most often as White (11/21, 52%) and South Asian (4/21, 19%). The RecMap website was accessed during the interviews by parents using a desktop or laptop computer (19/21, 90%), a tablet (1/21, 5%), and a smartphone (1/21, 5%).

<tbody>
<tr>
<td>Semistructured Interview and Think-Aloud Activity</td>
</tr>
<tr>
<td>Participants were invited to attend a web-based, one-on-one, semistructured interview using Zoom video conferencing software. The interview guide was field tested and adapted over 2 nonrecorded interviews using in-house research staff and a parent volunteer (Multimedia Appendix 1). Interviews were conducted by SC (a woman), who is a research coordinator with a Master of Science and has previous experience conducting qualitative interviews. Consenting participants had no previous relationship with the coordinator and were informed of the study objectives at the beginning of the interview. There were no other individuals present during each interview besides the participant and the research coordinator. Interviews were audio-recorded, deidentified, and transcribed verbatim using a third-party transcription service (SimplyTranscription). Field notes were made throughout the interviews, including during the think-aloud activity, in which the parent was observed navigating the website and shared their screen so the interviewer could ascertain the steps and clicks they used to complete the different tasks. The first part of the interview focused on understanding where parents look for COVID-19 information and for what purpose. Participants were then asked to visit the RecMap website on their electronic device of choice (eg, computer, tablet, or smartphone). The second part of the interview asked participants to provide feedback about the RecMap website and to “think aloud” as they were asked to navigate the website to find relevant health recommendations for children. The think-aloud activity is based in cognitive and psychological research, where participants talk aloud while performing a task to verbalize their thoughts that come to mind [20-22]. Think-aloud interview methods have formerly been used in combination to explore usability and perceived usefulness [12]. Participants were also asked to share possible knowledge mobilization strategies to increase parents’ awareness, use, and engagement with the RecMap website. No participants withdrew from the study, no repeat interviews were conducted, and transcripts were not returned to the participants for corrections or to provide feedback on the findings.</td>

<tbody>
<tr>
<td>Thematic Analysis</td>
</tr>
<tr>
<td>Thematic analysis was used to synthesize and identify common behaviors, processes, and preferences described in the semistructured interviews. Data management and analysis were facilitated using NVivo 14 Software (version 14.23.1; QSR International). Data collection and analysis occurred iteratively, with data collection occurring until data redundancy was achieved. Interviews were coded by SC (the primary coder) and categorized to facilitate the development of themes. A hybrid deductive and inductive approach guided analysis in which data were categorized into 4 components. An established framework, the Technology Acceptance Model, was used to deductively organize the data, and additional codes were inductively gathered as they emerged from the data [12-15,25]. The analysis was guided by the following six main steps: (1) comparing the transcript with the recording and revising to ensure alignment (data cleaning); (2) reading transcripts and data familiarization; (3) generating initial codes (using a code manual and testing the reliability of codes through verification by a second reviewer [SAE]); (4) summarizing data and identifying initial themes guided by the model (deductive) and coding themes that extend beyond the model (inductive); (5) connecting the codes, identifying themes, and generating a “thematic map;” and (6) corroborating and legitimating coded themes. The coding system was refined throughout the iterative data collection and analysis stages, using a secondary coder (SAE) to code approximately 10% of the transcripts and compare them to maintain intrarater reliability [26]. Any discrepancies between the reviewers were discussed and resolved through consensus. The focused codes were further refined through collaboration between the 2 authors into themes and subthemes that identified common factors contributing to parental preference, usability, and perceived usefulness. All codes and transcripts were then re-examined to ensure the consistency and accuracy of the interpretation. Preliminary findings and interpretations were continuously reviewed and discussed among the research team. Other strategies for maintaining rigor were followed, such as detailed study logs and audit trails to ensure transparency [26].</td>

No participants identified as being a legal guardian, aged 30 years or younger, with an income of <CAD $50,000 (US $37,100.25), an education below postsecondary, having ≥4 children, or their child being aged 1 year or younger. All participants identified as being partnered, except for 1 participant who selected “prefer not to answer.”

Semistructured Interview and Think-Aloud Activity
The data were categorized into 4 sections, each representative of key elements that deductively and inductively emerged from the data. The first section addressed our first study objective of parent information-seeking behaviors and preferences for
COVID-19. The second and third sections addressed our second objective, where we analyzed user experience based on 2 dimensions, namely, RecMap website usability and perceived usefulness of the RecMap website. The fourth section addressed our final objective of knowledge mobilization strategies to increase awareness, use, and engagement with the RecMap website. Illustrative quotes to support themes and subthemes are presented in Multimedia Appendix 2.

Parent Information-Seeking Behaviors and Preferences for COVID-19
Relevant parent information-seeking behaviors and preferences about COVID-19 were grouped into 3 themes described in subsequent sections.

Parents Seek COVID-19 Information From a Variety of Sources
Parents reported seeking COVID-19 information from a variety of sources. The majority of parents used the internet (eg, web-based search engines, visiting health websites, and social media) as their primary source and reported being very comfortable using this modality to look for information. Secondary sources included the news, radio, and respected friends, family, and health care providers. Parents sought information applicable to their local jurisdiction (ie, province and community) to ensure familiarity with their current guidelines and mandates.

Parents Changed Their Information-Seeking Behaviors During the COVID-19 Pandemic
Parents reported a change in their information-seeking behaviors throughout the pandemic, particularly related to their topics of interest and information-seeking frequency. At the start of the pandemic, many parents reported seeking COVID-19 information on a daily or weekly basis, and their topics of interest included COVID-19 signs and symptoms, isolation requirements, and case numbers. At the time of conducting these interviews, parents reported seeking information less frequently (eg, on a monthly basis or less) and revealed looking for information on topics such as vaccines, masking, or travel guidelines when relevant to their situation and when needing to make an informed health decision for their family.

Parents Look for Specific Features and Elements When Seeking COVID-19 Information
The majority of parents described looking for COVID-19 information that was credible and trustworthy, which they characterized as being from a reputable source (eg, health authorities and the government). Parents also looked for information that was convenient to access (eg, mobile-friendly through a smartphone), relevant to their current environment (eg, email directly from their workplace or their child’s school), and aesthetically pleasing (eg, simple and engaging).

RecMap Website Usability
The data from the think-aloud activity were grouped into the following three themes related to RecMap website usability: (1) RecMap website purpose and target audience, which explored parents’ overall thoughts about the usefulness of the website; (2) RecMap website presentation and navigation, which explored their preferences for layout, formatting, language, and how parents used the website; and (3) RecMap website functionality, which highlighted parents’ experiences with website features and overall usability.

RecMap Website Purpose and Target Audience
The purpose of the RecMap website was well understood by most parents; however, the purpose of the RecMap website was not described anywhere on its home page. Parents wanted clearer messaging on the home page about what the website could offer families and the types of health recommendations available for children.

The target audience of the RecMap website was described as “for everyone” (ie, academics, health care providers, and the public), but again, parents felt that the home page lacked content directly addressing the public (or lay audiences), especially families. Some parents also questioned if the RecMap website was intended for a Canadian or global audience, as some content seemed specific to Canada (eg, McMaster University and Cochrane Canada logos on embedded videos and the website being only available in English and French), while other content felt geared toward a broader population (eg, recommendations presented based on European sources).

RecMap Website Presentation and Navigation
The overall layout and format of the RecMap website were appealing to parents and were described as professional and simple. However, some parents did not readily see who the website was developed by, particularly within the first few moments of navigating the home page, and this led them to initially question its credibility. The color scheme of the website was said to be aesthetically pleasing, but some parents felt that an extra pop of color with more family-friendly graphics could better engage a lay audience. Parents also noted the navigation buttons were not always intuitively located, and they found some headings to be repetitive, with the font size not consistently proportionate between headings, subheadings, and body text.

The recommendations in the format of a list compared to a map on the RecMap website were preferred by most parents, as they felt that it was more familiar to them and easier to understand and navigate (Figures S1 and S2 in Multimedia Appendix 3). However, many parents commented that the list was lengthy and wondered how it was organized (eg, alphabetically or by date), as that impacted their ability to find relevant information quickly.

Parents felt that some terminology used on the website (eg, adolescence and conditional) was too complex and that many lay audiences would struggle to understand the terms “RecMap” and “plain language,” which were frequently used. Parents noted that although the navigation button titled “plain language recommendations” was well-situated on the home page, they cautioned that parents who are unfamiliar with this term may not know how to navigate and seek out these recommendations, which are tailored to lay audiences. Parents cautioned that it may lead to others exploring standard language recommendations first when they could benefit from plain language. Parents suggested refraining from titling these
recommendations as “plain language” and generating an alternative title that is clearer and more suitable for lay audiences.

Parents thought the website was easy to navigate, especially the home page, but found that it required several clicks to reach a specific health recommendation. Parents also found that navigating the recommendations in map view was challenging as many were unfamiliar with this format and required a few moments to understand what the headings and numbers signified (Figure S2 in Multimedia Appendix 3).

Parents used a variety of navigation strategies when asked to find a recommendation specific to children. Most parents’ initial instinct was to use the search function. Others clicked on a preset option that was located on the home page (ie, either the map, list, or plain language recommendations button). Parents described their strategy rationale as being based on a combination of comfort levels (eg, using the search function), convenience (eg, quick), and taking into consideration the existing features and information available on the website. Parents who clicked on the “plain language recommendations” option from the start often felt less overwhelmed with information compared to those who initially browsed the standard language recommendations. Additionally, parents noticed that when using the search function on the home page, the results generated standard language recommendations, but parents felt that results for plain language recommendations should be prioritized for lay audiences.

RecMap Website Functionality

Parents found a variety of features to be useful and improve their user experience and overall website usability. The RecMap website’s search feature was emphasized by parents as appealing because it was well-located and gave the freedom to search for any topic of interest. However, challenges were experienced when the use of basic search terms led to unsuccessful findings (eg, irrelevant or no recommended results), and parents had to adjust their terms multiple times or try a new navigation strategy to obtain relevant results.

The filter option on the list of recommendations was frequently used by parents. This feature was reported as practical, but with some complex and irrelevant categories for a lay audience (eg, adolescent and grading approach). Based on the available categories, parents thought that age group (eg, infant, child, or youth), world region, source, and year of publication were most relevant and suggested adding age range. They also felt that these categories should be rearranged and listed at the top for easy access.

Parents were divided on whether they liked the feature of a new tab opening up (within their web browser) for each specific recommendation that they clicked on and explored. Some parents enjoyed this feature because they could easily navigate between tabs to different recommendations, but some did not notice the new tab, which made it challenging for them to return to the home page.

Parents noted a few undesirable features and some technical barriers as they explored the website. Many parents found that the mailing list pop-up (eg, subscribe to receive information about upcoming activities) was distracting and appeared too soon before they had a chance to explore the full website. Some parents also experienced extended loading times (eg, when trying to access the recommendations in map view), which impacted the overall usability and user experience of the website.

Perceived Usefulness of the RecMap Website

Regarding perceived usefulness, two themes emerged as follows: (1) intentions to use the RecMap website, which looked at parents’ thoughts about its usefulness and their desire to share and discuss it with others and seek supportive information; and (2) parents’ awareness and expectations of the RecMap website, which explored whether parents were familiar with and had previously accessed the website and if it met their needs and expectations.

Intentions to use the RecMap Website

After completing the think-aloud activity, most parents discussed their intentions to use and share the website with others (eg, friends and family). Parents who were hesitant to use or share it suggested that the home page needed to be more user-friendly (for a lay audience) with clearer titles, quicker navigation, and improved search and filter options to seek out relevant plain language recommendations in a timely manner.

Parents felt that if needed, they would discuss the RecMap website with their health care provider or seek out supplementary information (eg, other web-based sources) to enhance their understanding of what was available on the website in order to make an informed health decision for their child.

Awareness and Expectations of the RecMap Website

Very few parents reported being aware of or previously accessing the RecMap website before this study. Parents suggested that their unawareness may be due to limited promotion, a lack of health care referral, or that the RecMap website did not appear in their search engine results for COVID-19.

The overall concept of the RecMap website was liked by most parents, and they perceived this tool to be useful. Parents highlighted that it gives users an opportunity to search for COVID-19 information from a credible source, and some positively compared it to a large COVID-19 web-based search engine.

Some parents expressed that parts of the RecMap website were not what they expected and wanted to see more information tailored for parents and lay audiences. This included addressing COVID-19 topics related to possible child COVID-19 complications and symptom management, which parents felt were not clearly addressed. Additionally, most parents did not expect that when navigating the website, they would have the option to see recommendations in both standard and plain language. This had taken many parents a few moments to realize, particularly those who were unfamiliar with the term “plain language.” They also wanted more clarification about what the recommendation map was compared to the
recommendation list and if there was a difference between them beyond format.

**Knowledge Mobilization Strategies**

Knowledge mobilization strategies were grouped into two themes: (1) recommendations to tailor the RecMap website for parents, which highlighted suggestions to make the website more user-friendly and accessible for parents; and (2) approaches to dissemination, which explored where and how to share information about the RecMap website within the parent community to increase awareness, use, and engagement.

**Recommendations to Tailor the RecMap Website for Parents**

To better tailor the website for parents, it was often suggested to develop a separate user interface within the website to split the content into lay or public and health care professional or academic. This would facilitate relocating the standard language recommendations, which most parents find challenging to understand. This would also enable more tailored features, where some parents suggested a “frequently asked questions” section to dispel myths or an ability to insert anonymous data about your child (eg, age and vaccine status) into the RecMap website to generate relevant recommendations. A “bookmark” or “share” option to save recommendations was also suggested by parents, as they described having busy schedules and wanting quick and easy-to-find information.

Parents felt that the accessibility of the website was another key element to highlight. A mobile-friendly website and mobile apps were mentioned by many parents, who reported that they often use their smartphones as a convenient tool to look for information. Even though the RecMap is currently accessible through a smartphone, the map of recommendations is inaccessible. Parents also felt that being mindful of contrasting colors on the RecMap website was important for the accessibility of those with various visual abilities.

**Approaches to Dissemination**

Parents shared a variety of dissemination strategies to increase awareness of the RecMap website within the parent community. Parents felt that sharing information in convenient and high-traffic locations where parents frequent often (eg, social media, such as Facebook, Instagram, TikTok, and Twitter; health and immunization clinics; schools; parent groups; at extracurricular activities or events such as soccer games) would increase parents’ awareness and thus website use. Other strategies included collaborating with credible and trusted organizations and individuals (eg, health authorities, health care providers, and schools) to share information through their networks in person or through a web-based presence.

Parents suggested that approaches to increasing awareness of the RecMap website should not be limited to just one but rather should consist of multiple captivating methods to attract and engage parents with different preferences and means to access information. Methods suggested included QR codes, handouts, posters, social media posts, advertisements and sponsors (eg, on the radio, podcasts, in parenting magazines, school newsletters), media interviews (eg, on the news and radio), and word of mouth from trusted individuals (eg, health care providers).

**Discussion**

**Principal Findings**

The aim of this study was to explore parental COVID-19 information-seeking behaviors and preferences, along with their experience when accessing and using the RecMap website. Parents also shared several knowledge mobilization strategies to facilitate parents’ awareness, use, and engagement of the RecMap website.

**Information-Seeking Behaviors and Preferences**

This study identified that most parents report using the internet as a primary source to look for COVID-19 health information. This is not surprising given that recent reports document that approximately 70% of Canadians and Americans use the web to search for health information [27,28]. There is also now an array of COVID-19-specific information on the web that has become easily and conveniently accessible to the public [2]. Of note, parents reported a change in their information-seeking behaviors and preferences since the pandemic started, with parents looking for information less frequently as the pandemic evolved. This is important to consider when planning future knowledge mobilization strategies aimed at parents and the general public.

**Barriers to Using the RecMap Website**

When parents initially accessed the RecMap website, most struggled to identify who developed it; thus, many parents questioned its credibility. Web-based tools that are immediately recognizable (eg, well-branded and clear messaging on the home page) may help increase credibility and should be considered for future knowledge mobilization efforts among the general public.

Additionally, there was some content and language within the RecMap website that was deemed too advanced or complex by participants and thus a barrier, such as recommendations that were written in standard language. However, some participants expressed benefits to having access to standard language and suggested a public-facing user interface to separate laypersons and the public from health care professionals or academic content. Similar interface designs have been used on other health-related information websites across Canada, including Alberta Health Service and Ontario Health [30,31]. This format (lay-friendly material upfront with the ability to access standard language content) will also provide more opportunities to customize the RecMap website for this population and address additional suggestions mentioned by participants (eg, messaging that is focused on what the RecMap website can offer the general public).

Parents also experienced technical barriers with the loading time of the recommendations in the map view. A study on web usability testing in parents found that technological difficulties were a key barrier to successfully using a website and its features [32]. Load time is also an important web performance metric that can directly impact user engagement. Websites that take
longer than 3 seconds to load have reported that almost 55% of users leave the website [33]. In fact, some of our participants mentioned that they would potentially exit a website and find a new one if the loading time was excessively long. Other minor barriers noted in this study were shortcomings in the visual design (eg, color and graphics), unclear titles, and challenges with returning to the home page. Similar barriers have been reported in previous research that explored website user experience and usability testing [12,34], highlighting the need for end user input into the design at an early stage.

**Facilitators for Using the RecMap Website**

While parents liked the concept and felt the RecMap website could be useful to them, they described several facilitators to optimize use. The concept of the RecMap has previously been used and implemented by the World Health Organization to house living guidelines and recommendations on tuberculosis prevention and care [35]. At this time, usability testing has not been formally completed with parents or the general public. However, the RecMap’s digitized dissemination format has been compared for usability to a conventional tuberculosis website containing guideline recommendations, and the RecMap was found to be more accessible, improve understanding, and enable decision-making [36].

Other facilitators for parents using the RecMap website included a professional and simple presentation, the availability of an internal search engine, and a home page that was easy to navigate. These suggested elements are in line with standards that have been identified for the development of digital-based health information resources. In particular, when information is aesthetically pleasing, easy to find and navigate, this can contribute to increased user trust, readability, and facilitation of understanding [37]. Other research has found that simple aesthetics [29], clearly described headings and labels, information that is logically organized [38], limited technological barriers [32], and being usable in stressful situations [29] are equally preferred by parents. The use of tailored features to meet the needs and preferences of parents was also suggested to improve website usability and quality [32]. This was recommended by our participants in the form of a frequently asked questions section or the ability to bookmark recommendations for easy access.

**Knowledge Mobilization Strategies**

In 2018, it was reported that almost 90% of Canadian internet users aged 15 years and older have a smartphone and that almost 50% check their smartphone at least every 30 minutes [39]. Many parents in our study reported that they typically use their smartphones to look for and access health-related information, however, the initial version of the RecMap was not specifically designed to be smartphone compatible. It is clearly important that health-based websites are mobile-friendly and compatible on devices with smaller screens to optimize viewing and ease of navigation. Better accessibility may also support user experience, which can lead to better user engagement and increase usage.

Mobile apps are another avenue to explore for the RecMap, as there is a rise in parents using apps to support their parenting [40]. This modality is versatile and can encompass multimedia elements (eg, graphics and videos) to engage users and push notifications to alert users of new information or updates on the application. This is an interesting feature to consider given that the RecMap contains living recommendations that are frequently updated or changed. It is equally important for parents that mobile apps are of high quality, relevant, visually appealing, interactive, and seamless (ie, easy to navigate, do not freeze, or crash); otherwise, there is a risk that flawed apps will be deleted by end users within minutes after being downloaded [40].

It has been previously reported that dissemination strategies appropriate for parents include targeting credible sources such as community centers, public health institutions, schools, physicians, and government agencies [41]. This is comparable to our findings, where parents suggested targeting schools, health clinics, and collaborating with credible and trusted organizations and individuals to increase the RecMap website’s awareness. Furthermore, collaborating with reputable messengers (eg, physicians) can be an effective strategy. In fact, it is suggested that 70% of patients would like their physician to recommend web-based health information for them to review [42]. Similar to our findings, it has also been suggested that using a combination of dissemination methods can be most effective. This includes a multiplatform approach of digital (eg, social media and websites), traditional (eg, brochures and radio), and unique means (eg, community “parent nights”) [41].

**Strengths and Limitations**

This work has important implications for knowledge mobilization strategies to enhance and contextualize products to meet diverse end users’ needs as we move beyond the pandemic and for other public health issues, including regular seasonal outbreaks and future epidemic approaches.

A strength of this study is the use of multiple methods. The think-aloud activity allowed us to collect direct data on user experience and parent thoughts while using the RecMap website, and the interviews provided us with an opportunity to clarify initial thoughts and ask further questions. Nevertheless, the majority of participants self-identified as White and of higher socioeconomic status, which limited the generalizability of study findings to a wider audience and was not representative of Canada’s ethnically diverse population. However, we were able to recruit participants who identified as both mothers (13/21, 62%) and fathers (8/21, 38%), which enabled us to gather differing perspectives in terms of parenting roles. Future studies may benefit from developing a recruitment strategy that targets those with different parenting roles, visible minority groups, those of lower socioeconomic status, and those living in geographically diverse locations (eg, rural). In doing so, a better understanding of the diverse needs of parents across Canada could be examined, and strategies (digital and nondigital) to support knowledge mobilization around COVID-19 in various contexts could be developed. It is also worth noting that all participants lived in Canada and had access to a similar health care setting.

https://formative.jmir.org/2024/1/e53593

Cyrkot et al
Directions for Future Research

Future work related to the RecMap website should focus on using an integrated knowledge translation model where end users (e.g., parents) codevelop and implement a plan to increase the awareness, use, and engagement of the website among the general public and lay audiences. Our group will also work to improve the usability of the RecMap website and implement the changes based on our findings related to parents’ user experiences. This may also include further work on mobile-friendly access (e.g., smartphones and mobile apps). These steps will enhance the existing RecMap website and ensure that it is user-friendly and meets the needs of parents and the general public. Future projects similar to RecMap that seek to share health recommendations should involve various end users (e.g., parents, health care providers, and the general public) during the conceptual phase of web-based tool development to better tailor the final product toward their specific goals and needs.

As public health approaches to COVID-19 evolve and the focus shifts to post–COVID-19 conditions, researchers developing knowledge mobilization strategies can use these findings to inform decisions for implementing knowledge. While the RecMap was not developed specifically to meet parents’ information needs during the pandemic, it provides a model for how rapidly changing evidence can be synthesized and presented to support decision-making. However, rapidly changing contextual factors may affect the potential use, relevance, and positioning of the RecMap to support knowledge needs around COVID-19 in the future. The waning of attention to COVID-19 guidelines internationally and jurisdictional changes to COVID-19 management question the advantages of resources such as the RecMap post pandemic. Future research should explore sustainable models of knowledge mobilization to support parental information-seeking behaviors. The pandemic highlighted how families engage with web-based health information and how changes in knowledge needs and information-seeking behaviors need to be considered.

Conclusions

This study reports on the COVID-19 information-seeking behaviors and preferences of parents, the RecMap website user experience (including barriers and facilitators), and potential knowledge mobilization strategies. The concept of the RecMap website was appealing to parents and has the potential to become a user-friendly web-based tool for parents. However, understanding how, when, and why parents search for COVID-19 information, as well as what aspects of the user experience can be improved, has provided meaningful insight and recommendations to improve the usability and perceived usefulness of the RecMap website. Additionally, appropriately tailored knowledge mobilization strategies targeted at parents will increase their awareness, use, and engagement of the RecMap website. This data will contribute to the enhancement of the COVID-19 RecMap website for parents and can inform the development of effective web-based tools for the general public about other health topics.

Acknowledgments

The authors would like to thank members of the Pediatric Parent Advisory Group for supporting this work through the design, research materials, and pilot testing of the survey and interview guide. We also acknowledge the input of the RecMap Knowledge Mobilization Advisory Committee.

This study received funding from the Canadian Institutes of Health Research (CIHR; REC 183153), awarded to Dr Holger Schünnemann (McMaster University). CIHR had no involvement in the study design, collection, data analysis and interpretation, or report writing, and was not part of the decision to submit the paper for publication. LH is supported by a Canada Research Chair in Knowledge Synthesis and Translation. LH and SDS are distinguished researchers with the Stollery Children’s Hospital Foundation and the Women and Children’s Health Research Institute.

Abstract

Background: Web-based learning activities are key components of continuing medical education (CME) for health care professionals (HCPs). However, the published outcomes of web-based educational interventions for early breast cancer (EBC) are limited.

Objective: This study aims to objectively assess knowledge, competence, and performance among HCPs following participation in 2 EBC-focused CME activities and to identify the remaining educational gaps.

Methods: We developed 2 CME-accredited web-based educational activities addressing high-risk EBC, including integration of shared decision-making to optimize patient care (touchMDT) and stratification for early identification of high-risk patients and novel treatment strategies (touchPANEL DISCUSSION). Knowledge, competence, and performance were assessed before and after the activities against an expanded outcomes framework (levels 1-5) using self-reported questionnaires and an analysis of anonymized data extracted from patient records.

Results: Six months after the launch of the activity, 7047 and 8989 HCP participants engaged with touchMDT and touchPANEL DISCUSSION, respectively. The overall satisfaction was 82% (a total score of 20.6 out of 25) for the touchMDT and 88% (a total score of 21.9 out of 25) for the touchPANEL DISCUSSION. For the evaluation of knowledge and competence (50 respondents before the activity and 50 learners after the activity), there was a significant increase in the mean number of correctly answered questions from pre- to postactivity (touchMDT: median 4.0, IQR 3.0-5.0 to median 5.5, IQR 4.0-7.0; mean 4.00, SD 1.39 to mean 5.30, SD 1.56 and touchPANEL DISCUSSION: median 4.0, IQR 4.0-5.0 to median 6.0, IQR 5.0-7.0; mean 4.32, SD 1.30 to mean 5.88, SD 1.49; both \( P < .001 \)). A significant improvement in self-reported performance (50 respondents before the activity and 50 learners after the activity) was observed in a combined analysis of both activities (median 3.0, IQR 2.0-3.0 to median 4.0,
IQR 3.0-5.0; mean 2.82, SD 1.08 to mean 4.16, SD 1.45; P<.001). Patient record analysis (50 respondents before the activity and 50 learners after the activity) showed that the HCPs used a range of measures to determine EBC recurrence risk and revealed no significant differences in adjuvant therapies used before and after the activity (P=.97 and P>.99 for Ki-67 <20% and Ki-67 ≥20% tumors, respectively). The remaining educational gaps included strategies for implementing shared decision-making in clinical practice and the use of genetic and biomarker testing to guide treatment selection.

Conclusions: Brief, web-based CME activities on EBC were associated with an improvement in HCP knowledge, competence, and self-reported performance and can help identify unmet needs to inform the design of future CME activities.

KEYWORDS
continuing medical education; early breast cancer; performance; risk stratification; shared decision-making

Introduction

Clinical Decision-Making in High-Risk Early Breast Cancer
Clinical decision-making in cancer can be complex, requiring health care professionals (HCPs) to consider multiple clinical factors, patient preferences, and environmental factors [1-3]. A multidisciplinary team approach can improve the overall quality of decision-making [4-7], and there is evidence that shared decision-making (SDM) with patients can lead to better adherence to treatment and outcomes [1,8-9]. However, obstacles such as lack of resource availability and patient factors (eg, cultures and health literacy) have prevented the complete integration of SDM into cancer care [1,10-14]. HCPs need to understand these obstacles to deliver high-level care tailored to the individual.

The complexity of treating high-risk early breast cancer (EBC) has increased further with the emergence of complex new data on risk stratification and treatment. These include data on the prognostic and predictive value of biomarkers and the benefits of cyclin-dependent kinase 4 and 6 inhibitors, second-generation selective estrogen receptor antagonists and degraders, and protein kinase B (Akt) inhibitors [15-20]. Furthermore, the guidelines on the management of EBC have been updated recently to reflect recent data, which can be interpreted as influencing clinical practice [5,21-28]. Because of this rapid influx of complex information, HCPs who treat EBC are challenged to keep up with practice changes; consequently, it can take time for new and emerging data to be effectively integrated into practice, and patients with EBC may not receive optimal care [29-32].

Effectiveness of Web-Based HCP Education in Breast Cancer
Effective continuing medical education (CME) programs are crucial to ensure that HCPs implement up-to-date, evidence-based practices for their patients. Although CME for HCPs has traditionally been delivered using face-to-face formats, web-based educational activities now offer a viable alternative approach [33]. To date, several studies have demonstrated the effectiveness of web-based HCP education for breast cancer [34-36]. However, gaps remain in the provision of independent web-based medical education programs for high-risk EBC treatment and effective SDM. Although a small number of programs have been developed in EBC [37-39], these have typically been nonaccredited, therefore not providing HCPs with continuing professional development credits for attendance; pharmaceutical company–led, therefore with the potential to be perceived as promotional; and restricted or limited in terms of access; therefore only accessible to those with the means to do so. To address these gaps and complement the currently available programs, accredited, independent, expert-led education available on free-to-access platforms is required to support the knowledge, competence, and performance of HCPs.

Study Rationale, Objectives, and Aims
An expanded 7-level framework for assessing the outcomes of CME programs was developed by Moore et al [40] in 2009. This framework evaluates participation (level 1), satisfaction (level 2), knowledge (level 3), competence (level 4), performance (level 5), patient health status (level 6), and community health status (level 7). These levels are now widely used and included in many consensus documents and practice recommendations [41]. To date, published Moore’s level 5 [40] outcomes analyses in medical education have largely used subjective self-reported outcomes [42-44]. Although these can provide valuable insights, they can be open to bias, for example, recall bias or social desirability bias [45,46]. An analysis of anonymized patient records provides a complementary objective measure of performance that may enhance the understanding of physician behavior changes in practice.

In this study, we developed and implemented 2 faculty-led, CME-accredited web-based educational activities in high-risk EBC. The objectives of this study were to (1) measure changes in knowledge, competence, and self-reported performance after participation in the activities; (2) objectively evaluate changes in performance using anonymized patient records; and (3) identify the remaining educational gaps.

Methods

Study Design
This was a web-based study that analyzed the impact of 2 educational activities in high-risk EBC through CME questionnaires and deidentified patient records. The target audience comprised oncologists (including breast cancer surgeons), oncology nurse specialists, pathologists, and radiologists from Asia, Brazil, and Europe (excluding the United Kingdom). Satisfaction, knowledge, competence, and performance were assessed according to levels 2 to 5 of the
expanded framework for assessing the outcomes of CME programs by Moore et al [40] using self-reported questionnaires and anonymized data extracted from patient records. Questionnaire distribution and data collection were carried out by an independent third party (nuaxia Limited, United Kingdom).

Ethical Considerations

All consents and ethical confirmations for this study were obtained before the completion of both outcome questionnaires. The personal data of HCPs and patients were anonymized. General Data Protection Regulation [47] consents were obtained in the European Union and North America for each questionnaire; adherence to additional requirements in local markets was required to be confirmed in line with European Pharmaceutical Market Research Association professional guidance [48]. For respondents to the patient records questionnaire, consents and ethical confirmations were obtained as part of the questionnaire in accordance with the British Healthcare Business Intelligence Association professional guidelines [49] to ensure patient confidentiality. As part of their written consent to participate in the questionnaires, the HCPs were required to agree to the statement, “As with all research, your identity and personal data are strictly confidential and will not be revealed without your explicit further consent. You have the right to withdraw your consent to participate in market research at any time.” Complete patient records were not obtained by touch Independent Medical Education (touchIME) or any third party; the HCPs were instructed to extract the required anonymized information into a questionnaire. Ethics approval was not applicable for this study because this analysis was not classified as “health research” according to the UK Research and Innovation definition that guides whether research requires Research Ethics Committee review and Health Research Authority approval [50,51]. The study was defined as “market research” per rule 1.1 of the European Pharmaceutical Market Research Association code of conduct, which states that market research does not require a Clinical Research Ethics Committee or independent review board approval [48].

Educational Activities

Educational gaps and learning objectives were identified before the start of activity development in October 2021 by touchIME (a provider of IME for the global HCP community) through a review of the published literature. The expert faculty members further inputted into the educational gaps and learning objectives at the start of activity development. Expert faculty members with a background in breast cancer and SDM were identified by touchIME medical directors through searches of literature indexed in the PubMed database, congress websites, and web-based educational videos. Patient faculty were identified using social media searches across multiple channels. The faculty members (CB, FB, MG, NH, CSH and KLA) were blinded to the plans to assess participation and satisfaction with the education and to publish the outcomes. All the expert faculty (CB, FB, MG, NH, CSH and KLA) involved in the educational activities are authors of this manuscript.

A total of 2 web-based educational activities, touchMDT: “how can shared decision-making be successfully integrated to optimize care of patients with high-risk early breast cancer?” and touchPANEL DISCUSSION: “new horizons in high-risk HR+ HER2- EBC: Risk stratification for early identification and novel treatment strategies” were developed by touchIME in collaboration with the faculty members (CB, FB, MG, NH, CSH and KLA; complete details and learning objectives are included in Multimedia Appendix 1). The touchMDT activity comprised three 13- to 15-minute videos, providing 42 minutes of education in total, and the touchPANEL DISCUSSION activity comprised three 11- to 15-minute videos, providing 39 minutes of education in total. The activities were CME accredited by the Accreditation Council for Continuing Medical Education and the American Nurses Credentialing Center at the University of South Florida Health. Both activities were translated (video subtitles and downloadable slides) from English into Brazilian Portuguese, Chinese Mandarin, French, German, Italian, and Spanish by an independent third party (UnBabel, United States), and both activities were free to access for 1 year (the permissible lifetime of an accredited educational activity) on the touchONCOLOGY website from March 30, 2022, to March 30, 2023 (touchMDT) and from June 15, 2022, to June 15, 2023 (touchPANEL DISCUSSION). The 2 activities featured together on the host website, but participation in both activities was not mandatory.

Various communication channels were used to reach the target audience, including direct publicity emails to the touchONCOLOGY database within the first 12 weeks of the activity launch, with a further reminder at around 6 months; display banners on the touchONCOLOGY website; advertisements in the peer-reviewed journal touchREVIEWS in Oncology and Haematology; publicity via various relevant medical society partnerships; and social media partnerships on Facebook (Meta Platforms, Inc.), LinkedIn (Microsoft Corp.), and Twitter (rebranded as X; X Corp) targeted at the HCPs throughout the lifetime of the activity.

Assessment of Educational Outcomes

Levels 1 and 2 (Participation and Satisfaction)

Levels 1 (participation) and 2 (satisfaction) were assessed separately for each activity (Multimedia Appendix 2). Level 1 included the number of HCPs who engaged in the web-based educational activities and the average time they spent viewing the videos, and it was the only assessment not evaluated using a questionnaire.

Level 2 (satisfaction) was assessed by scoring 5 statements of satisfaction (using a Likert scale) in a postactivity questionnaire.

Levels 3 to 4 and Level 5 (Knowledge, Competence, and Performance)

Levels 3 to 4 and level 5 were assessed using questionnaires completed by relevant respondents (HCPs completing the questionnaire before the activity) and learners (HCPs completing the questionnaire following the education). No pretesting was performed. The target audience was predefined by specialty (eg, oncologists [including breast cancer surgeons], oncology nurse specialists, pathologists, and radiologists) and by region (Brazil, France, Germany, Italy, and Spain). To avoid any pre-exposure bias and to obtain a statistically representative
sample size, data were collected using an independent samples model for each activity. For levels 3 to 4, separate questionnaires were developed for each activity (each comprising 7 questions), whereas for level 5, a combined questionnaire was developed for both activities (3 questions each for touchMDT and touchPANEL DISCUSSION). All questions were developed by touchIME medical directors and writers and were approved for medical accuracy by the faculty. An overview of the topics and the complete questionnaires are provided in Multimedia Appendices 3 to 6.

For the touchPANEL DISCUSSION activity, changes in performance were also assessed through an evaluation of redacted patient records. The HCPs were sent a web-based questionnaire that captured data on (1) general patient demographics and history, (2) risk assessment and stratification to predict disease recurrence, and (3) treatment. Each HCP was requested to extract all relevant nonidentifiable information from a single anonymized patient record into the questionnaire.

Self-Reported Confidence and Intention to Change Practice

As part of the questionnaires, respondents and learners were asked, “How confident are you in treating patients with breast cancer?” (mutually exclusive responses: “not confident,” “a little confident,” “somewhat confident,” “moderately confident,” and “extremely confident”) and “As a result of your participation in this session, will you make a change in your practice?” (mutually exclusive responses: “yes,” “uncertain—more education needed,” “uncertain—practical limitations,” “no—more education needed,” and “no—practical limitations”).

Identification of Outstanding Educational Gaps

A total of 5 potential educational gaps were included in the levels 3 to 4 and level 5 questionnaires (Multimedia Appendix 7), and the learners were asked to rank them by importance. The results were analyzed using a single transferable vote system (Multimedia Appendix 8 [52]). In addition, questions that were answered incorrectly by ≥30% (15/50) of the learners in all postactivity questionnaires were identified as educational gaps. The 30% cutoff was determined by touchIME as an indicator of the requirement for further education based on analyses of data from previous outcomes.

Fielding of the Questionnaires

Preactivity levels 3 to 4 questionnaires were fielded 1 to 2 weeks before launch, whereas postactivity levels 2 to 4 questionnaires were fielded immediately after launch to a different set of HCPs who had participated in the education. The questionnaires were distributed to a database of 20,420 HCPs and then “closed” once a prespecified number had responded (n=50).

The level 5 questionnaire and first patient records questionnaire were fielded 1 to 2 weeks before launch—to a different set of HCPs than those who answered the levels 3 to 4 questionnaires—and closed after completion by a prespecified number of respondents (n=50). A total of 26 weeks after launch, the postactivity level 5 questionnaire and second patient records questionnaire were distributed to the same set of HCPs who completed the level 5 questionnaire and patient records questionnaire before launch. Because of drop out over time, additional HCPs who were matched to the dropouts were surveyed postactivity, if needed.

The HCP participants’ specialties were all validated by nuaxia Limited against third-party data with the assistance of artificial intelligence. This comprised any combination of data from professional associations, hospitals, professional publications, and prescribing and insurance databases.

The participants were required to answer “yes” to the screening question “Do you treat patients with early breast cancer?” to be eligible to participate in the questionnaire study. The HCPs eligible to participate received an honorarium in the form of a digital reward, which could be redeemed via a number of reward partners. In accordance with industry regulations and professional body guidance, the honorarium received was limited to the fair market value for an HCP of that seniority.

Statistical Analyses

Data were analyzed using SPSS Statistics software (version 28.0.1; IBM Corp). The sample size (50 respondents and 50 learners for each activity) was predetermined by the level of funding, and by applying a power analysis, we determined a resulting margin of error of 10% for both the touchMDT and touchPANEL DISCUSSION. Knowledge, competence, and self-reported outcomes were compared for the overall population using an independent samples 2-tailed t test. Data were subdivided by region and years of experience, and a 2-way ANOVA was used to assess the variation in results by these demographics. Individual questions were analyzed with a paired samples 2-tailed t test and a 1-way ANOVA, followed by a cluster analysis, to provide insights into the overall change in correct answers across the questions asked and the specific changes in all the answers given. Data on the number of questions answered correctly were measured as a continuous variable. At the individual question level, the answers were categorical. For performance, measured by the redacted patient records questionnaire, pre- and postactivity comparisons were made using paired and independent samples 2-tailed t tests, chi-square tests, and cluster analysis. These tests were used to assess patient history, use of risk assessment and stratification strategies, and patient treatment pathways.

Results

Assessment of Educational Outcomes

Levels 1 and 2 (Participation and Satisfaction)

By 6 months after launch, 7047 and 8989 participants had engaged with the touchMDT and touchPANEL DISCUSSION activities, respectively. The participants were predominantly oncologists, and the majority were based in Italy for the touchMDT and Brazil for the touchPANEL DISCUSSION activities (Multimedia Appendix 9). Overall satisfaction was 82% (a total score of 20.6 out of 25) for touchMDT and 88% (a total score of 21.9 out of 25) for touchPANEL DISCUSSION (Multimedia Appendix 10). Multichannel publicity reach and impact for the touchMDT and touchPANEL DISCUSSION activities are reported in Multimedia Appendix 11.
Levels 3 and 4 (Knowledge and Competence) A total of 50 respondents and 50 learners were questioned to assess levels 3 to 4 outcomes (Table 1).

Table 1. Demographics of participating health care professionals (HCPs) for the touchMDT and touchPANEL DISCUSSION activities.

aData were collected 6 months after the launch of the touchMDT and touchPANEL DISCUSSION activities on September 29, 2022, and November 21, 2022, respectively. The questionnaire response categories differed between questionnaires and activities, meaning that some options were not applicable. The respondents and learners were the HCPs who completed the pre- and postactivity questionnaires, respectively.

bN/A: not applicable.

For the touchMDT and touchPANEL DISCUSSION activities, respectively, only 12% (6/50) and 18% (9/50) of the respondents answered at least 6 (86%) of the 7 questions correctly before the activity. This increased to 50% (25/50) and 70% (35/50) in the learners, respectively, after the activity (Figure 1). In Figure 1A, the heat maps show the proportion of respondents (N=50) and learners (n=50) who answered a specific number of questions correctly, as displayed by colors ranging from white (the lowest proportion of respondents and learners) to dark red (the highest proportion of respondents and learners). In Figure 1B, the box and whisker plots show the distribution of the number of questions correctly answered by all respondents and learners. In both plots, the horizontal red line within the box indicates the median, the “x” symbol represents the mean, the boxes indicate the IQR, and the vertical lines (whiskers) extend to the range of values, excluding outliers. The outliers are defined as values that fall outside a distance of 1.5 times the IQR from the upper and lower quartiles and are represented by empty circles. The respondents and learners were the HCPs who completed the pre- and postactivity questionnaires, respectively. For both activities, there was a statistically significant increase in the number of correctly answered questions from pre- to postactivity for all participants (touchMDT: median 4.0, IQR 3.0-5.0 to median 5.5, IQR 4.0-7.0; mean 4.00, SD 1.39 to mean 5.30, SD 1.39; P<.001 and touchPANEL DISCUSSION: median 4.0, IQR 4.0-5.0 to median 6.0, IQR 5.0-7.0; mean 4.32, SD 1.30 to mean 5.88, SD 1.49; P<.001; Figure 1). In subgroup analyses, significant increases in the number of correctly answered questions were observed irrespective of specialty or country for both activities and irrespective of years of experience for the touchPANEL DISCUSSION (Multimedia Appendices 12 and 13). Refer to Multimedia Appendix 14 for the responses to individual topics for the levels 3 to 4 questionnaires.
Figure 1. Summary of the number of correct responses for the levels 3 and 4 outcomes questionnaire before and after the launch of touchMDT and touchPANEL DISCUSSION. (A) Heat maps show the proportion of respondents (n=50) and learners (n=50) who answered a specific number of questions correctly, as displayed by colors ranging from white (the lowest proportion of respondents and learners) to dark red (the highest proportion of respondents and learners). (B) Box and whisker plots show the distribution of the number of questions correctly answered by all respondents and learners. In both plots, the horizontal red line within the box indicates the median, the “x” symbol represents the mean, the boxes indicate the IQR, and the vertical lines (whiskers) extend to the range of values, excluding outliers.

Level 5 (Performance)

A total of 50 respondents and 50 learners completed the level 5 questionnaire and the patient records questionnaire (Table 1). The dropout rate was 16% (8/50); therefore, 8 of the 50 learners were de novo HCPs who were matched to the dropouts.

Self-Reported

Preactivity, in total, 6% (3/50) of respondents answered at least 5 (83%) out of 6 questions with the best clinical option. This increased to 44% (22/50) of the learners after the activity (Figure 2). In Figure 2A, the heat maps show the proportion of respondents (n=50) and learners (n=50) who answered a specific number of questions correctly, as displayed by colors ranging from white (the lowest proportion of respondents and learners) to dark red (the highest proportion of respondents and learners).

In Figure 2B, the box and whisker plots show the distribution of the number of questions correctly answered by all respondents and learners. The horizontal red line within the box indicates the median, the “x” symbol represents the mean, the boxes indicate the IQR, and the vertical lines (whiskers) extend to the range of values, excluding outliers. The outliers are defined as values that fall outside a distance of 1.5 times the IQR from the upper and lower quartiles and are represented by empty circles. The respondents and learners were HCPs who completed the pre- and postactivity questionnaires, respectively. There was a statistically significant increase in the number of correctly answered questions from pre- to postactivity for all participants (median 3.0, IQR 2.0-3.0 to median 4.0, IQR 3.0-5.0; mean 2.82, SD 1.08 to mean 4.16, SD 1.45; P<.001). Refer to Multimedia Appendix 15 for the responses to individual topics for the level 5 questionnaires.

https://formative.jmir.org/2024/1/e50931

 JMIR Form Res 2024 | vol. 8 | e50931 | p.1454
In subgroup analyses of data by specialty, years of experience and country (Multimedia Appendix 16), increases in the number of questions with the correct clinical response were observed irrespective of specialty or years of experience, and in the subgroups of participants from Germany, Spain, and Italy.

**Patient Record Data**

The patient characteristics reported by the respondents and learners were broadly similar (Multimedia Appendix 17). The respondents and learners used a wide range of measures to determine the patient risk of recurrence (30 and 26 different combinations of measures, respectively; Multimedia Appendix 18). There was a significant difference between the number of respondents and learners selecting each measure ($\chi^2=508.474; P<.001$) and the number of measures selected ($\chi^2_{56}=203.125; P<.001$; Multimedia Appendix 19). The Ki-67 index use was >90% for both groups, and most of those who used the Ki-67 index reported patients who had tumors with a Ki-67 score of ≥20% (respondents: 30/48, 62.5% and learners: 30/47, 64%; Figure S1 in Multimedia Appendix 20). There was no significant difference between responders and learners regarding adjuvant therapy when analyzing patient record data by Ki-67 index, menopausal status, germline BRCA status, or the number of positive lymph nodes (Figure S2 in Multimedia Appendix 20).

**Identification of Outstanding Educational Gaps**

In ranking the unmet educational needs, touchMDT learners highlighted “strategies for implementing SDM in clinical practice” and “effective communication strategies in SDM to optimize patient outcomes” as key areas for future education, and touchPANEL DISCUSSION learners highlighted “using genetic and biomarker testing to guide therapy choice” and “individualization of treatment choice in high-risk hormone receptor–positive human epidermal growth factor receptor 2 negative (HR+ HER2–) EBC.” From the level 5 questionnaire, learners highlighted “using genetic and biomarker testing to guide therapy choice for patients with high-risk HR+ HER2- EBC” and “understanding the latest data on emerging treatments for high-risk HR+ HER2- EBC” as their most important unmet educational needs (Table S1 in Multimedia Appendix 20).

For the touchPANEL DISCUSSION, high levels of knowledge and competence were achieved for all 3 learning objectives. However, some unmet needs remained after participation in touchMDT, with 60% (30/50) and 36% (18/50) of the learners, respectively, being unable to demonstrate declarative knowledge (40/50; $P=.90$) for the level 5 questionnaire (Figure S3 in Multimedia Appendix 20).
of the current consensus on the use of patient decision aids to support SDM in breast cancer and being unable to demonstrate competence in supporting patients in understanding data and reaching a shared decision regarding neoadjuvant systemic therapy. In the level 5 questionnaire, ≥36% (18/50) of the learners were unable to provide the best clinical responses to the questions on reducing the patient burden (18/50, 36%), risk of recurrence (20/50, 40%), and chemotherapy treatment decisions (26/50, 52%).

Discussion

Principal Findings

This study evaluated the impact of 2 faculty-led, CME-accredited web-based learning activities on EBC. Participation in both activities resulted in high satisfaction scores and statistically significant improvements in self-reported knowledge, competence, and performance. Subgroup analyses indicated that the education was broadly beneficial, regardless of region, specialty, and experience. Patient record data analysis showed statistically significant differences in how the risk of recurrence was determined by responders and learners. The impact of the activities on therapeutic choice was limited, although this may be because of factors such as local guidelines, access to treatments, and individual patient characteristics. Approximately half of the learners (80/150, 53%) stated that they would change their practice in response to the educational material, further suggesting that the activities were valuable learning tools.

Participation in these web-based activities was considerably higher than could be achieved with traditional face-to-face programs and may also reflect the involvement of a multinational panel of recognized experts and the availability of translations. The latter is a major difference from traditional conference-based activities, as they are usually only available in 1 language, typically English.

Although many learners stated that they would change their practice, there remained a considerable number who were uncertain or who would not change their practice at the current time. The reasons for not changing practice were largely split between the requirement for more education and practical limitations. Although learners were not canvassed for specific details regarding practical limitations, we can speculate that they may relate to regional or national differences in institutional resources and structure or regulatory and reimbursement approvals of treatment. Indeed, documented barriers to change in clinical practice include institution-related issues such as flawed leadership and communication and insufficient organizational culture shift, and practical restrictions such as recently updated guidelines and access to emerging drugs [53]. In addition, a 2022 study on factors that influenced HCPs’ intent to put newly acquired learning into practice suggested that a lack of belief in one’s capabilities and the potential consequences of adopting new clinical behaviors can prevent HCPs from translating education into practice [54].

These data demonstrate the potential value of succinct web-based learning activities that are specifically designed to address knowledge gaps in complex and rapidly evolving medical fields. Although published data on outcomes following educational activities with similar methodologies remain limited, the results of this study are consistent with the results of a small number of previous studies in other disease areas [55-57]. Notably, the field of breast cancer is evolving rapidly, and it is essential for oncologists, particularly nonspecialists, to remain informed of the latest findings and recommendations [19-26]. Therefore, focused web-based learning activities may also be valuable for general oncologists to enable them to keep up-to-date with changes in specialist fields.

Strengths and Limitations

There were several strengths associated with this study:

1. The activities provided a holistic curriculum and unbiased education focused on clearly defined learning objectives.
2. The activities were translated into several languages and were available on a free-to-access website, which likely increased their global accessibility.
3. A broad target audience was successfully reached, highlighting the importance of the multichannel publicity strategy and the inclusion of faculty from often underrepresented geographies (Latin America and Asia-Pacific).
4. The multidisciplinary team approach and inclusion of a survivor of breast cancer ensured that the activities were directly applicable to the participants’ daily practice; the emotive element can also aid learning and retention [58].
5. The format used in the touchPANEL DISCUSSION allowed the latest evidence to be put into context for practicing physicians.
6. The development of the education in a short time frame allowed for emerging data to be communicated to the HCPs potentially ahead of publications and conventional educational formats.
7. A major strength was using an objective measure of performance to complement the more subjective self-reported data.

This study also has several limitations:

1. The conclusions that could be drawn from the main and subgroup analyses were speculative and limited because of the relatively small sample size.
2. All medical educational studies are affected by inevitable self-selection bias; that is, the HCPs who feel they lack knowledge on a specific topic are more likely to participate and, therefore, show a bigger impact of the education than might be the case for a wider audience.
3. This study only evaluated outcomes following 2 specific CME activities in EBC, and the conclusions may not be generalizable to other web-based learning formats.
4. An independent samples method was used for the levels 3 to 4 questionnaires and the self-reported level 5 questionnaire to avoid pre-exposure bias; however, this meant that the direct impact of education on each learner could not be determined. Therefore, we cannot rule out the possibility that other sources of education may have contributed to the reported outcomes.
Despite these limitations, this study offers the first comprehensive assessment of such activities using an accepted methodology.

**Identification of Needs for Further Education in High-Risk EBC**

Notably, only 30% (15/50) and 48% (24/50) of the touchMDT and touchPANEL DISCUSSION learners, respectively, answered all questions correctly in the levels 3 to 4 questionnaires. Similarly, only 20% (10/50) of the learners gave the best clinical response for all questions in the level 5 questionnaire. This may, in part, reflect a mixed audience but suggests that further education may be warranted to reinforce the content of these activities. To refine future educational activities, we identified several unmet needs during this study from the questions that were incorrectly answered after the activities. In addition, several self-reported educational gaps were identified, including implementing SDM in clinical practice, using genetic and biomarker testing to guide therapy choices, and understanding the latest data on emerging treatments.

**Future Directions**

Limitations of traditional CME approaches in affecting changes in physician performance have been previously reported [59]; however, the optimal format for continuing educational activities in both breast cancer and the wider medical field remains to be fully defined. This study and other similar studies show evidence that more engaging approaches have the potential to improve the effectiveness of CME [55-57,60,61]. Evaluation of the long-term impacts of CME on HCP performance, alongside assessment against Moore’s Levels 6 and 7 [40] to determine the effect of education on patient (level 6) and community (level 7) health will add further value to CME programs in the future. Activity formats that may be particularly relevant include experts sharing insights drawn from experience and their own clinical practice, conversational and panel discussion formats, and expert interviews supplemented by vignettes of consultation strategies. Furthermore, web-based delivery may offer scope for developing more individualized approaches. Web-based activities can also be made available as enduring materials, providing a resource designed for optimal HCP accessibility. Future studies will need to be designed to evaluate the comparative effectiveness of these different approaches to CME. In addition, in future studies, a larger sample size will increase the statistical power of the analyses.

**Conclusions**

Our study demonstrated that focused, free-to-access web-based CME activities on EBC were associated with improvements in HCP knowledge, competence, and self-reported performance. This study addressed the gaps in the provision of HCP-focused web-based IME programs that encompass recent advances in the high-risk EBC treatment landscape, the need for and approaches to effective SDM, and the gaps within the literature in terms of reporting outcomes from web-based CME activities. The identified unmet needs should be used to inform the design of future educational activities for this disease area. Further studies evaluating the long-term impact of education on HCP performance and on patient and community health will be valuable in defining the clinical impact of CME and the most effective channels for its delivery.

**Acknowledgments**

Medical writing support was provided by Steph Carter, and editorial support was provided by Cheryl Brant, both from touchIME, Cheshire, United Kingdom. The educational activities were jointly provided by the University of South Florida Health and touchIME. The authors would like to thank the touchIME audience outreach team (Joel Turner, Hannah Morton-Fishwick, and Louise Jarman) for the collection and analysis of the level 1 data. The authors would like to thank former employee of touchIME Sonia Mills for additional editorial support. Eli Lilly provided an independent medical education grant to fund the educational activity, medical writing, and editorial support but did not contribute directly to manuscript development, the decision to submit, or the submission process.

**Data Availability**

Abstract

Background: Despite the promising benefits of self-guided digital interventions for adolescents recovering from concussion, attrition rates for such interventions are high. Evidence suggests that adults can develop therapeutic alliance with self-guided digital interventions, which is in turn associated with intervention engagement. However, no research has examined whether adolescents develop therapeutic alliance with self-guided digital interventions and what factors are important to its development. Additionally, social presence—the extent to which digital encounters feel like they are occurring in person—may be another relevant factor to understanding the nature of the connection between adolescents and a self-guided digital intervention, though this has yet to be explored.

Objective: This qualitative study explored the extent to which adolescents recovering from concussion developed therapeutic alliance and social presence during their use of a self-guided digital mindfulness-based intervention. Additionally, this study aimed to determine factors important to adolescents’ development of therapeutic alliance and social presence with the intervention.

Methods: Adolescents aged between 12 and 17.99 years who sustained a concussion were recruited from 2 sites: a pediatric emergency department up to 48 hours after a concussion and a tertiary care clinic over 1 month following a concussion to capture adolescents who had both acute and persisting symptoms after concussion. Participants (N=10) completed a 4-week
mindfulness-based intervention delivered through a smartphone app. Within the app, participants listened to audio recordings of mindfulness guides (voice actors) narrating psychoeducation and mindfulness practices. At 4 weeks, participants completed questionnaires and a semistructured interview exploring their experience of therapeutic alliance and social presence with the mindfulness guides in the intervention.

**Results:** Themes identified within the qualitative results revealed that participants developed therapeutic alliance and social presence by “developing a genuine connection” with their mindfulness guides and “sensing real people.” Particularly important to the development of therapeutic alliance and social presence were the mindfulness guides’ “personal backgrounds and voices,” such that participants felt more connected to the guides by knowing information about them and through the guides’ calm tone of voice in audio recordings. Quantitative findings supported qualitative results; participants’ average score for therapeutic alliance was far above the scale midpoint, while the mixed results for social presence measures aligned with qualitative findings that participants felt that the mindfulness guides seemed real but not quite as real as an in-person connection would.

**Conclusions:** Our data suggest that adolescents can develop therapeutic alliance and social presence when using digital interventions with no direct human contact. Adolescents’ development of therapeutic alliance and social presence with self-guided digital interventions can be bolstered by increasing human-like qualities (eg, real voices) within interventions. Maximizing therapeutic alliance and social presence may be a promising way to reduce attrition in self-guided digital interventions while providing accessible treatment.

**Introduction**

Concussions are one of the most common injuries among adolescents, responsible for nearly 50,000 pediatric emergency department visits in Canada each year [1]. While most adolescents who sustain a concussion recover within 1 month, approximately 30% develop persistent postconcussion symptoms (PPCS) that continue longer than 1 month after their injury [2-4]. PPCS are associated with a variety of negative outcomes in adolescents, including reduced quality of life [5]. Despite the prevalence of PPCS and the detrimental effects that they have on the quality of life, few accessible evidence-based treatments exist for acute and persistent symptoms of concussion [6].

One promising intervention for those with acute or persisting concussion symptoms is mindfulness-based intervention (MBI) [7,8]. Most MBI research has focused on interventions delivered in-person. However, traditional in-person therapies are inaccessible for many due to financial barriers and sociodemographic disparities in access to health care. Moreover, a higher incidence of concussion in rural settings [9] means that many patients may have difficulty accessing specialized concussion care clinics, which are typically concentrated in urban settings [10]. Beyond geographical distance alone, specialized clinics often have long waitlists and operate solely during work and school hours, further complicating access to care. Additional barriers for adolescents to accessing treatment result from reliance on parental support for transport to and funding for in-person treatments. Finally, during infectious disease outbreaks such as the COVID-19 pandemic, in-person treatments may be severely limited or not available at all due to public health regulations. Taken together, in-person treatment for acute or persisting concussion symptoms in adolescents may not be readily accessible.

By contrast, self-guided digital interventions offer a potential solution to disparities in access to care for concussions in adolescents. A total of 95% of adolescents in Canada own a mobile digital device [11], highlighting that almost all youth in Canada have good access to digital care regardless of socioeconomic status. Digital interventions can be used anywhere and are a more affordable alternative to in-person treatments [12]. Some digital MBIs have also been shown to be effective in treating a range of conditions such as chronic pain, depression, anxiety, and stress [13,14], even when controlling for expectancy effects with active control comparison groups [15]. These conditions are also secondary consequences of concussion [2,16], which can further complicate the recovery process. Given digital MBIs’ effectiveness for treating these secondary consequences of concussion, they may have use for concussion recovery itself as well. However, attrition rates are high, and adherence suboptimal to digital interventions, with attrition rates as high as 52% in self-guided digital MBIs [12,17,18]. If patients do not adhere to treatment, they are less likely to benefit from it as intended. Thus, it is imperative to understand the factors underlying the large variation in self-guided MBI attrition rates.

One factor known to be essential for adherence and positive patient-reported outcomes following clinician-delivered behavioral interventions is the therapeutic alliance. Therapeutic alliance refers to the collaborative relationship and affective bond between a therapist and their patient [19,20]. The therapeutic alliance comprises 3 dimensions: the agreement on therapeutic goals, the agreement on therapeutic tasks, and the emotional bond between a therapist and their patient [21]. Particularly important to the conceptualization of therapeutic alliance is the collaborative nature of the relationship between a therapist and patient; this collaboration is integral to the success of psychotherapeutic treatments [19]. In face-to-face treatments, a strong therapeutic alliance is associated with positive treatment outcomes [20] and lower attrition [22]. Therapeutic alliance may also be relevant to patient adherence in the context of self-guided digital interventions. Self-guided
digital interventions lack the direct contact with human therapists found in in-person treatments. However, research suggests that individuals often respond to digital technology as if it was another person [23]. As such, researchers have explored whether individuals may anthropomorphize—or attribute human-like qualities to—digital interventions themselves and therefore develop therapeutic alliance with the interventions. Indeed, initial evidence from interventions for adults focused on addressing a range of health behaviors and outcomes [24-31] suggests that individuals can develop therapeutic alliance when using self-guided digital interventions by feeling a connection to the intervention or digital social actors within it. Intervention format varied across studies; interventions included audio recordings of human voice actors [30], human-like digital avatars [25], fully automated text-based “conversations” with an intervention [28,29], and intervention content delivered through multimedia modules [24,26,27,31,32], highlighting that therapeutic alliance can develop with self-guided digital interventions in a variety of contexts. Additionally, evidence from quantitative studies of self-guided digital interventions indicates that therapeutic alliance is positively associated with patient engagement [27,32] and therapeutic outcomes [31,32]. This suggests that similar to in-person treatments, feeling socially supported is important to adherence in self-guided digital contexts as well. However, none of these studies sampled adolescents. Adolescents’ experiences of therapeutic alliance with self-guided digital interventions may differ from those of adults, given that adolescents engage with digital technology in unique ways from adults [33,34]. As such, whether and how adolescents develop therapeutic alliance when using self-guided digital interventions remains to be explored.

The nature of therapeutic alliance in self-guided digital interventions may differ from that developed during face-to-face treatments, given the lack of real-time interaction with a human therapist. For example, previous research found that while participants felt emotionally connected to and anthropomorphized their self-guided digital intervention, at other times, they felt that the intervention was a thing rather than a real person [29,30]. Holter’s relational model of “making come-alive” and “keeping un-alive” [28,29] can provide theoretical context as to why therapeutic alliance in self-guided interventions may be unique from therapeutic alliance developed in in-person therapy. The model suggests that individuals engage in 2 types of relational processes when using self-guided digital interventions: “making come-alive,” or thinking of a digital intervention as a social actor with human-like qualities, and “keeping un-alive,” or viewing the intervention as an inanimate object without real emotions. Individuals’ dynamic interplay between “making come-alive” and “keeping un-alive” produces a therapeutic alliance that at once both involves emotional closeness to a digital intervention and emotional distance through recognition that the program is not a real human entity. Social presence may be a suitable construct for further understanding the therapeutic relationship and the extent to which individuals “make come-alive” or “keep un-alive” within self-guided digital interventions. Stemming from the communications and education literature, social presence is the extent to which a digital encounter feels like it is occurring in-person and has a sense of human connection to it [35-37]. Higher social presence is related to more trust in a web-based communicator [38] and greater relationship satisfaction, attachment, and perceived benefit of caregiving robots [39]. This suggests that social presence may approximate how much individuals experience a bond with social actors within a digital intervention. Social presence is also associated with satisfaction with, enjoyability of, and intention to use a mobile app or website [40-42]. Given the importance of these factors for adherence to treatment [43], attending to the social presence in self-guided digital intervention design may maximize adherence.

Social presence has not yet been examined in the context of a clinical intervention, and adolescents’ development of therapeutic alliance in the context of self-guided digital interventions is not well understood. This study sought to address these gaps in the literature and identify what factors may be relevant to adolescents’ development of therapeutic alliance and social presence in self-guided digital interventions. The aim of the present study was to determine if therapeutic alliance and social presence can be developed with audio-recorded mindfulness guides in a self-guided digital intervention among adolescents with acute or persisting concussion symptoms. Second, we aimed to determine what aspects of the intervention were important to the therapeutic alliance’s and social presence’s development.

Methods

Study Design
A qualitative exploratory design was used in the study. Since adolescents’ experiences of social presence and therapeutic alliance in clinical self-guided digital interventions are not yet well understood, we chose to use qualitative methods to explore the nuances of these experiences. Qualitative methods are well-suited for exploring participants’ experiences with digital applications, including what aspects of the application met their needs and what could improve their experience with the application. This was a planned secondary data analysis from an open-label pilot trial of a digital MBI for adolescents post concussion. The study was an open-label pilot trial because both the research team and participants knew that participants would be receiving a digital MBI. The pilot trial was a small-scale study and centered around the first stage of intervention development. The primary aim of the pilot trial was to gain information on the feasibility, credibility, and satisfaction of patient users with the digital MBI. The reporting of the study followed the Journal Article Reporting Standards for Qualitative Research (JARS-Qual) guideline [44].

Research Team and Reflexivity

Interviews were conducted by KMKO, OB, and RK. KMKO conducted interviews with the PPCS cohort (adolescents experiencing PPCS) and OB and RK with the acute cohort (adolescents recovering from acute concussion). KMKO has a bachelor’s degree in psychology and was a directed studies student at the University of British Columbia at the time of the interviews. They were trained and supervised while conducting the interviews by MC, a postdoctoral fellow at the University of British Columbia at the time of data collection. MC holds a
PhD in clinical psychology. OB has a bachelor’s degree in psychology and was a PhD candidate in experimental psychology at the time of the interviews. RK has a bachelor's degree in neuroscience and mental health and was a master’s candidate at the time of the interview. They were trained and supervised while conducting the interviews by AAL, a scientist at the Children’s Hospital of Eastern Ontario Research Institute. AAL holds a PhD in experimental psychology.

Interviewers were specifically trained to conduct interviews in a nondirective manner and were given feedback from supervisors during practice interviews. Given the self-guided nature of the intervention, the research team remained open to the possibility that participants would not develop a therapeutic alliance or social presence with their mindfulness guides. If participants did not develop a therapeutic alliance or social presence when using the app, the research team planned to change the intervention during subsequent stages of intervention development based on participant feedback in this study to better support future users. As such, interviewers explored whether or not participants experienced therapeutic alliance and social presence with curiosity and openness to participant feedback. The participants and interviewers were unknown to each other before the study. At the beginning of the interviews, participants were made aware that the interviewers were research assistants affiliated with the research team that conducted the study. They were told that the researcher was interested in learning about their experiences while using the mindfulness app.

Qualitative data were analyzed by KMKO and TO. At the time of data analysis, KMKO had approximately 2 years of experience conducting research about patient experiences with digital interventions. Based on their professional background and familiarity with the therapeutic alliance and social presence literature, KMKO brought certain assumptions to data analysis. For example, KMKO expected that participants would likely develop some degree of therapeutic alliance and social presence with the mindfulness guides given the human-like qualities present in audio recordings of the guides (eg, using real human voices). Additionally, because KMKO conducted interviews with the PPCS cohort, they had familiarity with the experiences of the PPCS cohort before beginning data analysis. Due to KMKO’s awareness of their preconceived expectations, they exercised caution during data analysis and engaged in constant peer debriefing with TO to ensure that findings were indeed based on participants’ accounts. TO is a Rehabilitation Sciences PhD student at the University of British Columbia who is trained in qualitative methodologies and has a background in psychology. TO was not versed in the therapeutic alliance, social presence, or digital intervention literature and did not conduct any of the interviews. As such, TO had limited assumptions about the findings going into data analysis.

Participants

The sample included 10 adolescents aged between 12 and 17.99 years who were either recovering from acute concussion (acute cohort) or were experiencing PPCS (PPCS cohort). The sample included both the acute cohort and the PPCS cohort because the digital MBI was designed both to help adolescents acutely recovering from concussion and those with persisting symptoms. As such, one of the primary aims of the pilot trial was to understand whether the digital intervention met the needs of both populations. In this study, we did not expect the acute cohort and PPCS cohort to differ with respect to their experiences of therapeutic alliance and social presence. Therefore, the 2 cohorts were collapsed into 1 overall sample for data analysis.

The acute and PPCS cohorts were recruited from 2 separate sites. Participants in the acute cohort (n=7) were recruited from the emergency department within 48 hours of sustaining a concussion. Participants in the PPCS cohort (n=3) were youth who sustained a concussion between 1 and 12 months before participation in the study and continued to experience concussion symptoms in at least 3 categories, as defined by the International Classification of Diseases, Tenth Revision criteria for PPCS [45]. They were recruited from a tertiary care concussion clinic. Additional eligibility criteria for the study included that participants were proficient in English and had access to a smartphone or tablet with an internet connection. Participants were excluded if they had a severe chronic neurological developmental delay resulting in communication difficulties, previous psychiatric hospitalization, previous diagnosis of a severe psychiatric disorder, such as schizophrenia (acute cohort only), or if participants were currently involved in other MBIs (PPCS cohort only). The acute and PPCS cohorts differed in size due to challenges associated with recruiting participants experiencing chronic concussion symptoms. In particular, given that recruitment was carried out during the COVID-19 pandemic, anecdotally, adolescents with PPCS faced greater barriers to care than usual, such as increased family stress and restricted access to the tertiary care concussion clinic where recruitment was carried out due to public health regulations.

Participants’ demographic information is summarized in Table 1. A total of 10 adolescents (mean age 15.93, SD 1.86 years) participated in our study. Overall, 7 participants identified as female, and 3 participants identified as male. Participants are described using pseudonyms to protect their identities.
Table 1. Participant demographic characteristics of adolescents recovering from concussion. Participant names presented in this table are pseudonyms to protect the participants’ anonymity.

**Ethical Considerations**

This study’s procedures were reviewed and granted ethics approval by the Behavioral Research Ethics Board at the University of British Columbia (H20-00120) and the Research Ethics Board at the Children’s Hospital of Eastern Ontario Research Institute (20/72X). Participants capable of consenting provided their informed consent, and parents also provided consent on their children’s behalf. Participants who were unable to consent provided assent instead, and their parents provided informed consent on their behalf. Participants were able to ask the research assistant questions that they had about the study procedures before providing their consent. With respect to study data, all participants were assigned a unique participant ID number that was linked to their data; as such, all study data were deidentified and stored in the secure platform, Research Electronic Data Capture (REDCap) [46,47]. Participants in the acute cohort were compensated for their participation with a CAD $10 (US $7.40) gift card and received a letter stating that they completed 10 hours of volunteer work, while those in the PPCS cohort were given a CAD $15 (US $11.11) gift card. Compensation differed between the 2 cohorts because they were recruited from separate sites, with data collection for each cohort led by teams at 2 different institutions. As such, the cohorts were compensated in accordance with the norms of the given institution leading each cohort’s data collection.

**Procedure**

Prospective participants for the acute cohort were approached in the emergency department. A member of the research team briefly described the study. Interested prospective participants were called by telephone by a research assistant for the eligibility screening and consent or assent process the next day.

Prospective participants for the PPCS cohort were approached at web-based psychoeducation sessions at a tertiary care concussion clinic. A research assistant provided prospective participants with information about the study and gave all participants a link to a survey on the secure platform, REDCap.

The survey allowed patients to provide consent to be contacted by the research team if they were interested in participating in the study. Interested prospective participants were called by telephone by a research assistant for the eligibility screening and consent or assent process.

Upon confirming participants’ eligibility and receiving informed consent, participants were emailed a unique link to register and download the intervention through REDCap. The intervention was developed by the research team and is hosted on the AmDTx app. The app was downloaded on participants’ smartphone or tablet, along with instructions for use. A research assistant also called participants by telephone to help instruct them through the app download process and answer any technical questions they had. Concurrently, participants were emailed links to complete baseline measures through REDCap. All data were collected and stored in a secure database on REDCap.

Participants then engaged with the intervention at their own pace over the course of 4 weeks, following which they received a link to complete outcome measures assessing social presence and therapeutic alliance on REDCap. After participants finished the outcome measures, they completed a 30–45–minute semistructured interview through Zoom (Zoom Video Communication) video call with a member of the research team. Audio of the interviews was recorded for transcription.

**Intervention**

During this pilot phase, participants completed 4 weeks of the 8-week treatment. The recordings of psychoeducation and mindfulness practices in the app were narrated by 2 professional mindfulness guides, Ruby and Brian. Ruby and Brian both have substantial mindfulness training and teaching experience. Moreover, Ruby (who led all the psychoeducation) had experience working with adolescents with concussion. The MBI was modeled based on mindfulness-based stress reduction [48] with meditations and content specifically designed for adolescents with concussion. The psychoeducation topics covered in the MBI involved pain acceptance, stress
management, and nonjudgement toward concussion symptoms. Mindfulness practices included mindful breathing, body scans, and mindful movement. Participants listened to the audio recordings of the mindfulness guides narrating the psychoeducation sessions and mindfulness exercises while using the app. Participants were encouraged to participate in the intervention for 15 minutes per day, for 4 days a week. The content was the same for all participants. See Multimedia Appendix 1 for images of the intervention content.

Throughout treatment, participants also received weekly SMS text messaging support from an “SMS text messaging coach,” who was a trained member of the research team. The SMS text messaging coach’s role was to support participants with any technical issues and problem-solve any barriers to engagement, such as having difficulty finding time to complete their mindfulness practices. SMS text messages sent to participants followed a highly templated SMS text messaging protocol. For a copy of the SMS text messaging protocol, see Multimedia Appendix 2.

Measures

Therapeutic Alliance

Therapeutic alliance was measured using the Working Alliance Inventory adapted for Guided Internet Interventions (WAI-I). The WAI-I is an adaptation of the Working Alliance Inventory–Short Form Revised designed for use with digital interventions. It is a self-reported, 12-item measure assessing participants’ alignment on tasks and goals with a digital intervention and their bond with their mindfulness guides during the intervention [49]. In this study, items were modified to reflect the MBI at hand (eg, “The goals of the app-based mindfulness program are in line with my goals”), including replacing the word “psychologist” in the original measure with “mindfulness guides” (eg, “The mindfulness guides who support me in the app-based program are really interested in my well-being”). Each item was assessed using a 5-point Likert scale ranging from 1 (never) to 5 (always). WAI-I total scores were calculated by summing items out of a possible 60 points. The WAI-I is a reliable measure with good construct, convergent, discriminant, and external validity [49].

Social Presence

In order to evaluate distinct aspects of social presence, 2 measures were used to capture how much digital encounters feel like they are occurring in-person and the ways in which digital encounters have human-like qualities. The first measure was adapted from Nowak and Biocca’s self-reported, 6-item Perceived Social Presence (PSP) scale [36]. The measure assessed how much participants felt like their mindfulness guides were real people and how much it felt like they were “with” their guides while using the app (ie, “To what extent was this as if you were in the same room with your mindfulness guide?”) [36]. We modified the wording of items to reflect that participants were reporting about their experiences with the mindfulness guides, as opposed to the wording “partner” used in the original measure. Items were measured on a Likert scale ranging from 1 (no extent) to 7 (full extent). The measure was scored by summing items out of a possible 42 points. The PSP scale has good internal consistency, convergent validity, and discriminant validity [36,50].

The second measure was the self-reported, 17-item Gunawardena Social Presence Indicators (SPI) scale [51] which assessed the human-like qualities of the audio-recorded mindfulness guides in the intervention. Participants were presented with 5-point bipolar items consisting of contrasting adjectives (ie, “personal-impersonal”) [51] and were instructed to circle the number that best reflected their perceptions of their mindfulness guides’ interpersonal qualities for each item. The measure was scored by summing items out of a possible 85 points. Higher scores reflected more negative perceptions of mindfulness guides. The SPI scale demonstrates good convergent validity [52,53].

Semistructured Interview

A semistructured, qualitative interview was developed by the research team to better understand participants’ experience with the app. Before the study’s commencement, the interview was pilot-tested with a 15-year-old nonparticipant to obtain feedback about understandability and was also reviewed by expert clinicians and researchers for content. The interview covered topics such as participants’ experience of therapeutic alliance and social presence with the mindfulness guides while using the app, as well as changes they would make to the app to improve those experiences (ie, “Can you tell me about your connection with your mindfulness guides? Is there anything you would have liked to change about your connection with your mindfulness guides?”). Other topics explored in the interview included participants’ satisfaction with the app content and ease of use and their satisfaction with support received from their SMS text messaging coaches, though data gathered from these questions is outside the scope of this study (for more information, see [54]). For a copy of the interview guide, see Multimedia Appendix 3.

Data Analysis

Quantitative Analysis

Participant demographics were summarized using descriptive and frequency statistics, as appropriate. Scores on the WAI-I and the PSP scale represent the degree to which participants developed therapeutic alliance and experienced social presence when using the app. As such, scores above the scales’ floor suggest participants developed some degree of therapeutic alliance and social presence. The scale midpoint was used for the SPI scale to indicate whether participants viewed their mindfulness guides more positively, neutrally, or negatively. We chose this method of examining our quantitative results because traditional quantitative data analysis was not appropriate for our data, given our small sample size. The quantitative results are used to supplement the main, qualitative results stemming from the semistructured interview by demonstrating the degree to which participants did or did not develop therapeutic alliance and social presence when using the intervention.
Qualitative Analysis

Qualitative interviews were audio recorded and transcribed verbatim using NVivo 12 software (Lumivero). Following transcription, interviews were analyzed by KMKO and TO using conventional content analysis [55]. The researchers first read each interview multiple times to familiarize themselves with the data. Transcripts were then open-coded, codes were grouped into meaningful clusters, and these clusters were used to form overarching categories that related to social presence and therapeutic alliance. Categories were discussed, refined, and finalized in consultation with MC. Content analysis allows for a mix of deductive and inductive analysis [56]. Deductive analysis was used to code transcripts based on understandings of social presence and therapeutic alliance gained from previous literature, while inductive analysis was used to explore how social presence and therapeutic alliance developed and were important in the novel context of self-guided digital interventions. Representative quotes were chosen to supplement the written findings.

Results

Quantitative Results

A total of 9 (90%) participants completed all quantitative measures. Descriptive values for the quantitative questionnaires are presented in Table 2. Participants’ mean therapeutic alliance score on the WAI-I was far above the WAI-I scale floor, suggesting that in general, our participants did develop therapeutic alliance with the mindfulness guides. The mean score for the bond subscale of the WAI-I was particularly high, suggesting that participants especially developed a sense of bonding with their guides, relative to their sense of agreement with guides on tasks or goals in the intervention.

Participants’ mean social presence score on the PSP scale was far above the scale floor, suggesting that participants developed a social presence with their mindfulness guides. Participants’ average score on the SPI scale was slightly above its scale midpoint—with lower scores indicating greater social presence. This result indicates that participants had fairly neutral impressions of their mindfulness guides’ interpersonal characteristics and the social presence experienced with the guides.

Qualitative Results

Developing a “Genuine Connection”

When asked about their mindfulness guides, many participants readily described developing an important emotional bond with their guides. For example, Gabrielle said that their connection with the guides “didn’t feel artificial... it felt like it was a genuine connection.” Olivier expressed, “I like that they kind of got what the listener was feeling... they had pretty good insight into various different things that... I was feeling.” Sophia also indicated feeling a sense of safety with their guides, stating, “I don’t know how to describe it. [The connection is] like feeling safe with someone.” This was echoed by Ella, who stated that listening to the guides “was just kind of like a comfortable situation, and you didn’t really feel like there was anything wrong.”

The participants further elaborated on how this connection with the guides helped them progress through the mindfulness program. Alex noted, “It just makes you feel like they were trying to help you the whole time. Like they want you to accomplish your goals... you can definitely tell that they’re like guiding you through.” Olivier highlighted that the guides also normalized challenges that arose during the program, citing 1 example where the guides said, “If you’re thinking that you’re bad at mindfulness, it’s normal for your thoughts to wander and all that. [The guides] just kind of understood.” This experience was shared with Kay, who said, “I would lose track of what I was doing, and they’re like, if you lose track like it’s okay, just come back to what we’re doing, think about this.” And I’m like,
“Okay, thank you.” The use of certain adjectives when describing the guides, such as “understanding” (Ella, Julian, and Olivier), “caring” (Ada and Olivier), “helpful” (Alex and Sophia), and “friendly” (Alex and Kay), further exemplified the participants’ feeling of being taken care of by the guides, which facilitated their progression through the program.

**Sensing “Real People”**

The use of human-like adjectives to describe the mindfulness guides indicates that participants viewed the guides as real people. Indeed, participants elaborated on the perceived realness of the guides. For example, Gabrielle mentioned that Ruby “felt like... a real person, like really genuine.” Ada also contrasted the realness of the guides to the absence of realness in automated computer voices; they said, “This is a person and like, again, not an automated voice message... it was at one point another person on the other side of the screen, it’s not like Siri talking back to you.” One participant even stated, “I would be surprised if [you] told me they weren’t real people” (Kay). Some participants additionally assigned a particular identity role to their guides, saying that their guides felt like “teachers” (Olivier), or “a parental figure” (Gabrielle); beyond feeling like real people, the mindfulness guides also felt like particular kinds of people for some participants.

In addition to feeling like their guides were real people, participants also noted that their experiences with the guides felt like real-life interactions. For example, Ada offered that it “felt like someone was talking in my ear when I was like, lying down and things... it definitely felt like there was like somebody there.” Alex highlighted that “it feels like they’re actually talking to you.” Gabrielle said “It felt like they were like right in front of me, too. So like, presence.” Multiple participants noted that the interactions with the guides felt private and personal, with both Alex and Ella describing that their mindfulness sessions with the guides felt like a “one-on-one talk” and Olivier saying that sessions “just felt like more like a conversation that they’re having with me, and it just felt like as though they’re talking to me rather than just talking and letting someone hear.”

As participants elaborated on their guides, however, tensions in their accounts were palpable when describing their ability to develop feelings of presence and connection despite the guides not actually being present. Ella offered, “This is probably going to sound weird, but [they were] understanding even though you couldn’t talk to them. It kind of felt like they were listening.” When asked to what extent it felt like the guides were present during the intervention, Sophia answered, “I feel like they’re with me, but not with me at the same time, because I know they’re not with me.” Ada noted that contextual factors were relevant to whether they felt like their guides were present or not, stating, “I don’t think I felt [like the guides were talking in my ear] when I was walking, because when I’m walking, I’m like, nine times out of ten having to pay attention to my areas around me... But when I was lying down, it was definitely there.” Kay also stated, “I wasn’t connected, but I wasn’t not connected.” The dissonance in the participants’ narrative accounts alluded to the sense that participants could not help but feel a connection with their guides but also did not want to deceive themselves into thinking that these connections were real—or at least, quite as real as an in-person connection would be. Indeed, Sophia said that “it felt like I was on a phone call with someone,” suggesting that while their interactions with guides did not necessarily feel like they were happening in-person, their relationship with the guides still felt more interactive than the completely noninteractive connection they actually had.

**Personal Backgrounds and Voices**

The mindfulness guides’ backgrounds and tone of voice emerged as factors key to the development of participants’ bond and sense of presence with the guides.

Getting to know the guides allowed the participants to “trust them” (Olivier) by getting the sense that the guides “knew what they were talking about” (Olivier). Some participants trusted Brian due to his personal experience with concussion. As Alex noted, Brian’s experience of having concussions in the past made him seem very “personable,” as participants felt that it was not “just someone like talking to you about it, it’s someone who’s actually experienced [concussion]” (Alex). Others trusted Ruby because of her professional and educational background, for example, because she mentioned her degree in psychology. Ada noted, “Obviously [Ruby] knew about concussions. And I respected that.” The sharing of the personal or professional backgrounds of the guides allowed participants to feel like the guides had “either been through this (ie, a concussion experience) or they’ve worked with other people who’ve been through this,” (Kay) which allowed them to trust the trajectory and goals of the intervention.

Most participants also expressed that the guides’ voices were important for helping them get to know the guides and making them feel real. Ada captured this sentiment by sharing, “I definitely think that you just kind of get to know a person by the way that they speak.” The most common descriptors of the guides’ voices were “calm” or “calming” (Sophia, Ella, Olivier, Marie-Claude, Sophia, Ada, and Kay) and “soothing” (Julian, Olivier, and Ada). When probed about why this tone of voice was important, participants shared that a calming voice allowed them to feel like they were being cared for, and this had important implications for the development of trust in the guides. For example, Sophia elaborated, “I think them being calm with their voices made me closer to feel like they’re actually here to help me instead of being rushed and stuff.” Thus, participants highlighted that factors that allowed them to get to know their mindfulness guides (ie, personal backgrounds and tone of voice) were beneficial for the development of their therapeutic alliance and sense of social presence, which in turn had benefits for their engagement with the app.

**Discussion**

**Overview**

This study aimed to determine whether and how therapeutic alliance and social presence could develop in the context of a self-guided digital MBI for adolescents post concussion. Qualitative and quantitative findings revealed that adolescents did develop therapeutic alliance through their use of the intervention, with qualitative findings providing insight into the use of the intervention.
factors important for its development; participants readily described experiencing a bond with the mindfulness guides in the intervention. While participants’ average score on the SPI scale was slightly above the scale midpoint, this may be explained by nuances uncovered with qualitative findings, which highlighted the tension in how the participants experienced social presence with their guides (eg, it felt real, but not quite as real as in-person connections). Indeed, this tension aligns with Holter’s relational model [29], suggesting that individuals’ connections with their mindfulness guides in this digital context involved both “making come-alive” and “keeping un-alive.” This, along with participants’ high average score on the PSP scale, suggests that participants did develop social presence during their use of the intervention. The guides’ personal backgrounds and the tone of their voices emerged as particularly important factors in the development of therapeutic alliance and social presence in a digital context. Additionally, participants stated that their connection with the guides and sense of the guides’ realness helped maintain their engagement with and interest in the intervention. Results extend previous findings that adults can develop therapeutic alliance with self-guided digital interventions [24-31] by demonstrating that adolescents also develop therapeutic alliance in self-guided digital contexts. Overall, findings highlighted the potential feasibility and use of maximizing therapeutic alliance and social presence to bolster participant engagement with self-guided digital interventions.

Since the onset of the COVID-19 pandemic, clinicians have identified the need for accessible, engaging, and effective digital interventions [57,58]. Digital interventions circumvent a number of accessibility barriers that limit adolescents’ access to concussion care. Therefore, they represent a promising treatment option for both acute and persistent concussion symptoms. However, numerous studies have noted particularly high attrition rates for self-guided digital interventions, which researchers have suggested are because of their limited human contact and lack of social support [12,17,18]. Our findings demonstrate that even in self-guided digital interventions, participants can develop therapeutic alliance and a sense of social presence in the program with audio recordings of mindfulness guides. This suggests that, despite the absence of a human for participants to directly interact with, adolescents can still experience being socially supported through self-guided interventions. Thus, it is important to consider ways of maximizing the human support participants feel during self-guided digital interventions to bolster participant engagement.

In self-guided contexts, factors that anthropomorphize digital guides—in other words, make them feel more human—emerged as particularly important to the development of therapeutic alliance and social presence among our sample. Participants highlighted that learning about the guides’ backgrounds (either their experiences of concussions or their background in psychology) helped them to feel connected to guides and trust that the content of the intervention would help them work toward their goals—both key aspects of therapeutic alliance. The guides’ voices also emerged as a salient factor that made guides feel like real people to participants, demonstrating that the “realness” of guides’ voices was key to the development of social presence. Indeed, when asked whether guides’ voices sounded like those of real people, every participant except 1 (Sophia) said yes. Thus, factors that increased participants’ ability to anthropomorphize their guides stood out as a potential mechanism important to the development of both therapeutic alliance and social presence in self-guided digital interventions. Our data align with quantitative findings that individuals experience greater social presence when digital conversational agents are characterized by higher levels of anthropomorphic cues (eg, human-like voices) [59]. Potentially, a higher level of anthropomorphic cues in self-guided digital interventions better enables individuals to “make come-alive” [28,29].

**Recommendations**

Our findings have several implications for researchers developing self-guided digital interventions for mental health concerns. Given that anthropomorphizing guides emerged as particularly important to the development of both therapeutic alliance and social presence in our sample, we recommend multiple strategies to increase the human-like qualities of audio-recorded guides in self-guided digital interventions. First, providing information about the guides’ personal connection with the topic of focus of the intervention (eg, concussion knowledge in this study) will promote how relatable and trustworthy guides seem to participants. Our findings suggest that guides either having personal experience with the topic of the intervention or having a background in psychology (and thus, seeming knowledgeable to participants about the intervention) may both be promising ways for mindfulness guides to encourage connection with participants and seem more real. Second, using real human actors to record audio for guides’ voices, as was done in our intervention, will seem more realistic and promote a greater bond with guides compared to using computerized voices. Guides may benefit from training in clinical microskills (eg, conveying warmth, genuineness, and empathy) [60] to ensure that their tone of voice is calming and soothing, both of which were identified by our participants as important attributes in guides’ voices for therapeutic alliance and social presence. Additionally, guides can facilitate participants’ sense of connection with them by anticipating and addressing potential challenges that may arise for participants. Participants in our sample reported that this helped them feel understood by the guides. Lastly, 1 key addition participants in our study suggested to increase their sense of connection with and humanness of guides was to show pictures of the guides’ faces. Indeed, previous research suggests that elements of a digital interface’s design—for example, providing identity cues like names and photos of the communicators within the interface—increase social presence [38,61]. Therefore, having an image of the voice actors who are the mindfulness guides may better allow participants to develop a narrative of who their guides are, impacting both the connection they feel to their guides (therapeutic alliance) and the extent to which the guides feel like real people (social presence).

**Limitations and Future Directions**

Given our small sample size, our findings are limited with respect to the quantitative analyses we were able to conduct. While it was a secondary focus of our study, having a larger sample may have allowed us to conduct formal quantitative
analyses as opposed to the descriptive analyses presented in this paper. Future research can use quantitative methods with a larger sample to formally explore the independent and interactive roles that therapeutic alliance and social presence play in the development of self-guided digital interventions.

Future research may also benefit from building upon this study’s results and previous research on adults [28] by exploring whether individual differences impact the extent to which adolescents experience therapeutic alliance and social presence during self-guided digital interventions and whether they benefit from experiencing them. Adolescents may differ in how much they desire and benefit from human support in digital interventions. For example, therapeutic alliance and social presence may be less important to the engagement of participants who are more introverted and potentially desire human support in therapeutic contexts to a lesser extent. Research can also examine whether sharing characteristics with guides (eg, race or ethnicity and gender) or not impacts how much participants develop therapeutic alliance and social presence with their guides. Potentially, participants may relate to guides who share their characteristics more, thus developing more of a connection with them.

Conclusions
This study found that adolescents with concussion develop therapeutic alliance and social presence in self-guided digital interventions and identified factors key to their development (eg, tone of voice and personal backgrounds). Our study is one of the first to examine the role of social presence in a clinical context with adolescents and demonstrate the use of social presence for encouraging adolescent engagement with self-guided digital interventions. Future research should focus on maximizing therapeutic alliance and social presence for digital intervention development by increasing the number of human-like qualities that guide the intervention process. This may address key concerns about self-guided digital interventions—high attrition rates and low participant engagement—to maximize their effectiveness. Doing so will allow for the development of digital interventions that are more accessible and less resource-intensive than in-person treatments, as well as being engaging for users. Ultimately, understanding the development of therapeutic alliance and social presence within self-guided digital interventions aids in the development of accessible and engaging digital treatments—one digital connection at a time.

Acknowledgments
We would like to thank the research teams and clinicians at the University of British Columbia, the GF Strong Rehabilitation Centre Adolescent Complex Concussion Clinic, and the Children’s Hospital of Eastern Ontario Research Institute for their dedication to the project. We thank Dr Jonathan Greenberg and Dr Ana-Maria Vranceanu for reviewing and providing feedback on the intervention.

Data Availability
The data analyzed during this study are not publicly available in order to protect the privacy and confidentiality of participants, given the small sample size. However, data are available from the corresponding author on reasonable request.

Conflicts of Interest
AAL reports being one of the authors of the mindfulness-based intervention for concussion protocol used in this study; she did not receive any financial benefit. AAL received funding from the Ontario Brain Institute Neurotech Early Research and Development (NERD) program for a separate component of the study. AAL has no other conflict of interest to disclose. MC reports being the CEO and chief scientist of Mobio Interactive and a major shareholder, owning approximately 23% of the company at the time of manuscript submission. RZ reports being an investigator on competitively funded research grants from the Canadian Institutes of Health Research, the Ontario Neurotrauma Foundation, the Physician Services Incorporated Foundation, the Children’s Hospital of Eastern Ontario (CHEO) Foundation, the Ontario Brain Institute, the Ontario SPOR Support Unit, the Ontario Ministry of Health, the Public Health Agency of Canada, Health Canada, and the National Football League Scientific Advisory Board. RZ is a clinical research chair in pediatric concussion from the University of Ottawa. RZ is the scientific director and minority shareholder of 360 Concussion Care (a learning health system and network of interdisciplinary concussion clinics in Ontario). VS receives royalties for the sales of a concussion book (Commotions Cérébrales) by Flammarion Québec. NDS has received research operating funds from multiple granting agencies (Canada Foundation for Innovation, Canadian Institutes of Health Research, Mitacs, Ontario Brain Institute, US Department of Defense, WorkSafeBC, VGH+UBC Hospital Foundation) for research related to traumatic brain injury diagnosis, prognosis, and treatment. He has received speaker fees for providing continuing medical education on these topics. He serves as chair of the American Congress of Rehabilitation Medicine’s Brain Injury Special Interest Group Task Force on Mild TBI (unpaid). He has served as an expert panel member for the Living Concussion Guidelines and as an external reviewer for other clinical practice guidelines on concussion/trumatic brain injury (unpaid). He has provided expert testimony and medical-legal consulting in the past 5 years (<10% of total income). The remaining authors have no conflicts of interest to report.

**Low-Fidelity Prototype of a Sensor-Dependent Interaction Platform: Formative Evaluation With Informal Caregivers of Older Adults With Cognitive Impairment**

Nikita Sharma¹,², PhD; Karen Grotenhuijs¹, MSc; J E W C van Gemert-Pijnen¹, PhD; Harri Oinas-Kukkonen², PhD; L M A Braakman-Jansen¹, PhD

**Abstract**

**Background:** Unobtrusive sensing technologies developed for monitoring deviant behaviors in older adult care require integration with an interaction platform to facilitate the flow of information between older adults and their caregivers. However, the continuous monitoring capabilities generate a considerable amount of data that must be interpreted, filtered, and personalized before being communicated to the informal caregivers based on their specific care needs and requirements.

**Objective:** For the effective implementation of unobtrusive sensing solutions (USSs) in the care of older adults with cognitive impairment, we aimed to explore the expectations and preconditions regarding the implementation of USSs from the perspective of informal caregivers. Subsequently, we designed and evaluated a low-fidelity prototype of an interaction platform for its conceptual workflow and usability, incorporating persuasive system design features based on the needs and requirements of informal caregivers.

**Methods:** Overall, 6 informal caregivers of older adults with cognitive impairment living alone participated in this qualitative interview study. We explored the expectation and preconditions regarding implementation through open-ended questions and conducted a formative evaluation (usability study with a think-aloud approach) to evaluate the conceptual workflow and used persuasive system design features in the interaction platform. Overall, a combination of inductive and thematic analyses was used to analyze the interviews.

**Results:** The results of this study present both positive and negative outcome expectations regarding the implementation of USSs, highlighting benefits such as objective decision-making and peace of mind and concerns about information overload and the potential substitution of human contact. Strategic information communication agreements between informal and formal caregivers were deemed crucial for the successful implementation of USSs in care. Overall, informal caregivers had a positive experience with the low-fidelity prototype of the interaction platform, particularly valuing the personalization feature.

**Conclusions:** In conclusion, to achieve successful implementation, a holistic design approach is necessary, and equal consideration should be given to the personalization-privacy paradox to balance users' needs and privacy.

Introduction

Background

The increase in the older adult population (≥65 years) imposes significant challenges on the organization and functioning of the current health care infrastructure worldwide [1]. It demands the active involvement of different stakeholders including informal caregivers, formal caregivers, general practitioners, technology developers, policy makers, and government organizations to maintain continuous care [2]. Primarily, informal caregivers are perceived as responsible for organizing and ensuring on-time care for older adults, which impacts their physical, financial, emotional, and social well-being [3,4]. Moreover, with the emergence of cognitive impairment or comorbidities, the care process becomes more complex and challenging for informal caregivers [5].

To support informal caregivers in delivering on-time care, sensor-based solutions, specifically those that are unobtrusive or device free (ie, do not demand direct involvement or attention from older adults), are being developed [6]. Studies have shown that unobtrusive sensing solutions (USSs) are in demand and appear to be useful among informal caregivers of older adults with cognitive impairment due to their 24/7 monitoring capabilities, which provide real-time insights into the health of care recipients [2,6]. A USS comprises 3 main units: a sensing unit responsible for collecting data from the care recipient, a computing unit responsible for analyzing the obtained sensing data, and a communicating unit that communicates the output of the computing unit to the informal caregivers to enable monitoring at a distance [7].

Over the past decade, there have been notable advancements and successful endeavors to facilitate the development of unobtrusive and ubiquitous sensing technology [8]. For example, Wi-Fi channel state information (CSI; as a sensing unit) can be used for monitoring physical activities (falls, sitting, hand gestures, etc), physiological activities (heart rate and breathing rate), and behaviors (sleeping patterns, personal hygiene, etc) [9-11]. Significant growth in the computing unit through the use of advanced machine learning methods (such as deep neural networks, generative adversarial networks, etc) to improve privacy, reliability (minimizing false alarms), and computing time is also evident [12,13]. However, efforts from the IT domain (communication unit), particularly in the direction of developing and designing interaction platforms adhering to the information communication (IC) needs and requirements of informal caregivers (or other stakeholders), are limited [14].

Designing an interaction platform according to the preferences of informal caregivers can assist in prioritizing and optimizing their care plans, thereby reducing the care (information) load [7].

In our previous multimethod study encompassing a survey and interviews with informal caregivers of older adults with cognitive impairment, diverse needs and requirements for the following 4 distinct care scenarios were explored: falls, nocturnal unrest, agitation, and normal daily life [7]. The findings indicated varying information needs regarding the mode, content, timing, and stakeholders involved, contingent upon the care scenario. In addition, these needs were observed to be influenced by the personal circumstances of caregivers and care recipients and the progression of illness in care recipients. Furthermore, to facilitate the designing of an interaction platform (ie, this study) persuasive system design (PSD) features, namely reduction, tailoring, personalization, reminders, suggestions, trustworthiness, and social learning, were identified for the involved care scenarios. One of the limitations that we observed was the lack of proper understanding of USSs among informal caregivers. Due to the technical novelty of the solution, informal caregivers perceived it as a black box, potentially introducing biases in their responses regarding its usefulness and expectations.

Objective

Building upon the findings from our previous study [7], the objectives of this study were two-fold: (1) to explore the expectations (positive and negative) and preconditions regarding implementing USSs in the care of older adults with cognitive impairment from the perspective of informal caregivers after showing them a video prototype of the solution and (2) to design and evaluate a clickable, low-fidelity (lo-fi) prototype of a sensor-dependent interaction platform, incorporating the identified PSD features regarding fall, agitation, and normal daily life care scenarios with informal caregivers.

Methods

Ethical Considerations

The Ethics Committee of the Behavioral, Management, and Social Sciences department at the University of Twente formally approved the execution of this study (request number 230141). Before engaging in the surveys and interviews, participants received both oral and written description elucidating the study’s objectives, methodologies, data collection procedures, storage protocols, and the intended use of the collected data. Subsequently, each participant provided a signed consent form. The participants were also free to withdraw from the study at any stage if they felt uncomfortable.

Finally, the participants were offered a small honorarium as a token of appreciation for their valuable time and contributions.

Study Design: Participatory Development

The study followed the Center for eHealth Research and Disease Management (CeHRes) road map to create a sensor-dependent interaction platform that can communicate the information obtained by USSs to informal caregivers of older adults with cognitive impairment [15]. The CeHRes road map fosters progress toward context-aware sensing and computing by offering early feedback regarding users’ needs and requirements to the designers and developers [15]. For instance, if informal caregivers prefer insights into emergencies only, the algorithm can be trained and optimized accordingly to provide relevant data, avoiding computing overload for the system and information overload for the caregivers. The framework encompasses 5 distinct but intertwined phases: contextual inquiry, value specification, design, operationalization, and summative evaluation (Figure 1 [7]). The description of these
phases, along with their relevance to this study, is provided in **Textbox 1**.

**Figure 1.** The Center for eHealth Research and Disease Management framework. IC: information communication; lo-fi: low-fidelity; USS: unobtrusive sensing solution. *The study by Sharma et al [7].

Participants

Participants were recruited from an already existing pool of candidates who had previously been involved in a similar study [7]. While previous experience with digital care technology was not a prerequisite for informal caregivers, all of them were users of the Caren Platform (a digital care platform; Caren [NEDAP]), implying that they had default experience with digital care technology [21]. Informal caregivers were approached for participation in this study via email. The participants received an invitation, along with an information letter describing the study’s purposes, procedures, and the researcher’s contact information. When an informal caregiver expressed willingness to participate, they were screened based on the following inclusion criteria: (1) providing unpaid care to a person with cognitive impairment who is a relative, friend, or someone else within their personal circle; (2) the person with cognitive impairment is aged ≥65 years; and (3) the person with cognitive impairment lives alone at home. Subsequently, an appointment for the evaluation session was scheduled with the researcher.

Materials: Designing the Lo-Fi Prototype of the Interaction Platform

Video Prototype

Given the novelty of USSs, a lack of awareness among informal caregivers about their working and implementation was observed. Therefore, to educate informal caregivers, a video prototype demonstrating the working, system architecture, and benefits of USSs in the care of older adults with cognitive impairment was created. While the video was largely inspired by previous studies that used Wi-Fi CSI as a technology in USSs for recognizing older adult activities [11], some brainstorming sessions with the research team (composed of eHealth researchers, experts, technology developers, and designers) also occurred to align it with the use case of care of older adults with cognitive impairment.

Overall, the video depicted 3 units of USSs, namely, sensing, computing, and communicating units. The “sensing unit” of the solution showed the working (how) and the manner of data collection (what) through Wi-Fi CSI (as an unobtrusive sensing technology). The “computing unit” of the solution presented the use of artificial intelligence (AI) algorithms for analyzing the collected data. In the “communicating unit” of the solution, the channel for communicating the computed information to the caregivers was presented. The video provides examples of 3 different care scenarios, namely fall incident, agitated behavior, nocturnal unrest, and normal daily life (drinking activity).

To make the video footage realistic, it was recorded in the eHealth house at the University of Twente, the Netherlands [22]. The video had a Dutch voice-over with English subtitles, given that informal caregivers were comfortable with Dutch. The video has a total duration of 3.5 minutes. It was presented to the participants at the start of the interview sessions to ensure that they had the necessary information to answer the questions posed in the interview, thereby promoting more informed responses. Figure 2 shows a simplified overview of the system architecture (as conveyed in the video) of the intended USSs.

Figure 2. Simplified overview of the system architecture of unobtrusive sensing solutions.

Lo-Fi Prototype

Overview

We designed the lo-fi prototype of the interaction platform using Figma software [22]. As the Wi-Fi CSI system is in the early development phase (Technology Readiness Level 2/4) [7, 23], a lo-fi prototype was chosen to gain initial insights from informal caregivers about the communication unit, showcasing the conceptual workflow and main functionalities of the interaction platform. Note that this interaction platform does not intend to change the behavior of the informal caregivers but requires persuasion to form (ie, F outcome) or alter (ie, A outcome) the behavior of informal caregivers for complying (ie, C change) with the information communicated (outcome: F and A; change: C) [24].

The findings from previous studies [2, 7, 25] were used to design the lo-fi prototype of the interaction platform. The studies by Wrede et al [2, 25] demonstrate the value of USSs in continuous and objective monitoring, leading to timely interventions. In particular, informal caregivers found USSs to be helpful in clearly classifying the care scenarios as urgent, nonurgent, and future risk. Further exploration in a multimethod study by Sharma et al [7] (comprising a survey [n=464] and interviews [n=10]) revealed divergent IC needs in different care scenarios (fall, nocturnal unrest, agitation, and normal daily), including mode, content, timing, intended users, feedback to the system for self-learning, and dialogue support. Furthermore, the study also identified 7 PSD features: 3 from primary task support (reduction, tailoring, and personalization), 2 from dialogue support (reminders and suggestions), 1 from system credibility (trustworthiness), and 1 from social support (social learning) for designing the interaction platform. On the basis of these findings, the conceptual workflow of the interaction platform and user interfaces for 3 care scenarios, namely, fall incident, agitated behavior, and normal daily life activities were designed. In addition to these features, a system verifiability feature was added to assess its necessity or impact on the interaction platform [26]. Table 1 presents the used PSD features, their interpreted meaning, and their application in the lo-fi prototype. The following sections provide details regarding the design of the conceptual workflow and user interfaces.

IC: information communication.
Design of the Conceptual Workflow

The conceptual workflow of the interaction platform is illustrated in Figure 3. This workflow reflects the logical flow of the interaction platform when personalizing the IC options. It starts from the log-in page, followed by choosing the preferred activities for monitoring; adjusting the communication preferences for the chosen activities; and the home screen, where multiple functionalities of the interaction platform can be checked or adjusted. Note that the feature of choosing the activities to be monitored and adjusting the preference is attributed to the personalization feature of the PSD model.

Figure 3. Conceptual workflow of the interaction platform.

Design of the User Interfaces

User interfaces for fall, agitation, normal daily life, and home screen were designed. As falling is an emergency scenario, informal caregivers expect to receive a direct call (reduction feature), and if they do not respond within 5 minutes, they expect a reminder notification (reminder feature) in their preferred content style (raw, interpreted, or suggestions). Furthermore, the details of the fall incident such as time, location, system’s confidence in prediction, and current state of the care recipient were made accessible to the informal caregivers. In addition, to support informal caregivers, options to obtain suggestions from the system regarding what to do and when to act (suggestion feature) and to directly communicate with formal caregivers were also provided. Finally, as informal caregivers desire a trustable system (with minimum false alarms), an option to provide feedback to the system about its predictions to enable self-learning was also added (trustworthiness feature). Figure 4 illustrates the interfaces for the fall scenario.
On the other hand, as agitation is an acute scenario, informal caregivers expect the system to monitor it for a few weeks and share a report tailored to the concerned stakeholders, that is, themselves or formal caregivers \((\text{tailoring feature})\). Interfaces depicting notification (in the preferred content style), details about agitation behavior (duration, system’s confidence in prediction, and other observations), suggestions from the system \((\text{suggestion feature})\), the possibility to share the report with formal caregivers, and an option to provide feedback to the system for its predictions were designed \((\text{trustworthiness feature})\). Figure 5 illustrates the interfaces for the agitation scenario. The user interface for normal daily life (Figure 3) presented multiple self-care activities (eating, drinking, showering, etc). The informal caregivers can adjust their preferences for the content, frequency, and depth of information they want to receive regarding the selected activity.

In general, informal caregivers demand a centralized care approach, that is, the possibility to access all the relevant care information such as general information, medical information, and communications with other stakeholders in 1 platform [7]. Thus, consistent with this requirement, the home screen contained the following functionalities: observing the present and past situation of the care recipient \((\text{reduction})\), obtaining more detailed information or reports about daily activities, general and medical information about the care recipient \((\text{verifiability})\), an overview of the involved formal and informal caregivers, communication options with the involved formal caregivers, and system credibility (Figure 6). In addition, an option to read the care experiences shared by other caregivers as a part of the social learning feature of the PSD model was added. Finally, options for app settings (adjusting preferences) and information about the organization or team developing the app to show system credibility \((\text{real-world feel})\) were also added.
Figure 5. Interfaces for agitation scenario.
Procedure

The semistructured interviews were conducted via Microsoft Teams with 33% (2/6) of the informal caregivers and in person with 67% (4/6) of the caregivers, based on their preference. The interview guide (Multimedia Appendix 1) was used and consisted of the following sections: (1) introduction (goals, procedures, and informed consent), (2) background information obtained from the participant, (3) video prototype to explore the expectations (positive and negative) and preconditions, (4) formative evaluation of user interfaces, and (5) closing remarks. Upon watching the video, participants were asked whether they had any further questions regarding the systems, and the questions were clarified. This video and explanation were important because, due to the novelty of USSs, informal caregivers are not very aware of this concept or type of sensing solution. Then, their expectations and preconditions regarding implementation were discussed in depth.
Thereafter, a formative evaluation (using a task-based and think-aloud approach) of the designed interaction platform was conducted using 5 tasks (Table 2). In task 1, the informal caregivers were asked to choose the emergency or acute situations of their care recipient that they want to monitor, followed by adjusting the IC preferences for the chosen activities. Similarly, in task 2, the informal caregivers were asked to choose and adjust their IC preferences for the daily life (self-care) activities of the care recipient that they want to monitor in the long term. Here, the use of PSD feature personalization was evaluated. Furthermore, for tasks 3 and 4, a possible sequence of actions in the fall and agitation scenarios was evaluated. Specifically, the ability of the platform to immediately call or notify informal caregivers (reduction), send reminder notifications in case they do not respond (reminder), provide suggestions to support the informal caregivers (suggestion), and maintain a transparent link between the system and caregiver by providing the prediction percentage (trustworthiness) were assessed.

Table 2. Tasks used to evaluate the conceptual workflow and persuasive system design features of the interaction platform.

<table>

aIC: information communication.

Finally, in task 5, the informal caregivers were asked to explore the home screen to check whether it satisfies their requirement of a centralized care platform and present evidence to validate the provided information (verifiability). They were encouraged to identify, suggest, and reason the functionalities that help them in improving the caregiving process. The sessions were conducted in Dutch by a native Dutch speaker and were audio recorded to facilitate analysis. The duration of each session was approximately 60 minutes. On the basis of the feedback obtained from the first 4 sessions, slight improvements in the design were made and further evaluated in the last 2 sessions.

Data Analysis

The recordings were transcribed verbatim by using the description software, Amberscript. Qualitative analysis was performed by using Atlas.ti [27]. A thematic analysis was performed, based on the six steps by Braun and Clarke [28]: (1) familiarizing with the data, (2) generating initial codes, (3) searching for themes, (4) reviewing themes, (5) defining and naming themes, and (6) producing the report. The transcripts were coded using a mixed inductive and deductive approach. An inductive approach was used for exploring the expectations and preconditions, whereas an inductive-deductive approach was used for analyzing the experiences with PSD features. All the transcripts were read by both researchers, NS and KG, in English and Dutch, respectively. Overall, the joint probability of agreement was 75%, followed by an in-depth discussion until consensus was reached regarding all the defined themes.

Results

This section is divided into 2 parts: first, the results related to the expectations and preconditions regarding implementation are presented, and second, the results corresponding to the formative evaluation of the lo-fi prototype including PSD features are presented.

Demographics

A total of 6 informal caregivers (mean age 58.7, SD 2.87 years) of older adults (mean age 85.7, SD 4.18 years) living alone participated in the study. Among the 6 participants, 4 (67%) were women and 2 (33%) were men. All informal caregivers (6/6, 100%) were children of the care recipient and were the primary informal caregiver. All care recipients (6/6, 100%) were living alone. Half of the care recipients (3/6, 50%) had Alzheimer disease, and the other half (3/6, 50%) had cognitive impairment due to other causes or no official dementia diagnosis. All informal caregivers (6/6, 100%) have used
technology previously in the care provision, differing from using communication platforms (Caren platform) or medication dispensers to personal alarm and monitoring systems. They have been providing care for at least the past 2 years, and their care hours ranged from 1.5 to 15 hours. Table 3 provides an overview of the characteristics of the interview participants.

Expectations and Preconditions

The expectations and preconditions regarding implementation are presented as three broad themes: (1) positive outcome expectations, (2) negative outcome expectations, and (3) preconditions for implementation.

Positive Outcome Expectations

Objective Decision-Making

The informal caregivers indicated that USSs could contribute toward making objective decisions regarding the care of their loved ones. Instead of relying solely on observations of both informal and formal caregivers or on what the care recipient mentions themselves, the system can provide the involved informal and professional caregivers with more objective and in-depth monitoring information. According to informal caregivers, this information not only enables prompt diagnosis of underlying health conditions but also facilitates objective communication among the professional caregivers, care recipient, and themselves. This fosters a shared understanding of the care situation, consensus about the provision of care, and better coordination regarding the response to the (emergency) situations:

- **Participant 2**
  
  It provides the facts, so what she herself isn’t mentioning yet, but what is actually already there, that could be beneficial to support her, to make better choices and to better understand what is going on.

- **Participant 3**
  
  It provides monitoring information, for example, we are now at a stalemate with my father; he should have more help and we need to request that, but he doesn’t want that because he believes he can still manage. It [the monitoring data] can prove that we are right, but it can also prove if he is right. If he is right, then we’ll have some peace for a while, so it indicates such things.

- **Participant 4**
  
  Safer Environments for Independent Living

Informal caregivers expected USSs to contribute to the feeling of safety of their loved one; they believe that the system will notice when a safety risk occurs. Moreover, it was mentioned that the system could give insight into whether it is safe for older adults to live independently at home. All informal caregivers (6/6, 100%) mentioned being interested in receiving information about safety matters, for instance, if the door has been opened or if the gas is on:

- **Participant 1**
  
  She [mother of informal caregiver] will feel safer. Her desire is to continue living at home for as long as possible, but she has concerns about it, like: “yes, I am alone and if something happens to me, well, what should I do then?” And this is a system that detects it [a fall] without her having to do anything. So, if she feels safer, she will also feel calmer, which has an impact on her dementia symptoms.

Providing Peace of Mind to Informal Caregivers

Some informal caregivers indicated that they expect USSs to contribute to their peace of mind and probably to the peace of mind of their care recipient also. They find it reassuring that the system acts as a safety net and alerts them or the care professionals when there is an emergency situation. Furthermore, they indicated that the system could confirm the well-being of their loved one, whereas without such a system, there would be uncertainty and doubt about the situation, and they might be unnecessarily worried about their loved one:

- **Participant 2**
  
  It brings peace of mind. It provides, like, you can’t fully rely on the technology, but knowing that you have an additional safety net, that you are a bit more at ease, and also for the person involved it helps.

- **Participant 3**
  
  I only see reassurance, you know, you receive, you know that everything is fine, but you receive a confirmation that it is indeed going well.

Stimulating Meaningful Conversations

A few informal caregivers indicated that if USSs can collect care-related information, they might be able to spend more meaningful time (personal conversations) with their loved ones. This is because the care component is important and requires a lot of attention, and they overlook the personal or relational aspect, thus impacting their relationship with the care recipient:

- **Participant 1**
  
  Because it’s not constantly asking “how are you doing,” there is an additional aspect behind it. Yes,
you still have to keep asking, but it’s more about showing interest in the person rather than focusing solely on the care component. So, I think there’s more room for the human aspect rather than just the caregiving aspect. [Participant 3]

It can help in relational aspect, I would really appreciate that, because I miss the conversations with my mother; there is always that caregiving component that comes in-between. [Participant 3]

Negative Outcome Expectations

Information Overload

A few informal caregivers also expressed concerns about the possibility of information overload from USSs. They mentioned that the continuous availability of information about the care recipient, enabled by USSs, might lead them to constantly check and monitor every aspect of their loved one’s situation. In addition, informal caregivers highlighted that receiving notifications might trigger panic and worry, particularly if they are unable to respond immediately, even after being aware of it:

At some point, you want to know everything. Especially if you’re worried, then it’s nice to be able to see a lot, yet you can’t do anything with it. [Participant 2]

If I look at myself... I think if I receive such a notification [emergency] then the first reaction is panic, okay that is a strong word, but as I already said: I work in healthcare myself. I see the most terrible things, that doesn't affect me. But when it concerns your own parents, it immediately causes stress. [Participant 4]

Feeling Obliged to Undertake Action

The informal caregivers also mentioned that once they are aware of their loved one’s situation, they cannot ignore the situation and they feel obliged to undertake actions according to the information provided by USSs. However, sometimes, it is simply not possible to take action immediately due to physical distance or other factors. However, some participants indicated not having the urge to immediately act upon the data or being able to filter important information; they suggested it might be problematic for other informal caregivers:

If I see worrying things, then I literally and figuratively have to go there, if I see it, then I have to go there: normally, you wouldn’t, or quickly call, but now you see it, so you feel compelled to go there... [Participant 4]

So for my situation that [information overload] won’t happen so quickly. For my sister, it might be a bigger struggle, as she is less able to distance herself from the situation as it is. I think when she receives detailed information from the system, she may feel the need to intervene, whereas I have less trouble with that. [Participant 6]

Substitution of Human Contact

Although not all informal caregivers expect the system to substitute the human contact of their care recipient, some of them perceived this as a risk from using USSs. They suggested that if USSs are capable of providing comprehensive insights into the health of the care recipient, it could potentially result in reduced or no visits from professional care staff. This is concerning, considering the already existing scarcity of professional caregivers:

It’s simply impossible to find enough staff, and apparently the situation is even worse in home care. So, if you’re going to develop technology to do more, with fewer people, to be more efficient, it means there will be less human contact, and that means less home care visits for my father, while on the other hand, he’s already experiencing so much loneliness. [Participant 4]

I find it a risk that people retrieve all their information from this system and they might start thinking they no longer need the contact moment, while it is actually so important. [Participant 1]

Preconditions for Implementation

Shared Decision-Making

According to informal caregivers, it is necessary to discuss and reach an agreement together with professional caregivers about IC, including which activities should be monitored, what communication strategy should be used, who should receive and respond to the information, and what should be the content of the information. This would be necessary to prevent unclarities, unfulfilled expectations, and unaddressed notifications or follow-ups, as it could otherwise potentially hinder the effectiveness of care provision:

You can benefit a lot from it [USSs] together and I think if you don’t do this together, everyone can get a lot of trouble from it. That’s not what you want. [Participant 1]

I would never fill it [the settings of the system] in alone, I would really do that together with other professional caregivers or informal caregivers. I think you should all agree with each other about how you fill this in and what you expect and so on...this would be a nice moment to put our heads together and make a choice together. [Participant 1]

It could be that you alert three parties simultaneously and one thinks, “hold on, I won’t do anything because the other two will take care of it,” and everyone assumes that of themselves. And then, nobody responds... [Participant 6]

USS as a Supportive Tool

The informal caregivers indicated that it is important to perceive USSs as a supportive tool rather than a tool to replace the human component in care:

They [persons with cognitive impairment] actually require people around them to be present. It’s better for them, otherwise, they will completely withdraw.
Human interaction, maintaining contact with others is extremely important. So that aspect should be preserved. The system should not result in less human contact, as that would further distance individuals with dementia. [Participant 1]

However, they expected the solution to provide concrete data to facilitate the conversations about and interpretation of the situation together with formal caregivers:

Cognitive decline happens slowly and there are some things that we [informal caregivers] can’t point out. Now it [wandering in the house] is starting to happen more and more. Such raw data can be important for such situations, especially if you have to go to the neurologist or something, then you can do a lot of things. [Participant 4]

It was also mentioned that care decisions should not solely be based on the information provided by the system. Instead, it is imperative to engage in discussions with professional caregivers before making definitive decisions:

So it’s a support system and it shouldn’t take over the analysis of the situation. It may give the numbers, but if on that basis it is said of oh, she [care recipient] only needs so much more care time, or this is no longer necessary since she can still handle this task herself. Yes, then we’re going the wrong way. [Participant 2]

Informal Caregivers’ Experiences With PSD Features and the User Interface Prototype

Overview

In general, the informal caregivers indicated being quite positive about the user interface prototype. Most of the screens were reported to be clear and understandable. However, there were also some negative experiences and suggestions for improvement. Overall, the experiences of informal caregivers are presented as three main themes: (1) positive experiences, (2) mixed experiences, and (3) suggestions for improvement.

Positive Experiences

Personalization: Options to Customize Settings

All informal caregivers (6/6, 100%) had a positive experience with the flexibility (not a one-time setup) of adjusting the interaction platform settings to accommodate their dynamic care needs, thereby improving the quality of life for care recipients. Specifically, they appreciated being able to personalize the settings based on their individual circumstances, the evolving condition of their care recipient, and the monitoring scenario at hand (such as emergencies or self-care activities):

I think this is a good thing. The more you can adjust it to fit your and well in this case my father’s needs and lifestyle, the quality of care can be improved. [Participant 4]

We’ll do everything first [make all the settings], and then I’ll figure it out, or change it later. It is nice that I could still make adjustments later on, so that it’s not a one-time set-up. [Participant 3]

That depends: do I live next door, or close by, then it might be sufficient to be the only one being notified. But this should be available, like imagine I’m away for a weekend. The other informal caregivers will temporarily take over, then I will adjust whether or not someone is available. And the professional caregivers should also receive that notification. So, I would like to have this screen [settings] flexible, so that you can set it individually, per day or per time. [Participant 5]

Well, it’s already quite intuitive. It is good that you can click through quickly on different options within each activity and it is indeed stored for future usage. Also, it is nice that you can always come back and adjust things later if needed. [Participant 6]

Tailoring: Provide Information According to the Stakeholder

Tailoring alerts, notifications, and reports based on the intended recipients (formal or informal caregivers) were found to be valuable in the development of the interaction platform. Informal caregivers felt that a formal caregiver may require different information compared to an informal caregiver:

The information to professionals should be sent as per their needs. Of course, it will be very different from what informal caregivers need. [Participant 2]

For example, the raw data obtained from the sensors could provide more meaningful information to the formal caregivers, whereas they found the interpreted data to be sufficient for themselves:

The raw data is more useful for the healthcare professional than data which is already interpreted by the system. I don’t want raw data because that won’t help me, so then I would go for interpreted data. [Participant 3]

Reduction: Being Informed About the Situation Directly

The reduction feature was used in 2 ways: to receive direct calls or notifications in emergency situations, and to provide a quick overview of the current and past activities throughout the day on the home screen. In emergency scenarios such as falls, informal caregivers found the system-generated alerts (via quick calls or notifications) to be valuable, as they have the potential to streamline the communication and facilitate on-time care. This automated approach eliminated the need for caregivers to contemplate whom to contact and bypassed potential delays when reaching out to formal caregivers:

It is about on-time care. I think, if something happens, what do you need to do? Whom should you call to organize care quickly? There must be logical thinking behind it and the system can do it quickly. [Participant 3]

What I find important is that there is an alarm service-like solution, but initially it could be directed straight to the caregiver, a direct signal from the system saying: “here we see a deviation, this is what the system, the technology detects and intervention
may be required here” or “we see a fall, immediate intervention in necessary.” [Participant 6]

Furthermore, all informal caregivers (6/6, 100%) found the possibility to glance at the current and past activities in the day on the home screen to be convenient:

I find this [home screen] quite clear, now, that you can see which activity has already been performed earlier today, but also what is happening at the moment. This is really nice, and at the top, okay so is the situation at the moment. [Participant 1]

Yes, I think this is fantastic, I must say. Specifically, the fact that you do indeed see an interpretation of the situation that the system has apparently determined and everything goes well. [Participant 6]

The informal caregivers were also positive about the functionalities of sending messages, finding contact information about caregivers, and connecting to an electronic client dossier as these would address the issue of having to use multiple systems:

I think it is always desirable to have everything in one place and not having to deal with various different systems again. [Participant 2]

**Trustworthiness: Insight Into the Reliability of the Information Provided in the System**

Most informal caregivers (4/6, 66%) indicated being positive about the system providing a reliability percentage regarding the notification and information. According to them, a reliability score increases their trustworthiness toward the system:

It is still a technology, sometimes false alarms may occur, for example, when she has dropped something and trying to pick it up. Then, that's okay, that system indicates it is reliability percent. I actually like it. It points towards the trustworthiness of the system and also indicates that at times it can miss classify some things. [Participant 2]

When the reliability percentage is high, they sense the urgency and seriousness of the situations and were compelled to take required actions:

A reliability of 80 percent, yes, that did something with me...I thought that I should really take this seriously, like really seriously. [Participant 1]

On the other hand, when the confidence percentage was low, informal caregivers might be slightly relaxed, but they still wanted to ensure the safety of the care recipient. However, they felt that an indication of a low or high confidence percentage might help formal caregivers to organize their care better. For example, they can prioritize their visits depending on the system’s reliability percentages:

For me, it’s fine to read that information, whether it is 50 percent or 80 percent, that doesn’t matter. But I think for professional caregivers that it does matter, because if they receive 6 notifications and one has 30 percent reliability and the other 80 percent. Then they will first go to the one with 80 percent reliability. [Participant 4]

Interestingly, 1 informal caregiver expressed that viewing percentages might be slightly confusing for them to interpret; thus, simple terms such as “very reliable” or “less reliable” can be used:

Now I can’t judge 10 percent or 80 percent or 20 percent or whether that’s right. [Participant 3]

Furthermore, informal caregivers demonstrated a willingness to offer feedback to the system to enhance the reliability of the system’s alerts. However, it was recognized that this responsibility should be shared with other caregivers, particularly formal caregivers, who are also involved in responding to alerts and, thus, can also provide context-aware and detailed feedback to enhance the system’s learning:

The system is self-learning, so I’m actually positive about it. I hope people understand that when they provide feedback, they need to specify what exactly went wrong, so that the system can learn from that. For example, if someone didn’t fall but just lay down on the couch, then this should be adjusted. The system can become smarter by processing more data and thus increase the reliability of notifications. So, it’s important to add more context in order for the system to learn from it. [Participant 5]

**Verifiability: Possibility to View the Electronic Health Record and Connect With Formal Caregivers**

The possibility to view the electronic health records and connect with the concerned formal caregivers was found to be very handy and desirable. These functionalities also support the notion of an all-inclusive platform:

For example, If I want to speak to Mrs. Baker [formal caregiver], I click on Mrs. Baker and she can guide me further. [Participant 1]

I think it is always desirable to have everything in one place and not have to deal with various different systems again, also considering different passwords and identification or authentication as well. [Participant 2]

**Mixed Experiences**

**Reminder: Receiving a Reminder in Case of a Missed Emergency Call**

Mixed experiences were reported regarding the reminder that was received in case of a missed emergency call. Some informal caregivers found it useful, and others thought that reminders were not necessary for them, as this would be more useful for formal caregivers, depending on their personal situation. One informal caregiver experienced the reminder as confronting:

I would like a care professional to receive such a reminder when she falls, because I am always at a distance. [Participant 1]

If I see this message, and realize I’ve missed the emergency call, then I feel like I should have been more attentive, then I would like to have the information quickly and in a concise format, without...
Suggestions: Receiving Suggestions Regarding What Actions to Take

The use of suggestions along with alerts or notifications was found to be debatable in older adult care. On one hand, informal caregivers found suggestions to be valuable in situations such as emergencies, where they panic or are unsure about the possible actions to take to facilitate the right care:

We all know what stress and panic can do, in those moments we can sometimes make stupid decisions, or forget the best order of doing things. So, having such a suggestion can serve as a helpful guide. [Participant 1]

I feel that falling is different from agitated behavior. Falling means immediate danger, while agitated behavior often arises in the context of the dementia process that people experience. In such cases, it would be helpful to receive tips on what to do. [Participant 2]

On the other hand, some informal caregivers felt that suggestion were unnecessary and subjective to the care experiences of the informal caregivers:

I think many people would appreciate it. You see, I’ve been working in healthcare for many years, so I’m familiar with these things. I believe there are many people who would benefit from receiving suggestions on what to do in certain situations. While I may quickly come up with solutions based on my experience, this is not the case for everyone. Thus I think many people would find it supportive. [Participant 1]

Moreover, informal caregivers expressed concern that if suggestions are system generated, they will be generic, which could potentially limit their thinking to the provided suggestions only, thus losing the personal touch in care and inducing the feeling of annoyance:

I find this terrible, very annoying. Because I’m already stressed out, and then I get those too obvious suggestions that say “do this, do that.” My stress levels are already high and then I read something stupid...no thank you. Very irritating... [Participant 2]

Overall, while the usefulness of suggestions differs from person to person, it would be valuable to have such an option for those who are willing to receive it.

Suggestions for Improving the User Interface Prototype

Overview

Overall, the conceptual workflow of the prototype of the interaction platform was assessed positively by the informal caregivers. They indicated that most of the screens were clear and understandable. However, they provided some suggestions about screens or connections that were perceived as less logical or where improvements could be made.

Improvements in Conceptual Flow

Informal caregivers highlighted that some choices regarding the notification settings were repetitive or unnecessary, which made the flow unclear or redundant. Specifically, in Figure 3 (third screen [agitation] and fourth screen [fall incident]), the option to share the respective information with the formal caregiver was given; however, informal caregivers already mentioned their choices to share or not share the information with formal caregivers while adjusting their preference (Figure 2). Consistent with an iterative process, this was adjusted for the next (last 2) interview sessions:

Here, I again have the choice if I want to share with a care professional. But if that happens again, then I wonder if I have set it up correctly in the settings. So does this still appear on my screen? In the beginning, you make a choice about sharing information with a care professional, and here that comes up again, so it’s kind of redundant. [Participant 3]

This is what I don’t understand. If I let the notifications go to the home care professionals for this situation, then I should not have to fill this in [choice for the content of the notification]. [Participant 4]

Furthermore, informal caregivers indicated that it was inconvenient to immediately receive the option to provide...
feedback to the system in case of an emergency notification as they mentioned, at that moment, they were not thinking about the feedback and were probably not the right person to provide the information. It was suggested to send a reminder to provide feedback at a later moment. Moreover, there should be an option to receive more details about the situation:

> Provide feedback on this notification, yes that can be useful, but it has to be at a later moment. You don’t do this in the notification itself, but you can add at a later moment what the issue was and whether the notification was accurate. [Participant 2]

> For this, I would appreciate a reminder. I don’t necessarily enjoy receiving a lot of notifications all the time, but specifically for this purpose, yes. It’s about helping each other and helping the system learn, and thus improving the care. And I think when I’m actually there [at loved one] or when I come from there, then I might forget that. So, a reminder would be helpful, but it would be good to have a choice in the type of notification. [Participant 3]

Informal caregivers also suggested that feedback should be provided to them after they received a notification, so that they know that someone handled the situation and what actions have been taken:

> I think that is a bit of a gray area, so you received or made a notification, but what happens with it? That I would expect to receive feedback on. [Participant 5]

> Now I still have the feeling like I have to go there because I don’t know if it [notification] has been received and if someone is going there. [Participant 1]

**Improvements in Visual Design**

The informal caregivers suggested to include a clear visual indication when a deviation in behavior was noticed by the system, for example, a warning sign. In addition, an informal caregiver mentioned it would be more useful to express reliability in words instead of percentages, as this might be easier to interpret. Finally, informal caregivers suggested that the prototype could be improved by providing information in a more visual manner and including more graphs, images, and pictograms, as this could make it easier to interpret the information they were looking for:

> At a glance, I can see that everything is going well...but then [in case of deviation] could have a different color like red, and for yourself there could be an exclamation mark or warning sign to indicate that this is not optional information but something that needs to be looked into because it is not as it should be. [Participant 5]

**Discussion**

**Principal Findings**

In this study, informal caregivers showed a significantly positive attitude toward using USSs driven by AI algorithms for providing care to home-dwelling older adults with cognitive impairment. However, a previous study that explored care recipients’ perspectives regarding AI in health care revealed hesitancy, primarily driven by worries related to safety, privacy, and autonomy [29]. This divergence could be attributed to factors: the difference in the study population and the potential lack of knowledge about USSs (in general, technological care solutions) among the previous study’s participants. The previous study by Richardson et al [29] focused on care recipients’ perspectives, whereas this study involved informal caregivers who might have a different perspective, as USSs will be monitoring the care recipient and it does not concern informal caregivers. Furthermore, many people have limited knowledge about AI algorithms and view AI as a “black box” [30]. Previous studies suggest that educating and engaging individuals about AI can enhance their trust in AI and contribute toward its successful implementation in health care [29,30]. In this study, USSs were explained using a video prototype and additional verbal explanations, which most likely increased the participants’ awareness of AI use. However, individual differences in understanding AI might also influence their positive and accepting attitude toward USSs.

USSs rely on AI algorithms to predict the behavior of older adults with cognitive impairment, which might not function flawlessly and could misclassify certain behavior patterns. Therefore, care providers need to be cautious and should not become overly reliant on USSs, as it may lead to incorrect care choices [31]. This would present an ethical issue regarding accountability, as it prompts the question of who is responsible and to what extent [31]. Educating caregivers about its use, capabilities, and limitations might help to overcome this risk. In addition, the risk of bias when using AI in health care should also be considered [31,32]. If the training data predominantly represent a specific population (sex, age, ethnicity, etc), they might create biases [32]. This risk could be mitigated by ensuring representative and inclusive training data sets, that is, including data from a wide range of individuals with different demographic characteristics and backgrounds when training the AI algorithm [32].

Furthermore, the informal caregivers recognize the value of USSs as a supportive tool in the care of home-dwelling older adults with cognitive impairment [2]. Specifically, USSs can facilitate appropriate care decision-making, contributing to their peace of mind while also creating a safe environment for their care recipients. However, they also expressed some concerns regarding the possible information overload, substitution of the human aspect in care provision, and overinterpretation of data. To mitigate these issues, they acknowledged the importance of setting up (make agreements about the monitored activities and strategies regarding communication) the solution together with other stakeholders (specifically, formal caregivers). This is consistent with the CeHRes road map, that is, for successful implementation of an eHealth technology, it is important to consider the perspectives and needs of the different stakeholders involved [15,33]. Moreover, it can be said that by combining the strengths of technology with the insights and expertise of caregivers, a more comprehensive and effective care approach and implementation could be achieved.
In addition, informal caregivers experienced the lo-fi prototype and the use of most PSD features elicited in a previous study as positive [7]. Particularly, participants valued the possibility to personalize the settings and change them to their preferences at any given moment in time. The use of the personalization feature, as suggested in the PSD theory, has the potential to enhance the usefulness of eHealth technologies such as USSs [7]. However, before making personalized solutions, the personalization-privacy paradox should be considered carefully [34]. This paradox demands right balance between offering personalized experiences and safeguarding user privacy [34,35]. This balance might be achieved by implementing robust privacy measures, obtaining informed consent, being transparent about data use, and providing users with control over their data as described in the ethical guidelines issued by the European Commission for trustworthy AI [36] and the European Health Data Space regulation [37]. Moreover, regarding the PSD features reminders, suggestions, and social learning, the experiences were slightly mixed. These findings emphasize the importance of a user-centered design approach, as the preferences of each individual can vary depending on the care situation, personal circumstances, and preferences in IC [15]. For example, the travel distance to the care recipient could influence their choice regarding whether they want to receive an emergency call when a fall incident occurred.

**Implications for Future Studies and Practices**

For the successful implementation of a complex eHealth intervention such as USSs for home-dwelling older adults with cognitive impairment, a holistic design approach is required [15]. It is important to consider the perspective of different key stakeholders such as informal and professional caregivers, care recipients, and care organizations and secondary stakeholders such as health insurers, governments, and technology businesses while designing and implementing such solutions. In future studies, it would be interesting to perform the next design iteration by using the results of this study as a starting point. Gradually, a high-fidelity prototype of the user interface could be created and evaluated with different stakeholders in the care of older adults with cognitive impairment. Furthermore, the creation of personas would be helpful in studies, as different types of end users may have different needs and requirements [38]. The personas could be based on characteristics such as caregiving experience, educational level, or need for cognition [38]. In addition, it would be interesting to explore the ethical implications of implementing a smart monitoring and communication system for home-dwelling older adults, which could be performed using in-depth interviews with involved stakeholders.

Before the implementation stage, a business modeling approach can be used. It provides insight into how value is generated and delivered to customers, which should be considered to bring eHealth technology to the market [39]. In addition, the implementation of such a solution requires guidelines and agreements (about how to work with such a system) within organizations and at the government level. Caregivers should be educated about how to interact with the system and interpret and communicate the data. In addition, it is essential to consider regulations such as Medical Device Regulation to determine whether USSs will be categorized as medical devices. Medical Device Regulation offers provisions to address privacy and security concerns, especially regarding medical devices that collect and process personal health data [40]. Furthermore, as USSs use AI, it is crucial to take into account the new AI Act proposed by the European Union (EU). This act aims to regulate the use of AI in EU countries, ensuring better conditions for the development and use of AI technologies (EU AI Act, 2023) [41]. In this act, different rules will apply to different risk levels, with USSs probably falling under the category of high risk, and they will be subjected to a high degree of regulations [41]. This might have consequences for the extent and manner in which AI is applied.

**Strengths and Limitations**

The key strength of this study is rooted in its methodology, specifically the adoption of a participatory development process that actively engaged informal caregivers during the early development stage of the interaction platform. The designed lo-fi prototype of the interaction platform provided an overview of the overall conceptual workflow and PSD features in different care scenarios to informal caregivers. While lo-fi prototyping is cost-effective, it can be seen as an opportunity for rapid development with end users in the early stages of development. Specifically, a task-based study design in conjunction with a think-aloud approach was used for this study. The task-based study design facilitated a realistic evaluation of user interactions with interfaces in various care scenarios [18,19], and the think-aloud approach provided direct access to users’ thoughts, perceptions, expectations, experiences, and decision-making processes during their interactions with the interfaces and PSD features [20]. By combining these 2 approaches, a comprehensive understanding of potential issues (in the used PSD features) and areas for improvement (in the conceptual workflow) was obtained, which could be incorporated into subsequent design iterations. In addition, the use of a video prototype assisted participants in comprehensively understanding the proposed USS. This, in turn, facilitated the development of more concrete and well-informed themes regarding the implementation outcomes and preconditions necessary for the successful integration of novel USSs.

Along with strengths, this study also has some limitations, which should be considered when interpreting the results. First, all the informal caregivers (6/6, 100%) who participated in this study had previous experience with technological interventions in care provision (eg, Caren platform) and had previously participated in related studies. While it is important to acknowledge that the findings of this study may not be fully generalizable to participants with no previous experience in digital care technology, the overall growth in digital literacy is noteworthy and holds promise for the realization of the study’s findings. Second, most informal caregivers (4/6, 67%) who participated in this study reported that their care recipient had received a formal diagnosis of cognitive impairment. However, some informal caregivers also expressed their own opinions regarding the indication of cognitive impairment in their care recipients. Given the scope of this study, which aimed to explore the perspectives of informal caregivers, their opinions hold high value in this study [42-44].
Third, it is important to note that this study was conducted in the Netherlands, which may limit the generalizability of the results to international health care infrastructure. Different countries have diverse regulations and policies regarding older adult care; thus, different expectations and preimplementation conditions regarding USSs can be imagined. Finally, it is worth mentioning that data saturation was not reached in this study, as new information was obtained from all interviews. This indicates that there may be additional themes that were not fully explored, suggesting that the results of this study may not be exhaustive. However, it is important to recognize that the design process was iterative, and during the evaluation of the lo-fi prototype, the aim was to further enrich the platform, making data saturation less critical for this stage of development [45].

Conclusions
Overall, informal caregivers of older adults with cognitive impairment had positive expectations regarding the implementation of USSs. They expect the use of such a system to contribute to care decision-making and to provide insight into the situation of the care recipient. However, information overload and loss of human aspect were perceived as risks. To successfully implement a USS, good communication and agreements among informal caregivers, formal caregivers, and the care recipient are needed, thus necessitating a holistic approach in the development and implementation process. Informal caregivers were quite positive about the lo-fi prototype of the user interface and the application of PSD features; however, there were also mixed experiences and suggestions for improvement regarding the conceptual flow and visual design of the prototype. Personalization of the settings of the prototype was perceived as highly valuable. The results of this study, especially the identified concerns, should be considered in the further development and implementation of USSs for home-dwelling older adults with cognitive impairment.

Acknowledgments
This study was funded by the European Union’s Horizon 2020 research and innovation program under the Marie Skłodowska-Curie grant (814072) for the ITN ENTWINE informal care. The authors would like to thank Prof Dr Paul Havinga, Jan Hendrik, and Dr Duc Le Viet for their valuable feedback.

Data Availability
In this study, some personal details about the participants were obtained, constraining our ability to make quantitative data available for any secondary analysis. However, upon request, a summary of the qualitative data (after anonymization) can be provided.

Conflicts of Interest
None declared.

Abstract

Background: To address needs for emotional well-being resources for Californians during the COVID-19 pandemic, the Together for Wellness/Juntos por Nuestro Bienestar (T4W/Juntos) website was developed in collaboration with multiple community partners across California, funded by the California Department of Health Care Services Behavioral Health Division federal emergency response.

Objective: This qualitative study was designed to explore and describe the perspectives of participants affiliated with California organizations on the T4W/Juntos website, understand their needs for web-based emotional health resources, and inform iterative website development.

Methods: After providing informed consent and reviewing the website, telephone interviews were conducted with 29 participants (n=21, 72% in English and n=8, 28% in Spanish) recruited by partnering community agencies (October 2021-February 2022). A 6-phase thematic analysis was conducted, enhanced using grounded theory techniques. The investigators wrote reflexive memos and performed line-by-line coding of 12 transcripts. Comparative analyses led to the identification of 15 overarching codes. The ATLAS.ti Web software (ATLAS.ti Scientific Software Development GmbH) was used to mark all 29 transcripts using these codes. After examining the data grouped by codes, comparative analyses led to the identification of main themes, each with a central organizing concept.

Results: Four main themes were identified: (1) having to change my coping due to the pandemic, (2) confronting a context of shifting perceptions of mental health stigma among diverse groups, (3) “Feels like home”—experiencing a sense of inclusivity and belonging in T4W/Juntos, and (4) “It’s a one-stop-shop”—judging T4W/Juntos to be a desirable and useful website. Overall, the T4W/Juntos website communicated support and community to this sample during the pandemic. Participants shared suggestions for website improvement, including adding a back button and a drop-down menu to improve functionality as well as resources tailored to the needs of groups such as older adults; adolescents; the lesbian, gay, bisexual, transgender, and queer community; police officers; and veterans.

Conclusions: The qualitative findings from telephone interviews with this sample of community members and service providers in California suggest that, during the COVID-19 pandemic, the T4W/Juntos website was well received as a useful, accessible
tool, with some concerns noted such as language sometimes being too “professional” or “clinical.” The look, feel, and content of the website were described as welcoming due to pictures, animations, and videos that showcased resources in a personal, colorful, and inviting way. Furthermore, the content was perceived as lacking the stigma typically attached to mental health, reflecting the commitment of the T4W/Juntos team. Unique features and diverse resources, including multiple languages, made the T4W/Juntos website a valuable resource, potentially informing dissemination. Future efforts to develop mental health websites should consider engaging a diverse sample of potential users to understand how to tailor messages to specific communities and help reduce stigma.

Introduction

Background

The COVID-19 pandemic brought unexpected difficulties related to activities of daily living for people worldwide. In addition to affecting physical health, COVID-19 also threatened emotional health. Diverse groups were impacted, including people of different ages [1-4], gender identities [5-9], races and ethnicities [10,11], and geographic locations [12-15]. Those who faced financial concerns [16,17] or lost their jobs [8,18] and those caring for children at home [5] struggled with a variety of additional pressures. For workers [19,20], including health care workers [21,22] and community-based service providers [23-26] in the United States, attempts to serve clients or patients were confounded by pandemic-related challenges such as concerns about infection, reductions in staffing, and transitions to remote care, making their jobs even more complex and challenging.

As stay-at-home orders proliferated, people began to look for ways to strengthen their ability to cope emotionally during the pandemic. Many turned to media outlets such as television, radio, and social media for news and information [27]. Unfortunately, the news often led to increased fear and worries about the COVID-19 virus, illness, death, loss of jobs, economic concerns, and more. Many used Twitter to read the views of others and express their own negative sentiments about the pandemic [28]. Social media use contributed to experiences of stress [27], whereas engagement in self-care activities such as being able to access and use personal support resources helped protect against mental health distress [29]. Consequently, researchers [27,30] called for creative developments to connect individuals with social support and mental health services. To overcome stigma and other barriers, researchers and developers turned to web-based digital tools to make resources for coping and information on emotional well-being more accessible.

In this context, the Together for Wellness/Juntos por Nuestro Bienestar (T4W/Juntos) website was developed in collaboration with multiple community partners across California, funded by the California Department of Health Care Services Behavioral Health Division federal emergency response, to directly address needs for free web-based emotional well-being resources for Californians during the pandemic. The purpose of this paper is to report the findings of a qualitative study on the perspectives of a sample of participants affiliated with California organizations who engaged with the T4W/Juntos website.

Development of the T4W/Juntos Website

The T4W/Juntos website was developed as part of the Federal Emergency Management Agency and Substance Abuse and Mental Health Services Administration crisis counseling contract with California. The goals for T4W/Juntos were developed with a multidisciplinary team of researchers, clinicians, digital resource development experts, and staff from community-based agencies in California. Goals centered on creating inclusive and accessible resources that would provide evidence-informed and evidence-based information to Californians to ease the stress experienced during the pandemic [31].

Meetings were held via Zoom (Zoom Video Communications) with the large collaborative team (4 to 18 members per meeting) to maximize input from community members. The community and study team members made decisions collaboratively about which types of resources to include on the website. The priority was to feature resources that facilitated learning about COVID-19 or offered ways to address anxiety and stress (eg, web-based meditations, breathing exercises, and direct links to warmlines and hotlines), strengthen resilience, cope with grief due to a recent loss, connect with other people (such as through web-based support groups), or support social justice (eg, antiracism and reducing hate crime). Resources included links to web-based toolkits, websites, videos, web-based applications, articles, and downloadable pamphlets. Some resources were available in multiple (up to 10) languages. Community partners’ emphasis on using neutral, nonclinical language to increase comprehension and relatability and reduce stigma led to a monitoring of the length and complexity of messaging for the website. In response to the community partner prioritization of videos to engage users, the team created videos of community members speaking about the website’s purpose and features in English and Spanish [31].

Prior Work

A previous paper related to T4W/Juntos described the process of website development [31]. A second paper described the results of an analysis of quantitative data from an electronically administered web-based survey that were collected at 2 time points (approximately 6 wk apart) from English- and Spanish-speaking adult participants. Of the 366 eligible participants, 315 (86.1%) completed the baseline survey and...
93 (61.3%) completed the follow-up survey, with baseline results showing substantial diversity in gender, gender identity, and race and ethnicity and 32.7% (103/315) having moderate depression or anxiety (2-item Patient Health Questionnaire or 2-item Generalized Anxiety Disorder score of ≥3) [32,33]. Significant predictors of baseline website engagement were Hispanic versus other race or ethnicity and COVID-19–related behavior changes. The use of the T4W/Juntos website during the month before the follow-up survey was significantly associated with a pretest-posttest reduction in depression (2-item Patient Health Questionnaire score), and greater website engagement at baseline predicted reduced hotline use before follow-up [34]. An analysis of short qualitative answers that 199 (63.2%) out of 315 participants typed into textboxes in response to open-ended questions in the previously described web-based survey led to insights into safety concerns and fears during the pandemic and perceived benefits from and suggestions for improving the website [35].

Research Aims
With the goal of supplementing the quantitative results, the aim of this qualitative study was to describe the perspectives of a diverse subset of participants associated with various California community organizations who completed the baseline surveys regarding their experiences with the T4W/Juntos website. We also focused on participants’ needs for website resources that could support emotional well-being for themselves, their families, their clients, or their community. Finally, we sought insight to inform iterative website development in the future.

Methods
Recruitment
The larger sample described previously was recruited during the pandemic through invitations that were sent primarily by email, while stay-at-home orders were in effect, from 11 community partner agencies throughout the state of California to their affiliated community members with information about the website, its purpose, and the research study. Each of the 315 participants who consented and completed the baseline survey was given the option to indicate their interest in participating in a potential future telephone interview by clicking a box at the end of the survey. In total, 73.9% (233/315) of the participants clicked on the box to indicate their interest in being interviewed. Inclusion criteria were being aged ≥18 years, having access to the internet, having already completed the baseline web-based survey in English or Spanish, and agreeing to provide contact information. Using convenience sampling, participants who spoke English or Spanish were contacted via telephone by research staff approximately 2 weeks after completion of the baseline survey, starting with those who were the first to finish the survey, to offer an interview, confirm availability, and set a date and time for the interview. After 15 interviews were conducted, purposive sampling was used to maximize diversity in race and ethnicity, gender, and age. The final sample comprised 29 participants. The interviews (in English or Spanish) were conducted between October 2021 and February 2022.

Ethical Considerations
This study was reviewed and approved by the University of California, Los Angeles, Institutional Review Board of UCLA’s Human Research Protection Program (20-002163-AM-00008). After reading the web-based consent document, each participant clicked to give consent at the time of enrollment in the larger survey study, which included consent to a future potential interview. Our team only contacted individuals who agreed to be contacted for interviews using the contact information they provided. Participants reconfirmed their approval to participate and be audio recorded at the time of the interview. To protect the privacy and confidentiality of participants, the list of the names of the participants and their assigned codes was kept in a password-protected file available only to the principal investigator and project director. Their confidential contact and personal information were kept separate from all other data. Any potentially identifying information was deidentified on the transcriptions of audio-recorded interviews, including any names or descriptors that could possibly identify a participant; all names were changed to code numbers that were used instead of names by the researchers during data analysis. Participants received a US $25 e-gift card after completing the interview.

Data Collection
Demographic data were retrieved from the baseline survey for each of the 29 interview participants. A semistructured interview guide in English and Spanish that was developed by a multidisciplinary team was subsequently used by 2 research team members to conduct all interviews via telephone. Interview questions were designed to explore participants’ perceptions of any aspect of the T4W/Juntos website; gain insight into participants’ needs for support in relation to the resources available via the website for themselves and their families, clients, or communities; and obtain guidance on further development of the website. Audio recordings of interviews in Spanish were professionally translated into English, and all interviews were professionally transcribed verbatim and checked for accuracy. As already noted, identifiers were removed, and code numbers were used instead of names to label transcripts and organize the data.

Data Analysis
Demographic data were analyzed for frequencies using Stata/MP (version 17; StataCorp LLC) [36] for the sample of 29 participants. For the thematic analysis of the 29 transcripts, the study team was guided by a modification of the 6-phase process outlined by Braun and Clarke [37,38]. First, the study team familiarized themselves with the data in all transcripts. Second, the team engaged in initial coding using techniques from grounded theory methodology to enrich our approach [39]. Thus, most codes were developed using the gerund form of verbs, known as process codes, to heighten our focus on the actions taken by participants, as shown in the data [39,40]. To create process codes, coders used heuristic questions to ask What is happening here? and What are they doing here? This allowed coders to get closer to the participants’ point of view while reducing the tendency to prematurely project their own interpretations onto the data [39]. In the third and fourth phases, coders scrutinized the first 12 coded transcripts to identify the
most frequently occurring and significant codes and, through discussion and debate, identified a total of 15 overarching codes. Then, the data from all 29 transcripts were imported into ATLAS.ti Web (version 22.1.5; ATLAS.ti Scientific Software Development GmbH) [41] and coded based on the 15 overarching codes. In the fifth phase of analysis, data reports were created using ATLAS.ti Web [41] based on each of the 15 overarching codes. These were exported to Microsoft Excel (Microsoft Corp) so that the data in each code group could be further examined. Using constant comparison, we sifted, sorted, combined, and collapsed the data in the 15 groupings to form 4 themes, each with a central organizing concept that provided a clear definition of the theme [38]. We continued to compare data with data to develop the properties for each of the 4 themes. Finally, in the sixth phase, each theme was named, and its properties were refined. With a focus on the research aims, the research team then produced a written report interpreting the meaning of each theme.

The overall process of data collection and analysis was influenced by the team’s commitment to social justice and to the goal of understanding the data of each participant while considering their context. Thus, at various points during the research process, each member of the 5-member analysis team engaged in dialogue together and in individual writing of reflexive memos to name any judgments (positive and negative) or concerns that were felt while engaged in the research process, with the goal of reducing the influence of bias on the collection and interpretation of data [38,39].

Results

Participant Characteristics and Sample Demographics

The demographics of our sample of 29 participants are presented in Table 1. Of the 29 participants, 16 (55%) voluntarily shared that they were employed in peer support, hospice care, or health care sales or at a community agency doing health-related work. A total of 72% (21/29) of the interviews were conducted in English, and 28% (8/29) were conducted in Spanish. The duration of the Spanish interviews ranged from 22 to 72 (mean 32, SD 16.61) minutes, and that of the English interviews ranged from 15 to 85 (mean 38, SD 15.49) minutes.
Table 1. Demographics and depression and anxiety scores of community participants in California who were interviewed during the COVID-19 pandemic (N=29).

Qualitative Thematic Analysis Results

Thematic analysis of the qualitative data led to the identification of four themes: (1) having to change my coping due to the pandemic, (2) confronting shifting perceptions of diverse groups on mental health stigma, (3) “Feels like home”—experiencing a sense of inclusivity and belonging in T4W/Juntos, and (4) “It’s a one-stop-shop”—judging T4W/Juntos to be a desirable and useful website.

Theme 1: Having to Change My Coping Due to the Pandemic

Overview

Participants shared that, during the pandemic, they had to change the way in which they coped with daily life stressors. This was represented by 5 properties: increased use of technology to connect with others on the internet, intentionally identifying self-care tips and techniques, coping by helping other people, relying on in-home socialization, and drawing on spiritually oriented coping (Figure 1).

Increased Use of Technology to Connect

Participants found that their use of technology increased during the pandemic, and they had to learn to accept their increased reliance on the internet to be connected in various ways. For example, they used technology to connect with information on a variety of topics and be able to accomplish work for their jobs. They used technology to connect with other people for social reasons; this included using Zoom to connect with friends, family, and their faith communities. They also joined web-based support groups and community groups where they could engage in dialogue with others. One participant described how they felt more “comfortable” having conversations on the internet:

I think I’ve become more dependent on the internet. I also found that not having to deal with people face to face most of the time makes me feel more comfortable. Honestly, it’s easier for me to have a chat on the computer than in real life.

Participants said that they relied on technology to meet their therapeutic needs more than before the pandemic. They found web-based resources to be “easier to forward” and share with others. They described resources on the internet to be “more documented” and viewable. They reported how they learned to click links to use web-based resources, which, for many, was a new behavior.

Intentionally Identifying Self-Care Tips and Techniques

Participants helped themselves by seeking out practical approaches, including self-care tips and techniques. This meant that they were using technology to meet their therapeutic needs, something they had not necessarily done before. They used warmlines, crisis lines, and teletherapy to meet their needs. They learned about meditation and breathing exercises, which they found especially desirable because the stress of the pandemic was experienced as personally difficult. However, participants found it challenging to find “accurate” resources. This put them on a quest to find “reliable” web-based resources they could use to reduce stress. Participants explained that they continued searching on the internet even if their immediate need was resolved because they wanted to have resources ready just in case they needed them in the future. In addition, some used art to self-soothe during the pandemic, whereas others sought “self-improvement” strategies.

Coping by Helping Other People

When asked to say more about how they handled their own stressful experiences during the pandemic, participants repeatedly spoke of helping other people in their personal lives and on the job. It seemed that helping other people was itself a strategy they used to cope. A participant spoke of others who felt “invisible” and as if other “people don’t respect them” and how difficult it was for them because “they’ve lost their purpose because they can’t go to work or can’t do the job they used to”
do. They noted how important it was to share with others that “there’s hope...that there are people out there trying to make a difference, trying to help, trying to listen.” Participants’ efforts were extended to various types of people, including family members, friends, and coworkers, and those who self-identified as health workers reported that they helped both individual clients and families. Experiences of helping others stood out to them; they felt a sense of “satisfaction” from their helping work. One participant said the following:

And the reason I liked it is—and the reason is the feedback, the participation and everything, is actually one of the ways that it makes me feel like not only I’m sharing a resource, but I’m sharing a resource that I know is good—I hate sharing things that I know are not good—and I wanted to like what I’m doing here.

Relying on in-Home Socialization

Finding others to fulfill social needs and desires was mainly limited to whoever was in the home. Participants relied on their family members or roommates for dialogue, socialization, and friendship during the pandemic. However, pets also played an important role as they provided “joy, stress relief, and companionship.” Many described the importance of going on walks with their dogs as it brought about daily exercise and also could open up dialogue with neighbors, which was highly valued at this time of social isolation. One participant shared how meaningful it was to live with their 2 dogs and son. They said the following:

If I had to live by myself, I don’t know how I would get through this. I really mean it. I’m being perfectly honest.

Drawing on a Spiritually Oriented Approach to Cope

With few options for socialization, participants shared that they turned to spiritually oriented routes for coping. They turned to “God” and relied on their faith to keep them going. One participant stated that they could not imagine how anyone could “get through” the pandemic “without God.” For some, listening to religious radio programs filled a crucial need in their daily lives during the pandemic. Others reported using prayer or reading scriptures. A participant described how religion provided “guidance” on daily life:

[Faith in God] helps me first and foremost, that helps me not to have fear. I think that a lot of people now are controlled by fear. And so that helps me, y’know; that strengthens me and gives peace to my heart. I feel secure with my health habits, with my diet, well, because I’m connected to God, and because I get my health practices from the Bible. So, I feel that all around, my mental, my physical, my emotional, all my wellbeing, I dedicate that to God for his blessing. And so, y’know, I think that’s the biggest part of it.

Theme 2: Confronting a Context of Shifting Perceptions of Mental Health Stigma Among Diverse Groups

Overview

When discussing T4W/Juntos and its purpose in helping with emotional well-being, participants were concerned about the context during the pandemic related to public views on mental health. They raised the issue of shifting views on mental health stigma within different communities and how it impacts people. They reported how stigma differs based on age or generation, race, or ethnicity and how the T4W/Juntos website would be received within a context of overarching stigma in various communities. They also suggested ways to reduce stigma. This is reflected in 3 properties (Figure 2).

Figure 2. Theme 2 from qualitative analysis of interview data from community participants in California during the COVID-19 pandemic (N=29): confronting a context of shifting perceptions of mental health stigma among diverse groups.

Experiences With Mental Health Stigma Vary Across Generations

Mental health stigma was perceived as an issue for all generations. Participants explained that stigma itself was the backdrop that set the stage for how the T4W/Juntos website would or would not be received. This could have an impact on whether community members would embrace the website.
Participants explained that there was a difference in how older and younger generations experienced mental health stigma. Older adults who grew up during a time when mental illness was considered “bad” and “dangerous” were described as rejecting the possibility of seeking treatment for their mental health problems. They described a dual process in which the older generation felt too stigmatized to seek mental health support, but at the same time, they perpetuated the stigma surrounding mental health within their communities. Older adults were perceived as having negative beliefs about mental health concerns, sometimes viewing them as a personal “weakness” or a result of lack of religious practice (e.g., “devil’s work”) rather than a psychological condition. They were seen as discouraging other people from reaching out for such treatment, help, or resources. One participant shared how older people spoke about mental health treatment:

Looking for help, like, with a therapist...they shouldn’t be sharing their opinions. That’s what I’ve heard, “Why would you see a therapist, if they’re not God?”...that’s what I’ve heard. Like, “Why should you go around telling them your problems?”

Isolation was perceived as a major contributor to older adults’ mental health issues, especially for those who lived in residential settings. This raised concerns during the pandemic because participants reported that resources tailored to older adults living in such settings were not available, especially for those who were “losing loved ones” due to COVID-19. Participants worried about older adults “not being able to see their families” during the COVID-19 pandemic and how they would cope as stigma could be a barrier to obtaining the help they needed.

Younger generations were perceived as having grown up with greater awareness of mental health and, therefore, were affected by stigma in a different way. They were thought to be “more empowered” to openly discuss mental health issues. In particular, participants noted a more welcoming conversation about mental health on social media among younger generations, including during the pandemic. The differences between generations were described by one participant as follows:

I feel like that [the older generation] was like, “We’re not telling anyone our business.” And “This is family business, keep it to yourself.” Whereas like the mid-30s and maybe late 20s, they’re like, “You know what? Let’s talk to somebody, let’s get help, let’s like—We’re not going to suffer in silence.”

Stigma Is Experienced in Unique Ways in Different Racial and Ethnic Communities

Mental health stigma was perceived as experienced variably based on race and ethnicity, which had implications for the context of the pandemic. Participants shared examples of how Black, Latine, Asian, and other minoritized communities faced more mental health stigma in general compared with other communities due to a combination of societal and cultural factors. One Latine participant said the following:

Because I grew up culturally Latino, so, there is a huge stigma around mental health where you couldn’t just say, “Oh, I’m feeling anxious,” or “I’m feeling a little depressed.”

Another participant said that, in their Asian American community, mental health was “heavily stigmatized” and people “don’t tend to like to ask for help.”

The words participants heard being used to stigmatize mental health or people with emotional challenges, such as “crazy” and “weak,” were similar across racial and ethnic minoritized groups. While all people were seen as actively avoiding being labeled as having a mental health issue, those from minoritized communities were perceived as especially cautious because such negative mental health labels could be used as “leverage” against them. Therefore, a winning strategy used by community-based health workers in our sample was to “give them the information without having to use that word [mental health].” Others described avoiding being labeled by addressing physical rather than psychological symptoms. This provided a perspective for addressing mental health by taking care of physical health. One participant explained this as follows:

I think if the focus is not so much on mental illness but mental wellness, mental health, and that connection between the mind and the body, and that it’s all important, and addresses the person as a whole.

Recommendation on Effective Ways to Combat Mental Health Stigma

Participants recommended providing accessible educational resources on mental health to the public. One suggested that stigma could be reduced if mental health was discussed in the same way in which health providers engaged in “teaching someone how cancer works.” Other suggestions included the strategy of individuals openly sharing their personal stories of mental health struggles to dismantle stigma and encourage help-seeking behaviors. One participant explained that we need “to recognize that we all have trauma, and to set the example ourselves.”

In terms of sharing the T4W/Juntos website and other resources, participants suggested that, rather than just directing people where to go, we should share our experiences honestly. One participant recommended saying things such as “This happened to me and I went here to get help. That helped me a lot because I did this” or “I also went through the same situation.”

Participants encouraged efforts to create safe and supportive spaces, especially for marginalized individuals who may face additional stressors, such as “LGBTQAI+ students,” adolescents, and older adults. Participants reported that they would feel more comfortable recommending a warmline where individuals could connect with trained volunteers, therapists, or peers who could listen and provide support rather than “an Excel [sheet] of resources.” While participants endorsed efforts such as the T4W/Juntos website, they recommended investing in “more intersectional conversations” where leaders “that really represent a community” could share things such as “this is me, and this is what I’m going through. This is what I do to deal with it. This is where I go for help.” This approach was perceived to increase “comfort” and “acceptance,” unlike “faceless” things, because it could reduce stigma and negative perceptions of help seeking.
Theme 3 “Feels Like Home”: Experiencing a Sense of Inclusivity and Belonging in T4W/Juntos

Overview

Participants provided robust reports of feeling welcomed and included when visiting the T4W/Juntos website. This sentiment is reflected in 4 properties: feeling included due to welcoming tone and visuals; feeling included due to the substantial, diverse, and quality resources on T4W/Juntos; many languages making T4W/Juntos “more accessible”; and recommending ways to increase inclusivity on T4W/Juntos (Figure 3).

Feeling Included Due to Welcoming Tone and Diverse Visuals

The images and overall tone of T4W/Juntos gave participants a sense of belonging when using the website. They described the site’s imagery as “cheerful,” “friendly,” “bright,” “happy,” “fun,” “calming,” and “light and airy.” One participant explained the following:

...the color scheme and the font, it’s just very inviting and not intimidating. Cause I think finding like health resources or mental health services or any of these topics, they’re very heavy. So, having a page that’s bright and makes it simple and has the cute little icon next to each topic makes it a little more digestible.

Other participants focused on T4W/Juntos’ esthetics. One participant indicated that it was “well-balanced” with “just enough seriousness.” Another participant highlighted the site’s “high production value” in terms of visual and auditory content. The quality of the content was valued, including the mix of both cartoon and real images, the “scenery” in graphics, and the quality of the spoken Spanish in videos.

Participants noted the importance of diversity in T4W/Juntos’ images in helping them feel included. They appreciated seeing the “authentic representation” of various ages, gender identities, abilities, sexualities, and races and ethnicities, among other characteristics, in “these beautiful faces” they saw on the website. Participants indicated that T4W/Juntos “feels like home” because the images were specifically representative of California’s population. One participant stated the following:

I feel like it covered populations and community members across California who would be possibly using the website. And also, just showing that diversity. So, I think that creates a welcoming environment as well if people can see themselves represented in some capacity on the website, especially on the front page.

Unlike other mental health websites that participants described as judgmental or exclusionary, participants felt that T4W/Juntos was not overly “clinical” or “bashing you with some mental illness stigma.” Furthermore, T4W/Juntos’ diverse representation was different from that of other sites where “only one type of person” was represented, which meant that visitors to T4W/Juntos would not “feel like they’re an outsider,” as one participant succinctly explained:

...if there’s nobody on the website that I can identify with, maybe it doesn’t...doesn’t tally to me kind of thing. There’s plenty of opportunity, I think, for anyone to feel like they fit [on T4W/Juntos].

Feeling Included Due to the Substantial, Diverse, and Quality Resources on T4W/Juntos

The quality, quantity, and variety of resources present on the T4W/Juntos site greatly contributed to participants feeling welcome and included. Some expressed appreciation in broad strokes, noting that there were resources for “every ethnicity” and “different ages” and that the T4W/Juntos team “took many different things into account.” Other participants valued the inclusion of resources for specific groups, such as African American individuals, American Indian and Alaska Native individuals, the “LGBTQIA2+ community,” parents, children, and people living with disabilities. Knowing that the resources were intentionally selected for T4W/Juntos mattered. One participant noted that “…the thought put into making [T4W/Juntos] usable or worthwhile to a number of different communities was made and paid attention to.” Another interviewee found it “refreshing to realize that the [T4W/Juntos]
project...had equity kinda built from the top up.” One participant encapsulated this by saying the following:

> It just felt like I was coming to a buffet, a big place to finally like heal, y’know? It was like “Oh, I don’t even have to eat this. There’s like a little bit of that, more of that.” And there’s really—the variety of choices, and the way that it was put, it was very inviting. Also, it was very welcoming, and I left feeling satisfied, but also, I left—like there was stuff that I could share with people. And I did.

“This Is Kinda Cool”: Many Languages Make T4W/Juntos “More Accessible”

Linguistic accessibility was another important aspect of the T4W/Juntos site that made participants feel included. Because of California’s multicultural population, participants believed that T4W/Juntos needed to be offered in multiple languages, especially Spanish and Vietnamese, for it to be considered “culturally appropriate” and widely accessible. One participant stated that “I love that the website already has a few options in different languages...Just thinking about the different audiences [will] make it that much more accessible.” The creation and availability of a Spanish translation contributed to another participant’s feelings of inclusion:

> So, it made me welcome and then it also made me understand more, like I said, because it was in Spanish and English.

Others noted the need for content in more languages; some specified a desire for content in Vietnamese, Indigenous languages (broadly), and Mixtec due to the large population of Mixtec-speaking migrant workers in California.

In addition to being offered in multiple languages, many participants lauded the site for being written in “everyday” and “plain” language that was “easy to understand” and “basic.” Another participant expressed their thought process upon first hearing about T4W/Juntos:

> I was like, “This is kinda cool. Let’s check this out.” It wasn’t something like, “Oh, wait, this is way beyond my expertise, or this is something I don’t fully understand.”

Although many found T4W/Juntos easy to understand, a few respondents said that the language was inaccessible or overly professional. For instance, one person commented that the “writing [in T4W/Juntos] was too academic,” and therefore, it “wasn’t an easy read. It was like reading a textbook or a law book.” Others noted that terms such as “resilience” or “anxiety” made the site feel overly clinical and not intended for the average user.

There was concern that some users with low computer literacy may not be able to use the site. For example, one participant cautioned that some Spanish speakers may not necessarily know the word for “link” in English or Spanish (enlace). Furthermore, several participants who worked with immigrant communities indicated that many in these groups cannot read or write in Spanish or English, which precludes them from making use of the T4W/Juntos site.

**Recommending Ways to Increase Inclusivity on T4W/Juntos**

Some participants advocated for changes or additions that would further widen the net of inclusivity. For example, participants suggested adding information on mental health symptoms and treatment options; trauma and its potential effects; support for basic needs such as housing, rental assistance, and financial support; information about civic engagement (eg, how to register to vote and contacting local officials); and recreational activities such as art classes and book clubs.

Although many participants found the wide breadth of representation on T4W/Juntos to be quite impressive, some wanted even more diverse visual representation. Some perceived a few groups to be conspicuously absent on the site, such as the lack of representation of older adults. One participant stated the following:

> ...older adults have really had a hard time with isolation and access and I don’t really see older adults represented, at all—at all, at all, at like, at all, in this whole thing. Not just the graphics, but the people you’ve chosen to be on the little videos, the images, the content, there’s nothing about older adults, that I found.

Another participant specified the need for more youth representation:

> ...make sure that we have as many opportunities for youth to be able to see themselves talking, working with each other, reaching out, but really knowing that we’re all here for them. And I think that was one of the things...that I would really suggest, is that opportunity.

Other suggestions included adding more representation of men of color, including “African American men, Latino men and Armenian men,” as well as police officers and military veterans as these groups tend to avoid seeking treatment due to stigma against mental health. Others suggested that representation be enhanced with more images or voices of people with disabilities: individuals from the lesbian, gay, bisexual, transgender, and queer community; and actual community members.

**Theme 4 “It’s a One-Stop-Shop”: Judging T4W/Juntos to Be a Desirable and Useful Website**

**Overview**

Participants judged the website as a hub that brought many things together in one place, making it a “one-stop-shop.” For this reason, most described it as a desirable website. Their perceptions reflect 4 main ways in which they experienced the website: perceiving T4W/Juntos as trustworthy, being equipped with a “first step” tool to use and share, finding navigation to be simple and clear, and easily accessing useful information (Figure 4).
Perceiving T4W/Juntos as Trustworthy
Participants valued the website due to the reliable information on it that had been curated from credible sources, which was able to combat misinformation. One participant reported the following:

*I feel like it’s done by UCLA, UC Davis, all names that I really trust...it’s a name that people recognize and that you can trust. So, I have no reservations whatsoever about this website...I know that when I scroll all the way at the end with the different sponsors or collaborations made it legit.*

Seeing the real faces and hearing the real voices of community members in the videos plus the logos of respected agencies on the website enhanced the sense that it was “legitimate.” Trustworthy information was especially desirable to combat the misinformation they reported hearing about in many communities.

Being Equipped With a “First Step” Tool to Use and Share
Participants felt equipped because the website gave them tools necessary not just for learning about resources but also for sharing with clients, friends, and family members. One participant noted how T4W/Juntos was something they had been searching for but had not found:

*And it just was primarily what it felt like, a resource portal. And so, it felt like the right door to go get help, rather than the wrong door. So that’s a good way of putting it. It felt like I had finally opened the right door that I’d been looking for.*

As a tool, T4W/Juntos was judged as helpful because it allowed participants to gain access to needed mental health resources during the pandemic, with options so that clients could start “where they want to” with the goal of receiving help. They liked having access to specialized information that addressed a wide range of topics, such as resources on grief for pregnant women or up-to-date COVID-19 information. They found it desirable because it was designed for the “average person,” so it was useful as a “first step” even for those with no previous knowledge about mental health resources.

Navigating Is Simple and Clear
Participants perceived T4W/Juntos to have appealing features such as inviting colors and fonts, which made the content “more digestible.” The technology functioned smoothly, including the hyperlinks and videos. One participant said the following:

*And it’s really easy to go on there, navigate, and look for information. And it’s also a good way to empower the clients I work with, so they can go and do their own research about any resources they may need in regards to mental health.*

The process of searching for information was clear even when working with groups lacking digital literacy, which they noted was required for some websites. One participant noted the following:

*Honestly, this is one of the pages that I remember my mom and I—even though we were dazed and emotionally exhausted—we were able to understand and get the information because it was all so simple. That was the only thing I can tell you. Despite everything that happened, we saw that if we were going from one place to another looking for information or trying to analyze, sometimes it was very elaborate. We needed something like they say in English, “short and sweet,” not fancy or too negative. Something within the positive and informative things but without being research papers that we had to be reviewing and analyzing, because we didn’t have the capacity to do that. We needed simple and easy to understand information.*

Easily Accessing Useful Information
The ease of using T4W/Juntos to access information was a valued feature. Participants found the website to be a user-friendly “one-stop-shop,” a place where they could find plenty of useful resources to choose from all at once. They preferred this to having to type specific topic words into a search engine to find needed resources individually. Some especially endorsed the feature that allowed them to receive immediate active help through a direct crisis number, whereas others favored the option to receive informational help by downloading materials to read. While participants overall considered T4W/Juntos to be easy to use, some suggested making the pages more “scroll-friendly...like Instagram,” and another participant suggested adding an “emergency exit” button so that users could quickly switch to a different site if needed for safety reasons.
Discussion

Principal Findings

The qualitative findings from telephone interviews as a complement to quantitative surveys suggest that, during the COVID-19 pandemic, the T4W/Juntos website was well received by both community health service providers and community members in the interview sample as a useful, accessible tool, with some concerns noted such as language sometimes being too “professional.” Our findings further suggest that the pandemic catalyzed significant changes in the way people coped, which fueled a shift to digital solutions when other options were suddenly off-limits due to stay-at-home orders. Our participants tended to their own emotional well-being personally and assisted their friends and families, and some also engaged in trying to help clients or patients as well. Their pivot to reliance on technology during the pandemic ranged from finding new techniques for soothing stress to connecting with others in a meaningful way via the internet to meet socialization and support needs. Roommates were crucial for socializing, as was also suggested by Shigeto et al [42], because social distancing limited social contact. Similar to other studies [43-45], our participants found pets to provide companionship and effective ways to cope with the isolation of stay-at-home orders. Notably, as other researchers found, being able to help other people during the pandemic in and of itself gave participants a mood boost [43,46]; this made the T4W/Juntos website even more valuable because participants could share it with others.

Similar to the findings of other studies [47-49], our participants shared that mental health stigma and taboo attitudes had often thwarted attempts to access needed mental health care, and this was especially the case for those from ethno-racially minoritized communities and older adults. However, participants did not perceive the T4W/Juntos site as invoking stigma, judgment, or condescension. They were particularly cognizant of the efforts of the development team to create a site that was neither intimidating nor shaming. They found it to be a digital space that successfully communicated that someone was out there trying to help others in a world that was otherwise shut down due to COVID-19. The collaborative approach to the development of the website may have been why the written text and verbal communication in the site’s videos were described as an example of a positive way to talk about mental health.

To combat stigma through a website, input from potential users, such as our participants, is crucial for design enhancement. As already noted, during the development of T4W/Juntos, input from various members of diverse California communities addressed the making of the website, including the goal of reducing stigma related to mental health [31]. Efforts to reduce stigma require sensitivity to the language used; with T4W/Juntos, we intentionally used neutral, nonclinical language so that experiences such as stress, anxiety, depression, and grief were addressed as normal aspects of life that many of us deal with [31]. Our participants recommended featuring pictures, animations, and videos to showcase resources in a personal way that is colorful and inviting without stigma and that reflects the commitment of the T4W/Juntos team. In addition, several short videos in English and Spanish were created to introduce each section of the T4W/Juntos website with the goal of making users feel more comfortable with the topics; volunteers from diverse California communities served as relatable actors who were filmed during the pandemic via Zoom in their homes. The diverse representation is likely why participants said that the website felt comfortable. We also included links to active warmlines and hotlines so communication with an actual human being was possible through telephone and texting [31,34,35]. However, consistent attention to making these links convenient and prominent on the website is needed over time to maintain a steady focus on reducing stigma. Additional efforts could be made in the future to link to more and different venues available on the internet where diverse community leaders talk about their own emotional health concerns or share what they have found helpful. In addition to the immediate sense of welcome, participants found the extent and variety of the content on T4W/Juntos (ie, the plentiful links to various resources) to communicate supply rather than unmet demand. The sense of options for resources was understood as high accessibility, which somehow also reduced stigma. Participants seemed to relish what they perceived to be a bounty of ready resource links, including content in multiple languages. This, during the pandemic, was appreciated because it was a time when avenues for the typical sources of useful or desirable material were severely reduced.

The sense of belonging reported by participants suggests the profound impact of a culturally competent design in enhancing user engagement with and experience on the website. For example, the colorful look of T4W/Juntos was developed in collaboration with community members [31]. The decisions to give T4W/Juntos an upbeat feel, feature relatable people from diverse California communities in the videos, and provide options in diverse languages were all made collaboratively with community partners. The team’s intentional efforts and commitment to convey diversity resonated with participants, making the website “feel like home.” Furthermore, as the partnering organizations behind the creation of the website were clearly listed on the site for the purpose of transparency regarding who was behind the website, participants perceived it to be a trustworthy tool.

Overall, our findings highlight that the T4W/Juntos website functions as a comprehensive, inclusive, and user-friendly platform for coping with mental health challenges, particularly during the pandemic. It was a web-based “one-stop-shop” due to the culmination of several integrated features that generated positive regard. However, despite its many strengths, there were also suggestions for improvements to the website to further enhance inclusivity. As was suggested by some participants, more resources, pictures, stories, and testimonials are needed to reduce stigma, specifically for older adults; adolescents; lesbian, gay, bisexual, transgender, and queer communities; police officers; and veterans. In terms of functionality, certain adjustments were requested, including a “back” button and a drop-down menu for a better user experience.
Limitations

Some aspects of this study were restrained due to the pandemic. For example, we were only able to interview English- and Spanish-speaking adults. In addition, we used convenience sampling with recruitment based on invites from clients and community partners of staff and providers of community partner agencies. While this approach resulted in a diverse sample, it included community-based health and wellness workers and is not necessarily representative of California residents. Nonetheless, during the COVID-19 pandemic, these voices were extremely valuable and garnered important insights. While 55% (16/29) of the participants indicated that they worked in community-based support or health care, we did not collect specific data on employment status or occupation. We can only assume based on education and other factors that approximately half of our sample were community members not employed in health care. Thus, future research should systematically collect employment data as context for participants’ level of familiarity with health-related resources.

Relatively, the COVID-19 pandemic put limits on potential participants’ ability to engage in a study when they were dealing with other worries. Thus, our sample was diverse in some ways but could have been more reflective of California’s population. For example, we were successful in recruiting 7% (2/29) of participants who were Southeast Asian; however, no participants self-identified as being from South Asian or East Asian communities despite the large numbers in California. Future research should expand recruitment efforts to be inclusive of the many subgroups in the state to bring insight from a more diverse sample.

Conclusions and Future Implications

Our results complement the findings of the quantitative evaluation that showed engagement in website use and an association with reduced depression over time [34]. The results underscore the value of collaborating with members of the target community to have a meaningful impact when designing a digital tool for the public. Specific partner website design suggestions to include videos; language accessibility; diverse representation; and colorful, cheerful visuals contributed to the positive reception of this website. The findings suggest that, while T4W/Juntos has been effective in addressing diverse needs, there are ongoing opportunities to maximize inclusivity and user experience.

First, future studies on mental health website development would benefit from engaging with a diverse sample of the target group and conducting pilot tests to learn more specifically what accessibility means to potential users. Second, the results showed that mental health stigma continues to be an issue, especially among minoritized communities. Hence, resources tailored to such groups must consider what stigma looks like to members of each group and how to address it in the specific context of minoritized communities so that valuable information about mental health will be received and accepted. Finally, participants indicated that the T4W/Juntos website was useful for their personal needs, sharing with loved ones, or incorporating into their work with minoritized communities. The website’s unique features—especially its diverse representation and availability in multiple languages—make it a valuable addition to the mental health resource landscape, and thus, it may be recommended for dissemination throughout the state of California, especially when including input from other diverse populations.

Acknowledgments

The authors would like to acknowledge the community partner agencies in the state of California who collaborated in the development of the Together for Wellness/Juntos por Nuestro Bienestar website and assisted in disseminating information that led to the recruitment of our sample, including African Communities Public Health Coalition, Boat People SOS, Cal Voices, California LGBTQ Health and Human Services Network, Healthy African American Families II, Health Education Council, National Alliance on Mental Illness California, United Parents, and Visión y Compromiso, and our collaborators at Chorus Innovations and University of California, Davis. Funding was obtained from a Federal Emergency Management Agency and Substance Abuse and Mental Health Services Administration grant (which was managed by the California Mental Health Services Authority through the California Department of Health Care Services for COVID-19 crisis intervention prevention; 700-FEMA-2021-UCLA), a California Health Care Foundation grant (award G-31202), and an award from the California Department of Health Care Services (award 21-10458).

Data Availability

The data sets generated during and analyzed during this study are available from the corresponding author on reasonable request.

Authors’ Contributions

MVH, KBW, and DFR conceived and designed the study. MVH analyzed and interpreted the data and drafted and revised the manuscript. JL, MPC, and JIM analyzed and interpreted the data and made substantial contributions to drafting and revising the manuscript. DFR collected and participated in the analysis and interpretation of the data. KBW also critically revised the draft for important intellectual content. All authors granted final approval for the version to be published.

Abstract

Background: Over the previous 4 decennial censuses, the population of the United States has grown older, with the proportion of individuals aged at least 90 years old in the 2010 census being more than 2 and a half times what it was in the 1980 census. This suggests that the threshold for constraining age introduced in the Safe Harbor method of the HIPAA (Health Insurance Portability and Accountability Act) in 1996 may be increased without exceeding the original levels of risk. This is desirable to maintain or even increase the utility of affected data sets without compromising privacy.

Objective: In light of the upcoming release of 2020 census data, this study presents a straightforward recipe for updating age-constrained thresholds in the context of new census data and derives recommendations for new thresholds from the 2010 census.

Methods: Using census data dating back to 1980, we used group size considerations to analyze the risk associated with various maximum age thresholds over time. We inferred the level of risk of the age cutoff of 90 years at the time of HIPAA’s inception in 1996 and used this as a baseline from which to recommend updated cutoffs.

Results: The maximum age threshold may be increased by at least 2 years without exceeding the levels of risk conferred in HIPAA’s original recommendations. Moreover, in the presence of additional information that restricts the population in question to a known subgroup with increased longevity (for example, restricting to female patients), the threshold may be increased further.

Conclusions: Increasing the maximum age threshold would enable the data user to gain more utility from the data without introducing risk beyond what was originally envisioned with the enactment of HIPAA. Going forward, a recurring update of such thresholds is advised, in line with the considerations detailed in the paper.

Introduction

A person’s age is a singular piece of information. It is linked inextricably to an individual, incrementing ceaselessly throughout life and unable to be modified (despite some having tried [1]). Age is a fundamental piece of information that we routinely use to describe or categorize a person. Age values commonly occur in health data, either directly or more usually as implied by the patient’s date of birth (often aggregated by the year of birth). Thus, age is a useful piece of information when looking to match 2 records pertaining to the same individual [2], and, therefore, within an anonymized data set containing person-level information, the presence of an age value contributes to the risk of reidentification.

With microdata records, a rule of thumb is that the relative amount of reidentification risk that any value contributes is inversely proportional to the number of people in the population who share that value. For example, the sex value “male” is low risk as almost half the population shares that same value. This extends to a combination of values from several fields. The
When working with data sets with US patients, the US decennial census data contain group-level counts that can be incorporated into risk calculations. For example, one may use the census to look up the size of the population of all female patients aged 90 years and older (the census value will serve as an approximation due to shifts in population over time). Note that it is the absolute count of patients that is most relevant, rather than the proportion of a population subgroup relative to the full population.

Age values are not represented equally across the range of all ages. It is natural and expected for age cohorts to reduce in size as a function of age due to increased rates of mortality. While historical events such as epidemics of malign diseases can affect cohorts differently and birth rates over time along with emigration and immigration play a role in cohort population size, in general, population counts are decreasingly frequent in older people. Hence, there are, for example, fewer nonagenarians (individuals aged between 90 and 99 years) than there are octogenarians (aged between 80 and 89 years). Thus, especially in the population of very advanced age people, the reidentification risk contributed by age increases year-on-year as the number of individuals who share the same age reduces. To mitigate this within a data set where sensitive information is also present, it is sensible to constrain age values to some maximum. The HIPAA (Health Insurance Portability and Accountability Act) of 1996, in its Safe Harbor approach to the deidentification of data sets [3], gives a maximum age of 90 years to which all higher values should be lowered.

The risk of reidentification, or “disclosure risk,” is related to the amount of utility that a data set of personal information contains. As the risk is reduced, so is the value of the data set in terms of its usefulness. Aggregation or constraining, while reducing risk, will inherently reduce the granularity of information the data contain, since these methods effectively introduce error to the raw data values, and the quality of any statistical inference based upon the data will suffer as a result. Thus, there is a trade-off between reducing the disclosure risk of a data set and maintaining a level of utility that is sufficient to address questions of interest.

Enabling more granular year-of-age information is beneficial for studying health outcomes in the older populations. Through improved diets, better medical care, and generally healthier lifestyles, people are living longer. In addition to these environmental factors, a spike in birth rates following World War II into the early 1960s has also contributed to the high proportion of individuals aged over 60 years currently living in the United States [4]. With the growth of the older population in the United States and abroad [5], the development of efficacious drugs and treatments for an aging population is becoming increasingly important [6].

This prompts the question of whether the age threshold given by HIPAA is still appropriate. While 90 years of age may have been a good choice 2 and a half decades ago, is it still a good choice today, or could it be raised, and data set utility improved as a result? In consideration of the ways in which an age value contributes to the disclosure risk of a data set, we make the case that this threshold can be increased without reducing disclosure risk.

Methods

Overview

Data from the previous 4 decennial US population censuses were acquired [7] and investigated. As HIPAA was enacted in 1996, presumably, the age-constraining guidance of age of 90 years was based upon data from the most recent census, which was in 1990. At the time of writing, the most recent census is that of 2010, so that is used in support of updated guidance through comparison to the corresponding 1990 census counts.

Analyses used data from the census’s population “PCT12” tables that consist of population counts grouped by combinations of state, sex, and single year of age (at the census year). Using these counts, we can constrain subsets of these 3 variables while aggregating across others. For example, we can sum the population counts across all states for all ages of 92 years and older, grouping by sex (ie, one sum for male and another for female individuals).

To illustrate trends over time, we performed similar computations on data from the 1980 and 2000 censuses. Having obtained these counts, we then compared them across different census years and generated illustrative plots. Findings are presented in simple graphs along with distributions across the United States illustrated by choropleth maps.

All analysis was performed in the computational language R (R Foundation for Statistical Computing). Given the small data storage and compute costs and the public availability of the data, we were able to perform all the analysis on personal computers.

Ethical Considerations

The exploration of reidentification risks associated with varying specificities of age information for older individuals carries certain ethical implications. Although the data under study were publicly available, using it in combination with proprietary data sets and record linkage technologies may elevate the risk of reidentification. The analysis herein was carried out in a technical environment that did not contain any data sets to which the census data could be linked.

The degree of privacy protection afforded to any proprietary data set must be assessed in the context of possible linkages to readily accessible data sets. In fact, HIPAA stipulates those linkages to “reasonably available information” be accounted for in statistical determinations of privacy risk [3].
This analysis does not require review from an institutional review board as per the US Department of Health & Human Services regulations for the protection of human participants (45 CFR 46.104(d)) [8]. In particular, this is “Research that only includes interactions involving…survey procedures…” and meets the criterion that “The information obtained is recorded by the investigator in such a manner that the identity of the human subjects cannot readily be ascertained, directly or through identifiers linked to the subjects.”

**Results**

**Overall US Population and Sex Considerations**

The 1990 census showed that 1.02 million people were aged 90 years or older (Figure 1). In the 2010 census, this had risen by approximately 84% to 1.87 million. The increase was around 40% from 1990 to 2000 (a similar figure to the increase between 1980 and 1990) but smaller at 30% from 2000 to 2010. An increase was evident in both male and female individuals, although their increases were neither similar nor uniform.

The figure of 1.02 million people who were aged 90 years or older was presumably the number that was deemed acceptable for HIPAA when it was enacted in 1996. In 2000, the census data began to include numbers for individuals aged between 90 and 99 years, so we could look up at which age, in 2010, the population was at least this size. With reference to Figure 2, we see that at the age of 92 years and above, the count in 2010 exceeded the required 1.02 million, but at the age of 93 years, it was below this number.

Since the numbers of male and female individuals at any age are far from equal (Figures 1 and 2), it can be argued that it is more sensible to consider the sexes separately, especially since sex values are normally present within a health data set. As there are fewer male than female individuals, presumably, the number of male individuals at least 90 years of age in the 1990 census (n=244,000; the blue dashed line in Figure 2) is a sufficiently large equivalence class size for either sex. In 2010, to achieve the same number, an age of 92 years would be required for male individuals, but for female individuals, it would be 95 years (since the number of people aged 96 years or older falls short by a few thousand).

**Figure 1.** Male and female individuals (in 1000s) at least 90 years of age over the previous 4 decennial US population censuses.
Figure 2. Male individuals, female individuals, and individuals of both sexes (in 1000s) at and above the given ages in the 2010 census. The dashed lines show the numbers of individuals who were aged 90 years and older in the 1990 census.

State Level Considerations
A state-level examination of age is also worthwhile since state data are often included in health data sets. Results can best be illustrated by choropleth maps. Figure 3 shows shading based upon the proportion of people aged 90 years and older in the 1990 census. Alaska had the lowest proportion of people (0.7 per 1000) aged 90 years and older, followed by Nevada (1.8) and Utah (2.4), with the Midwest (Iowa=7.2) and Northeastern regions generally having higher values, along with Florida (4.9). Figure 4 shows the numbers of those aged 90 years or older in 2010 compared with 1990. Nevada has seen the greatest increase (411%), followed by Hawaii (402%), with all states having shown an increase of at least 134% (Nebraska) and those in the Midwest generally seen a smaller increase.

With regard to absolute counts, among all states, Alaska had the smallest number of nonagenarians in 1990 with 358 (Wyoming was second with 1527). In 2010, although Alaska still had the smallest such population, the number increased by a factor of just over 4 to 1438 (Wyoming was second with 2899). If we assume that the decline in population by individual age year in Alaska follows a similar trend to that of the overall US population (Figure 2), it stands to reason that a maximum age cutoff of 93 years would maintain a level of anonymity at least equivalent to what the age-constraining threshold of 90 years achieved in 1990.
Figure 4. Choropleth map of the percentage change in the number of people aged 90 years or older between 1990 and 2010 by state. Alaska and Hawaii are shown (not to scale) to the left of the contiguous states.

Discussion

Recommendations for the Present Day

The increase in longevity seen in the US population over recent decades means that constraining ages to 92 years would achieve at least as low a level of disclosure risk, based on the 2010 census, as 90 years did when it was introduced in HIPAA in 1996. This is desirable to implement as it effects an improvement in the utility of the data set if one accepts that keeping numbers “round” is an insufficient reason for continuing to use 90 years. Furthermore, if constraining is done differentially for the sexes, as is sensible if sex information is present in a data set, since female individuals tend to live longer, then female individuals’ ages can be constrained to 95 years, based on the 2010 census, and achieve the same level of risk protection as male individuals in 1990.

The increases in the proportions of the “oldest old” have not been uniform across the United States, with those underrepresented in 1990 going some way to “catch up” in 2010. HIPAA’s Safe Harbor method allows state values to be retained (along with 3-digit zip codes), so presumably constraining age to 90 years in 1990 was sufficient to have low enough risk levels in each state individually. Based upon the subsequent changes in Nevada and Alaska, there are strong grounds for raising the threshold to 93 years.

In addition to states, Safe Harbor also references 3-digit zip codes. This geographic unit consists of all zip codes with a fixed first 3 digits. Safe Harbor stipulates that 3-digit zips are permissible, provided that the area has a population greater than 20,000 according to the latest available census. It is worth noting that this threshold is based on the dynamic count of current census data rather than an underlying list of static 3-digit zips that are not permitted. This approach is consistent with our recommendation of basing age constraints on current population counts rather than on a static age threshold.

Our recommendation for raising the age-constraining threshold above 90 years is ultimately predicated on the assumption that population counts that combine age with other variables permitted by Safe Harbor would be at least as great as they were at the time HIPAA was enacted. For example, in 3-digit zips with populations above 20,000, we would assume that the count of individuals aged 93 years exceeds the corresponding count from 1990.

Future State

With the release of a new census every 10 years, one may perform an analysis of this sort and provide updated recommendations. It is important, however, to consider the implications of making such updates over time. One consequence of decennial updates is that a reader of the data set must be aware of the age threshold that was used in order to properly analyze the data. Even as age thresholds are likely to increase over time, some health data sources will be late to adopt due to operational constraints. However, in the event that the age threshold decreased, data sources would be required to modify their age-binning procedures.

The emergence of privacy-preserving technology has enabled aggregate-level counts to be computed with statistical privacy guarantees [9,10]. When using counts that were computed through a privacy-preserving method that may alter the true count value, one must understand the quantitative framework used in the computation and modify the methodology accordingly. For example, when using a population count to derive an age-constrained value, one might use the lower end of a 1-sided 99% CI associated with the purported population count.

Due to these technology considerations, special care will be needed when using population counts from the 2020 census. In 2020, population counts were computed using differential privacy [11], which introduces an element of variance into the results. In larger geographic regions, the reported population count of a group with a given combination of variables such as...
Further Considerations

It is routine for personal identifiable information to be replaced by a pseudorandom key that serves as a patient ID, enabling data sets to be linked without exposing an individual’s personal identifiable information. Such linking facilitates the creation of longitudinal data sets, which introduce additional considerations into privacy risk assessment.

For certain fields of a transient nature, such as state of residence or disease diagnosis, the presence of new values over time may enable an attacker to more effectively triangulate a patient’s information, elevating the risk of reidentification. A similar phenomenon can occur with a maximum age cutoff: if a data set from 5 years ago shows an individual to be 89 years old, yet a current data set shows the same individual (as identified by the same “linking token”) to be 90 years old, it is simple enough to deduce that they are actually 94 years old but have been constrained to 90 years.

Another consideration is that changes to the threshold pose a challenge for naive patient matching strategies that may use age or year of birth value as a component of a patient ID used to match patients across data sets (for example, using year of birth in combination with a hash of first name, last name, and address). It is advisable to instead include a patient’s actual (nonbinned) year of birth as part of the hashing input.

In practice, the only instance where current census data are referenced in HIPAA’s Safe Harbor criteria is the list of regions determined by the first 3 digits of a zip code. Any such region with a population under 20,000 is deemed to pose an unacceptable reidentification risk and is not permitted to be part of a Safe Harbor data set [15]. Any change to the Safe Harbor criteria, such as a dynamic age-constraining threshold, would need to come from the US Department of Health and Human Services.

Conclusion

Age is a critical variable when it comes to health data. While having a maximum age threshold is valuable for protecting patient privacy, such a threshold limits the granularity of insights into patient outcomes for the older population. Therefore, the threshold should be increased to the extent that it is possible to do so while staying below HIPAA’s original level of permitted risk.

The decennial release of updated demographic statistics is a sensible time to reevaluate accepted thresholds for variable constraints such as age. When using the census as a reference, thoughtful consideration must be given to both biases in the data collection as well as the use of privacy-preserving technologies.

Acknowledgments

The authors would like to thank Daniel Barth-Jones for his review and helpful insight around regulatory considerations and the use of differential privacy in the census.

Abstract

Background: A growing number of mobile health (mHealth) technologies are being developed to support HIV preexposure prophylaxis (PrEP) adherence and persistence; however, most tools have focused on men who have sex with men (MSM), and few are available in Spanish. To maximize the potential impact of these tools in reducing gender and racial/ethnic disparities and promoting health equity, mHealth tools tailored to Spanish-speaking people and transgender women are critically needed.

Objective: The aim of this study is to adapt and tailor 2 mHealth technologies, PrEPmate and DOT Diary, to support daily PrEP adherence and persistence among Spanish-speaking MSM and English- and Spanish-speaking transgender women and to evaluate the feasibility and acceptability of these tools.

Methods: PrEPmate, an interactive, bidirectional, text messaging intervention that promotes personalized communication between PrEP users and providers, and DOT Diary, a mobile app that promotes self-management of PrEP use and sexual health through an integrated electronic pill-taking and sexual activity diary, were previously developed for English-speaking MSM. We conducted 3 focus groups with 15 English- and Spanish-speaking transgender women and MSM in San Francisco and Miami to culturally tailor these tools for these priority populations. We then conducted a 1-month technical pilot among 21 participants to assess the usability and acceptability of the adapted interventions and optimize the functionality of these tools.

Results: Participants in focus groups liked the “human touch” of text messages in PrEPmate and thought it would be helpful for scheduling appointments and asking questions. They liked the daily reminder messages, especially the fun facts, gender affirmations, and transgender history topics. Participants recommended changes to tailor the language and messages for Spanish-speaking and transgender populations. For DOT Diary, participants liked the adherence tracking and protection level feedback and thought the calendar functions were easy to use. Based on participant recommendations, we tailored language within the app for Spanish-speaking MSM and transgender women, simplified the sexual diary, and added motivational badges. In the technical pilot of the refined tools, mean System Usability Scale scores were 81.2/100 for PrEPmate and 76.4/100 for DOT Diary (P=.48), falling in the “good” to “excellent” range, and mean Client Satisfaction Questionnaire scores were 28.6 and 28.3 for
PrEPmate and DOT Diary, respectively (maximum possible score=32). Use of both tools was high over the 1-month pilot (average of 10.5 messages received from each participant for PrEPmate; average of 17.6 times accessing the DOT Diary app), indicating good feasibility for both tools.

Conclusions: Using a user-centered design approach, we culturally tailored PrEPmate and DOT Diary to support daily PrEP use among Spanish-speaking MSM and English- and Spanish-speaking transgender women. Our positive findings in a technical pilot support further testing of these mHealth interventions in an upcoming comparative effectiveness trial.

Introduction
Preexposure prophylaxis (PrEP) with a daily pill of Truvada (tenofovir disoproxil fumarate/emtricitabine) [1-6] or Descovy (tenofovir alafenamide/emtricitabine) [7] has demonstrated high efficacy for HIV prevention, and these are the most commonly prescribed PrEP regimens in the United States [8]. Although more people are initiating PrEP nationally each year [9], retention in PrEP care has been poor. In clinical practice, 37% to 62% of patients discontinue PrEP by 6 months [10-13], with higher discontinuations among people of color [4,14-16], youths [15,17], and the publicly insured (Medicaid) [18]. Reasons for discontinuation include low self-perceived risk, difficulty taking a daily pill, and cost or insurance lapses [17,19,20]. As many individuals who stop PrEP continue to be exposed to HIV, with a number of seroconversions occurring after PrEP discontinuation [10,13,19,21-23], the lack of PrEP persistence has emerged as one of the critical challenges in PrEP implementation [24]. Strategies to support ongoing PrEP use are critically needed to address HIV disparities and maximize the public health impact of PrEP.

Mobile technologies are increasingly being used to support preventive health behaviors [25-29]. Sexual and gender minority individuals may particularly benefit from mobile health (mHealth) interventions that can increase health-related communication and care access and help address stigma to reduce health disparities. Our team has developed 2 innovative mHealth strategies to support PrEP retention in care and adherence among gay, bisexual, and other men who have sex with men (MSM). First, PrEPmate is an interactive, bidirectional, text messaging intervention between PrEP users and their providers that supports PrEP use through its personalized communication component [30]. In 2016, we completed a randomized control trial and demonstrated increased retention in care and PrEP adherence among young MSM in Chicago [31]. Second, DOT Diary is a mobile app that promotes self-management of PrEP use and sexual health through an integrated electronic pill-taking and sex diary that delivers real-time feedback on the level of PrEP protection. The app includes a sexual risk calculator that provides personalized feedback on the overall level of HIV risk on and off PrEP and gamification components to increase app engagement. In 2018, we completed a pilot clinical trial evaluating DOT Diary among young MSM, demonstrating higher levels of feasibility, acceptability, and adherence [32].

Although each mHealth approach has demonstrated high acceptability or preliminary impact in clinical trials, these technologies were originally developed for English-speaking MSM. In the United States, Hispanic/Latino people are disproportionately affected by HIV, accounting for 29% of new diagnoses in 2021 [33], and there is currently a gap in access to HIV prevention interventions tailored for Spanish-speaking populations. To prepare for broad-scale implementation, these mHealth tools need to be tailored to Spanish-speaking MSM and English- and Spanish speaking transgender women, 2 populations who are at risk for HIV acquisition and could benefit from additional PrEP support. In this study, we conducted a user-centered design study to elicit preferences to tailor both interventions to support daily PrEP use among Spanish-speaking MSM and English- and Spanish-speaking transgender women in the United States. We then built English and Spanish versions of PrEPmate and DOT Diary into scalable technology platforms and conducted a technical pilot to optimize functionality of both mobile tools. This work was conducted in 2 geographically diverse sites in the United States.

Methods

Study Population
Eligible participants were cisgender men or transgender women who were aged 18 years or older, were HIV-negative by self-report, were currently taking PrEP or discontinued PrEP within the past year, owned a smartphone, were willing and able to receive SMS text messages and download the DOT Diary app to their phone (technical pilot only), spoke Spanish (for Spanish focus groups, technical pilot) or English (for English focus groups, technical pilot), and were willing to turn on their video during the focus group (for virtual focus groups).

Participants were recruited across 2 locations/sites: the San Francisco Bay Area in California (Bridge HIV within the San Francisco Department of Public Health) and the greater Miami area in Florida (University of Miami). Recruitment methods included clinic-based recruitment; online and social media strategies (eg, Facebook, Instagram, Craigslist, Grindr, Scruff); distributing posters, flyers, and palm cards advertising the study; and direct outreach at local venues, including community-based organizations and community events. Additionally, we recruited
from former study participants who consented to be contacted about future research.

**Interventions**

Development and prior testing of PrEPmate and DOT Diary in English-speaking MSM have been described previously [31,34-35]. Briefly, PrEPmate is a text messaging–based intervention grounded in the information, motivation, behavioral skills theory of behavior change [36]. PrEPmate promotes personalized communication between patients and clinic staff through interactive weekly “check-in” messages asking participants how PrEP is going, allowing staff to identify patients needing more help in taking PrEP, and customized daily pill-taking reminder messages [30]. Additionally, the platform provides daily pill-taking reminders in the form of fun facts, affirmations, quotes, and jokes and supports 2-way communication between patients and PrEP navigators, including reminders for upcoming clinic visits. As part of onboarding, participants are provided links to key information about PrEP (PrEP Basics) [37] and video testimonials of peers taking PrEP.

Dot Diary is a mobile phone app that integrates an electronic pill-taking and sex diary and delivers real-time feedback on PrEP protection. Using the self-management model [38] to increase self-efficacy and patient empowerment, participants log daily PrEP pill-taking and sexual behaviors in the app, which then provides real-time feedback on the level of protection achieved from PrEP (high, medium, low) and customized instructions on doses of PrEP needed to achieve or maintain high protection (Figure 1). Participants can also view a weekly and monthly calendar and a summary page displaying the number of doses in the past 30 days and proportion of sex acts covered by PrEP.

**Figure 1.** Screenshot of the DOT Diary app.

Prior to initiating focus groups, all content in both tools was translated into Spanish through a multistep process. First, a professional translation service was contracted to conduct the initial translation. Our study team provided the translation services with guidelines and examples of language preferred by the community. After receiving the translated text, several native Spanish-speaking research staff reviewed the translations for cultural appropriateness and sensitivity and revised the language to ensure a community-focused perspective. As there are regional differences in Spanish language colloquialism and slang, staff discussed and agreed upon language that could be more broadly acceptable and meet local community standards across different regions. To tailor content for transgender women, additional content was developed and added by research staff, including research staff who identify as transgender.

**Focus Groups for Adapting Interventions**

We conducted 3 focus groups with Spanish-speaking MSM and English- and Spanish-speaking transgender women (1 each) in San Francisco and Miami (15 participants total). Eligible participants were consented in person or online using an information sheet prior to initiation of the focus group. Focus groups were conducted using a Health Insurance Portability and Accountability Act–compliant videoconferencing program (Zoom) or in person in a private room. Using a discussion guide, we elicited preferences on intervention content (eg, tailored text messages, dosing reminders), language, layout, usability, and
functionality, first for PrEPmate, then for DOT Diary with a focus on tailoring these tools for Spanish-speaking MSM and English- and Spanish-speaking transgender women. Screenshots of the app and text message examples were shared using the share screen function in Zoom. At the end of the group, participants completed a brief postgroup questionnaire on demographics, technology use, and initial impressions of both mHealth PrEP support tools. Focus groups were led by 2 research staff members trained in qualitative methods and user-centered design principles and fluent in English or Spanish (for Spanish focus groups). Groups lasted 90 minutes to 120 minutes and were audio recorded and professionally transcribed and translated (for Spanish focus groups) verbatim.

Guided by user-centered design principles [39], we used rapid qualitative methods to analyze the focus group data [40]. After each focus group, key findings from the discussion were summarized in a debrief note. Data captured in this template were focused on information needed to refine and adapt the interventions for our priority populations. Upon receipt of transcripts from the focus groups, members of the team reviewed the transcripts and captured additional details to ensure completeness. These data were used to refine the app before the initiation of the technical pilot.

**Technical Pilot to Assess Usability and Acceptability of the Adapted Interventions**

After finalizing revisions to PrEPmate and DOT Diary, we optimized the functionality of PrEPmate and DOT Diary in a 1-month pilot among 21 MSM and transgender women daily PrEP users recruited in San Francisco and Miami. Eligible participants attended an in-person or online screening visit where they were consented in person or via Docusign and completed a baseline survey to assess demographics, sexual practices, and use of technology. Eligible participants were enrolled, randomized 1:1 to receive either PrEPmate or DOT Diary, and provided access to the intervention. Participants completed in-person or online surveys at baseline and 1-month visits and a brief qualitative exit interview on the acceptability of the intervention at the 1-month visit only. At baseline, participants responded to questions on demographics, sexual behavior, PrEP use, and mobile phone and app use. At the 1-month visit, participants completed the System Usability Scale (SUS) [41], a 10-item instrument that evaluates usability and acceptability of the interventions (scores ranging from 0 to 100), and the Client Satisfaction Questionnaire (CSQ-8) [42], an 8-item instrument that provides scores ranging from 8 to 32. We compared SUS and CSQ-8 scores according to the study arm using t tests. Participants were also asked to rate the components of both interventions, complete questions on social benefits and harm, and complete the PrEP Adherence Self-Efficacy Scale (PrEP-ASES) [43]. Participants were reimbursed US $75 for each visit completed. We evaluated app analytics (including logins to the app and use of different app components) for both interventions. Zoom audio recordings of interviews were transcribed verbatim. Interview content was summarized on a debrief template based on the interview guide, and key quotes were also extracted. Additional team members reviewed the transcript of the audio recording and compared it with the debrief report to ensure completeness, and the original interviewer reviewed and validated any changes. Content of the debrief template for each interview was added to a Microsoft Excel file to create a matrix, and rapid qualitative methods were used to analyze interview data [40]. Each participant debrief template was entered in a single row, and each column addressed different domains and feedback on different components of the interventions. Common themes in each column were then synthesized as key findings.

**Ethical Considerations**

All study procedures were approved by the University of California San Francisco Institutional Review Board (IRB# 20-30256). Focus group participants were provided an information sheet in English or Spanish describing study procedures and risk and benefits of study participation. Technical pilot participants provided written informed consent prior to initiation of study procedures. Focus group transcripts were transcribed in a way to remove any identifying information. Survey data for both phases only contained de-identified data and were coded by a subject number. A Business Associates Agreement was established with both PrEPmate and DOT Diary developers to ensure confidentiality and security of data. Focus group participants were paid US $75 for completing the focus group, and technical pilot participants were paid US $75 for completing each visit (US $150 total).

**Results**

**Findings From the Focus Groups**

Demographics of the 15 focus group participants are shown in Table 1. Mean age was 37.9 (SD 9.4) years; 9 (56%) self-identified as transgender woman, and 6 (38%) identified as cisgender men. A substantial proportion self-identified as Latino(a) or Hispanic (6/14, 43%) and reported currently taking PrEP (11/15, 73%), having health insurance (11/15, 73%), having a primary care provider (13/15, 87%), and using iOS (7/15, 47%) or Android (6/15, 40%) mobile phones.
Table 1. Sociodemographic characteristics and preliminary acceptability of DOT Diary and PrEPmate among English and Spanish-speaking men who have sex with men and transgender women focus group participants in San Francisco, California and Miami, Florida (N=15).

For PrEPmate, participants liked the “human touch” in the messaging and felt like someone cared about them, although a few participants were unclear if the messages were an automatic response from the system versus a reply from a staff member and said they were unsure if engaging with PrEPmate would lead to communicating with a person. They recommended explaining the messaging system and who would be responding to messages during the onboarding process. They also thought PrEPmate would be helpful for scheduling appointments and answering questions. Participants liked the daily pill-taking reminder messages, especially the fun facts, gender affirmations, transgender historical facts, and jokes, and thought these reminder messages would be most helpful for those who have not yet established their pill-taking routine. In general, transgender women participants liked the tone and language of the trans messages, although they commented that one message related to “two-spirit identity utilized an outdated term” and recommended removing or rephrasing this message. They also recommended adding additional trans-affirming messages and those on the history of transgender people, as well as messages providing information about COVID-19. Spanish-speaking participants suggested text messages in Spanish, such as “Una pastille al día, te puede salvar la vida” (“one pill a day can save your life”). Regarding frequency of messaging, participants suggested that a text be sent out after an initial 2-week period asking if they would like to continue receiving messages. Participants varied in their message frequency preference, including once a week, twice a week, or once every 2 weeks. Participants felt the links to PrEP facts and brief videos were helpful, particularly the video on how PrEP works in the body that was available in English and Spanish. They recommended additional videos highlighting stories and testimonials from people like them taking PrEP, which could help reduce stigma.

For DOT Diary, participants had generally positive feedback for the app and particularly liked the adherence tracking and protection level features, including the bright colors indicating protection level (red, yellow, green). They also thought the calendar view was clear and understandable and understood what the different symbols represented. Participants felt there were too many questions in the sexual diary and recommended simplifying the information being collected. One participant stated:

...say all I really want out of this, personally, would be like, you know, did I have sex on this date. And then, if it’s relevant to my risk, like maybe what types of acts I engaged in with an option to possibly put a name or more information in a notes field. But like I can see how people would look at this and felt like it was collecting too much information.

In particular, participants expressed concern that entering specific information about a partner and rating them could negatively impact the relationship. Although a participant suggested that it might be helpful if the app could track dosing of other medications, others felt that the app should just stick to reminders and information about PrEP, as adding the tracking of additional medications may overcomplicate the app. Regarding the sexual risk assessment tool component, only a few participants found this would be a helpful tool—possibly those having a larger number of sexual partners with different people on a regular basis. When asked about the sex trends and insights page, some participants felt that it looked too much like a business plan, with too many graphs and being difficult to understand; these participants recommended that the language and appearance be simplified to make it more accessible. Finally, participants appreciated the idea of earning badges:

Yeah. I like the—the way I seem them is I seem the as, you know, achievement, like, for example, Xbox. You do so many things on a particular game, you get an achievement.

This gamification acts as a motivator and affirms that a person is doing well.

Almost all participants reported that they would use PrEPmate (14/15, 93%) and DOT diary (14/15, 93%). For PrEPmate, the daily pill-taking reminder messages were considered the most useful component (13/15, 87%), and the weekly check-in messages were considered both among the most useful (6/15, 40%) and least useful (6/15, 40%) features in PrEPmate. For DOT Diary, the home screen circle indicating level of protection and the ability to track sexual partners and encounters in the diary were considered the most useful components (10/15, 67% for both), and the “badges” were considered the least useful (5/15, 33%).
Summary of Changes Made to PrEPmate and DOT Diary After Focus Groups

Refinements made to our mHealth tools based on feedback from focus groups are summarized in Table 2. For PrEPmate, we revised our onboarding messaging to clarify that, although the reminder and check-in messages were automated, an actual staff member would respond to messages sent by participants in the system. We also refined the language of trans-specific messages and messages in Spanish based on feedback from participants and added additional content to better tailor the app for these populations. Added examples of transgender affirmative messages and the history of transgender people include:

- “We resist, actively, every time we affirm ourselves.”
- “#StayAffirmed. We got this! Time for our pill of the day.”
- “For generations, South Asian hijra (trans) communities have ‘adopted’ young boys who were rejected by or fled from their biological families.”

We added messages with links to additional video content based on focus group feedback. As most participants appreciated having an initial 2 weeks of reminder messages along with weekly check-in messages, we decided to keep this messaging frequency for the technical pilot.

For DOT Diary, participants liked the core features of the app, so we kept the adherence tracking and protection level feedback intact, along with the weekly and monthly calendars summarizing dosing and sexual activity. Based on feedback that the sexual diary was too detailed, we reduced the number of questions and took out the partner rating feature, as several participants found that off-putting. To keep the app streamlined and simple, we decided against adding the ability to track other medications. We also removed the sexual risk assessment tool component of the app given the low level of interest in that feature and simplified the sex trends and insights page based on participant input. Based on participant feedback and input from our Spanish-speaking staff, we revised Spanish-language text in DOT Diary to be more culturally appropriate for sexually active MSM. For example, the phrase for “I rimmed them” was changed from “Le di un beso negro” to “Le comi el culo,” and the phrase for “I jerked them” was changed from “Le hice una paja” to “Le corri la paja.” Finally, we added a series of badges that participants could earn through use of the app, which could be viewed in a “badge collection” section, based on focus group feedback that gamification could increase engagement and dosing in the app.

Findings From the Technical Pilot

Overview

From July 2021 to August 2021, 21 participants were randomized to the DOT diary (n=11) and PrEPmate (n=10) arms: 12 (57%) in Miami and 9 (43%) in San Francisco. Table 3 describes the baseline characteristics of the technical pilot participants by study arm. Overall, mean age was 38.3 (SD 7.6) years; of the 21 participants, 12 (57%) self-identified as cisgender man, and 9 (43%) identified as transgender women; and 9 (43%) of the 21 participants tested the tools in Spanish. The majority self-identified as Latino(a) or Hispanic (17/21, 81%), had completed a college education or higher (12/19, 63%), were currently employed (13/20, 65%), lived in their own house or rented a house (17/21, 81%), and did not have a primary partner (15/20, 71%). The mean number of partners was 2.0 (SD 3.1) in the past 3 months; approximately one-half reported anal sex (10/21, 48%), use of alcohol (11/21, 52%), and any substance use (13/21, 62%) in the past 3 months. A total of 12 (12/21, 57%) participants were using PrEP for more than 12 months, and 15 (15/21, 71%) reported a very good or excellent ability to take daily PrEP during the study. Most participants (15/21, 71%) reported using the iOS mobile phone operating system, and 6 (6/21, 29%) reporting using an Android phone. Most participants had a phone contract billed monthly (15/19, 79%) and used 5 or more apps weekly (15/21, 75%). Of the 21 participants, 15 (71%) reported using apps for dating, 13 (62%) reported using apps for health, and 12 (57%) reported using apps to send reminders.

Mean SUS scores were 81.2 (SD 13.1) for PrEPmate and 76.4 (SD 12.2) for DOT diary ($P=.48$), corresponding to adjective ratings in the “good” to “excellent” range [44] (Table 4). The highest score for both mHealth tools was on the item “I thought the system was easy to use” (DOT Diary: 4.9, SD 0.4; PrEPmate: 4.8, SD 0.5). The score on the item “I found the various functions in DOT Diary/PrEPmate were well integrated” was higher for PrEPmate than for DOT diary (4.6, SD 0.7 vs 3.6, 1.4; $P=.09$).

<sup>a</sup>t test.
<sup>b</sup>Scores range from 1 (strongly disagree) to 5 (strongly agree).
<sup>c</sup>Scores range from 1 to 4.

Mean CSQ-8 scores were 28.6 (SD 4.4) for PrEPmate and 28.3 (SD 3.2) for DOT Diary (P=.87). The highest scores (3.7) were on items “Would you recommend DOT Diary/PrEPmate to a friend?”, “Did using DOT Diary/PrEPmate help you take PrEP daily?”, and “In an overall, general sense, how satisfied are you with DOT Diary/PrEPmate?” The lowest score (3.1) was on item “Did you get the kind of support you wanted from DOT Diary/PrEPmate?”

Most of the participants (60-100%) rated each of the components of DOT Diary and PrEPmate as 5 (very helpful) on a 5-point Likert scale (Figures 2 and 3). For DOT Diary, all participants rated the components “Daily reminder notification to take pill,” “Calendar view: pop-up showing protection level, dosing, and sexual activity on a given day,” and “Home screen indicating level of protection” as very helpful. For PrEPmate, all participants rated the components “Having a text messaging platform to communicate with the study team” and “Daily pill-taking reminder messages” as very helpful. Most participants reported they reviewed the PrEP Basics information (6/8, 75%), and one-half reported they watched the PrEP videos (4/8, 50%).
At the 1-month follow-up visit, the mean PrEP-ASES score was 9.4 (SD 1.6) for DOT Diary and 9.3 (SD 0.9) for PrEPmate (P=.80).

After participating in this study, most participants reported feeling good about helping others or the community (15/16, 94%), being more confident in taking PrEP (14/16, 88%), and having a better understanding of sexual behaviors and risk (14/16, 88%). One participant reported a social harm related to having trouble getting or keeping housing in the DOT diary arm.

**Feasibility of the Tools**

Among 10 participants assigned to the PrEPmate arm, 1 participant withdrew at the enrollment visit, and the remaining 9 participants responded to at least one check-in message. During their study participation, the mean total number of incoming messages sent from participants was 10.5 (range: 4 to 42), and the mean time to the first response for each weekly check-in message was 21 hours (range: 13 minutes to 67 hours). Most incoming messages from participants were in response to weekly check-ins, and some were related to scheduling appointments.

Among 11 participants assigned to the DOT Diary arm, they opened the app, on average, 17.6 (SD 21.4; range: 2-67) times, with an average duration of 2.77 (SD 3.12) minutes per session (range: 5 seconds to 9.49 minutes). Across all participants, the cumulative time spent in the app ranged from 15 seconds to 2 hours and 26.5 minutes, with an average of 34 (SD 43.8) minutes. The most frequently used functions included diary entries (mean 79.9, SD 132.2 accesses) and taking a dose (15.9, SD 21.2 accesses), whereas the least used features were the...
monthly calendar view (mean 3.7, SD 4.5 accesses) and the summary statistics page (mean 1.3, SD 2.1 accesses).

**Exit Interviews**

The follow-up exit interviews were completed by 17 participants approximately 1 month after enrollment (10 in the DOT Diary arm, 7 in the PrEPmate arm). Regarding PrEPmate, most participants found the system straightforward and easy to use and navigate. They found the onboarding process to be clear and fast, and the onboarding links were a good resource for PrEP information. Both Spanish-speaking and transgender participants reported liking the daily fun facts, affirmations, historical messages, and jokes, which were interesting and not too intrusive. The regularity of these daily messages was helpful as pill-taking reminders, as a Spanish-speaking participant said, “A very – very – very accurate reminder,” and was particularly helpful on days when participants were out of their usual routine, such as waking up late or if they were on their day off. Additionally, participants found access to a PrEP navigator helpful, as it provided reminders to get labs completed. As constructive feedback, participants said that more variety and types of messages were needed, including other topics not related to LGBTQIA+ communities, as over time, the messages “start[ed] to get a little stale,” remarked an English-speaking transgender participant. Participants suggested having more information about PrEP efficacy and the window of time they had to take their pill, as well as HIV testing and other HIV prevention strategies. Participants liked the weekly interaction and being checked on by the navigator, although some participants were still unclear whether messages were automated or coming from an actual person and suggested that this be clarified during the onboarding process, with the staff member saying, “I will occasionally reach out to you through PrEPmate.” Regarding DOT Diary, participants appreciated logging their encounters and receiving notifications, and the reminders for taking daily PrEP were especially useful, particularly for those who don’t have an established pill-taking routine. Participants also found it helpful to know their protection levels, which made them feel more confident having sexual encounters; they also liked the feature showing how many more doses were needed to reach full protection levels. Reported cons of DOT Diary included not being able to retroactively log a dose taken earlier, not seeing the little dot added to the calendar that identified an encounter, and not having reminders for an upcoming 3-month lab visit. Several participants commented on the language used in the app. A young transgender woman (age 24 years) in San Francisco felt the pop-up congratulatory message after taking a dose was a bit “cheesy,” saying “it felt like it was someone who was, like 50, trying to relate to me as a youth, which always feels weird.” A 46-year-old Spanish-speaking MSM in Miami was shocked and amused by the Spanish translation of language in the app and felt that the language was sexually empowering but also a bit taboo, while a 41-year-old English-speaking transgender woman in San Francisco found the language used to identify sex acts as “grotesque.” Several participants liked reporting their sexual encounters, saying “it’s a calendar of your sex life,” and liked seeing a visual record of their sexual encounters, as it helped them be more mindful of their sexual activity:

**It’s like a mirror right? Because it perhaps shows you in another way what your activity has been or Okay, I see that perhaps I’m more active on the weekends or anything. So, it gives you like that reflection of what our activity is.**

An MSM in Miami reported the amount of information the app requested was somewhat intrusive, although he said this was not a dealbreaker and may have found it more useful if he had more sexual partners. Several participants recommended including a function to add doses retroactively and to support on-demand or 2-1-1 PrEP dosing. Participants also wanted to be able to customize the alarm ring tone, as some of the alarm tones were low volume and difficult to hear. On the summary data page, one participant suggested adding information about the total number of sexual partners for the month. Finally, most participants found the onboarding experience easy, although 1 participant found the onboarding survey a bit tedious and another participant recommended separating questions about their male and transfemale partners.

**Discussion**

**Principal Findings**

This study describes findings from 2 phases of formative research, including focus groups and a technical pilot, to tailor 2 innovative mHealth daily PrEP support tools for Spanish-speaking MSM and English- and Spanish-speaking transgender women in the United States. In addition to translating the tools into Spanish, key adaptations informed by our formative work included culturally tailoring content and language within our interventions to our 2 priority populations (both PrEPmate and DOT Diary), clarifying that navigators will respond to text messages from participants during the onboarding process (PrEPmate), and simplifying the sexual diary and adding motivational badges to the app (DOT Diary). In a 1-month technical pilot of these tools, both PrEPmate and DOT Diary demonstrated feasibility based on use of the tools as assessed via paradata and good-to-excellent acceptability assessed via self-report.

A growing number of mHealth tools are being designed and evaluated to support PrEP uptake, adherence, and persistence [45]; however, few tools have been specifically designed or tailored for Spanish-dominant individuals in the United States. Several studies suggest that culturally adapted behavioral interventions for Latino men may outperform standard treatment, and culturally and linguistically tailored resources in Spanish to support PrEP use among MSM and transgender women could help address disparities in PrEP use in these populations [46]. Recent studies have highlighted community-centered approaches to developing these tools for Spanish-speaking populations. MacCarthy and colleagues [47] investigated strategies for improving mobile technology–based HIV prevention interventions with Latino MSM and Latina transgender women. Key findings included that requiring smartphone use could reduce participation in low-income participants; variability in participant preferences regarding personalization, frequency, and timing of text messages; recommendation for messages to be sent on the same days and at the same times to help
participants anticipate receiving information; and the importance of recognizing different language literacies and diverse countries of origin. Although the PrEPmate text-messaging intervention can be used on non-smartphones, the DOT Diary intervention does require use of a smartphone. Tracking individuals who were excluded due to not having a smartphone will be important in future studies and implementation to assess the impact of this requirement on equitable outcomes. Regarding message timing, in both PrEPmate and DOT Diary, the timing of messages can be customized and are set to be delivered at the same time each day. Cantos and colleagues [48] used the Assessment, Decision, Adaptation, Production, Topical Experts-Integration, Training, and Testing (ADAPT-ITT) framework to develop an HIV prevention mobile app to increase uptake of PrEP among Latino sexual minority men called SaludFindr. Through in-depth interviews, they found both general barriers that were common to non-Latino groups, as well as Latino-specific barriers, including lack of available clinics to provide culturally concordant care and limited availability of Spanish language information on PrEP.

Although most technology-based HIV prevention tools being developed have focused on MSM, a few mHealth interventions have been tailored specifically for transgender women. In a cross-disciplinary scoping review of mobile technology interventions to improve HIV prevention and care in transgender and gender diverse youth, Sken and Cain [49] highlighted the importance of gender affirmation as a key social determinant of health for transgender youth, and several interventions have been guided by the gender-affirmative framework [50], which centers the interactive process in which a person receives social recognition and support for their gender identity and expression. In this review, behavioral self-monitoring and access to HIV prevention services were the most frequent features across disciplines. Similarly, our DOT Diary app utilizes self-monitoring and management to promote building of a daily pill-taking routine, and content within our interventions is designed to support gender affirmation (eg, trans-specific affirmation messages in PrEPmate). In the TechStep study, Reback and colleagues [51] developed several culturally responsive technology-based interventions (text messaging, web app, and eCoaching) tailored for transgender and gender diverse youth through focus groups and consultation with youth advisory boards in the Adolescent Trials Network, which was subsequently evaluated in a 3-arm sequentially randomized HIV prevention trial. Finally, Morris and colleagues [52] tailored the individualized Texting for Adherence Building (iTAB) intervention through focus groups with transgender and nonbinary individuals and evaluated this approach alone and in combination with motivational interviewing in a large randomized controlled trial among transgender and nonbinary PrEP users. In this study, adherence outcomes as measured by drug levels were mostly similar between the arms, although self-reported adherence was higher in the iTAB + motivational interviewing group versus the iTAB alone group. Together, these studies highlight the importance of adopting a user-centered approach to tailoring mHealth interventions for our priority populations.

The next step for our mHealth tools will be to incorporate changes suggested in our technical pilot exit interviews to further tailor these tools in Spanish and for transgender women. For PrEPmate, we will refine the content and language used in the text messages based on participant feedback and augment the onboarding process to have navigators clearly describe their role in monitoring and responding to text messages. For DOT Diary, we will add a function to retroactively add a dose after the dosing period has passed and refine the language used in the app based on participant feedback. Additionally, through another study, we will adapt and tailor this app to support on-demand and 2-1-1 PrEP use among MSM (IR34MH121139). With both of these tools optimized, we will then conduct a large multisite randomized controlled trial to compare the effectiveness of PrEPmate versus DOT Diary among English- and Spanish-speaking MSM and transgender women through a study funded by the Patient-Centered Outcomes Research Institute.

Limitations

This study had several limitations. First, the number of participants enrolled in the focus groups and technical pilot was small; therefore, the pilot study was not designed to evaluate the efficacy of the interventions. In addition, due to the short duration of the pilot, longer-term feasibility and acceptability could not be evaluated, and participants were only able to test 1 of the 2 interventions. Still, formative work through focus groups and optimizing usability in a technical pilot are important steps in developing and tailoring interventions prior to evaluating their efficacy in large randomized controlled trials. Social desirability may have impacted participant responses in the focus groups and technical pilot; however, we used a computer-assisted self-interview to assess usability and acceptability, we used paradata metrics from PrEPmate and DOT Diary to objectively assess feasibility, and participants in focus groups and exit interviews were reminded that there were no right or wrong answers and were encouraged to provide honest feedback that would help us best improve the tools. Additionally, for both phases of this study, participants were enrolled in San Francisco and Miami, potentially limiting generalizability of the findings. However, both regions are in high-priority Ending the HIV Epidemic jurisdictions and have large Spanish-speaking Latinx populations, and one site is located in the South, the region accounting for over one-half of new HIV diagnoses nationally. In addition, Miami-Dade County is the metropolitan statistical area with the highest rate of new HIV diagnoses in the United States [53]. Despite these limitations, our study had several strengths, including enrolling a substantial proportion of Spanish-dominant participants and transgender women across 2 diverse sites; the user-centered approach incorporating input from our participants into the final design of our interventions; and the mixed methods approach to evaluate feasibility and acceptability in our technical pilot.

Conclusions

Using a user-centered design approach, we tailored the PrEPmate text messaging intervention and the DOT Diary mobile app to support PrEP adherence and persistence for Spanish-speaking MSM and English- and Spanish-speaking...
transgender women in the United States. Preliminary testing in a technical pilot demonstrated high acceptability and feasibility of the adapted versions of these tools and support further evaluation in an upcoming comparative effectiveness trial of PrEPmate versus DOT Diary in a large national US study.

Acknowledgments

This study was funded by a Gilead Investigator Sponsored Research grant IN-US-412-5777. TST was financed in part by the Coordenação de Aperfeiçoamento de Pessoal de Nível Superior - Brasil (CAPES) - Finance Code 001, Conselho Nacional de Desenvolvimento Científico e Tecnológico (CNPq), and Fundação de Amparo à Pesquisa do Estado do Rio de Janeiro (FAPERJ). We thank all the participants for their helpful insights and feedback in this study.

Data Availability

Survey data for the technical pilot have been uploaded to the Dryad Repository [54]. Focus group transcripts will be made available upon request.

Conflicts of Interest

AYL has received funding for investigator-sponsored research studies from Gilead Sciences and Viiv Healthcare and has led studies in which study drug has been donated by Gilead Sciences. SB has received funding for research studies from GSK. SDL has received funding for research studies from Gilead Sciences, Merck, and Janssen. TST received consulting fees from Gilead Sciences. The other authors have no conflicts of interest to disclose.

Abstract

Background: Cataract surgeries are among the most performed surgeries worldwide. A thorough patient education is essential to inform patients about the perioperative process and postoperative target results concerning the intraocular lens and objectives for visual outcomes. However, addressing all relevant aspects and questions is time-consuming. Mobile apps can facilitate this process for both patients and physicians and thus be beneficial. However, the success of such an app depends on its user friendliness and acceptance by patients.

Objective: This study aimed to evaluate the user friendliness and acceptance of a cataract surgery education app on mobile devices among patients undergoing cataract surgery, the characteristics of patients who benefit the most from app use, and the influence of the app on patient satisfaction with treatment.

Methods: All patients who underwent cataract surgery at an ophthalmological practice from August 2020 to July 2021 were invited to participate in this randomized controlled trial. Out of 493 invited patients, 297 (60.2\%) were enrolled in this study. Patients were randomized into 3 different groups. Half of the patients were offered to participate in Group 1 with use of the “Patient Journey” app. However, if they decided not to use the app, they were included in Group 2 (app denial). The other half of the patients were included in Group 3 (control) with no use of the app and with information provided conventionally. The app provided general information on the ophthalmological center, surgeons, cataract, and treatment options. Different questionnaires were used in all 3 groups to evaluate satisfaction with the perioperative process. Group 1 evaluated the app. Demographic characteristics, such as age, gender, and educational degree, were assessed.

Results: Group 1 included 77 patients (median age 69 years). Group 2 included 61 patients, and their median age was higher (median age 79 years). Group 3 included 159 patients (median age 74 years). There was no difference in satisfaction with the perioperative process and clinic between the 3 groups. Almost all app users appreciated the digital details provided for the organization and the information on the surgery. Age did not play a major role in appreciation of the app. Female patients tended to appreciate the information provided more than male patients. Patients who did not have a higher university degree experienced more benefits from the informational content of the app and were the most satisfied with the information. However, male patients and academics were in general more aware of technology and handled the app more easily.

Conclusions: The app showed high user friendliness and acceptance, and could particularly benefit specific patient groups. App users demonstrated a noninferior high satisfaction with the treatment in the ophthalmological center in comparison with patients who were informed about the surgery only conventionally.
Introduction

Changes in Health Care Toward Digitalization

Health care is currently undergoing a substantial transition due to technological progress that reshapes clinical workflows. The progress in digitalization opens the door for new ways to organize, diagnose, educate, and treat patients. In 2023, the number of smartphone end users reached almost 7 billion globally, which equals roughly 86% of the world’s population [1]. Compared to 7 years earlier, these numbers almost doubled (3.7 billion or 49.4% in 2016) [1]. Intriguingly, mobile phone–based apps can provide valuable new platforms to address patients’ and physicians’ needs. In recent years, many apps in health care were developed driven by an increasing public interest in digital health care products. In 2017 alone, 3.7 billion mobile health (mHealth) app downloads were counted worldwide [2], showing a continuous almost exponential growth over the last few years. Health apps on mobile devices, also known as mHealth apps, are global software programs that can be used by patients, health care professionals, or other care givers. In Germany, since the end of 2019, the Digital Health Care Act (Digitales Versorgungsgesetz, DVG) allows app developers to enter a process at a governmental agency to receive reimbursement for the download and use of the app from statutory health insurances. This has given another boost to the development of apps with greater and proven quality [3].

mHealth in Ophthalmology

In March 2020, a review identified 131 ophthalmology-related mobile apps, with 32% of the apps designed for visual acuity testing and screening, 13% designed for eye relaxation exercises, and 12% designed for professional training. The remaining apps included tools to detect color blindness, tools that served as low vision aids, or tools aimed to provide assistance and patient education. Strikingly, less than 5% were documented to have been tested for validity [4].

A recent review by Nagino et al [5] summarized published data on the clinical utility of 48 mobile apps in ophthalmology. Of those, 35% supported clinical ophthalmological examination, 27% intended to detect ophthalmological diseases, 20% supported medical personnel, 10% informed patients about ophthalmological diseases, and 6% were designed to encourage compliance. Only 2 apps reported significant efficacy in treating diseases [5]. An app for glaucoma treatment reminded patients to administer intraocular pressure (IOP) lowering eye drops [6]. Patients enrolled in the study showed higher adherence when being reminded by the app. The IOP lowering effect was however not significant in any of the subgroups [6]. Patients with macular diseases that required regular injections benefited in terms of visual acuity when provided with mobile hyperacutivity home monitoring via an app and discontinued treatment less often [7].

However, most health apps in ophthalmology and other disciplines still lack evidence of clinical effectiveness and thus lack the rational basis to qualify for reimbursement [8,9]. For the vast majority of apps available in digital app stores, no published scientific data or proof of efficacy is available.

On the other hand, digital apps hold great potential value for health care providers in optimizing work processes and flows. Additionally, in light of the looming physician shortage and ever-increasing patient consultations, apps can be valuable tools to offer new ways of interaction between patients and physicians and can add value by improving patient education [10].

Cataract Surgery

Cataract is a very common condition that is highly associated with aging and ultimately occurs in every individual. The initial symptoms include reduced visual acuity and increased glare sensitivity. Depending on the localization of increased opacity, cataracts can be divided into nuclear, cortical, or subcapsular cataracts. In an observational study by Klein et al [11], the cumulative incidence of nuclear cataract increased from 2.9% in persons aged 43 to 54 years at baseline to 40% in those aged 75 years or older. For cortical and posterior subcapsular cataract, the corresponding numbers were 1.9% and 21.8% and 1.4% and 7.3%, respectively. These numbers illustrate the disease burden and high number of patients experiencing the consequences of cataract. Accordingly, cataract surgery is ranked as the most common surgical procedure performed in the European union, with almost 5 million surgeries performed in 2017 alone. Multiple studies have demonstrated gains in visual function and quality of life after surgery [12-14]. The standard technique in Europe is the removal of the opacified lens by phacoemulsification and the implantation of an artificial intraocular lens (IOL). The surgery is mostly conducted under topical or peribulbar anesthesia [15,16]. In complicated cases, general anesthesia or the use of short-acting sedatives may be necessary. Although phacoemulsification was the standardized procedure for a long time, novel approaches that allow better precision in incisions and fragmentation of the lens have emerged. In this light, laser-supported phacoemulsification, such as nanosecond and femtosecond laser, promise better accuracy and less strain on the cornea without any effect on visual outcomes [17-19]. Furthermore, new developments in IOL design have led to a vast selection of different available lenses, such as multifocal or enhanced depth of focus lenses, possibly increasing quality of life [20]. With the obvious plethora of different options, patients frequently feel overwhelmed regarding the choice of the perioperative process and the targeted refraction (monofocal near or distance vision, and multifocal satisfactory near, intermediate, or distance vision). These questions and decisions possibly involve higher out-of-pocket costs for the patient as newer techniques and IOL designs are often not covered by statutory or private health insurances. Furthermore, multifocal lenses are also known to have potential negative aspects due to phenomena such as glare,
halos, and loss of contrast sensitivity. This may lead to unsatisfactory results in some patients and thus require highly accurate refractive outcomes, including limited astigmatism, in order to achieve good function and postoperative tolerance [21]. To ensure good outcomes and patient satisfaction, the treating ophthalmologist must provide sufficient information and time to the patient, provide guidance throughout the process, and carefully select patients suitable for implantation of specific lenses.

**Perioperative Journey of Patients**

As for every intervention or surgery, the patient’s journey is linked to uncertainty and a certain degree of anxiety. For fields other than ophthalmology, mHealth apps seem to be acknowledged by patients in a perioperative setting. In studies with mobile apps, patients felt more taken care of, with a clear focus on the patient’s satisfaction and health. Furthermore, the apps proved to be more cost-effective and efficient in health care services [22,23]. Likewise, a recent study was able to improve the adherence of cataract patients to postoperative management through the use of reminder messages on a mobile app, which also provided links to educational videos online [24].

However, there is no published study on patients undergoing cataract surgery who have been guided by a mobile app throughout the perioperative process as a whole. Therefore, this study aimed to assess the acceptance and satisfaction with a mobile app accompanying the patients in their cataract surgery journey. As cataract patients are mostly in the second half of their life, this investigation addresses the use of mHealth in an elderly population. Additionally, the study also addresses the question of which group of patients benefits the most from app use.

**Methods**

**Study Patients**

All patients who presented to a local ophthalmological practice center and underwent cataract surgery over a period of 1 year (August 2020 to July 2021) were offered to participate in this prospective, single-center, randomized controlled trial. Invitations to the trial were sent by mail to the patients 2 to 3 weeks prior to the pre-examination day. Invitations comprised relevant information on the trial and a consent sheet for participation and data. Out of 493 patients who received an invitation to participate, 297 (60.2%) were willing to be enrolled in this study. Over the duration of the study, of the 297 patients, 181 (60.9%) were operated on 1 eye and 116 (39.1%) were operated on both eyes. Patients who consented were randomized by even and uneven patient numbers issued by the health care information system (software) into 3 groups as follows: (1) Patients with even patient numbers were offered to participate in the interventional group (Group 1) with the use of the mobile app; (2) Patients who did not want to use the app were included in the app deny group (Group 2); (3) Patients with uneven patient numbers were included in the control group (Group 3) without access to the app. Group 1 received personal login details and information on the download and use of the app.

**App Description**

The app used in this trial was the “Patient Journey” app (Versions 4.15.0, 4.26.8, and 4.30.0; Interactive Studios). The app can be installed on all devices with iOS (Apple) and Android (Google) operating systems. The app was free for all participants.

The app uses an adjustable content management system with the possibility of own branding. The app versions used in this study had the following 4 sections: (1) General information on the ophthalmological center and surgeons along with contact information; (2) Information on appointments (surgery, and preoperative and postoperative follow-ups); (3) Information about the disease (cataract), treatment, anesthesia options, and IOL; and (4) Preoperative, perioperative, and postoperative behavioral recommendations and the medication treatment scheme (Figure 1).
In the third section, a video on cataract development, symptoms, and therapy was available. This video was almost 3 minutes long and included real ophthalmologists and patients who were interviewed in a hospital. Furthermore, pictures and text in the app provided information on IOLs, anesthetic procedures, and postoperative care. Questionnaires were included in order to find a suitable IOL and target refraction. Early preoperative instructions comprised information about necessary blood tests, the need to schedule an appointment with the anesthesiologist in the case of surgery under general anesthesia, and the prohibition to directly drive a car after the pre-examination visit owing to mydriasis. One day before the surgery, patients received information about the time, location, and course of the surgery, and in the case of general anesthesia, they received information about the necessity of preoperative fasting. On the surgery date, patients were, if needed, reminded to continue preoperative fasting and instructed about postoperative behaviors, including intake of medications, wearing of an eye patch, taking a shower, performing physical activity, and observing possible symptoms like pain or foreign body sensation. Postoperative care in the app comprised information about scheduled appointments in the practice as well as about common and warning postoperative symptoms, including their management or the necessity to schedule an additional examination. Push notifications could be set to remind the patient to apply anti-inflammatory drops or to keep the appointments.

Study organizers stayed in contact with patients from all 3 study groups on a regular basis from invitation to the study 2 to 3 weeks before the pre-examination visit until 4 to 6 weeks after the first cataract surgery and after the second cataract surgery, if performed. Patients in all study groups communicated with the practice and were informed about the surgery conventionally while attending ophthalmologist appointments or via a phone call. App users additionally received necessary information about the surgery and could schedule appointments or contact the practice over the app. Patients who could not manage to install the app on their own were offered support for the installation and set-up of the app in the practice at the pre-examination visit or via a phone call. See Multimedia Appendix 1 for a demonstration video of the cataract app.

Patient Survey

For the study, 6 different nonvalidated digital questionnaires were developed by study organizers to address the characteristics of the participating patients and their satisfaction with the app and the practice. Several validated questionnaires were taken into account for the development of these questionnaires [10,25-28]. Groups 1 and 2 had to fill out 3 questionnaires, while Group 3 had to fill out 2 questionnaires. Please change to: "All 3 groups were asked to provide answers to questions regarding satisfaction with the practice. Group 1 additionally had questionnaires that addressed the app (installation and handling), previous use of other health care apps, and the highest educational degree. Group 2 was also asked about the reasons
for denying to use the app, as well as about previous use of other health care apps and the highest educational degree. Group 3 provided answers to questions regarding previous experience with other health care apps and the highest educational degree.

All questionnaires were electronically accessible and could be completed on a webpage of the app developer Interactive Studios (Table 1). See Multimedia Appendix 2 for the questionnaires used in the study groups.

Patients who could not fill out the questionnaires online on their own were offered personal support in the practice or via a phone call. Demographic characteristics, including age, gender, and prior cataract surgery, were extracted from medical health records available in the practice. App use data of the entire cohort (Group 1) were collected by the app developer and could be accessed online by the study organizers. Individual personal data were not attainable due to data privacy.

The collected data were subjected to descriptive and quantitative analyses using IBM SPSS Statistics 27 (IBM Corp). Statistical significance was reached at $\alpha=.05$.

### Ethical Considerations

This study was approved by the Ethics Committee of Landesaerztekammer Baden-Wuerttemberg (Stuttgart, Germany; approval number: F-2021-004) as a study involving human subjects and followed the ethical considerations of the Declaration of Helsinki. All participants were thoroughly informed about the study, and if approved, they signed an informed consent form allowing research on the gained data. All obtained data were deidentified, and no images allowing reidentification of the subjects were included. Participants did not receive any monetary compensation. No generative artificial intelligence system was used in any portion for manuscript writing.

### Results

#### Demographics of the Groups

The study included 297 patients who underwent cataract surgery. Of the 297 patients, 77 (25.9%) used the app (Group 1), 61 (20.6%) did not want to use the app (Group 2), and 159 (53.5%) were included in the control group (Group 3). In all groups, more female patients were included. The median patient ages were 69, 79, and 74 years, respectively. The mean patient age was significantly higher in Group 2 than in the other 2 groups (Kruskal-Wallis test, $P<.001$). All patients were asked for their highest degree of education. In Group 1, most patients had completed a professional apprenticeship or a higher university degree. In Group 2, only 8 patients had a higher educational degree. This difference between groups approached significance (chi-square test, $P=.05$). The majority of patients had surgery on only 1 eye.

\(^a\)P value is the probability of rejecting the correct null hypothesis.
\(^b\)P value was calculated using the chi-square test.
\(^c\)P value was calculated using the nonparametric Kruskal-Wallis test.

Characteristics of Group 2 (App Denial)
Patients who dismissed the app were asked for their reasons. Most (41/61, 67%) answered that they were missing a suitable device. Moreover, 9 patients reported no interest or a lack of technological competence for the use of the app. Two patients mentioned insufficient vision. Most (49/52, 94%) of the patients in this group had no previous experience with health care apps. Group 3 had a relatively high percentage of patients (23/141, 16.3%) who had previous experience. Moreover, in Group 1, 26% (20/77) of patients already had an experience with health apps (chi-square test, \(P=.01\)).

Patient Satisfaction With the Ophthalmological Center During Cataract Surgery
After 4 to 6 weeks, patient satisfaction with the ophthalmological center where they had their surgery was evaluated in all groups (Table 3). In Group 1, 65% (46/71) were very satisfied, 34% (24/71) were fairly satisfied, and 1% (1/71) were unsatisfied. Similar responses were provided in the other 2 groups. In Group 2, 67% (40/60) were very satisfied and 32% (19/60) were fairly satisfied. In Group 3, 66.9% (105/157) were very satisfied and 31.2% (49/157) were fairly satisfied.
### Table 3. Comparison of groups regarding satisfaction with the center and possible areas for improvement within the ophthalmological center.

<sup>a</sup> P value was calculated using the chi-square test.

Most patients felt counseled and informed comprehensibly (Group 1: 70/73, 95.9%; Group 2: 57/59, 96.6%; Group 3: 148/158, 93.7%) and in detail (Group 1: 70/73, 95.9%; Group 2: 57/59, 96.6%; Group 3: 150/157, 95.5%). Over 90% of patients in all groups completely agreed or agreed in this matter (Table 3). The vast majority (Group 1: 67/73, 91.8%; Group 2: 57/59, 96.6%; Group 3: 155/158, 98.1%) also felt friendly and attentively treated. There was no significant difference in the response to the questions between the 3 groups (chi-square test, P>.05). Overall, in Group 1, patients were significantly more satisfied with the ophthalmological center when they felt extensively (chi-square test, P=.02) and comprehensibly (chi-square test, P=.006) counseled. The same was true for patients in Group 1 who agreed completely to the statement that they were friendly and respectfully treated (P=.001).

Additionally, patients were asked for areas of possible improvement of the center. Overall, in all groups, roughly 40% (Group 1: 31/76, 40.8%; Group 2: 24/65, 36.9%; Group 3: 72/165, 43.6%) had no complaint (multiple answers were possible). In Groups 2 and 3, 35.4% (23/65) and 31.1% (51/165), respectively, mentioned the center’s organization (multiple answers were possible). In Group 1, the percentage was smaller at 26% (20/76). More patients complained about insufficient communication (multiple answers were possible) in Group 1 (9/76, 11.8%) than in Groups 2 and 3 (3/65, 4.6% and 5/165, 3.0%, respectively; Table 3). More patients mentioned a lack of counseling and information in the center (multiple answers were possible) in Group 2 (7/65, 10.8%) than in Groups 1 and 3 (5/76, 6.6% and 10/165, 6.1%, respectively; Table 3). There were no significant differences between groups.

### Results in Group 1 (App Use)

#### Communication Forms

To ascertain the acceptability of this mode of communication, patients were inquired about their willingness to communicate exclusively through the app. Surprisingly, none of the patients expressed agreement for an exclusively digital communication channel. A significant majority (60/77, 78%) of respondents expressed a preference for a hybrid communication mode, involving both the app and traditional telephone channels. An interesting gender-based trend was observed, with men showing a slightly higher inclination toward this hybrid mode (chi-square test, P=.08). A minority (67/77, 8%) of respondents expressed an exclusive preference for the app. Meanwhile, 14% (11/77)
of participants expressed a leaning toward solely using the telephone for communication.

**Software Installation on the Mobile Device**

The vast majority (59/73, 81%) of patients in Group 1 handled the process of installation very well. Only 5 (7%) patients saw it as a burden and described the installation process as troublesome. However, half (38/77, 49%) of the patients needed support to install the app. Significantly more male patients (chi-square test, $P=.03$) and people with a higher degree of education at a university (chi-square test, $P=.004$) were able to install the app without external help.

Android was the most prevalent operating system (54/77, 70%). The app was used 50 days on average, and the average use time was 6 minutes 44 seconds per session. The most read articles concerned the type of IOL that can be inserted (312 views) and the postoperative recommendation on patient’s behavior (275 views). Information on the practicing doctors (264 views), the process of surgery preparation (243 views), and the recommendations for this appointment (205 views) were also of interest. The description of technical diagnostic examinations was of less interest (less than 5 views).

**Satisfaction With the App**

Participants in Group 1 were asked 1 week postoperatively about the overall experience with the app. In general, the users were very satisfied with the experience (very pleased: 37/77, 48%; pleased: 35/77, 46%). Only 3 (4%) patients were unpleased and none of the patients were very unpleased (Figure 2). There was no difference in satisfaction for patients aged under 70 years, those aged between 70 and 80 years, and those aged 80 years or above. The appreciation for the app 1 week postoperatively was greater among patients with a previous vocational education than among patients with a university degree (chi-square test, $P=.07$).

**Figure 2.** Responses of participants in Group 1 (app use; n=77) regarding app satisfaction after 7 days postoperatively with respect to overall satisfaction, handling, understanding, abbreviations and orientation throughout the perioperative process.

![Figure 2](https://formative.jmir.org/2024/1/e55742/figure2.png)

Most patients also agreed that the handling of the app was pleasing (73/77, 95%), and texts and abbreviations were easy to understand (76/77, 99% and 69/77, 90%, respectively). The vast majority (70/77, 91%) also agreed with the statement that the app provides orientation throughout the perioperative process (Figure 2). Patients who received support for the installation were more satisfied with the app within the first 7 postoperative days (chi-square test, $P=.003$).

**Informational Content of the App**

Patients were also asked about the content provided in the app. Almost all respondents stated that the app is clearly phrased (74/77, 96%), provides sufficient data (68/77, 88%), and provides easy access (67/77, 87%) (Figure 3). Over 90% also agreed that the content is trustworthy (71/77, 92%) and useful (72/77, 94%) during the perioperative process. Patients with a lower degree of education found the content significantly more useful (chi-square test, $P=.04$). Women tended to find the content more useful (chi-square test, $P=.08$). There was no variation in content appreciation across different age groups.
Figure 3. Responses of participants in Group 1 (app use; n=77) regarding app content with respect to clarity, extent, access, trustworthiness, and usefulness.

**Design of the App**

Patients were also queried regarding the design of the app. Satisfaction with the graphical representations was expressed by 90% (69/77) of patients. A predominant proportion (74/77, 96%) of patients concurred that the textual layout was easily legible. A substantial majority (69/77, 90%) affirmed the clarity in content presentation (Figure 4). No significant variations were observed based on age group or gender.

Figure 4. Responses of participants in Group 1 (app use; n=77) regarding graphics, text, and clear presentation of the content in the app.
Re-evaluation After 4 to 6 Weeks and Final Suggestions on the Patient’s Journey

Four to six weeks after surgery, patients were asked if the app helped in the whole process. We found that 80% (58/73) of patients stated that the app was helpful. Approximately 20% thought that the app was less helpful (10/73, 14%) or not helpful (1/73, 6%). Patients who had previously used a health app did not appreciate the app significantly more (chi-square test, \( P = .77 \)), but those who had installed the app with help were significantly more satisfied with it (chi-square test, \( P = .02 \)). After 4 to 6 weeks, a higher proportion of female patients expressed appreciation for the app compared to male patients, though the difference was not statistically significant (chi-square test, \( P = .12 \)). Patients with a high degree of satisfaction with the ophthalmological center tended to be more satisfied with the app throughout the cataract surgery journey (chi-square test, \( P = .13 \)). Patients with a lower degree of educational training reported significantly higher satisfaction with the app (chi-square test, \( P = .04 \)), while patients with a university degree reported less satisfaction (chi-square test, \( P = .01 \)).

There were 11 unsatisfied participants, and they were asked why they did not approve of the app. Multiple responses were possible. Five respondents declared that the app did not provide new information. Four mentioned ill functioning of the app or misleading information. Three agreed that the push notifications were disturbing. One patient favored personal contact with a physician.

These respondents were also asked how to improve the app and make it more helpful. Multiple answers were again possible. Four respondents suggested an improvement in the design. Three wanted more personalized functioning of the app, for example, regarding the push notifications. Only 2 proposed an improvement of the informational content and text. Three patients did not provide any suggestions.

Patients who agreed that the app was helpful were also asked how they would improve the app. Eight respondents thought that personalization of the app would be helpful. This mainly concerns the setting of notifications. Four patients desired an improvement of appointment scheduling. Three respondents addressed concerns regarding the font size and contrast of the font and background. Two desired an improvement of the content of the text, and one desired a desktop version of the app.

Discussion

Principal Findings

In this study, 297 patients who underwent cataract surgery were enrolled, and 3 different groups were established. An adaptable mobile app was used by 77 patients in Group 1 for at least 2 weeks prior to the pre-examination day and for 4 to 6 weeks after surgery. Group 2 included patients who denied use of the app, and Group 3 included control patients.

In our study, almost all patients who used the app reported good user friendliness and appreciated the digital data provided for the organization, and the scheduling and information of the surgery. Age did not play a major role in the appreciation of the app when agreeing to use the app, although patients in Group 2 were significantly older. Patients who did not have a higher university degree had the most benefits from the informational content of the app and were the most satisfied with the information. Female patients tended to appreciate the information provided more than male patients. However, male individuals and academics are in general more aware of technology and can handle the app more easily. Nevertheless, other individuals can benefit from the use of the app throughout the cataract surgery journey. App users demonstrated a noninferior high satisfaction with the treatment in comparison with patients who were only conventionally informed about the surgery.

Satisfaction With the Ophthalmological Center

Among all groups, most respondents in this study were very satisfied with the organization and the ophthalmological center where they underwent the surgery. This is in line with the findings of most other studies on the perioperative satisfaction of patients [29-31]. In these studies, outpatients were very content with the information provided, the politeness, the surgical results, and the professional competence.

Cataract Surgery Satisfaction With a Focus on the Information or Content Provided

In our study, almost all enrolled patients felt well informed during the perioperative process, and there was no significant difference between the 3 study groups. Multiple other studies have confirmed that during the process of a surgical intervention, the degree of information provided is a significant predictive factor of satisfaction [31]. For cataract surgery, preoperative information supplied by a video or other digital content can improve knowledge among patients. The app used in our study included such a video. Pager [32] demonstrated in a randomized controlled trial that preoperative display of a video on the phacoemulsification procedure significantly increases patient understanding of and satisfaction with the cataract surgery while decreasing unease. Patients showed these results independent of past cataract surgery and notwithstanding that, in general, patients stated they had already obtained sufficient information beforehand [32]. Another study showed that information levels were higher in patient groups that received additional information from digital animated videos [33]. However, these videos as well as other information should be thoroughly selected by the ophthalmological center as digital or social media information, such as that on YouTube, might be misleading [34].

Consideration of Age and Gender in the Use of Digital Devices

In this study, the average age of participating respondents was unsurprisingly high, with a median age of 69 years in Group 1, 79 years in Group 2, and 74 years in Group 3. Age seemed to play no obvious role in Group 1, which was the interventional user group. No evidence was found that age influenced the use of the app or satisfaction with the app. However, patient age in Group 2 (app denial) was significantly higher, indicating that older patients might be hesitant to use digital devices. Male
patients tend to be more aware of technology than female patients, and a higher educational background favors easier handling of the app. Another study demonstrated that male elderly people had more ease with the use of the internet and digital devices [35]. This is also true for the use of medical apps. Elderly females seem to be more difficult to reach with these innovative new technologies than males [36]. Perceived serenity and a sense of control while using the app, personal innovativeness, self-perceived effectiveness, and service possibilities were aiding factors to animate mHealth use among elderly communities [36,37].

**mHealth and Higher Educational Background**

This study showed that patients with a lower degree of educational training appreciated the content of the app more than those with an academic degree. Patients who do not screen the internet beforehand for consistent information might benefit more, as general understanding and basic knowledge are lower. Studies have evaluated mHealth in diverse ethnic and educational groups, as well as in older and low-income groups. The results showed that mobile devices might be the preferred method of collecting health information from these groups [38]. Patients from low-income backgrounds appreciate the use of mHealth technology to both manage chronic diseases and overall health. As educational and socioeconomic gaps strongly correlate with higher rates of chronic conditions, such as obesity, diabetes, and hypertension, in these communities, mHealth can prove to be an asset [39]. Apps can provide a low threshold source of information and empower people in these communities to improve health outcomes.

**Economic Perspective on mHealth**

The willingness to use a mobile phone and the readiness of a mobile phone are prerequisites for establishing mHealth in clinical practice. The use of mHealth should also benefit and facilitate workflows within medical centers. If the physician’s time invested in the patient’s education on the disease and surgical interventions can be reduced while keeping the knowledge and satisfaction levels high, the center can gain in terms of workflow effectiveness. However, integration in the work process of a clinic can be troublesome, and it has been proven to be a burden for both health care professionals and consumers [3,40]. Development of the cataract education app was encouraged by the desire to reduce the number of common questions raised by patients as well as include additional information so that patients’ visits to the ophthalmologist would be optimized without loss of quality and satisfaction. In this study, patients received all relevant information material concerning the app by mail, could download the app, and could inform themselves about the surgery prior to the appointment for surgery pre-examination. Study organizers believe that this might have helped to reduce the time needed for explanation about the app and the surgery for app users. On the other hand, the time needed might have increased for other patients who did not have prior experience with such health care apps before and needed support for the app setup or standard consultation about the surgery. However, patient consultations could have been more efficient once the app was installed and patients could attend postoperative examinations after being informed over the app. Additional human resources were needed for the preparation and adaptation of the informational content of the app and information about the app, as well as for periodic review of the arrangements of patient appointments and entry into the app database. In the future, complete integration of the app within the software of the ophthalmological center should be pursued, so that all relevant data could be synchronized automatically. The employees of the practice also needed educational courses and an adaptation period in order to learn about the content of the app and be able to support patients with app use. Study organizers found this process to be uncomplicated for employees who owned smartphones and had prior experience with other apps and to be time-consuming for others. Patients in this study were reluctant to shift the communication and scheduling of the ophthalmological center to a solely digital mode. However, from the health economics perspective, mHealth has already been demonstrated to be a valuable and effective tool in health care systems and environments with limited resources [41,42]. We believe that short time investments in the development of the app, preparation of information material, and education of employees can provide long-term benefits for the optimization of workflow in the ophthalmological center.

**Limitations**

The limitations of this study include the inclusion of patients from a single outpatient health care center, analysis of the app for a single disease treatment, and testing of the app solely in elderly patients. The allocation within this clinical study was not blinded; therefore, the outcome ascertainment might have been influenced by the knowledge of this allocation and furthermore might be evident in the median age of the groups investigated. The study was also limited by the fact that the education of app users was not limited to a solely digital form via the app as they also received conventional information.

**Conclusion**

Mobile apps with high user friendliness have the capacity to increase patient knowledge, ensure satisfaction with the treatment, and improve workflows; however, they still face challenges regarding clinical effectiveness, lack of integration in health care delivery, and further validation processes in safety and privacy [9,10]. Further analysis and large multicenter prospective clinical trials are needed to show areas for improvement, prove the potential benefits of apps, and identify specific patient groups that could benefit the most from app use. Future studies could also investigate if apps help to optimize patient management while reducing the duration of consultation, including surveying medical professionals about their experiences with patients using apps. Furthermore, we recommend further developments to synchronize apps with the software of health care centers in order to optimize management and increase the usability of apps.

Abstract

Background: It was only upon the occurrence of the COVID-19 pandemic that the demand for web-based consultations with physicians grew at unprecedented rates. To meet the demand, the service environment developed rapidly during the pandemic.

Objective: This study aimed to identify the current status of the use of web-based consultations with physicians among young and middle-aged Chinese individuals and explore users' perspectives on key factors that influence its use in terms of optimizing benefits and compensating for disadvantages.

Methods: We conducted semistructured interviews with 65 individuals (aged 18 to 60 years) across China between September and October 2022. The interviewees were selected through snowball sampling. They described their experiences of using web-based physician consultations and the reasons for using or not using the service. Based on the Andersen Behavioral Model, a qualitative comparative analysis was used to analyze the factors associated with the use of web-based physician consultations and explore the combinations of these factors.

Results: In all, 31 (48%) of the 65 interviewees used web-based consultation services. The singular necessary condition analysis revealed that the complementary role of the service and perceived convenience are necessary conditions for the use of web-based consultation services, and user’s confidence in the service was a sufficient condition. Based on the Andersen Behavioral Model, the configuration analysis uncovered 2 interpretation models: an enabling-oriented model and a need-oriented model. The basic combination of the enabling-oriented model included income and perceived convenience. The basic combination of the need-oriented model included complementary role and user’s confidence.

Conclusions: Among the factors associated with the use of web-based consultations, perceived convenience, complementary role, and user’s confidence were essential factors. Clear instructions on the conduct of the service, cost regulations, provider qualifications guarantee, privacy and safety supervision, the consultations’ application in chronic disease management settings, and subsequent visits can promote the positive development of web-based consultations.

web-based consultation; Andersen Behavioral Model; qualitative comparative analysis; perceived convenience; complementary role; user's confidence; China
Introduction

The term “internet health care service” refers to a closed-loop service that includes health education, medical information inquiry, electronic health files, disease risk assessment, web-based consultation with physicians, electronic prescription, remote consultation, and remote treatment and rehabilitation via the internet and other technological means [1].

The COVID-19 pandemic created a demand for internet health care services at an unprecedented rate [2-4], as patients became reluctant to go to hospitals because of the fear of infection [5,6]. Accordingly, an increasing number of hospitals and internet companies started to, and continue to, venture into the internet health care industry. Reports show that 52% of outpatient departments in Germany have already adopted internet health care services [7]. By June 2022, more than 1700 hospitals in China were providing services using the internet, an increase from 100 in December 2018 [8].

These rapid changes and the quick adoption of internet health care services during the pandemic, however, have impeded the possibility of sufficient analyses on the experience of accessing these services and on how providers can complement the functions of these services to make them more accessible and attractive to users, as well as promote patients’ intention to use the service.

In this study, we only focus on web-based consultations with physicians, which is a core and controversial segment of internet health care services. Some researchers have studied the barriers to and facilitators of web-based consultations and found that perceived convenience, emotional preference, perceived risks, etc, influence behavioral intention [9,10].

However, factors associated with the use of web-based consultations are mixed. Understanding which factors are essential is conducive to optimizing benefits and compensating for disadvantages. Given that young (18-35 years) and middle-aged (35-60 years) individuals are the groups that use web-based consultations the most frequently, we conducted interviews among them to explore the reasons why web-based consultations are used or not used. Then, based on the Andersen Behavioral Model, we applied a qualitative comparative analysis (QCA) approach to analyze evidence from the interviews, to identify how combinations of these interdependent factors lead to the use of web-based consultations with physicians.

Methods

Theoretical Background

The Andersen Behavioral Model, developed by Andersen [11] in 1968, has been widely used to analyze the factors associated with health service use based on 3 dimensions: predisposing, enabling, and need factors [12-14]. Based on the Andersen Behavioral Model, this study also discussed the factors affecting web-based consultations with physicians in China.

QCA Methodology

The use of web-based consultation has complex influences rather than a single effect. QCA has been applied to explore the different combinations of health care interventions because it bridges qualitative and quantitative methodologies [15]. Based on set theory, QCA compares characteristics of the cases in relation to the outcomes by a scoring system. Moreover, QCA has an advantage in analyzing small samples, which usually requires 10 to 80 cases [16,17]. Crisp-set QCA (csQCA) yields binary scores of 0 and 1, indicating “full out” or “full in” in certain conditions [18].

Sample Selection and Data Collection

The semistructured interviews were centered around three broad questions: (1) Do you have experience using internet health care services? (2) If yes, which function do you use and why do you use it? Which function do you never use and why are you reluctant to use it? and (3) If no, why do you never use internet health care services? When describing their experiences, the participants were asked to share examples and not only feelings about internet health care services.

We conducted interviews with residents of provinces in Eastern, Western, and Central China between September and October 2022.

The initial 5 samples were selected by convenience, and they were patients visiting the China-Japan Friendship Hospital. Subsequently, we asked them to recommend 1 or 2 interviewees, such as their friends, colleagues, or relatives, randomly. We repeated this process until the information on why internet health care services were or were not used was saturated. To obtain representative samples, we analyzed the characteristics of former samples and provided detailed requirements with regard to age, location, income, education, and sex for the following samples.

In total, 70 participants were interviewed, and 5 interviews were excluded owing to a lack of information regarding web-based consultations with physicians. The sample size for QCA should be at least $2^k$, where $k$ is the number of conditions [17,19]. The study includes 6 conditions; hence, the sample size should be at least 64. Ultimately, the study included 65 interviews.

Variable Measurement and Calibration

We analyzed the transcripts using a team-based inductive approach. First, the audio data were transcribed verbatim by a third-party company specialized in transcriptions in the Chinese language; once transcribed, the audio recordings were subsequently discarded to protect the participants’ confidentiality. Second, the first round of open coding was conducted using NVivo 12 (QSR International), and we coded the transcripts independently. We discussed and resolved discrepancies and then recoded the data to compile the major themes. Finally, based on the Andersen Behavioral Model, both the conditions and the results were identified by the lead author, reviewed by coauthors, and finalized by the corresponding author (see Table 1). In this study, csQCA was conducted using a program for crisp and fuzzy set with the fsQCA3.0 package (Charles C Ragin and Sean Davey).

**Ethical Considerations**

This study was approved by the China-Japan Friendship Hospital (approval 202-ky-032). We asked the participants whether they would be willing to be interviewed over the phone. Once the participants confirmed that they were interested in participating in the study, we made an appointment with them before the interview. At the beginning of the interview, we reviewed a consent form with the participants and obtained their verbal consent to proceed. Interviews were conducted primarily through phone calls because we aimed to reach more residents from different regions across China. All interviews were recorded and transcribed verbatim for data analysis. No compensation was provided for participation.

**Results**

**Participants’ Characteristics**

Participants were recruited from the provinces of Beijing, Shanghai, Guangdong, and Zhejiang in Eastern China (31/65, 48%); Jilin, Henan, and Jiangxi in Central China (14/65, 22%); and Sichuan, Yunan, and Qinghai in Western China (20/65, 31%). In total, 38% (25/65) of the participants were male and 62% (40/65) were female, and the participants’ average age was 35.4 (range 18-51) years (Table 2).
Participants’ Experiences of Web-Based Consultations

In total, 31 (48%) out of 65 participants had experience consulting with physicians over the web. During the COVID-19 pandemic, web-based consultations allowed people to avoid going out and minimized the risk of infection. Although web-based consultations were not always feasible with regard to curing diseases, the participants used them as a prediagnosis tool, which helped them make appropriate decisions regarding what to do next about their potential condition. Participant 1 shared his web-based consultation experience with us:

*My wife was suffering from gallstones. We paid for an appointment with a famous physician to receive advice on the need for surgery. After uploading the results of an exam and consulting with the physician through the internet, we accepted his suggestion and she underwent an operation.*

Factors Explaining the Use of Web-Based Consultations With Physicians

*Necessity Analysis of Individual Conditions*

The first step of QCA is to examine whether a single condition (including its noncollection) is necessary for a complete merger. When the consistency level is greater than 0.8, the condition is considered sufficient for the use of web-based consultations with physicians. When the consistency level is greater than 0.9, the condition is regarded as necessary for the use [17,20,21].

Table 3 shows the test result of the necessary conditions for the use of web-based consultations with physician using the fsQCA 3.0 package. The consistency of “complementary role” and “perceived convenience” exceeded 0.9. Thus, the complementary role of web-based consultations and its perceived convenience are necessary conditions for the use (consistency of 0.968 and 0.935, respectively), followed by user’s confidence (consistency of 0.806), which is a sufficient condition for the use.

Adequacy Analysis of Conditional Configuration

In operating the truth table, the configuration analysis was applied to reveal the sufficiency analysis of the use caused by different configurations composed of multiple conditions. We set the consistency threshold to 0.8 and the case frequency threshold to 1 and calculated the complex solution, parsimonious solution, and intermediate solution.

As indicated in Table 4, there are 4 paths to promote the “use of web-based consultation with physicians.” Among the 4 combined paths, the unique coverage of S2 and S4 was 0.177 and 0.274, respectively. The unique coverage of S1 and S3 was 0.032. In total, these 4 paths showed strong explanatory power due to the good consistency (0.953) and the relative high coverage (0.661).

aGeneral conditions.
bGeneral conditions do not appear.
cCore condition.
dCorresponding conditions with path do not matter.
eCore conditions do not appear.
Based on the Andersen Behavioral Model [11], we merged the 4 paths into 2 to build a more explanatory model. The first interpretation model is an enabling-oriented model (M1), which includes paths S1 and S2. The basic expression is $M_1 = \text{age} \times \text{income} \times \text{perceived convenience} \times \text{complementary role}$ ($\times \text{education} \times \times \text{user's confidence}$). The basic combination is the enabling dimension including income and perceived convenience. That is, when web-based consultation brings perceived convenience, the relative high-income group will opt for it.

The participants regarded time saving and avoiding infection during the COVID-19 pandemic as the main conveniences brought by web-based consultations, whereas they regarded complex conduct procedures and late responses as inconveniences.

Participant 2 used web-based consultations because of its time saving characteristic. He said the following:

*I have always made appointments with physicians through Haodaifu [an internet health care platform]. I am satisfied with their services because this website informs me about an upcoming appointment beforehand. Meanwhile, the physicians come [for the consultation] on time. The waiting time is not much.*

Participant 3 used web-based consultations to avoid COVID-19 infection. She said the following:

*I get nervous when my little kid feels any discomfort. On the one hand, I am afraid to go to the hospital because of the risk of infection owing to the COVID-19 pandemic. On the other hand, I also get worried about the adverse consequences of delaying [the child’s treatment]. As a result, I usually opt for a web-based consultation immediately, and use it to determine the necessity of an in-person visit.*

Participant 4 complained about the complex procedures that lack instructions. He said the following:

*The registration process is complex. A lot of personal information must be entered before beginning the web-based consultation. Due to a lack of clear instructions, it is difficult to figure out how to begin the service. I attempted to register the system, but it was unable to use the service.*

The second interpretation model is a need-oriented model ($M_2$), which includes paths S3 and S4. The basic expression is $M_2 = \text{complementary role} \times \text{user's confidence} \times \sim \text{income} \times \sim \text{education} \sim \text{perceived convenience}$ ($\times \sim \text{age} \times \text{age} \times \text{education} \times \sim \text{perceived convenience}$). The basic combination is the need dimension including complementary role and user's confidence. That is, regardless of age and education, when web-based consultations are needed, the relative non-high-income group does not care whether it is inconvenient and will opt for it.

In terms of minor problems or primary suggestions, web-based consultations were regarded as complementary to conventional consultations. Participants 3 and 5 said the following, respectively:

*I also get worried about the adverse consequences of delaying [the child's treatment]. As a result, I usually opt for a web-based consultation immediately, and use it to determine the necessity of an in-person visit.*

Some specialties, such as dentistry and ophthalmology, require careful examination through the use of instruments before making the diagnosis. Regarding urgent cases, it would still be better for patients to visit the hospital.

Compared with in-person consultations, web-based communications are less smooth because physicians are unable to observe the patient’s body language and emotions. Some participants mentioned that web-based consultation services cannot perform laboratory tests and physical exams when it comes to diagnosis. Moreover, the costs of web-based consultations are not yet covered by the social health care insurance system. This means that patients will have to bear the cost of internet health care services. Due these reasons, some participants did not regard it as a substitute for in-person consultations. Regarding this, Participants 6 and 7 stated the following, respectively:

*If it is not face-to-face consultation, I am afraid I could not describe [the symptom] clearly and the doctors would misunderstand me.*

*For senior physicians of P Hospital, the cost of a web-based consultation is three times that of a conventional consultation. Meanwhile, the expenditure on web-based consultations cannot be reimbursed by social healthcare insurance.*

Some participants do not have confidence in web-based consultation services owing to privacy, safety, and qualification concerns, as well as problems surrounding web-based diagnosis.

Below is an interview excerpt of Participant 8, who has experience in using text web-based consultations but not video consultations:

*Although I never used video consultations, I am afraid that the system records the whole process automatically. I am worried that the video will be misused without my permission. Meanwhile, it is difficult to confirm the qualification of the doctors providing the service. After visiting the professor in C Hospital for a lung infection, I uploaded the results of a chest CT for further suggestions. I doubted the suggestion made by the professor’s students primarily. Given the busy schedule of the professor, his students had made the initial suggestions, which were later checked by the professor himself. So, I only trust the platforms run by public hospitals.*

**Robustness Test**

To test the robustness, we increased the consistency level from 0.8 to 0.85 and we also decreased it to 0.72. The result showed that the configuration paths after the adjustment were consistent with those before the adjustment, and the coverage and consistency did not change substantially. Therefore, the results were robust.
Discussion

Principal Findings

We examined the current status of the use of web-based consultations with physicians and the factors associated with the service among young and middle-aged Chinese individuals. About half (31/65, 48%) of 18- to 60-year-old residents have experienced web-based consultations. Among the factors associated with the use of web-based consultation, perceived convenience, complementary role, and user’s confidence were found to be the most essential factors.

Optimizing Web-Based Consultations

We found that perceived convenience is a necessary condition enabling participants to use web-based consultations. In this study, time saving and avoiding COVID-19 infection, which are conveniences provided by web-based consultations, promote the participants’ use of it. Participants in our study, similar to patients in other countries, strongly wish to spend less time to access the services, both when making appointments and while waiting for the appointment at the location; they prefer web-based access to appointment scheduling, want SMS text messaging services for reminders, and prefer for physicians to be available during evenings and weekends [22]. The web-based consultation system provided patients with time-saving and convenient solutions for their health care needs across all treatment processes. Patients could make appointments according to their own schedule and do not have to spend time traveling to the appointments. These findings concur with the research done in the United States. Almathami et al [23] conducted a survey in Saudi Arabia and found that saving time would increase the motivation toward the use of web-based consultations.

The COVID-19 pandemic positively influenced web-based consultation use. This is in line with findings of past studies. Studies show that internet health care services enable patients to avoid going out, decrease the time spent at hospitals when patients need to visit hospitals, and minimize infection risks [3,22,24]. Thus, it is not surprising that the COVID-19 pandemic catalyzed the development and use of the service. Although the service cannot fully substitute traditional in-person appointments, various patients were willing to use web-based consultations in the post–COVID-19 era in the long term.

In our research, participants remarked about the unclear instructions hampering the use of the service. Prior studies also find that patients who lack basic internet-related knowledge are excluded from internet health care services [25,26]. The web-based consultation environment requires patients to be well versed in using web-based platforms and electronic gadgets, and the skill levels regarding this vary by patient. Those with low literacy or limited internet-related knowledge are reluctant to use the service. This potential situation was highlighted in prior studies [27,28]. In the future, web-based consultation providers could attempt to assist persons with less accessibility to the platforms by creating intuitive instructions or even providing staff to support these people and explain how they can navigate the service step-by-step. They can also train patients on the use of available technologies prior to them making an appointment. For example, a video on how to book a web-based consultation could be provided on the front page to guide patients.

Focusing on the Needs of Residents

We found that once the participants’ needs were met, they opted to use web-based consultations with physicians.

In the study, although web-based consultations do not have provisions for laboratory tests and physical exams, they serve as a supplement for minor issues and primary suggestions. Meanwhile, some studies reported that web-based consultations improved outcomes in chronic disease management such as diabetes and hyperactivity disorder [29,30]. Considering patients’ preference and need, applying the service in chronic diseases management and subsequent visits may expand its complementary role and benefit patients to a greater extent.

Our results found that some participants did not regard web-based consultations as complementary due to its cost. This is in line with previous studies that found that the cost is a barrier influencing the use of the service, even in high-income countries [26]. Moreover, similar to Germany and the United States, clear regulations about web-based consultations are lacking in China; accordingly, not only do the costs of web-based consultations vary widely, but expenditures on the service are not yet covered by the social health insurance systems [5,31]. Thus, the economic burden on patients may impede their use of web-based consultations.

Users’ confidence is a sufficient factor influencing the use of web-based consultations in the study. The participants use the service if they feel safe. Several participants expressed concerns about the safety and privacy of web-based platforms, as well as the qualification of physicians. This corroborates the findings of prior studies, wherein participants expressed their concern about such safety and privacy issues and believed that the safety and privacy of users should be guaranteed by clear regulations for such services [32,33]. These regulations should ensure that patient data cannot be misused for purposes other than health care or shared without patients’ informed consent. Best practices and standards should also be created to ensure that providers have the relevant qualifications and service quality to provide web-based consultations.

Limitations

Because of the COVID-19 pandemic, our semistructured interviews were mostly conducted through phone calls. This hindered our ability to observe the participants’ body language and nonverbal cues. Nonetheless, we contacted the participants to explain the topic and purpose of the interview. We shared the questions with the participants 1-7 days in advance, which the participants deemed as adequate and reasonable, enabling them to provide more comprehensive information.

Conclusions

In conclusion, the Andersen Behavioral Model represents a profound reflection and exploration of the factors associated with web-based consultation use from the user’s perspective. Additionally, the csQCA offers guidance for optimizing the
benefits of the service. Perceived convenience, complementary role, and user’s confidence are the essential influencers associated with the use of the service. Clear instructions, comprehensive regulations, and appropriate application can promote the positive development of web-based consultations.

Acknowledgments
We would like to thank the interviewees who participated in the study. Abstract

Background: The COVID-19 pandemic added to the decades of evidence that public health institutions are routinely stretched beyond their capacity. Community health workers (CHWs) can be a crucial extension of public health resources to address health inequities, but systems to document CHW efforts are often fragmented and prone to unneeded redundancy, errors, and inefficiency.

Objective: We sought to develop a more efficient data collection system for recording the wide range of community-based efforts performed by CHWs.

Methods: The Communities Organizing to Promote Equity (COPE) project is an initiative to address health disparities across Kansas, in part, through the deployment of CHWs. Our team iteratively designed and refined the features of a novel data collection system for CHWs. Pilot tests with CHWs occurred over several months to ensure that the functionality supported their daily use. Following implementation of the database, procedures were set to sustain the collection of feedback from CHWs, community partners, and organizations with similar systems to continually modify the database to meet the needs of users. A continuous quality improvement process was conducted monthly to evaluate CHW performance; feedback was exchanged at team and individual levels regarding the continuous quality improvement results and opportunities for improvement. Further, a 15-item feedback survey was distributed to all 33 COPE CHWs and supervisors for assessing the feasibility of database features, accessibility, and overall satisfaction.

Results: At launch, the database had 60 active users in 20 counties. Documented client interactions begin with needs assessments (modified versions of the Arizona Self-sufficiency Matrix and PRAPARE [Protocol for Responding to and Assessing Patient Assets, Risks, and Experiences]) and continue with the longitudinal tracking of progress toward goals. A user-specific automated alerts-based dashboard displays clients needing follow-up and upcoming events. The database contains over 55,000 documented encounters across more than 5079 clients. Available resources from over 2500 community organizations have been documented. Survey data indicated that 84% (27/32) of the respondents considered the overall navigation of the database as very easy. The majority of the respondents indicated they were overall very satisfied (14/32, 44%) or satisfied (15/32, 48%) with the database. Open-ended responses indicated the database features, documentation of community organizations and visual confirmation of...
Conclusions: Our database extends beyond conventional electronic medical records and provides flexibility for ever-changing needs. The COPE database provides real-world data on CHW accomplishments, thereby improving the uniformity of data collection to enhance monitoring and evaluation. This database can serve as a model for community-based documentation systems and be adapted for use in other community settings.

Introduction

The COVID-19 pandemic added to the decades of evidence that public health institutions are routinely stretched beyond their capacity, particularly in rural areas [1]. Local and state-level health department resource deficiencies reduce their ability to address health disparities [2]. Although the pandemic affected nearly everyone, communities of color, those residing in rural and frontier counties particularly around meatpacking plants, and other vulnerable populations disproportionately experienced COVID-19–related morbidity and mortality in addition to negative economic consequences [3-8]. Community health workers (CHWs) are a cost-effective intervention for achieving health equity [9]. They can establish trust with individuals and families adversely impacted by the social determinants of health (SDoH), sometimes called social risk factors, and effectively connect them to partner organizations that can address their needs.

The Communities Organizing to Promote Equity (COPE) project is an initiative to address health disparities in 20 counties across Kansas, in part, through the deployment of CHWs. This program also includes Local Health Equity Action Teams (LHEATs), which are community coalitions comprised of community residents, organizational leaders, and a cadre of CHWs who were hired for this project [10]. The goal of the COPE project is to mobilize communities to work together and prioritize local health equity issues, develop feasible strategies to address health equity barriers related to SDoH, collaborate with organizations in the community to strengthen access to services, and elevate the community’s voice in public health planning. One of the primary roles of COPE CHWs is developing partnerships with organizations in their respective counties. These partnerships enable CHWs to connect individuals and families with existing resources and services to address their needs. CHWs build community and individual capacity. They identify individuals who need assistance through community events, self-referrals, or referrals from organizations/clinics and actively work with these individuals to develop tailored plans to address their needs. CHWs are active members of their county’s LHEAT and provide insights from clients’ experiences to support the implementation of LHEAT-driven strategies and community-based events.

To document the project’s wide range of both community-based and client-based efforts, we reviewed 7 existing data tracking systems that accommodate CHW workflows, including electronic medical record (EMR) systems and available community-based documentation systems. Some of the limitations of the existing systems included (1) an exclusive focus on medical needs without documenting social risk factors like employment or housing status, (2) community-based platforms that focus on implementing a referral system but fail to track client goals and progress, (3) systems that lack a structure for progress evaluation and reporting, and (4) limitations on customization for specific project needs (eg, could not accommodate tracking of partnerships and events). In these existing systems, CHWs are often required to document in multiple platforms, resulting in fragmented data and increased redundancy, errors, and inefficiency.

Accurate documentation of CHWs’ influence on the community, public health, and health care processes is vital, particularly as states like Kansas consider Medicaid reimbursement models for CHWs [11]. We could not identify an existing platform, system, or database that efficiently captured specific information about partners at community organizations/facilities, events/activities, client demographics and outcomes, and longitudinal assessment of care plans [11]. Thus, we developed a data collection system capable of recording such information through a user-friendly interface with rigorous security measures for storing clients’ protected health information. We are unaware of other data tracking systems covering the full scope of CHW activities. This database includes details on partner organizations supporting medical and social needs, community outreach events, information about client encounters, and progress toward client’s goals. Further, we can customize workflows to account for unique geographic needs and resources. Finally, this system integrates all program activities into a single platform, simplifying program monitoring and evaluation.

In this paper, we describe the COPE database development process and outline the platform’s features and functionality. The lessons learned through this process and the values of this unique database can support further implementation and similar efforts to develop CHW client management systems.

Methods

Database Development

We applied the principles of human-centered design to develop a database covering the varied needs of the COPE project and serving as a data tracking, quality improvement, and evaluation system and data storage on a Health Insurance Portability and Accountability Act–compliant record system, improved client engagement, enrollment processes, and identification of resources.
platform [12]. The human-centered design approach allowed for iterative development informed by a multidisciplinary team of users. We engaged highly experienced CHWs with 20 years of experience (TMN and AS) and a physician well-versed in partnering with CHWs (HA) as the architects of the system’s functionality and user-friendly interface. The team conducted weekly meetings with the program engineers (MS and KO) to iteratively design and refine features. Pilot tests of the database features occurred over several months with 60 CHWs to ensure that the functionality supported their daily use and to identify areas for improvement. The engagement of COPE project management and evaluation staff ensured the pragmatic design of features to support quality improvement feedback to CHWs and facilitate the generation of automated monitoring reports for routine dissemination to community partners.

Three CHW experts mapped the requirements for data collection and created structured proformas indicating the different fields to be captured and their relevance to client outcomes and CHW productivity. For instance, a needs assessment was embedded within the database for CHWs to identify clients’ SDoH barriers, which CHWs would use to create goals for the client and allow them to track client progress toward goal completion, identify organizations providing services or commodities, and document reasons for goals not completed. These features enhanced the ability of CHWs to track clients and link them to critical community resources. Further, a tracking system was incorporated to monitor how CHWs were spending their time and to notify them when contact with a client was needed.

The plans were provided to 2 software developers who engineered the client and server-side applications. The proformas were modified as necessary to improve uniformity and ease of use. Consensus among the development team ensured the capture of valuable data while avoiding overdocumentation. These proformas were used to create mock-up screens envisioned for the database, and the engineering team mapped the pathway from a data entry interface to data transfer and storage. The system was designed to maintain client confidentiality and included user authentication requirements and a data partition to restrict access by county. Only CHWs who were user-assigned to a county had access to the client data within the county. Users must authenticate access through Microsoft’s Azure Active Directory to access the system. In addition to strong password requirements, multifactor authentication was required for each user account to add an extra layer of security. The application also included a time-out mechanism that logged the user out if they were determined to be inactive. The application was built using Microsoft’s Azure cloud hosting and used industry-standard practices for infrastructure—including but not limited to the encryption of data at rest and in-transit, network isolation, and the principle of least privilege for access management policies.

The COPE database team produced a minimum viable product (a beta version with essential components) and then integrated an iterative process incorporating feedback from CHWs into the development of the database at multiple stages (ie, a local development, staging, and production environment), which was sustained through the database implementation process to refine the product. Early development included a staging environment that was deployed to the cloud. The staging environment allowed the team to test the infrastructure and application code safely as new features were introduced to the database. Through this staging environment, CHWs interacting with the database provided feedback (eg, adapting need assessment items, altering information shown in client charts, adding an alert feature), which were integrated with the initial development of the database. Once essential functionality was established, a production environment was created for use by CHWs, supervisors, and administrators. Ongoing feedback via individual meetings, emails, or in-person communications was collected from CHWs and discussed during weekly meetings with the database engineer; once approved, changes were deployed to the production environment. To ensure Health Insurance Portability and Accountability Act (HIPAA) compliance, the production environment uses industry-standard network isolation, data encryption, and access control to protect against breaches and unauthorized use of the application or its data [13].

**Continuous Quality Improvement and Evaluation**

To evaluate CHW performance, we employed a continuous quality improvement process [14]. This process allows for evaluating CHW workflows and accomplishments based on the number of clients enrolled, progress of client status and goals, and productivity measures. The continuous quality improvement plan is completed monthly for CHWs in each participating county. The supervisor provides feedback at the team and individual levels regarding the continuous quality improvement results and opportunities for improvement.

Primary partners in each county receive a quarterly report, which includes information on the number of partnerships entered, events completed, clients served, and individual client progress toward goals. Examples of local successes and challenges experienced by the LIHEAT and CHW teams are also included. This frequent feedback allows each county to reflect on future goals and helps identify trends across the statewide project. Data exports can also be used to evaluate overall project outcomes. The COPE database was designed to be flexible, allowing the team to continue to innovate for future needs. Specifically, these established feedback systems with CHWs and partnering organizations and weekly meetings with the database engineer to implement technical changes supports the ability to adapt any feature, customize workflows, and alter alert systems, thereby maintaining flexibility of the database.

**Data Collection**

A database feedback survey was conducted at 19 months after implementation (May 2022). A link to a 15-item REDCap (Research Electronic Data Capture) survey was emailed to all COPE CHWs and CHW supervisors. Close-ended questions consisted of demographic items (eg, age, education level, primary language) and assessed feasibility of database features and overall satisfaction. Respondents were asked to rank order the perceived importance of various database features. A Friedman test was conducted to determine whether participants had a differential rank-ordered preference for the database features. Open-ended questions assessed individuals’ perspectives toward accessibility and usability of the database.
and database features. Quantitative results were analyzed using SPSS statistics (version 29.0.0; IBM Corp). Qualitative results were analyzed using inductive content analysis [15].

Ethics Approval

The protocol for this study was approved by the University of Kansas Medical Center institutional review board (STUDY00148455: COPE Project). This study was conducted in compliance with standards established by Good Clinical Practice, the International Council for Harmonisation, and the Declaration of Helsinki. Informed consent was obtained from all individual participants included in this study. Survey data were deidentified and stored on the University of Kansas Medical Center’s secure network drive specifically designated for storage of sensitive personal data. Data access will be restricted to those with appropriate institutional review board authorization and limited to principal and coinvestigators, statisticians, and data analysts involved in the analyses. All computer files and systems will be password-protected and accessible only by authorized personnel. The described data were collected as part of quality improvement in which CHW staff were asked to complete a feedback survey; no compensation was required.

Results

Database Development Process

The COPE database development process spanned 5 months and then went live for community pilot testing among COPE CHWs. The addition of auxiliary functions and refining of existing features continued for an additional 5 months. The development involved 613 cumulative working hours of the software developers and approximately 150 person-hours in active discussions with the COPE team. From the user perspective, CHWs each have access to enter client information, create assessments and goals, and update encounters and client status. They can also add and review events and partnerships within the database. CHW supervisors have additional rights to delete events, partnerships, client goals, or encounter information for flexibility purposes. This functionality facilitates quality improvement and provides a pathway for deduplication of records. At launch, the database had 60 active users in 20 counties, with the flexibility to expand.

Database Components and Function

The COPE database is a secure, HIPAA-compliant, comprehensive, electronic, cloud-based application [16]. All user-specific logins are password secured with multifactor authentication and linked to county-specific access. Client documents such as consent forms and other protected health information are stored in a HIPAA-compliant environment [16]. CHWs and supervisors can locate client information, partners, and events pertinent to their daily work by using the web application interface. Data exports are packaged as CSV files to maintain compatibility with analysis software and are only available to system administrators. Exports can include or exclude identifiable data depending on analysis needs and the intended purpose for the data (eg, quality improvement reviews, evaluation analyses).

The database facilitates linkages to organizational partnerships by capturing contact information, facility location, services offered, and service areas. Once the partnership information is entered, users can build queries of organizations filtered by county, name, and services provided to facilitate client referrals. The database also includes data from community events such as the name and location of the hosting organization(s), event’s purpose, intended beneficiary population(s), and number of attendees. Event locations and partner addresses can be geocoded and overlayed with markers of community needs or vulnerability to guide the strategic deployment of resources to high-priority communities. During and after partner community events, the database is utilized for tracking client referrals and CHW engagement.

For client interactions, the system organizes client demographics, insurance status, and SDoH needs assessments (based on modified items from the Arizona Self-sufficiency Matrix and the PRAPARE [Protocol for Responding to and Assessing Patient Assets, Risks, and Experiences] tool; Figure 1) [17,18]. Once the client assessment is performed and entered in the database, client goals and care plans populate under the client’s chart, allowing CHWs to track progress and goal completion while working with clients (Figure 2). CHWs and clients establish time-bound goals and follow them to completion. Protocols were developed to support CHWs as they work with clients to prioritize needs. CHWs can document client referrals from partnering organizations and send referrals out to service organizations. This allows for monitoring the number of referrals, both into and out of organizations. Once applicable goals are completed, CHWs can close the loop with the referring organization or provider.
Figure 1. Screenshot of the staging environment used to train community health workers on entering and updating clients’ needs in the Communities Organizing to Promote Equity database. The data depicted were created for training purposes and are not from an actual client. SDoH: social determinants of health.

Figure 2. Screenshot of the staging environment used to train community health workers on how clients’ needs are populated as goals and tracked for follow-up and resolution in the Communities Organizing to Promote Equity database. The data depicted were created for training purposes and are not from an actual client. CHW: community health worker.

Algorithms and reports are generated to automate alerts for overdue actions and generate population-level summaries for real-time tracking and auditing. For efficient follow-up and priority setting, an automated alerts-based dashboard specific to the user’s account can notify the user of clients needing follow-up and upcoming events. The dashboard also builds a list of clients currently active, personalized to each CHW, including basic demographic and contact information, dates of the last contact, and the client’s status (eg, engaged, referred, discharged) (Figure 3).
Database Usage and CHW Feedback

To date, over 60 CHWs have utilized the database across 20 counties in Kansas. The database contains over 55,000 documented encounters across more than 5,079 clients. Available resources from over 2,500 community organizations and partners have been documented. Nearly all current CHW and CHW supervisors (32/33, 97%) from the 20 COPE counties completed the survey. Of the respondents, 31% (10/32) were in the age range of 24-34 years, 25% (8/32) in the age range of 35-45 years, 25% (8/32) in the age range of 46-56 years, and 19% (6/32) in the age range of 57-67 years. CHW respondents reported a wide range of educational attainment with 9% (3/32) having a high school diploma or GED (general educational development) equivalent, 19% (6/32) some college, 22% (7/32) associate degree, 31% (10/32) bachelor’s degree, 16% (5/32) master’s degree, and 3% (1/32) having a doctorate’s degree. Most CHWs indicated English as their primary spoken language (24/32, 75%), with the remaining 25% (8/32) reporting Spanish as their primary language. CHWs reported spending an average of 7 hours each week on database documentation. Of the respondents, 84% (27/32) indicated that the overall navigation of the database was very easy. The majority of the respondents indicated that they were overall very satisfied (14/32, 44%) or satisfied (15/32, 48%) with the database.

Respondents ranked the following database features in order of most to least important: (1) dashboard (mean 3.26), (2) database alerts (mean 3.42), (3) assessments (mean 3.55), (4) goals (mean 3.97), (5) client demographics (mean 4.23), (6) time tracking (mean 5.68), (7) event charts (mean 5.90), and (8) partnership charts (mean 6.00). There was significant agreement on the rank-ordered preference for the database features ($\chi^2 = 49.5$; $P < .001$) with a Kendall $W$ of 0.228, which indicates moderate agreement between individuals on the preferable ordering of database features.

In their open-ended responses, CHWs described how the database helped build connections with community organizations by establishing them as partners. Documentation of community organization involvement and provision of these data to corresponding partners have translated into increased engagement at community events, increasing the resources
available to community members. Feedback on event and partner data documentation has highlighted the need for improved workflows, specifically for client referrals during community events. Further, insights from CHWs led to the development of client transfer methods so that clients could be securely transferred within the database to another CHW, thereby enabling full access to client status and notes. This allowed clients to continue to progress toward goal completion. Lastly, a database component consistently mentioned by CHWs, further contributing to improved client enrollment processes, was the ability to provide clients with visible confirmation that all consent forms and data are stored in a HIPAA-compliant record system.

Discussion

Principal Results

The robust community-engagement strategies employed by the COPE project require the development of a novel comprehensive database. The COPE database enhances the workflow and facilitates documentation for this innovative project by capturing process and evaluation data regarding individual and community needs and resources, thereby addressing health inequities and adverse SDoH. The data captured by this system extend beyond the conventional medical needs captured by existing EMRs while providing the required flexibility necessary for the ever-changing needs in communities. Finally, it provides a platform to document and quantify community-related information from the needs of individual members to the presence of key partner organizations positioned to meet these needs. The critical role CHWs play in improving community health outcomes and reducing the cost of health care is increasingly recognized [19-23]. However, little has been published on the process or outcomes of CHWs’ work. This project has contributed to the evidence base documenting the impact of CHWs on health inequities. Clients are empowered to complete goals with the assistance of CHWs. A client’s progress is thoroughly documented in the system, thereby establishing successful processes for connecting clients to services and identifying barriers to care. CHW documentation of client referrals (eg, from partnering organizations to service organizations) allows for monitoring of health barriers by demographics and locations and helps to close the loop with the referring partner. The database tracks client status (eg, referred, engaged, discharged), encounters with clients, progression toward goals, and client appointments with partnering organizations. The result is an efficient and effective case management support system to ensure clients receive the right care at the right time. This documentation demonstrates the impact and reach of CHWs, which is key to supporting health policy changes necessary for expanding and sustaining the CHW workforce through Medicaid or Medicare reimbursement models [24].

Data captured in the COPE database will enhance understanding of CHW workflow and CHWs’ ability to bridge gaps in current health systems. These data are critical to support the health policy changes necessary for expanding and sustaining the CHW workforce [25]. A multisectoral coalition with representation from state and local health departments, federally qualified health centers, community-based organizations, CHW leaders, and universities is advocating for sustainable models for the CHW workforce in Kansas through Medicaid and Medicare reimbursement [26]. Medicaid reimbursement for services provided by CHWs is a developing area of health policy and may require documentation systems like that of EMRs; however, these systems are not always applicable for the type of work conducted by CHWs, which may result in an undervaluation of their work and impact. As Kansas advances policy to support Medicaid reimbursement for CHWs, our database is being leveraged to track CHW performance and outcomes, as it is uniquely positioned to support CHW activities conducted outside the clinical setting [27]. Accordingly, this system could benefit community-based organizations or local health departments that employ CHWs.

Limitations

There were limitations to concurrently developing a novel database platform while launching the COPE project. Given the timeline for system development, alternative strategies for tracking CHW activities were needed in the initial months of the project (eg, spreadsheets, forms stored on secure servers). These early data were transferred upon system deployment. Moreover, system customization and refinements were expedited by immediate and iterative feedback, starting with the first CHWs we hired. The database relies on the end user to close the loop with clients when provided with resources and to determine the effect of those resources. These outcome data are also provided to the referring partners. At this point, the database is not linked to an EMR system; however, the capacity to establish this linkage does exist. Interoperability with other systems implemented in federally qualified health centers and hospitals limited widespread implementation in the initial stages of launch. Most EMRs are not able to accommodate bidirectional data movement between the EMR and external databases. Consequently, depending on where a CHW is employed, this lack of EMR interoperability may create a double documentation issue for the end user.

Further, lack of infrastructure may cause potential limitations in the future. Currently, the project lacked support from a software firm, for example, EPIC or eClinicalWorks, which limited the applicability of the system’s interoperability. We anticipate interoperability with large-scale EMRs in the future, which would ideally allow the inclusion of needed documentation and information from CHWs into clinical care encounters, further facilitating the ability for dynamic navigation with CHWs and health care providers. With the expansion of the current systems’ novel features supporting medical and social needs, community outreach events, and progress toward client’s goals, clinic-based health care providers’ desire for closed-loop referral information can be improved to enhance community-centered care [28].

Comparison With Prior Work

We acknowledge there are existing systems with rigorous features to capture essential aspects of CHW work; however, in the interest of avoiding multiple approaches to capturing the comprehensive range of CHW activities along with individual
and project performance measures, we opted to build our own system. We could not identify an existing platform, system, or database that efficiently captured specific information about partners at community organizations/facilities, events/activities, client demographics and outcomes, and longitudinal assessment of care plans [11]. CHWs, the ultimate end users, designed and refined this system to optimize utility and performance. The current database system collaborates with organizations such as health departments, community-based organizations, health insurance providers, and federally qualified health centers in addition to consulting with similar platforms to incorporate feedback into the database design and discuss possibilities for interoperability of 2 or more systems.

Sustainability
The COPE CHW project managers are continuously monitoring the operability of the database, including frequent review of user feedback and routine communication with system programmers to recommend adaptations and quickly resolve any system malfunctions. User feedback has been particularly helpful in the development and initial implementation phases in tailoring database components to meet CHW, supervisor, and administrator needs. Additionally, the database team collects feedback from partnering organizations and potential new clients looking to adopt the system for their organization. Processes are currently under development to streamline CHW feedback so that CHWs can directly send communications in real time to the database team regarding recommended changes or issues.

Acknowledgments
We thank the Communities Organizing to Promote Equity (COPE) project team (the authors and Vicki Collie-Akers, Kristina Bridges, Clarissa Carrillo, Yvonne Chen, Tatiana Darby, Megan Diniz, Jody Hoener, Allison Honn, Milan King, Nadine Long, Daniel Parente, Mariana Ramirez, Mary Ricketts, Skylar Vance, Jennifer Woodward, Kara Knapp). COPE community health workers, Local Health Equity Action Team members across the state, our partnering organizations, and community residents for all of their hard work and contributions to our shared mission of achieving health equity for communities in Kansas. This work was supported by Kansas Department of Health and Environment through a grant from the Centers for Disease Control and Prevention (grant CDC-RFA-OT21-2103).

Data Availability
There are no data to share publicly from this project. Data references in this manuscript are limited to quality assurance and improvement and would not be useful to those outside of the Communities Organizing to Promote Equity project.

Authors’ Contributions
All authors provided substantial contributions to the design of the work and the conceptualization of this project. HA, KJS, TMN, CMP, AS, and SF-K contributed to the interpretation of data for the work and drafted the final manuscript. All other coauthors provided critical revisions and final approval of the manuscript for publication. All authors agree to be accountable for all aspects of the work and assure the accuracy and integrity of the work represented within this manuscript. Generative artificial intelligence was not used in any portion of the manuscript writing. Funding acquisition was led by SF-K.

Conflicts of Interest
None declared.

Abstract

Background: Effective emotional regulation (ER) skills are important for sexual function, as they impact emotional awareness and expression during sexual activity, and therefore, satisfaction and distress. Emotion regulation interventions may offer a promising approach to improve sexual health. Web-based emotion regulation may be a therapeutic strategy for men and women with sexual health concerns. Nevertheless, there is a scarcity of intervention trials investigating its effects in this context, much less using the internet.

Objective: This study aims to investigate the effects of a web-based emotion regulation training program for sexual function in both men and women.

Methods: The participants were recruited based on their self-reported sexual problems, which for men was defined by a score of <25 on the International Index Erectile Function (IIEF) and for women by a score of <26.55 on the Female Sexual Function Index (FSFI). The final sample included 60 participants who were randomized to either a web-based emotion regulation training for sexual function or to a waitlist control group. The treatment consisted of an 8-week web-based emotion regulation training for sexual function. The participants were assessed at baseline, post intervention, and the 3-month follow-up.

Results: Of the 60 participants included, only 6 completed all 3 assessment points (n=5, 20% in the treatment group and n=1, 5% in the waitlist control group) after receiving the intervention. At follow-up, there were no significant differences between groups in any measure. Among the intervention completers, large-to-moderate within-group effect sizes were observed between the assessment points on measures of emotion regulation, depression, lubrication, orgasm, thoughts of sexual failure, and abuse during sexual activity. The adherence rate was very low, limiting the generalizability of the findings.

Conclusions: Participants who completed the intervention showed improvements in both sexual function domains and emotion regulation. Nonetheless, due to a high dropout rate, this trial failed to collect sufficient data to allow for any conclusions to be drawn on treatment effects.

**Introduction**

**Background**

Sexual dysfunctions involve difficulty in the ability to respond sexually or obtain sexual pleasure and are common and often disabling conditions [1]. Their etiology is multifactorial and encompasses biopsychosocial factors [2]. Throughout the lifespan, it has been estimated that 40% to 45% of adult women and 20% to 30% of adult men in the general population fulfill the criteria for at least 1 sexual dysfunction [3]. As an example, in the last available national survey in the United Kingdom, 51.2% of women and 41.6% of men who had sex in the last year reported at least 1 sexual problem [4].

The cognitive-affective model of sexual dysfunctions [5] posits that both healthy individuals and those with physical or mental conditions respond differently to sexual situations. While men and women without sexual dysfunctions respond to sexual situations with positive affect, expectations of success, and perception of control, those with sexual dysfunctions respond with anxiety, negative affect, and expectations of failure. In addition, preoccupations about erection and disengagement/thoughts about failure in men and lack of erotic thoughts in women have been found to be negatively correlated with sexual arousal. Across both sexes, sadness and disillusion are negatively associated with sexual arousal [6].

Emotion regulation (ER), the process by which emotions are generated, experienced, and used [7], has also been associated with sexual response cycle difficulties (arousal, lubrication, orgasm, pain, erection, and ejaculation) in both men and women [8-11]. Taking into consideration the high prevalence rates of emotion regulation difficulties and the high comorbidity of sexual disorders with other mental disorders [12], studies are needed to address ER interventions for sexual dysfunctions. The few studies investigating the effects of ER interventions have reported positive results, such as a reduction in sexual compulsivity, drug use, HIV risk behaviors, anxiety, and depression [13], and improvements in sexual functioning and quality of life [14].

Learning effective ER skills is important for sexual function, as they impact emotional awareness and expression during sexual activity, and, therefore, satisfaction and distress [15]. There is evidence that adaptive ER strategies are associated with better sexual function and mental health (anxiety and depression) [6] and reduced sensitivity and reactivity to negative stimuli [15].

Psychosexual interventions have been shown to be effective in treating sexual disorders [16]. They combine several interventions to address disorders experienced by both sexes. Generally, they are based on cognitive and behavioral interventions but can also include couple and systemic therapy components [17]. Most often, psychosexual therapies based on cognitive behavior therapy include (1) psychoeducation about sexual function, (2) cognitive challenges to negative sexual attitudes and distortions, and (3) behavioral activation via sex therapy—specific techniques [18]. The benefits of psychosexual therapies not only involve functional aspects but can also improve other domains of life, such as personal well-being and relationship quality and satisfaction [19,20].

Sexual dysfunctions are often perceived as sensitive, embarrassing, and potentially stigmatizing by those concerned. The relative anonymity of web-based approaches may offer an opportunity to attend therapy sessions in an environment that is perceived as safer and more private, while not requiring much investment of time for both the therapist and the client [21-23].

In general, web-based psychological interventions have been found to be effective in treating a range of conditions. The potential benefits of web-based interventions include their anonymity, availability, and convenience of pace/time [24]. In addition, web-based interventions can support active learning via interactive components [25].

To date, only a few studies have investigated the effects of web-delivered interventions for sexual dysfunctions. None of these studies included ER training. In one study, a treatment program for various sexual dysfunctions led to improvements in sexual functioning in 67% (n=39) of the participants, with improvements maintained at 1-month follow-up [26]. Similarly, treatment was found to be superior to a waitlist control condition in a study on internet-delivered sex therapy for erectile dysfunction [27] and in a study comparing web-delivered cognitive behavioral therapy (CBT) to an internet discussion forum control group [28].

Despite the importance of ER for sexual function, web-based ER interventions have, to our knowledge, not been developed and tested to any greater extent in people with sexual dysfunction. Therefore, this study aims to tackle this gap in the literature as the first ER web-based intervention designed to improve sexual function.

**Aim**

This study aimed to investigate the effects of a web-based ER training program for sexual function in male and female participants experiencing sexual dysfunction named TREP3S (Portuguese acronym for Emotion Regulation Training for Sexual Health). The training was provided in the form of an 8-week web-based program with therapist support via email on a secure treatment platform. We expected that TREP3S group participants would show improvements in self-reported outcomes compared to the waitlist control group.

**Methods**

**Overview**

Participants were recruited from the general public via the internet. Advertisements concerning the project and invitations to take part in the study were disseminated using social media.
(Facebook and Instagram) for 4 months, targeting the Brazilian Portuguese–speaking population. Additionally, participants of a previous web-based survey known as the Sexual Health and Emotion Regulation (SHER) study who had volunteered to participate in future studies were also contacted.

The following inclusion criteria were used: (1) access to a computer/tablet or phone with an internet connection; (2) between 18 and 65 years of age; (3) fluent in Brazilian Portuguese; (4) self-reported sexual problems, as assessed in men by a score of <25 on the International Index Erectile Function (IIEF) and in women by a score of <26.5 on the Female Sexual Function Index (FSFI); and (5) in a stable relationship for at least the preceding last 3 months. The exclusion criteria were: (1) medical conditions that could interfere with the intervention, (eg, diabetes, cancer, and cardiovascular issues) or (2) currently receiving psychological or psychiatric treatment.

Figure 1 illustrates the recruitment steps according to the CONSORT (Consolidated Standards of Reporting Trials) guidelines. After providing informed consent on the platform, the volunteers filled out a screening questionnaire to see if they met the inclusion criteria. For those whose responses indicated suitability for participation in the study, a phone contact was established to verify their eligibility and motivation to participate in the study. Following this, the included participants completed a baseline questionnaire.
Two separate block-randomization lists were created via a computer-generated (SealedEnvelope) block-randomization procedure (comprising a block size of 4 for 2 groups) with a 1:1 randomization ratio. The computer-generated sequence was generated by an independent researcher who was not involved in the trial. The actual allocation of participants to the TREPS intervention group or the waitlist control group was conducted by a clinical psychologist who was not involved in the project. Moreover, the researchers did not influence the allocation of the participants.

After randomization, the TREPS intervention group received the emotion regulation training for sexual function for 8 weeks, while the waitlist control group received no intervention. Both primary and secondary outcomes were assessed online on the study website at baseline, end of treatment, and the 3-month follow-up.
Ethical Considerations

All study procedures were approved by the Ethics Review Panel of the University of Luxembourg (ERP-20-029 SHER). The study was also registered on ClinicalTrials.gov (NCT04792177), and the protocol was published [29]. Prior to taking part in this study, the participants provided electronic informed consent. Personal data collected in this study included information about sociodemographic characteristics and sexual and mental health. To ensure confidentiality, the data collected were pseudonymized and a unique identifier was generated so that participants’ identities could not be disclosed. No compensation was offered to the participants.

Measures

Primary Outcome

The primary outcome measures were IIEF and FSFI scores for the male and female participants, respectively. The main reason for using these scores as main outcomes was that both have shown good reliability and validity for the Brazilian-speaking population [30,31]. For the IIEF, a cut-off score of 25 has been found to discriminate between diagnosis and no diagnosis [32], while for the FSFI, the respective score is 26.55 [33,34].

The IIEF is a 15-item, self-administered questionnaire for assessing sexual functioning in men [35]. Answers are given on a 6-point Likert scale. The IIEF encompasses 5 different domains of sexual functioning: erectile function, orgasm function, sexual desire, intercourse satisfaction, and overall satisfaction. Ferraz and Cicconelli [36] translated and adapted the scale to Brazilian Portuguese. Its psychometric properties have been reported by Gonzáles et al [30].

The FSFI is a 19-item questionnaire for the assessment of sexual functioning in women in the domains of sexual functioning (eg, sexual arousal, orgasm, satisfaction, and pain) [37]. Answers are provided using a 5-point Likert scale. Hentschel et al [31] translated and validated the FSFI into Portuguese.

Secondary Outcomes

The secondary outcome measures encompassed questionnaires about sexual function, mental health (anxiety and depression), ER, sexual self-perception, and thoughts during sexual activity. Sexual function was assessed with both the Sexual Quotient (SQ), using both the female [38] and male versions [39]. The SQ is a brief and comprehensive tool comprising 10 items that are answered on a scale from 0 (never) to 5 (always). It addresses general sexual function, stages of the sexual response cycle (desire, arousal, orgasm), and sexual satisfaction. Scores range between 0 and 100, with a score of ≤60 indicating sexual dysfunction.

Depression and anxiety symptoms were assessed via the Patient Heath Questionnaire-9 (PHQ-9) and the Generalized Anxiety Disorder-7 (GAD-7). Both instruments are frequently used self-report diagnostic tools for assessing mental health disorders. The PHQ-9 [40] is a 9-item screening instrument that also provides an assessment of depression severity. The diagnostic validity of the tool has been established for its Brazilian version [41].

The GAD-7 [42] is a brief self-report measure specifically developed to assess generalized anxiety disorder. It has good reliability, as well as criterion, construct, factorial, and procedural validity. The Brazilian version has satisfactory psychometric properties [43].

The Difficulties in Emotion Regulation Scale (DERS) was used to assess ER. It covers several facets of ER, including difficulties relevant to an individual’s (1) acceptance of emotional responses, (2) ability to engage in goal-directed behavior under distress, (3) ability to control impulsive behaviors when distressed, (4) access to ER strategies, and (5) emotional clarity. Participants rate their degree of agreement with each statement on a scale from 1 (almost never; 0 to 10%) to 5 (almost always; 91 to 100%). The DERS was developed by Gratza and Roemera [44] and validated in Brazil by Miguel et al [45], with its psychometric properties confirmed by Cancian et al [46].

To assess sexual self-perception, the Sexual Self-Schema Scale (SSSS) was used [47]. It consists of 30 items assessing respondents’ perception of themselves as a sexual person compared to others of the same gender and age. Answers are provided using a 5-point Likert scale ranging from 1 (not at all descriptive of me) to 5 (very much descriptive of me). The psychometric properties of its Brazilian version have been found to be satisfactory [48].

To assess sexual thoughts during sexual activity, the Sexual Modes Questionnaire (SMQ) and its Automatic Thoughts subscale [49] were used. This self-report scale consists of 30 items in the male version and 33 items in the female version. Respondents are asked to rate the frequency, ranging from 1 (never) to 5 (always), with which they have experienced specific automatic thoughts during sexual activity. The psychometric properties of its Brazilian-adapted version have been evaluated [48].

Intervention

The intervention consisted of 8 weekly modules delivered via the internet using a secure web-based contact handling system (eg, similar to internet banking) [50]. Each module consisted of a video presentation, texts, and an exercise (homework) to complete during the week. Access to the intervention modules was granted weekly on the same day, and participants were expected to report homework assignments to the therapist until the day before the next module. The participants were able to contact the therapist via the web-based platform and could expect a reply within 24 hours. No face-to-face or telephone contact with the research team was allowed during the intervention (except for technical problems). Table 1 summarizes the contents of the modules.
Table 1. Summary of the intervention modules.

<table>
<thead>
<tr>
<th>Time frame</th>
<th>Module</th>
<th>Content</th>
</tr>
</thead>
<tbody>
<tr>
<td>Week 1</td>
<td>Psychoeducation on sexual function</td>
<td>This module covers information about sexuality, the sexual response cycle (desire, excitement, plateau, orgasm, resolution), and the main difficulties that men and women may face in their sexual function, such as erectile dysfunction, premature ejaculation, desire disorders, pain disorders, and anorgasmia. It also differentiates the psychological characteristics of a functional sexual response from a dysfunctional sexual response and clarifies the difference between sexual function and sexual satisfaction [51].</td>
</tr>
<tr>
<td>Week 2</td>
<td>Psychoeducation on emotions and emotional regulation</td>
<td>This module defines emotions, their evolutionary aspects, emotion functions, emotion response cycles, emotion components (physical sensations, thoughts, and behaviors), and the long-term consequences of maintaining an emotional state for a longer period. It also defines pleasant and unpleasant emotions, the relationship between unpleasant emotions and avoidance behaviors, and avoidance strategies (emotional suppression, distraction, and behavioral avoidance) [52-54].</td>
</tr>
<tr>
<td>Week 3</td>
<td>Relaxation strategies: breathing and muscle relaxation</td>
<td>This module goes over the common physiological responses to anxiety and stress (eg, increases in heart rate, respiration, and muscle tension) and teaches 2 relaxation strategies: breathing relaxation and progressive muscle relaxation [52-54].</td>
</tr>
<tr>
<td>Week 4</td>
<td>Cognitive flexibility</td>
<td>This module refers to the rational component of emotion regulation. It aims to conceptualize and enhance cognitive flexibility. Moreover, the triad situation-thought-emotion is explained and detailed through the concepts of what distinguishes thoughts and interpretations, and what automatic thoughts and cognitive distortions are. The identification of negative thought patterns and the most common cognitive distortions related to sexuality are described [52-54].</td>
</tr>
<tr>
<td>Week 5</td>
<td>Nonjudgmental awareness</td>
<td>This module aims to teach participants to experience their emotions in the present moment in a nonjudgmental way. The module also differentiates between experiencing an unpleasant emotion from experiencing an unpleasant emotion resulting from negative beliefs and reactions (snowball effect) [52-54].</td>
</tr>
<tr>
<td>Week 6</td>
<td>Self-acceptance and compassion</td>
<td>This module focuses on 2 psychological concepts necessary for better emotion management: acceptance and self-compassion. These are important in order not to avoid emotional experiences and to diminish self-criticism associated with sexual difficulties [52-54].</td>
</tr>
<tr>
<td>Week 7</td>
<td>Emotion analysis</td>
<td>This module presents a step-by-step flowchart of how to identify emotions when experiencing them. By identifying emotions properly, we can facilitate effective emotion regulation. The flowchart comprises 6 items to pay attention to when identifying an emotion: (1) emotion, (2) event-trigger situation, (3) evaluation/interpretation, (4) physical sensations, (5) previous similar experiences, and (6) behavior [52-54].</td>
</tr>
<tr>
<td>Week 8</td>
<td>Sexual emotional exposures</td>
<td>This module summarizes all the previous modules and suggests a series of sexual experiences where participants pay attention to emotions experienced during the sexual activities (exposure). This gradual approach diminishes the risk of intense emotions and avoidant behaviors. By succeeding with the exposure and obtaining pleasure during the activities, feelings of danger/discomfort diminish, and more adaptive evaluations arise, facilitating the identification and modification of emotional behaviors.</td>
</tr>
</tbody>
</table>

The supporting clinician was a clinical psychologist and a European-certified psychosexologist. The waitlist control group received the same treatment at the end of the 3-month follow-up assessment.

**Data Analysis**

The baseline data present normal univariate distribution according to skewness (−2 to 2) and kurtosis (−7 to 7). The sociodemographic characteristics of the 2 groups were compared using chi-square tests. Next, a 1-way analysis of variance (ANOVA) on outcome variables was performed to examine group differences at baseline. Mann-Whitney U tests were carried out to compare the 2 groups (intervention and control) at baseline, at the end of intervention (T1), and at follow-up (T2). Given the large amount of missing data (over 80%), we did not impute missing data or estimate missing data using mixed model analyses [33]. All participants who received the intervention and completed the 3 assessment points were compiled and analyzed for within-group efficacy estimation. A within-group nonparametric Fisher test was run to assess pre-post changes. Data were considered significant at a P<.05.

For the parametric analysis, the effect size was calculated using Cohen $d$. For the nonparametric analysis, effect sizes were calculated using $\eta^2$ [55]. All statistical analyses were conducted with SPSS software (version 20.0; IBM Corp).

**Results**

**Participants’ Characteristics**

Initially, 60 participants completed the baseline questionnaires and were randomly assigned to one of 2 groups (intervention and waitlist control). Due to the high dropout rate and incomplete measures, we decided to merge the groups to compensate to some extent for the small sample size at post intervention. Table 2 shows the characteristics of the participants who fully adhered to the intervention and completed all the assessments (baseline, end of intervention, and 3-month follow-up).

**Intervention Adherence**

Intervention adherence was assessed by examining the number of participants who accessed the platform and opened the weekly modules. More participants completed the end-of-intervention and follow-up assessments than those who completed all the intervention modules. Taking into consideration the total number of participants included in the study, adherence to the different modules varied between 14 (n=2) and 76.6% (n=23). The mean number of modules completed within the 8 weeks was 3.2 in the intervention group and 3 in the control group (after they had completed their intervention). Table 3 summarizes the number of participants who read and watched the modules.

\(^a\)When the intervention was offered to the second group, only 20 (67%) of the initial 30 participants completed the questionnaire and were therefore considered as the second intervention group.

An open-ended question section was used for the participants who completed the study, asking for suggestions and comments. A total of 3 topics emerged: (1) self-confidence, (2) influence on our emotional state of how we imagine others are seeing us, and (3) sexual repression during childhood and adolescence and its consequences in adult life. In addition, 1 participant suggested that the video materials should be longer.

Between-Group Analysis

When comparing the intervention group (n=12, 40%) and the waitlist control group (n=16, 80%), statistically significant differences were found at baseline regarding the subscales about automatic thoughts of abuse (intervention: mean 21.47, SD 7.98; waitlist control: mean 15.40, SD 5.40; \(P=0.004\); \(d=0.81\)) and lack of partner attention (intervention: mean 13.20, SD 4.80; \(P=0.03\); \(d=0.61\)). At the end of the intervention (T1), differences were found regarding orgasm capacity and frequency in the intervention group (n=6, 20%) (mean 3.09, SD 2.54) and waitlist control (n=10, 50%) (mean 2.50, SD 1.47; \(P=0.04\); \(\eta^2=0.28\)), as well as automatic thoughts of failure (intervention group: mean 4.43, SD 3.50; waitlist control: mean 9.33, SD 2.61; \(P=0.01\); \(\eta^2=1.08\)).

Multimedia Appendix 1 presents the between-group comparisons at the 3 assessment time points.

Within-Group Analyses

The intervention effect size calculation was conducted by combining all participants who completed the intervention and the 3-month follow-up assessment (n=5). The results indicated large within-group effect sizes for some of the outcome measures related to improvements in ER (DERS total score, \(\eta^2=0.95\); DERS goals, \(\eta^2=0.94\); DERS nonacceptance, \(\eta^2=0.76\)), depression (PHQ-9, \(\eta^2=0.73\)), orgasm (FSFI: orgasm \(\eta^2=1.25\)), lubrication (FSFI: lubrication, \(\eta^2=0.98\)), and failure automatic thoughts in a sexual context (EPA: failure, \(\eta^2=0.95\)).

Medium effect sizes were found on all other factors of the DERS (\(\eta^2\)=ranging from 0.50 to 0.68), anxiety (GAD-7, \(\eta^2=0.43\)), arousal and partner connection in terms of the female version of the SQ (SQf: arousal and connection, \(\eta^2=0.34\)), preliminaries (SQf: preliminaries, \(\eta^2=0.38\)), abuse automatic thoughts in a sexual context (EPA: abuse, \(\eta^2=0.38\)), and sexual self-schema (SSSS: loving/warm, \(\eta^2=0.34\)).

Table 4 summarizes the within-group calculations.

Table 5 shows sexual function symptom scores for each participant who completed at least 2 assessment points.

Discussion

Principal Findings

This study aimed to investigate the effects of a web-based ER training program for sexual function. The trial faced a substantial dropout rate, but the preliminary results suggest that the TREPS protocol provided some improvements in relation to sexual function, albeit mainly for mental health and ER abilities. Although no significant effects were seen in the main outcome measures after the 3-month follow-up in the controlled between-group analyses, large and moderate within-group effect sizes were found for a range of components in the within-group analyses.

First, based on complete case analyses and the combined sample, large effects were found for the ER assessment as well as the depression and anxiety measures. Internet-based ER interventions for depression and emotional disorders have been shown to be efficacious with moderate-to-large between-group effect sizes [56-58]. The improvements we observed in this study are in line with those reported for face-to-face interventions focusing on mood disorders [59].

Regarding sexuality, moderate-to-large effects were found regarding the sexual components of arousal/lubrication and orgasm but not in other domains or the overall sexual function score. These sexual domains are more susceptible to individual sex practices and may have benefitted most from the intervention. This is plausible, as frustration with partners was frequently reported in participants’ responses to homework activities, and such components are associated with sexual desire, arousal, and satisfaction [60,61]. Regarding automatic thoughts in sexual activity, there were large intervention effects concerning failure and disengagement thoughts and a moderate effect concerning abuse thoughts. These findings are particularly relevant since both aspects have been suggested as the main cognitive components of sexual dysfunction in women [62,63].

Against our expectations, several factors did not allow us to strictly adhere to the published study protocol [29]. The 2 main changes concerned the follow-up, which was reduced from 6 to 3 months, and the conversion of the initially planned waitlist group into a second intervention group, assessed after receiving the intervention and 3 months later. These changes were implemented to counteract the high dropout rate in the intervention group.

Even though high attrition rates in web-based interventions for sexual function have been described in the past [29,63], the dropout rate in this study superseded those previously reported. When designing the study, precautions regarding adherence were made as suggested in the literature, such as a weekly scheduled treatment program, reminders, direct feedback, and positive messaging upon assignment completion [64,65].

Since no feedback was obtained from nonadherers, any conclusions must remain speculative. Our main hypothesis concerns the COVID-19 pandemic. The intervention was carried out during the COVID-19 outbreak, which affected Brazilians to a larger extent than other countries—by October 2021, Brazil had over 21.6 million infections and over 600 thousand deaths [66]. The number of completed modules was low, which is likely to have impacted the overall response to treatment. Among the participants, only 14% (n=7) accessed the last module, and less than 22% (n=11) accessed more than half of the intervention. Other web-based intervention studies focusing on male sexual disorders (erectile dysfunction) have reported similar findings. For instance, in one study, only 8% of the participants reached the final module, with 54% accessing just up to module 4 (out of 7) [28]. In a similar vein, a 70% dropout rate was reported for another web-based CBT program on sexual dysfunction [19].

Given the limited availability of internet interventions addressing sexual problems, further research is needed to understand the reasons behind the observed high dropout rates in the existing literature. As speculations, potential explanations can be made...
related to the nature of the sexual dysfunction, expectations, or outcomes.

Concerning the nature of the problem, given the personal and often taboo nature of sexuality and intimacy, it is reasonable to consider that worries about privacy or social stigma may significantly influence participant adherence to these interventions. Regarding treatment expectations, the concerned population often does not identify sexual problems as biopsychosocial complex problems. This perspective can lead to unrealistic expectations regarding the duration and effectiveness of interventions.

Regarding outcomes, individuals with sexual problems usually have misconceptions about sexual function and response. It is possible that if sufficient improvement is perceived after the psychoeducational phase (usually initial modules) of internet interventions, they might decide not to continue with the intervention.

Although adherence was low in this trial, the treatment remains easily scalable. The web-based intervention can be easily disseminated or updated at almost no cost and, therefore, is much cheaper than traditional face-to-face specialized treatments. Special attention must be paid to improving adherence.

Another important aspect concerns the unequal participation of men and women. While the TREPS training was developed for both men and women, only women participated in the study. This may be attributed to a higher level of interest among women in research studies [59,67] and related to how we recruited the participants. In addition to social media advertisements and contact with participants from a previous questionnaire study who volunteered to participate in future studies, we credited the female sample to a Brazilian female sexual health social media influencer (mainly followed by women), who shared the study on her social media account.

Limitations
First, the high dropout rate precludes any significant conclusions to be drawn from the results. Significant attrition should be addressed as a risk factor in future similar web-based ER training for sexual function. In addition, and in contrast to the potential advantages of web-based interventions (eg, anonymity, ease of access, etc), the high dropout rates in programs of this kind may indicate a serious limitation to the suitability of web-based training concerning sexual health. Second, most participants were highly educated, which affects the generalizability of the results and their scalability. Third, since the inclusion criteria were based on self-report measures, response bias and possible failures to detect interfering medical conditions not known by the participants may have occurred. Fourth, we did not assess participants’ expectations regarding the effects of the training, so it remains unclear as to whether these impacted the results.

Recommendations
For future studies, we recommend some changes in the study design and treatment components. Regarding recruitment, it would be advisable to have a referral system from a specialized sexual or mental health care service. Perhaps the recommendation of the training from a health service could improve adherence. Regarding the intervention, attention should be paid to the points raised by the intervention adherers, such as increasing the length and the amount of information provided per module. Moreover, there are currently no comparisons between web-based ER training for sexual health and face-to-face interventions. For this reason, comparisons between different intervention delivery methods such as face-to-face individual or group format interventions and web-based programs will be important. Future trials would also benefit from the inclusion of partner-related assessments.

Conclusions
Our preliminary results suggest that web-based ER training may be an effective supplementary or alternative treatment for sexual disorders. Completers of the intervention presented improvements both in sexual function domains as well as in emotion regulation. Nonetheless, due to a high dropout rate, this trial failed to collect sufficient data to allow for any conclusions to be drawn on treatment effects.

Despite its limitations, this study presents valuable information about web-based ER interventions for both mental and sexual health treatments. The improvements in ER skills, mental health, and specific sexual domains call for the further development and evaluation of such interventions. Further research is needed to better understand the feasibility and scalability of similar protocols and how male participants would respond to them.

Abstract

Background: While it is treatable, uncorrected refractive error is the number one cause of visual impairment worldwide. This eye condition alone, or together with ocular misalignment, can also cause amblyopia, which is also treatable if detected early but still occurs in about 4% of the population. Mass vision screening is the first and most critical step to address these issues, but due to limited resources, vision screening in many rural areas remains a major challenge.

Objective: We aimed to pilot-test the feasibility of using smartphone apps to enhance vision screening in areas where access to eye care is limited.

Methods: A vision screening program was piggybacked on a charity summer camp program in a rural county in Sichuan, China. A total of 73 fourth and fifth graders were tested for visual acuity using a standard eye chart and were then tested for refractive error and heterophoria using 2 smartphone apps (a refraction app and a strabismus app, respectively) by nonprofessional personnel.

Results: A total of 5 of 73 (6.8%, 95% CI 2.3%-15.3%) students were found to have visual acuity worse than 20/20 (logarithm of minimal angle of resolution [logMAR] 0) in at least one eye. Among the 5 students, 3 primarily had refractive error according to the refraction app. The other 2 students had manifest strabismus (one with 72–prism diopter [PD] esotropia and one with 33-PD exotropia) according to the strabismus app. Students without manifest strabismus were also measured for phoria using the strabismus app in cover/uncover mode. The median phoria was 0.0-PD (IQR 2.9-PD esophoria to 2.2-PD exophoria).

Conclusions: The results from this vision screening study are consistent with findings from other population-based vision screening studies in which conventional tools were used by ophthalmic professionals. The smartphone apps are promising and have the potential to be used in mass vision screenings for identifying risk factors for amblyopia and for myopia control. The smartphone apps may have significant implications for the future of low-cost vision care, particularly in resource-constrained and geographically remote areas.

Introduction

Visual impairment impacts individuals’ ability to participate in activities of daily living and social integration, disrupting their quality of life and health. To mitigate the impact of visual impairment, regular eye exams are important. However, regular eye exams are still a luxury for many people for various reasons that lead to limited access to eye care.

For instance, in sub-Saharan Africa, there are only 2 ophthalmologists per million people, while the global mean is 32. It is the only region in the world where the prevalence of moderate and severe vision impairment has increased from 1990 to 2020 [1,2]. Even in developed countries, disparity in eye care is a grim reality. According to US Centers for Disease Control, the percentage of American adults who reported not having an eye examination within the past year ranged from 20% to 30% [3]. The number is even higher among older persons residing in nursing homes, 53% of whom had not seen an eye care provider in the past year [4]. Inconvenience or inability to visit hospitals, cost concerns, and the limited scale of the eye care work force are the major reasons [4].

The World Health Organization and the International Agency for the Prevention of Blindness launched the VISION 2020: The Right to Sight initiative, aiming to eliminate avoidable blindness in the world by 2020 [5]. In 2021, the agency recognized that uncorrected refractive error is still a major cause of blindness and vision impairment in the world, affecting 86 million individuals [6], although it is treatable with glasses.

The rates of annual vision screening among school-aged children in developed countries are relatively high, but there are still gaps. Strabismus is one of the main risk factors for amblyopia, but it is usually not included in screening protocols due to a lack of professional skills in school nurses. When a child is flagged for amblyopia based on a stereopsis test, the vision disorder is often already present and may be difficult to treat. In 2002, the American Academy of Pediatrics strongly urged the development of efficient strabismus screening technology for preschool and school-aged children [7,8].

A number of studies and reports have suggested that community eye care programs should use health workers with entry-level qualifications and platforms to help patients in remote areas more easily access professionals; these are the 2 key approaches to the success of public vision programs [9,10]. However, a gap in these approaches is the lack of detailed vision examinations for informing medical decisions. This may cause excessively high false-positive referral rates [11]. To address this gap, we have invented several key technologies for smartphone-based vision testing, which include computer vision and psychophysical methods for measuring ocular misalignment [12,13], refractive error [14], and retinal degeneration [15]. Key features of these apps are that no specially made attachment is needed in order to use them and they run on standard smartphones. With minimal training, laypersons can use the apps to perform vision tests as long as their smartphones are compatible. The accuracy of these apps has been evaluated previously against standard clinical testing methods in hospital settings [12,14]. This paper reports the findings from a school vision screening program that used the apps we developed for the first time. We aimed to demonstrate the feasibility of an app-based vision screening program involving both strabismus and refractive error tests performed by nonprofessionals.

Methods

Vision Testing Apps

The app for strabismus assessment (Figure 1) has been validated and evaluated previously in a clinical setting by comparing it with standard clinical methods, including the modified Thorington test, the cover test with prism, and synoptophores [12]. When the app was used in this study, the automated cover test mode was used, in which one of the subject’s eyes was covered while the computer vision algorithm kept tracking the status of both eyes, and the app automatically took a snapshot of both eyes with a flash as soon as the covered eye was uncovered. This mode allowed the examiners to perform cover/uncover or alternating-cover tests. In this study, the cover/uncover test was performed. The app calculates ocular alignment using the Hirshberg method and gives results in prism diopters (PDs) [13].

Figure 1. Two vision screening apps were used in this study. On the left is the photo screening app based on the Hirschberg test to measure ocular alignment. Here, the tester has zoomed in to check the visualization of the measurement. On the right is the interface of the refraction measurement app, which captures images of the patient’s face with the selfie camera and shows stimuli (the letter E has been chosen here) on the left of the screen according to a viewing distance estimated from the face images.

The app for refractive error measurement (Figure 1) has been validated previously and evaluated in a clinical setting by comparing it with standard clinical methods, including autorefractors and noncycloplegic subjective refraction [14].

https://iformative.jmir.org/2024/1/e55270 JMIR Form Res 2024 | vol. 8 | e55270 | p.1591 (page number not for citation purposes)
The app estimates refractive error by measuring the far point distance for discerning 20/20 Tumbling E letters [14] or the 20/20-equivalent clock dial chart [16]. When Tumbling E letters are used, the result is spherical equivalent (SE) power in diopters (D), and when the clock dial chart is used, the results give spherical power and cylindrical power based on 2 far points for perpendicular lines. In this study, the Tumbling E letter stimuli were used first to determine the SE, and then clock dial chart was used to estimate cylinder power around the SE range.

**Vision Screening Protocol**

Participants first underwent visual acuity testing at a 5-m distance from a standard Tumbling E chart (Figure 2). There are 5 letters on each line from 20/40 downwards. Participants were given 0.02 log units credit for each extra letter read. Participants who had visual acuity worse than 20/20 in at least one eye were tested further for refractive error with the refraction app (Figure 1). Near phoria was measured with the strabismus app (Figure 1) approximately 40 cm from the phone while the participants were instructed to fixate on the phone flash. The vision measurement with apps was performed by personnel without optometry expertise. All vision tests were performed under a noncycloplegic condition.

**Figure 2.** A standard Tumbling E eye chart was used in vision screening of 73 children in Sichuan, China, in 2023.

**Participants**

A total of 73 fourth and fifth graders in Meigu County, Sichuan, China, who attended a charity summer camp in 2023 were screened for vision as a part of the charity program. All children lived locally and were members of the Yi people, an ethnic minority group in China. The per capita gross domestic product in Meigu County is about US $2270, 18% of the Chinese national average. Being in a low-income mountainous area, most of the children had never undergone vision testing due to very limited access to local eye care services. They needed to be taught how to report the orientation of the letter E on the eye chart.

**Ethical Considerations**

The vision screening was one component of the charity summer camp program. Consent for the vision test was included in the summer camp consent form. Participants received free tutoring classes, meals, and school supplies during the 2-week summer camp. Other than that, they were not compensated specifically for participating in the vision screening. This paper reports the results of a secondary data analysis. The vision measurement data, with individual identifiable information removed, were shared by the charity program. This research received approval with exemption of consent from the Institutional Review Board of Massachusetts Eye and Ear. The study was conducted in accordance with the tenets of the Declaration of Helsinki.

**Results**

We identified 5 students (7%, 95% CI 2.3%-15.3%) as having visual acuity worse than 20/20 in at least one eye (Table 1). Measuring refraction with the app showed that 2 students had astigmatism (patient P1, cylinder –1 D in the left eye, patient P4, cylinder –0.5 D in the right eye). One student was found to be hyperopic in both eyes (patient P3, sphere +3.2 D in both eyes), and also was strabismic (72-PD esotropia). This was probably a case of accommodative esotropia [17]. His refractive error was not measured directly at the site, but estimated based on the commonly used near point distance of human eyes (25 cm). According to the app, his near point was at 1.2 m, which corresponds to –0.8 D, where he could not see 20/80 letters at close range and maintained 20/80 vision beyond the near point. Therefore, the estimate of his refractive error was 4 – 0.8 = 3.2 D. According to Mantyjarvi’s [18] findings in a hyperopic population, the amplitude of accommodation is at least 4 D, based on which the estimate would also be 3.2 D. Another student was also found to be strabismic (patient P4, 35-PD exotropia). The 2 students with manifest strabismus were suspected to have amblyopia. The student with the worst visual acuity among the participants (20/100 in the right eye and 20/167 in the left eye) had moderate myopia (patient P5, sphere –3 D in both eyes), and her near-phoria was 7-PD esotropia. This student was given a pair of off-the-shelf glasses (–3 D for both eyes), and her vision in both eyes improved to 20/33.
Table 1. Among the 73 students screened in a rural area in China, participants who had visual acuity lower than 20/20 in at least 1 eye (5 of 73 children) are listed here. Refraction and phoria were measured using the 2 apps shown in Figure 1. The text describes the estimation method.

<sup>a</sup>logMAR: logarithm of minimal angle of resolution.
<br><sup>b</sup>Refraction for patient 3 was calculated based on the near point acquired by the refraction app.
<br><sup>c</sup>Manifest strabismus, measured without cover.

Figure 3 shows the distribution of the near-phoria of the students, excluding the 2 students with manifest strabismus, who are listed in Table 1. Phoria was under 10 PD in the majority. The median phoria was 0.0 PD (IQR 2.9-PD esophoria to 2.2-PD exophoria). There was 1 outlier, a student with 26-PD esophoria and normal visual acuity. Excluding this outlier, the mean phoria of the group was 0.2 (SD 4.1)-PD esophoria.

**Discussion**

**Summary**

By using 2 mobile apps designed for vision testing, ocular alignment and refraction measurements were successfully and easily incorporated in school vision screening. The testing results provided much richer information than conventional vision screening, which normally does not include the 2 tests. Based on this particular screening, the vision issues among the rural-area, school-aged children were primarily uncorrected refractive error and amblyopia.

**Interpretations**

While myopia prevalence rates are very high in East Asia, including China, where in some economically developed cities, it is even above 80% among school-aged students [19], the majority of the fourth and fifth grade students in this screening had emmetropic vision (uncorrected visual acuity better than 20/20). Ample outdoor activity time and a light burden of study requiring the use of near vision, as we witnessed and surveyed during the summer camp, are likely the main reasons for the large differences between these students and their urban counterparts. Nevertheless, 4% (3/73) of the children mainly
had refractive error (patients P1, P2 and P5 in Table 1). This rate is very similar to the prevalence (4.1%) found in the rural child population in India [20]. In addition, there were 2 students (2.7%) with manifest strabismus (patients P3 and P4 in Table 1). This rate is within the range of strabismus prevalence (2.06%-3.9%) among children in Taiwan in the years 2014 to 2019 [21]. As for the phoria of the nonstrabismic students in this study (mean phoria 0.2-2.0 PD esophoria, SD 4.1 PD; IQR 2.9-2.4 PD esophoria to 2.2-2.0 PD esophoria), it is similar to the normative range found among 879 elementary school students by Lyon et al [22] using the modified Thorington test (mean 1-1PD exophoria, SD 4 PD; IQR 2.0-2.0 PD esophoria to 2-2 PD exophoria).

The consistency with epidemiology findings from other large population-based vision screening studies suggests that the screening results in this study are probably reliable. A difference from previous screening studies, though, is that this screening study used smartphone-based strabismus and refractive error tests, while most vision screening studies were conducted by professionals using conventional optometry methods. For instance, in the screening study by Dandona et al [20], strabismus was assessed using a penlight and refractive error was measured using a streak retinoscope and handheld autorefractor; both measurements were made by ophthalmic professionals. Our study provides a proof of concept that vision screening tests, including for strabismus and refractive error, can be performed using smartphone apps by persons without optometry expertise. A further study to develop the use of this simple and portable approach to mass vision screening is warranted.

Limitations

One limitation of this study was that the vision test results were not verified by clinical gold standard testing due to the nature of the education charity program. However, it should be noted that the main focus of this study was not to evaluate measurement accuracy, as previous evaluation studies have already addressed that aspect. The difference from our previous evaluation is that this study involved a sample that included people with and without eye conditions, while previous studies deliberately selected patients with a wide range of conditions.

Implications

Thanks to their affordability, ubiquity, and validity, smartphone-based vision screening tools have the potential to play a pivotal role in mass vision screening efforts, particularly in areas where access to eye care is limited. These innovative tools may impact eye health care by providing a cost-effective and convenient solution for screening, identifying, and addressing vision issues, especially in underserved communities.

One example of such technology is the Peek Acuity app (Peek Vision), which has made significant strides in the field of mobile vision screening. This app has been deployed to screen tens of thousands of individuals in some studies in Africa [9,23,24]. Its success in large-scale vision screening efforts underscores the scalability and effectiveness of smartphone-based apps. By offering an efficient way to measure visual acuity, the Peek Acuity app has empowered health care providers to reach more people, making it a useful tool for addressing visual impairment.

Another photoscreening app, GoCheck Kids (Gobiquity Inc), is primarily designed to assess for amblyopia risk factors [11,25]. By analyzing eccentric photorefraction red-reflex images, the app does not require patients to respond, and it therefore can be used to examine preverbal children. The app has been tested in clinical trials by comparing it with its counterparts among dedicated screening devices, such as iScreening [26]. It is reported by the company that developed GoCheck Kids that 4 million children have been screened [27].

Considering the successful deployment of these smartphone apps, we expect that a mobile technology–based vision screening approach, operated by personnel with basic training, will be scalable and will complement service programs provided by ophthalmic clinicians and dedicated screening devices (eg, iScreen, Spot Vision Screener). The mobile app approach is particularly suitable for low-resource countries and could also be used for screening in classrooms. Compared to Peek Acuity and GoCheck Kids, the screening apps assessed in this study can measure refractive error and strabismus quantitatively rather than flagging for risk factors (GoCheck Kids) or not measuring these most common conditions at all (Peek Acuity).

Our future investigations will aim to assess the positive and negative predictive values of these apps in large-scale vision screening programs, building upon the feasibility demonstrated in this preliminary study.

Acknowledgments

The phoria testing app was developed with support in part from the National Institutes of Health (NIH; grant SBIR R44 EYO25902 awarded to EyeNexo LLC, which GL cofounded). The refraction testing app was developed in collaboration with EyeNexo by GL’s lab with support in part from the NIH (grant EYO34345), a Harvard Catalyst award (National Center for Advancing Translational Sciences; NIH award UL1 TR002541), and financial contributions from Harvard University and its affiliated academic health care centers. Abstract

Background: University students frequently report elevated levels of stress and mental health difficulties. Thus, the need to build coping capacity on university campuses has been highlighted as critical to mitigating the negative effects of prolonged stress and distress among students. Since the COVID-19 pandemic, web-based stress management resources such as infographics and web-based workshops have been central to supporting university students’ mental health and well-being. However, there is a lack of research on students’ satisfaction with and uptake of these approaches. Furthermore, mental health stigma has been suggested to have not only fueled the emergence of these web-based approaches to stress management but may also influence students’ help-seeking behaviors and their satisfaction with and uptake of these resources.

Objective: This study explored potential differences in students’ satisfaction and strategy use in response to an interactive infographic (an emerging resource delivery modality) presenting stress management strategies and a web-based workshop (a more common modality) presenting identical strategies. This study also examined the relative contribution of students’ strategy use and family-based mental health stigma in predicting their sustained satisfaction with the 2 web-based stress management approaches.

Methods: University students (N=113; mean age 20.93, SD 1.53 years; 100/113, 88.5% women) completed our web-based self-report measure of family-based mental health stigma at baseline and were randomly assigned to either independently review an interactive infographic (n=60) or attend a synchronous web-based workshop (n=53). All participants reported their satisfaction with their assigned modality at postintervention (T1) and follow-up (T2) and their strategy use at T2.

Results: Interestingly, a 2-way mixed ANOVA revealed no significant group × time interaction or main effect of group on satisfaction. However, there was a significant decrease in satisfaction from T1 to T2, despite relatively high levels of satisfaction being reported at both time points. In addition, a 1-way ANOVA revealed no significant difference in strategy use between groups. Results from a hierarchical multiple regression revealed that students’ strategy use positively predicted T2 satisfaction over and above strategy use.

Conclusions: While both approaches were highly satisfactory over time, findings highlight the potential utility of interactive infographics since they are less resource-intensive than web-based workshops and students’ satisfaction with them is not impacted by family-based mental health stigma. Moreover, although numerous intervention studies measure satisfaction at a single time point, this study highlights the need for tracking satisfaction over time following intervention delivery. These findings have implications for student service units in the higher education context, emphasizing the need to consider student perceptions of family-based mental health stigma and preferences regarding delivery format when designing programming aimed at bolstering students’ coping capacity.

Introduction
Overview
The overwhelming reports of stress, distress, and mental health difficulties among university students necessitate urgent action to build coping capacity on university campuses. In a recent survey conducted with 96,489 students across 137 universities by the American College Health Association, 51.2% of university students reported moderate psychological distress, while 24% indicated serious psychological distress [1]. As such, building coping capacity on university campuses is critical, given the negative effects of prolonged stress and distress on academic performance, well-being, and daily functioning [2-4].

Recently proposed theoretical models provide insight into the ways in which university students cope with stress and distress. The Health Theory of Coping [5] posits that university students’ approaches to coping with distress and difficulty exist along a continuum ranging from low- to high-intensity strategies that can be classified as healthy (low risk for adverse health outcomes) or unhealthy (high risk for adverse health outcomes). For example, high-intensity unhealthy coping strategies that pose a risk for unintended negative physical, psychological, and social consequences include substance abuse, self-harm, and suicidality. By contrast, high-intensity coping strategies classified as healthy include social support and professional support. Similarly, low-intensity, unhealthy coping strategies include negative self-talk and rumination, while low-intensity, healthy coping strategies include self-soothing and relaxing or distracting activities. This theory further suggests that individuals will move from lower-intensity coping practices (eg, negative self-talk and self-soothing) to higher-intensity practices (eg, suicidal ideation and professional support) proportional to the degree of distress they experience. Regularly engaging in lower-intensity healthy coping behaviors such as self-soothing, positive self-talk, and breathing exercises can enhance one’s future capacity to cope with distress, difficulty, and uncomfortable emotions [5,6].

Previous research has identified lower-intensity healthy coping strategies (eg, progressive muscle relaxation, diaphragmatic breathing, and meditation) that are effective at promoting resilience by reducing distress and increasing well-being in university students [7,8]. Specific cognitive, behavioral, and mindfulness-based approaches have been shown to effectively reduce levels of anxiety, depression, and the physiological stress response [9-11]. These findings emphasize the value of increased availability of lower-intensity resources that promote coping capacity among university students. Additionally, the use of lower-intensity resources to build coping capacity can also decrease the need for more intensive one-on-one therapeutic services, as university mental health services are struggling to meet elevated demands [12-14]. Therefore, providing students with resources and instruction on these accessible, acceptable, and lower-intensity healthy coping strategies is a timely priority for universities [13,14].

Barriers to Building Coping Capacity in University Students
Barriers to optimal mental health and well-being on university campuses extend beyond a lack of resources [14]. In particular, mental health–related stigma among students functions as a barrier in this context [15,16]. Specifically, mental health stigma has been shown to inhibit help-seeking behaviors among university students [17,18]. According to a systematic review of quantitative and qualitative studies conducted by Clement et al [19], mental health stigma exhibited a negative association with help-seeking. Furthermore, young adults’ perceived stigma from others (eg, family members) regarding seeking mental health treatment undermines their willingness and opportunities to seek help [20]. Similarly, a recent systematic review found that the second most commonly reported barrier by university students to help-seeking behavior was mental health stigma [21]. Specifically, students expressed being worried about their family or friends not being able to understand their situation or that they would perceive them in an unfavorable light.

A body of literature also demonstrates that university students’ cultural, racial, or ethnic identities may have an impact on their help-seeking behaviors. Specifically, university students from certain cultures, races, and ethnic groups may be at greater risk of experiencing mental health difficulties [22] and may be less likely to receive mental health treatment [23]. However, a systematic review and meta-analysis conducted by Wang et al [24] found that culture was not a significant contributor to mental health information-seeking behavior. Thus, the intersectionality of cultural, racial, and ethnic identities in the context of mental health resource use is highly complex, with inconclusive findings, and beyond the scope of this study. Interestingly, as reported in a systemic review by Lui et al [21], stigma around mental health was a key contributor to help-seeking for university students. As such, an individual’s perceptions around the degree of mental health stigma that is present in their familial context provide an opportunity to examine the potential role of mental health stigma in influencing university students’ satisfaction with and use of resources for their mental health and stress management.

Taken together, the above literature demonstrates that there is a need for innovative approaches to the delivery of mental health and well-being resources to university students, which accounts for the impact of mental health stigma on help-seeking in the higher education context. Stigma-related barriers to help-seeking behaviors on university campuses have, in part, fueled the emergence of alternative web-based approaches for sharing stress management and well-being resources with students.

Emergence and Utility of Web-Based Resources for Stress Management

During the COVID-19 pandemic, web-based resources became central in providing students with stress management support remotely [25] and have been disseminated using different modalities. Particularly, standard in-person workshops were adapted to a web-based format to be delivered on the web. These web-based workshops have gained popularity in the university context, as they allow students to learn and engage with stress management material remotely while still providing them with the opportunity to ask for clarifications from an experienced facilitator. Similarly, mental health and well-being service delivery through interactive infographics has gained popularity in recent years, given their utility for conveying complex information in a concise, visually appealing, and layperson-friendly manner to general audiences [26,27]. Moreover, interactive infographics include features for users to engage with the content (eg, links to guided audio recordings and strategy practice). However, despite their emerging use, research on the use of infographics for promoting mental health and stress management among university students is scarce. Specifically, although user satisfaction and uptake have been highlighted as crucial elements associated with intervention effectiveness in university students [28], to our knowledge, studies have yet to examine students’ acceptability of emerging modalities of resource provision (eg, web-based workshops and interactive infographics). Thus, there is a need for further evidence on students’ satisfaction, uptake, and use of these web-based resources, as well as which factors contribute to satisfaction with these web-based approaches to university mental health resource provision.

Furthermore, investigations into university students’ satisfaction with interactive infographics and web-based workshops for stress management should consider common barriers to students accessing mental health support [15,16]. Given the level of autonomy that is inherent in using web-based mental health resources [29], ensuring adherence to intervention recommendations (eg, at-home practice of strategies taught) is another challenge that may impact web-based resource satisfaction [30,31]. Furthermore, adherence to resources may vary as a function of the modality of web-based stress management resource provision [31,32]. For instance, some self-guided web-based resources (eg, websites) have been associated with lower levels of adherence [32]. Importantly, research has suggested a potential positive association between adherence, which is measured as participants’ frequency of strategy use, and satisfaction with a web-based mental health intervention [33,34]. Thus, there has been a call to monitor and promote adherence (ie, strategy use) in the dissemination of self-guided web-based resources to optimally support user satisfaction with them [35].

This Study

Drawing on the interdisciplinary literature reviewed above, the overarching aim of this study was to explore students’ relative satisfaction and strategy use when presented with a stress management resource delivered through a web-based workshop (a relatively common mode of resource delivery) versus an interactive infographic (an innovative, emerging mode of resource delivery). This study also aimed to explore potential contributing factors to sustained satisfaction with these 2 modalities of resource delivery, specifically the role of strategy use (ie, adherence) and family-based mental health stigma. The first objective was to examine whether university students’ satisfaction with web-based stress management resources would differ as a function of their delivery format (ie, interactive infographics and web-based workshops) and over time. The second objective was to examine whether students’ strategy use would differ as a function of delivery format. The third objective was to explore the relative contribution of students’ strategy use and family-based mental health stigma in predicting their sustained satisfaction with the interactive infographic versus the web-based workshop. Given the exploratory nature of the study objectives, no specific hypotheses were made. Specifically, for the first objective, based on anecdotal and clinical experience in mental health service delivery, it was anticipated that there might be a differential response such that the participants in the interactive infographic group maintain their satisfaction for a longer period of time than participants in the web-based workshop group given the continued ease of accessing the interactive infographic (ie, self-guided and can be accessed anywhere at any time). However, in the absence of a body of literature examining university students’ satisfaction with the 2 modalities over time, no specific hypothesis was proposed.

Methods

Ethical Considerations

This study was approved by the McGill University Research Ethics Board (#21-10-040). Participants who indicated an interest in participating in this study were invited to complete a web-based survey where the first page of the survey was the consent form explaining that participation in this study was optional and completely voluntary, that responses would be confidential, and that participants could choose not to answer any of the questions should they not want to. Each participant was identified on Qualtrics (Silver Lake) using a unique participant ID number associated with their email address; identifiable data (ie, email addresses) were deleted from Qualtrics once data collection was complete. The master list matching participant information to their unique study ID was protected with a password, saved on a password-protected computer, and was only accessible to the principal investigator and graduate student research assistants working on this study. For the web-based workshop, participants were informed ahead of time that they may choose to keep their cameras off for the duration of the workshop and can log in with only their first name or pseudonym to further preserve confidentiality. Participants were compensated CAD $10 (US $7.43) through electronic transfer for each satisfaction survey completed, up to a maximum of CAD $20 (US $14.85) for completing both satisfaction surveys (T1 and T2).

Participants

A total of 168 undergraduate students were recruited during the Winter 2022 semester. Of those 168 students, 3 graduate
students were excluded from the analyses, given evidence suggesting that undergraduate and graduate students have different stressors and coping strategies [36]. In addition, 1 student was excluded for not completing the demographic questionnaire. A total of 164 students were randomized to either the interactive infographic group (n=81) or the web-based workshop group (n=83). After the randomization, 51 were excluded from the primary analyses due to attrition. Thus, the final sample was composed of 113 students (interactive infographic group n=60; web-based workshop group n=53). Of this final sample of 113 students (mean age 20.93, SD 1.53 years), 88.5% (100/113) self-identified as women, 9.7% (11/113) self-identified as men, and 1.8% (2/113) self-identified as nonbinary. The participants self-identified as White (47/113, 41.6%), Asian (44/113, 38.9%), multiple ethnicities (10/113, 8.9%), Arab or Middle Eastern (5/113, 4.4%), Black or African (4/113, 3.5%), and Hispanic or Latinx (3/113, 2.7%). The participants enrolled in diverse faculties, including arts (66/113, 58.4%), science (20/113, 17.7%), dual majors (11/113, 9.7%), nursing (6/113, 5.3%), law (3/113, 2.7%), and others (7/113, 6.2%).

**Intervention Development and Description**

Both interventions (ie, the interactive infographic and web-based workshop) were researcher-developed for the purposes of this study and focused on four main areas of stress management: (1) pause or break, (2) positive awareness, (3) kindness to self, and (4) social connection. These areas came from a review of the literature on stress management programs for university students [7,9,37]. Pause or break draws on principles of mindfulness, which may be defined as paying attention to what we sense or experience in this moment, on purpose, and with nonjudgmental acceptance [38,39]. Positive awareness promotes our ability to notice the positive things that happen to us [40-42]. Kindness to self draws on research in the area of self-compassion [43,44]. Lastly, building social connections draws on research in the area of social connectedness, such that the aim is to enhance an individual’s sense of belongingness with other people, groups, or their communities, as well as to maintain and strengthen these connections over time [45-47].

Both the interactive infographic and web-based workshop included psychoeducation around stress as well as evidence-based, low-intensity healthy strategies for stress management and to build coping capacity [5,7,8]. Specifically, students were provided with clear descriptions of each of the 4 areas of stress management described above, as well as a variety of research-based stress management strategies pertaining to each area using clear text descriptions, images, videos, guided audio recordings, links to relevant websites, and podcasts. The interactive infographic and the web-based workshop (including a resource sheet that was provided to all workshop attendees) contained identical content; only the delivery format differed. Table S1 in Multimedia Appendix 1 provides a detailed outline of the intervention content.

**Procedure**

**Overview**

Participants were recruited on the web through flyers advertising the study. Potential participants were invited to provide consent and complete a brief demographic survey hosted on the web on Qualtrics. Participants were then randomly assigned to either the interactive infographic group or the web-based workshop group. All participants then received an email providing further information about the study procedure based on their assigned condition and were asked to select their preferred time slot (among 3 choices within the same week) to review the interactive infographic or attend the web-based workshop. Participants were not informed of the nature of the condition to which they were not assigned.

Both the interactive infographic and web-based workshop sessions were scheduled to be delivered at least 1 week after the completion of the demographics survey. After their respective interventions, participants completed a web-based satisfaction questionnaire at 2 time points: immediately after the intervention (postintervention: T1) and 2 weeks later to assess their sustained satisfaction and frequency of strategy use over the 2-week period (follow-up: T2). Between T1 and T2, participants were not provided with any specific instructions or guidelines for practicing strategies. Following completion of the study, participants were debriefed regarding the study purpose and design and received all materials from both interventions.

**Interactive Infographic Group**

Participants in the interactive infographic group received access to the interactive infographic (in PDF format) through Qualtrics. Participants were instructed to review the interactive infographic content and practice the embedded stress management strategies for a total of 30 minutes. To guarantee that participants engaged with the interactive infographic for the full duration, a timer embedded in the Qualtrics page only allowed participants to proceed to the next page of the survey once the 30 minutes had passed. To support participants’ continued use of the strategies presented on the interactive infographic between T1 and T2, the interactive infographic was subsequently shared with participants through email.

**Web-Based Workshop Group**

Participants in the web-based workshop group attended a 30-minute workshop through Zoom (Zoom Video Communications). All workshops were delivered by the same research assistant, who followed an oral script. Similar to the interactive infographic group, to support participants’ continued use of the strategies presented during the web-based workshop between T1 and T2, a 1-page resource sheet summarizing the information and strategies presented during the workshop was shared with participants through email.

**Measures**

**Satisfaction**

Participants’ satisfaction with the stress management resources was assessed using an 8-item researcher-developed questionnaire...
based on the new world Kirkpatrick model for program evaluation [48]. Specifically, the questions assessed participants’ (1) reaction (satisfaction, engagement, and relevance) and (2) learning (knowledge, skills, attitude, confidence, and commitment), which correspond respectively to levels 1 and 2 of the new world Kirkpatrick model. For instance, sample items related to (1) reaction included: “I found the infographic/workshop useful for me and I found that the infographic/workshop was presented in an engaging manner,” while sample items related to (2) learning included:

The strategies presented in the infographic/workshop helped me better understand how to manage my stress and improve my wellness and I feel confident in my understanding of the suggested strategies in the infographic/workshop.

Participants responded on a 4-point Likert scale (1=“strongly disagree” to 4=“strongly agree”). The possible sum satisfaction scores ranged from 8 to 32, where a higher sum score denoted greater satisfaction. This measure demonstrated good internal consistency at T1 (Cronbach α=0.82) and at T2 (Cronbach α=0.90).

**Strategy Use**

Participants’ frequency of strategy use was assessed using a researcher-developed single-item measure at T2. Although participants were introduced to numerous strategies within their stress management resource (Table S1 in Multimedia Appendix 1 provides an outline of the strategies taught), this particular item asks participants about their overall use of any combination of the strategies taught. Specifically, this item corresponds to level 3 (behavior) of the new world Kirkpatrick model for program evaluation [48]. Participants were asked to respond to the following item: “Over the past two weeks, how often did you use the strategies presented in the infographic/workshop?” Participants responded using a 4-point Likert scale (1=“never” to 4=“every day”), where a higher score indicated more frequent use of strategies.

**Family-Based Mental Health Stigma**

Perceived mental health stigma from family members (ie, family-based mental health stigma) was assessed using a researcher-developed single-item measure at baseline. Participants were asked to think about their experiences with mental health-related stigma within their immediate (eg, parents and siblings) or extended family (eg, grandparents, aunts, and uncles) and were asked to respond to the following item: “In my family, I feel there is stigma associated with talking about having mental health difficulties.” Participants responded on a 5-point Likert scale (1=“strongly disagree” to 5=“strongly agree”), where a higher score indicated greater family-based mental health stigma.

**Data Analysis**

For the first objective, a 2-way mixed ANOVA was conducted to examine the effect of group (interactive infographic and web-based workshop) and time (T1 and T2) on students’ satisfaction with web-based stress management resources. For the second objective, a 1-way ANOVA was conducted to examine potential group differences in strategy use. Lastly, for the third objective, separate hierarchical multiple regressions were run for the interactive infographic group and the web-based workshop group to examine whether family-based mental health stigma predicted students’ sustained satisfaction with web-based stress management resources at T2, even when controlling for their strategy use.

Results

**Main Analyses**

**Objective 1**

The first objective sought to compare group differences in university students’ satisfaction with an interactive infographic versus a web-based workshop for stress management over time (from T1 to T2). A 2-way mixed ANOVA revealed that there was no significant interaction between group (interactive infographic and web-based workshop) and time (T1 and T2) on students’ satisfaction (Table 1). In addition, there was no significant main effect of group, indicating that, regardless of time (T1 and T2), there were no group differences in students’ satisfaction between the interactive infographic and the web-based workshop; overall, students in each group were highly satisfied at both T1 and T2. However, there was a significant main effect of time, where satisfaction decreased for all students from T1 to T2, regardless of their assigned group.

Objective 2
The second objective sought to compare group differences in students’ strategy use with an interactive infographic versus a web-based workshop for stress management over the 2-week study period (assessed retrospectively at T2). A 1-way ANOVA revealed that there was no significant difference in strategy use between the interactive infographic group (mean 2.02, SD 0.57) and the web-based workshop group (mean 2.13, SD 0.62; F4,111=1.065; P=.30).

Objective 3
The third objective sought to examine the potential contribution of students’ strategy use and family-based mental health stigma in predicting their sustained satisfaction with each web-based stress management approach at T2. We ran 2 hierarchical multiple regression analyses (1 for each group), where strategy use frequency was entered in step 1 and family-based mental health stigma was entered in step 2. Table 2 presents the results of the hierarchical multiple regression analyses.

The hierarchical regression results revealed that, in the infographic group, students’ strategy use frequency explained 25% of the variance in sustained satisfaction at T2 (F1,58=19.27; P<.001; R²=0.25). Specifically, strategy use frequency (β=.50; P<.001) emerged as a significant positive predictor of students’ sustained satisfaction at T2. When controlling for strategy use frequency, family-based mental health stigma (β=.03; P=.83) did not emerge as a significant predictor of sustained satisfaction at T2 (F1,57=0.05; P=.83, ΔR²=0.00).

In the web-based workshop group, students’ strategy use frequency explained 11% of the variance in sustained satisfaction at T2 (F1,50=6.14; P=.02; R²=0.11). Specifically, strategy use frequency (β=.33; P=.02) emerged as a significant positive predictor of students’ sustained satisfaction at T2. When controlling for strategy use frequency, family-based mental health stigma contributed an additional 10% explained variance in sustained satisfaction at T2 (F1,50=6.42; P=.01; ΔR²=0.10). Thus, family-based mental health stigma (β=-.32; P=.01) emerged as a significant negative predictor of students’ sustained satisfaction at T2. The full model of strategy use frequency and family-based stigma surrounding mental health difficulties significantly predicted sustained satisfaction at T2 in the web-based workshop group (F2,50=6.60; P=.003; R²=0.21), for a total of 21% explained variance.

Discussion

Overview

Previous literature has noted the promising benefits of web-based stress management resources for university students, including their cost-effectiveness and flexibility [49-52]. However, it remains unclear how readily students accept interactive infographics, a relatively new and innovative resource modality, compared to the widely adopted standard web-based workshops. This study was thus guided by 3 overarching objectives. The first objective was to compare university students’ satisfaction with an interactive infographic versus a web-based workshop over time (from T1 to T2). The second objective was to compare strategy use between students who engaged with an interactive infographic versus a web-based workshop. Building on the first and second objectives, the third objective was to examine whether students’ sustained satisfaction with each of the web-based stress management approaches at T2 could be predicted by their strategy use and family-based mental health stigma.

The findings from this study demonstrated that across time points, university students who received web-based stress management support through the interactive infographic and the web-based workshop did not significantly differ from one another in their satisfaction with the resources. Furthermore, the findings revealed that university students’ strategy use did not significantly differ between the interactive infographic group and the web-based workshop group. Taken together, these findings suggest that when identical psychoeducation content and evidence-based stress management strategies are delivered to university students, their satisfaction and strategy use over time do not differ as a function of whether they received the stress management instruction through an interactive infographic or a web-based workshop. Rather, in this study, students were highly satisfied with both the interactive infographic and the web-based workshop. Since research on the use of interactive infographics for promoting mental health and stress management among university students is scarce, these novel findings suggest that the delivery of stress management support through interactive infographics may be well-received by university students. Thus, the use of interactive infographics within the context of university-wide stress management and mental health programming warrants further investigation, particularly since they are a novel approach and are less resource-intensive than other resources (eg, in-person and web-based workshops). Additionally, as highlighted in the mental health information seeking literature, students are consistently turning to web-based resources for support; thus, there is a need for universities to provide students with new online approaches to resource delivery to enhance their well-being [21]. Offering evidence-based self-directed resources could benefit university students who prefer self-reliance to address mental health difficulties and can mitigate reported challenges such as time constraints and stigma [21,53].

Although many intervention studies measure satisfaction at a single time point [54], the importance of measuring satisfaction over time following intervention delivery has been highlighted, as there is a possibility that acceptability may change during the weeks following exposure to the intervention [55,56]. Indeed, in this study, students’ satisfaction with the interactive infographic and the web-based workshop significantly decreased from T1 to T2. However, it should be noted that, given the small magnitude of these decreases across both groups (ie, less than a 2-point decrease across groups on a scale ranging from 8 to 32), these decreases may not be clinically meaningful. Furthermore, students’ satisfaction remained relatively high across the 2 time points, with mean scores ranging from 25.97 to 27.89 out of 32 for both groups (Table 1). Nevertheless, we propose 3 possible interpretations for the decrease in satisfaction from T1 to T2, even though it remained relatively high over time. First, it is possible that the observed decrease in satisfaction over time was related to students’ initial enthusiasm regarding the strategies presented in the program, which may have been followed by barriers encountered over the two weeks that followed, such as a lack of time to engage in strategy practice [57,58]. This may have, in turn, slightly negatively impacted their satisfaction with the resources. Another potential explanation for this finding is that participants may be less likely to recall resource content with the passage of time, resulting in a less favorable satisfaction rating when followed up with at a later date. Finally, as with any repeated measures design, other unmeasured confounding variables present during the intervention period may explain this time effect as well. Thus, additional studies are needed to examine factors that may influence satisfaction with stress management resources over time to support the sustainability of resource use in the long term.

Furthermore, this study considered that students’ self-directed practice of the strategies presented, along with their family-based mental health stigma, may have an influence on their sustained satisfaction with the interactive infographic and the web-based workshop. Indeed, the frequency of strategy use was a significant predictor of university students’ sustained satisfaction with both modalities at T2. The more frequently participants used strategies over the 2 weeks, the higher they rated their sustained satisfaction with the web-based stress management resource at T2. This finding is not surprising since previous literature on intervention adherence has shown that greater adherence to self-directed web-based interventions is positively related to more favorable outcomes [59]. However, further research into the temporal nature of the relationship between strategy use and satisfaction is needed, as it remains unclear whether increased strategy use leads to greater satisfaction or vice versa. Nevertheless, this finding highlights the degree to which strategy use and sustained satisfaction are intertwined. In the context of stress management intervention design and delivery in university settings, this suggests that importance should be placed on (1) providing students with a variety of strategies such that they can find ones that they like and that work for them, as well as (2) building a community or environment within the university where strategy use is supported and encouraged.

Interestingly, after controlling for the frequency of strategy use, students’ family-based mental health stigma significantly predicted the web-based workshop group’s sustained satisfaction.
at T2, over and above students’ strategy use. Specifically, when students had greater family-based mental health stigma, their sustained satisfaction with the web-based workshop at T2 was lower. Although it was delivered remotely, the web-based workshop was conducted over Zoom in the presence of a live facilitator and other student attendees, unlike in the context of reviewing an interactive infographic. According to a systematic review conducted by Pretorius et al [29], young people (aged 25 years or younger) tend to be concerned about their privacy and confidentiality even when they are engaging in web-based help-seeking. While participating in the web-based workshop, students with higher levels of family-based stigma may have felt negatively due to the internalization of their perceived stigma from others, as suggested by literature [60,61], which may have negatively influenced their satisfaction. Thus, reports of family-based mental health stigma may have had a greater impact on participants in the web-based workshop group relative to participants in the interactive infographic group because of the relatively lower levels of privacy and confidentiality inherent in workshop participation.

In contrast, students’ family-based mental health stigma did not significantly predict the interactive infographic group’s satisfaction at T2 over and above their strategy use. Due to the relatively private nature of engaging with interactive infographics, students who received the stress management resource through this delivery format did not directly interact with the resource providers or other students while engaging with the infographic. Thus, it is plausible that their satisfaction was less influenced by perceived mental health stigma while acquiring stress management knowledge and practicing the strategies. These findings highlight that, even in the context of web-based stress management initiatives, mental health-related stigma may still be an important factor to consider for university students’ satisfaction with specific resource delivery formats.

Limitations and Future Directions
While these findings shed new light on university students’ satisfaction with online stress management approaches and the associations between their satisfaction and family-based mental health stigma, they should be interpreted within the context of several limitations. First, this study did not directly address the impact of university students’ culture, race, and ethnicity on their help-seeking behavior and instead focused on students’ perceived family-based mental health stigma. Future studies may wish to explore potential cultural, racial, and ethnic differences in university students’ uptake of and satisfaction with different modalities for mental health resource provision. Second, women accounted for a large majority of the sample (100/113, 88.5%), which also limits the generalizability of findings. Future studies may benefit from examining the acceptability of web-based resources for stress management with samples that are more diverse in terms of gender identity. Third, this study used a researcher-developed single-item approach for measuring strategy use and family-based mental health stigma. A limitation of this approach is that it is impossible to calculate internal consistency estimates of reliability [62]. However, it has been suggested that there is no difference in the predictive validity of single-item measures and multi-item measures [63]. Furthermore, an advantage of using single-item measures is the increased brevity and thus feasibility of capturing a psychological construct (eg, individuals’ beliefs) in a simple screening [62]. The fact that both variables were found to be significantly related to sustained satisfaction, despite being limited to single-item measures, demonstrates that these single-item measures have the potential for use, and it is a first step for tapping into individuals’ perceptions of family-based mental health stigma. Lastly, this study examined students’ satisfaction with the 2 web-based stress management approaches but did not compare their effectiveness. Although this was an important first step, future studies are needed to evaluate the effectiveness of different formats of web-based resource delivery, such as interactive infographics and web-based workshops, on students’ mental health-related outcomes (eg, stress, mindfulness, and well-being). Additionally, given findings on the impact of family-based mental health stigma on satisfaction among students in the web-based workshop group, future studies may want to examine specific strategies to address or mitigate the impact of family-based mental health stigma in the context of web-based workshop delivery.

Contributions
Despite these limitations, the findings from this study contribute to our understanding of university students’ satisfaction with web-based stress management approaches, in addition to their association with their family-based mental health stigma. Given the impact of stigma on mental health service and resource use [15,64], as well as the paucity of research examining students’ receptivity to interactive infographics for stress management and well-being resource delivery, this study is a first step in demonstrating the relationship between university students perceived mental health stigma and satisfaction with both interactive infographics and web-based workshops. These findings have implications for student service units in the higher education context. Specifically, they highlight the importance of carefully considering student perceptions of mental health stigma and preferences regarding format of delivery when designing programming to support building students’ coping capacity [34,65].

Conclusion
Since the COVID-19 pandemic, web-based stress management resources are increasingly being delivered to university students to support their elevated mental health and well-being needs. This study provides preliminary evidence that students’ satisfaction with web-based stress management resources may not differ as a function of delivery modality (ie, whether the instruction is delivered through an interactive infographic or a web-based workshop). This study thus has implications for future approaches to mental health service delivery in universities, as the results demonstrate students’ high satisfaction with 2 different web-based delivery formats. Moreover, findings emphasize the negative impact of students’ perceived mental health stigma on their satisfaction with web-based workshops. Overall, while both an interactive infographic and a web-based workshop elicited high levels of satisfaction across time points in this study, results highlight the utility of interactive infographics since they are less resource-intensive than workshops, easy to access and distribute, and given that
students’ satisfaction with them is not impacted by family-based mental health stigma.

Data Availability
The data generated or analyzed during this study are not publicly available since the authors documented on the institutional ethics board that the data will not be shared with any other researchers.

Authors’ Contributions
SC made substantial contributions to the study’s methodological design, data collection, data analysis, interpretation of the results, manuscript writing, and editing of the final manuscript. LB, JP, and NLH made substantial contributions to the study conceptualization, design, data collection, data analysis, interpretation of the results, and critical revisions of manuscript drafts and approved the final manuscript. BNB made substantial contributions to the study conceptualization, design, and critical revisions of manuscript drafts and approved the final manuscript.

Conflicts of Interest
None declared.

Abstract

Background: About 11 million Americans are caregivers for the 6.7 million Americans currently living with dementia. They provide over 18 billion hours of unpaid care per year, yet most have no formal dementia education or support. It is extremely difficult for clinicians to keep up with the demand for caregiver education, especially as dementia is neurodegenerative in nature, requiring different information at different stages of the disease process. In this digital age, caregivers often seek dementia information on the internet, but clinicians lack a single, reliable compendium of expert-approved digital resources to provide to dementia caregivers.

Objective: Our aim was to create a dementia caregiver resources website to serve as a hub for user-friendly, high-quality, and expert-reviewed dementia educational resources that clinicians can easily supply to family caregivers of people with dementia.

Methods: An interdisciplinary website development team (representing dementia experts from occupational therapy, nursing, social work, geriatrics, and neurology) went through 6 iterative steps of website development to ensure resource selection quality and eligibility rigor. Steps included (1) resource collection, (2) creation of eligibility criteria, (3) resource organization by topic, (4) additional content identification, (5) finalize resource selection, and (6) website testing and launch. Website visits were tracked, and a 20-item survey about website usability and utility was sent to Veterans Affairs tele-geriatrics interdisciplinary specialty care groups.

Results: Following website development, the dementia caregiver resource website was launched in February 2022. Over the first 9 months, the site averaged 1100 visits per month. The 3 subcategories with the highest number of visits were “general dementia information,” “activities of daily living,” and “self-care and support.” Most (44/45, 98%) respondents agreed or strongly agreed that the website was easy to navigate, and all respondents agreed or strongly agreed that the resources were useful.

Conclusions: The iterative process of creating the dementia caregiver resources website included continuous identification, categorization, and prioritization of resources, followed by clinician feedback on website usability, accessibility, and suggestions for improvement. The website received thousands of visits and positive clinician reviews in its first 9 months. Results demonstrate that an expert-vetted, nationally, and remotely available resource website allows for easy access to dementia education for clinicians to provide for their patients and caregivers. This process of website development can serve as a model for other clinical subspecialty groups seeking to create a comprehensive educational resource for populations who lack easy access to specialty care.

Introduction

The proportion of the world population that is aged over 60 years old is projected to almost double between 2015 and 2050 [1], and with it, the prevalence of dementia and the number of families caring for people with dementia will also increase. About 11 million Americans (70% female) currently provide 18 billion hours of unpaid dementia care per year [2], many without formal dementia education or support. These informal dementia caregivers, such as friends and family members, generally do not have the knowledge or expertise to handle the myriad challenges dementia caregiving can present. This contributes to the high rates of caregiver stress and burnout, often leading to institutionalization for the person with dementia [3-5]. While clinicians (broadly defined to include all health care professionals who care for patients [6]) recognize that supporting the family caregivers of their patients with dementia is important, most do not have the time or ready access to the best educational resources for management of the varied aspects of dementia care (eg, activities of daily living, instrumental activities of daily living, safety, and navigating neuropsychiatric symptoms) at all stages of the disease. Therefore, clinicians require a compendium of high-quality, expert-reviewed resources that are easily available to them to supplement their care and to address common caregiver questions throughout the disease progression.

While some health care systems have dedicated dementia specialists or robust community dementia support, the majority do not [7]. Moreover, people with dementia and their caregivers living in rural areas or experiencing low socioeconomic status face additional barriers to accessing specialty dementia care, education, and support [8]. This often leaves caregivers to find dementia education on their own or rely on recommendations from their primary care team. Many caregivers turn to the internet to find information about caring for someone with dementia and for caregiver support. However, web-based resources are not necessarily scrutinized to ensure information accuracy or to consider the health literacy skills, technology skills, and cognitive and sensory skills of the target audience [9,10]. Similarly, because information is placed in varied locations with varying degrees of quality, cost, and access, this search can be confusing for many caregivers, leading to an increase in misinformation and further caregiver strain [11-14]. Currently, there are hundreds of websites offering advice regarding dementia; however, this plethora of choices can often be confusing or inconvenient for busy clinicians or family caregivers to navigate. It is important for clinicians to be able to direct caregivers of people with dementia to high-quality, easy-to-navigate educational content housed in a single central location that has an expert clinician–curated selection of diverse resources.

Our caregiver resources website aimed to provide clinician-vetted, easy-to-access, and dementia-specific education resources that prioritized the caregiver audience and provided a comprehensive overview of the neurodegenerative disease process, with different resources for different stages of dementia. The website development team (WDT) was comprised of 6 Veterans Affairs (VA) telehealth-based clinical dementia experts based at various Geriatric Research Education and Clinical Centers (GRECCs) centers of excellence focused on serving aging veterans. Members of the WDT had combined decades of dementia experience and represented multidisciplinary backgrounds (neurology, geriatrics, nursing, social work, and occupational therapy). The WDT used an iterative strategy to gather input from interdisciplinary geriatrics clinicians with decades of experience caring for individuals with dementia and their caregivers and create a compendium of clinician-approved, web-based dementia care resources.

Methods

Website Creation Overview

The process of creating this website resource, outlined in Figure 1, included 6 iterative steps over the 1.5 years of website development to ensure resource information quality and appropriateness for informal dementia caregivers. Steps included (1) resource collection, (2) creation of eligibility criteria, (3) resource organization by topic, (4) additional content identification, (5) finalize resource selection, and (6) website testing and launch. Figure 1 shows the development of the dementia caregiver resources website and the summary of the sequential steps taken to develop the educational resource website.
**Step 1: Resource Collection**

The WDT leveraged their existing geriatrics contacts among 18 VA tele-geriatrics programs across the country and asked them to share the dementia caregiver educational resources they found most useful in their clinical practice. The only requirements for these resources were that they needed to be directed to a patient or caregiver audience and freely available on the internet remotely. This request yielded a total of 25 different web-based resources. The WDT reviewed the resources, which varied widely in content, addressing not only physical and cognitive changes related to dementia but also psychosocial, emotional, and familial or community impacts throughout the disease process. Additionally, the resources varied in overall quality, availability (some resources were directly available on the web, others required payment or a subscription, some were applicable only in a particular state or region, etc), visual clarity (challenging to read, difficult to print out, etc), length, format, and consideration for audience. The WDT used these 25 resources as their starting point for Step 2.

**Step 2: Creation of Resource Eligibility Criteria**

Based on a thorough review of resources collected in Step 1, the WDT developed specific eligibility criteria for selecting additional resources for the website. Eligibility criteria for potential resources included the following:

1. Remotely and nationally available (not programming specific to one location or region)
2. Easily accessible in printable or sharable format (PDF, Word [Microsoft Corporation] document, video, etc)
3. Appropriate health literacy level for the family caregiver audience
4. Visual and cognitive ease (eg, large and easy-to-read font, good use of white space and images, and a lack of excessive color or low contrast)
5. Open access resources (eg, not commercially sponsored, behind a paywall, or requiring email registration)

International resources were excluded if they provided country-specific data, policy, or programming. Stand-alone resources (eg, PDFs, Word documents, and videos) were given preference over general dementia or caregiving websites, as some websites can be difficult to navigate, share, and print. Preference was given to resources that were not likely to undergo excessive changes or that seemed to require infrequent updating. While this compendium was created by VA clinicians within the United States, the WTD identified resources that were applicable to dementia caregivers, regardless of veteran status.

**Step 3: Resource Organization by Topic**

In parallel to the gathering of resources from the large national VA tele-geriatrics network and the creation of the eligibility criteria, WDT members met bimonthly and also regularly shared candidate resources with other team members through email. Similar resources were grouped into categories and subcategories, identifying important gaps in content. Categories and subcategories were formed with the goal of providing as much education on common dementia-specific challenges as possible while also trying to provide at least 3 resources in varied formats for each section. Using a category and subcategory organization allows clinicians to easily provide the right resource at the right time for a given caregiver’s dementia care needs, as well as easily display the plethora of resource topics that could impact caregivers throughout the disease process, thus offering a potential “roadmap” for caregivers. So, depending on the caregiver’s needs and interests, the clinician can tailor the website experience. Again, this process of categorization was iterative, and as the identification of resources continued, categories and subcategories were edited, added, or deleted to best organize the content. The 10 finalized categories are included in Textbox 1.
Each category had associated subcategories. For example, the category of “behavioral changes” was further divided into subcategories including wandering, sundowning, anxiety, aggression, and repetitive questions. There were 34 finalized subcategories in total. While most categories had a similar organizational scheme, the categories of “comprehensive dementia care guides” and “additional websites” differed. The “comprehensive dementia care guides” category housed resources that spanned multiple topic areas and dementia stages and required more time to navigate due to the amount of information provided. These guides were given their own organizational scheme and were available for clinicians to give to caregivers or family members interested in a more in-depth resource. The “additional website” category housed general dementia websites that were deemed useful by the WDT but were made up of multiple pages requiring further link selection and thus did not meet the original eligibility criteria for simplicity.

**Step 4: Additional Content Identification**

Upon review of the initial 25 resources suggested and the WDT discussions around important categories and subcategories, gaps in various topic areas were identified (eg, brain health, dementia and nutrition, and emergency preparedness). The WDT members then embarked on a broad internet search to find additional resources that fit the eligibility criteria and filled notable gaps in the established categories and subcategories. This included an expedited review of topic areas and dementia education products from esteemed organizations, such as the Alzheimer’s Association, the National Institute on Aging, etc, which helped to organize the thorough list of categories and subcategories. This included an expedited review of topic areas and dementia education products from esteemed organizations, such as the Alzheimer’s Association, the National Institute on Aging, etc, which helped to organize the thorough list of categories and subcategories. The WDT continued to meet regularly to identify, vet, and organize candidate resources using the eligibility criteria and, if appropriate, add them to the compendium. At the end of the content identification process, there were 170 resources that were candidates for inclusion.

**Step 5: Finalize Resource Selection**

All 170 candidate resources were organized into categories and subcategories, with each subcategory housing between 3 and 10 vetted resources. The WDT then individually reviewed all the resources in each subcategory, and each team member ranked their first, second, and third choices based on the eligibility criteria outlined above as well as the overall quality of the resource, suitability to the corresponding category and subcategory, and perceived clinical utility for clinicians and caregivers. WDT members also identified specifically why they liked or did not like each of the resources and if they had any “honorable mentions” among those that were not ranked as their top 3 choices in each subcategory. After all resources were ranked, the team collated the rankings and chose the resources with the most first, second, and third rankings. When there were more than 3 quality options available for a given subcategory, the WDT discussed them as a group and used their clinical judgment to make the final selections. This detailed analysis of resources helped the team decide whether to add or exclude additional resources, which resulted in some subcategories having more than 3 resources. This process resulted in 3-6 quality resources per subtopic area with a variety of media formats (PDF, video, etc). There were 132 resources selected for final inclusion on the website.

Once the list of resources was finalized, the WDT reached out to the authors or organization for each resource to gain permission to display the resource link on the compendium website. The caregiver resources website only provided links to the resource, ensuring all credit for the resource went to the authors or organization. This also ensured that, if there were updates to the resource in the future, the WDT would only be responsible for providing the updated link. All resources received author permission.

**Step 6: Website Testing, Launch, and Evaluation**

The WDT, in collaboration with the VA tele-geriatrics website developer, created the structure, organization, and overall look of the website. The initial target end users of this website are clinicians caring for people with dementia, although some clinicians may share the whole website (as opposed to specific resources) with caregivers. Therefore, additional care was taken when choosing resources to consider caregivers of people with dementia (who are often older adults with age-related sensory challenges). This included being mindful of category and subcategory organization, language used, font size, white space,
photo content, thumbnail images to ensure inclusivity and demonstrate diversity, etc.

A link to the beta version of the website was sent nationally through email to 60 geographically diverse VA tele-geriatrics specialists who attended a meeting in which the website goals were described. The email also solicited feedback on content, visual appeal, usability, and organization. All feedback was discussed by the WDT and led to further modifications to the website’s appearance and organization. The finalized website launched in January 2022 through an email announcement to the larger VA tele-geriatrics interdisciplinary specialty care group (119 members) who were asked to share the website with their colleagues inside and outside the VA network. Additionally, to increase visibility, the WDT also described the website creation process and demonstrated the use of the website in a case-based national webinar to an audience of 117 clinicians.

A 20-item survey containing a combination of quantitative and qualitative questions was established to gather interdisciplinary clinician feedback on the website’s usability and accessibility and to solicit suggestions for improvement. Survey questions and design were informed by a review of literature on evaluation of health care resources and education websites and content [15-20]. The survey was implemented on the Survey Monkey (Momentive Global Inc) platform and disseminated in the same email as the website launch announcement as well as during the national webinar. A request to complete the survey regarding the resource website was sent through email to all members of the VA tele-geriatrics interdisciplinary specialty care group as well as the 117 attendees of the case-based national webinar. Email recipients were also invited to forward the email with the website link and survey to any colleagues they deemed appropriate. Because of this, it is unknown how many people received the survey link. The survey was open from September 14, 2022, to November 1, 2022.

**Ethical Considerations**

This work was conducted as part of the VA Office of Rural Health-funded “GRECC-Connect” program education and evaluation core activities and was determined to be quality improvement by the VA Bedford Healthcare System Institutional Review Board, not human subjects research. Participants were invited to take part in the optional survey through email. Participation was voluntary and no compensation was provided. Individual participation was not tracked, and individually identifiable data were not collected.

**Results**

**Final Website**

Figure 2 shows a section of the landing page for the dementia caregiver resources website and highlights the table of contents and organizational scheme. The website is housed under the VA Geriatric Scholars website [21].

The website includes 10 categories and 34 subcategories. A table of the final website organization, as well as the number of resources available and the number of visits by subcategory in the first 9 months after launch, is outlined in Table 1.

Website Usage
In its first 9 months after launch, the website averaged 1100 visits per month between February 2022 and October 2022. A data assessment was completed to determine the number of visits each subcategory had over 9 months (Table 1). Website users frequented the subcategories of general dementia information (625 visits), activities of daily living (450 visits), and self-care and support (492 visits) the most often throughout the 9-month assessment period. This information is supported by the evaluation survey, where participants were specifically asked what resources were most useful to them. Many participants ranked the larger categories of dementia overview, daily activities, and caregivers’ self-care and support in their top 3 most used resource categories.

Survey Results
A total of 60 survey responses were recorded, with each question reported receiving a response from 72% (43/60) or more of the respondents. Survey responses came primarily from clinicians in the fields of nursing, pharmacy, medicine, social work, and rehabilitation. The number of years of clinical practice for respondents ranged from 0-5 years to 30+ years, with 65% (39/49) reporting 10 years or more in the field. A total of 75% (37/49) of respondents reported their caseload was comprised of 50% or more patients aged older than 65 years.

All respondents reported that it was likely or very likely that they would recommend the website to a colleague in the future, and almost all respondents (51/52, 98%) stated that it was likely or very likely that they would recommend the website to a patient or caregiver. To further assess the reach of the website, or very likely that they would recommend the website to a colleague in the future, and almost all respondents (51/52, 98%) stated that it was likely or very likely that they would recommend the website to a patient or caregiver. To further assess the reach of the website, participants were specifically asked what resources were most useful to them. Many participants ranked the larger categories of dementia overview, daily activities, and caregivers’ self-care and support in their top 3 most used resource categories.

Survey Results
A total of 60 survey responses were recorded, with each question reported receiving a response from 72% (43/60) or more of the respondents. Survey responses came primarily from clinicians in the fields of nursing, pharmacy, medicine, social work, and rehabilitation. The number of years of clinical practice for respondents ranged from 0-5 years to 30+ years, with 65% (39/49) reporting 10 years or more in the field. A total of 75% (37/49) of respondents reported their caseload was comprised of 50% or more patients aged older than 65 years.

All respondents reported that it was likely or very likely that they would recommend the website to a colleague in the future, and almost all respondents (51/52, 98%) stated that it was likely or very likely that they would recommend the website to a patient or caregiver. To further assess the reach of the website, participants were asked who they had shared the website with. A total of 51% (25/49) of respondents reported that they primarily shared it with family caregivers, 67% (33/49) with colleagues at the VA, and 16% (8/49) with colleagues outside of the VA. A total of 18% (9/49) of respondents stated that they shared directly with their patients and 14% (7/49) with their personal friends and family. Respondents indicated they had shared the resource website by all the following mechanisms: sharing the overall web page link electronically, sharing links to specific resources electronically, downloading and saving specific resources to send electronically in the future, printing out resources and either handing or mailing them to their recipients, and adding links to resources in their care plan.

A total of 98% (44/45) of survey respondents either agreed or strongly agreed that the website was easy to navigate. Similarly, all respondents either agreed or strongly agreed that the resources on the website were useful for their clinical practice. When asked if the website was easy to find, 77% (34/44) agreed or strongly agreed that the website was easy to find. Survey questions allowing for free-text responses yielded further insight regarding clinician’s overall impressions of the utility of the website and allowed for suggestions for website improvement.

When asked for suggestions on how to improve the website, many respondents identified additional resource subcategories that they thought would be useful, such as resources on death and dying, exercise, and speech pathology (specifically cognition, communication, and swallowing). They also requested more resources offered in video format.

While the website received the majority of positive feedback, the limitation most identified by survey respondents was the inability to easily find the website. Participants stated that they had trouble finding the website through search engines such as Google and wished it were more accessible or visible to those that may not have the direct link (Textbox 2).

Textbox 2. Qualitative responses to open-text questions regarding overall impressions of the dementia caregiver resources website and suggestions for improvement.

- The majority of comments regarding overall impressions of the website were positive.
  - “It is amazing and very comprehensive. Great place to start for someone that is just beginning to be a caregiver for someone with dementia!”
  - “Better than Google for finding information.”
  - “It is an excellent resource with a well-rounded variety of well vetted information from clinical experts.”
  - “It’s everything we need in one space!”
  - “Our caregivers are starving for this information.”
- Some respondents described the ways in which they had successfully used the website in their clinical practice.
  - “I facilitate a dementia educational class for caregivers and share website with them. It has helped them access additional information.”
  - “(I) provided link and or printout to caregivers, as part of education for caregivers in order to manage dementia related behaviors and self-care.”
- Some participants described the ways in which they had trouble finding the website.
  - “I couldn’t find it by Googling. I only found it by using the link provided.”
  - “I wish it showed up just from a Google search so I could find it more easily.”
Discussion

Overview

This paper describes the iterative process of creating the dementia caregiver resources website, a compendium of geriatrics clinician-approved resources presented in an organized, user-friendly format, as well as feedback regarding the website’s usability, accessibility, and suggestions for improvement. The 6-step development process can serve as a model for other clinical subspecialty groups seeking to create comprehensive educational resources. The success of the dementia caregiver resources website is evidenced by the number of visits to the website and the positive clinician reviews received within the first 9 months of its launch.

Previous research has found that family caregivers are using a variety of web-based resources to look for education on the diagnosis and progression of dementia, including searching the internet, reading informal journals or news articles, social media, watching TV, etc [22]. However, even with caregivers receiving information from varied sources, most caregivers expect their health care team to provide them with educational recommendations or reliable resources as a starting point. Many caregivers express confidence in their health care team but report that it can be challenging to connect with them due to clinician’s or caregivers’ busy schedules [23-25]. Furthermore, due to the degenerative nature of dementia, which causes a continuous decline in function, caregivers regularly require education on a variety of developing symptoms [26-28]. This points to a gap the caregiver resources website fills in providing vetted resources, all in one space, for clinicians to give to caregivers whenever needed without requiring additional health care visits.

Similarly, ensuring the topic areas and resources chosen would meet the needs of caregivers and families throughout the dementia spectrum was an important criterion during the process of creating and evaluating this web-based resource. The WDT’s process of continuous identification and prioritization of quality resources, along with iterative assessment of knowledge gaps and reorganization of topics and subtopics, allowed for a breadth of content areas that matched caregivers’ information-seeking trends. These trends show caregivers seek information on disease-specific diagnosis and treatment; disease-focused health care services; caregiver support and self-care; general caregiving skills; and, to a lesser degree, financial and legal information and accommodations [28-30]. Similarly, once the website launched, the team received additional confirmation from the evaluation that the content and organizational structure provided on the website were of great use to caregivers and health care teams alike.

Given the lack of geriatrics specialty care and trained geriatricians available, with even less access to specialty care for rural caregivers, the dementia caregiver resources website can provide resources and education to bridge the gap between specialty medical appointments or for those who are unable to see a geriatrics clinician due to location, limited availability, etc. Finally, those involved in dementia care can use the website to easily find appropriate information at any stage of the disease process to address the specific concerns the caregiver is facing at any given time—in other words, the right information at the right time.

Limitations

There were limitations in the creation and dissemination of the dementia caregiver resources website. The goal of this clinical project was to provide quality resources as quickly as possible to clinicians to then give to their informal dementia caregiving audience. Some clinicians reported sharing specific resources with caregivers, while others reported sharing the website in its entirety. While caregiver feedback was not initially gathered (due to the intended end users being clinicians and the general scope of the project), caregivers were key recipients of the educational information, and therefore, not gathering their input could be a potential limitation of the project. The next steps of this project will include an assessment of caregiver perspectives regarding the website. Additionally, the content does not include all available dementia resources, as it is limited to those that the WDT could review and select within the available time frame of the project.

Another limitation of website dissemination was the location of the website. The website was not easily searchable through common search engines such as Google or Bing, and because it was housed within the GRECC-Connect parent website, it was even more difficult to find. Therefore, to disseminate the website, the end user had to be given the direct URL or know where to look within the GRECC-Connect parent website. Additionally, those in highly rural areas may have difficulty viewing certain resources, such as videos, on the website due to decreased access to high-speed internet. However, the WDT made an effort to ensure that each subcategory had options that did not require high-speed internet access, such as PDFs and Word documents. These challenges clearly limit the number of caregivers who will be able to easily access the website’s information, which further decreases the ability to accurately assess the impact of the website in future evaluations. Lastly, because we provide links to resources that reside on other content creators’ websites, there is the possibility of a change in access or content that is out of our control. The WDT has supplied their contact information so that end users can alert the team to difficulties with accessing the resources and so that visitors can suggest additional resources.

Conclusion

This article describes the iterative process of creating and evaluating the dementia caregiver resources website, a compendium of geriatric expert-approved resources for clinicians to provide targeted education to family caregivers of people with dementia. While there is a plethora of web-based dementia caregiving information available, there lacked a single web-based compendium that housed a plethora of quality resources in an organized fashion, so that navigation was not confusing or inconvenient for busy clinicians. The WDT identified and organized the highest quality resources available that provided education on a wide variety of topics impacting people with dementia and their caregivers. Given the growing number of people with dementia and the heavy reliance on family caregivers without access to specialty dementia care, clinicians benefited from this single-site compendium. The
dementia caregiver resource website received thousands of visits and positive clinician feedback, including 98% (44/45) of survey participants agreeing that the website was easy to navigate and all respondents agreeing that the resources were useful, demonstrating it to be a valuable resource for clinical care. Moving forward, there is potential for caregivers to navigate through the whole website without clinician direction to specific resources. Therefore, the next steps include gathering caregiver feedback and perspectives on the website. Clinicians can refer to the free, publicly available dementia caregiver resources website for expert-reviewed, organized, and quality resources [21]. This process can serve as a model for clinical subspecialty groups, creating comprehensive educational resources available for other populations who lack easy access to specialty care. For those developing a web-based resource that is accessible to both clinicians and older adults themselves, it may be beneficial to include experts in universal website design, specifically for older adult end users, from the beginning of the process to ensure a quality user experience for the broadest audience.

Acknowledgments
This work was made possible by the Veterans Health Administration New England Geriatric Research Education and Clinical Center (GRECC) and the VA Office of Rural Health supported GRECC-Connect program. The authors would like to thank Dr William Hung, GRECC-Connect national program lead; Dr Thomas Caprio, GRECC-Connect education core lead; and Leah Walker, social worker for Madison Wisconsin Veterans Health Administration, for their guidance and feedback throughout the website development process. A special thank you to the health care professionals and website users who completed the website survey and shared their thoughts with them. The views expressed are those of the authors and do not necessarily reflect those of the United States Department of Veterans Affairs.

Data Availability
All data generated or analyzed during this study are included in this published article (and its appendices).

Conflicts of Interest
None declared.

Multimedia Appendix 1
Dementia Caregiver Resources website survey. Survey questions and answer choices, percentage of respondents, and number of respondents reported. Survey questions did not require an answer to submit the survey therefore creating variation in the sample size for each question.

Abstract

Background: Since June 2021, patients with hemophilia A with antifactor VIII inhibitors and those with severe hemophilia A without antifactor VIII inhibitors treated with Hemlibra have had to choose between a community or hospital pharmacy. The French reference center for hemophilia developed the HEMOPHAR e-learning program for community pharmacists for dispensing emicizumab.

Objective: This study aims to evaluate the efficiency and safety of this new care pathway by assessing the HEMOPHAR e-learning program.

Methods: The methodology is based on Kirkpatrick’s model for evaluating the immediate reaction of trained community pharmacists (level 1), their level of acquired knowledge (level 2), and their professional practice after 3 months of dispensation (level 3).

Results: The HEMOPHAR e-learning program reached a large audience, with 67% (337/502) of the eligible community pharmacists following it. The immediate reaction was overall satisfying. High rates of engagement were reported with 63.5% (214/337) to 73.3% (247/337) of completed training modules, along with high rates of success with quizzes of 61.5% (174/337) to 95.7% (244/337). We observed that 83.9% (193/230) of the community pharmacists needed less than 2 attempts to pass the quiz of the module related to professional practice, while the other quizzes required more attempts. Advice on compliance and drug interactions were most frequently provided to patients by the community pharmacists.

Conclusions: This study suggests ways to improve the training of community pharmacists and to optimize coordination with treatment centers. This study also reports on the feasibility of switching to a community pharmacy in a secure pharmaceutical circuit, including in the context of a rare bleeding disease.

Introduction
While community pharmacists have long served as safety consultants for patients with minor illnesses, the literature highlights the multifaceted and evolving role of the community pharmacists to improve care pathways especially for patients requiring urgent care [1] or for the management of chronic diseases [2-4]. Evidence of the effectiveness of community pharmacists’ interventions exists for the management of chronic diseases [4], vaccination [5], and optimization of transitions of care [6,7]—the latter referring to the movement of patients across institutions, among providers, between different levels of care, and to and from home. The main pitfall that may occur during these transitions is discontinuity in the patient’s care pathway, leading to potential complications [8]. But offering standardized training regarding processes and procedures for all the involved stakeholders has shown to be a facilitator [9].

The transition of care has typically been implemented in France for patients with hemophilia A with or without inhibitors. This disease is a rare bleeding disorder whose treatment relies on factor VIII injections or bypass agents. Chronic treatment for hemophilia A has been available only in French hospital pharmacies, and monthly dispensing was conditional on reimbursement of these drugs [10]. In France, the delivery of drugs to patients’ homes is outstanding and is only legally reimbursable of the training program are effective or appreciated, and which ones need to be improved.

The e-questionnaire is informative to help determine which elements of the training program are effective or appreciated, and which ones need to be improved.

Methods
Content of the HEMOPHAR e-Learning Program
Community pharmacists receive personal log-in codes for the HEMOPHAR e-learning program from the national reference center for hemophilia (Lyon, France). They can take the course at any time on working days. They can also interrupt the program and resume it at a later date without losing their progress through the program. The program comprises four e-learning modules: (1) presentation of the disease, (2) therapeutic management, (3) organization of care, and (4) practice in the community pharmacy (Multimedia Appendix 1). At the end of each module, the community pharmacist can participate in a quiz composed of 4 or 5 questions. Quizzes are mandatory to obtain the certificate of achievement (with at least 80% of correct answers), but this certificate is not mandatory to dispense emicizumab.

Study Design
We designed a cross-sectional study based on the Kirkpatrick model [15] based on 2 closed surveys and an analysis of secondary data. The evaluation of the training program comprised the investigation of 3 information levels.

Level 1, related to “Reaction,” referred to the evaluation of the immediate feedback of community pharmacists who attended the HEMOPHAR e-learning program. Invitations to complete e-questionnaire were sent via email to community pharmacists who completed the training and obtained the certificate of achievement within 48 hours post training. The e-questionnaire was intentionally short and composed of 8 questions, including 5 questions based on a 4-item Likert scale (“not at all satisfied,” “not very satisfied,” “somewhat satisfied,” and “very satisfied”) and 3 closed-ended questions (yes/no). The estimated time to complete this e-questionnaire is approximately 1 minute. This questionnaire is informative to help determine which elements of the training program are effective or appreciated, and which ones need to be improved.

Level 2, related to “Learning,” referred to knowledge acquisition during the program. This level consists of accurately measuring pharmacists to follow the HEMOPHAR e-learning program by systematically sending an email invitation with personalized log-in details, as soon as the patient has chosen the community pharmacy.

More than 1 year after the implementation of this training program, a nationwide study called “PASODOBLEDEM1” was conducted to evaluate the direct reaction of the community pharmacists following the implementation of the HEMOPHAR e-learning program and the use and functionalities of the available training resource, and to evaluate their professional practice at least 3 months after the first dispensation of emicizumab.
the knowledge acquired during the active training modules. In contrast to immediate reactions to training (level 1), this second level allows for the measurement of specific outcomes by collecting data regarding usage targets such as participation rate, completion rate, or time spent on training to supplement participant feedback.

Level 3, related to “Behavior,” consisted of evaluating the professional practice of community pharmacists at least 3 months after the first dispensation of emicizumab, to determine whether they have followed the HEMOPHAR e-learning program. Specific e-questionnaires were elaborated using Likert-based scoring for both trained and untrained community pharmacists dispensing emicizumab. Level 3 consists of determining whether the training program has a direct impact on the participants’ dispensing behaviors. The community pharmacists were informed about the purpose of and estimated time required to complete the survey via email before opting to complete the e-questionnaire. The level 3 e-questionnaire was composed of 13 multiple-choice questions. The estimated time to complete this questionnaire is approximately 8 minutes.

The contents of the questionnaires were initially developed by a multidisciplinary team composed of hospital and community pharmacists and research scientists specialized in methodology and care accessibility. A scientific committee was specifically constituted for the PASODOBLEDEMI I study to challenge and validate the purposes, methodology, questionnaires, and expected outcomes. This committee was coordinated by the national reference center for hemophilia and composed of hospital and community pharmacists, physicians, and the French association of patients with hemophilia (French: Association Française des Hémophiles). Following the recommendations of the scientific committee, the content of the e-questionnaires has evolved by integrating operational and organizational aspects and optimizing literacy. The e-questionnaires were finally tested in real-life conditions on a sample of eligible populations. The content of the questionnaires was finally validated by the scientific committee in July 2022.

Sample Size
Since emicizumab became available in French community pharmacies, from June 2021 to December 2022, a total of 337 volunteer community pharmacists followed at least 1 of the 4 training modules available in the HEMOPHAR e-learning program. The expected minimum sample size for the questionnaire related to the reaction of the community pharmacists (level 1) was intended to encompass the maximum number of the trained participants who obtained the certificate of achievement during the month preceding the study start date. From July to December 2022, in total, 26 of the 337 community pharmacists completed the short e-questionnaire immediately after following the HEMOPHAR e-learning program, representing the Reaction sample (level 1). As the answers were not divergent, we did not consider it appropriate to extend the duration of data collection. At least 3 months after the implementation of the dual circuit of dispensing, 180 community pharmacists completed the e-questionnaire concerning their professional practice. The Behavior sample (level 3) contains community pharmacists who followed at least 1 of the 4 modules in the HEMOPHAR e-learning program (154/337, 45.7%). The expected minimum sample size for this questionnaire was at least 30%, which has been far exceeded. A total of 363 community pharmacists were included in this study, representing 67% of the eligible community pharmacists in France (337/502 active community pharmacies, last updated in September 2022; Figure 1).

Figure 1. Number of community pharmacists included in the 3 levels of the PASODOBLEDEMI I study. *A total of 26 community pharmacists have either completed the Roche training (n=8) or have not completed any training (n=18).

Statistical Analysis
Baseline characteristics were described by counts and percentages for categorical variables and medians and IQRs for continuous variables, mentioned in parentheses in the following order in the Results section: community and hospital pharmacy. Statistical analysis was performed using R (version 4.1.1; The R Foundation) software.
Ethical Considerations
The study complies with reference methodology MR-004 (“related to research not involving the human person, studies and evaluations in the health field”) [16]. This French legislation mentions that the persons involved in the research or their legal representatives (or both) are informed beforehand and individually of any processing of their personal data for the purposes of research for the present methodology (Title II 2.5.1 related to information of participants); therefore, it did not require written consent from the study participants. No incentive was offered to participate in the survey. All the collected data from community pharmacists were nonsensitive and were stored by the study sponsor (Hospices Civils de Lyon) on a secure server for 15 years. The ethics committee of the Hospices Civils de Lyon approved the study (n°2022-06-01, obtained on June 14, 2022). The PASODOBLEDEMI I study was registered in ClinicalTrials.gov (NCT05449197; related to the evaluation of Reaction, Learning, and Behavior).

Results
Level 1: Immediate Reaction After the HEMOPHAR e-Learning Program
Immediate satisfaction with the HEMOPHAR e-learning program was high, with 18 (69.2%) community pharmacists very satisfied and 8 (30.8%) somewhat satisfied (Table 1). Nearly 3 out of 4 community pharmacists were very satisfied because the training content met their expectations (n=17, 67.4%) and was considered relevant to their professional practice (n=19, 73.1%). They were less very satisfied with the communication format (n=14, 53.8%) and the duration of the training (n=13, 50.0%). Overall, 8 (30.8%) community pharmacists planned to follow another learning program. Finally, 96.2% (25/26) of them would recommend the HEMOPHAR e-learning program to their colleagues.
Level 2: Learning and Knowledge Acquired During the Training

A median delay of approximately 9 (IQR 3-21) days was observed between the day the community pharmacists received their connection codes and the day they logged in to the HEMOPHAR e-learning program. Among the community pharmacists who started at least 1 of the 4 training modules, 81.9% (276/337) of them started all the training modules available in the HEMOPHAR e-learning program, and 40.9% (113/276) of them completed it. The training modules related to the presentation of the disease and the one related to therapeutic management reached most of the community pharmacists, with more than 80% of them having started the training modules (Table 2). Once the training modules were started, between 60% and 75% of community pharmacists completed them.

aCommunity pharmacists who completed the training modules, with or without attempting the related quizzes.  
bDenominators are the number of community pharmacists who started the training module (n=337).

Community pharmacists usually need more than 1 attempt to pass the quiz at the end of each module (Figure 2). The quiz related to the organization of care was the most successful with a 95.7% success rate associated with the lowest number of attempts. The time spent per quiz varied greatly with 50% of the community pharmacists, who needed 6.8 minutes for the presentation of the disease module, 3.5 minutes for the therapeutic management module, 1.5 minutes for the organization of care module, and 2.6 minutes for practice in the community pharmacy module.

Figure 2. Number of attempts at the quizzes for each of the training modules in the HEMOPHAR e-learning program.
Level 3: Behavior During Professional Practice of Community Pharmacists

The community pharmacists reported that mostly 1 patient chose their pharmacy for dispensing emicizumab (90.9%, 140/154 unique community pharmacies). Nearly half of the community pharmacists (74/154, 48.1%) who responded to the Behavior questionnaire followed the HEMOPHAR e-learning program for more than 3 months, and one-third of the sample (51/154, 33.1%) followed the program for more than 12 months.

During their professional practice, community pharmacists may be faced with organizational constraints. Even though the HEMOPHAR e-learning program covers all aspects of organization and documentation management, community pharmacists have reported that they did not always rely on the documents available (Figure 3). For example, the most used document was the one containing the stakeholders’ contact information (90.3%, 139/156) and the liaison document for emicizumab (85.7%, 132/154), unlike the checklist, which was used for only 78.6% (121/154) of the community pharmacists. Overall, 89.6% (138/154) of community pharmacists reported that they did not observe any discontinuity in the pathway of care of the patient in general. Those who encountered problems of continuity of care reported constraints in terms of personnel, particularly during the holiday season, and those relating to the supply of emicizumab or those due to a prescription delay by the hospital, even though 76% (117/154) of respondents reported that patients systematically anticipate the renewal of prescription before their arrival at the community pharmacy. About 84.4% (130/154) of the community pharmacists reported that they did not need a third party to manage the dispensation until now (autonomy). Regarding the time spent in supplying emicizumab, 80.5% (124/154) of the community pharmacists received the drug in less than 24 hours.

Figure 3. Organizational items reported from the community pharmacists who followed the HEMOPHAR e-learning program (n=154).

Community pharmacists who followed the HEMOPHAR e-learning program have reported the frequency of advice provided when dispensing emicizumab (Figure 4). The most frequent advice provided by the community pharmacists concerned the importance of medication adherence, with 25.3% (36/154) of the trained community pharmacists having provided this advice time systematically at every visit of the patient or their caregiver and 24.7% (38/154) having provided this advice often. Administration of emicizumab was addressed sometimes, according to 48.1% (74/154) of the community pharmacists, as well as the impact of drug interactions when self-medicating (41.6%, 64/154; sometimes). The mode of action of emicizumab was the least discussed topic between patients and community pharmacists. Most pharmacists felt they had sufficient information for dispensing emicizumab and managing their relationship with patients (92.2%, 142/154). However, we observed that 36.4% (56/154) of community pharmacists trained with the HEMOPHAR e-learning program expressed the need for therapeutic education support.
Discussion

The PASODOBLEDEMI I study represents the first nationwide survey to evaluate the systemic impact of the implementation of the dual dispensing circuit, quickly after its implementation, with high institutional expectations. The strengths of the PASODOBLEDEMI I study lie in its holistic approach using the Kirkpatrick evaluation model [15] and the high-quality representative sample, which enhances the validity of the findings, especially for the Behavior sample in evaluating professional practice at 3 months. We report 36% (180/502) representativeness, with more than 30% representation from each French department, reaching 65% in Hauts-de-France and 63% in Auvergne Rhône-Alpes. Representativeness was lesser for Provence-Alpes-Côte d’Azur (18%) and Ile-de-France (21%) but remained consistent with that reported in other surveys [17,18]. The size of the Reaction sample was considered sufficient (n=26) because of the convergence of the satisfaction ratings.

The HEMOPHAR e-learning program reached a large audience with 67% of the community pharmacists being eligible. The immediate reaction was overall satisfying despite mixed feedback related to the format and duration, which will be reviewed for the next version of HEMOPHAR (ie, version 2). High rates of engagement were reported, with 63.5% to 73.3% of training modules having been completed and high rates of success of 61.5% to 95.7% with the quizzes. As it is possible to take the quiz without attending the training modules, we hypothesized that some community pharmacists tested their knowledge to auto-evaluate their need for training. As an example, 76.4% of them succeeded in the quiz related to the presentation of the disease, while 63.5% of them completed the related training module. We also observed that 83.9% of the community pharmacists needed less than 2 attempts to pass the quiz in the module related to professional practice, while the other quizzes required more attempts. Advice on compliance and drug interactions were most frequently provided to patients by the community pharmacists. The mode of action of emicizumab was less frequently mentioned, which may reflect the effectiveness of the hospital education that patients received.

The e-learning format was evaluated as the best way to educate community pharmacists for dispensing emicizumab and helping them to play an important role with this patient community in primary care [19,20] because the e-learning program provides both theoretical knowledge and practical skills for health professionals and educational reinforcement for patients [21]. Comparison with other training methods, such as classroom teaching or lectures, has shown that e-learning is associated with equally satisfactory results [22]. The HEMOPHAR e-learning program represents a strong model for effective training and skill development among community pharmacists, by offering accessibility, flexibility, cost-effectiveness, multimodal learning, tracking and assessment, and updateability. Moreover, community pharmacists can return to the training modules at any time to review the videos or to download useful documents. A complementary approach would comprise affective peer coaching to increase the uptake and effectiveness of a variety of community pharmacist-led enhanced patient care services [23]. Also, the gamification of training programs presents a promising perspective for the advancement of training and development efforts by offering several advantages, including increased learner engagement, immediate feedback, collaborative learning, development of critical thinking skills, and data-driven optimization [24].

The main limitation of the PASODOBLEDEMI I study is the absence of a control group (ie, untrained community pharmacists). We were constrained by regulatory issues from accessing the list of community pharmacies chosen by the patients from among hemophilia treatment centers. So, we first relied on the community pharmacists who attended the HEMOPHAR e-learning program and then publicly invited all the eligible community pharmacists through social networking platforms (LinkedIn, Facebook, Twitter, etc) and academic societies (French society of pharmaceutical sciences, unions for health professionals, etc) to take the survey.

In France, the short training by telephone on the proper use of the product provided by Roche-Chugai to community pharmacists and validated by the French authorities was not sufficient to optimize the dual circuit for dispensing emicizumab. The HEMOPHAR e-learning program is much broader and goes beyond the strict use and storage of the product to increase the role of community pharmacists in the management of this rare bleeding disorder, becoming a new model of care [25]. Other countries have made the same decision in evolving the dispensing circuit such as Australia [26]. If hemophilia treatment...
centers ensure adequate education and training on the technique for subcutaneous injection for patients, community pharmacists are not, to our knowledge, trained to dispense emicizumab. Other initiatives have been developed for enhancing the role of community pharmacists for consultation services [1] and for urgent care [27], which could result in increased confidence and capability in offering the service, with many community pharmacists recognizing and embracing a shift in their roles. An evaluation of patients’ and carers’ satisfaction will be the next step in the PASODOBLEDEMI II study (registered in ClinicalTrials.gov NCT05450640).

The PASODOBLEDEMI I study provides a holistic approach based on the Kirkpatrick model for evaluating the reaction, learnings, and behaviors of community pharmacists after attending the HEMOPHAR e-learning program. With high engagement rates, the community pharmacists benefited from high quality and relevance of the content on autonomy, flexibility, and interactivity, and encompassing the whole national territory. A future certification program will provide recognition for community pharmacists’ educational efforts. The success of the HEMOPHAR e-learning program in the context of the emicizumab dual dispensing circuit may pave the way for other treatments to be made available in community pharmacies, reaching institutional expectations and enhancing the access to treatment for patients with rare diseases.

Acknowledgments
We thank the scientific committee of the PASODOBLEDEMI I study: BC (community pharmacist, copresident of the French Society of Pharmaceutical Sciences [French: Société Francophone des Sciences Pharmaceutiques Officielles]), Yesim Dargaud (National Reference Center for Hemophilia, Lyon), FF (cochair of the Provence-Alpes-Cote-d’Azur Unions for Health Professionals [French: Société Française de Pharmacie Clinique], Marseille), Nicolas Giraud (president of the French Hemophilia Association [French: Association Française des Hémophiles]), Rémi Varin (hospital pharmacist, Rouen), and Fabienne Volot (Expert Center Coordinator, Dijon). The authors thank the team from Roche-Chugai laboratories for their follow-up on the project (Loïc Bergougnoux, Aurélie de Lehvenfehl). This research was funded by the Roche-Chugai laboratories.

Abstract

Background: Young men are vastly underrepresented in lifestyle interventions, suggesting a need to develop appealing yet effective interventions for this population.

Objective: This study aimed to determine the acceptability of a self-guided lifestyle intervention designed specifically for young men (age: 18-35 years old).

Methods: Semistructured interviews and surveys were completed by 14 men following completion of a remotely delivered, 12-week lifestyle intervention. The intervention included 1 virtual group session, digital tools, access to self-paced web- and mobile-based content, and 12 weekly health risk text messages. We quantitatively and qualitatively examined young men’s experiences with the intervention components of a remotely delivered, self-guided lifestyle intervention targeting weight loss. Data were integrated using convergent mixed methods analysis.

Results: Men were a mean age of 29.9 (SD 4.9) years with a mean BMI of 31.0 (SD 4.5) kg/m². The self-guided aspect was not acceptable, and a majority preferred more check-ins. Participants expressed a desire for a social aspect in future lifestyle interventions. All men found the focus on health risks appealing. A majority of men found the study-issued, Bluetooth-enabled scale acceptable.

Conclusions: Acceptability of the self-guided lifestyle intervention was perceived as suboptimal by young men. The findings highlight the need to add intervention components that sustain motivation and provide additional social support for young men.

Introduction

Young men with obesity during young adulthood have twice the mortality risk of men with a healthy BMI (kg/m²) [1]. Despite heightened risk, young men are underrepresented in lifestyle interventions targeting weight loss [2-5]. Low enrollment among young men may stem from their limited concern about weight gain [6,7] or the absence of lifestyle interventions designed to meet the specific needs of men [8]. Adapting interventions to align with the needs and preferences of young men [9,10] while also raising awareness about the

Gender-specific lifestyle interventions indicate promise for engaging men to lose weight and include different features appealing to men (eg, sports-based or self-guided approach) [9,12-15]. Implementing a self-guided approach appears efficacious in producing initial weight loss and satisfaction among young men [14,16,17] and is consistent with young men’s preferences for convenient interventions [9]. When considering age, young adults demonstrate a preference for interventions that reduce intensity and promote autonomy [18].

In a pilot weight loss trial targeting young men, a self-guided approach, paired with health risk messaging, promoted modest weight loss compared with the control [11]. However, it remains unclear which specific elements are perceived as helpful in supporting weight loss for young men.

To improve young men’s engagement with weight loss, it is critical to adapt behavioral weight loss interventions based on their needs. Guidelines for behavioral intervention development are outlined in the Obesity-Related Behavioral Intervention Trials (ORBIT) model and recommend using an iterative process to reach optimal treatment outcomes for the target population [19]. The ORBIT model specifically notes using mixed methods approaches for defining and refining interventions and for feasibility pilot testing [19]. Prior to a rollout of a behavioral weight loss intervention, it is important to determine the acceptability of the intervention among users, which is often captured quantitatively through measures of satisfaction, attendance, and efficacy [20-23]. Satisfaction is a key construct to consider when developing an intervention, given that higher levels of satisfaction with an intervention are associated with favorable weight loss outcomes [24]. However, qualitative measures of satisfaction with interventions are limited in behavioral weight loss trials [24-26], especially as they relate to young men. As a result, our understanding of young men’s experiences with behavioral weight loss is limited.

Indeed, studies are needed that incorporate both quantitative and qualitative user feedback and experience with the intervention. To that end, we used a mixed methods approach to explore the experiences of young men who completed a 12-week lifestyle intervention designed specifically for this population. The primary aim of this paper was to explore young men’s satisfaction with specific intervention components of a self-guided lifestyle intervention to inform future development of interventions [11].

Methods

Study Design

This study was part of a randomized clinical trial in which 18 men received the intervention and 17 men were allocated to delayed treatment control. We report data for the 14 men who were randomized to the intervention and completed the 12-week follow-up visit, an exit interview, and a survey following the visit to provide feedback on the intervention components (retention rate: 14/18, 78%). The full design, protocol, and exclusion criteria are detailed elsewhere [11].

Ethics Approval

All procedures were approved by the institutional review board at Virginia Commonwealth University (IRB# HM20015458).

Recruitment

Men between the ages of 18 years and 35 years with a BMI of 25 kg/m² to 45 kg/m² were recruited across North America and locally in the greater Richmond, Virginia, area during a 2-month period (January 2021-March 2021) using unpaid recruitment advertisements distributed through email listservs, university postings, and researchmatch.org. Advertisements for the intervention emphasized that the lifestyle intervention was self-guided, included images of men exercising and a health risk message, and described some of the inclusion criteria (ie, BMI, age, men). Interested participants completed online screening via Research Electronic Data Capture (REDCap) to determine initial eligibility and were contacted by a member of the study team to schedule an orientation to learn more about the study and engage in an informed consent process. All participants provided written informed consent.

Sample

Participants for the main trial [11] were eligible if they met the following inclusion criteria: (1) age 18 years to 35 years and (2) BMI between 25 kg/m² and 35 kg/m². Exclusion criteria included (1) medical contraindications to exercise without medical clearance, (2) a diagnosis of type 1 or 2 diabetes, (3) report of a heart condition, (4) a history of anorexia or bulimia nervosa, (5) report of compensatory behaviors in the last 3 months, (6) hospitalization for psychiatric conditions in last 12 months, (7) participation in another weight loss program (8) ≥5% weight loss in the last 3 months, (9) not able to read or speak English, (10) did not possess a mobile device, or (11) lived or resided outside of North America. Only participants assigned to the intervention arm were eligible for the current aims.

Intervention

Men received the 12-week lifestyle intervention that was primarily self-guided and grounded in behavioral self-regulation [27] and health risk messaging guided by the extended parallel process model [28]. The intervention was remotely delivered and included 1 group session delivered via Zoom. The group session was followed by self-paced content accessible through a private intervention website, 12 weekly health risk text messages (automated and nonresponsive), and personalized feedback at baseline and 12 weeks based on assessment data. All participants were provided with a Bluetooth-capable scale. All intervention content included health risk messaging applying the extended parallel process model’s constructs (perceived susceptibility, perceived severity, self-efficacy, response efficacy) [28]. The messaging highlighted health risks specific to young men, including the association between obesity and cardiovascular disease, and evidence-based strategies for facilitating weight loss and mitigating cardiovascular disease risk. The baseline feedback report was delivered via email and included the participant’s current BMI, weight, 5% and 10% weight loss goals, daily calorie goal, and health risk messaging. The 12-week feedback report included the participant’s BMI,
weight, percentage of weight loss achieved during the intervention, and health risk messaging. Each intervention component is described in greater detail in the following paragraphs.

The virtual group session occurred via Zoom at the start of the intervention. The session was 45 minutes and led by a licensed clinical psychologist with expertise in behavioral weight loss treatment. Men were provided with psychoeducation regarding health risks of obesity [29,30] and behavioral self-regulation principles [31]. Additionally, men received training in evidence-based behavior change techniques for managing weight [31] and engaged in small group experiential activities to apply and practice skills to increase self-efficacy. In addition, men received instructions on how to access the website and content covered during the session.

Digital tools included access to a private intervention website with evidence-based content, tools for self-monitoring, and a Bluetooth-capable scale. The intervention website was hosted through a private server and was accessible via web and mobile devices throughout the 12-week intervention. The website offered additional psychoeducation on healthy weight management, diet, and physical activity and behavioral change techniques for making changes to health behaviors. Content was adapted for health behaviors relevant to young men [9], which focused on improving fitness and reducing consumption of alcohol, sugar-sweetened beverages, processed meals and fast food, and foods high in fat. The website also housed links to publicly and commercially available online videos and apps for physical activity, self-monitoring diet, and meal preparation. See Figure 1 for example screenshots of the intervention website.

To reinforce extended parallel process model constructs, 12 weekly health risk text messages were sent throughout the intervention. For example, “Eating out and fast food can put men at high risk for heart disease due to high fat, calories, and sodium. Cutting back on fast food and the meals you eat away from home can lower your risk! Check out meal planning tips on [study website] for ways to reduce your risk.”

**Figure 1. ACTIVATE Private Intervention Website and Features.**

### Measures

At 12 weeks, participants were asked to report the acceptability of a variety of aspects of the intervention on a 7-point Likert scale. Participants rated aspects of the intervention (eg, male only, young adult only, self-guided) they found appealing upon joining the intervention (1=not appealing at all; 7=very appealing). Participants rated intervention components (group session, text messages, website) and certain features (length, frequency, relevance) perceived as helpful with weight loss (1=not helpful; 7=very helpful). Participants also rated intervention components and delivery methods not offered (eg, in-person meetings focused on physical activity, online meetings about diet).

A female PhD student (JMR, student investigator) with extensive interviewing experience conducted 14 interviews by phone in a private setting. On average, interviews lasted 15 (range: 8-29) minutes. The semistructured interview guide included open-ended questions about motivations for joining, satisfaction with the intervention, challenges and successes with the intervention, and recommendations for future interventions (Multimedia Appendix 1). Standardized probes were used to elicit responses about intervention components that were considered helpful or unhelpful for intervention goals. Interviews were audio-recorded and transcribed verbatim.

### Statistical Analysis

Descriptive statistics were computed for each question assessing intervention acceptability. Intervention components were deemed acceptable if the mean satisfaction score for each item was ≥5 (1 point above the central point of the 7-point scale) [32]. Descriptive statistics were computed using SPSS Version 27 (IBM Corp). A directed content analysis was used to qualitatively code the semistructured interviews [33]. The coders consisted of 2 men with education in public health and behavioral medicine (MS...
and BS degrees) who were not investigators of the study. Both coders were trained by the student investigator with extensive experience in qualitative research (JMR). First, 4 transcripts were reviewed by the student investigator (JMR) to develop an initial codebook of primary and secondary codes. Transcripts were then analyzed in batches of 2 to 4 by the 2 coders, with minimal involvement by the student investigator. Interencoder reliability (kappa > 0.80) and fidelity to the codebook were maintained during coding [34]. Incongruent codes were flagged, discussed, and reviewed at weekly meetings with the student investigator. All discrepancies were resolved through group consensus. Although data achieved saturation after 10 coded interviews [35], all data were coded. Coded categories were grouped by intervention components and aspects of participant satisfaction. Subcategories of each pre-identified theme were cross compared for word similarities to identify overlap in responses. Data were coded using NVivo 12.0 (QSR International).

JMR served as the student investigator and conducted this study as part of her doctoral dissertation in Social and Behavioral Sciences. Under guidance of the other senior authors, JMR made all final decisions throughout the study process. She considered her role as student investigator and her gender from conceptualization to the reporting of findings. Many factors, including time and financial constraints, were taken into account when determining who would collect and analyze the data. JMR collected the semistructured interview data due to availability, experience, and direct contact with participants throughout the study. After each interview, JMR documented her assumptions in memos. Given JMR’s vested interest in her doctoral dissertation, she took a minimal role in coding to mitigate potential bias in the qualitative findings. Her involvement in the qualitative data analysis primarily revolved around facilitating discussion on coding discrepancies and providing qualitative training.

A convergent mixed methods analysis [36] was used following standard guidelines [37]. Specific items from the quantitative data were integrated with corresponding themes related to intervention materials, in which qualitative data were embedded into quantitative data to explain acceptability ratings of intervention components.

**Results**

Of the 18 men, 14 completed the 12-week follow-up visit after completing the intervention (retention: 78%). Participants’ mean age was 29.0 (SD 4.8) years, with a mean BMI of 31.0 (SD 4.7) kg/m$^2$, and 29% (4/14) identified as racial and ethnic minorities. Demographic characteristics of the participants who completed the follow-up visit are displayed in Table 1. On average, participants lost –1.8% (SD 2.8%) of their initial body weight at 12 weeks (range: –9.5% to +1.3%). Results are described in 3 thematic areas in the following sections. Exemplary quotes from qualitative interviews corresponding to themes and subthemes are provided in Table 2.

Appealing Aspects of the Intervention or Motivations for Joining

During interviews, a desire to lose weight was the most common reason for joining the study (8/14, 57%). Other reasons for joining included meeting the advertised age and gender demographic (7/14, 50%), gaining knowledge (6/14, 43%), getting in shape (5/14, 36%), and the self-guided aspect (4/14, 29%).

I liked that it was targeted at my age group by my demographic in general. I feel like there are a lot of weight loss programs for other demographics. And this is the first one that I see that civically targeted, you know, and my age group.

Most participants did not report hesitation about joining the intervention. Those who reported a reluctance (3/14, 21%) about joining the intervention were mainly concerned about having enough time. The quantitative results indicate that the majority of participants found the intervention appealing and decided to join because of the emphasis on general lifestyle changes (13/14, 93%), focus on health risk (14/14, 100%), and weight loss (11/14, 79%). The lowest percentage of men rated the self-guided component (5/14, 36%) or minimal in-person contact (5/14, 36%) as reasons for joining. See Table 3.

</table>
Acceptability of Intervention Components

Less than one-half (5/14, 36%) of the men rated the overall intervention acceptable (satisfaction >5). For specific components, the majority of the participants in the interviews mentioned the Bluetooth scales (11/14, 79%), recommended apps (9/14, 64%), and text messages (10/14, 71%) were helpful for weight loss.

For the digital tools, participants discussed finding the Bluetooth scale’s features, which included an app to track metrics and progress, helpful. One young man shared his thoughts on the Bluetooth scale:

*The scale was really, really useful actually, especially starting out because I could see, like, all the different metrics that I had no idea of before.*

Quantitative findings indicated the percentage of men who found the recommended apps as acceptable (rating ≥5) was lower than those in the qualitative findings. In particular, less than one-half of men (6/14, 43%) found the recommended applications to self-monitor diet acceptable. Over one-half of men (8/14, 57%) found the recommended applications to self-monitor physical activity acceptable. See Table 3.

A low percentage of men found the meal planning strategies (1/14, 7%) and the intervention website (4/14, 29%) as acceptable (rating ≥5). Less than one-half of the participants found the strategies taught in the group session helpful (5/14, 36%) and the website content motivating (2/14, 14%).

The quantitative data indicate over one-half of men found the text messages motivating (9/14, 64%), helpful (9/14, 64%), and raised awareness of the health risks of weight gain (11/14, 79%) and cardiovascular disease (8/14, 57%).

The qualitative data indicate participants found the weekly text messages served as good reminders. One-half (7/14, 50%) of the qualitative interviews indicate participants found the text messages of benefit. The other one-half (7/14, 50%) either did not find the messages helpful or had mixed feelings about them—some felt the content of the text messages did not have enough variety or were something that could be easily disregarded. One young man shared thoughts on the weekly health risk messages:

*The text message that we got, it was good accountability, but it was also [sic] something that you just kind of slough off because it’s just like here’s a fact.*

Preferences for an Ideal Intervention

Of the participants, 71% (10/14) described a desire for a social aspect to the intervention, and almost all men (13/14, 93%) preferred an online group component for discussion. In particular, 93% (13/14) of men wanted an online group meeting focusing on physical activity. Participants discussed the desire for a message board or ongoing discussion with other participants to help with motivation or accountability throughout the intervention. Over one-third (5/14, 36%) also mentioned a desire for a more personalized experience and to receive more feedback (5/14, 36%). A participant shared:

*Maybe a social component, more so than the accountability part, you know. Just like a shared experience kind of thing.*

The majority (8/14, 57%) of participants wanted more contact from the intervention. For the most part, participants preferred to have midpoint or monthly online group check-ins, as opposed to weekly check-ins.

Discussion

Principal Findings

This convergent mixed methods analysis provides insight into young men’s experiences with a self-guided lifestyle intervention to inform future intervention development for this vastly underrepresented population. We explored 3 key areas: motivations for joining and appealing aspects of the intervention, acceptability of specific intervention components, and preferences for an ideal intervention.

Motivations for joining and acceptable intervention components of a lifestyle intervention were key areas explored in this study. Qualitative and quantitative data surrounding motivations for joining and acceptable intervention components were fairly consistent. First, qualitative data indicated men’s interest in joining the study was related to age and gender. This underscores the importance of designing recruitment messaging specifically for young men as a way to enhance enrollment in lifestyle interventions [38]. Furthermore, the emphasis on health risks emerged as a key motivator for young men to participate in the lifestyle intervention. However, the existing literature on leveraging health risks to prompt health behavior change among men presents mixed findings. Although some findings suggest that fear of health complications [8] and a desire to improve health [16] act as motivators for engaging with weight loss behaviors, other research indicates that young men may prefer to avoid discussions about associated health risks [10]. It is plausible that the use of health risk messaging in recruitment

aPercentage of participants rating intervention features acceptable (>5 on a 7-point scale).
The overall acceptability of the self-guided lifestyle intervention among young men was found to be suboptimal. However, young men reported high acceptability of the study-issued scale and companion app to track weight. Additionally, the online delivery method was well-received by men. Therefore, prioritizing remote delivery of lifestyle interventions for participants who are meeting weight loss goals could enhance accessibility, scalability, and convenience [40,41]. It is worth noting that young men perceived the self-guided aspect as somewhat “hands-off” and lacking personalization. Specifically, young men expressed dissatisfaction with the website, which did not offer new weekly content throughout the active intervention period. Collaborating with young men in future interventions to co-design weekly content might render higher appeal and engagement with the intervention.

Young men highlighted a preference for adding a social aspect in future interventions. Specifically, men reported wanting a shared similar experience—which is a reported benefit of using online platforms for sharing weight loss experiences [42]. Recent data underscore the potential for peer support to promote weight loss in a reduced intensity lifestyle intervention, but the majority of sample was adult women [43]. Of note, these preferences for a shared similar experience could be somewhat negated in standard behavioral weight loss interventions, which are predominantly women [2,44]. Qualitative data indicate men do not feel comfortable discussing men’s health issues and weight loss around women [45]. Thus, integrating a private online platform for young men to discuss relevant health issues might be one strategy for improving this population’s engagement with weight management. In addition to the desire for an online social platform, young men also reported a preference for online group sessions related to physical activity. This finding is consistent with formative data suggesting young men have a greater desire for interventions to focus on physical activity than young women, particularly as it relates to peer support and accountability [18]. Although physical activity is less effective at producing weight loss compared with diet alone [46], promoting physical activity upfront as a way to engage men could have a “spill-over” effect on other behaviors such as diet.

Last, incorporating social support via personalized weekly feedback derived from self-monitoring and goal progress is an evidence-based behavioral change technique [47] that might potentially boost motivation and engagement among young men. Despite men performing well in a self-guided lifestyle intervention targeting weight loss [14], young men in this study expressed a preference for monthly check-ins to aid in accountability. Therefore, future endeavors should consider testing different levels of intensity to determine the optimal level of support needed for men to achieve weight loss goals while also addressing time-related barriers faced by young men.

Limitations
This study had several limitations. The sample was mostly non-Hispanic White with a college education. Given the racial and education disparities in both obesity prevalence and enrollment in behavioral weight loss interventions [48,49], more research is warranted to investigate the weight management needs and preferences of young men from marginalized racial and ethnic identities or men without a college education. These data were collected during COVID-19. Rapid shifts toward digital health interventions and the unique context of a global health pandemic may have impacted the findings in numerous ways (eg, desire for weight management, social connection). The treatment-seeking sample might not be generalizable to young men broadly. Moreover, we only interviewed men who returned for their follow-up visit. Thus, important elements for enhancing engagement were potentially missed in the present sample. Interviews were of shorter duration than a typical qualitative interview. However, given the specific goals and deductive design of the qualitative data and pairing of quantitative data, the depth of the participant responses was sufficient in addressing the paper objectives. Men who completed the interviews were slightly older than men who were lost to follow-up (30 years old vs 26 years old). Therefore, more work is needed to understand the preferences and experiences of emerging adult men specifically. Last, this study tested a “bundled” intervention package, which limited our ability to delineate effects of individual intervention components. Future research should apply rigorous factorial designs, such as the multiphase optimization strategy (MOST) [50], to delineate individual and combined effects and acceptability of intervention components to develop an optimized intervention package for young men.

Strengths
This study had several strengths. To our knowledge, this is the first mixed methods study to report young men’s experiences with and the acceptability of a remotely delivered, self-guided lifestyle intervention targeting weight loss. In future work, fully embracing user-centered design will allow us to identify elements that improve the participant experience and related outcomes in lifestyle interventions [51]. Additionally, we had high agreement between coders. Last, we followed standard guidelines for the best practice of integrating the qualitative and quantitative findings [37]. Behavioral weight loss trials can benefit from a mixed methods design—using qualitative and quantitative data to complement inherent weaknesses in each, generate robust findings, and enhance validity [52].

Conclusions
Our findings suggest that the acceptability of a self-guided approach was less than optimal among young men. To improve acceptability, potential enhancements might include incorporating online group sessions focused on physical activity, providing personalized feedback based on self-monitoring and goal setting, or implementing an online platform to foster peer support among young men. Further refinement of this lifestyle intervention is necessary before conducting a large-scale randomized controlled trial. A cost-efficient design, such as MOST [50], could be utilized to determine the most effective individual and combined intervention components offering the greatest clinical benefit while considering practical aspects such as cost and scalability. These interventions could enhance...
engagement among young men by augmenting the self-guided approach to include additional support such as optional online group exercise classes. These classes might be a relevant time to emphasize the importance of physical activity—as it relates to men’s health. Findings also suggest a social component could enhance accountability for men attempting weight loss. More research is needed to expand our understanding of young men’s experiences with weight management over a longer-term follow-up and engagement strategies for reaching emerging adults.

Acknowledgments
The authors would like to acknowledge Ronald Evans, PhD; Autumn Lanoye, PhD; Morgan Meyer, MS; Justin Guan, MS; and Ronston Jackman, BS, for their help executing this trial. We thank the study participants who dedicated time to participate in this study. JMR was supported by National Institutes of Health (NIH)/National Cancer Institute (NCI) training grant T32CA093423 and Virginia Commonwealth University (VCU) Department of Health Behavior and Policy to carry out this trial and received funding support from NIH/NCI grant T32CA193193 to prepare portions of this manuscript and publication costs. Additional resources were provided by the VCU OPT for Health lab (JGL PI) and VCU Clinical and Translational Science Award (CTSA; UL1TR002649). The NIH had no involvement in the study design, collection, analysis, and interpretation of these data.

Conflicts of Interest
JGL discloses grant funding from WW International, unrelated to the current work. The remaining authors have no other competing interests to disclose.

Abstract

**Background:** The escalating prevalence of cesarean delivery globally poses significant health impacts on mothers and newborns. Despite this trend, the underlying reasons for increased cesarean delivery rates, which have risen to 36.3% in Portugal as of 2020, remain unclear. This study delves into these issues within the Portuguese health care context, where national efforts are underway to reduce cesarean delivery occurrences.

**Objective:** This paper aims to introduce a machine learning, algorithm-based support system designed to assist clinical teams in identifying potentially unnecessary cesarean deliveries. Key objectives include developing clinical decision support systems for cesarean deliveries using interoperability standards, identifying predictive factors influencing delivery type, assessing the economic impact of implementing this tool, and comparing system outputs with clinicians’ decisions.

**Methods:** This study used retrospective data collected from 9 public Portuguese hospitals, encompassing maternal and fetal data and delivery methods from 2019 to 2020. We used various machine learning algorithms for model development, with light gradient-boosting machine (LightGBM) selected for deployment due to its efficiency. The model’s performance was compared with clinician assessments through questionnaires. Additionally, an economic simulation was conducted to evaluate the financial impact on Portuguese public hospitals.

**Results:** The deployed model, based on LightGBM, achieved an area under the receiver operating characteristic curve of 88%. In the trial deployment phase at a single hospital, 3.8% (123/3231) of cases triggered alarms for potentially unnecessary cesarean deliveries. Financial simulation results indicated potential benefits for 30% (15/48) of Portuguese public hospitals with the implementation of our tool. However, this study acknowledges biases in the model, such as combining different vaginal delivery types and focusing on potentially unwarranted cesarean deliveries.

**Conclusions:** This study presents a promising system capable of identifying potentially incorrect cesarean delivery decisions, with potentially positive implications for medical practice and health care economics. However, it also highlights the challenges and considerations necessary for real-world application, including further evaluation of clinical decision-making impacts and understanding the diverse reasons behind delivery type choices. This study underscores the need for careful implementation and further robust analysis to realize the full potential and real-world applicability of such clinical support systems.

Introduction

Background

The ability to provide care to both women and newborns during delivery is one of the most important aspects of health care and is often used as a metric to assess health care across different countries. Cesarean delivery is one of the most important aspects of delivering babies since it has a considerable impact on the mother’s health and well-being. Despite the increased prevalence of this procedure over the last few years, the reasons behind this trend still remain unclear. Reports suggest that this increment is a global phenomenon, with the rate of cesarean deliveries almost tripling from 6.7% to 19.1% between 1990 and 2014 [1,2]. Research on the impacts of cesarean deliveries has focused on the risk of infection, hemorrhage, organ injury, and complications related to anesthesia or blood transfusion [3,4]. There is also a higher risk of complications in subsequent pregnancies, such as uterine rupture, abnormal placental implantation, and the need for hysterectomy [5,6]. As for the infant, cesarean deliveries can lead to respiratory problems, asthma, and childhood obesity [5]. In light of this, in 2015, the World Health Organization stated that cesarean delivery rates higher than 10% were not associated with a reduction in maternal or newborn mortality, even though other complications could not be fully assessed [7]. In contrast, there is no evidence of the benefits of this procedure for women or babies when there is no clear medical need; therefore, it is paramount to focus on identifying and reducing such cases [2]. It was estimated that in 2018, there were 8.8 million unnecessary cesarean deliveries [8]. It was with this in mind that a committee was established in Portugal with the specific purpose of decreasing the percentage of cesarean deliveries nationwide. One of the policies resulting from this committee’s work was the reduction of government funding per inpatient cesarean delivery episode for hospitals with rates of cesarean deliveries above 25%; as of 2020, the number of cesarean deliveries in Portugal stands at approximately 36.3%, nearing the all-time high of 36.9% in 2009 [9]. Furthermore, studies have shown that several countries could benefit from similar policies [8]. A quantitative analysis estimated that a reduction in cesarean deliveries could save millions of dollars [10] worldwide. Therefore, lowering the proportion of cesarean deliveries can yield health and financial benefits for both institutions and patients alike. With these considerations in mind, we developed a machine learning, algorithm-based support system to assist clinical teams in identifying cases of potentially unnecessary cesarean deliveries. As such, in this paper, we propose to (1) elaborate on how clinical decision support systems for cesarean deliveries can be developed using interoperability standards; (2) understand, based on the data collected, which features have the most significant impact on predicting delivery type; (3) conduct a concise economic analysis to assess the potential financial impact of implementing the proposed clinical decision support tool; and (4) compare the system’s output with clinicians’ responses.

Rationale and Related Work

Regarding the related work, several teams already tackled the potential of predicting the delivery type before birth. We found studies related to predicting a successful vaginal birth after a previous cesarean delivery, such as the work of Lipschuetz et al [11], where a gradient boosting method was used to predict such an event using prenatal data to do so. Grobman et al [12] performed a similar study with a multivariable logistic regression model. Different modalities of data were also used to predict delivery type. Fergus et al [13] introduced a method of predicting delivery type using fetal heart rate signals. Similarly, the work from Saleem et al [14] proposed a method for predicting delivery type using interactions between the fetal heart rate and maternal uterine contraction. Finally, some studies focus on predicting the delivery mode, such as the work of Ullah et al [15], where a boosting algorithm was used to predict a delivery mode with enriched data sets. In addition, Gimovsky et al [16] introduced decision trees to predict cesarean deliveries by physician group with an area under the receiver operating characteristic curve (AUROC) of 0.73. The works of Rossi et al [17] resulted in a 7-variable model with an AUROC of 0.78, and the works of Guedalia et al [18] resulted in a model with an AUROC of 0.82, reaching 0.93 with a first cervical examination. Finally, the works of Meyer et al [19] focused on selecting something suitable for a trial of labor after cesarean delivery with an area under the precision recall curve graph around 0.351. However, to the best of our knowledge, there was no model tested in clinical practice with an interoperable format of communication such as Fast Healthcare Interoperability Resources (FHIR), which tried to not only predict delivery type but also provide support about possibly wrong deliveries, and none with simulation about financial implication, making our paper a potential novelty on different dimensions.

Methods

Materials

Data were retrospectively collected from 9 different public Portuguese hospitals across the country, focusing on obstetric information and encompassing maternal data, various fetal data points, and the method of delivery retrospectively. The inclusion criteria are all mothers with a registered outcome of the pregnancy from 2019 to 2020. There were no exclusion criteria. Each institution used identical electronic health record software, ensuring that the data columns remained consistent.

Clinical Comparison

The clinical comparison was performed by sending questionnaires to clinicians with a relationship with obstetrics to assess 10 patients, with only access to the variables used by the model, and to answer 3 questions for each. The first question was to give a score from 1 to 10 of how likely it was that a
patient would give birth through cesarean delivery, the second question was to select the feature or variable that most influenced the decision, and the third question was to select which feature they would require to make a better assessment. We sent the questionnaire to 20 people and obtained 6 answers, totaling 60 patient assessments. For these 10 patients, we also predicted the delivery type using our model to compare it with the clinicians’ answers. These patients were new and were not seen by the model during the training phase.

Analysis

All null representations were standardized. Data were prepossessed by removing features with high missing rates (>90% overall). The imputation process was performed using the k-nearest neighbor imputation method (for continuous variables) or a new category (NULLIMP) for categorical variables. Weight was categorized into percentiles defined specifically for Portuguese babies [20]. For this study, the birth type was reduced to binary. All assisted birth were merged into vaginal birth, and cesarean delivery remained as the other class. Procedures and diagnoses were also used and were encoded as binary features, and we took the time to analyze each one of them to avoid leakage because there were procedures obviously related to cesarean deliveries and vaginal deliveries. Feature creation was performed through the free-text variable related to the prescribed medication. Medicine names were collected from it and converted into Anatomical Therapeutic Chemical classification group level 4, which represents chemical subgroups. We also created some new features from data in the data set, namely new categories related to the labor and condition of the baby. In addition, data quality issues were addressed, such as impossible values that were transformed into null values. The main variables affected by data quality were BMI or weight and gestational age. The data were split into training and test sets in a 0.75:0.25 manner. From the overall data sets that comprised over 200 columns, only a few columns were selected (see Table 1). We used a mixture of features selected by surveying the literature [21-23] and features with a high correlation with the outcome. The tested models were logistic regression, decision tree, random forest, 3 different boosting methods (as implemented by extreme gradient boosting [XGBoost], light gradient-boosting machine [LightGBM], and scikit learn), and a linear model based on stochastic gradient descent.

The evaluation was performed with repeated stratified cross-validation with 10 splits and 2 repetitions, with 2 full cycles of dividing the training set into 10 equal parts and using 9 as the training set and 1 as the validation set. The results are shown in Table 2. The application programming interface (API) for serving the prediction model was developed using FastAPI. We wrote all the code in Python (version 3.9.7; Python Software Foundation).

**Table 2.** Repeated cross-validation (10 × 2) results in the training set with mean AUROC\(^a\) and 95% CI for the best hyper-parameters found for each algorithm. Wilcoxon test was used for comparing with the best performing algorithm.

**Ethical Considerations**

This study received institutional review board approval from all hospitals included in this study with the following references: Centro Hospitalar São João (08/2021), Centro Hospitalar Baixo Vouga (12-03-2021), Unidade Local de Saúde de Matosinhos (39/CES/JAS), Hospital da Senhora da Oliveira (85/2020), Centro Hospitalar Tamega Sousa (43/2020), Centro Hospitalar Vila Nova de Gaia/Espinho (192/2020), Centro Hospitalar entre Douro e Vouga (CA-371/2020-06_MP/CC), and Unidade Local de Saúde do Alto Minho (11/2021). All methods were carried out per relevant guidelines and regulations. The need for informed consent was waived by the ethics committee.

**Results**

**Descriptive Statistics**

The number of samples varied across the hospitals, ranging from 2364 to 18,177. Distributions of the selected variables are presented in Table 1. The sum of all samples was 73,351. The outcome variable distribution is stated in Table 3.

**Model**

The AUROC is presented in Table 2 for the best hyper-parameters found for each algorithm in the training data. All models used the variables indicated in Table 1.

While XGBoost was the best-performing algorithm, we selected LightGBM [24] because of its speed and lower memory requirements, which we believe are better suited for deployment in a low-hardware environment. The threshold selected for deploying the model was 0.7457, which rendered the metrics in the test set, as shown in Table 4.
Deployment

The purpose of this model is to serve as an API for usage within a health care institution and to act as a supplementary clinical decision support tool for obstetrics teams. For this to happen, a health information system must make the requests to the API. Even though a concrete, vendor-specific information model and input health information system were used, we hope to create a more interoperable clinical decision support system that can be used by every system that acts on birth and obstetrics departments. Therefore, we built it around the HL7 FHIR standard (R5 version) to simplify the method of interacting with the API. This decision, opposed as to using a proprietary model for the data, sits upon the usage of FHIR resources: bundle and observation for request and returning the result as a message through a custom operation called "$predict." It is intended to publish the profiles of these objects to facilitate access to the API using standardized mechanisms and data models. The current build of the profiles can be seen in the published FHIR implementation guide where the current specifications are described in detail [25]. The process is illustrated in Figure 1. We deployed this model in production in a single hospital without a user interface, collecting only the data and predictions for later discussion and analysis. We collected 3231 requests. During this period, 123 (3.8%) alarms were triggered. From this, we tried to understand the level of certainty for the decision and check the difference from the threshold of these alarms. The distance to the threshold for 73 was lower than 0.1 and was bigger than 0.1 for 50 (1.55%) cases.

Figure 1. Deployment and decision mechanism of the model. EHR: electronic health record; FHIR: Fast Healthcare Interoperability Resources.

Clinical Comparison

The median scores given by each clinician are presented in Figure 2. We also predicted the result using our model as stated in Figure 2. The model misclassified only 1 record (ID 4). As for the analysis of missing features for the responders, they were divided into 3 categories: (1) existent in the data set but not included in the model, (2) nonexistent in the data set, and (3) existent in the data set and included but that particular information was not filled for the patient assessed. Out of 60 responders, this rendered a total of 37 (62%) with nonexistent features and 23 (38%) with existent features but no information was provided at that moment. No feature mentioned existed in the data set but had not been included in the model. From the 37 nonexistent features, 14 (38%) were new clinical assessments, 14 (38%) were linked to information from previous births, 5 (15%) were connected to more in-depth information about provided information (ie, a motive for induction), and 4 (11%) were related to the mother’s choice (if she wanted a cesarean delivery). As for feature importance, from the 60 answers, 33 (55%) stated that labor was the most important factor. Further, 9 (15%) stated the number of previous vaginal births, 5 (8%) stated the evolution of weight, and another 5 (8%) stated the number of previous cesarean deliveries as being the

most important. The remaining 8 (14%) were various features, such as BMI, neuroaxis techniques, gestational age, and weight of the mother. Of all of these, 54 (90%) were in the top 10 features of the model.

Figure 2. Validation data. The color represents the actual birth type. The boxplot represents the median and IQR of the reviewers, and the x-axis represent the patient cases. There were 6 vaginal births and 4 cesarean deliveries. ID 4 represents wrong predictions of the model.

**Potential Financial Impact**

The financial support provided to public hospitals in Portugal is partially tied to the rate of cesarean deliveries. To assess the potential impact of this mechanism on Portuguese public hospitals, we conducted a simulation. We got data for every public hospital for the last 12 months and applied a 3.8% reduction (the rate of warnings triggered in the new data set) and recalculated the rate of cesarean deliveries. The increase in support was calculated by the state-mandated rate as shown in Table 5. With this new rate, we observed that implementing our tool would result in financial benefits for 30% (15/48) of the public hospitals. Specifically, 5 hospitals would begin receiving support instead of no support at all. Further, 3 hospitals would experience a doubling of their financial benefit, while 2 hospitals would see a 50% increase. Furthermore, 1 hospital would receive an additional one-third of financial support. If we assumed that only half of the warnings found in the new data were actually true (1.9%), we found that only 6 hospitals would be benefited: 3 from 0 to 0.25, 2 from 0.25 to 0.50, and 1 from 0.50 to 0.75.

**Table 5.** With this new rate, we observed that implementing our tool would result in financial benefits for 30% (15/48) of the public hospitals. **Discussion**

**Principal Findings**

The first thing to address about this model is the number of biases that we introduced in the model by choice. We joined all vaginal delivery types into a single category (assisted and nonassisted), which introduces a bias since these delivery modes are indeed different. Second, the fact that we want to predict if the delivery type was wrongly chosen, mainly for the case of a cesarean delivery that did not need to be so, is also a bias. We used this approach because the initially collected data did not have the representation of such events. Thus, the biases of possibly wrong delivery types were present in the training data. We attempted to minimize this issue by selecting a threshold that gave the model higher sensitivity than specificity so that only large probabilities would trigger an alarm for human consideration. Parallel to this, we are starting to gather labeled cases, with the help of clinicians to create a better training data set. Furthermore, since the data were collected from different hospitals, differences in the data input can also occur. Even though the health information system is the same, the processes that originate the data and are being used for secondary purposes could introduce several biases in the data. This is an issue that was accepted from the start regarding the mechanism of data collection and model training. Despite this, we reached a model with a very high AUROC (88%, 95% CI 0.8795-0.8815), which is encouraging when compared to the state-of-the-art, which is between 0.73 and 0.82 [16-18]. Moreover, assuming that more...
data are provided, and proper labeling is done regarding the outcome variable (such as a clinical evaluation of needless cesarean deliveries) is added as well, a better model could be developed.

Regarding the preliminary clinical evaluation, it was only possible to obtain an overview of the possible comparison due to the number of responders. Despite that, the results are encouraging, since the model seems to behave better than humans with the data provided. However, this is a biased vision since clinicians in the real world have access to more data and information than the model has. It is encouraging, but caution is advised before more tests and evaluations are done. As for the deployment, future work could be the improvement of the API to map all variables to an ontology such as SNOMED CT or similar, making it easier for every system and person to access it and obtain a suggestion of the delivery type. Finally, we believe the assessment can be improved. A more robust clinical assessment is necessary, as well as a thorough analysis of the impact of the tool in the real world, since we need to create the bridge between the results of the model and how clinical decisions are affected by it. A full cost-effectiveness analysis is also necessary to understand the real-world impact of the model. Further, an interesting result is the fact that 38% of the answers regarding the most important data element missing from the patient record refer to data that are being collected but was missing for that specific patient, raising an important question about data input methodology, interoperability, and quality. If we cannot have access to data when these matter the most, these can become meaningless. Missing data are a problem of biomedical data as a whole. However, when specifically targeted at machine learning usage of this data for predicting something, we did not find any work comparing them with clinicians. However, we did find reporting of similar missing values in obstetrics data [27] and we also found works of a similar nature using machine learning models with robust handling of missing data such as XGBoost [28] to counter this problem. This indicates that our model has the potential to counter the missing data problem as well since LightGBM can also handle missing data natively.

Conclusions

We believe we have developed a robust system capable of detecting potentially incorrect cesarean delivery decisions, which could positively impact real-world medical practice. However, before implementation, several challenges must be addressed, particularly the need for further evaluation of the system’s impact on clinical decision-making and the reasons underlying suboptimal delivery-type decisions. Cesarean deliveries may be performed for various reasons, from a mother’s preference to a decision made by the obstetrics team. This system is not designed to impede medical practice or to highlight flawed decisions, potentially scrutinizing specific professionals. Such caution is necessary when implementing systems like these. While having a high AUROC is beneficial, the real-world impact is another consideration. The assumptions and biases associated with autonomous systems supporting clinical practice must be carefully considered. Nonetheless, the metrics and results we have achieved so far are promising for positively influencing health and economic outcomes.

Abstract

Background: The use of mobile technologies in fostering health promotion and healthy behaviors is becoming an increasingly common phenomenon in global health programs. Although mobile technologies have been effective in health promotion initiatives and follow-up research in higher-income countries and concerns have been raised within clinical practice and research in low- and middle-income settings, there is a lack of literature that has qualitatively explored the challenges that participants experience in terms of being contactable through mobile technologies.

Objective: This study aims to explore the challenges that participants experience in terms of being contactable through mobile technologies in a trial conducted in Soweto, South Africa.

Methods: A convergent parallel mixed methods research design was used. In the quantitative phase, 363 young women in the age cohorts 18 to 28 years were contacted telephonically between August 2019 and January 2022 to have a session delivered to them or to be booked for a session. Call attempts initiated by the study team were restricted to only 1 call attempt, and participants who were reached at the first call attempt were classified as contactable (189/363, 52.1%), whereas those whom the study team failed to contact were classified as hard to reach (174/363, 47.9%). Two outcomes of interest in the quantitative phase were “contactability of the participants” and “participants’ mobile number changes,” and these outcomes were analyzed at a univariate and bivariate level using descriptive statistics and a 2-way contingency table. In the qualitative phase, a subsample of young women (20 who were part of the trial for ≥12 months) participated in in-depth interviews and were recruited using a convenience sampling method. A reflexive thematic analysis approach was used to analyze the data using MAXQDA software (version 20; VERBI GmbH).

Results: Of the 363 trial participants, 174 (47.9%) were hard to reach telephonically, whereas approximately 189 (52.1%) were easy to reach telephonically. Most participants (133/243, 54.7%) who were contactable did not change their mobile number. The highest percentage of mobile number changes was observed among participants who were hard to reach, with three-quarters of the participants (12/16, 75%) being reported to have changed their mobile number ≥2 times. Eight themes were generated following the analysis of the transcripts, which provided an in-depth account of the reasons why some participants were hard to reach. These included mobile technical issues, coverage issues, lack of ownership of personal cell phones, and unregistered number.

Conclusions: Remote data collection remains an important tool in public health research. It could, thus, serve as a hugely beneficial mechanism in connecting with participants while actively leveraging the established relationships with participants or community-based organizations to deliver health promotion and practice.
Introduction

The use of mobile technologies in engaging people and communities to choose healthy behaviors and to improve their health is becoming an increasingly common phenomenon in global health programs [1-4]. Mobile technologies have increasingly become a common mode of delivering telemedicine in sub-Saharan Africa and other low- and middle-income countries (LMICs) given improvements in coverage [5], with the prospects of improving access to information pertaining to health care services in areas where health care systems lag in meeting minimum health standards [6,7]. Mobile phone technology use in clinical studies is a potential avenue for both the follow-up of participants in research [8-10] and the provision of targeted and tailored messaging to facilitate behavior change support. For instance, patients now progressively receive reminders regarding clinic appointments [11], medication uptake [12], health promotion [13,14], medical treatment or diagnosis [15], and accessing information on disease outbreaks and other health-related data [16] through SMS text messaging systems and telephone calls; all these methods have collectively contributed to better health [1,17]. These digital interventions are reinforced by the high level of mobile phone penetration in many LMICs.

Mobile technologies typically exist in the form of internet-enabled devices such as smartphones, tablets, and watches [18]. Mobile phones constitute the most commonly used mobile technologies for cellular communication in LMICs [19,20] and are used as a cellular communication system for making and receiving phone calls, video calls, text and instant messaging, surfing the internet, GPS navigation, and playing games [21]. For the purposes of this study, the focus was particularly restricted to mobile phones, with the form of cellular communication being restricted only to phone calls.

Research conducted in the sub-Saharan African region has shown that individuals who participate in research studies are intermittently reached through the phone, which is the most commonly used method in the region [22]. Among African countries, South Africa has the third highest number of people who are active mobile phone users, providing a robust platform for telemedicine prospects [22]. For example, 97% of households in South Africa have access to a mobile phone [23]. According to the Independent Communications Authority of South Africa 2019 report on the state of information and communications technology, an estimated 82% of the country’s total population have a smartphone [24], with 88% of the population reported to have prepaid mobile cellular subscriptions and 12% of the population reported to have contract subscriptions [24]. Although mobile technologies have shown some success in their effectiveness in health promotion initiatives and in improving health knowledge, the use of mobile phones in delivering these interventions within clinical practice and research raises some concerns [25]. For example, although a large proportion of people own mobile phones, there are low retention rates in clinical research, and this has been largely attributed to challenges of participant reachability and accessibility by phone [22]. For instance, in a clinical trial conducted in Togo, out of an approximate proportion of 13,726 respondents who had provided their mobile number, 80% could not be reached on that number [26].

In addition, research conducted in Côte d’Ivoire among patients who were receiving antiretroviral treatment showed that out of the 7000 patients who were traced telephonically after initially actively participating in the research but were lost at the point of follow-up in the study, only 40% of the patients could be reached on the telephone number that was provided [27]. A randomized controlled trial conducted in South Africa among 400 HIV-positive patients found that only 60.3% of the patients could be reached telephonically after being contacted a maximum of 3 times via telephone on different days and at different times for every phone number that the participant had provided [22]. In addition, another South African study indicated that reachability by phone is a common challenge in the country. This is caused, for instance, by theft and loss of phones, which results in connectivity loss with respondents and loss to follow-up [28]. Although several scholars have investigated the effectiveness of mobile phones in follow-up studies [1,6-8,13,24,27-29], there is a dearth of literature in South Africa that has qualitatively explored the challenges that participants experience in terms of being contactable through mobile technologies. Gaining insight into these challenges will help in developing targeted strategies to facilitate ways for research staff and researchers to remain in contact with participants over time and for follow-up research. The results could also potentially inform the use of mobile technologies for reaching patients in a clinical setting.

The trial is being conducted in Soweto, South Africa. It is the Bukhali preconception health trial, which is nested in the Healthy Life Trajectories Initiative [30]. The aim of the trial is to optimize the physical and mental health of young women, fostering positive dynamic changes in their health for themselves, and where relevant, for future cohorts. In this trial, young women received intervention materials and resources delivered by community health workers, referred to as “Health Helpers.” These materials include health literacy materials, multimicronutrient supplements, health screening and referral conducted in person, nutritional risk and support, and monthly sessions that help with modifying or transforming health behaviors. The monthly sessions were conducted telephonically by the Health Helpers with on-site visits scheduled every 6 months [30-32]. However, there have been challenges in contacting participants for booking and delivering monthly trial sessions because the participants were unreachable on the contact numbers registered for the study. Therefore, this study aimed to explore the challenges that participants experienced...
with regard to being contactable through mobile technologies, using both quantitative and qualitative data.

**Methods**

**Study Design**

A convergent parallel mixed methods research design was applied. It is a research design that involves the collection and analysis of quantitative and qualitative data separately, which are then compared simultaneously to better understand the phenomenon under study [33]. The main presumption of the research design was that both quantitative and qualitative data offer varying information, with the qualitative data providing narrative accounts of the participants and the quantitative data providing scores on selected variables [33]. This design provides a broader insight into the issue being studied by comparing the findings and results to discern whether they confirm or disconfirm each other. Combining both qualitative and quantitative methods as complementary methods has the potential to contribute to broader applicability of the findings in other settings or with other wider populations [33-36]. This method is applicable in this study given that the quantitative data provided insight into data on many Bukhali trial participants, whereas the qualitative data provided an in-depth narrative account of the mobile phone challenges faced by participants and other reasons for being hard to reach.

**Participants and Recruitment**

The study population consisted of young women aged 18 to 28 years who participated in the trial within the precinct of the Chris Hani Baragwanath Academic Hospital, located in Soweto, Johannesburg, South Africa, and were recruited into the intervention arm of the Bukhali trial [30]. Soweto is a largely overpopulated and multilingual area that lies on the outskirts of the greater Johannesburg city. It is characterized by several socioeconomic issues, namely, joblessness, gender-based violence, and food insecurity, as well as factors hindering healthy behaviors [37], which have the potential to influence the mobile phone use patterns of young women.

Overall, the study team contacted participants telephonically to (1) deliver monthly sessions to the participants, (2) book subsequent monthly sessions for the participants, (3) arrange to have supplements delivered to the participants’ homes, or (4) follow-up on the participants who have experienced an adverse event. The mobile phone information of the participants was captured by the study team to enable the team to reach the participants. For the quantitative component of this study, we included all young women who were contacted telephonically between August 2019 and January 2022. These women were contacted to either have a session delivered to them or to be booked for a session (n=363) out of the wider group of Healthy Life Trajectories Initiative participants. This was done to identify young women who were reachable and those who were unreachable. Participants who had (1) in-person contact with the study team (either off-site to deliver supplements or on-site to deliver a session), (2) contact via SMS, or (3) contacted through other means of communication (eg, home visits or instant messaging) were excluded from this study to focus on the extent to which participants could be contacted by phone.

The standard process used by the intervention team to facilitate the intervention involved making several call attempts to reach the participants. All call attempts and contact statuses of the participants were captured on a contact log. At most, 3 call attempts were made and if the participants were still unreachable, the study team generated tracing lists that prompted them to trace these participants by conducting further fieldwork to update the contact details of the participants. For the purposes of this study, we restricted the call attempts to only 1 call attempt given that the study only aimed to provide a cross-sectional picture and not an analysis that focuses on more longitudinal repeated attempts, which was beyond the scope of this study. Thus, participants who were reached at the first call attempt were classified as “reachable.” Participants whom the study team failed to make contact with at the first call attempt were classified as “hard to reach” or “failed to make contact.” In the same period, some participants changed their mobile number once, some did it several times, and others did not change their number. A flowchart indicating the stages of participant recruitment is shown in Figure 1.
For the qualitative component, a subsample of participants (n=20) who were part of the *Bukhali* trial for ≥12 months were recruited telephonically for those who were easily contactable, and recruitment was performed by a fieldwork team for those who were hard to reach. This sample of participants was purposively selected using a convenience sampling technique. A group of 20 participants was selected by drawing them from the same group of young women who participated in the trial between August 2019 and January 2022. The final group of women who participated in the trial would be booked to receive a monthly session either in person, telephonically, or through SMS or to have supplements delivered to them. We then first restricted this group to only young women whom we failed to make contact with, those who had a session delivered to them, and those who were booked for a session. Furthermore, participants who could not be reached after repeated call attempts were excluded, and we then further restricted the sample to those who only had 1 call attempt. This resulted in a group of those who were contactable and those who were hard to reach, and this group was included in the quantitative analysis. Thereafter, 20 young women who were included in the qualitative analysis were selected from the 363 young women who were included in the quantitative analysis. This was done by selecting the record IDs of young women extracted from REDCap (Research Electronic Data Capture; Vanderbilt University), a secure database that stores data for research studies [38]. Qualitative data were collected only for this group of young women given that the trial aimed to deliver an intervention that fosters behavior change. Thus, the lack of contactability or loss to follow-up of this group of participants poses a substantial threat to the effective delivery of the intervention and could potentially have adverse biases on the conclusiveness of the results of the trial, which could have significant effects on the credibility and reliability of the trial.

**Data Collection**

**Quantitative Data Collection**

Quantitative data collection was conducted, and the data were recorded and stored on REDCap [38]. The data included a set of interview-led administered questionnaires that collected baseline data on the demographic characteristics of the participants. The variables that were used in this study to show a descriptive profile of the sociodemographic characteristics of the participants who were contactable and those who were hard to reach included (1) age, (2) family size, (3) highest level of education, (4) vocational activity, (5) type of dwelling unit, (6) times in the past 12 months when family went hungry, (7) phone ownership, (8) contract type, and (9) type of cell phone.

In this component of the study, the first outcome of interest was the “contactability” of the participants. Two groups of young women were of interest in this phase of analysis. These were (1) young women who were contactable and (2) young women who were hard to reach at the first call attempt. The second outcome was the “mobile number changes of participants,” which were captured on REDCap. These number changes were tracked from randomization to the trial. The number changes were categorized as (1) no number change, (2) 1 number change, or (3) >2 number changes.

**Qualitative Data Collection**

Overall, 20 participants were interviewed individually using an in-depth interview guide by 2 female interviewers who were fluent in both English and other South African vernacular languages. The interview schedule was developed by the study team to capture the participants’ reasons for changing their mobile numbers and to discern why staying in contact with participants was challenging. Interview questions focused on young women’s demographic characteristics, questions around...
ownership of a mobile phone or mobile phones, mobile phone use behavior and patterns, and receipt of health information. The interviews were conducted face-to-face with the participants within the precinct of the Chris Hani Baragwanath Academic Hospital in February and March 2022. The interviews lasted between 30 and 40 minutes and were audio recorded. Interview notes were captured during each scheduled interview session to record the participants’ main accounts and nonverbal cues. Before analysis was conducted, the recordings were transcribed to their original form and translated into English, where necessary.

Data Analysis

Quantitative Data Analysis
To statistically analyze the differences between the 2 groups of participants (failed to make contact and contactable), the data were analyzed descriptively at univariate and bivariate levels. At the univariate level, to visually illustrate the differences between the contact status of participants by mobile number change, a graph was generated to compare the proportion or rate of mobile number change of each group in relation to another. Similarly, another graph was generated to identify the most cited and least cited outcomes of the attempted call for participants we failed to make contact with. At the bivariate level, a contingency table was generated to depict the differences in the results of the tabulation of observations at each level of a variable for both groups, that is, cross-tabulation of the 2 groups to show the relationship or differences in the proportions and frequencies of the sociodemographic characteristics of the 2 groups. This table included the Pearson chi-square test of association to statistically identify the independence or association between the 2 groups or categorical variables and accompanying sociodemographic covariates. All data were analyzed using STATA (version 17; StataCorp) [39].

Qualitative Data Analysis
A reflexive thematic analysis approach was used for analysis using MAXQDA software (version 20; VERBI GmbH) [36], which helped in the recording, coding, and interpretation of the transcripts. Reflexive thematic analysis is an interpretive method that enables researchers to establish the outcome of the work rather than following a specific theory [35]. Six steps were used in the analysis. In the first step, data familiarization was conducted by checking the quality of the transcripts against the recordings to understand the data thoroughly, which would make it possible to search for patterns and meanings. This involved reading and rereading transcripts and taking notes. In the second step, initial codes were generated by labeling and organizing participants’ narratives to form a complete meaning. In the third phase, initial themes were generated by sorting initial codes that had been generated into themes and identifying meanings and relationships between the initial codes. In the fourth phase, the themes were reviewed by identifying coherent patterns and ensuring that the generation of themes was supported by sufficient data. This also included collapsing overlapping themes and regenerating and improving the codes and themes. This was done as a collective effort among KM, LMS, and CED. In the fifth phase, themes were defined and named by linking each narrative to an appropriate theme. Finally, in the sixth phase, the narratives of the participants were presented under each generated theme in a concise manner.

Ethical Considerations
Ethics approval was granted by the Human Research Ethics Committee (Medical) located at the University of the Witwatersrand (M190449). All participants provided written informed consent to participate and consented to have the interviews audio recorded.

Although the information provided by the participants was captured on an audio recorder, the data were protected by securely storing them in a password-protected computer in a secure locked cabinet. The identities of the participants were protected through the deidentification of all their personal information and characteristics. The transcripts contained ID numbers that represented each participant’s response.

Results

Quantitative Results
The sociodemographic characteristics of the participants (N=363) are presented in Table 1. Of the 363 participants, 174 (47.9%) were hard to reach telephonically, whereas 189 (52.1%) were easy to reach telephonically. Most participants (133/243, 54.7%) who were contactable did not change their mobile number. The highest percentage of mobile number changes was observed among participants who were difficult to reach, with three-quarters of the participants (12/16, 75%) being reported to have changed their mobile number ≥2 times (Multimedia Appendix 1). Although 58% (101/174) of the participants could not be reached as the attempted call went to voicemail, 29.3% (51/174) of the participants were reported to have taken the call when the attempted call was placed, and only 2.2% (4/174) of the participants took the call but ended it (Multimedia Appendix 2).

Table 2 shows the mobile phone information of both hard-to-reach participants and contactable participants. There was a significant difference in mobile phone ownership among participants who were hard to reach and those who were contactable, as 96.8% (183/189; P=.03) of those who were contactable owned a personal cell phone compared with 91.4% (159/174) of those who were hard to reach. Most of the young women (both contactable and hard to reach) had a smartphone (297/342; ≥80% each; P=.02) and did not have a phone contract (324/342; >90% each). Results indicated no statistically significant differences in these variables among participants who were hard to reach and participants who were contactable.

**Qualitative Results**

**Overview**

Table 3 shows the sociodemographic profile of the interview participants. The mean age of the participants who were interviewed was 22 (SD 2.94) years. In addition, 50% (10/20) of the participants had a secondary school qualification, 40% (8/20) had not completed secondary education, and only 10% (2/20) had a tertiary qualification at the time of the assessment. Almost all the participants (19/20, 95%) lived with a parent or relative, whereas only 5% (1/20) of the participants lived with her partner and 65% (13/20) of the participants were not in a relationship at the time of assessment.

Textbox 1 presents an overview of the superordinate themes and subthemes generated from the qualitative analysis. As presented in Textbox 1, this section is sorted into the narrative findings, with illustrative quotations provided for each superordinate theme and subtheme.

Textbox 1. Themes focusing on young women’s reasons for being hard to reach.

Superordinate theme and subthemes
- Mobile phone technical issues
  - Coverage issues
    - Electrical unreliability
    - Network connectivity issues
  - Lack of ownership of personal cell phone
  - Unregistered number
- Use patterns
  - Cell phone theft in the community
  - Stalking behavior
- Inconsistent SIM use
- Availability of data and airtime
- Lack of interest in possessing a mobile phone

Mobile Phone Technical Issues
Technical barriers were reported by most participants as a major challenge that affected the efficiency, functioning, and usability of their mobile phones. Key challenges reported by the participants that resulted in inherent limitations in operating their mobile phones included poor battery life, faulty charging system, mobile phone and app crashes, and an inadequate touch screen response. Such challenges resulted in the participants not being easily contactable or contactable at all. Some participants resorted to changing their mobile phones or using alternative communication methods such as using the phones of individuals within their social networks:
I’ve experienced battery challenges and the charging system, ja that’s the only thing that’s been wrong with my phone. I had to charge my phone a certain way and I couldn’t even use it until I finished charging and the battery will finish fast sometimes when I’m trying to do something. [Participant 2, 25 years old, single]

The phone I was using, it lived on life support. I had to use it while it was in a charger at home. The charger also was faulty so sometimes I would think it’s on and it’s off. [Participant 9, 20 years old, single]

It sometimes jams. The battery finishes quickly while you are chatting. So those are the challenges that I face with my phone. [Participant 16, 20 years old, in a relationship]

My phone has problems. Like it just switches off, because it fell once, and now every time it hits hard or something, it just switches off, and it is going to take time for it to switch on, so I wait for it to switch on. [Participant 1, 25 years old, single]

The touch screen doesn’t work properly now because it fell sometime last year. I don’t know if it’s a space issue or just the phone itself because sometimes when I get incoming calls the phone rings but then I can’t touch it for me to be able to pick up the call because of the touch screen problems with the phone. [Participant 13, 20 years old, single]

It has a tendency to freeze if it fell, maybe if I’m receiving a call, I can’t answer it because the phone is frozen, you know. [Participant 15, 25 years old, single]

**Coverage Issues**

Coverage issues such as network and electricity made it difficult for some participants to be contactable. Participants indicated that they could not receive calls or messages or had to change their mobile SIMs because of challenges concerning the connectivity, reliability, and quality of the mobile network. This included signal weakness and network availability issues with some mobile service providers being cited as having general network unreliability or the network being offline in some instances. Participants reported experiencing unreliability of the electric supply owing to frequent power cuts. This greatly affected their ability to use their mobile phones, thus being unable to be in touch with people:

My network becomes very slow, sometimes I don’t even get calls I just get messages that I have a missed call but then it didn’t even ring if you don’t have electricity. It’s been hectic hey, we didn’t have electricity on Sunday. [Participant 2, 22 years old, single]

It has been a while since we have been without electricity but right now, we don’t have it because they said that the substation was on fire. [Participant 7, 21 years old, single]

I first bought the Telkom sim card but then I don’t know what happened with the coverage in Orlando, but it was giving me problems, so I couldn’t get network, so I used my MTN sim card. I think I got it like two years ago. I was not using it as frequently as the Telkom number, so I had to use the MTN number. [Participant 9, 20 years old, single]

Telkom network is problematic, sometimes you want to make a call, it will tell you that there is no service, things like that. Sometimes the sim card does not connect. I will find myself taking it out and putting it back on but still, so I decided to change MTN, then, MTN gave me a problem of taking my airtime every time when I recharged. [Participant 1, 25 years old, single]

**Lack of Ownership of Personal Cell Phone**

Some participants indicated that they were not easily contactable because they do not currently own their own personal cell phone or previously did not own one. The reasons attributed to the lack of ownership ranged from the phone being reported to be broken, stolen, lost, or not having one at all. Despite this, participants used alternative means of communication to try and be contactable. Participants reported using their social networks to try and solve the problem of not having a mobile phone by sharing a phone with their siblings, peers, or partners. However, sharing a phone limited their ability to stay connected with others and to be reachable because their time with the device was limited. In some cases, this was exacerbated by the participants not living close to the people they shared the phone with. In other instances, participants’ social networks would not relay the message back to them. These narratives are reflected in the following excerpts:

I didn’t have a phone for two months, so I spent quite a while without a phone. I used parents’ phones. It was for when people couldn’t get hold of me, they would call my parents for emergencies. [Participant 18, 22 years old, single]

I didn’t have a phone for four months. I was not reachable. I used my boyfriend’s phone. The first number that I applied with is my grandmothers, that was the first one. I did not have a phone at that time, and so I applied with her phone, and they tried to call her, but it did not get through to her. Because her phone, she is a person that does business, it would switch off and she would not find the charger, and then it would be charged after a while, and then I gave them the number of my partner, and then they said that they can’t get me with that one as well. [Participant 10, 24 years old, in a relationship]

I stayed for a long time without a phone. I think it had been two years without having a phone. I used to borrow my friend’s phone if for instance there is someone who had asked for my number, then I would give them my friend’s number, and my friend would tell me that so and so had phoned, they called me because you don’t have a phone. So, when people wanted my number, I would give them my friend’s number. It was not easy for them to get hold of me.
because sometimes I am at my home, and she is at her home. [Participant 1, 25 years old, single]

Other participants further highlighted that they were not contactable because their mobile phone was stolen or had gone missing:

I lost my phone and then I took time to do the sim swap and by the time I decided to do it, they had already given the number to someone else. [Participant 9, 20 years old, single]

I started by using said provider, yes I was using said provider first, and now I am on another provider because my phones got lost. [Participant 11, 22 years old, single]

I had a phone, it was last year, I had another phone and they mugged me in March. [Participant 20, 24 years old, in a relationship]

One participant lost her mobile phone due to theft, but her mobile SIM was still in her possession. As an alternative means of communication, she would insert her SIM card in other people’s phones and reach out to people given that she did not have the financial means to buy a new phone:

I was going to the mall and then I was mugged but then I have a sim card which I did a sim swap, yes so every time I need a phone, I can contact people I wasn’t able to contact. [Participant 12, 24 years old, in a relationship]

**Unregistered Number**

Another factor contributing to the difficulty in reaching participants is the unregistered status of their mobile numbers. Some participants reported that they had lost their phones with the mobile SIM card. Two participants reported that they bought new phones and SIM cards and went to a mobile phone store to get a SIM swap, but the mobile phone store could not perform the SIM swap. One reason for this was because their previous mobile numbers were no longer registered under the participants’ names and had been reassigned to new owners. Another reason was the inability to recall the last 5 numbers called on the SIM, which is a requirement for performing a SIM swap. Consequently, participants had to purchase new SIM cards with new mobile numbers, different from those recorded by the trial:

I had to go this year January to Telkom to do a sim swap because I had applied for jobs with that number. Then when I got to Telkom, they told me that that number was not registered under my name, you see these sim cards that you get on the streets. So, I had to start another sim and so I started afresh with that number. [Participant 17, 20 years old, single]

They took my number in January and then I got this one in February. [Participant 11, 22 years old, single]

I lost the phone and then when I went to do the sim swap, they told me I couldn’t do it because the numbers were wrong, and that I wanted the last five numbers that I last called, and so I was not able to continue with the sim swap. [Participant 7, 21 years old, single]

**Use Patterns**

Although many participants owned a personal cell phone, an inconsistent pattern of mobile phone use was observed in the narratives of the participants, which impacted the ability to contact them. Some participants reported that they did not carry their mobile phones outdoors and only used the device at home. However, the reasons for this behavior were not reported by the participants:

I don’t use it when I am on the road, even when I am going to town or to the mall, I usually leave it behind. [Participant 3, 21 years old, single]

When I go outside, I don’t take it with me, I leave it at home. I use it when I know that I am not going anywhere. [Participant 11, 22 years old, single]

Sometimes I’m at school, and sometimes I’m busy and I left it at home and went to the shops, ja I’m not on my phone every time, I just use my phone only when I do important things. ja. [Participant 14, 21 years old, in a relationship]

I couldn’t go out with it, like I had to use it at home. When I go out, I leave it at home so I had to tell the person that I am meeting that we are meeting at a specific time and place, and I just had to hope they will be there. [Participant 9, 20 years old, single]

Conversely, some participants reported that their communities were not safe and there was a high rate of mobile phone theft in their area. This prompted them to not use their mobile phones in public. This has contributed to participants not being easily contactable given that they use their mobile phones inconsistently:

I don’t carry my phone in the streets. It’s not safe because most of the time there’s people taking other people’s phones, most of the time, like maybe in a week we’ll hear about 2 people, 3, ja so it’s not safe. [Participant 2, 22 years old, single]

I use when I am at home alone, outside there are a lot of thieves, when you are outside and you are using your phone, they take it from you. [Participant 10, 24 years old, in a relationship]

Conversely, another participant indicated that she was no longer comfortable using her phone or taking calls as she had experienced continuous threatening harassment over the phone from an unknown individual. This thus resulted in other people finding it difficult to reach her:

There were people walking me, and I didn’t know where they were getting my number from. They would tell me where I was, meanwhile, I don’t know them and I didn’t see them, then I decided to change my number. [Participant 3, 21 years old, single]

**Inconsistent SIM Use**

For other participants, their inconsistent mobile phone behavior was largely because of the participants owning dual SIM cards.
Participants reported that they often used one mobile number more than the other, whereas another participant indicated that she had to change her SIM cards frequently given some technical issues she was experiencing with the card. Similarly, another participant reported changing her SIM cards frequently because she would lose 1 SIM because of repeatedly changing mobile devices and thereafter had to replace it with another SIM card. Another participant’s inconsistent use of her mobile phone was largely because of her younger sibling who did not own his own personal cell phone. Given this circumstance, she shared her phone with her younger sibling as he frequently took out the participant’s SIM card and put his own for a certain period. This greatly affected the participant’s ability to receive calls or messages, thus making her seemingly unreachable. Other participants indicated that the procedures for performing a SIM swap are often offline every time they went to do one. This has led to the participants’ losing interest in doing a SIM swap and has prompted them to change their mobile number. All these factors have thus contributed greatly to the participants being unreachable:

The sim card used to get lost because I kept changing the phones. I was using the other network’s * number. The 060. So now I am using another network. I don’t know the other network’s number, but this one. [Participant 10, 24 years old, in a relationship]

My younger brother likes using it a lot because he likes logging in on Facebook and chat with his friends and then bring it back. He takes out my starter pack and puts in his own. Maybe they call me, and it goes to voicemail, that is because my sim card is out. [Participant 1, 25 years old, single]

I have two numbers and there is one that I always use and the other one that I use sometimes, because I have two sim cards, and both are in the phone. So sometimes I give people the number that I don’t use every day. [Participant 16, 20 years old, in a relationship]

I used to use two starter packs because I wanted to use Telkom and MTN, and at the time I was using Cell C as well. I had a lot of starter packs, and I changed the numbers a lot. Telkom was giving me problems, and then MTN used to take airtime every time when I recharged. I didn’t know where my airtime was going every time when I recharged the number, so yeah, I used to change the number a lot. [Participant 1, 25 years old, in a relationship]

Because when I do a sim swap, they ask a lot of questions, so I sometimes find that it is better if I change the number. Yes because this time I had to do a sim swap, and they said I should go to Shoprite with my ID and my proof of address, when I got to Shoprite, they said that their machines were offline, and then that is where I gave up, and then I said it is better that I change my numbers, because the numbers of most of the people that I know, I have them, I have written them in my book. [Participant 11, 22 years old, single]

You know what, I was tired of changing number so I decided that you know what, let me stick to this number because a lot of people have this number, and they call me on it, when I give out my CVs, this is the number that I use, so I don’t take it out, this is the one that I am using. [Participant 17, 20 years old, single]

Interestingly, 1 contrary finding from 1 participant’s narrative showed that the participant had the same number for >10 years and decided not to change her number to ensure that she remained contactable:

I’ve had this number for more than 10 years I think, the reason why it was more it made sense to do a sim swap instead of changing numbers it was for convenience and with this phone number I had registered it on a lot of platforms, you know when you apply online when they ask you to leave your details you leave your number, so the first thing that came to mind is that for people to be able to get hold of me it’d better to have the same number and also because had lost contacts as well for me to get back my contacts I had to have the number I was using. [Participant 15, 25 years old, single]

Availability of Data and Airtime

Other participants reported that a major challenge that they face, which has resulted in them not being able to stay in contact with people or being difficult to reach, is that airtime and data costs are very steep, and they lack the financial ability to afford data and airtime and thus cannot purchase it regularly. As a result, there are times when they do not have any airtime or data on their phone and thus cannot make or return any calls or messages received:

When I don’t have money where I am, or I don’t have money at that time. It depends on whether I have data at the time. If in a week my data finishes on Wednesday, then I will buy it on Sunday. There are days when I don’t have data. Maybe for a short while, for maybe two or one week. [Participant 16, 20 years old, in a relationship]

I was supposed to attend the interview today and I was unable to go, because I did not have data and I saw the message on a Friday. [Participant 3, 21 years old, single]

Before I bought a new phone, I used Vodacom, but I just didn’t like it because their data and airtime are expensive. So, the other phone came with an MTN sim, and I carried on with that one. [Participant 18, 22 years old, single]

Lack of Interest in Possessing a Mobile Phone

Some participants reported no interest in possessing a mobile device to stay in contact with their social networks or being contactable on the phone. One of the common reasons for this was that the participants were often in the vicinity of their social networks and could communicate in person as opposed to communicating via mobile phone. Others mentioned that they do not have friends with whom to communicate, whereas others
hardly used their phones and often misplaced it given the lack of importance they give to owning a phone:

Not that important, it’s not that important in fact. Because I don’t spend a lot of time on the phone, so I wouldn’t say that it is important. Eh, they can contact me during the day but sometimes I don’t answer the phone. I think I don’t like it that much to have it all the time, I feel like I can stay without a phone. [Participant 16, 20 years old, in a relationship]

It’s not that important. It’s just to keep boredom off. I don’t care much about the phone. [Participant 10, 24 years old, in a relationship]

I don’t spend a lot of time on the phone, so I wouldn’t say that it is important. I think I don’t like it that much to have it all the time, I feel like I can stay without a phone. [Participant 16, 20 years old, in a relationship]

I am very reckless with my phone. I don’t use my phone often so I just leave it on the table or the cupboard or wherever and then I leave the house and people will call me and not reach me until I started to realise that okay, I need to send my CV somewhere and a phone is necessary to have on you. [Participant 5, 28 years old, single]

One participant indicated that she had previously lost her phone before purchasing a new one months later. The amount of time she spent without a phone resulted in her losing interest in possessing a phone as she had grown accustomed to being a nonmobile user:

I didn’t see the importance of having a phone. I stayed a long time, like I didn’t care about the phone. I stayed for a long time without it, and I didn’t feel like I didn’t have a phone. So, I didn’t see the importance of having a phone, even though I saw other people with phones, but for me, I never had that feeling of not having a phone. I had already gotten used to not having a phone. [Participant 12, 24 years old, in a relationship]

In contrast to these findings, other participants indicated that possessing a mobile phone was important to them and helped them to stay in touch with their social networks, to keep abreast of any job opportunities that may arise, to apply to university or college, and to access emails and the internet. These findings are reflected in the following excerpts:

It’s very important because they need to find me every time I’m needed and most things I do on the phone, so I view it most times. I use my cell phone a lot, like every day. [Participant 2, 22 years old, single]

I use my phone all the time like 10 hours. When I wake up, before I go to bed, and I always provide the alternative number in case my phone is maybe low, or I have lost it. I always put in an alternative number. [Participant 9, 20 years old, single]

It’s important because even the study get hold of me on that phone. When people are looking for me, they get hold of me on that phone. Even now the study helped me because if I didn’t have a phone, I would not be reachable because it has been a while since I have been here. [Participant 19, 22 years old, single]

Discussion

Principal Findings

This study aimed to explore the challenges that participants experience in terms of being contactable through mobile phones in a trial conducted in Soweto, South Africa. This study highlighted that although most participants who are difficult to contact do own a personal cell phone, which is a smartphone, most of them face a myriad of interrelated mobile phone challenges, particularly technical and coverage issues, mobile theft in their communities, and high costs of data and airtime. Consequently, these challenges contribute to participants’ need to change their mobile numbers, which subsequently has the potential to affect their reachability. The novelty of this study was the use of a mixed methods research design. It was important to conduct a study of this nature within the context of Soweto, a resource-constrained setting, which is characterized by a short supply of free public Wi-Fi, unequal mobile coverage, and comparably high data costs [40], among other factors.

This study was descriptive in nature. Therefore, caution should be exercised when interpreting the results of this study as no significant associations were found in the quantitative analysis. The quantitative results of this study showed that a large proportion of individuals owned a mobile phone. This result is in line with previous literature, which has shown that mobile connectivity in South Africa has grown rapidly with a mobile penetration rate of >95%, with 91% of all phones being smartphones [1,17,24]. Although this was also corroborated by the qualitative findings, a key finding was that some participants were mobile phone sharers, whereas others had no phones at all and thus relied on their social networks who had phones and often depended on using these phones for a short while to be in touch with other individuals. Previous literature has shown that the use of mobile phones is an inherent part of people’s lives, which exists in socioeconomic practices and realities [15]. Although South Africa has seen an exponential increase in mobile phone ownership and access, the high cost of mobile phones still represents a formidable barrier that limits mobile phone use [40]. In fact, the lack of income has been reported as the primary factor in the lack of phone ownership in many LMICs [41,42]. This largely surpasses other probable barriers such as the perceived importance of using a mobile phone and technical literacy [41,42].

Given that this study aimed to explore the challenges that participants experience in terms of being contactable through mobile phones, overall, the quantitative and qualitative findings in this study suggest that the socioeconomic context of the participants is a major factor that has contributed to their mobile use behavior and difficulty in reaching them. Thus, the findings of this study uniquely contribute to the existing body of knowledge in various ways. First, although phone ownership has increased rapidly in South Africa, there are some important use gaps that remain pronounced, and these are evident in an
LMIC such as Soweto. To illustrate this, although phone ownership may be predominantly high among both groups included in this study, their socioeconomic backgrounds are complex and create different realities, which subsequently leads to variability in mobile phone use and usability. Thus, daily realities such as unemployment, poverty, and infrastructural barriers have the potential to prevent them from fully using their devices in a sustainable manner. In addition, the challenges that were explored in this study in terms of participants being contactable through the mobile phone show that the experiences of youth are vastly different, and complexities around socioeconomic backgrounds and environmental settings create different realities pertaining to phone possession and use. Although the participants may reside in one central area, the circumstances of young people (phone sharers, phone owners, and non–phone owners) differ quite substantially, not only depending on their age, level of education, or vocational activity but also on factors such as socioeconomic circumstances, family structure, household resources, and livelihood patterns. This aligns with the evidence from the World Bank, which has shown that 50% of South African inhabitants who reside in urban settings live in low-income settings, accounting for approximately 40% of the individuals who constitute the working population and catering to approximately 60% of nonworking citizens who live in cramped family settings [29].

These previous findings align with the qualitative results of this study, which demonstrated that most participants were individuals who were still in early young adulthood (18-25 years), with >90% of them Not in Education, Employment, or Training and only 5% had a mobile phone contract. Previous studies have also indicated a digital divide along gender lines [43]. The study indicated that women are more at risk of poor mobile phone use compared with men and attributed it to economic inequality, namely, women’s lower educational attainment and poor income levels [43]. These findings illuminate the way mobile phone use is interwoven with the daily realities and experiences of the participants, which has the potential to prevent the participants from fully using their devices in a sustainable manner.

Existing research has further shown that individuals who earn a low income have limited connectivity, which is inhibited by disparities in wealth, resources, and other opportunities, presenting a challenge in terms of using mobile technologies [44]. This finding is strongly congruent with the qualitative findings, which revealed that participants faced a myriad of mobile phone challenges, leading to them being hard to reach, which is in line with what the study aimed to explore (challenges experienced in terms of being contactable over the mobile phone). Such structural inequalities that make it hard for participants to be easy to reach include coverage issues, high costs of data, and airtime and safety in their communities. Furthermore, the quantitative results of this study showed that in addition to the fact that most participants only have a secondary school qualification and are Not in Education, Employment, or Training, approximately one-third of these participants have been reported to live in households that are food insecure. Household constraints serve as important factors for people’s access to mobile technology [45]. Another study showed that ownership of a mobile phone necessitates the need to have a phone that is in good working condition (available data and airtime, functional battery, and network signal) and the financial freedom to sustain this without giving up other necessities [46]. All these factors are unevenly distributed, with those living in resource-constrained settings being the most disadvantaged [46]. These findings thus suggest that the mobile phone challenges experienced by the participants are interwoven with their socioeconomic backgrounds, thus making it difficult to maintain mobile technology use.

This study further found that the proportion of those who own phones decreased with each successive age category for both participants who were hard to reach and those who were contactable. These findings are supported by the previous literature, which showed that age is a social determinant of digital inequality [22]. A curvilinear relationship was found between age and digital use in LMICs [22]. For instance, 1 study conducted in India showed that phone ownership was >66% for participants aged 15 to 24 years but only 55% for those aged 25 to 44 years [41]. In addition, a study conducted in Tanzania found that women aged ≤30 years were 17% less likely to remain phone owners (Roessler, P, unpublished data, December 2018).

Mobile technologies have the potential to improve health behaviors among individuals participating in clinical research [38]. For instance, the COVID-19 pandemic has led to an increased need to use mobile technologies for health promotion because of social distancing and nationwide lockdowns [47]. This reliance on mobile technologies means that challenges in reaching these participants could disrupt the continuity of health promotion for both research and clinical practice. Participants could, for example, seek health advice outside of their health care system or not attend their regular health sessions [39] owing to unresolved concerns via telephone. This may thus lead to clinical interventions being highly inefficient. Thus, using mobile phones in any clinical study can inform how these devices could be used in future interventional research. Although this study found that the mobile challenges that participants face are mostly influenced by structural inequalities, it is pivotal to note that addressing and alleviating these structural inequalities is beyond the scope of this study.

However, several feasible solutions exist for the problems encountered in this study. To maximize engagement in mobile health studies, health promotion initiatives can be delivered via in-person consultations or sessions with the participants. These in-person consultations would afford participants the opportunity to have increased personal contact with the study team and to obtain study support and personalized study feedback. This strategy has proved to be successful in a previous clinical trial where personalized care, including allowing participants to share their personal problems and enabling participants to increase contact with the study team or investigators, helped in maximizing engagement [48]. This could include fieldwork to complement the use of mobile technologies and thus ensure participant retention. Furthermore, advisory groups could be created by bringing together the participants and giving them an opportunity to engage in discussions around crafting possible solutions to the mobile technology barriers that were identified.
in this study. In addition, automated health promotion messages could be relayed to the participants’ phones, particularly in instances where calls do go through but are not answered by participants.

**Strengths and Limitations**

The strength of this study was the use of a convergent parallel mixed methods approach, which assisted in exploring the quantitative findings by relating the findings obtained from the qualitative and quantitative analyses. The use of this method thus helped in providing comprehensive insight into the mobile phone behaviors of young women and the factors that contributed to this behavior. A limitation of this study was that the quantitative analysis was only restricted to the first instance (ie, the first call attempt in which some young women were hard to reach and some were easily contactable). Therefore, repeat instances or call attempts for subsequent monthly sessions were excluded. This could have provided a broader longitudinal picture of the time from randomization to infancy of all call attempts and whether any demographic characteristics were associated with these changes. However, this was beyond the scope of this study as the focus was only on providing a descriptive profile of women who were hard to reach while comparing their demographic profile with those who were easily contactable.

**Conclusions**

Despite the availability of mobile technology and network accessibility, there are substantial economic barriers that prevent young adults from fully benefitting from technology. These barriers consequently affect health promotion and behavioral changes. For individuals to remain digitally connected, multiple strategies should be used. For research, remote data collection remains an important tool in public health research and could thus serve as a hugely beneficial mechanism in connecting with participants while actively using established relationships with participants or community-based organizations to deliver health promotion and practice. With increasing phone ownership in LMICs including South Africa, greater accessibility to less expensive or free data networks or digital platforms is needed universally across South Africa to ensure more equitable access to such technologies.

LMIC: low- and middle-income country
Abstract

Background: In oncohematology, both the development of the disease and the side effects of antineoplastic treatment often take a toll on patients’ physical and nutritional well-being. In this era of digital transformation, we launched a pioneering project for oncohematologic patients to promote adherence to a healthy lifestyle and improve their physical and nutritional well-being. We aim to achieve this goal by involving doctors and nutritionists through the Nootric app.

Objective: This study aims to assess the impact of the use of eHealth tools to facilitate nutrition and well-being in oncohematologic patients. We also aim to determine the usefulness of physical-nutritional management in improving tolerance to chemotherapy treatments within routine clinical practice.

Methods: We designed a descriptive, observational, longitudinal, prospective cohort pilot study that included a total of 22 patients from March to May 2022 in the Vinalopó University Hospital. The inclusion criteria were adults over 18 years of age diagnosed with oncohematological pathology in active chemotherapy treatment. An action plan was created to generate alerts between the doctor and the nutritionist. In the beginning, the patients were trained to use the app and received education highlighting the importance of nutrition and physical exercise. Sociodemographic, clinical-biological-analytical (e.g., malnutrition index), health care impact, usability, and patient adherence data were collected. Tolerance to chemotherapy treatment and its health care impact were evaluated.

Results: We included 22 patients, 11 (50%) female and 11 (50%) male, ranging between 42 and 84 years of age. Among them, 13 (59%) were adherents to the program. The most frequent diseases were lymphoproliferative syndromes (13/22, 59%) and multiple myeloma (4/22, 18%). Moreover, 15 (68%) out of 22 patients received immunochemotherapy, while 7 (32%) out of 22 patients received biological treatment. No worsening of clinical-biological parameters was observed. Excluding dropouts and abandonments (n=9/22, 41%), the adherence rate was 81%, established by calculating the arithmetic mean of the adherence rates of 13 patients. No admission was observed due to gastrointestinal toxicity or discontinuation of treatment related to alterations in physical and nutritional well-being. In addition, only 5.5% of unscheduled consultations were increased due to incidents in well-being, mostly telematic (n=6/103 consultation are unscheduled). Additionally, 92% of patients reported an improvement in their nutritional habits (n=12/13), and up to 45% required adjustment of medical supportive treatment (n=5/11). There were no cases of grade 3 or greater gastrointestinal toxicity. All of this reflects improved tolerance to treatments. Patients reported a satisfaction score of 4.3 out of 5, while professionals rated their satisfaction at 4.8 out of 5.
Conclusions: We demonstrated the usefulness of integrating new technologies through a multidisciplinary approach. The Nootric app facilitated collaboration among the medical team, nutritionists, and patients. It enabled us to detect health issues related to physical-nutritional well-being, anticipate major complications, and mitigate potentially avoidable risks. Consequently, there was a decrease in unscheduled visits and admissions related to this condition.

Introduction

Background

Hematological malignancies encompass a heterogeneous group of diseases that have different behaviors, evolution, treatments, and prognoses. However, all of them similarly compromise the patient’s nutritional and physical status. This is because both the development of the disease and antineoplastic treatment can lead to caloric-protein malnutrition, leading to a high prevalence of adverse effects in daily clinical practice [1]. New treatments and conventional chemotherapy lead to toxicity in the gastrointestinal tract, which has a direct impact on the patient’s well-being and survival [2-9]. Medical management is often insufficient to carry out a comprehensive assessment of the patient’s physical and nutritional well-being. Therefore, professional support in this aspect through the application of information and communication technologies (ICTs) in patients’ everyday environment outside the hospital is a useful tool to improve well-being and reduce health care costs [6,10-12]. There is increasing evidence showing that lifestyle interventions can improve symptoms, quality of life, and even overall survival rates for patients with cancer. Digital interventions can help implement physical-nutritional behavior modifications and empower patients through healthy lifestyle education and support [13].

An effective system for patient physical-nutritional monitoring and treatment after nutritional risk assessment appears to be lacking. We identified the need for a standardized system to prevent and treat malnutrition related to these diseases. Currently, there are studies involving mobile apps for nutritional control and support to monitor dietary intake among patients who are hospitalized and face nutritional risks. These apps have demonstrated good acceptance among patients and have the potential to be useful dietary evaluation tools for use in clinical practice. These results suggest that such tools could be extrapolated to the field of oncohematology consultations [14].

The studies available so far confirm that the application of mobile apps, among other appropriately designed digital interventions, can be effective tools in nutritional interventions [2,3,15]. It is estimated that 59% or more of the currently available apps are health-related [2]. Some studies show that mobile app interventions can improve the quality of life of patients with malignant hemopathies by reducing symptoms [16].

However, many of these apps are not developed by nutrition experts, validated by official agencies, or part of routine use in the hospital setting. The use of mobile apps for nutritional interventions to improve dietary patterns, avoid or reduce side effects, and improve patient physical and nutritional well-being is a new challenge currently facing health care.

Therefore, we have launched a pioneering project with the aim of improving and mitigating malnutrition and side effects through proper nutritional and physical well-being monitoring. We aim to deliver this digital nutrition service via the Nootric app, thereby promoting patients’ adherence to a healthy lifestyle.

In this study, we included under the term “oncohematological patient” those who met the inclusion criteria: adults over 18 years of age with a diagnosis of oncohematologic pathology undergoing active treatment. The hematologic malignancies included were mostly lymphoproliferative syndromes and multiple myeloma. We analyzed only nutritional and physical parameters within this group.

Objectives

We evaluated an intervention designed to support oncohematological patients in active treatment. The primary goal was to assess how eHealth tools in nutrition and well-being management impact patients in oncohematology. Additionally, we aimed to determine the usefulness of physical-nutritional management in improving tolerance to chemotherapy treatments within routine clinical practice.

As secondary objectives, on the one hand, we aimed to evaluate the usefulness of the application of a physical-nutritional intervention among oncohematological patients by observing serial cases. On the other hand, we wanted to evaluate the adequacy and acceptability of this app in this group of patients. We aimed to qualitatively evaluate how knowledge guides the reorientation of intervention strategies regarding physical-nutritional well-being in these patients. Finally, we aimed to understand the nutritional and physical requirements throughout each phase of these patients’ treatment, considering the potential implications for their well-being. Measures of engagement with the intervention and semistructured interviews with intervention participants were used to evaluate the feasibility of the intervention.

Methods

Study Design

A descriptive, observational, prospective, longitudinal cohort pilot study was conducted among oncohematological patients in our hospital center (Figure 1).

Recruitment took place between April and May 22. The exposure, follow-up, and data collection period lasted 3 months.
(from May 22 to August 22). The sample consisted of 22 patients and was not divided under any concept at the beginning of the study. During study development, patients who had good adherence were included in the exposed cohort. However, those who dropped out of the study and had a low adherence rate were included in the unexposed cohort. They were not taken into account in the analysis of the results, and no comparative study was performed. To ensure that older adults were not excluded due to the digital gap, we included patients aged above 80 years old, and during the first visit, we encouraged them to continue using the Nootric app.

**Figure 1.** Study flow diagram.

---

**Study Setting**

This study was conducted in the province of Alicante, Spain, at Vialopó University Hospital, which tends to a culturally, linguistically, and socioeconomically diverse population. The participants were recruited from the hospital’s hematology department.

**Participants**

Patients were eligible to participate if they (1) were aged ≥ 18 years, (2) had a documented diagnosis of oncohematological pathology, and (3) were receiving medical treatment for cancer at the time of study initiation. Patients were excluded from the study if they (1) were children, adolescents, or pregnant women; (2) were due for surgery with hospital nutritional treatment; (3) were following nutritional care or hospital treatment; (4) had any acute or chronic condition that the practitioner believed limited their ability to participate in the study; (5) were unable to provide written consent; (6) were not literate; and (7) did not have a smartphone.

**Intervention: OncohematoNootric Program**

**Overview**

In recent years, there has been a growing use of eHealth tools, such as mobile apps, in nutritional interventions with good acceptance and results [2,3]. These technologies have been applied in different health care settings, such as mental health support and chronic disease management, to enable interaction with patients and promote engagement with health care interventions. Ultimately, they aim to increase the acceptability, use, and effectiveness of interventions [17,18]. However, to date, few studies have evaluated the effectiveness of these apps in routine clinical practice within the health care environment. There have been no studies in patients with hematological malignancies undergoing treatment [4].

The OncohematoNootric program involves a continuous approach and follow-up of patients by their physician and nutritionist through the Nootric app over 3 months via face-to-face/telematic consultations, voice calls, and direct chat through the app.
The intervention aims to provide nutritional-physical support tools to oncohematology patients receiving treatment who may develop adverse effects that put their physical and nutritional well-being at risk. The program provides training and information. It also facilitates risk assessment and clinical support, as needed, with the help of a physician-nutritionist alarm system.

**Education Website**

Nootric is a digital nutrition service that creates personalized nutrition plans tailored to the oncohematological patient, featuring recipes compatible with the potential side effects of treatment. It augments cognitive-behavioral therapy and provides guides and challenges that address aspects related to nutrition and its application in daily life. Physicians can monitor patients through the app using a dynamic panel that displays real-time actions. It also includes a chat feature to communicate with a dietitian-nutritionist.

In this study, all patients received dietary and exercise recommendations from professionals. The Nootric app aimed to help patients improve their health and well-being by facilitating behavioral changes.

**Intervention Development and Patient Involvement**

The intervention was designed in conjunction with patients, medical and nutritional health professionals, and professionals with expertise in eHealth and wellness management programs and technologists. No generative artificial intelligence (AI) was used in this study.

For program implementation, a training session on the use of the Nootric app was held with different medical teams. When the candidate patient was selected by the center, the team gave them a patient information sheet, an informed consent form, and an information leaflet. Once the patient agreed to participate in the pilot, they handed over the signed consent form and began to participate. The center registered the patient on the Nootric website by entering a code assigned to the patient. Once this registration was completed, the patient downloaded the app and logged in. Next, the patient completed a series of forms that served as a basis for the dietitian-nutritionist to establish their personalized plan. In addition, a clinical-biological test was performed via a blood test requested by the medical team and carried out at the hospital, after which the results were recorded, and the nutritional counseling intervention was initiated. At the beginning of the intervention, the health care professionals oriented the patient on the use of the Nootric application and emphasized the importance of good nutrition and physical exercise. Each patient received a weekly menu and shopping list, was able to upload photos of their meals during follow-up, and had direct access to an app-based chat with a nutritionist. During the study, the patient was able to contact their dietitian-nutritionist through the app’s chat function to solve nutritional doubts and receive motivational support to increase physical activities and food recording.

During the project, improvements were made to the app to provide better patient care, including adapting 70 menu prescriptions to be compatible with the potential side effects of the treatment, configuring menu items to ensure suitability for the most common side effects, and preparing and adapting informative guides and challenges. Other improvements included sending activity and hydration reminders, optimizing the internal messaging system for medical professionals to exchange information with nutritionists, and making functional changes to facilitate uploading files for medical professionals.

An action plan was created to generate alerts between the physician and nutritionist with all the possible adverse events that patients could present (e.g., hyporexia, weight loss, skin and nail changes, diarrhea, dyspepsia, pain according to a visual analog scale, edema, fatigue, constipation, dysphagia, odynophagia, mucositis, canker sores, nausea, vomiting, diarrhea, insomnia, urinary and bladder problems, anuria, bleeding, flu-like symptoms, fever, xerostomia, rash, and pruritus), along with their severity criteria and the action plan to be followed by the doctor and nutritionist.

When any of these issues were detected, the nutritionist informed the doctor, who carried out an unscheduled telematic/presential consultation with the patient to resolve the issue with the nutritionist’s support. On the other hand, if the issue was detected by the doctor, the latter informed the nutritionist so that the patient could receive support from both. In this way, both professionals were always kept up to date on incidents and procedures. The communication channel between professionals was the Nootric web platform.

For patients who were observed to have low adherence to the program during the pilot, the professionals studied the potential causes and intensified their actions to avoid dropout.

During the follow-up period, a weekly evaluation of the variables under study was carried out by the professionals. Biweekly follow-up meetings were held with the team to track the program and make possible improvements. Patients completed weekly program evaluation forms. After the follow-up study, a satisfaction survey was conducted to qualitatively evaluate patient satisfaction and program usefulness.

A new clinical-biological test was performed to comparatively analyze the results obtained before and after the intervention (Figure 2).
Study Outcomes
The primary outcome of the study was the health impact of the use of an eHealth tool related to nutrition and physical well-being on the oncohematological patient. This was measured by determining the following variables: nº alerts resolved, nº emergency visits, nº unscheduled consultations, nº treatments suspended, nº hospital admissions and improvement in nutritional habits according to the patient's perception. nº patients referred to the hospital’s Nutrition Unit, nº patients requiring adjustment of support treatment, and nº patients with gastrointestinal toxicity (which determines the impact on improving tolerance to treatments). The secondary outcomes included assessing the perceived improvement in the patients’ physical and nutritional well-being, determined through satisfaction and usefulness questionnaires at the end of the intervention. We also sought to assess the feasibility of the intervention, focusing on usability, acceptability, and adherence regarding different intervention components.

Data Collection and Study Procedures
The variables were collected on a form based on Microsoft Office Excel 2021 (Microsoft Corp), with each coded and subsequently exported to the SPSS statistical software (version 28.0; IBM Corp). To describe continuous variables with normal distribution, measures of central tendency were used, such as arithmetic mean. The qualitative variables were presented as frequency and proportion.

The variables collected at the beginning of the pilot study, during follow-up, and at the end were: (1) sociodemographic, including sex, age, level of education, main disease, comorbidities, and medication; (2) clinical-biological-analytical, with the following parameters included in the blood analysis to assess nutritional status and treatment toxicity and direct the professionals’ action plan: hemoglobin, creatinine clearance, calcium, total protein, albumin, vitamin B12, folic acid, ferritin, malnutrition index, total cholesterol, liver enzymes aspartate aminotransferase, alanine aminotransferase, alkaline phosphatase, and gamma-glutamyl transferase, cancer medical treatment scheme, food consumption patterns measured through the form provided by Nootric through the app, and BMI; (3) health care impact; (4) usability; and (5) adherence.

To weight the usability of the application, the following user interaction variables were considered: viewing, rating, comments on recipes, uploaded photos, access to the chat, review of a guide or completion of a challenge (framed in cognitive-behavioral training), points achieved (result of the gamification provided by Nootric), and exercises displayed. Adherence was determined by analyzing each patient’s use of the Nootric app during the program application period. For adherence, the percentage of access to the Nootric application was calculated, considering the 120-day access as 100% adherence.

The evaluations performed can be viewed in more detail in Tables 1 and 2 and Figures 3-5. The data extracted from the patients’ medical records included results of the blood analysis, main disease, comorbidities and their medication, cancer medical treatment scheme, and health care impact variables.
Table 1. Variables related to patients’ sociodemographic characteristics, oncohematological diseases, cancer medical treatment received during the study, and adherence to the program during 12 weeks of intervention (N=22).

*a*Patients received medical treatment, physical-nutritional recommendations, and close monitoring by their multidisciplinary assistance program. Most of the study population consisted of patients without severe comorbidities (18/22, 80%).

*b*These include rituximab, cyclophosphamide, doxorubicin, vincristine, and prednisone, (R-CHOP); adriamycin, bleomycin, vinblastine, and dacarbazine (ABVD); rituximab, bortezomib, cyclophosphamide, adriamycin, and prednisone (VR-CAP); and methotrexate, regimens with melphalan, and 5-azacitidine.

*c*Therapeutic regimens included daratumumab, bortezomib, venetoclax, obinutuzumab, ibrutinib, imatinib, and nilotinib.

*d*These included 3 women and 3 men. Dropouts were considered as users with adherence rates below 7%, and they were not accounted for in the analytical results, body variables, and interactions with the app.

Ethical Considerations
This study was approved by the Ethics Committee of Vinalopo´ University Hospital on March 30, 2022. All research activities involving human patients in this study have been treated in accordance with the ethical guidelines established by The Organic Law on Data Protection. All necessary approvals were obtained, including for the analysis of the research data.

This study complies with the ethical provisions outlined in the informed consent, and any additional analysis has been conducted in accordance with the existing ethical approvals. Informed consent was obtained from all patients for the conduct of this study and publication of this article, and no compensation was provided. Patients were informed that the doctor would receive information about their progress.

To protect the privacy and confidentiality of the participants, all data collected in this study were anonymized before the analysis. Measures were taken to ensure that the participants’ identifiable details were not disclosed. We used an anonymous identification system that consisted of assigning an alphanumeric code to each patient registered on the Nootric web platform and in the Nootric app. No one else, apart from Ribera’s medical team and Nootric’s team of nutritionists, had access to the data in the Nootric app and website, which are confidential and encrypted.

The original informed consent allows for secondary analysis without additional consent; this includes data collected from the participants’ medical history.

Sociodemographic Variables
Of the 22 included patients, 11 (50%) were female and 11 (50%) were male, with an average age of 70 (range 42-84) years. Among them, 13 (60%) patients were under 65 years and 9 (40%) were over 65 years. The variables regarding...
sociodemographic characteristics, treatment received during the study, and program adherence are described in Table 1.

**Clinical-Biological-Analytical Variables**

A clinical-biological test was conducted for all patients at the beginning of the study, but only 13 (59%) out of 22 patients completed it. On this population, we performed the analysis of the results. Table 2 presents all the analyzed laboratory parameters and the results at the beginning and end of the intervention. Some of the relevant data are shown in Figure 3. Some patients received corticosteroid therapy, which increases the risk of developing steroidal hyperglycemia. These patients benefited from an adapted physical-nutritional plan. There were no patients in the study who presented with alterations in blood glucose levels. Of the 2 (15%) patients who had dyslipidemia at baseline, 1 (8%) patient did not maintain dyslipidemia at the end of the study. Furthermore, 1 (8%) patient presented with iron overload secondary to a high transfusion requirement. Iron chelation therapy was initiated, which triggered a grade 3 hepatotoxicity. After discontinuing it, it improved clinically and analytically to grade 1. Of 6 (46%) patients with malnutrition at baseline, only 1 (8%) patient still had malnutrition at the end of the study. Of the 4 (30%) patients who presented with hypoproteinemia at baseline, 1 (23%) did not have it at the end. Moreover, 1 patient (8%) presented with a folic deficit at baseline and maintained it at baseline despite having received supportive treatment and dietary recommendations.

The clinical interview confirmed that treatment compliance was inadequate. Among 13 patients who had anemia at the beginning of the study, 3 (23%) did not maintain it at the end of the study. Conversely, 3 (23%) of the 13 patients who had anemia at the end of the study did not have it at baseline. None of the causes were caused by vitamin B12, folic acid, or iron deficiency but by myelotoxicity due to targeted cancer therapy.

**Program Adherence and Usability**

A total of 6 (27%) out of 22 patients abandoned the study due to a lack of adherence to the program, attributed to advanced age, insufficient socioeconomic level to ensure proper use of the app, lack of family support for improving adherence, and lack of initiative to establish a change in the physical-nutritional routine. They were not taken into account in the analysis of the results. In addition, users with less than 7% adherence were considered dropouts (3/22, 14%), and they were not taken into account in the analysis of the results. None of these patients were older adults or dropped out due to the digital gap.

Excluding dropouts and abandonments (n=9, 30%), the adherence rate was 81%, established by calculating the arithmetic mean of the adherence rates of 13 patients, much higher than the average rate in well-being. Of the 22 patients, between 7 and 11 (30%-50%) perceived an improvement in well-being, determined by the satisfaction survey conducted at the end of the study. To determine the adherence rate of each patient, the use of the app by the patients was evaluated and the parameters were n° interactions with the app, use of the chat with the nutritionist, n° interactions with the recipes, n° photos of recipes uploaded by the patients, and gamification points earned (Figure 4). Regarding the impact of usability, we obtained an average of 655 impacts per app user (Figure 4).

**Impact on Health Care**

Regarding the impact on health care quality, Table 2 and Figure 5 show data that demonstrates highly satisfactory results. None of the total emergency visits were related to physical and nutritional well-being. No hospitalizations occurred during the study for any cause, including those related to physical and nutritional well-being. No patient had to be referred to the hospital’s Nutrition Unit. Of the total number of medical consultations carried out, only 5.5% (6/103) were unscheduled and none of them were carried out for physical or nutritional issues. A total of 7 patients presented toxicity, among which 5 (71%) were cases of digestive toxicity. Of the 11 patients who required adjustment of supportive or symptomatic treatment due to toxicity, 5 (45%) had digestive toxicity. No treatment was suspended due to physical or nutritional conditions.

The patients showed an improvement in tolerance to chemotherapy treatments since there were no cases of grade 3 or higher gastrointestinal toxicity, defined as complications requiring intravenous support treatment. There were also no hospitalizations, emergency visits, or chemotherapy treatment discontinuations for this reason. A high percentage of patients (12/13, 92%) perceived an improvement in their nutritional habits.

**Impact on Patients’ Perceived Improvements in Physical and Nutritional Well-Being**

At the end of the study, the Nootric team disseminated an anonymous survey to measure satisfaction and usefulness for the patients and medical professionals involved. This enabled us to evaluate the impact on the perceived improvement in the patients’ physical and nutritional well-being. We observed that the users who adhered adequately to the program showed an improvement in this aspect. A total of 12 questionnaires were filled out by patients.

The average satisfaction rating among professionals was 4.8 out of 5, while patients rated their satisfaction at 4.3 out of 5. Table 3 highlights these results.
Table 3. Results of the impact on the perceived improvement in patients’ physical and nutritional well-being. A satisfaction and usefulness questionnaire was carried out for the patients involved at the end of the study (n=13).

Discussion

Context

Our study is based on a multidisciplinary nutritional and exercise support program for oncohematological patients undergoing active treatment using new technologies. This study provides initial data on the effectiveness of a novel physical and nutritional support program aimed at patients with malignant hematologies (largely represented in our study as lymphoproliferative syndromes and multiple myeloma) receiving targeted cancer treatment. It also provides a detailed evaluation of the implementation, adoption, and overall acceptability of this digital care intervention through a mobile app. The evaluation design has been adapted to the study objectives to provide new data to enable a better estimation of such an intervention’s impact and inform further development of digital care interventions for malignant blood diseases under active treatment.

Principal Findings

We did not observe any hospital admissions or discontinuation of chemotherapy treatment related to the patients’ physical-nutritional well-being, supporting the benefit of the program. Adequate nutritional support was provided to ensure patients’ well-being and mitigate the need for referral to the hospital’s Nutrition Unit. Regarding the impact on physical and nutritional well-being, we observed that users who adhered adequately to the program improved in this aspect.

We observed a reduction in the number of unplanned consultations related to physical and nutritional well-being. In terms of impact on health care quality, the results demonstrated highly satisfactory results. None of the total emergency visits were related to physical and nutritional well-being. Moreover, the intervention received a high satisfaction rating from both professionals and patients.

Regarding other works in the field, there is little information about the best nutritional support for patients with cancer [9,19,20]. Antineoplastic agents are known to be associated with gastrointestinal complications that lead to physical and nutritional repercussions, which can decrease well-being and result in death due to malnutrition [19]. Additionally, early nutritional intervention can improve prognosis and reduce the disease’s complication rate [12,19].

One study used a novel mobile app to assess and evaluate dietary behaviors in 39 oncologic patients. Although 5 patients dropped out prior to the study, the authors concluded that participants who tracked their daily dietary habits using a mobile phone app were more likely to reach their nutritional goals than the control patients. Other studies have used mobile apps to record nutritional status and activity levels in patients with breast cancer or other or other diseases, but none of them are similar to our study [20]. Our study was performed by a multidisciplinary team using both the app and the internet to maintain contact with the patients. Furthermore, the multidisciplinary team tailored each patient’s diet to suit their individual needs throughout their cancer treatment journey, particularly addressing gastrointestinal toxicities associated with active chemotherapy. This underscores the effectiveness of such technologies for integration into clinical practice without compromising the human touch in health care delivery.

Limitations and Strengths

This study highlights the importance of eHealth programs in addressing nutrition and well-being among oncohematology patients, offering significant value in multidisciplinary care management. The use of the Nootric app allowed for improved health care indicators and physical-nutritional well-being, promoting better patient outcomes.

Another notable strength of this study is the finding that over 50% (n=11) of the patients improved their physical-nutritional habits, leading to a considerable enhancement in their perception of well-being.

In terms of limitations, we must point out that this study has a small sample size of 22 patients, which may limit the generalizability of the results. Moreover, we experienced a 27% (6/22) dropout rate due to a lack of adherence to the program, which could have affected the overall results. In addition, not all of those who completed the study completed the clinical-biological tests. Finally, we acknowledge that the 12-week follow-up period might not adequately capture the program’s clinical impact on adherence to healthy habits and improved physical and nutritional well-being.

Conclusion

In conclusion, using targeted eHealth programs for nutrition and well-being among oncohematological patients undergoing active treatment offers significant value in multidisciplinary care management. This is achieved through enhanced interaction between physicians, dietitian-nutritionists, and patients via a...
digital nutrition service, such as the Nootric app. Supporting patients throughout their cancer journey, these technologies serve as valuable tools for integration into clinical practice without detracting from the human aspect of health care. Therefore, implementing projects that leverage new technologies in routine holistic clinical practice for oncohematological patients could prove cost-effective in both the short and long term. By facilitating the early detection of health issues related to physical-nutritional well-being and anticipating potential complications, these initiatives may help reduce unscheduled visits and admissions related to this condition.

Acknowledgments
We extend our gratitude to all the patients and families involved in this study.

Abstract

Background: With the rapid shift to telehealth, there remains a knowledge gap in how video-based care is implemented in interdisciplinary primary care (PC) settings.

Objective: The objective of this study was to gain an in-depth understanding of how video telehealth services were implemented in PC from the perspectives of patients and interdisciplinary PC team members at the Veterans Health Administration (VHA) 2 years after the onset of the COVID-19 pandemic.

Methods: We applied a positive and negative deviance approach and selected the 6% highest (n=8) and the 6% lowest (n=8) video-using PC sites in 2022 from a total of 130 VHA medical centers nationally. A total of 12 VHA sites were included in the study, where 43 PC interdisciplinary team members (August-October 2022) and 25 patients (February-May 2023) were interviewed. The 5 domains from the diffusion of innovation theory and the nonadoption, abandonment, scale-up, spread, and sustainability (NASSS) framework guided the development of the 2 study interview guides (provider and patient). We identified themes that emerged across all interviews that were associated with the implementation of video-based care in interdisciplinary PC settings, using directed-content rapid analysis of the interview transcripts. The analysis was guided by 5 a priori NASSS domains: (1) patient condition or characteristic, (2) technology, (3) adopter system, (4) health care organization, and (5) adaptation over time.

Results: The study findings include the following common themes and factors, organized by the 5 NASSS domains: (1) patient condition or characteristic—visit type or purpose (eg, follow-up visits that do not require physical examination), health condition (eg, homebound or semihomebound patients), and sociodemographic characteristic (eg, patients who have a long commute time); (2) technology—key features (eg, access to video-enabled devices), knowledge (eg, how to use videoconferencing software), and technical support for patients and providers; (3) adopter system—changes in staff roles and clinical practice (eg, coordination of video-based care), provider and patient preference or comfort to use video-based care, and caregiver’s role (eg, participation of caregivers during video visits); (4) health care organization—leadership support and access to resources, scheduling for video visits (eg, schedule or block off digital half or full days), and training and telehealth champions (eg, hands-on or on-site training.
for staff, patients, or caregivers); (5) adaptation over time—capacity to improve all aspects of video-based care and provide continued access to resources (e.g., effective communication about updates).

**Conclusions:** This study identified key factors associated with the implementation of video-based services in interdisciplinary PC settings at the VHA from the perspectives of PC team members and patients. The identified multifaceted factors may inform recommendations on how to sustain and improve the provision of video-based care in VHA PC settings as well as non-VHA patient-centered medical homes.

**Introduction**

With the rapid expansion of telehealth services since the onset of the COVID-19 pandemic, numerous studies have focused on health care clinicians’ perspectives on telehealth service implementation in primary care (PC). These studies primarily focused on satisfaction [1-4] and barriers to and benefits of telehealth services [5-24]. Regarding barriers to PC telehealth implementation, some clinicians have experienced challenges [5-14], such as technical issues with video and patient portals, privacy or confidentiality concerns, workflow and scheduling changes, low reimbursement rates, improper telecommunication infrastructure, inability to conduct physical examinations, difficulty maintaining the therapeutic relationship with patients, skill and comfort with technology, and access to technology [5-24]. However, clinicians and patients have shared several benefits of PC telehealth implementation [21,25-34], such as reducing infection and communicable disease exposure, eliminating commute time and patients’ transportation expenses, improved medication management, better evaluation of patients’ home environment, continuity of outpatient care, flexibility in scheduling appointments, and effective screening and triaging [5-9,21,25-34].

Despite its barriers and challenges, during the COVID-19 pandemic, video-based care has garnered high levels of satisfaction among health care clinicians and patients [1-4]. However, little is known about telehealth implementation at the national level, its use among interdisciplinary PC team members, and its sustainment beyond the initial phases of the pandemic. To address these knowledge gaps, the diffusion of innovation theory and the nonadoption, abandonment, scale-up, spread, and sustainability (NASSS) framework [35], an evidence-based, theory-informed, pragmatic model, are used to help understand the factors associated with the implementation of a technology-supported health care program. The NASSS framework builds on the work of the diffusion of innovation theory [36] and addresses the success of telehealth services, referred to in this study as video-based care. Guided by 5 NASSS domains and the corresponding subdomains, this study identifies the common factors (across patients, providers, and sites) that are associated with achieving fully mainstreamed implementation of video-based care.

The main objective of this study is to understand PC team members’ and patients’ perspectives on the implementation of video-based services within the Veterans Health Administration (VHA) 2 years after the onset of the COVID-19 pandemic. VHA PC is based on a patient-centered medical home model that includes interdisciplinary team members (physicians, nurse practitioners, physician assistants, nurses, social workers, clinical pharmacists, and mental health specialists) who work together to coordinate the provision of care, including video-based care. The VHA is well-suited to examine these issues given its over 2 decades of experience in video-based care [37-40] and its rapid expansion of video-based services in PC at the onset of the COVID-19 pandemic [41].

**Methods**

**Study Setting, Site Selection, and Recruitment**

To have a greater understanding of the interdisciplinary PC team members’ and patients’ perspectives on the use of video-based services at the VHA, we applied a positive and negative deviance approach [42,43] and selected the 6% highest (n=8) and the 6% lowest (n=8) video-using PC sites in 2022 from a total of 130 VHA medical centers nationally. For each of the 16 selected VHA sites, we contacted the medical directors and chiefs of staff through email and shared the study materials, such as the study information sheet and study approvals. We specified in the study information sheet that participation in the study was voluntary, and if they decided to participate, they could withdraw from the study at any time or refuse to answer any question. VHA medical center directors and chiefs of staff from 12 sites (6 low and 6 high) agreed to participate in the study. The 12 study sites represent all 5 US regions (3 West, 3 Midwest, 2 Southwest, 2 Southeast, and 2 Northeast), where 9 are urban and 3 are rural.

For the provider interviews, the inclusion criteria to participate was to be a member of a VHA interdisciplinary PC team at any of the 12 study sites. After receiving approval at the 12 VHA sites, we were then referred to the PC chief of staff at each site, who assisted with the recruitment process by sharing the study information sheet with their PC team members. Interested PC team members (n=53; 3-5 per site) contacted our study team to express that they wanted to participate in a 30-minute interview. Up to 3 follow-up emails were sent to schedule the study interviews. A total of 43 PC staff members (3-4 per site) were interviewed by 2 study members remotely through Microsoft Teams during August-October 2022. All interviews were audio-recorded and transcribed.
For the patient interviews, we began the recruitment process in January 2023 by randomly selecting a total of 120 VHA PC patients (10 per site) using the VHA electronic health records. The study inclusion criteria included (1) at least 1 PC visit during the past 2 years (2021-2022), (2) a valid US postal address, and (3) a phone number. We first mailed the study recruitment letters to all potential study participants, explaining the purpose of the study, that study participation was voluntary, and that all collected interview data would be kept confidential. We also explained that they had the option to opt out by calling a designated study phone number, and if they chose not to opt out, we may contact them (by phone) in 2-3 weeks to schedule a 30-minute phone interview. To minimize the burden on the 2 study members, we mailed the recruitment letters in 2 batches (60 letters in January 2023 and 60 letters in February 2023). We contacted 83 recruited patients by phone (up to 3 phone calls) with the following results: (1) 42 (51%) voice messages (no answer), (2) 7 (8%) wrong phone numbers, (3) 9 (11%) refusals, and (4) 25 (30%) completed phone interviews (2-3 per site) during February-May 2023. The response rate for patient interviews was 33% (\(\frac{25}{83-7}\) \times 100). We stopped recruiting patients after reaching data saturation [44]. All interviews were audio-recorded and transcribed.

**Semistructured Interview Guide**

For this study, 2 semistructured interview guides (provider and patient) with open-ended questions were used. Both interview guides were developed based on 5 of the NASSS domains [35] pertaining to telehealth implementation: (1) patient conditions, illness, and characteristic; (2) technology; (3) adopter system; (4) health care organization; and (5) adaptation over time (see Table 1 for details).

| 3C. Caregiver’s role | Provider | • What are the advantages and disadvantages of using VVC from your patients’ perspectives? Did you or your team provide any consultation/help with setting up VVC visits? |
| **Health care organizations** | | |
| 4A. Leadership support and resources | Provider or leadership | • What changes had to take place in your practice/clinic to implement VVC? |
Study Population
A total of 43 PC team members and 25 PC patients were interviewed remotely. PC team members represented different roles in the PC team, including 16 primary care providers (PCPs), which included physicians, physician assistants, and nurse practitioners; 12 nurses; 3 clinical pharmacists; 3 social workers; 2 mental health specialists (eg, psychiatrists and clinical psychologists); 4 scheduling clerks or supervisors; and 3 health care leadership team members. A diverse group of patients with respect to age, gender, race, ethnicity, and place of residence (rural or urban) were interviewed.

Analysis
We identified emerged themes and factors across all provider and patient interviews that were associated with the implementation of video-based care in interdisciplinary PC settings, using directed-content rapid analysis [45,46] of the interview transcripts. This analysis was based on substantive significance [47], and it was guided by 5 a priori NASSS domains (mentioned above). A structured template was created to summarize data from each interview, with 3 team members (CH, SH, and CDM) revising the template after independently analyzing a single transcript and reviewing the others’ templates for consistency. A summary matrix of the summaries was then used to consolidate all the interview findings. Key points were transposed and sorted into NASSS framework–identified themes, then reviewed and validated by 2 project team members (CH, SH, or CDM).

Ethical Considerations
This study was part of an ongoing quality improvement effort, and hence it was exempt from review by the institutional review board at the VHA Greater Los Angeles Healthcare System. Following study protocols, audio-recorded verbal consent was sufficient for participation in the study. To protect the privacy of study participants, all collected study information was deidentified and kept confidential. Each patient interviewee received a US $30 VHA canteen voucher after completing the interview. Provider interviewees did not receive any monetary incentives since their participation in the study was during the workday.

Results
Overview
In this section, the emerged themes and factors from the directed-content rapid analysis of provider and patient qualitative interviews are discussed in detail. The emerged or identified themes (or identified factors) were common across all patient and provider types. Table 2 displays the study findings for each of the 5 NASSS domains and the corresponding subdomains.
**Table 2. Factors guided by the nonadoption, abandonment, scale-up, spread, and sustainability (NASSS) framework that impact the use of video-based services in primary care settings at the Veterans Health Administration.**

| Visit type or purpose | Follow-up visits to address an issue that has already been examined during an in-person visit (eg, discussing side effects from a newly prescribed medication)  
• Follow-up visits for chronic disease management (eg, diabetes and hypertension)  
• Getting a referral to see a specialist  
• Continuity of care for patients who relocate to another state  
• Medication reconciliation  
• Clinical pharmacy (eg, review new prescriptions or respond to questions)  
• Conducting social work assessments (eg, assess patient’s home environment)  
• Video visits are appropriate for mental health counseling  
• Video-based care is a good fit for patients who do not need a physical exam |
| Health condition, illness, or patient type | Established patients (eg, who have been with the same clinician for many years)  
• Patients with mobility issues (eg, homebound or semihomebound)  
• Patients who cannot come into the clinic for various reasons (eg, substance abuse, posttraumatic stress disorder, or anxiety)  
• Recently discharged patients from a hospital stay or urgent or emergency care  
• Patients in palliative care  
• COVID-19–positive patients |
| Sociodemographic characteristics | Patients who live far away or in rural areas  
• Patients who are experiencing homelessness  
• Patients who are working, going to school, or have family obligations  
• Patients who would like to save money on gas and transportation cost  
• Patients who have working or employed caregivers who need to be present during a visit  
• Patients who have access to a private or quiet space with no disruptions |
| **Technology** | |
| Key features of videoconferencing technology | Video-enabled devices for patients and primary care team members (at the office or teleworking)  
• Access to high-speed broadband and stable internet connectivity  
• Robust network coverage at the office  
• User-friendly, simple-to-use videoconferencing software |
| Knowledge about technology | Be able to use a video-enabled device and navigate the videoconferencing software  
• Test the technology before using it for the first time (eg, download the app ahead of time or test the video links) |
| Technical support | IT support for primary care team members at the office or when teleworking  
• IT support for patients  
• Before the first video visit, the IT help desk conducts a test call with patients to ensure everything is set for a videoconferencing visit |
| **Adopter system (staff, patient, and caregiver)** | |
| Changes in staff roles and clinical practice | Involve primary care team members in the video-based care coordination process (eg, if a nurse visit happens, then the primary care provider joins the video-based visit)  
• A video-based care flow that mimics the in-person care process  
• Telehealth protocols for different departments, services, and types of care  
• Staffing flexibility (eg, remote provider who floats or provider coverage for other clinics) |
| Clinician and patient preferences and comfort | Provides flexibility to patients and providers to connect  
• Patient and provider preference or comfort level to use video  
• Patients who are not distracted (eg, they are at home and not in a store or driving)  
• Telehealth is less stressful for some patients |
| Caregiver’s role | The caregiver is present to help with the video visit (eg, troubleshoot technical issues)  
• The caregiver can be part of the video visit if there is a need to participate (eg, provide information)  
• The caregiver can provide emotional support during the video visit |
| **Health care organization** | |

https://formative.jmir.org/2024/1/e52830
### Leadership support and resources

- Leadership support at all levels (eg, primary care chief of staff, clinic, or medical director) and at all service lines (eg, primary care providers, nursing, scheduling, or pharmacy)
- Veterans Health Administration–issued tablets or iPads sent to qualified patients
- Access to a private or quiet office space for providers to conduct video visits

### Scheduling, reminders, or day of video-based appointment

- Scheduling video visits involves multiple steps and need to ensure the patient is ready to connect remotely on the day of the visit
- Schedule or block off remote half or full days (ie, create telehealth clinic days)
- More availability of telehealth appointments compared to in-person appointments
- Timeliness of video visits compared to in-person appointments
- Treat a video-based visit same as an in-person visit (eg, patients should dress appropriately, prepare a list of questions, and have their medication list ready to review)
- Automatically enroll new patients in video-based care

### Trainings and telehealth champions

- Online trainings and resources are available for patients and providers
- Prioritize video-based care trainings for all, including newly hired staff and newly enrolled patients
- Provide hands-on and site- or team-specific training or education for all providers, staff, and patients
- Identify on-site staff and patient telehealth champions to assist with hands-on training or education

### Adaptation over time

#### Capacity to improve

- Improve technical resources, personnel support, hands-on or site-specific trainings, or education about video-based care coordination and scheduling
- Access video links from patient’s portal that is embedded in the electronic health record system

#### Continued access to resources

- Effective and widespread communication about changes in resources and new updates to the videoconferencing software or video-based care management system and options
- Annual video-based care training day for providers, staff, and patients to learn about updates

### Patient Condition, Illness, and Characteristic

#### Visit Type or Purpose

Video-based care was considered most suitable for follow-ups to routine care, particularly for patients with chronic conditions. Seeing new patients and care requiring a physical assessment was preferably done in-person. A patient explained:

> If I need a quick medicine change or something along those lines where I don’t need to be physically examined then I would, yes, use a video call. [Patient 18]

Moreover, video visits allow providers to assess patients’ home environment.

> Video appointments give much more insights to the patients’ home status, their pride, their pets... their current living conditions that we can discuss about. [Leadership 1]

> I do believe the best place to take care of the patient is in their home... so, the more video we could do, I think the better we would be at taking care of Veterans. We could touch them more often. [Physician 15]

Video visits also allowed better medication reconciliation, as patients could just show their bottles through the video camera.

> They’re at home with their pills. They can pull them all out. They don’t have to drag them into the appointment. [Clinical pharmacist 3]

Video-based care is conducive for explaining new medications or laboratory results to patients. Blood pressure readings were cited as being video-appropriate, as patients usually have their own equipment and can be overseen by their clinician while taking their own blood pressure at home. Mental health specialists felt comfortable using the technology for telemental health sessions, stating the proven effectiveness and comparability of video to in-person care.

#### Health Condition, Illness, or Patient Type

For older patients with difficulty ambulating and those who depend on family members for transportation to the clinic, video-based care is a viable option. Similarly, for established patients who have been with the same PCP for many years, and for patients who cannot come to the clinic for a variety of reasons (eg, substance abuse and anxiety), video-based care might be a good alternative. Moreover, video-based care is appropriate for patients in palliative care, COVID-19–positive patients, and recently discharged patients. One patient explained:

> Following up from emergency room visits or hospital stays, those are pretty easy to do over the phone or video because you should be okay. You shouldn’t have any other issues, or if you are having issues, as long as they’re not extreme and you don’t need to go back to the ER. [Patient 17]
Sociodemographic Characteristics

Even though younger patients might be more amenable to video-based care, age is arbitrary when understanding how to use telehealth technology.

We still live in a reality where people think that elderly people are not technologically savvy, and I don’t think that is correct. [Physician 7]

It’s our older population that are not working that I think we see more of them in the virtual appointments than anything. [Nurse 8]

Therefore, age should not be an exclusion criterion, but it often is. A social worker further explained that, at times, it is unrealistic for patients to be expected to come into the clinic when there is no need for them to make that extra effort.

Patients with long commutes to their local VHA clinics appreciated video visits. This allowed them to save time and money on gas and transportation. For patients who are traveling within the continental United States and who need continuity of care, video-based care can be a good option. Similarly, patients who work, have family obligations or go to school and accordingly have a hard time scheduling a clinic or in-person visit found video care to be beneficial. One patient explained:

Sometimes, I’ll set my appointment when I’m picking up my son and I’m waiting outside... and it’s usually a really good time. I’m in my car and it’s very quiet. [Patient 21]

Technology

Key Features of Videoconferencing Technology

Access to video-enabled devices (either a smartphone or laptop), as well as high-speed broadband and stable internet connectivity, is necessary for video-based care. At times, patients living in rural areas lacked the wireless bandwidth to take video calls. Homeless-experienced or low-income patients lacked suitable equipment (eg, a smartphone) for video services, but this issue was ameliorated by the Digital Divide Consult program that provided VHA-issued iPads or tablets for qualified patients. Yet some patients who received iPads still faced barriers to video-based care and did not use them because of internet connectivity issues or a lack of broadband access.

I saw that also happen with one of my Veterans. He wouldn’t show up on his video appointments. And I know he had a VA-issued iPad. [Physician 10]

Knowledge About Technology

Even though video-based care might be more suitable for tech-savvy patients and providers who can use video-enabled devices, it is still important for both patients and providers to conduct at least 1 test call before using the VHA video-based technology for the first time (eg, download the app ahead of time and test the video links).

Technical Support

IT support is available for PC team members at the office or when teleworking. IT support for patients is also available, which can help patients ensure everything is prepared for their upcoming videoconferencing visit. A video test call can be done with the IT help desk or a live web-based chatbot to ensure patients’ devices are compatible with the videoconferencing software, but often these services are underused by patients.

Adopter System (Staff, Patient, and Caregiver)

Changes in Staff Roles and Clinical Practice

There have been challenges in video-based care coordination, as some aspects and processes of in-person visits are not easily transferable to video-based visits. For example, after a nurse conducted the initial video-based check-in (eg, going over vitals and the patient’s medication list), the video call was dropped during the transfer, and the PCP was unable to join the video visit. Creating processes and procedures to manage video-based care coordination among PC team members is key for providing team-based video care.

Additionally, video-based care can provide staffing flexibility. For example, video-based providers float and provide coverage at other clinics. Regarding clinical practice, there is a need to set up video-based care protocols and guidelines for different departments, services, and types of care, so there is guidance as to when video visits are appropriate.

Provider and Patient Preference or Comfort

Video-based visits provide flexibility for patients and providers to connect remotely. Provider and patient preferences regarding video-based care are important factors, given that there were strong opinions among providers against video-based care.

We have some providers that refuse to conduct video appointments... they just don’t like change. [Nurse 5]

Regarding patient preference and comfort coming into the clinic, video-based care offers a less stressful option for patients to connect with their providers. One patient explained:

I was back in the comfort of my personal space where I feel safe, and I can open up and talk better than at an office where you’re not as comfortable because it’s not your space... And I feel that I was able to open up more and really benefit from the mental healthcare than when I go to the office because I’m already like stressed because I’m there and I’m in a hospital environment and I don’t like hospitals at all. [Patient 23]

However, there was a concern with distracted patients during video visits.

Sometimes the patient does not engage enough with you, or they get distracted by the environment. [Physician 2]

They might log on, but they’re busy doing their hair. It’s almost like they’re facing timing of a friend or a family member. [Mental health specialist 03]

Overall, patients preferred occasional in-person visits to feel like they were receiving adequate attention and care. Generally, patients have strong opinions either for or against video-based care.
Caregiver’s Role

In some instances, it is important for caregivers to be present during the visit and be involved in the patient’s care, such as providing emotional support, having a better understanding of the health condition, and sharing information about what the patient is going through. Video-based visits can provide more opportunities for caregivers to get more involved with patient care. One patient explained:

I think it’s wonderful because it gave my wife a better feel for what was going on with me. [Patient 14]

Another patient shared:

I did have one session with my husband because I was trying to get him qualified as a caregiver. So, we had a video appointment for that. It was very convenient and a great option because, at the time, I was bedridden with a back injury before I had back surgery. And he was pretty much taking full time care of me to get me out of bed, showered, dressed, the whole thing. It was very helpful to have that option that we could all meet and have that evaluation done. [Patient 22]

In another instance, a social worker explained:

They’d [adult son] rather just schedule that time to be at their parent’s house and sign into the video than come in person. [Social worker 3]

Health Care Organization

Leadership Support and Resources

Leadership support at all levels (eg, PC chief of staff and clinic or medical director) and from all departments (eg, PCPs, nursing, scheduling, and pharmacy) is key for the successful implementation of video-based care in PC. Additionally, having a designated physical space (eg, a private quiet space with no distractions or interruptions) and computer hardware, such as video-enabled devices, are a necessity for the successful implementation of video-based care.

Scheduling, Reminders, and Day of Video Appointment

Before scheduling a video-based PC visit, schedulers or clerks ask patients a series of questions about the types of devices they own to determine if a video visit is feasible. The scheduler or clerk also sends the patient the video link and creates the follow-up appointment. Before the day of the video appointment, reminders through SMS text messages as well as email are sent. Automatically enrolling new patients for video visits is also an option, which makes scheduling for video-based visits easier. In-person or clinic visits are still the most frequently scheduled across clinics. However, after the provider puts in the video request that the patient agreed to, some schedulers or clerks failed to follow through with scheduling the video-based appointment.

Video clinics are being underutilized, not because of lack of patient interest. It’s being underutilized because schedulers are not calling patients to make the appointment in the video clinic. [Physician 2]

There is also the option to block off half or full days for video visits. Patients shared that video visits were more timely and easier to schedule compared to in-person appointments. Video-based visits should be treated just the same as an in-person visit. As such, patients need to dress appropriately, prepare a list of questions, have their medication list ready to review and find a quiet place for the video call.

Trainings and Telehealth Champions

Video-based care training for PC team members is done through formal web-based training. However, hands-on training or trial-and-error is the best way to learn how to use the VHA video technology.

I think the best way people can walk somebody else through it is if they do it themselves. [Physician 13]

Training should be tailored for each clinic and team member, so each can understand their role in the video-based care process. VHA leadership noted that they combined multiple video training courses into 1 web-based course for new providers. An optional 1-day intensive training course is also available. Ultimately, having a telehealth champion who provides hands-on, personalized training and updates to PC team members can be critical to effectively educating the PC team on how to use video-based care.

We did have a super user in the clinic who was able to go in and show everyone how to do it [ie, use VA video technology]. [Nurse 3]

For patients, training for video-based visits usually falls on the nurses, schedulers, clerks, technicians, or other clinic staff who enroll patients in video-based scheduling for the first time. Having a patient telehealth champion, for example, a veteran sharing how they benefited from a video visit, might be helpful in providing peer-to-peer mentoring and promoting video-based visits. Overall, it seems that patients choose to have more telehealth appointments after being trained.

Once we get it set up for them [patients] and they feel comfortable with the whole [thing]—they’re utilizing it [VA video technology] quite a bit. [Nurse 8]

Adaptation Over Time (Capacity to Improve and Continued Access to Resources)

Suggestions for improving video-based care at the VHA centered around 5 main areas: technological resources, personnel support, training, care coordination, and scheduling. Regarding resources, video-based care should be connected to the patient’s electronic health care records for easier access to the web-based appointment link. Accessibility of video on cellular devices, like using SMS text messages to quickly communicate with patients. There is a need to hire more clerical staff to assist with video-based care scheduling and technical support (eg, a telehealth enrollment coordinator role on the team or a telehealth help center to assist veterans with technical issues). Beyond personnel support, there is a need for more physical space in
clinics, so they could have privacy to conduct telehealth visits. Other suggestions included having more resources to support video technology, such as choosing site-specific internet networks and improving network coverage overall.

Recommendations to improve training focused on having nonclinical staff administer patient education in group and in-person settings. Patients need adequate training to use VHA video technology.

We need to teach them. We need to take the time and put the investment... but too often, we blame the patient, I think inappropriately. [Physician 11]

When asked about care coordination, the video care process should mimic the flow of in-person care while striving for “care management and the same depth of treatment.”

Regarding scheduling, providers asked for separate days designated for video and face-to-face appointments. It is important to have 1 centralized platform or web-based grid where all types of appointments, telehealth and in-person, can be scheduled. Schedulers or clerks should have a script or checklist to ensure that patients understand their video-based care options. Finally, site-specific telehealth management is needed, acknowledging that regional differences and specific site needs may affect each VHA clinic’s telehealth or video adoption and implementation.

**Discussion**

**Overview**

In this study, the 5 NASSS domains that pertained to the implementation of telehealth services guided the qualitative analysis and identified key factors associated with the implementation of video-based services in PC from interdisciplinary team members’ and patients’ perspectives 2 years after the onset of the COVID-19 pandemic. In terms of patient condition, illness, and characteristics, the study findings concurred with previous studies that video-based care is most appropriate for follow-up visits that do not require physical examinations, and in some cases, it might be well-suited for follow-up visits for chronic care management [48,49]. This study corroborated findings from previous studies that video visits are appropriate for semi- or fully homebound patients with mobility issues who benefit from having a caregiver present at their medical appointments [50,51]. Similar to previous studies, convenient access to video-based care was needed for patients with full-time jobs, family obligations, transportation difficulties, and long travel distances for in-person care [5-24].

Regarding age, the study findings illustrated that regional differences and specific site needs may affect each VHA clinic’s telehealth or video adoption and implementation.

Study participants shared many areas of improvement that can help sustain telehealth adaptation over time. Like previous studies [53], the study findings highlighted that it is important for health care organizations to have the capacity to improve technological resources, personnel support, training, and video-based care coordination and continue to provide access to these resources. In addition, the study findings also highlight the importance of improving scheduling processes and platforms to better meet the needs of all providers and patients. Finally, it is important to acknowledge that site-specific telehealth management is needed, since regional differences and specific site needs may affect how each VHA clinic implements telehealth or video-based care in PC settings.

**Limitations**

The major strengths of this study are the following: first, the study included 12 VHA medical centers located in geographically diverse settings. Second, these study sites, including 9 urban and 3 rural, had varying rates of video use, ranging from lowest to highest. Third, the directed-content rapid
analysis, guided by a priori NASSS domains, identified emerged themes or factors across all interviews (43 PC team members and 25 PC patients). Despite this, the study has several limitations. First, this study did not examine the differences between patient types, appointment types, provider types, and sites. Instead, the factors that were identified in this study were common across all patients, all PC team members, and all sites. Future studies should consider which factors differentiate between sites (eg, urban vs rural), provider types (eg, mental health specialists vs PCPs), patient types (eg, male vs female and with diabetes vs without diabetes), as well as appointment types (mental health visit vs PC visit). Second, since this study did not use probability sampling strategies to select the study sites or the provider study sample, the generalizability of the study findings to all VHA PC clinics and providers is limited. Furthermore, even though simple random sampling was used to select the patient study sample, the study’s main purpose was to have an in-depth understanding of the implementation process of video-based care at the selected VHA study sites. Hence, the generalizability of the study findings to all VHA patients is limited. Third, the generalizability of study findings may be limited in non-VHA health care systems for various reasons, including that VHA clinicians do not have the same cross-state licensure restrictions, especially since the passage of the Anywhere-to-Anywhere Act (in May 2018) [54,55], where VHA expanded telehealth services by allowing health care clinicians to treat patients across state lines; and VHA has a capitated payment system, which makes it easier to implement telehealth since it is not subject to third-party payer arrangements [54]. However, recent COVID-19 telehealth waivers have increased non-VHA health care providers’ and clinics’ telehealth capability, such as allowing telehealth services across state lines. Therefore, there are more similarities now between VHA and non-VHA telehealth services than even in the recent past. As such, study findings may still be applicable to non-VHA clinical settings and contribute to the growing evidence base surrounding factors most salient to the successful implementation of telehealth services at PC clinics.

Conclusions

Given that VHA PC is based on a patient-centered medical home model that includes interdisciplinary team members who work together to coordinate the provision of care, including video-based care, we examined the implementation of video-based care in interdisciplinary PC settings from the perspectives of PC team members as well as patients at 12 different VHA health care settings (9 urban and 3 rural). Guided by 5 a priori NASSS domains and the corresponding subdomains, we identified common factors (across patients and PC team members) that were associated with the implementation of video-based care in interdisciplinary PC settings. We identified multifaceted factors that resulted from the qualitative analysis of the collected interview data may help inform recommendations on how to sustain and improve video-based care in VHA PC settings and other non-VHA patient-centered medical homes.

Abstract

Background: Accessible and effective approaches to mental health treatment are important because of common barriers such as cost, stigma, and provider shortage. The effectiveness of self-guided treatment is well established, and its use has intensified because of the COVID-19 pandemic. Engagement remains important as dose-response relationships have been observed. Platforms such as Facebook (Meta Platform, Inc), LinkedIn (Microsoft Corp), and X Corp (formerly known as Twitter, Inc) use principles of behavioral economics to increase engagement. We hypothesized that similar concepts would increase engagement in self-guided digital health.

Objective: This 3-arm randomized controlled trial aimed to test whether members of 2 digital self-health courses for anxiety and depression would engage with behavioral nudges and prompts. Our primary hypothesis was that members would click on 2 features: tips and a to-do checklist. Our secondary hypothesis was that members would prefer to engage with directive tips in arm 2 versus social proof and present bias tips in arm 3. Our tertiary hypothesis was that rotating tips and a to-do checklist would increase completion rates. The results of this study will form a baseline for future artificial intelligence–directed research.

Methods: Overall, 13,224 new members registered between November 2021 and May 2022 for Evolution Health’s self-guided treatment courses for anxiety and depression. The control arm featured a member home page without nudges or prompts. Arm 2 featured a home page with a tip-of-the-day section. Arm 3 featured a home page with a tip-of-the-day section and a to-do checklist. The research protocol for this study was published in JMIR Research Protocols on August 15, 2022.

Results: Arm 3 had significantly younger members ($F_{2,4564}=40.97; P<.001$) and significantly more female members ($\chi^2=92.2; P<.001$) than the other 2 arms. Control arm members (1788/13,224, 13.52%) completed an average of 1.5 course components. Arm 2 members (865/13,224, 6.54%) clicked on 5% of tips and completed an average of 1.8 course components. Arm 3 members (1914/13,224, 14.47%) clicked on 5% of tips, completed 2.7 of 8 to-do checklist items, and completed an average of 2.11 course components. Completion rates in arm 2 were greater than those in arm 1 ($z$ score=3.37; $P<.001$). Completion rates in arm 3 were greater than those in arm 1 ($z$ score=12.23; $P<.001$). Engagement in all 8 components in arm 3 was higher than that in arm 2 ($z$ score=1.31; $P<.001$).

Conclusions: Members engaged with behavioral nudges and prompts. The results of this study may be important because efficacy is related to increased engagement. Due to its novel approach, the outcomes of this study should be interpreted with caution and used as a guideline for future research in this nascent field.

Introduction

Background
Since its earliest use in the mid-1990s, digital health promised personalized treatments that patients could access from home. It was anticipated that treatment would have a broad reach, resulting in improved health outcomes and decreased costs [1-3]. Over the past 2 decades, and with increasing consistency, research examining the efficacy of self-guided digital health interventions show evidence of efficacy, especially for those with mental health concerns [4-7].

Although digital health interventions appear to be effective, poor adherence and lack of compliance have remained consistent patterns in research [8-10]. This pattern was first recognized in 2005 and coined The Law of Attrition [11].

As early as 2009, systematic reviews identified poor adherence and lack of compliance as engagement issues that required attention [12]. These issues persist, as demonstrated by a recent meta-analytic review on digital interventions for depression, which showed efficacy but highlighted compliance as a major challenge [13].

Adherence and compliance are complex and rooted in several systemic and individual factors [14-19]. However, it is an important topic as evidence indicates a dose-response relationship, and higher levels of engagement are associated with improved health outcomes [20,21].

Moreover, digital health interventions are becoming increasingly common and accessible. Patients' use of, and trust, in these interventions has been intensified by the COVID-19 pandemic. The use of self-guided digital health interventions for mental health concerns is growing [22,23] because of access barriers such as high cost, stigma, and lack of access due to a shortage of professionals who can meet this growing demand [24,25].

How do we increase engagement in digital health programs to maximize their efficacy?

Behavioral Economics

Overview
Behavioral economics leverages psychological experimentation to develop theories about human decision-making. The field has identified a range of unconscious biases around how people think and feel [26,27].

The utility of behavioral economics is vast. Digital health has leveraged the discipline to investigate how people use digital health programs and to gain insights into the characteristics of people who use them. Several digital health studies have investigated the use of these strategies, including cooperative games and incentives [28], gamification [29,30], serious games [31,32], and positive behavioral support [33,34].

Our Use of Behavioral Economics
In our study, we examined the effectiveness of the nudge theory and behavioral prompts in 2 ad libitum self-guided digital behavior change courses.

Nudge Theory
Nudge theory, popularized in the 2008 book Nudge: Improving Decisions About Health, Wealth, and Happiness [27], leverages indirect, positive suggestions to influence decision-making and behavior.

There is a lack of quality research analyzing the use of nudges in digital health. A 2019 scoping review examined the use of nudges in both web-based and real-world settings in physical activity interventions [35]. Of the 35 publications reviewed, 8 were web-based studies. The authors concluded that although nudging may be an effective approach to promote physical activity, there are large gaps in research, and further studies that are explicitly based on nudge insights are needed.

A 2020 editorial in Personalized Medicine addressed the meaningful adoption of nudges in digital health [36]. The authors acknowledged that using nudges in digital health interventions is rare and advocated for the use of nudges to promote positive behavior change.

Behavioral Prompts
In applied behavioral analysis, behavioral prompts are cues specifically designed to encourage a specific task [34]. In this study, we used 2 types of behavioral prompts anchored in the nudge theory: daily tips and a to-do checklist (Table 1).

Table 1. Example nudges and prompts.

**Directive, Social Proof, and Present Bias Tips**

Directive content, as the name suggests, offers concrete suggestions to members [37]. These types of tips are brief and instructional.

Social proof is derived from the behavioral economics concept where we tend to copy the actions of those around us. These tips speak of our tendency to be swayed by other people’s choices, which we attempt to mirror [38,39].

Present bias is the inclination to prefer a smaller present reward now over a larger reward later. These tips encourage users to perform a task that provides an immediate benefit [40,41].

**Our Use of Behavioral Prompts and Technical Functionality of Tips and to-Do Checklist Items**

An example of a course tool in both Overcoming Anxiety and Overcoming Depression courses is goal setting. Goal setting is an important component of cognitive behavioral therapy (CBT). However, in a self-guided environment, many members are unsure of how to set personal goals. Evolution Health encourages members to review goals set by others as examples.

Figure 1 shows an example of a tip of the day that encourages members to review the goals of other members.

Figure 2 shows an example of the completed to-do checklist item, set goals. In this figure, the item is marked complete by a check box. This signifies that a member has clicked on the item and visited the page.

**Figure 1.** Present bias tip: review other members’ goals.

**Figure 2.** Completed to-do checklist item, set goals.

By clicking on either the tip (Figure 2) or the to-do checklist item (Figure 3), the member is brought to member goals, a course component that allows members to browse various goals set by other members (Figure 3).

Engagement experiments in popular non-health care digital platforms are common. Although they are scientific in nature, they are not typically published, as they are conducted within private companies.

For example, social network sites such as Facebook (Meta Platforms, Inc), LinkedIn (Microsoft Corp), and X Corp. (formerly known as Twitter) generate revenue based on ad revenue derived from page views and the time members spend on their site. In a 2015 presentation, it was revealed that LinkedIn had >400 controlled experiments being conducted per day [42]. Similar studies with an ad libitum population are required for digital health, and this study is an attempt to fill this gap.

We have not observed sufficient evidence in the literature to determine whether nudges and prompts can be strategically applied to increase engagement with and decrease attrition in the courses for depression and anxiety [43]. Furthermore, because of the nascent state of behavioral economics within digital health, we did not find any quantitative benchmarks that would help us determine whether our use of nudges and prompts was successful.
Objectives

Our primary hypothesis (H1) was that members would engage with the tips and to-do checklist. Engagement of the members was determined by the percentage of tips that were clicked on compared to the number shown. Because there is no prior literature, we first needed to establish baseline data. Data were reported as observational and served as a benchmark for future studies.

Our secondary hypothesis was that members would prefer to engage with directive tips in arm 2 versus social proof or present bias tips in arm 3. To assess the preference for engagement, we compared the number of tips clicked in arm 2 versus those clicked in arm 3.

Our tertiary hypothesis was that the addition of tips and a to-do checklist would increase completion rates with course tools. Increased completion rates were determined by comparing completion rates in arms 2 and 3 with those in arm 1 (control group).
In each hypothesis, we assessed whether engagement was influenced by gender or age.

**Methods**

**Overview**

The digital health platform used in this study was managed by Evolution Health. Evolution Health is an evidence-based, self-guided digital health platform that features courses and brief interventions based on behavior change techniques including CBT, stages of change, structured relapse prevention, normative feedback, and harm reduction.

The platform offers interactive courses and quizzes for people with mental health, addiction, and obesity issues. The platform contains a moderated community based on social cognitive theory.

Memberships are available to individuals who register through the organization’s free-to-consumer program and white-label instances that are licensed by employers, insurance companies, employee assistance programs, educational institutions, nonprofit organizations, for-profit health care organizations, and individual therapists.

The research protocol for this study was published in *JMIR Research Protocols* on August 15, 2022 [44]. The International Registered Report Identifier is DERR1-10.2196/37231.

**The Interventions**

The 2 interventions in this study contain self-guided interactive behavior change treatment courses based on best practices, and both have been examined extensively in the literature [9,45-53].

The 2 interventions have undergone several iterations. For example, Overcoming Anxiety was the first intervention noted in *The Law of Attrition* (previously known as The Panic Center) paper by Eysenbach [11]. In that iteration, the course contained a tunnel design with 12 successive sessions. The course now has a gamified free-form matrix design, among other technical and usability enhancements.

Table 2 outlines each course’s current theoretical construct and evidence base. Table 3 outlines the main course components.

aCBT: cognitive behavioral therapy.
Ethical Considerations

At registration, all members endorsed a checkbox to confirm that they consented to have their nonidentifiable data used for research purposes and approved the platform’s privacy policy. The participants did not receive compensation for their involvement. The platform is available in several languages, and the English language privacy policy and terms of use are presented in Multimedia Appendix 1. All data collection policies and procedures adhered to the international privacy guidelines [54-56] and the Helsinki Declaration of 1975 [57].

This study was conducted on self-guided treatment for depression and anxiety, but it did not measure clinical outcomes. Although the study participants were randomly assigned to a control or intervention arm, the study was a randomized controlled trial and not a randomized clinical trial [58]. This study did not assess whether the study participants’ engagement with course tools decreased the depressive symptoms, severity of panic attacks, or frequency of panic attacks.

As described earlier, evidence indicates that higher levels of engagement are associated with improved health outcomes, and the literature observes dose-response relationships. However, any clinical outcomes related to the engagement strategies used in this study will need to be tested in future research.

As the study was based on unidentifiable data and no clinical measures were tested, it was deemed exempt from further review by the Evolution Health Institutional Review Board (IRB#000014034, FWA00033737).

Power and Sample Size

The study was designed to have a power of 0.95, indicating a 95% probability of correctly detecting a statistically significant difference in engagement with tips between the 2 treatment groups (arm 2 vs arm 3). On the basis of a 2-tailed t test with a conventional α level (.05) for statistical significance, we required a sample of 1302 members with 651 in each group to detect a small effect size of Cohen $d=0.2$. Refer to Multimedia Appendix 2 for the CONSORT-EHEALTH (Consolidated Standards of Reporting Trials of Electronic and Mobile Health Applications and Online Telehealth) checklist [59].

Randomization

During the registration process, new members were assigned to 1 of the 3 arms using a random number generator (Figure 4). Randomization was conducted using simple randomization.

Figure 4. Recruitment process.

Intervention Groups

Arm 1

Members randomized to arm 1 were presented with a dashboard that did not contain behavioral nudges. Figure 5 presents a screenshot of the arm 1 dashboard for a member who chose to engage with the depression course.
Arm 2

Members randomized to arm 2 were presented with a dashboard that contained a tip-of-the-day section containing directive content. The randomization strategy for the 31 directive tips was randomization without replacement.

Figure 6 presents a screenshot of the arm 2 dashboard for a member who chose to engage with the depression course.
Members randomized to arm 3 were presented with 2 sections that contained nudges. The first was a tip-of-the-day section containing social proof and present bias cues. At each log-in, members saw a new tip. The randomization strategy for the tips was randomization without replacement. There were 15 social proof tips and 15 present bias tips.

In addition to the tip of the day, arm 3 featured a to-do checklist that listed 8 course components. When a member clicked on a component, they were brought to the exercise. As mentioned previously, if a member clicks on a to-do checklist item, it is marked complete with a check mark.

Figure 7 presents a screenshot of the arm 2 dashboard for a member who chose to engage with the depression course.
Figure 7. Member home page for arm 3.

Data Collection

A custom data collection interface and reporting mechanism were developed by Evolution Health. Age and gender data were collected at registration or through a secure sign on with various white-label instances. Data were collected for each member who was randomized into the experiment. The course components promoted by tips and to-do checklist items are listed in Textbox 1. Members who participated in both courses were not counted twice.

The following behaviors were tracked in the custom database for each tip and to-do checklist item that was randomly presented to a member:

- If the nudge was shown
- If the nudge was clicked on
- If a member completed the course component described in the tip or to-do checklist item.

It was possible for a single member to participate in both courses. However, the study design was to test the behavioral prompts, not the courses. The participants were randomized to an intervention arm, in which behavioral nudges and prompts were consistent across courses.

</tbody>
</table>

Participants
As there were no barriers to registration and many new members registered with the platform for purposes other than treatment, we removed those who registered but did not return to the intervention (nonparticipants) from the analysis.

Data Analyses
All data were analyzed using mixed effect logistic regression with members as a random variable. Mixed effect logistic regression was conducted using the gImer() function from the lme4 package in R software (R Foundation for Statistical Computing), with the default optimizer Bound Optimization BY Quadratic Approximation, a derivative-free optimization algorithm used for problems with bound constraints.

For the tip-of-the-day section, the outcome variable was whether a user clicked on a tip presented to them (no or yes), and the predictors were arm (2 or 3), gender (female or male), and age group (18 to 30 years to >60 years).

For the to-do checklist items, the outcome variable was whether a user clicked on a checklist item (no or yes), and the predictors were gender and age group.

For the course components, the outcome variable was whether a user completed a component (no or yes), and the predictors were arm (1, 2, or 3), gender, and age group.

Results
Overview
Between November 2021 and May 2022, data were collected from new members who self-registered for Evolution Health’s self-guided treatment program for anxiety and depression. All members were randomized into 1 of the 3 arms.

First, members with test accounts and unauthenticated accounts were removed from the data set, resulting in a population of 13,224 members. Then, members whose accounts were missing demographic data (376/13,224, 2.84%) were removed from the data set, followed by members aged <18 (129/13,224, 0.97%), resulting in a population of 12,719 members.

Finally, of the 13,224 members, 8567 (65.46%) with nonparticipant accounts were removed, resulting in a study population of 4567 (34.53%). Of the 4567 members, 1788 (39.15%) were randomized into arm 1, 865 (18.94%) into arm 2, and 1914 (41.9%) into arm 3 (Figure 8).
**Figure 8.** Study population.

**Demographic Characteristics**

The average age of the members in arms 1, 2, and 3 was 44.4 (SD 10.69), 45.4 (SD 10.62), and 41.8 (SD 11.17), respectively (Table 4). The 51 to 60 years age group was the most populous age category in each of the arms (arm 1: 777/1788, 43.45%; arm 2: 420/865, 48.6%; and arm 3: 586/1914, 30.61%). The members of arm 3 were somewhat younger ($F_{2,4564}=40.97$; $P<.001$) than the other 2 arms.

Regarding gender (Table 5), most members identified as women (arm 1: 1466/1788, 81.99%; arm 2: 751/865, 86.8%; and arm 3: 1770/1914, 92.48%). Few members identified as transgender individuals, nonbinary or third gender individuals, or preferred not to say (arm 1: 5/1788, 0.28%; arm 2: 1/865, 1.2%; and arm 3: 2/1914, 0.1%). Arm 3 had more female members ($\chi^2=92.21$; $P<.001$) than the other 2 arms.

During the study period, there were 13,510 total log-ins, with initial registration considered as 1 log-in (Table 6). The average number of log-ins for male members was 3.89 and female members was 2.83. The average visit duration (AVD) for members who engaged with depression and anxiety course tools ranged from 6 minutes and 45 seconds, with 7.65 pages viewed, to 24 minutes and 21 seconds, with 12.56 pages viewed.

**Tip of the Day**

In arm 2, there were 31 revolving tips, and in arm 3, there were 30 revolving tips. Therefore, the probability of a member assigned to the arm 2 seeing a specific tip at least once is .088, and the probability of a member assigned to the arm 3 seeing a specific tip at least once is .091.

A total of 11,431 tips were displayed, of which 564 (4.93%) were clicked on (Table 7). In arm 2, 3622 tips were shown, of which 190 (5.24%) were clicked on. In arm 3, 7809 tips were shown, of which 374 (4.79%) were clicked on. Mixed effect logistic regression revealed no statistically significant differences between the 2 arms regarding the number of tips clicked on \( (P=.25) \).

Table 7. Tips shown and clicked on (N=11,431).

</tr>
<tr>
<td>Tips clicked on</td>
<td>190 (5.24)</td>
<td>374 (4.79)</td>
<td>564 (4.93)</td>
</tr>
</tbody>
</table>

In arm 2, female members clicked on 171 (5.82%) tips out of the 2937 tips shown to them and male members clicked on 19 (2.8%) tips out of the 682 tips shown to them, whereas in arm 3, females members clicked on 350 (4.94%) out of the 7081 tips shown to them and male members clicked on 24 (3.3%) out of the 722 tips shown to them (Table 8).

There were no statistically significant differences between number of tips clicked on between age groups (Table 9).

Table 8. Tips shown and clicked on by gender category (N=10,018).

<table>
<thead>
<tr>
<th></th>
<th>Arm 2, n (%)</th>
<th>Arm 3, n (%)</th>
<th>Total, n (%)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tips shown to female members</td>
<td>2937 (100)</td>

<td>9 (100)</td>
</tr>
<tr>
<td>Tips clicked on</td>
<td>0 (0)</td>
<td>0 (0)</td>
<td>0 (0)</td>
</tr>
</tbody>
</table>

Mixed effect logistic regression (Table 10) revealed that female members clicked on more tips than male members \( (z\text{ score}=2.58; \text{ }P=.01) \). Although the role of gender and engagement should be more thoroughly examined in future studies, this finding is consistent with other research on platform components [60].

There were no substantial differences between age groups.

### To-Do Checklist

As outlined in Textbox 1 and illustrated in Figure 5, the to-do checklist contained 8 items. The members of Arm 3 completed an average of 2.7 (34%) out of 8 course components.

The checklist item with the highest engagement was complete the depression and anxiety test, which was completed by 51.4% (55/107 of the members; Table 11). The second most popular item was watch the getting started video, with 48.2% (923/1914) of the members engaging with the behavioral cue. The checklist item with lowest engagement was upload my image with nearly one-fifth (360/1914, 18.8%) of the members engaging with the behavioral cue.

It should be noted that 2 items read a community post and complete the depression and anxiety test were hidden for some members. This is due to these elements being feature flags and some Evolution Health clients and research partners choosing to hide these features from their membership base.

Although this resulted in a lower number of members seeing these cues and having access to the course components, the percentage of members who viewed the cues and engaged with the components was noteworthy.

Table 12 lists the engagement results for checklist use and gender. Mixed effect logistic regression found that female members clicked on more checklist items than male members (z score=2.07; P=.04). Although the role of gender and engagement should be more thoroughly examined in future studies, this finding is consistent with other research on platform components [60].

Tables 13 and 14 list the engagement with checklist use and age. Members aged 41 to 50 years and 51 to 60 years were significantly less likely to click on a to-do checklist item (z score=2.1; P<.04) than members aged 18 to 30 years (z score=4.35; P<.001). No other differences were found between the age groups.

</tbody>
</table>

aOR: odds ratio.
The course component with the highest completion rate was *complete the depression and anxiety test*, with 51.4% (60/117) in arm 3, 47% (17/36) in arm 2, and 24.1% (47/195) in arm 1. The course component with the lowest completion rate was *upload my image*, with 18.65% (357/1914) in arm 3, 1.9% (16/865) in arm 2, and 0.73% (13/1788) in arm 1.

As mentioned previously, the 2 items *read a community post* and *complete the depression and anxiety test* were not seen by all members. Some Evolution Health clients do not offer these 2 tools to their membership base. Consequently, there are high engagement percentages but low member use.

For technical reasons, the completion of 2 components *review a worksheet* and *watch the getting started video* were not captured in arm 1. However, about one-third of the members in arm (606/1914, 31.66%) reviewed a worksheet compared to about 2% of those (21/865, 2.4%) in arm 2, and almost half (923/1914, 48.22%) of the members in arm 3 watched the *getting started video* compared to about 3% of those (24/865, 2.8%) in arm 2.

Engagement with 6 of the 8 measurable components was higher in arm 2 than in arm 1 (z score=3.59; P<.001) and higher in arm 3 than in arm 1 (z score=10.91; P<.001). Engagement in 8 of the 8 components was higher in arm 3 than in arm 2 (z score=4.93; P<.001).

Overall, the use of the tips and to-do checklist items resulted in increased engagement. Members in the control arm completed an average of 1.52 course components versus 1.8 course components in arm 2 and 2.11 course components in arm 3.

**CBT Course Completion Rates**

The purpose of CBT is to help individuals deal with overwhelming problems; this is achieved by teaching people how to deal with negative thoughts and beliefs [61]. In traditional in-person therapy, the duration of CBT treatment depends on a variety of factors, including health disorders (eg, depression, anxiety, posttraumatic stress disorder, and sleep disorders), symptom severity, duration of therapy, practitioner availability, cost, willingness of the patient to do homework, convenience, culture, treatment settings, and the therapeutic alliance [62].

The recommended duration of CBT varies. Harvard Medical School recommends 30- to 60-minute sessions over 12 to 20 weeks [63], the United Kingdom’s National Health Services recommends 30- to 60-minute sessions once a week or every 2 weeks for 6 to 20 sessions [64], and the Mayo Clinic states that therapeutic encounters can range from 5 to 20 sessions [65].

According to the US National Institutes of Health’s National Library of Medicine, some people undergoing CBT feel much better after a few sessions, whereas others need treatment for several months [66]. In Canada, the Centre for Addiction and Mental Health notes that some people improve in 4 to 6 sessions, whereas others may need >20 sessions [67].

Structured CBT sessions are 1 of the 8 course components in the Evolution Health platform, and like the 7 other course components examined in this study, members’ engagement is optional. The courses Overcoming Depression and Overcoming Anxiety both comprised 9 sessions. On average, 41% (1851/4567) of the members chose to engage with and complete session 1 (Table 15).

If members completed a course, they received a course completion certificate (Figure 9).

Unlike the platform’s addiction courses, where some members are incentivized by customer sponsors to complete a course (eg, some human resource clients reward their employees for completing the quit smoking behavior change course), to the best of our knowledge, participants in the Overcoming Depression and Overcoming Anxiety courses were not rewarded for course completion or receiving a certificate.

Although the goal of CBT is to decrease symptoms and the duration of treatment varies widely per individual, course completion may be a poor indicator of wellness. However, as engagement is the primary measure of this study and the literature indicates that higher levels of engagement are associated with improved health outcomes, it may be beneficial to form a baseline observation for course completion rates.

Regarding course completion, 31 members in the Overcoming Depression course and 88 members in the Overcoming Anxiety course received course completion certificates. There were no statistically significant differences in the course completion rates between the 3 arms.

In addition, 256 of 4567 members of the N members received a certificate for completing a supplementary 1-session *more help* course, which was less intense and dealt with specific subjects such as overcoming grief, problems in relationships, or role transitions. A greater proportion of members in arm 2 received more certificates for the *more help* course than did the members in arm 1 (P=.02). There were no differences of interaction between gender or age groups.
Discussion

This 3-arm randomized controlled trial tested whether behavioral nudges and prompts could be successfully applied within 2 self-guided treatment digital health programs for anxiety and depression.

Demographic Characteristics

The average age of the members was 43.8 years, and 87.3% (3987/4567) identified as female members. The average number of log-ins for female members was 2.83 versus 3.89 for male members. The average number of log-ins should be interpreted with caution, as in other studies on the Evolution Health population; engagement appears to follow the properties of power laws [53].

H1 Summary: Engagement With Behavioral Nudges and Prompts

Our H1 was to analyze whether the members would engage with the tips and to-do checklist.

Regarding gender, mixed effect logistic regression found that female members clicked on more tips than male members (z score=2.58; P=.01).

Members in arm 3 completed an average of 2.7 (34%) out of the 8 course components featured on the to-do checklist. Engagement ranged from 18.81% (360/1914; upload my image) to 51.4% (55/107; complete the depression and anxiety test).

Mixed effect logistic regression found that female members clicked on more checklist items than male members (z score=2.07; P=.04). Members aged 41 to 50 years and 51 to 60 years were significantly less likely to click on a to-do checklist item (z score=2.1; P=.04) than members aged 18 to 30 years (z score=4.35; P<.001). No other differences were found between the age groups.

Secondary Hypothesis Summary: Members’ Preference of Directive Tips in Arm 2 or Social Proof or Present Bias Tips in Arm 3

There were no statistically significant differences in the number of tips clicked on between directive tips in arm 2 and social proof and present bias tips in arm 3 (P=.25).

Tertiary Hypothesis Summary: Tips and to-Do Checklist

Completion rates of 6 out of the 8 course tools increased in both experimental arms from baseline use in arm 1. Completion rates in arm 2 were greater than those in arm 1 (z score=3.59; P<.001), and completion rates in arm 3 were greater than those in arm 1 (z score=10.91; P<.001).

A total of 2 out of the 8 course tools (review a worksheet and watch the getting started video) did not have arm 1 baseline statistics. However, completion rates for review a worksheet in arm 2 versus arm 3 increased from 2.4% to 31.66%. The completion rate for watch the getting started video increased from 2.8% to 48.22%.
Completion rates for the course component complete CBT session 1 were slightly higher in arm 2 (376/865, 43.5%) than in arm 3 (806/1914, 42.11%). Completion rates of arm 2 were greater than those in arm 1 (z score=2.99; P=.003), and completion rates in arm 3 were greater than those in arm 1 (z score=2.91; P=.004). Completion rates of the both arms 2 and 3 were significantly higher than those in arm 1 (669/1788, 37.42%).

The highest increase in course component use was for the upload my image component, with 0.73% (13/1788) of the members uploading an image in arm 1, 1.9% (16/865) in arm 2, and 18.65% (357/1914) in arm 3. This is interesting as personalization in digital applications is now common; however, the Evolution Health platform is designed to be anonymous, and before uploading, members were advised to only upload nonidentifying images.

However, high z scores require further investigation. For example, high scores may be due to arm 3 members being more likely to complete components than arm 1 members.

**CBT Course Completion Rates**

In the literature, efficacy studies analyzing general CBT completion rates are rare, and this is due to complexities surrounding the delivery of CBT for different indications, symptom severity, duration of therapy, practitioner availability, cost, willingness of the patient to do homework, convenience, culture, treatment settings, and therapeutic alliance.

Owing to the nature of the medium, measuring course completion rates in digital health courses is relatively simple. However, digital health courses should not be held to different standards than traditional in-person therapy, where treatment success is often measured by the therapist by observing decreases in symptoms.

In 2005, Eysenbach [11] published The Law of Attrition, which recognized that a substantial portion of users drop out of eHealth (digital health) trials before completion and that the high dropout rate makes the efficacy of digital health programs less believable. The paper noted that researchers often compare digital health dropout rates with those of clinical drug trials.

Similar to traditional CBT, where treatment can run from a few weekly sessions to >20 sessions, the digital health literature has shown dose-response effects. Users of self-guided digital health courses interact with devices, not trained therapists. Until digital health platforms can unobtrusively and accurately detect symptom severity, measuring course completion rates will continue to be an inaccurate measure of efficacy.

As higher levels of engagement are associated with improved health outcomes [20,21] and due to the complex methodological issues associated with establishing efficacy rates in population-based digital health CBT programs with high reach, research should continue to focus on strategies that increase adherence and engagement [8-10,12].

**Practical Implications**

The arm 3 home page is presently the default setting for the home pages for the Overcoming Anxiety and Overcoming Depression courses. We expect to see increases in course engagement based on the use of behavioral nudges and prompts. Ongoing data collection from all members will contribute to future research.

**Strengths and Limitations**

A strength of this study is that it was conducted in an ad libitum environment. Unlike many digital health studies, a large study population in the thousands was leveraged rather than smaller groups. As participants were not aware of participating in the experiment, this limited participant bias and the Hawthorne effect.

A limitation is that, especially due to the anonymity of members, we have no way of identifying participants or validating their demographic information. Although we have no way of knowing whether the registrants are people with depression or anxiety who are seeking help, the removal of nonparticipants should mitigate the effects on the overall results.

Some Evolution Health clients promote certain course tools, or health care professionals may direct their clients to use certain platform attributes. Therefore, the tips or to-do checklist items may not be a factor in their engagement. Second, many members may simply ignore the behavioral cues and complete certain course tools based on their own preference.

The behavioral cues related to read a community post and complete the depression and anxiety test were not seen by all members. This is due to these elements being feature flags and some Evolution Health clients choosing not to offer these tools to their membership base. Although this resulted in fewer members seeing these cues and having access to the course components, the percentage of members who viewed the cues and engaged with the components was noteworthy.

As this study was designed to form a baseline for future research, there are some methodological issues that can be explored further. For example, unlike the tips presented in arm 2, the use of tips in arm 3 may or may not have been influenced by adding the to-do checklist. Alternatively, using directive tips in arm 3, rather than social proof and present bias tips, may increase the use of the to-do checklist.

Notably, our evidence indicates that nudges and prompts increase engagement in self-guided treatment programs for depression and anxiety. On the basis of these encouraging yet preliminary results, we can proceed with more sophisticated studies that will examine more enhanced strategies designed to increase platform engagement.

**Future Directions**

As mentioned earlier, there has been scant published research regarding the implementation of behavioral economic strategies designed to increase engagement in digital health programs. At minimum, this randomized controlled trial was successful in confirming member engagement through the use of these strategies.

As recommended by Aschbacher et al [68] in a recent study involving digital mental health and dose responses, machine learning models can help enable precision by analyzing
engagement patterns over time. Combined with another recent paper by Forbes et al [24] analyzing digital interventions for depression, which noted that it is important to develop standardized ways of reporting adherence and engagement so that effective comparisons across different interventions could be measured, baseline outcomes need to be established.

The baseline outcomes of this study can serve as guidelines for future studies. With machine learning models in place and with the goal of improving member outcomes and platform efficacy, Evolution Health considers the following research questions:

• Will members of addiction-focused courses (eg, managing drinking and quitting smoking) follow similar engagement patterns if nudges and prompts are made available to them? Which nudges and prompts can be used universally, and which work best for specific mental health or addiction indications?

• The average member logged into the platform 2.38 times. Can specific tips be introduced at onset to promote log-ins?

• There were no statistically significant differences in the number of tips clicked on between directive tips in arm 2 and social proof and present bias tips in arm 3 (P=.25). However, arm 2 featured 31 rotating directive tips and arm 3 featured 15 social proof tips and 15 present bias tips. Which tips were most engaging (eg, directive, social proof, or present bias tips)? Which content areas were most engaging (eg, goal setting, community themed, or specific exercises such as the depression and anxiety tests)? Which tips were the most engaging for specific age groups?

• The average arm 3 member clicked on 2.7 out of 8 to-do checklist items. Which items were those members most likely to click on first? Were there specific patterns of engagement that may influence which tips should be shown to specific members?

• The course components differ in the effort required to complete them. For example, completing a CBT session is more intensive than the few minutes required to complete the depression and anxiety test. Furthermore, one member may take several minutes to contemplate their goals, whereas others may have concrete goals already established. Future research should analyze duration in relation to each course component, as these data may be leveraged to create tailored tips or to-do content for specific user engagement patterns.

• The AVD for members who engaged with depression and anxiety course tools ranged from 6 minutes and 45 seconds, with 7.65 pages viewed, to 24 minutes and 21 seconds, with 12.56 pages viewed. In the future, AVD may be used as a benchmark, as overall engagement may be an important metric to calculate when observing dose-response relationships.

• Members arrived at the platform through the free-to-consumer program and white-label instances licensed by clients that range from employers, insurance companies, employee assistance programs, educational institutions, nonprofit organizations, for-profit health care organizations, and individual therapists. Measuring AVD from these referral sources and patterns of course tool use may assist in creating targeted engagement recommendations.

• The depression and anxiety test has been validated in a separate study, and the algorithm reports whether members qualify for 30 separate mood and anxiety disorders [48]. Symptoms related to these disorders were also collected and reported to the members. Future research should analyze these data to investigate the possible relationships between symptomology, symptom severity, and engagement patterns.

• A recent paper by Forbes et al [24] analyzing patient adherence with digital interventions for depression noted that it is important to standardize reporting adherence and engagement. Our future work will focus on establishing baseline metrics. For example, an acceptable click rate for a tip is x% or an acceptable click rate for a to-do checklist item is y%.

• The platform contains courses for addictive behaviors (eg, smoking cessation and problem drinking), in which members who complete these courses receive a certificate of completion. We are aware that some workforce members received incentives from their human resources department for completing courses and receiving certificates. It may be worthwhile to compare the course completion rates between incentivized addictive behavior courses and nonincentivized mood disorder courses.

• This experiment examined the use of behavioral prompts. Future studies may examine overcoming behavioral barriers such as bounded rationality or choice architecture.

It cannot be assumed that the outcomes observed on the Evolution Health platform will be replicated in other environments. Further research in the combined fields of digital health and behavioral economics is required.

Conclusions

Members of the Evolution Health platform’s self-guided digital health courses engaged with behavioral nudges and prompts. From this preliminary analysis, it appears that both the tips and to-do checklists increased engagement in course components. To the best of our knowledge, this is the first randomized controlled trial designed to test the implementation of behavioral nudges and prompts in web-based self-guided courses for mood disorders. The results of this study may be important because efficacy is related to increased engagement.

Owing to its novel approach, the outcomes of this study should be interpreted with caution but may be used as a guideline for future research.

Data Availability

The data sets generated during and analyzed during this study are not publicly available due to Evolution Health’s data privacy policy, terms of use, and user agreement but are available from the corresponding author on reasonable request.
Research emerging from this and ongoing data collection will be leveraged to train artificial intelligence models to better understand how to increase and encourage healthy behavior changes. Making these data publicly available may have the opposite effect and enable the development of models that can detect and target susceptible populations.

The rich data set from this study, ongoing engagement data that are continually collected, or other platform data sets can be made available to researchers interested in conducting studies for noncommercial purposes. Interested researchers are encouraged to contact Evolution Health.

Conflicts of Interest

TVM is the chief executive officer and founder of Evolution Health, the owner of the Evolution Health digital health care platform. RF is an Evolution Health board member. No funds were received for conducting this study.

Abstract

Background: Digitalizing oral health data through an app can help manage the extensive data obtained through oral health surveys. The Tooth Memo app collects data from oral health surveys and personal health information.

Objective: This study aims to evaluate the evaluate the time efficiency, reliability, and user satisfaction of the Tooth Memo app.

Methods: There are 2 sections in the Tooth Memo app: oral health survey and personal oral health record. For the oral health survey section of the Tooth Memo app, different data entry methods were compared and user satisfaction was evaluated. Fifth-year dental students had access to the oral health survey section in the Tooth Memo app during their clinical work. The time required for data entry, analysis, and summary of oral health survey data by 3 methods, that is, pen-and-paper (manual), Tooth Memo app on iOS device, and Tooth Memo app on Android device were compared among 3 data recorders who entered patients’ information on decayed, missing, and filled permanent teeth (DMFT) index and community periodontal index (CPI), which were read aloud from the database of 103 patients by another dental personnel. The interobserver reliability of the 3 different data-entering procedures was evaluated by percent disagreement and kappa statistic values. Laypeople had access to the personal oral health record section of this app, and their satisfaction was evaluated through a Likert scale questionnaire. The satisfaction assessments for both sections of the Tooth Memo app involved the same set of questions on the app design, usage, and overall satisfaction.

Results: Of the 103 dental records on DMFT and CPI, 5.2% (177/3399) data points were missing in the manual data entries, but no data on tooth status were missing in the Android and iOS methods. Transferring data from paper to computer took an average of 55 seconds per case. The manual method required 182 minutes more than the iOS or Android methods to clean the missing data and transfer and analyze the tooth status data of 103 patients. The users, that is, 109 fifth-year dental students and 134 laypeople, expressed high satisfaction with using the Tooth Memo app. The overall satisfaction with the oral health survey ranged between 3 and 10, with an average (SD) of 7.86 (1.46). The overall satisfaction with the personal oral health record ranged between 4 and 10, with an average (SD) of 8.09 (1.28).

Conclusions: The Tooth Memo app was more efficacious than manual data entry for collecting data of oral health surveys. Dental personnel as well as general users reported high satisfaction when using this app.

Introduction

Oral diseases such as tooth decay and gum disease remain prevalent in Thailand. According to the eighth National Oral Health Survey conducted in 2017 in Thailand [1], a significant percentage of the Thai population (31.2%-73.8%) had untreated caries, and less than 20% of the population was free of gum disease. The oral health survey is a crucial epidemiological method in dental health care that helps to understand the extent and prevalence of oral health problems [2]. The survey also provides preliminary data for planning projects to promote oral health locally and nationally [3]. Thailand conducts its national oral health survey every 5 years, recording several complex oral health measures according to the World Health Organization guidelines [4]. However, collecting data on oral health can be a time-consuming and error-prone process, leading to potential inaccuracies in diagnoses and treatment plans. Fortunately, advancements in mobile technology have made it possible to streamline data collection and analysis, providing a more efficient and reliable approach to oral health management.

Collecting data using pen-and-paper can lead to errors when transferring data to an electronic database due to poor legibility, unclear handwriting, smudged or fading ink, etc. Furthermore, manually entering data from a large number of participants into a database can be time-consuming. In today’s modern era, using technological devices in health care is becoming increasingly common [5-7]. Therefore, using an app on smartphones or tablets to input data may be more convenient than using computers and can increase the speed of analyzing and summarizing data [8,9], save time in transferring data from physical documents to electronic forms [10], and minimize paper expenses [10]. In the long term, data collected in mobile apps may help in the development of a database for research and advance the understanding of the state of oral health nationwide. Mobile apps for dental health care can be useful for improving access to oral care information, promoting preventive measures, simplifying appointment scheduling, monitoring the health of children and young people, and potentially offering features for virtual consultations or teledentistry [11,12]. The implementation of mobile health has the potential to enhance the delivery of health services [12]. Unfortunately, no mobile app is currently available for collecting oral health survey data. However, many mobile apps for oral health promotion aim to increase knowledge and promote healthy oral health behaviors [13].

The Oral Health Survey Mobile Application (OHSMA) [14] was created to collect data of oral health surveys. Unfortunately, OHSMA was only available on Android devices. iOS users could only access OHSMA through a web-based platform that required internet connectivity. Dental health professionals found the app inconvenient to use because of its limited availability. Due to these issues, the use of OHSMA was discontinued. A new offline-capable app would be more beneficial for digitizing oral health survey data. It is important to note that dental history plays a significant role in forensic identification. However, obtaining patient records can be challenging because these may be spread across different hospitals and clinics [15]. A dental history record of the general population could be a potential solution to this challenge. Additionally, an individual’s oral health record could provide better insight into their past treatments, which could help dental professionals plan future dental services. A possible solution to address the challenge of oral health care in the general population is to create an individual dental history record. This record could provide valuable information to dental professionals about an individual’s past treatments, enabling them to plan better dental services for the future. Furthermore, people can maintain a personal oral health record to remember past oral health events and share it with their dentists. It is also important to note that the general Thai population does not visit dentists regularly [16], and raising awareness of oral health concerns could help encourage more regular dental checkups.

Introducing Tooth Memo—the revolutionary mobile app designed to digitize oral health survey data and personal oral health information. Unlike OHSMA [14], its predecessor, Tooth Memo is an improved version and is compatible with both Android and iOS devices. Tooth Memo can be used offline, thereby making it very useful for conducting oral health surveys in areas with limited internet connectivity, especially in rural areas. This app offers several upgrades that can help health care workers to interpret the data more efficiently. For example, this app can calculate the mean decayed, missing, and filled permanent teeth (DMFT) index for all participants in each survey instantly and notify the health care worker if the examination is incomplete or complete. Tooth Memo has not only dental health surveys but also other survey forms for dental development and research. The current version of the Tooth Memo app is designed to provide a more constructive experience for health care workers, making it easier for them to conduct oral health surveys and interpret the data more efficiently. This innovative app offers dental health professionals a convenient and user-friendly way to input data, thereby saving time and cutting down on paper expenses. Due to the addition of new design features, enhanced appearance, and increased functions in the Tooth Memo app compared to those in OHSMA, user satisfaction with this app was re-evaluated. By providing dental health professionals with a reliable and efficient tool for data collection, Tooth Memo has the potential to improve the quality of dental care and promote better oral health outcomes for all. This study was conducted to evaluate the time efficiency, reliability, and user satisfaction of the Tooth Memo app.

Methods

Study Population and Methodology

This cross-sectional study compares the efficiency of 3 data collection methods for oral health surveys and explores the user satisfaction with the Tooth Memo app. The 3 methods for oral health survey data collection are (1) pen-and-paper (manual), (2) Tooth Memo app in iOS (iOS), and (3) Tooth Memo app in Android (Android). The Tooth Memo app was designed for 2 types of users: dental personnel who record oral health survey data and laypeople who record their own oral health information.

Tooth Memo App

The Tooth Memo app is designed for dental professionals to easily collect and analyze oral health survey data as well as manage personal oral health records. The Tooth Memo app is an improved version of OHSMA [14], in which the pitfalls or weaknesses of OHSMA have been addressed. This app is available for installation from the App Store or Play Store in both iOS and Android devices, respectively, and supports Thai or English language use based on the device setting. iPhone or iPod touch requires iOS 13.0 or later versions. Android phones require Android 6.0 and later versions. There are 2 account types in this app: (1) dental personnel and (2) general user (Figure 1).

Figure 1. Screenshots of the (A) first page, (B) Android sign-in page, (C) iOS sign-in page, and (D) account selection in the Tooth Memo app.

The Tooth Memo app has 2 main sections. The first section, that is, oral health survey (Figure 2), allows dental professionals to record the oral health survey data according to the fourth and fifth editions of World Health Organization Oral Health Surveys-Basic Methods [4,17]. Dental personnel can record dentition status [17]; prosthetic needs; number of posterior occlusal pairs; DMFT index; and the decayed, missing, and filled permanent surfaces (DMFS) index. Gingival health can also be recorded using the community periodontal index (CPI) [4] and simplified oral hygiene index [18]. Tooth Memo provides a function for uploading individual characteristics, including name, gender, and age of each survey participant, for convenient usage. Dental personnel can collect the surveyed data on each device with or without internet connectivity. The recorded data will be retained in each data-entering device, and a summary report can be created and exported as an Excel spreadsheet. The user can also upload the name list of the sample before the survey. There are notices for incomplete data collection.
Figure 2. Screenshots of the oral health survey in the dental personnel feature: (A) first page, (B) gingival status forms, (C) dental status forms, and (D) list of participants.

Figure 3. Screenshots of the personal oral health record in the general user feature: (A) first page, (B) tooth type selection, (C) dental chart for data entry, and (D) status and treatment for each tooth.
Capability Assessment

The study aims to test the interobserver reliability of 3 different data-entering procedures, namely pen-and-paper (manual), iOS app (iOS), and Android app (Android), using the dentition status (DMFT) and gingival status (CPI) of 103 patients from the database of the Department of Community Dentistry, Chulalongkorn University. For each data-entering procedure, 3 data recorders entered each patient’s information on DMFT and CPI, while a dental personnel read out this information aloud simultaneously from the database. The data recording by pen-and-paper was transferred to the computer, and the timing for entering and summarizing the data in the manual method was recorded. The interobserver reliability was assessed using test-retest reliability (κ) and percent agreement among different methods.

Satisfaction Assessment

Oral Health Survey

1. Dental students collected oral health survey data through the Tooth Memo app during their clinical work, and their satisfaction with the app was evaluated using a questionnaire. These students had no experience with other apps for oral health surveys, although they are familiar with mobile apps. Tooth Memo is their first app for oral health surveys. Each dental student examined 4-8 patients during their clinical work.

2. In this study, all fifth-year dental students of the 2022 academic year from the Department of Community Dentistry, Faculty of Dentistry, Chulalongkorn University, were recruited.

Personal Oral Health Record

1. Laypeople who can read Thai and voluntarily participated in this study recorded their dental status and treatments in Tooth Memo, and their satisfaction was evaluated after using the app.

2. The minimum sample size for this study was estimated using the GPower 3.1 Program [19] for a 1-sample case. The 2-sided t test for difference of means from constant (1-sample case) was used for calculating the required sample size by given α (.05), power (.95), and effect size (0.318) [14]. The suggested total sample size was 131.

Overall Satisfaction

User satisfaction was evaluated with a newly developed self-administered questionnaire in Thai via a Google form. The questionnaire had undergone a thorough revision process based on the findings of a previous study [14]. Modifications were made to improve the clarity and relevance of the questions. The revised questionnaire was then pilot-tested in a sample group to evaluate its effectiveness in capturing the intended information. The feedback from the pilot test was used to further refine the questionnaire and ensure that the questions were clear, concise, and easy to understand. The questionnaire had 2 parts, with identical questions for each section of the Tooth Memo app (personal oral health record and oral health survey). Satisfaction with the design and usage of Tooth Memo and the overall satisfaction were evaluated. The satisfaction questions on the design of Tooth Memo were related to the font style, size, and color, appropriate and sufficient content in each page, continuity in content across pages, and the channel for consultation if a problem occurs. The satisfaction questions on the usage of Tooth Memo included registration, recording the data, summary and report, searching the recorded data, and loading speed. Each part of the questionnaire had nine 5-point Likert scale questions concerning users’ satisfaction. The scores ranged from 1 to 5 (1=least appropriate, 2=less appropriate, 3=moderately appropriate, 4=highly appropriate, and 5=most appropriate). Additionally, there was an 11-point rating scale (0-10 points) concerning overall satisfaction.

Data Analysis

Capability Assessment

We compared the errors incurred and time taken for data entry and data summarizing among the 3 methods. Inter-rater reliability was analyzed using Cohen kappa [20], Fleiss kappa, and percent disagreement [21]. This study follows the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) guidelines [22] for reporting.

Satisfaction Assessment

User satisfaction was analyzed using SPSS software (version 29.0; IBM Corp) through descriptive statistics, mean, standard deviation, frequency, and percentage. The proportion of each score among the satisfaction questions was analyzed using frequency and percentage.

Ethics Approval

The study protocol was approved by the Human Research Ethics Committee of the Faculty of Dentistry at Chulalongkorn University (HREC-DCU 2023-001) before the study began. Consent was obtained from the Department of Community Dentistry, Chulalongkorn University, to access data for the research. The participants were provided with a clear information sheet outlining the project’s aims, and they were free to choose whether they wanted to participate in this study. The questionnaires were designed to be anonymous. The study participants were informed that they could withdraw from the research at any time and were not obligated to complete the questionnaire. Completing and submitting the questionnaire were considered as participants’ consent to participate in this study. As compensation for their time, a toothbrush was given to the participants.

Results

In 103 dental records, 5.2% (177/3399) data points were missing in the manual entries. However, the Android and iOS methods showed no missing data on tooth status. It is worth noting that complete CPI information was provided by all 3 methods.

Capability Assessment

Our findings showed that analyzing the dmft/DMFT (decayed, missing, and filled primary teeth/decayed, missing, and filled permanent teeth) data on iOS and Android platforms takes less than a minute. The app performed the dmft/DMFT calculations; so, the time required for data analysis is negligible. In the manual method, transferring data from paper records to the
The computer took 95 minutes, averaging approximately 55 seconds for each case. Additionally, cleaning up missing data consumed 63 minutes, while the analysis of DMFT required an additional 25 minutes. As a result, the manual method took 182 more minutes than the iOS or Android method to transfer data to the computer and analyze the data of 103 patients. The summary of the time taken for each step in the data entry methods can be found in Multimedia Appendix 1. Of the 103 patients, 42.7% (44/103) were females and 7-10 years of age, with an average age of 7.40 (SD 0.61) years. The dmft and DMFT of 103 patients were 5.32 and 0.29, respectively. dt/DT (decayed primary teeth/decayed permanent teeth), mt/MT (missing primary teeth/missing permanent teeth), and ft/FT (filled primary teeth/filled permanent teeth) were 4.83/0.23, 0.18/0, and 0.31/0.06, respectively. Moreover, 5.8% (6/103) of the patients had healthy gingival status (CPI score = 0) and 11.6% (12/103) needed scaling (CPI score = 2). The overall Fleiss kappa was 0.93 among the 3 methods, and Table 1 shows the Cohen kappa and percent disagreement among the 3 methods. The Tooth Memo app in both iOS and Android platforms showed superior results compared to those obtained using pen and paper. The iOS and Android versions of the app recorded complete data with no missing information. Additionally, there was a lower percentage of disagreement between the data collected using the app on the iOS and Android platforms.

Satisfaction Assessment

In this study, 109 fifth-year dental students aged 21-23 years collected oral health survey data in Tooth Memo during their clinical work. Of these students, 62.4% (68/109) were males. The overall satisfaction of the users ranged between 3 and 10, with an average (SD) of 7.86 (1.46) (Figure 4A). The users were generally satisfied with the app’s design and usage, with average scores ranging from 4.0 to 4.18. The average design satisfaction scores ranged from 4.0 to 4.17, while the average usage satisfaction scores ranged from 4.06 to 4.18. The medians of the design and usage satisfaction scores were both 4. The design satisfaction scores of each question ranged from 2 to 5 (Table 2). Most fifth-year dental students used tablets rather than mobile phones, and most of them used the iOS platform. The proportions of satisfaction levels for each question are presented in Figure 4B.

In our study, 134 laypeople reported their satisfaction after using the personal oral health record section of Tooth Memo. The users were 15-80 years old, and 26.9% (36/134) were males. Equal numbers of laypeople used the iOS and Android platforms to access the personal oral health record section of the Tooth Memo app. The overall satisfaction scores ranged between 4 and 10, with an average (SD) of 8.09 (1.28) (Figure 5A). The laypeople were generally satisfied with the app’s design and usage, with average scores ranging from 4.02 to 4.15. The average design satisfaction scores ranged from 4.02 to 4.16, while the average usage satisfaction scores ranged from 4.06 to 4.15. The medians of the design and usage satisfaction scores were both 4. The design satisfaction scores of each question ranged from 2 to 5, and the proportions of different satisfaction levels for each question are shown in Figure 5B.

**Discussion**

The Tooth Memo app demonstrated good reliability, high time efficiency, and high user satisfaction. Tooth Memo was developed based on the experience of OHSMA [14] and interviews with stakeholders. The Tooth Memo app has various forms for different indexes in the oral health survey. User-friendly functions were developed, such as operating without internet connectivity, a button for patients with no tooth decay, notification of completeness of data collection, and provision of only the necessary active buttons. The recorded data will be stored in each device. All recorded data and the analysis results can be exported into an Excel form.

Tooth Memo provides only the necessary active buttons at each data entry point to minimize data entry mistakes. Screenshots of the active buttons for each data entry point, that is, tooth status, treatment need of each tooth, and gingival status are shown in Multimedia Appendix 2. During the design phase, there was a concern regarding the size of the button. Eventually, it was decided that the button should be large enough to...
accommodate data collection. In mobile devices, the button size is 8x8 millimeters, while in tablets, it is 12x12 millimeters, which makes data entry easier. For process simplicity, registration is only required once for each device during the first use. These points were not included in the satisfaction assessment but were open for comments at the end of the survey. However, no comments were received regarding these points.

This app can benefit researchers, as it has various forms for recording the gingival and dental status. Screenshots of the DMFS, active buttons, and code explanations are given in Multimedia Appendix 3. The dmfs/DMFS (decayed, missing, and filled primary surfaces/DMFS) with the explanation for each code is given in Multimedia Appendix 3. There are functions for reducing the time for data collection, such as the “no tooth decay” button for patients without tooth decay (Multimedia Appendix 3) and the active button’s automatic move after each data entry. The participant name list can be uploaded in the app before going to the site for data collection so that the time spent in filling those data at the site can be saved. Moreover, Tooth Memo can display the data collection status of each participant (Figure 2D). The users who participated in the oral health survey were fifth-year dental students. Although their familiarity with using mobile apps may have influenced their satisfaction results compared to other age groups, they were able to provide valuable insights about the user interface and suggest areas for improvement.

Additionally, Tooth Memo can be an individual’s personal dental history recorder. The tooth status and dental treatment of each tooth can be recorded along with the date of examination and treatment, especially endodontic treatment, which needs further dental procedures. The scatter data of each person can be gathered in their device along with the date and place. The recorded data will benefit future treatment plans or even forensic purposes. The accuracy of recording can be enhanced if each individual can ask the dental personnel about their tooth status and treatment after their dental visit.

This study examines the capability of the “Tooth Memo” for collecting oral health survey data. The time spent on data entering was controlled by simultaneous data entry using the 3 methods. The difference between the time taken in the manual method and the time taken in the iOS or Android methods was attributed to the time spent for transferring data into a computer, cleaning the missing data, and analyzing the data. The manual method takes 182 more minutes than the iOS or Android method because a previous study [14] had already shown higher satisfaction with the mobile app than the pen-and-paper method.

All users indicated high satisfaction with the design and usage of Tooth Memo. Responses to all satisfaction questions indicated high user satisfaction for both sections of Tooth Memo. We did not compare the satisfaction rates between the manual method and the iOS/Android method because a previous study [14] had already shown higher satisfaction with the mobile app than the pen-and-paper method.

As Tooth Memo is a newly developed mobile app, users may not be familiar with the app. However, app unfamiliarity might be present only in the learning period. Nevertheless, some users did indicate low satisfaction with both sections of Tooth Memo. Some comments for improvement were related to enhancing the design by adding new interactive and attractive user-friendly features and increasing the stability of the app.

We do not have any other app to compare with our app. Our app is the first of its kind to collect oral health survey data and provide personalized individual oral health records. We are aware of other data collection apps for health [5,6,12,23-28] and non–health data [29-31], but there is no specific app like ours. There was only 1 app [14] for oral health survey data collection, but it was discontinued due to its inconvenience. Therefore, we were unable to make any comparisons. Interestingly, there are many apps [12,13,32-45] for oral health promotion that aim to promote knowledge and behaviors related to oral health; there is also an artificial intelligence app that can detect dental caries [43]. Our app follows the standard format used by most apps such as banking or other utility apps.

As per the feedback provided by some users, there are some areas for improvement in Tooth Memo’s oral health survey section. Although this app has a user-friendly interface and can record the data of a large number of participants in each survey and can record many surveys, there are some disadvantages that need to be considered. The log-in system is unstable on the new version of iOS, data files cannot be exported on certain devices, and there is no interface for iPad users. Additionally, data cannot be shared among users with the same account, and there were some miscalculations in the summary data. To improve the system, these issues need to be addressed. Despite these drawbacks, the survey provides explanations for each code, collects both dental and gingival status, and provides a summary of each participant’s data, along with the data collection status for each participant. Similar to other mobile apps such as the
electronic medical records app [46] and Ru Tan Ya app [47]. Tooth Memo enhances the effectiveness of self-care, improves continuity of care, simplifies data collection, decreases overhead costs, reduces mortality in various kinds of patients, saves time for professionals, and helps to avoid transcription errors.

The Tooth Memo mobile app is an innovative tool that empowers individuals to take control of their oral health. By providing accurate data on previous treatments, this app helps users make informed decisions about their dental care. It also serves as a helpful reminder for any untreated teeth that require attention, ensuring that users stay on top of their oral hygiene. Additionally, this app offers a convenient mobile record of an individual’s dental health history, which can be a valuable resource for those who do not regularly visit the dentist. Overall, this app is an excellent resource for anyone looking to improve their oral health and increase their oral health literacy. But Tooth Memo is not just a game changer for data collection. This app also has the potential to significantly aid in forensic identification, as a record of an individual’s oral health history can provide valuable insight into their past treatments and dental services. Furthermore, having a record of the dental history of the general population can make it easier for the health care system to obtain patient records, which are often scattered across different hospitals and clinics.

There are several mobile apps for data collection [29-31,48] for various types of research. These apps incur a lower cost and are more effective for data collection than the pen-and-paper method similar to the findings reported in our study. Digital data collection can provide more data security, accountability, and accuracy, save time, and even reduce costs.

One limitation of this study is that the Tooth Memo app is currently in the development stage and is not widely used. Therefore, we cannot conduct a long-term study yet to explore and analyze the results from different groups of participants. However, once this app is launched to the public, we will be able to gather more data and make necessary improvements to provide an effective and user-friendly app that meets the needs of the users. Since this is the first app for oral health survey data collection and personalizing individual dental history, there is no comparable information to compare the satisfaction levels of users. Nonetheless, the feedback provided by the users was useful for further improvement.

The Tooth Memo app significantly reduces the time and effort required for data entry and analysis. This app also had fewer missing data points and lesser disagreement between data entry platforms. Users expressed high levels of satisfaction with the app’s design and functionality.

Acknowledgments
We wish to express our gratitude to the Ratchadaphiseksomphot Endowment Fund, Chulalongkorn University, for funding this project. We also extend our thanks to Mr Kiratijuta Bhumichitr and his team for developing the software. We appreciate the support and assistance provided by all the participants and colleagues in completing this project. Additionally, we would like to thank Professor Lakshman Samaranayake for his invaluable suggestions during the rewriting process.

Data Availability
The data sets generated during and analyzed during this study are available from the corresponding author on reasonable request.

Authors’ Contributions
PPP analyzed the data and interpreted the results. PD and PPP conceived the ideas, designed the software and this study, collected and validated the data, wrote, critically revised, and gave the final approval of this manuscript.

Conflicts of Interest
None declared.

Abstract

Background: There is an ongoing debate about whether digital mental health interventions (DMHIs) can reduce racial and socioeconomic inequities in access to mental health care. A key factor in this debate involves the extent to which racial and ethnic minoritized individuals and socioeconomically disadvantaged individuals are willing to use, and pay for, DMHIs.

Objective: This study examined racial and ethnic as well as socioeconomic differences in participants’ willingness to pay for DMHIs versus one-on-one therapy (1:1 therapy).

Methods: We conducted a national survey of people in the United States (N=423; women: n=204; mean age 45.15, SD 16.19 years; non-Hispanic White: n=293) through Prolific. After reading descriptions of DMHIs and 1:1 therapy, participants rated their willingness to use each treatment (1) for free, (2) for a small fee, (3) as a maximum dollar amount, and (4) as a percentage of their total monthly income. At the end of the study, there was a decision task to potentially receive more information about DMHIs and 1:1 therapy.

Results: Race and ethnicity was associated with willingness to pay more of one’s income, as a percent or in dollar amounts, and was also associated with information-seeking for DMHIs in the behavioral task. For most outcomes, race and ethnicity was not associated with willingness to try 1:1 therapy. Greater educational attainment was associated to willingness to try DMHIs and 1:1 therapy. Income was inconsistently associated to willingness to try DMHIs or 1:1 therapy.

Conclusions: If they are available for free or at very low costs, DMHIs may reduce inequities by expanding access to mental health care for racial and ethnic minoritized individuals and economically disadvantaged groups.

(JMIR Form Res 2024;8:e49780) doi:10.2196/49780

KEYWORDS
digital mental health; ethnicity; health disparities; internet-based CBT; cognitive behavioral therapy; intervention; mental health; mental health care; race; therapy
psychiatric medication as a first-line treatment, and more likely to be forcibly detained for mental health concerns [2,3]. The existence of these biases may, understandably, lead socially and economically disadvantaged individuals to distrust traditional mental health services [4,5], such as face-to-face, one-on-one therapy (1:1 therapy), in which an individual patient receives assessment and intervention from a specialty provider. Digital mental health interventions (DMHIs) leverage technology (eg, websites and apps) to provide mental health assessment or intervention. DMHIs such as internet-based cognitive behavioral therapy have demonstrated efficacy relative to control conditions such as waiting lists and care as usual and may have roughly similar efficacy to 1:1 therapy [6]. These interventions may have the potential to reduce the public health burden of psychopathology because both the general public and health providers appear to find them acceptable for use and dissemination [7-9].

Despite the promise of DMHIs, there is an ongoing debate about whether DMHIs can reduce racial and ethnic, as well as socioeconomic, inequities in access to mental health care. DMHIs may reduce economic barriers because most popular DMHIs offer a “freemium” model, in which users can access some content for free and pay to receive the full version of the intervention. Notably, even the “premium” versions of a DMHI are generally much less expensive than other forms of treatment. The 2 most popular smartphone apps for depression and anxiety, for example, require users to pay US $13-15 a month [10,11]. Furthermore, given that many popular DMHIs offer unguided self-help [10,12], DMHIs may appeal to individuals whose trust in traditional services has been undermined.

On the other hand, racial and ethnic minoritized individuals have been poorly represented in research on DMHIs [13]. Experts have also raised concerns that lower internet access, digital health literacy, awareness of digital health interventions, availability of culturally sensitive interventions, and ability to pay for digital health interventions may exacerbate existing inequities in access to care [14]. These factors may make DMHIs less appealing rather than more appealing to members of racial and ethnic minoritized groups and individuals from lower socioeconomic status [15-17]. Before touting DMHIs as having the potential to reduce disparities in access to mental health care, there should be evidence that these interventions are equally acceptable, or more acceptable, than traditional mental health services for racial and ethnic minoritized individuals or those from lower socioeconomic statuses [18].

In order to study the acceptability of DMHIs and 1:1 therapy is to measure the self-reported willingness of individuals to engage with these interventions. While querying willingness to use as a measure of potential engagement is not equivalent to the more face valid option of offering DMHIs and 1:1 therapy to large numbers of individuals and capturing racial and ethnic and socioeconomic differences in engagement, it is more feasible. According to the Theory of Planned Behavior [18], attitudes, norms, and perceptions, such as self-reported willingness to use, can be used to predict many different types of behaviors, such as seeking mental health treatment [19,20]. Thus, the relationship between attitudes and willingness to use self-help interventions could predict future use. Understanding the demographics of individuals most likely to use DMHIs and 1:1 therapy can help target engagement efforts and, consequently, broaden the reach of these evidence-based self-help interventions to racially and ethnically marginalized groups.

Objective

We conducted a nationally representative survey on participants’ willingness to use DMHIs and 1:1 therapy. Participants were adults living in the United States and recruited through the web-based survey research tool Prolific. Participants rated their willingness to use each treatment (1) for free, as well as their willingness to pay for the treatments (2) for a small fee, (3) as a maximum dollar amount, and (4) as a percentage of their total income. At the end of the study, we gave participants the option to engage in a behavior that we observed: information-seeking about DMHIs or 1:1 therapy. We also compare the relative willingness of participants to learn more about DMHI and 1:1 therapy.

Methods

Participants

Participants (N=423) were recruited through Prolific [21], a web-based survey platform. Participants were eligible if they were aged 18 years or older and lived in the United States. We obtained a sample of adults meant to be representative of the intersection of age, race and ethnicity, and sex-assigned at birth using US census data.

Measures

Demographics

We collected information on age (in years), gender identity (male, female, and nonbinary), yearly income (in US dollars), highest educational attainment, race, and ethnicity. Race and ethnicity were combined and defined as Asian, Hispanic, non-Hispanic Black, non-Hispanic White, or other (eg, multiracial or Middle Eastern).

Internalizing Distress

We measured internalizing distress with the Kessler Psychological Distress Scale (K6) [22,23]. K6 is a 6-item scale that asks participants the frequency of distress symptoms (eg, depression and nervousness) they have experienced over the past month on a 4-point scale (0=none of the time and 4=all of the time). Scores can range from 0 to 24, with higher scores indicating higher distress. K6 has been demonstrated to have criterion validity [24] and was an internally consistent measure of internalizing distress in this sample (α=.87).

Willingness to Pay

First, participants received descriptions of unguided DMHIs and 1:1 therapy. DMHIs were described as “websites, computer programs, or smartphone apps” that “include information and exercises designed to help people learn skills that improve their...
mental health or well-being.” It was further described that in unguided DMHIs, “individuals learn content from a website or an app on their own. They do not have access to a coach or mentor.” 1:1 Therapy was defined as “counseling in which people receive support from a trained mental health professional who has completed a degree in counseling psychology, clinical psychology, or a related field.” It was further clarified that in “one-on-one therapy from a professional, one individual receives support from one therapist.”

Willingness to pay was evaluated with a series of different outcomes, which were presented in a randomized order by treatment (DMHI questions first vs 1:1 therapy questions first):

1. For free: Participants were asked to rate their agreement with the statement “I would be willing to use an unguided web-based self-help program or smartphone app for free.” For 1:1 therapy, a parallel question was used, replacing “an unguided web-based self-help program or smartphone app” with “weekly one-on-one therapy with a professional.” Responses were recorded on a 7-point Likert scale (1=strongly disagree and 7=strongly agree) with a higher score indicating a greater willingness to use.

2. Low cost: Participants were asked to rate their agreement with the statement “I would be willing to pay US $13 per month for an unguided web-based self-help program or smartphone app.” For 1:1 therapy, a parallel question was used, replacing “an unguided web-based self-help program or smartphone app” with “weekly one-on-one therapy with a professional” and replacing “US $13 per month” with “US $100 per month (US $25/session).” Responses were recorded on a 7-point Likert scale (1=strongly disagree and 7=strongly agree) with a higher score indicating a greater willingness to pay. The value for DMHIs was chosen to reflect the cost of premium versions of unguided DMHIs. For 1:1 therapy, the values were chosen to reflect the cost of therapy with insurance coverage.

3. Maximum dollar amount: Participants were asked to type “the maximum dollar amount” they would be “willing and able to pay” for “an unguided web-based self-help program or smartphone app” and for “one-on-one therapy with a professional.” Responses were recorded as dollar amounts starting from US $0 and with a maximum of US $10,000,000, although they were capped at US $800 for 1:1 therapy and US $60 for DMHIs.

4. Percentage income: Participants were asked to enter “the maximum percentage” of their monthly that they thought they would be willing and able to pay for “an unguided web-based self-help program or smartphone app” or “one-on-one therapy with a professional.” Responses were recorded as percentage amounts in a 0% to 100% range. We opted to ask participants this question, in addition to a maximum exact dollar amount, given evidence that response quality tends to be better with percentage metrics than when asking people to answer in dollar amounts [25].

**Statistical Analyses**

The data and code for all analyses are available in the Open Science Framework website [26]. All analyses were performed in the R programming language [27] using R (version 4.3.1; R Core Team) with the R Studio GUI (version 2023.6.0.421; R Studio Team) [28]. A P<.05 was chosen as the criterion for statistical significance given the exploratory nature of the study. First, we present descriptive statistics to characterize the sample demographics by race and ethnicity. For categorical and ordered variables, we present the number of individuals endorsing each level of the variable. For continuous variables, we present means, SDs, and IQRs. Next, we report simple descriptive statistics (ie, median and IQR) on the various willingness to pay metrics by race and ethnicity.

To address potential differences in willingness to use DMHI and 1:1 therapy, we regressed the various willingness to use outcomes on race and ethnicity, educational attainment, and income, controlling for age and distress. For the ordinal outcomes (ie, agreement with willingness to use for free or for a small fee), the regressions were ordinal logistic regression [29]. For the percentage and raw dollar amount outcomes, we used linear regressions. For the binary outcome (ie, the decision to learn more or not about DMHI and 1:1 therapy), the regression of interest was a binary logistic regression predicting the selection of information (yes vs no). We verified that multicollinearity was low for the variables ultimately included in our model (ie, race and ethnicity, educational attainment, income, distress, and age). We also verified the results were not sensitive to influential cases and different modeling strategies (eg, using beta regression for the bounded percentage outcomes). Additionally, for the ordinal outcomes, we verified the proportional odds assumptions of ordinal regression were met for all the variables.

R packages were used for general programming needs (conflicted [30] and tidyverse [31]), to facilitate data cleaning and analysis (MASS [32], effects [33], broom [34], psych [35], rstantix [36], and effectsize [37]), and for making for tables (gtsummary [38], labelled [39], kableExtra [40], and flextable [41]) and figures (ggpubr [42], ggpubr [43], and scales [44]). When examining willingness to pay as a maximum percentage of financial resources, we addressed outliers through winsorization. Responses that were >3 SDs above the mean were set to the value 3 SDs above the mean (6 values were winsorized for willingness to pay for unguided DMHIs and 9 values were winsorized for one-on-one psychotherapy).

**Ethical Considerations**

The University of Pennsylvania Institutional Review Board approved this study (#843424). Participants provided written informed consent to take part in the study. The study consisted of a web-based survey lasting approximately 15 minutes. The study was described as being about attitudes toward different mental health interventions. Participants were informed that their data would be collected and analyzed in an anonymous fashion. Individuals were paid US $5 for their participation in the study.

**Results**

**Demographics**

The sample appeared fairly representative of the United States in terms of age, gender identity, as well as race and ethnicity.
There were differences between the racial and ethnic groups in age, income, and educational attainment (Table 1). Descriptive statistics for the various willingness to use and pay for DMHIs and 1:1 therapy are presented in Figures 1 and 2, respectively. Willingness to use DMHIs was relatively high when they are described as being “free.” Participants were much less likely to say they would be willing to use DMHIs if they had to incur a small fee to do so. Across these outcomes, racial and ethnic differences suggested that relative to non-Hispanic White individuals, racial and ethnic minoritized individuals were more willing to use or pay for DMHIs. Similarly, willingness to use 1:1 therapy was very high when they are described as being “free.” Willingness dropped when participants were asked to pay a small monthly fee (ie, US $100 or $25 per session) for 1:1 therapy.

Figure 1. Willingness to use digital mental health interventions (DMHIs) or one-on-one therapy (1:1 therapy) for free or a low cost in a nationally representative sample of Prolific users in the United States (N=423). (A) Willing to try DMHIs for free; (B) willing to try DMHIs for a small fee (US $13); (C) willing to try 1:1 therapy for free; and (D) willing to try 1:1 therapy for a small fee (US $100).
Figure 2. Willingness to use digital mental health interventions (DMHIs) or one-on-one therapy (1:1 therapy) as a percentage of income or a raw dollar amount in a nationally representative sample of Prolific users in the United States (N=423). (A) Willingness to pay for DMHIs as a percentage of income; (B) willingness to pay for DMHIs as a raw dollar amount; (C) willingness to pay for 1:1 therapy as a percentage of income; and (D) willingness to pay for 1:1 therapy as a raw dollar amount.

Willingness to Try DMHIs or 1:1 Therapy, if Free or a Small Fee

Table 2 shows the results of ordinal logistic regressions predicting willingness to use DMHIs or 1:1 therapy, when described as for “free” or for a small fee (ie, US $13 for DMHI vs $25 a week for 1:1 therapy), from race and ethnicity, education, and income, controlling for sociodemographic factors and internalizing distress. Race and ethnicity did not predict willingness to try DMHIs or 1:1 therapy for free or for a small fee, although the differences suggested racial and ethnic minoritized individuals were more rather than less willing to try DMHIs. Educational attainment appeared associated with a greater willingness to try DMHIs or 1:1 therapy for free, or 1:1 therapy for a small fee, but the effects of educational attainment on willingness measured crossed the \( P<.05 \) threshold. Income was not associated with willingness to willingness to try DMHIs or 1:1 therapy for free. It was associated with a willingness to try DMHIs or 1:1 therapy for a small fee, although the effect was small (Table 2).
Table 2. Race and ethnicity and socioeconomic factors as predictors of willingness to try digital mental health interventions (DMHIs) versus one-on-one therapy (1:1 therapy) for free or a small fee in a nationally representative sample of US adults (N=423).

**Willingness to Try DMHIs or 1:1 Therapy, as Percent of Income or Raw Dollar Amount**

Tables 3 and 4 show the results of regressions predicting willingness to pay for DMHIs or 1:1 therapy as a percentage of monthly disposable income (Table 3) or as a raw dollar amount (Table 4). Compared to non-Hispanic White adults, racial and ethnic minoritized individuals were willing to pay more for DMHIs as a percentage of their income (Table 3) or as a raw dollar amount (Table 4). Examining the pairwise contrasts revealed that these differences were the largest and statistically significant when comparing non-Hispanic Black adults to non-Hispanic White adults for a percentage of their income (P<.001; Table 3) or a raw dollar amount (P<.001; Table 4), as well as for Hispanic adults for a raw dollar amount (P=.04). The other minoritized groups, Asian and Other (eg, multiracial and Middle Eastern), appeared somewhat more willing to pay but the differences were small and not statistically significant.
Educational attainment was inconsistently associated with willingness to pay. For example, it appeared unrelated to willingness to pay for either DMHIs or 1:1 therapy (Table 3). However, when willingness was assessed on a dollar metric, greater educational attainment was associated with a greater willingness to pay for 1:1 therapy, with effects most pronounced for college graduates and those with a master’s degree or greater educational attainment. By contrast, although educational attainment was associated with greater willingness to pay for DMHIs, the pairwise contrasts comparing the educational groups to those with a high school degree or less were small and not statistically significant. Income was associated with a greater willingness to pay for both DMHIs and 1:1 therapy in raw dollar amounts (Table 4) but not as a percentage of income.

**Decision to Learn More About DMHIs and 1:1 Therapy**

Race and ethnicity predicted the decision to learn more about DMHIs \( (P=.02) \) and 1:1 therapy \( (P=.02; \) Table 5). Compared to non-Hispanic White individuals, non-Hispanic Black individuals, Hispanic individuals, and individuals classified as “Other” (eg, multiracial and Middle Eastern) were more likely to choose to learn more about both DMHIs and 1:1 therapy. Asian individuals were somewhat less likely to choose to learn about DMHIs but somewhat more likely to learn about 1:1 therapy. Educational attainment was associated with a decision to learn more about DMHIs \( (P=.02) \) but not 1:1 therapy \( (P=.30) \). Income was not associated with the decision to learn about DMHIs \( (P=.92) \) or 1:1 therapy \( (P=.20) \).

Discussion

Principal Findings

Across several metrics, we found that members of racial and ethnic minoritized groups were either willing to pay more for DMHIs than non-Hispanic White participants or had similar levels of willingness. These differences were especially large when comparing non-Hispanic Black and Hispanic adults to non-Hispanic White adults. Race and ethnicity was not a consistent predictor of willingness to use 1:1 therapy. The other sociodemographic factors had somewhat more predictable relation to willingness to use DMHIs and 1:1 therapy. More educated individuals were more likely to say they would pay for 1:1 therapy or try DMHIs if the interventions were free. Income was associated with a higher willingness to pay for services, although the associations were less consistent.

Limitations

While we recruited a nationally representative sample of individuals, our sample size (N=423) may have been too low to detect small associations between sociodemographic factors and willingness to use or pay that would nonetheless be of interest. Additionally, we did not measure participants’ experiences with DMHI, which was likely low, or 1:1 therapy, which was likely higher overall [45]. Finally, while our results are informative in terms of capturing attitudes toward DMHIs and 1:1 therapy, the data we collected are self-reports of a prospective, relatively low burden behavior and may not reflect the decision to use mental health services in the real world. A notable bias of self-report data includes a limitation on self-knowledge (eg, individuals may not be aware of how they would act in the event they needed to choose between DMHIs and 1:1 therapy) as well as a sometimes low correspondence between self-report and behavior [46]. Other possible biases include overly positive responding and social desirability (eg, individuals presenting themselves as more willing to seek treatment than they are likely to do in real life). It is worth noting that for these biases to affect our results, which pertain to racial or ethnic differences, the biases would have to operate differentially across the groups we considered.

Several strengths of this study are worth noting. First, we operationalized willingness to use and willingness to pay in a variety of ways that support a similar conclusion: that racial and ethnic minoritized individuals are willing to use and pay for DMHIs. Additionally, we measured a behavioral proxy of treatment seeking—a willingness to learn more about different interventions—to further contextualize our results. Finally, we explored racial and ethnic and socioeconomic differences in a diverse sample of individuals.

Comparison With Previous Work

Our results suggest that racial and ethnic minoritized individuals are roughly equally likely, or perhaps even more likely, to use DMHIs than non-Hispanic White individuals. Previous work has suggested that racial discrimination in health care may lead members of minority groups to lose trust in health care systems [4,5]. Given this history of discrimination and inequitable treatment in health care settings, alternatives to traditional services—such as unguided digital self-help interventions—may be especially appealing to members of socioeconomically disadvantaged groups and racial and ethnic minoritized individuals. An implication of these findings is that when low...
levels of engagement are seen in DMHIs, it is unlikely that these effects are due to racial and ethnic minoritized groups having an overall low willingness to use DMHIs and may instead reflect access issues (eg, DMHI advertisement not reaching racial and ethnic minoritized individuals). Additionally, our results revealed a notable reaction to costs: around two-thirds (65.2%, 276/423) of individuals are unwilling to use DMHIs if there is even a small cost associated with the interventions. These findings reiterate how costs may be a barrier to mental health treatment and support other calls to enhance the accessibility of DMHIs for racial and ethnic minoritized individuals [14,47]. Recent research has compared strategies to increase the adoption of DMHIs in health care [48]. Future research can explore the effectiveness of these strategies on increasing adoption of DMHIS, specifically, among racial and ethnic minoritized individuals.

Conclusions

These findings do not support the concern that DMHIs appeal selectively to racial and ethnic majority members and wealthier individuals. Instead, racial and ethnic minoritized individuals indicated a greater willingness to pay for DMHIs, and income was inconsistent with willingness to pay for DMHIs. The promotion of effective and affordable DMHIS could be an important way to reduce inequities and expand access to mental health care for socially and economically disadvantaged groups. Importantly, our results suggested that the willingness to use interventions when they are delivered for free is quite high for both DMHIs and 1:1 therapy.

Data Availability

The data sets generated during and/or analyzed during this study are available in the Open Science Foundation website [26].

Abstract

Background: Cybersecurity is a growing challenge for health systems worldwide as the rapid adoption of digital technologies has led to increased cyber vulnerabilities with implications for patients and health providers. It is critical to develop workforce awareness and training as part of a safety culture and continuous improvement within health care organizations. However, there are limited open-access, health care–specific resources to help organizations at different levels of maturity develop their cybersecurity practices.

Objective: This study aims to assess the usability and feasibility of the Essentials of Cybersecurity in Health Care Organizations (ECHO) framework resource and evaluate the strengths, weaknesses, opportunities, and threats associated with implementing the resource at the organizational level.

Methods: A mixed methods, cross-sectional study of the acceptability and usability of the ECHO framework resource was undertaken. The research model was developed based on the technology acceptance model. Members of the Imperial College Leading Health Systems Network and other health care organizations identified through the research teams’ networks were invited to participate. Study data were collected through web-based surveys 1 month and 3 months from the date the ECHO framework resource was received by the participants. Quantitative data were analyzed using R software (version 4.2.1). Descriptive statistics were calculated using the mean and 95% CIs. To determine significant differences between the distribution of answers by comparing results from the 2 survey time points, 2-tailed t tests were used. Qualitative data were analyzed using Microsoft Excel. Thematic analysis used deductive and inductive approaches to capture themes and concepts.

Results: A total of 16 health care organizations participated in the study. The ECHO framework resource was well accepted and useful for health care organizations, improving their understanding of cybersecurity as a priority area, reducing threats, and enabling organizational planning. Although not all participants were able to implement the resource as part of information computing technology (ICT) cybersecurity activities, those who did were positive about the process of change. Learnings from the implementation process included the usefulness of the resource for raising awareness and ease of use based on familiarity with other standards, guidelines, and tools. Participants noted that several sections of the framework were difficult to operationalize due to costs or budget constraints, human resource limitations, leadership support, stakeholder engagement, and limited time.

Conclusions: The research identified the acceptability and usability of the ECHO framework resource as a health-focused cybersecurity resource for health care organizations. As cybersecurity in health care organizations is everyone’s responsibility, there is potential for the framework resource to be used by staff with varied job roles. Future research needs to explore how it
Cybersecurity is a growing challenge for health systems worldwide as the rapid adoption of emerging technologies in health care has led to increased vulnerabilities to cyber threats; these threats can significantly erode public trust and compromise patient safety [1]. While the challenge has been increasing for some time, the COVID-19 pandemic put the health sector into the spotlight, leading to increased numbers of cyberattacks during the pandemic period. Such was the scale of activity in this period that the World Health Organization (WHO) reported a 5-fold increase in attempted cyberattacks directed at WHO staff and the wider public and called for increased vigilance globally [2]. Health care systems need to be prepared for threats to continuous operations and develop their resilience in a world with substantial and accelerated technological changes.

The health sector has unique vulnerabilities to cyberattacks, most importantly the threat to patient safety and the potential loss of human life. Other unique vulnerabilities include limited funding available (both for information computing technology [ICT] services and cybersecurity), particularly in public institutions, resulting in a lack of human resources and the ability to address legacy infrastructure across health systems. Cybercriminals have forced health and social care providers to pay large sums in ransom following cyberattacks to regain access to vital technology and systems that are essential for the day-to-day functioning and care of patients [3,4]. Excluding ransom sums demanded by hackers, the average cybersecurity incident costs a health care organization US $10 million [5].

Research into health care cybersecurity has highlighted important vulnerabilities at the global level. While there are a range of technological challenges in securing medical devices and systems, human error is the primary driver of cyber breaches. Estimates from electronic health record breaches in the United States suggest that 73% of incidents were due to poor human security (eg, carelessness or negligence and falling victim to phishing scams) [6]. In May 2021, the Irish health care system was struck by the Conti ransomware attack through a phishing email with a malicious Microsoft Excel (Microsoft Corporation) file attached, which affected more than 80% of its ICT infrastructure [7]. The implications of the attack on patients and services were substantial, as staff were locked out of systems and patient care was disrupted for several months [8]. Despite these challenges, there remains a lack of commonality of language and published global documents from multilateral organizations that provide comprehensive guidance for the health sector in strengthening cybersecurity.

Given the high stakes of maintaining secure health care ICT systems, it is critical to develop workforce awareness and training as part of a safety culture and continuous improvement within health care organizations. While there is limited research, current evidence suggests that providing cybersecurity training to staff is associated with improved cyber hygiene practices, including reduced phishing email click rates [9]. Although most cybersecurity toolkits and frameworks focus on practices across all critical sectors and are not specific to the health care context, more guidance for the health sector has been developed in recent years, including the Health Care and Public Health Sector Cybersecurity Framework Implementation Guide [10]. Nonetheless, such guidance is in its infancy, and there remain limited open-access, health care–specific resources to help organizations at different levels of maturity develop their cybersecurity practices.

In 2020, the Institute of Global Health Innovation, Imperial College London, published the Essentials of Cybersecurity in Health Care Organizations (ECHO) framework, developed through research on capacity and maturity levels across health care organizations worldwide and Delphi research with leading figures in the fields of cybersecurity, ICT, and health policy [11,12]. The ECHO framework, which includes 6 dimensions (Figure 1 [11]), outlines the most important elements for health care organizations to consider and can act as a “minimum standard” or an aspirational checklist, depending on an organization’s resources and its cyber maturity. Following its release, the research team worked with cybersecurity experts and web developers to create the web-based ECHO framework resource. This resource provides key guidance based on each component of the ECHO framework and a checklist that can be used by health care organizations to track progress. As the ECHO framework resource and checklist is designed to be used across high-, middle-, and low-income countries with varied critical infrastructure, it can also be downloaded and used offline.

This study aimed to assess the usability and feasibility of the ECHO framework resource. A secondary aim was to evaluate the strengths, weaknesses, opportunities, and threats associated with implementing the ECHO framework resource at the organizational level.
Methods

Study Design

We conducted a mixed methods, cross-sectional study of the acceptability and usability of the ECHO framework at individual health care organizations. A convergent parallel (also known as simultaneous triangulation) mixed methods design was used, which involved conducting qualitative and quantitative components simultaneously and giving them equal priority. The research team kept both components independent during data collection and analysis and only mixed data during interpretation. This design enabled the collection of different but complementary data on the same topic, which offers the benefits of reducing the limitations of qualitative or quantitative methodologies on their own, triangulating findings, and developing a fuller understanding of the research subject [13].

Ethical Considerations

The study protocol was approved by the Imperial College’s Science, Engineering, and Technology Research Ethics Committee (21IC6775). All participants were emailed information about the study, including a full participant information sheet, and asked if they would be interested in taking part. Participants were made aware that their participation is voluntary, and they were free to withdraw at any stage of the study by contacting the research team. Signed participant consent was received from all participants. The data collected were stored securely on the Imperial College London OneDrive and accessed on Imperial-owned, password-protected computers. Survey responses were pseudonymized, with geographic coordinates, IP addresses, names, and contact details removed before the data analysis, and stored in secure folders only accessible to the research team. Participants in the research were not compensated.

Model

The research model was developed based on the technology acceptance model (TAM) [14]. The TAM measurement scale assesses an individual’s acceptance of technology based on perceived usefulness and perceived ease of use, which are hypothesized to be fundamental determinants of user acceptance. Though not developed for the health sector, the TAM has been used by health researchers across disciplines to measure the acceptance of digital technologies in health care and education settings [15-17].

Survey questions were adapted from previously published scales. The survey instrument was tested for clarity and comprehensiveness with 1 methodological expert and 1 ICT professional before implementation. We included additional elements of the technology acceptance model-2 (TAM2) framework, specifically subjective norm (eg, perception of the organizational factors and individuals’ approval or disapproval), job relevance (eg, the extent of relevance of the resource to job function), and attitude (eg, extent of positive perception of the resource topic). Using a 5-point Likert scale for each construct, the quantitative survey (Multimedia Appendix 1) assessed (1) perceived usefulness, (2) perceived ease of use, (3) attitude, (4) intention to use, (5) job relevance, and (6) organizational factors or external control.

Material

Participants were provided with a URL, website link, and access password to the web-based ECHO framework resource and written instructions on how to navigate the content and checklist. Participants were also informed how they could download the content and checklist for offline use. When designing the web-based resource, care was taken to ensure the website was easy to navigate and clearly identified the 6 core dimensions of the ECHO framework (Figure 2). The website was hosted on Squarespace, with website traffic encrypted by Secure Sockets Layer (SSL).
Participants and Recruitment

Members of the Imperial College Leading Health Systems Network and other health care organizations identified through the research teams’ networks were invited to participate in the research by email. The invitation email outlined the requirement for an individual with ICT or cybersecurity oversight within the organization to participate on the organization’s behalf. Convenience sampling was used, and participants from mixed ICT roles, depending on the organizational structure, were included. The inclusion criteria were health care provider organization that uses an individual or individuals with an ICT- or cybersecurity-focused job role. Participants were excluded if they were not health care providers or did not have an ICT or cybersecurity function.

Data Collection and Analysis

Study data were collected through Qualtrics web-based surveys 1 month and 3 months from the date the ECHO framework resource was received by the participants. The survey instrument (Multimedia Appendix 1) was broken down into 2 parts. Part 1 explored technology acceptance quantitatively (based on the TAM or TAM2 framework). Part 2 explored technical and content acceptability, feasibility, and usability qualitatively (including strengths, weaknesses, opportunities, and threats analysis).

Quantitative Analysis

Quantitative data were analyzed using R software (version 4.2.1; R Foundation for Statistical Computing). Descriptive statistics of the answers for each survey question were calculated by calculating the mean and 95% CIs. To determine significant differences between the distribution of answers by comparing results from the 2 survey time points, 2-tailed t tests were used. The significance level for all statistical tests was set at a P value of <.05, and a 2-sided hypothesis was considered for all tests. Analysis was conducted by comparing all responses from surveys across time points as well as by comparing survey respondents based on whether they were public or private organizations and whether they were from high-income countries (HICs) or low- and middle-income countries (LMICs).

Qualitative Analysis

Following completion of the survey data collection on Qualtrics, we imported and qualitatively compared the long-form survey responses from the baseline, 1-month, and 3-month surveys through directed content analysis in Microsoft Excel.

The thematic analysis relied largely on the use of deductive coding, which uses a top-down approach to making connections and categorizing themes under the TAM framework. As such, the 4 nodes that formed the starting point of the analysis were the process of change, acceptability and feasibility, content appraisal, and experiences with the framework. The research team also used an inductive approach to capture additional concepts, using a line-by-line review of long-form responses to derive additional codes with regard to experiences of implementing the framework. The 2 researchers independently coded the long-form responses from the baseline (NO and FO) and 1-month and 3-month surveys (NO and MP). A third research team member (SG) was used to ensure that codes were clearly defined and being applied consistently.

Results

Participant Characteristics

In total, 16 health care organizations participated in the baseline survey. A total of 14 (87%) health care organizations went on to complete the 1-month survey and 12 (75%) completed the 3-month survey. Table 1 outlines the sector and country each

Figure 2. Essentials of Cybersecurity in Health Care Organizations (ECHO) framework resource website content (home page).
participant organization belonged. Participants represented a variety of country classifications as defined by the World Bank [18], with baseline participation from low-income countries (LICs; n=3, 18%), LMICs (n=4, 25%), middle-income countries (n=3, 18%), and HICs (n=6, 37%). Different types of health care organizations were also represented from across the public (n=9, 56%), private (n=6, 37%), and nongovernmental organization (NGO; n=1, 6%) sectors.

Baseline Analysis

Participants in the baseline survey reported ECHO framework resource usefulness across 2 domains: framework effects and framework features. The framework effects considered useful were the ability to better improve cybersecurity in health care organizations, reduce threats, and protect data. Participants also noted the framework was useful in prompting the development of cybersecurity policies and protocols and in facilitating organizational evaluation of cybersecurity practices. The framework features participants considered most useful were its health industry focus, its comprehensiveness, its actionability, and the ease with which it could be understood.

Participants reported what they liked most across 3 domains: content, structure or presentation, and perspective taken. The content areas specifically highlighted as most liked were “Dimension 2: Governance” and “Dimension 3: Organizational Strategy.” On structure or presentation, respondents liked the clear, concise, and focused design of the ECHO framework resource. As reported when asked about usefulness, the health sector focus, as well as a focus on “the human side” of cybersecurity and that the ECHO framework was...
complementary to other frameworks, were most liked. Participants reported what they least liked across 2 domains: content and framework features. Several domains and components were mentioned as aspects that individual respondents did not like, along with a lack of methodology and information on how to assess cybersecurity in the resource. Some respondents also noted that there was no comparison with other frameworks within the resource. Regarding framework features, participants noted a high level and lack of detail as the aspect least liked.

**Figure 3** outlines the barriers to implementation described by participants in the baseline survey. Workforce challenges were noted based on an existing organizational commitment to other frameworks, health sector staff shortages, and ICT staff shortages. Competing high-level commitments were outlined as a governance challenge. Time and funding to implement the ECHO framework resource were also reported as challenges by respondents.

**Figure 3.** Concept map of identified barriers to implementing the framework. ICT: information computing technology.

---

**Quantitative Analysis Results**

The TAM explores the attitudes the respondents have regarding the usefulness of the technology. Across the 2 surveys, the lowest mean score on usefulness statements (4.46, SD 1.38) was in response to “Using the ECHO framework makes it easier to do my job,” while the highest mean score (5.23, SD 1.33) was for “Using the ECHO framework for cybersecurity improves the quality of work I do.” In comparing responses to “Using the ECHO framework for cybersecurity improves the quality of the work I do” between participants in HICs and LMICs between 1- and 3-month surveys, there was a trend toward significance in the LMIC subgroup analysis over time ($P = .06$), where the mean Likert score reduced from 6.12 (SD 0.99) to 4.42 (SD 1.90; **Figure 4**), but this was not statistically significant.

Responses to ease-of-use statements ranged from the lowest average Likert score (5.04, SD 1.04) in response to the statement “Interacting with the ECHO cybersecurity framework is often encouraging” to the highest score (5.27, SD 1.15) to “The ECHO cybersecurity framework provides helpful guidance in performing tasks.” Mean scores for attitude questions, including “I think the ECHO framework for cybersecurity scale up is a good/wise idea” and “I am positive towards the ECHO framework for cybersecurity,” were consistently above 5.

External control questions explored the impact of external forces on the usability and acceptability of the ECHO framework resource. While mean scores related to the statement “I have no difficulty accessing and using the ECHO framework for cybersecurity in online and/or PDF format” remained above 5 across the 1- and 3-month surveys, subgroup analysis revealed a trend toward a significant increase in mean score in the 3-month survey among HIC participants ($P = .09$), but this was not statistically significant.

Mean responses to how well the 6 components of the ECHO framework captured the cybersecurity needs of the organization were as follows: context (5.19, SD 1.36); governance (5.00, SD 1.13); organizational strategy (5.07, SD 1.23); risk management (5.08, SD 1.23); awareness, education, and training (5.23, SD 1.36); and technical capabilities (5.08, SD 1.32). While not significant in the HIC group, subgroup analysis of responses on awareness, education, and training showed a significant ($P = .04$) reduction in responses between the 1-month and 3-month survey among LMIC participants (Figure 5). Mean responses on ease of adoption were as follows: context (4.77, SD 1.33); governance (4.61, SD 1.27); organizational strategy (4.50, SD 1.50); risk management (4.42, SD 1.30); awareness, education, and training (5.04, SD 1.25); and technical capabilities (4.54, SD 1.36). In subgroup analysis, changes to the scoring of the adaptability of risk management in public sector facilities trended toward significant ($P = .06$), but this was not statistically significant.
Qualitative Analysis Results

Acceptability and Feasibility

Thematic analysis of responses describing the experience of implementing the resource outlined varied experiences between organizations. Some respondents were unable to implement the resource, while others had only partly implemented it by the time they completed the 1-month survey. Of those who had used the resource, the experience was described as positive, based on it being easy to use and understand, and negative, based on its redundancy based on existing guidelines and tools used by some health care organizations. In responses to the 3-month survey, more participants reported that they had implemented the survey and noted that it had been useful in discussions with organizational leadership but required time to communicate it to all relevant stakeholders.

Participants most liked that the ECHO resource was well structured, user-friendly, comprehensive, current, relevant, easy to understand, teachable, practical, and globally relevant. It was also noted that the checklist was straightforward. They least liked that the resource can only be used as a reference, the time needed to implement, specific dimensions (eg, context, governance, awareness, education, and training dimensions), and the checklist functionality. The need for digital literacy was also noted as a challenge in some LMIC contexts.

Process of Change

Participant responses were positive in response to the process of change questions, although some noted that they were unable to implement the ECHO framework resource in their practice. Thematic analysis of 1-month survey responses to the question “What have you learned from the ECHO framework?” included the usefulness of resources for raising awareness, usefulness as a reference guide, and its ease of use based on familiarity with other standards, guidelines, and tools (eg, NIST, ISO027001, and other frameworks). A non-ECHO–specific learning was the importance of feasible and sustainable cybersecurity planning. The 3-month survey responses reflected the same themes but additionally included that the ECHO framework was useful for developing organizational strategy.
Thematic analysis of responses to the question “Have you noticed any changes in how your organization is approaching cybersecurity?” found participants were taking cybersecurity more seriously or organizations making it more of a priority, putting more importance on the “people” aspect of cybersecurity, and in some health care organizations, implementing incident management processes and other aspects suggested in the ECHO framework.

Content Appraisal
Participants noted the context section was difficult to engage with, particularly in relation to implementation costs, cultural factors, and staff willingness.

It was noted that developing best practice in cybersecurity, as discussed in the governance dimension, sounds straightforward but seems to be the hardest thing to do without proper step-by-step guidance. Specific organizational-level challenges related to the components of the dimension were also discussed, including the challenge of developing work-from-home policies, and clinical safety assessment hindered by lack of awareness from stakeholders.

Challenges raised in operationalizing the components outlined in “Dimension 3: Organizational Strategy” included budget constraints, engaging the board, getting other stakeholders involved, and a lack of time. Specific organizational challenges related to the components of the dimension were also discussed, including developing firewall protocols, communication strategies, etc.

Challenges related to risk management were specific organizational challenges faced by individual participants, including third-party or supply chain risk, asset identification and management, and simulation, due to human resource limitations. The lack of trained personnel, lack of time, and limited budget were challenges raised by several participants.

In responses to the question on “Dimension 5: Awareness, Education, and Training,” participants noted an organizational-level challenge in engaging a large employee base in cybersecurity that is not addressed in the ECHO framework but also recognized that it was a domain often neglected. One participant also noted the practical challenges in ensuring appropriate access to systems based on training and qualifications. Again, capacity challenges and a lack of time were highlighted as barriers to implementing components within the awareness, education, and training domains of the framework.

Challenges raised in operationalizing the technical capabilities components outlined in the ECHO framework included budget constraints, both in funding cybersecurity activities or personnel in the organization and in replacing legacy systems with new technology; lack of time; and difficulty acquiring human capital with appropriate cybersecurity knowledge and skills. Some organizations also reported a challenge around the large scale of the infrastructure that requires attention as part of cybersecurity activities and the regular patching and software updates required to maintain security.

Experiences With the Framework
A limited number of participants expressed concerns about their ability to take part in the research. In baseline data collection, participants were asked, “Now that you know the detailed timeline for this feasibility study, do you think you/your organization will face difficulties in implementing the framework?” A total of 9 (56%) out of 16 participants responded “yes,” with the majority listing time and staffing resources as potential barriers to implementation. The subsequent surveys asked, “Have you had any difficulties to taking part in the study? If the answer is ‘Yes,’ what are they?” A total of 4 (29%) out of 14 participants responded “yes” in the 1-month survey, and 3 (25%) out of 12 participants responded affirmatively in the 3-month survey. Affirmative responses to the questions in the 1- and 3-month surveys came exclusively from participants in HICs, and the reasons for the difficulties in taking part were primary time barriers, followed by a lack of human and financial resources and a lack of prioritization of the study in the organization.

Discussion
Principle Findings
The ECHO framework resource was well accepted and useful for health care organizations, improving understanding of cybersecurity as a priority area in health care organizations, reducing threats, and enabling users to develop organizational planning. Participants particularly liked the ECHO framework’s health sector focus and the resource’s easiness to understand, comprehensiveness, and actionability. The mean score participants gave in the 1- to 3-month surveys to “Using the ECHO framework for cybersecurity improves the quality of the work I do” trended toward significant among LMIC participants, but these results were not statistically significant. This suggests a potential challenge in the long-term usefulness of the ECHO resource in its current format. Based on reported barriers to implementation, it is possible that continued engagement with the framework resource over time further challenges the constraints identified by diverting time and resources, which could be perceived to reduce its potential to improve the quality of work.

Although not all participants were able to implement the ECHO framework resource as part of ICT cybersecurity activities (see challenges noted in Figure 3), those who were able to implement were positive about the process of change. Learnings from the implementation process included the usefulness of the resource for raising awareness as a reference guide and that it was easy to use based on familiarity with other standards, guidelines, and tools. More broadly, it was reported that the resource was useful in driving discussions on the importance of cybersecurity with leadership. Some participants also noted that the introduction of the framework resource encouraged organizations to take cybersecurity more seriously, prioritize it, and put more importance on the “people” aspect of cybersecurity. Subgroup analysis of the statement “I have no difficulty accessing and using the ECHO framework for cybersecurity in online and/or PDF format” also revealed a trend toward a significant increase in mean score over time among HIC participants, suggesting
the resource also became easier to use over time among this cohort, but this was not statistically significant.

Participants had overarching comments on the content appraisal of the 6 dimensions of the ECHO framework. They noted that several of the sections were difficult to operationalize due to costs or budget constraints, human resource limitations, leadership support, stakeholder engagement, and limited time. Select dimension-specific challenges noted were the challenge of operationalizing governance dimension components without step-by-step guidance and the difficulty undertaking activities to secure the large scale of the infrastructure outlined in the technical capabilities dimension in some health care organizations. “Dimension 5: Awareness, Education, and Training” received the highest mean score on how well the 6 components of the ECHO framework captured the cybersecurity needs of the organization. While recognizing this domain is often neglected, the qualitative analysis identified challenges moving forward, including how to engage a large employee base in cybersecurity. It may be for this reason that a significant reduction in mean score among LMIC participants between the 1-month and 3-month surveys was identified through subgroup analysis (Figure 5).

Comparison With Previous Literature

Existing research notes the inadequacy of informatics and cybersecurity education among health care professionals [19,20]. Kamerer and McDermott [19] note that existing education calls for nurses to meet a minimal competency in informatics but does not outline the intersection between security with informatics and patient safety. However, findings from this study suggest nuances in the need for education and training within resource-limited environments with competing priorities. While participants frequently expressed their views on the importance of the awareness, education, and training component of the ECHO framework resource, they also noted major institutional capacity challenges. In quantitative analysis, despite this component scoring the highest on usefulness, participants significantly reduced usefulness scores over time. Taken together, these results highlight the need for increased understanding and research on balancing the need for cybersecurity education and training as a key priority in health care organizations with long-term priorities and capacity. Alami et al [21] note that appropriate cybersecurity can become a value-creation mechanism, suggesting cost-effectiveness and cost-benefit analyses of the resource may generate evidence on its longitudinal impact on financial expenditure and human resource time.

Barriers to implementing the ECHO framework resource described by participants, specifically limited time and funding, have also been echoed as implementation challenges in previous research. Branley-Bell et al [22] noted time pressure and fatigue as a barrier to secure behavior in the health care context, and financial barriers were cited in interviews with cybersecurity experts in Canadian and American health care organizations [23]. Our research findings expand on these more commonly reported barriers, as participants further noted workforce shortages and competing governance priorities, including the mandated use of other frameworks and overlapping compliance and reporting requirements, as barriers to implementing ECHO. Standardizing requirements and using select international standards would help eliminate the high burden of dealing with the many frameworks, regulations, and standards surrounding cybersecurity. This would also be consistent with previous digital health research that has found LMIC settings often have poor physical infrastructure and limited human resource capacity and expertise [24,25]. Further research is required to analyze these barriers in greater detail, including an exploration of where governance may be simplified and where additional human resources would be best placed to enable increased interaction with cybersecurity initiatives.

Strengths and Limitations

The research study provides a comprehensive usability and feasibility analysis of a resource for developing cyber resilience within health care organizations. Developing usable resources on this topic is of particular importance as health care organizations face increasing cyber vulnerabilities as the use of digital technology in health increases and the technology itself becomes more complex. The worldwide diversity of participant organizations in the study is a key strength. Participants were from HICs, middle-income countries, and LICs and represented public, private, and NGO providers to capture diverse perspectives and a wide range of implementation experiences. Finally, the mixed methods approach used by a multidisciplinary research team leads to more nuanced insights into the process of change, acceptability and feasibility, and resource content appraisal.

The limitations of the research must also be discussed. Although there is precedent for using small sample sizes in usability research [26], the small sample size of the study challenged the ability to determine statistical significance in subgroup analyses. Another limitation is the implementation of the framework resource within ICT teams in health care organizations. While the approach enabled homogeneity among participants, the findings are not generalizable if used by other actors within health care organizations, for example, leadership or clinically facing staff. Finally, participant organizations in the research were self-selecting, with implications for the interpretation of findings, as those with more experience and interest in health care cybersecurity may have been more likely to opt into the study and influence the findings.

Implications for Research, Practice, and Policy

Future research should build on the results of this formative research study to improve the design and content of the ECHO cybersecurity framework resource for use in health care organizations. High mean scores and positive qualitative comments by participants highlight that the resource is useful and applicable in health care organizations worldwide. However, lower mean scores on statements such as “Using the ECHO framework makes it easier to do my job,” coupled with the workforce shortages, competing governance priorities, limited time, and funding described by participants, suggest that further iteration of the resource is required to make it more responsive to these challenges. There is the potential for a larger-scale trial of version 2.0 to both gain participation from a larger group of participants internationally and validate the resource across HICs.
and LMIC contexts. However, version 2.0 may benefit from additional qualitative work to determine how ECHO could be made, at least in part, context-specific for different organizations and environments based on the ability to resource for implementation or adoption.

Previous research and academic commentary have highlighted the need for increased cybersecurity education and training [7,27]. As such, a key area of need for further investigation is how the ECHO framework resource can be used as a training tool on cybersecurity for all health care staff or organizational leadership, as well as an informational resource for ICT teams. For example, it may be possible to develop short educational snapshots on aspects of the framework that can be presented to all staff members in health care organizations through email updates; posters; other quick, attention-grabbing, and time-mindful actions; or short training courses that cover the basics of health care cybersecurity as presented in the ECHO framework. Care must be taken to ensure training courses enable staff to engage in cybersecurity topics and risk reduction from the beginning of their employment with the organization and through continuous learning over time while remaining mindful of the workloads and time required to engage in the learning. Such initiatives will require cocreation with intended users and additional testing on acceptability and feasibility.
